The above command will download a complete version of the Bazaar repository for `mysql-proxy`. The main source files are located within the `trunk` subdirectory. The configuration scripts need to be generated before you can configure and build `mysql-proxy`. The `autogen.sh` script will generate the configuration scripts for you:

```
shell> sh ./autogen.sh
```

The script creates the standard `configure` script, which you can then use to configure and build with `make`:

```
shell> ./configure
shell> make
shell> make install
```

If you want to create a standalone source distribution, identical to the source distribution available for download:

```
shell> make distcheck
```

The above will create the file `mysql-proxy-0.7.2.tar.gz` (with the corresponding current version) within the current directory.

14.6.3. MySQL Proxy Configuration Options

To start `mysql-proxy` you can just run the command directly. However, for most situations you will want to specify at the very least the address/host name and port number of the backend MySQL server to which the MySQL Proxy should pass on queries.

You can specify options to `mysql-proxy` either on the command line, or by using a configuration file and the `--defaults-file` command-line option to specify the file location.

If you want to use a configuration file, then the file should be formatted as follows:

- Options must be specified within a configuration group named `mysql-proxy`. For example:

  ```
  [mysql-proxy]
  admin-address = host:port
  ```

- All configuration options should be specified in the form of a configuration name and the value you want to set.
- For options that are a simple toggle on the command-line (for example `--proxy-skip-profiling`, you must use `true` or `false`. For example, the following is invalid:

  ```
  [mysql-proxy]
  proxy-skip-profiling
  ```

  But this is valid:

  ```
  [mysql-proxy]
  proxy-skip-profiling = true
  ```

- The configuration file should have permissions of `0660` (readable and writable by user and group, no access for everybody).

Failure to adhere to any of these requirements will trigger an error during startup.

A list of the supported configuration file and command line otpions are given in the tables below.

Table 14.3. `mysql-proxy` Help Options

Format	Config File	Description	Introduction	Deprecated	Removed
--help	help	Show help options	0.8.0		
--help-admin	help-admin	Show options for the admin-module	0.8.0		
--help-all	help-all	Show all help options	0.8.0		
--help-proxy	help-proxy	Show options for the proxy-module	0.8.0		

Table 14.4. `mysql-proxy` Admin Options

Format	Config File	Description	Introduction	Deprecated	Removed
--admin-address	admin-address	Defines the listening address and poirt for the admin module	0.8.0		
--admin-lua-script	admin-lua-script	Script to execute by the admin module	0.8.0		
--admin-password	admin-password	Password for authentication for admin module	0.8.0		
--admin-username	admin-username	Username for authentication for admin module	0.8.0		
--proxy-address	proxy-address	Listening address:port of the proxy server	0.8.0		

Table 14.5. `mysql-proxy` Proxy Options

Format	Config File	Description	Introduction	Deprecated	Removed
--no-proxy	no-proxy	Don't start the proxy module	0.8.0		
--proxy-backend-addresses	proxy-backend-addresses	Address:port of the remote MySQL server	0.8.0		
--proxy-fix-bug-25371	proxy-fix-bug-25371	Enable the fix for Bug#25371 (for mysqld > 0.8.0.12) for older libmysql versions	0.8.0		
--proxy-lua-script	proxy-lua-script	Filename for Lua script for proxy operations	0.8.0		
--proxy-pool-no-change-user	proxy-pool-no-change-user	Don't use the protocol CHANGE_USER to reset the connection when coming from the connection pool	0.8.0		
--proxy-read-only-backend-addresses	proxy-read-only-backend-addresses	Address:port of the remote MySQL server (read only)	0.8.0		
--proxy-skip-profiling	proxy-skip-profiling	Disabled profiling of queries	0.8.0		

Table 14.6. `mysql-proxy` Applications Options

Format	Config File	Description	Introduction	Deprecated	Removed
--basedir	basedir	Specify the base directory to prepend to paths in the config	0.8.0		
--daemon	daemon	Start in daemon-mode	0.8.0		
--defaults-file	defaults-file	Specify the configuration file	0.8.0		
--event-threads	event-threads	The number of event-handling threads	0.8.0		
--keepalive	keepalive	Try to restart the proxy if a crash occurs	0.8.0		
--log-back-trace-on-crash	log-back-trace-on-crash	Try to invoke the debug and generate a backtrace on crash	0.8.0		

Format	Config File	Description	Introduction	Deprecated	Removed
--log-file	log-file	Specify the file for logging error messages	0.8.0		
--log-level	log-level	Logging level	0.8.0		
--log-use-syslog	log-use-syslog	Log errors to syslog	0.8.0		
--lua-cpath	lua-cpath	Set the LUA_CPATH	0.8.0		
--lua-path	lua-path	Set the LUA_PATH	0.8.0		
--max-open-files	max-open-files	Specify the maximum number of open files to support	0.8.0		
--pid-file	pid-file	PID file to store the process ID (when in daemon mode)	0.8.0		
--plugin-dir	plugin-dir	Path to the plugin files	0.8.0		
--plugins	plugins	List of plugins to load	0.8.0		
--user	user	Specify the user to use when running mysql-proxy	0.8.0		
--version	version	Show the version information	0.8.0		

Except as noted in the details below, all of the options can be used within the configuration file by supplying the option and the corresponding value. For example:

```
log-file                              = /var/log/mysql-proxy.log
log-level                             = message
```

- `--help`

Version Introduced	0.8.0
Command-Line Format	`--help`
Config-File Format	`help`

Show available help options.

- `--help-all`

Version Introduced	0.8.0
Command-Line Format	`--help-all`
Config-File Format	`help-all`

Show all help options.

- `--help-admin`

Version Introduced	0.8.0
Command-Line Format	`--help-admin`
Config-File Format	`help-admin`

Show options for the admin-module.

- `--help-proxy`

Version Introduced	0.8.0
Command-Line Format	`--help-proxy`
Config-File Format	`help-proxy`

Show options for the proxy-module.

- `--admin-address=host:port`

Version Introduced	0.8.0	
Command-Line Format	`--admin-address`	
Config-File Format	`admin-address`	
	Permitted Values	
	Type	`string`
	Default	`:4041`

The host name (or IP address) and port for the administration port. The default is `localhost:4041`.

- `--admin-lua-script=script`

Version Introduced	0.8.0	
Command-Line Format	`--admin-lua-script`	
Config-File Format	`admin-lua-script`	
	Permitted Values	
	Type	`filename`
	Default	

The script to use for the administration module for the proxy.

- `--admin-password=pass`

Version Introduced	0.8.0	
Command-Line Format	`--admin-password`	
Config-File Format	`admin-password`	
	Permitted Values	
	Type	`string`
	Default	

The password to use to authenticate users wanting to connect to the administration module of `mysql-proxy`. The administration module uses the MySQL protocol to request a username and password for connections.

- `--admin-username=user`

Version Introduced	0.8.0	
Command-Line Format	`--admin-username`	
Config-File Format	`admin-username`	
	Permitted Values	
	Type	`string`
	Default	`root`

The username to use to authenticate users wanting to connect to the administration module of `mysql-proxy`. The default username is `root`. The administration module uses the MySQL protocol to request a username and password for connections.

- `--basedir`

Version Introduced	0.8.0	
Command-Line Format	`--basedir`	
Config-File Format	`basedir`	
	Permitted Values	
	Type	`filename`

The base directory that will be prepended to all other filename configuration options. The base name should be an absolute (not relative) directory. If you specify a relative directory, `mysql-proxy` will generate an error during startup.

- `--defaults-file`

Version Introduced	0.8.0
Command-Line Format	`--defaults-file`
Config-File Format	`defaults-file`

The file to use as the file with configuration information. If not specified, configuration options are only taken from the command line.

- `--event-threads=#`

Version Introduced	0.8.0	
Command-Line Format	`--event-threads`	
Config-File Format	`event-threads`	
	Permitted Values	
	Type	`numeric`
	Default	`1`

The number of event threads reserved to handle incoming requests.

- `--keepalive`

Version Introduced	0.8.0
Command-Line Format	`--keepalive`
Config-File Format	`keepalive`

Creates a process surrounding the main `mysql-proxy` which will attempt to restart the true `mysql-proxy` process in the event a crash or other failure.

> **Note**
>
> The `--keepalive` option is not available on Microsoft Windows. When running as a service, the `mysql-proxy` service will automatically restart.

- `--log-backtrace-on-crash`

Version Introduced	0.8.0
Command-Line Format	`--log-backtrace-on-crash`
Config-File Format	`log-backtrace-on-crash`

Logs the backtrace to the error log and tries to initialize the debugger in the event of a failure.

- `--log-file=filename`

Version Introduced	0.8.0	
Command-Line Format	`--log-file`	
Config-File Format	`log-file`	
	Permitted Values	
	Type	`filename`

The name of a file to be used to record log information.

- `--log-level=level`

Version Introduced	0.8.0	
Command-Line Format	`--log-level`	
Config-File Format	`log-level`	
	Permitted Values	
	Type	`enumeration`
	Valid Values	`error`, `warning`, `info`, `message`, `debug`

The log level to be used when outputting error messages. The specification will output that level (or lower) of a given error message. For example, `message` will also output `info`, `warning`, and `error` messages.

- `--log-use-syslog`

Version Introduced	0.8.0
Command-Line Format	`--log-use-syslog`
Config-File Format	`log-use-syslog`

Causes errors to be sent to the syslog (Unix/Linux only).

- `--lua-cpath=path`

Version Introduced	0.8.0	
Command-Line Format	`--lua-cpath`	
Config-File Format	`lua-cpath`	
	Permitted Values	
	Type	`filename`

The `LUA_CPATH` to be used when loading compiled modules or libraries for Lua scripts.

- `--lua-path=path`

Version Introduced	0.8.0	
Command-Line Format	`--lua-path`	
Config-File Format	`lua-path`	
	Permitted Values	
	Type	`filename`

The `LUA_CPATH` to be used when loading modules for Lua.

- `--max-open-files=#`

Version Introduced	0.8.0	
Command-Line Format	`--max-open-files`	
Config-File Format	`max-open-files`	
	Permitted Values	
	Type	`numeric`

The maximum number of open files and sockets supported by the `mysql-proxy` process. You may need to increase this with certain scripts.

- `--no-proxy`

Version Introduced	0.8.0
Command-Line Format	`--no-proxy`
Config-File Format	`no-proxy`

Disable the proxy module.

- `--plugin-dir=path`

Version Introduced	0.8.0	
Command-Line Format	`--plugin-dir`	
Config-File Format	`plugin-dir`	
	Permitted Values	
	Type	`filename`

The directory to use when loading plugins for `mysql-proxy`.

- `--plugins=plugin,...`

Version Introduced	0.8.0	
Command-Line Format	`--plugins`	
Config-File Format	`plugins`	
	Permitted Values	
	Type	`string`

A comma-separated list of the plugins to be loaded.

- `--proxy-address=host:port`

Version Introduced	0.8.0	
Command-Line Format	`--proxy-address`	
Config-File Format	`proxy-address`	
	Permitted Values	
	Type	`string`
	Default	`:4040`

The listening host name (or IP address) and port of the proxy server. The default is `:4040` (all IPs on port 4040).

- `--proxy-read-only-backend-addresses=host:port`

Version Introduced	0.8.0	
Command-Line Format	`--proxy-read-only-backend-addresses`	
Config-File Format	`proxy-read-only-backend-addresses`	
	Permitted Values	
	Type	`string`

The listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.

> **Note**
>
> Setting this value only configures the servers within the corresponding internal structure (see `proxy.global.backends`). You can determine the backend type by checking the `type` field for each connection.
>
> You should therefore only use this option in combination with a script designed to make use of the different backend types.

When using this option on the command-line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-read-only-backend-addresses 192.168.0.1:3306 --proxy-read-only-backend-addresses 192.168.0.2
```

When using the option within the configuration file, you should separate multiple servers with a comma. The equivalent of the above example would be:

```
...
proxy-read-only-backend-addresses = 192.168.0.1:3306, 192.168.0.2:3306
```

- `--proxy-backend-addresses=host:port`

The host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.

When using this option on the command-line, you can specify the option and the server multiple times to specify multiple backends. For example:

```
shell> mysql-proxy --proxy-backend-addresses 192.168.0.1:3306 --proxy-backend-addresses 192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers with a comma. The equivalent of the above example would be:

```
...
proxy-backend-addresses = 192.168.0.1:3306, 192.168.0.2:3306
```

- `--proxy-pool-no-change-user`

Version Introduced	0.8.0
Command-Line Format	`--proxy-pool-no-change-user`
Config-File Format	`proxy-pool-no-change-user`

Disables the use of the MySQL protocol `CHANGE_USER` when reusing a connection from the pool of connections specified by the `proxy-backend-addresses` list.

- `--proxy-skip-profiling`

Disables profiling of queries (tracking time statistics). The default is for tracking to be enabled.

- `--proxy-fix-bug-25371`

Version Introduced	0.8.0
Command-Line Format	`--proxy-fix-bug-25371`
Config-File Format	`proxy-fix-bug-25371`

Gets round an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.

- `--proxy-lua-script=file`

Version Introduced	0.8.0	
Command-Line Format	`--proxy-lua-script`	
Config-File Format	`proxy-lua-script`	
	Permitted Values	
	Type	`filename`

The Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while `mysql-proxy` is running then the updated content will automatically be used when a new connection is made.

- `--daemon`

Version Introduced	0.8.0
Command-Line Format	`--daemon`
Config-File Format	`daemon`

Starts the proxy in daemon mode.

- `--pid-file=file`

Version Introduced	0.8.0	
Command-Line Format	`--pid-file`	
Config-File Format	`pid-file`	
	Permitted Values	
	Type	`filename`

Sets the name of the file to be used to store the process ID.

- `--user=user`

Version Introduced	0.8.0	
Command-Line Format	`--user`	
Config-File Format	`user`	
	Permitted Values	
	Type	`string`

Run `mysql-proxy` as the specified `user`.

- `--version`

Version Introduced	0.8.0
Command-Line Format	`--version`
Config-File Format	`version`

Show the version number.

The most common usage is as a simple proxy service (that is, without addition scripting). For basic proxy operation you must specify at least one `proxy-backend-addresses` option to specify the MySQL server to connect to by default:

```
shell> mysql-proxy
--proxy-backend-addresses=MySQL.example.com:3306
```

The default proxy port is `4040`, so you can connect to your MySQL server through the proxy by specifying the host name and port details:

```
shell> mysql --host=localhost --port=4040
```

If your server requires authentication information then this will be passed through natively without alteration by `mysql-proxy`, so you must also specify the authentication information if required:

```
shell> mysql --host=localhost --port=4040 \
   --user=username --password=password
```

You can also connect to a read-only port (which filters out `UPDATE` and `INSERT` queries) by connecting to the read-only port. By default the host name is the default, and the port is `4042`, but you can alter the host/port information by using the `--proxy-read-only-address` command-line option.

For more detailed information on how to use these command line options, and `mysql-proxy` in general in combination with Lua scripts, see Section 14.6.5, “Using MySQL Proxy”.

14.6.4. MySQL Proxy Scripting

You can control how MySQL Proxy manipulates and works with the queries and results that are passed on to the MySQL server through the use of the embedded Lua scripting language. You can find out more about the Lua programming language from the Lua Website.

The primary interaction between MySQL Proxy and the server is provided by defining one or more functions through an Lua script. A number of functions are supported, according to different events and operations in the communication sequence between a client and one or more backend MySQL servers:

- `connect_server()`: This function is called each time a connection is made to MySQL Proxy from a client. You can use this function during load-balancing to intercept the original connection and decide which server the client should ultimately be attached to. If you do not define a special solution, then a simple round-robin style distribution is used by default.
- `read_handshake()`: This function is called when the initial handshake information is returned by the server. You can capture the handshake information returned and provide additional checks before the authorization exchange takes place.
- `read_auth()`: This function is called when the authorization packet (user name, password, default database) are submitted by the client to the server for authentication.
- `read_auth_result()`: This function is called when the server returns an authorization packet to the client indicating whether the authorization succeeded.
- `read_query()`: This function is called each time a query is sent by the client to the server. You can use this to edit and manipulate the original query, including adding new queries before and after the original statement. You can also use this function to return information directly to the client, bypassing the server, which can be useful to filter unwanted queries or queries that exceed known limits.
- `read_query_result()`: This function is called each time a result is returned from the server, providing you have manually in-

jected queries into the query queue. If you have not explicitly inject queries within the `read_query()` function then this function is not triggered. You can use this to edit the result set, or to remove or filter the result sets generated from additional queries you injected into the queue when using `read_query()`.

The table below describes the direction of flow of information at the point when the function is triggered.

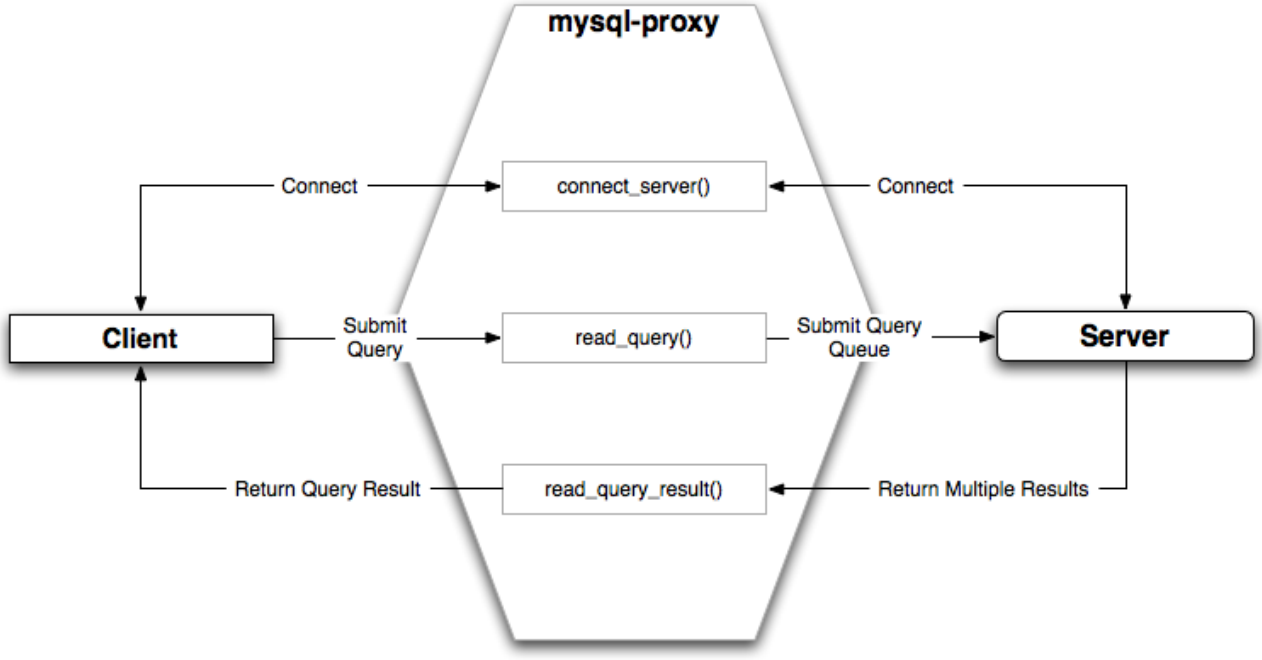
Function	Supplied Information	Direction
`connect_server()`	None	Client to Server
`read_handshake()`	None	Server to Client
`read_auth()`	None	Client to Server
`read_auth_result()`	None	Server to Client
`read_query()`	Query	Client to Server
`read_query_result()`	Query result	Server to Client

By default, all functions return a result that indicates that the data should be passed on to the client or server (depending on the direction of the information being transferred). This return value can be overridden by explicitly returning a constant indicating that a particular response should be sent. For example, it is possible to construct result set information by hand within `read_query()` and to return the resultset directly to the client without ever sending the original query to the server.

In addition to these functions, a number of built-in structures provide control over how MySQL Proxy forwards queries and returns the results by providing a simplified interface to elements such as the list of queries and the groups of result sets that are returned.

14.6.4.1. Proxy Scripting Sequence During Query Injection

The figure below gives an example of how the proxy might be used when injecting queries into the query queue. Because the proxy sits between the client and MySQL server, what the proxy sends to the server, and the information that the proxy ultimately returns to the client do not have to match or correlate. Once the client has connected to the proxy, the following sequence occurs for each individual query sent by the client.



1. The client submits one query to the proxy, the `read_query()` function within the proxy is triggered. The function adds the query to the query queue.

2. Once manipulation by `read_query()` has completed, the queries are submitted, sequentially, to the MySQL server.

3. The MySQL server returns the results from each query, one result set for each query submitted. The `read_query_result()` function is triggered for each result set, and each invocation can decide which result set to return to the client

For example, you can queue additional queries into the global query queue to be processed by the server. This can be used to add statistical information by adding queries before and after the original query, changing the original query:

```
SELECT * FROM City;
```

Into a sequence of queries:

```
SELECT NOW();
SELECT * FROM City;
SELECT NOW();
```

You can also modify the original statement, for example to add `EXPLAIN` to each statement executed to get information on how the statement was processed, again altering our original SQL statement into a number of statements:

```
SELECT * FROM City;
EXPLAIN SELECT * FROM City;
```

In both of these examples, the client would have received more result sets than expected. Regardless of how you manipulate the incoming query and the returned result, the number of queries returned by the proxy must match the number of original queries sent by the client.

You could adjust the client to handle the multiple result sets sent by the proxy, but in most cases you will want the existence of the proxy to remain transparent. To ensure that the number of queries and result sets match, you can use the MySQL Proxy `read_query_result()` to extract the additional result set information and return only the result set the client originally requested back to the client. You can achieve this by giving each query that you add to the query queue a unique ID, and then filter out queries that do not match the original query ID when processing them with `read_query_result()`.

14.6.4.2. Internal Structures

There are a number of internal structures within the scripting element of MySQL Proxy. The primary structure is `proxy` and this provides an interface to the many common structures used throughout the script, such as connection lists and configured backend servers. Other structures, such as the incoming packet from the client and result sets are only available within the context of one of the scriptable functions.

Attribute	Description
`connection`	A structure containing the active client connections. For a list of attributes, see `proxy.connection`.
`servers`	A structure containing the list of configured backend servers. For a list of attributes, see `proxy.global.backends`.
`queries`	A structure containing the queue of queries that will be sent to the server during a single client query. For a list of attributes, see `proxy.queries`.
`PROXY_VERSION`	The version number of MySQL Proxy, encoded in hex. You can use this to check that the version number supports a particular option from within the Lua script. Note that the value is encoded as a hex value, so to check the version is at least 0.5.1 you compare against `0x00501`.

`proxy.connection`

The `proxy.connection` object is read only, and provides information about the current connection, and is split into a `client` and `server` tables. This allows you to examine information about both the incoming client connections to the proxy (`client`), and to the backend servers (`server`).

Attribute	Description
`client.default_db`	Default database request by the client
`client.username`	Username used to authenticate

Attribute	Description
client.scrambled_password	The scrambled version of the password used to authenticate
client.dst.name	The combined address:port of the Proxy port used by this client (should match the --proxy-address configuration parameter)
client.dst.address	The IP address of the of the Proxy port used by this client
client.dst.port	The port number of the of the Proxy port used by this client
client.src.name	The combined address:port of the client (originating) TCP/IP endpoint
client.src.address	The IP address of the client (originating) TCP/IP port
client.src.port	The port of the client (originating) TCP/IP endpoint
server.scramble_buffer	The scramble buffer used to scramble the password
server.mysqld_version	The MySQL version number of the server
server.thread_id	The ID of the thread handling the connection to the current server
server.dst.name	The combined address:port for the backend server for the current connection (i.e. the connection to the MySQL server)
server.dst.address	The address for the backend server
server.dst.port	The port for the backend server
server.src.name	The combined address:port for the TCP/IP endpoint used by the Proxy to connect to the backend server
server.src.address	The address of the endpoint for the proxy-side connection to the MySQL server
server.src.port	The port of the endpoint for the proxy-side connection to the MySQL server

proxy.global.backends

The proxy.global.backends table is partially writable and contains an array of all the configured backend servers and the server metadata (IP address, status, etc.). You can determine the array index of the current connection using proxy.connection["backend_ndx"] which is the index into this table of the backend server being used by the active connection.

The attributes for each entry within the proxy.global.backends table are shown in this table.

Attribute	Description
dst.name	The combined address:port of the backend server
dst.address	The IP address of the backend server
dst.port	The port of the backend server
connected_clients	The number of clients currently connected.
state	The status of the backend server. See Backend State/Type Constants [1331]
type	The type of the backend server. You can use this to identify whether the backed was configured as a standard read/write backend, or a read-only backend. You can compare this value to the proxy.BACKEND_TYPE_RW and proxy.BACKEND_TYPE_RO.

proxy.queries

The proxy.queries object is a queue representing the list of queries to be sent to the server. The queue is not populated automatically, but if you do not explicitly populate the queue then queries are passed on to the backend server verbatim. Also, if you do not populate the query queue by hand, then the read_query_result() function is not triggered.

The following methods are supported for populating the proxy.queries object.

Function	Description
append(id,packet,[options])	Appends a query to the end of the query queue. The id is an integer identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet. The optional options should be a table containing the

Function	Description
	options specific to this packet.
`prepend(id,packet)`	Prepends a query to the query queue. The `id` is an identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.
`reset()`	Empties the query queue.
`len()`	Returns the number of query packets in the queue.

For example, you could append a query packet to the `proxy.queries` queue by using the `append()`:

```
proxy.queries:append(1,packet)
```

The optional third argument to `append()` should contain the options for the packet. If you want to have access to the result set through the `read_query_result()` function, you must set the `resultset_is_needed` flag to true:

```
proxy.queries:append( 1, packet, { resultset_is_needed = true } )
```

If that flag is false (the default), proxy will:

- Send the resultset to the client as soon as the resultset is received
- Reduce memory usage (because the resultset is not stored internally for processing)
- Lower latency of results back to the client
- Pass on data from server to client unaltered

The default mode is therefore quicker and useful if you only want to monitor the queries sent, and the basic statistics.

If, however, you want to perform any kind of manipulation on the returned data, you must set the flag to true, which will:

- Store the resultset so that it can be processed
- Allow modification of the resultset before it is returned to the client
- Allow you to discard the resultset in place of returning it to the client

`proxy.response`

The `proxy.response` structure is used when you want to return your own MySQL response, instead of forwarding a packet that you have received a backend server. The structure holds the response type information, an optional error message, and the result set (rows/columns) that you want to return.

Attribute	Description
`type`	The type of the response. The type must be either `MYSQLD_PACKET_OK` or `MYSQLD_PACKET_ERR`. If the `MYSQLD_PACKET_ERR`, then you should set the value of the `mysql.response.errmsg` with a suitable error message.
`errmsg`	A string containing the error message that will be returned to the client.
`resultset`	A structure containing the result set information (columns and rows), identical to what would be returned when returning a results from a `SELECT` query.

When using `proxy.response` you either set `proxy.response.type` to `proxy.MYSQLD_PACKET_OK` and then build `resultset` to contain the results that you want to return, or set `proxy.response.type` to `proxy.MYSQLD_PACKET_ERR` and set the `proxy.response.errmsg` to a string with the error message. To send the completed resultset or error message, you should return the `proxy.PROXY_SEND_RESULT` to trigger the return of the packet information.

An example of this can be seen in the `tutorial-resultset.lua` script within the MySQL Proxy package:

```
if string.lower(command) == "show" and string.lower(option) == "querycounter" then
        ---
        -- proxy.PROXY_SEND_RESULT requires
        --
        -- proxy.response.type to be either
        -- * proxy.MYSQLD_PACKET_OK or
        -- * proxy.MYSQLD_PACKET_ERR
        --
        -- for proxy.MYSQLD_PACKET_OK you need a resultset
        -- * fields
        -- * rows
        --
        -- for proxy.MYSQLD_PACKET_ERR
        -- * errmsg
        proxy.response.type = proxy.MYSQLD_PACKET_OK
        proxy.response.resultset = {
                fields = {
                        { type = proxy.MYSQL_TYPE_LONG, name = "global_query_counter", },
                        { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
                },
                rows = {
                        { proxy.global.query_counter, query_counter }
                }
        }

        -- we have our result, send it back
        return proxy.PROXY_SEND_RESULT
elseif string.lower(command) == "show" and string.lower(option) == "myerror" then
        proxy.response.type = proxy.MYSQLD_PACKET_ERR
        proxy.response.errmsg = "my first error"

        return proxy.PROXY_SEND_RESULT
```

`proxy.response.resultset`

The `proxy.response.resultset` structure should be populated with the rows and columns of data that you want to return. The structure contains the information about the entire result set, with the individual elements of the data shown in the table below.

Attribute	Description
`fields`	The definition of the columns being returned. This should be a dictionary structure with the `type` specifying the MySQL data type, and the `name` specifying the column name. Columns should be listed in the order of the column data that will be returned.
`flags`	A number of flags related to the resultset. Valid flags include `auto_commit` (whether an automatic commit was triggered), `no_good_index_used` (the query executed without using an appropriate index), and `no_index_used` (the query executed without using any index).
`rows`	The actual row data. The information should be returned as an array of arrays. Each inner array should contain the column data, with the outer array making up the entire result set.
`warning_count`	The number of warnings for this result set.
`affected_rows`	The number of rows affected by the original statement.
`insert_id`	The last insert ID for an auto-incremented column in a table.
`query_status`	The status of the query operation. You can use the `MYSQLD_PACKET_OK` or `MYSQLD_PACKET_ERR` constants to populate this parameter.

For an example of the population of this table, see `proxy.response`.

Proxy Return State Constants

The following constants are used internally by the proxy to specify the response to send to the client or server. All constants are exposed as values within the main `proxy` table.

Constant	Description
`PROXY_SEND_QUERY`	Causes the proxy to send the current contents of the queries queue to the server.
`PROXY_SEND_RESULT`	Causes the proxy to send a result set back to the client.
`PROXY_IGNORE_RESULT`	Causes the proxy to drop the result set (nothing is returned to the client).

As constants, these entities are available without qualification in the Lua scripts. For example, at the end of the `read_query_result()` you might return `PROXY_IGNORE_RESULT:`

```
return proxy.PROXY_IGNORE_RESULT
```

Packet State Constants

The following states describe the status of a network packet. These items are entries within the main `proxy` table.

Constant	Description
`MYSQLD_PACKET_OK`	The packet is OK.
`MYSQLD_PACKET_ERR`	The packet contains error information.
`MYSQLD_PACKET_RAW`	The packet contains raw data.

Backend State/Type Constants

The following constants are used either to define the status of the backend server (the MySQL server to which the proxy is connected) or the type of backend server. These items are entries within the main `proxy` table.

Constant	Description
`BACKEND_STATE_UNKNOWN`	The current status is unknown.
`BACKEND_STATE_UP`	The backend is known to be up (available).
`BACKEND_STATE_DOWN`	The backend is known to be down (unavailable).
`BACKEND_TYPE_UNKNOWN`	Backend type is unknown.
`BACKEND_TYPE_RW`	Backend is available for read/write.
`BACKEND_TYPE_RO`	Backend is available only for read-only use.

Server Command Constants

The following values are used in the packets exchanged between the client and server to identify the information in the rest of the packet. These items are entries within the main `proxy` table. The packet type is defined as the first character in the sent packet. For example, when intercepting packets from the client to edit or monitor a query you would check that the first byte of the packet was of type `proxy.COM_QUERY`.

Constant	Description
`COM_SLEEP`	Sleep
`COM_QUIT`	Quit
`COM_INIT_DB`	Initialize database
`COM_QUERY`	Query
`COM_FIELD_LIST`	Field List
`COM_CREATE_DB`	Create database
`COM_DROP_DB`	Drop database
`COM_REFRESH`	Refresh
`COM_SHUTDOWN`	Shutdown
`COM_STATISTICS`	Statistics
`COM_PROCESS_INFO`	Process List
`COM_CONNECT`	Connect
`COM_PROCESS_KILL`	Kill
`COM_DEBUG`	Debug
`COM_PING`	Ping
`COM_TIME`	Time

Constant	Description
COM_DELAYED_INSERT	Delayed insert
COM_CHANGE_USER	Change user
COM_BINLOG_DUMP	Binlog dump
COM_TABLE_DUMP	Table dump
COM_CONNECT_OUT	Connect out
COM_REGISTER_SLAVE	Register slave
COM_STMT_PREPARE	Prepare server-side statement
COM_STMT_EXECUTE	Execute server-side statement
COM_STMT_SEND_LONG_DATA	Long data
COM_STMT_CLOSE	Close server-side statement
COM_STMT_RESET	Reset statement
COM_SET_OPTION	Set option
COM_STMT_FETCH	Fetch statement
COM_DAEMON	Daemon (MySQL 5.1 only)
COM_ERROR	Error

MySQL Type Constants

These constants are used to identify the field types in the query result data returned to clients from the result of a query. These items are entries within the main `proxy` table.

Constant	Field Type
MYSQL_TYPE_DECIMAL	Decimal
MYSQL_TYPE_NEWDECIMAL	Decimal (MySQL 5.0 or later)
MYSQL_TYPE_TINY	Tiny
MYSQL_TYPE_SHORT	Short
MYSQL_TYPE_LONG	Long
MYSQL_TYPE_FLOAT	Float
MYSQL_TYPE_DOUBLE	Double
MYSQL_TYPE_NULL	Null
MYSQL_TYPE_TIMESTAMP	Timestamp
MYSQL_TYPE_LONGLONG	Long long
MYSQL_TYPE_INT24	Integer
MYSQL_TYPE_DATE	Date
MYSQL_TYPE_TIME	Time
MYSQL_TYPE_DATETIME	Datetime
MYSQL_TYPE_YEAR	Year
MYSQL_TYPE_NEWDATE	Date (MySQL 5.0 or later)
MYSQL_TYPE_ENUM	Enumeration
MYSQL_TYPE_SET	Set
MYSQL_TYPE_TINY_BLOB	Tiny Blob
MYSQL_TYPE_MEDIUM_BLOB	Medium Blob
MYSQL_TYPE_LONG_BLOB	Long Blob
MYSQL_TYPE_BLOB	Blob
MYSQL_TYPE_VAR_STRING	Varstring

Constant	Field Type
MYSQL_TYPE_STRING	String
MYSQL_TYPE_TINY	Tiny (compatible with MYSQL_TYPE_CHAR)
MYSQL_TYPE_ENUM	Enumeration (compatible with MYSQL_TYPE_INTERVAL)
MYSQL_TYPE_GEOMETRY	Geometry
MYSQL_TYPE_BIT	Bit

14.6.4.3. Capturing a connection with connect_server()

When the proxy accepts a connection from a MySQL client, the connect_server() function is called.

There are no arguments to the function, but you can use and if necessary manipulate the information in the proxy.connection table, which is unique to each client session.

For example, if you have multiple backend servers then you can set the server to be used by that connection by setting the value of proxy.connection.backend_ndx to a valid server number. The code below will choose between two servers based on whether the current time in minutes is odd or even:

```
function connect_server()
        print("--> a client really wants to talk to a server")
        if (tonumber(os.date("%M")) % 2 == 0) then
                proxy.connection.backend_ndx = 2
                print("Choosing backend 2")
        else
                proxy.connection.backend_ndx = 1
                print("Choosing backend 1")
        end
        print("Using " .. proxy.global.backends[proxy.connection.backend_ndx].dst.name)
end
```

In this example the IP address/port combination is also displayed by accessing the information from the internal proxy.global.backends table.

14.6.4.4. Examining the handshake with read_handshake()

Handshake information is sent by the server to the client after the initial connection (through connect_server()) has been made. The handshake information contains details about the MySQL version, the ID of the thread that will handle the connection information, and the IP address of the client and server. This information is exposed through the proxy.connection structure.

- proxy.connection.server.mysqld_version: The version of the MySQL server.
- proxy.connection.server.thread_id: The thread ID.
- proxy.connection.server.scramble_buffer: The password scramble buffer.
- proxy.connection.server.dst.name: The IP address of the server.
- proxy.connection.client.src.name: The IP address of the client.

For example, you can print out the handshake data and refuse clients by IP address with the following function:

```
function read_handshake()
        print("<-- let's send him some information about us")
        print("    mysqld-version: " .. proxy.connection.server.mysqld_version)
        print("    thread-id     : " .. proxy.connection.server.thread_id)
        print("    scramble-buf  : " .. string.format("%q",proxy.connection.server.scramble_buffer))
        print("    server-addr   : " .. proxy.connection.server.dst.name)
        print("    client-addr   : " .. proxy.connection.client.dst.name)

        if not proxy.connection.client.src.name:match("^127.0.0.1:") then
                proxy.response.type = proxy.MYSQLD_PACKET_ERR
                proxy.response.errmsg = "only local connects are allowed"

                print("we don't like this client");

                return proxy.PROXY_SEND_RESULT
```

```
        end
end
```

Note that you have to return an error packet to the client by using `proxy.PROXY_SEND_RESULT`.

14.6.4.5. Examining the authentication credentials with `read_auth()`

The `read_auth()` function is triggered when an authentication handshake is initiated by the client. In the execution sequence, `read_auth()` occurs immediately after `read_handshake()`, so the server selection has already been made, but the connection and authorization information has not yet been provided to the backend server.

You can obtain the authentication information by examining the `proxy.connection.client` structure. For more information, see `proxy.connection`.

For example, you can print the user name and password supplied during authorization using:

```
function read_auth()
        print("    username      : " .. proxy.connection.client.username)
        print("    password      : " .. string.format("%q", proxy.connection.client.scrambled_password))
end
```

You can interrupt the authentication process within this function and return an error packet back to the client by constructing a new packet and returning `proxy.PROXY_SEND_RESULT`:

```
proxy.response.type = proxy.MYSQLD_PACKET_ERR
proxy.response.errmsg = "Logins are not allowed"
return proxy.PROXY_SEND_RESULT
```

14.6.4.6. Accessing authentication information with `read_auth_result()`

The return packet from the server during authentication is captured by `read_auth_result()`. The only argument to this function is the authentication packet returned by the server. As the packet is a raw MySQL network protocol packet, you must access the first byte to identify the packet type and contents. The `MYSQLD_PACKET_ERR` and `MYSQLD_PACKET_OK` constants can be used to identify whether the authentication was successful:

```
function read_auth_result(auth)
        local state = auth.packet:byte()

        if state == proxy.MYSQLD_PACKET_OK then
                print("<-- auth ok");
        elseif state == proxy.MYSQLD_PACKET_ERR then
                print("<-- auth failed");
        else
                print("<-- auth ... don't know: " .. string.format("%q", auth.packet));
        end
end
```

14.6.4.7. Manipulating Queries with `read_query()`

The `read_query()` function is called once for each query submitted by the client and accepts a single argument, the query packet that was provided. To access the content of the packet you must parse the packet contents manually.

For example, you can intercept a query packet and print out the contents using the following function definition:

```
function read_query( packet )
        if packet:byte() == proxy.COM_QUERY then
                print("we got a normal query: " .. packet:sub(2))
        end
end
```

This example checks the first byte of the packet to determine the type. If the type is `COM_QUERY` (see Server Command Constants [1331]), then we extract the query from the packet and print it out. The structure of the packet type supplied is important. In the case of a `COM_QUERY` packet, the remaining contents of the packet are the text of the query string. In this example, no changes have been made to the query or the list of queries that will ultimately be sent to the MySQL server.

To modify a query, or add new queries, you must populate the query queue (`proxy.queries`) and then execute the queries that you have placed into the queue. If you do not modify the original query or the queue, then the query received from the client is sent to the MySQL server verbatim.

When adding queries to the queue, you should follow these guidelines:

- The packets inserted into the queue must be valid query packets. For each packet, you must set the initial byte to the packet type. If you are appending a query, you can append the query statement to the rest of the packet.
- Once you add a query to the queue, the queue is used as the source for queries sent to the server. If you add a query to the queue to add more information, you must also add the original query to the queue or it will not be executed.
- Once the queue has been populated, you must set the return value from `read_query()` to indicate whether the query queue should be sent to the server.
- When you add queries to the queue, you should add an ID. The ID you specify is returned with the result set so that you identify each query and corresponding result set. The ID has no other purpose than as an identifier for correlating the query and resultset. When operating in a passive mode, during profiling for example, you want to identify the original query and the corresponding resultset so that the results expect by the client can be returned correctly.
- Unless your client is designed to cope with more result sets than queries, you should ensure that the number of queries from the client match the number of results sets returned to the client. Using the unique ID and removing result sets you inserted will help.

Normally, the `read_query()` and `read_query_result()` function are used in conjunction with each other to inject additional queries and remove the additional result sets. However, `read_query_result()` is only called if you populate the query queue within `read_query()`.

14.6.4.8. Manipulating Results with `read_query_result()`

The `read_query_result()` is called for each result set returned by the server only if you have manually injected queries into the query queue. If you have not manipulated the query queue then this function is not called. The function supports a single argument, the result packet, which provides a number of properties:

- `id`: The ID of the result set, which corresponds to the ID that was set when the query packet was submitted to the server when using `append(id)` on the query queue. You must have set the `resultset_is_needed` flag to `append` to intercept the resultset before it is returned to the client. See proxy.queries [1328].
- `query`: The text of the original query.
- `query_time`: The number of microseconds required to receive the first row of a result set.
- `response_time`: The number of microseconds required to receive the last row of the result set.
- `resultset`: The content of the result set data.

By accessing the result information from the MySQL server you can extract the results that match the queries that you injected, return different result sets (for example, from a modified query), and even create your own result sets.

The Lua script below, for example, will output the query, followed by the query time and response time (that is, the time to execute the query and the time to return the data for the query) for each query sent to the server:

```
function read_query( packet )
        if packet:byte() == proxy.COM_QUERY then
                print("we got a normal query: " .. packet:sub(2))

                proxy.queries:append(1, packet )

                return proxy.PROXY_SEND_QUERY
        end
end

function read_query_result(inj)
        print("query-time: " .. (inj.query_time / 1000) .. "ms")
        print("response-time: " .. (inj.response_time / 1000) .. "ms")
end
```

You can access the rows of returned results from the resultset by accessing the rows property of the resultset property of the result that is exposed through `read_query_result()`. For example, you can iterate over the results showing the first column from each row using this Lua fragment:

```
for row in inj.resultset.rows do
        print("injected query returned: " .. row[1])
end
```

Just like `read_query()`, `read_query_result()` can return different values for each result according to the result returned. If you have injected additional queries into the query queue, for example, then you will want to remove the results returned from those additional queries and only return the results from the query originally submitted by the client.

The example below injects additional `SELECT NOW()` statements into the query queue, giving them a different ID to the ID of the original query. Within `read_query_result()`, if the ID for the injected queries is identified, we display the result row, and return the `proxy.PROXY_IGNORE_RESULT` from the function so that the result is not returned to the client. If the result is from any other query, we print out the query time information for the query and return the default, which passes on the result set unchanged. We could also have explicitly returned `proxy.PROXY_IGNORE_RESULT` to the MySQL client.

```
function read_query( packet )
        if packet:byte() == proxy.COM_QUERY then
                proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_needed = true} )
                proxy.queries:append(1, packet, {resultset_is_needed = true})
                proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()", {resultset_is_needed = true} )

                return proxy.PROXY_SEND_QUERY
        end
end

function read_query_result(inj)
        if inj.id == 2 then
                for row in inj.resultset.rows do
                        print("injected query returned: " .. row[1])
                end
                return proxy.PROXY_IGNORE_RESULT
        else
                print("query-time: " .. (inj.query_time / 1000) .. "ms")
                print("response-time: " .. (inj.response_time / 1000) .. "ms")
        end
end
```

For further examples, see Section 14.6.5, “Using MySQL Proxy”.

14.6.5. Using MySQL Proxy

There are a number of different ways to use MySQL Proxy. At the most basic level, you can allow MySQL Proxy to pass on queries from clients to a single server. To use MySQL proxy in this mode, you just have to specify the backend server that the proxy should connect to on the command line:

```
shell> mysql-proxy --proxy-backend-addresses=sakila:3306
```

If you specify multiple backend MySQL servers then the proxy will connect each client to each server in a round-robin fashion. For example, imagine you have two MySQL servers, A and B. The first client to connect will be connected to server A, the second to server B, the third to server C. For example:

```
shell> mysql-proxy \
     --proxy-backend-addresses=narcissus:3306 \
     --proxy-backend-addresses=nostromo:3306
```

When you have specified multiple servers in this way, the proxy will automatically identify when a MySQL server has become unavailable and mark it accordingly. New connections will automatically be attached to a server that is available, and a warning will be reported to the standard output from `mysql-proxy`:

```
network-mysqld.c.367: connect(nostromo:3306) failed: Connection refused
network-mysqld-proxy.c.2405: connecting to backend (nostromo:3306) failed, marking it as down for ...
```

Lua scripts enable a finer level of control, both over the connections and their distribution and how queries and result sets are processed. When using an Lua script, you must specify the name of the script on the command line using the `--proxy-lua-script` option:

```
shell> mysql-proxy --proxy-lua-script=mc.lua --proxy-backend-addresses=sakila:3306
```

When you specify a script, the script is not executed until a connection is made. This means that faults with the script will not be raised until the script is executed. Script faults will not affect the distribution of queries to backend MySQL servers.

> **Note**
>
> Because the script is not read until the connection is made, you can modify the contents of the Lua script file while the proxy is still running and the script will automatically be used for the next connection. This ensures that MySQL Proxy remains available because it does not have to be restarted for the changes to take effect.

14.6.5.1. Using the Administration Interface

The `mysql-proxy` administration interface can be accessed using any MySQL client using the standard protocols. You can use the administration interface to gain information about the proxy server as a whole - standard connections to the proxy are isolated to operate as if you were connected directly to the backend MySQL server.

In `mysql-proxy` 0.8.0 and earlier, a rudimentary interface was built into the proxy. In later versions this was replaced so that you must specify an administration script to be used when users connect to the administration interface.

To use the administration interface, you should specify the username and password required to connect to the admin point (using the `--admin-username` and `--admin-password` options). You must also specify the Lua script to be used as the interface to the administration service by using the `admin-lua-script` script option to point to a Lua script.

For example, you can create a basic interface to the internal components of the `mysql-proxy` system using the following script, written by Diego Medina:

```

function set_error(errmsg)
    proxy.response = {
        type = proxy.MYSQLD_PACKET_ERR,
        errmsg = errmsg or "error"
    }
end

function read_query(packet)
    if packet:byte() ~= proxy.COM_QUERY then
        set_error("[admin] we only handle text-based queries (COM_QUERY)")
        return proxy.PROXY_SEND_RESULT
    end

    local query = packet:sub(2)
    local rows = { }
    local fields = { }

    -- try to match the string up to the first non-alphanum
    local f_s, f_e, command = string.find(packet, "^%s*(%w+)", 2)
    local option

    if f_e then
            -- if that match, take the next sub-string as option
            f_s, f_e, option = string.find(packet, "^%s+(%w+)", f_e + 1)
    end

    -- we got our commands, execute it
```

```
    if command == "show" and option == "querycounter" then
            ---
            -- proxy.PROXY_SEND_RESULT requires
            --
            -- proxy.response.type to be either
            -- * proxy.MYSQLD_PACKET_OK or
            -- * proxy.MYSQLD_PACKET_ERR
            --
            -- for proxy.MYSQLD_PACKET_OK you need a resultset
            -- * fields
            -- * rows
            --
            -- for proxy.MYSQLD_PACKET_ERR
            -- * errmsg
            proxy.response.type = proxy.MYSQLD_PACKET_OK
            proxy.response.resultset = {
                    fields = {
                            { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
                    },
                    rows = {
                            { proxy.global.query_counter }
                    }
            }

            -- we have our result, send it back
            return proxy.PROXY_SEND_RESULT
    elseif command == "show" and option == "myerror" then
            proxy.response.type = proxy.MYSQLD_PACKET_ERR
            proxy.response.errmsg = "my first error"

            return proxy.PROXY_SEND_RESULT

    elseif string.sub(packet, 2):lower() == 'select help' then
            return show_process_help()

    elseif string.sub(packet, 2):lower() == 'show proxy processlist' then
            return show_process_table()

    elseif query == "SELECT * FROM backends" then
        fields = {
            { name = "backend_ndx",

--]]

proxy.global.query_counter = proxy.global.query_counter or 0
```

```
function proxy.global.initialize_process_table()
    if proxy.global.process == nil then
        proxy.global.process = {}
    end
    if proxy.global.process[proxy.connection.server.thread_id] == nil then
        proxy.global.process[proxy.connection.server.thread_id] = {}
    end
end

function read_auth_result( auth )
    local state = auth.packet:byte()
    if state == proxy.MYSQLD_PACKET_OK then
        proxy.global.initialize_process_table()
        table.insert( proxy.global.process[proxy.connection.server.thread_id],
            { ip = proxy.connection.client.src.name, ts = os.time() } )
    end
end

function disconnect_client()
    local connection_id = proxy.connection.server.thread_id
    if connection_id then
        -- client has disconnected, set this to nil
        proxy.global.process[connection_id] = nil
    end
end

---
-- read_query() can return a resultset
--
-- You can use read_query() to return a result-set.
--
-- @param packet the mysql-packet sent by the client
--
-- @return
--   * nothing to pass on the packet as is,
--   * proxy.PROXY_SEND_QUERY to send the queries from the proxy.queries queue
--   * proxy.PROXY_SEND_RESULT to send your own result-set
--
function read_query( packet )
        -- a new query came in in this connection
        -- using proxy.global.* to make it available to the admin plugin
        proxy.global.query_counter = proxy.global.query_counter + 1

end
```

To use the script, save the first script to a file (`admin.lua` in the example below) and the other to `reporter.lua`, and then run `mysql-proxy` specifying the admin script and a backend MySQL server:

```
shell> mysql-proxy --admin-lua-script=admin.lua --admin-password=password \ »
     --admin-username=root --proxy-backend-addresses=127.0.0.1:3306 -proxy-lua-script=reporter.lua
```

In a separate window, connect to the MySQL server through the proxy:

```
shell> mysql --user=root --password=password --port=4040
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1798669
Server version: 5.0.70-log Gentoo Linux mysql-5.0.70-r1

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

In another different window, connect to the `mysql-proxy` admin service using the specified username and password:

```
shell> mysql --user=root --password=password --port=4041 --host=localhost
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1
Server version: 5.0.99-agent-admin

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

You can monitor the status of the proxy by asking for a list of the current active processes:

```
mysql>  show proxy processlist;
+---------+---------------------+--------------------------+
| Id      | IP Address          | Time                     |
+---------+---------------------+--------------------------+
```

```
| 1798669 | 192.168.0.112:52592 | Wed Jan 20 16:58:00 2010 |
+---------+---------------------+--------------------------+
1 row in set (0.00 sec)

mysql>
```

For more information on the example, see MySQL Proxy Admin Example.

14.6.6. MySQL Proxy FAQ

Questions

- 15.6.6.1: Is the system context switch expensive, how much overhead does the lua script add?
- 15.6.6.2: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.
- 15.6.6.3: Can I use MySQL Proxy with all versions of MySQL?
- 15.6.6.4: If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?
- 15.6.6.5: Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?
- 15.6.6.6: Can MySQL Proxy handle SSL connections?
- 15.6.6.7: In load balancing, how can I separate reads from writes?
- 15.6.6.8: What is the limit for `max-connections` on the server?
- 15.6.6.9: As the script is re-read by proxy, does it cache this or is it looking at the file system with each request?
- 15.6.6.10: With load balancing, what happen to transactions ? Are all queries sent to the same server ?
- 15.6.6.11: Can I run MySQL Proxy as a daemon?
- 15.6.6.12: What about caching the authorization info so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?
- 15.6.6.13: Would the Java-only connection pooling solution work for multiple web servers? With this, I'd assume you can pool across many web servers at once?
- 15.6.6.14: Could MySQL Proxy be used to capture passwords?
- 15.6.6.15: Can MySQL Proxy be used on slaves and intercept binlog messages?
- 15.6.6.16: MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?
- 15.6.6.17: How does MySQL Proxy compare to DBSlayer ?
- 15.6.6.18: I currently use SQL Relay for efficient connection pooling with a number of apache processes connecting to a MySQL server. Can MySQL proxy currently accomplish this. My goal is to minimize connection latency while keeping temporary tables available.
- 15.6.6.19: The global namespace variable example with quotas does not persist after a reboot, is that correct?
- 15.6.6.20: I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.
- 15.6.6.21: If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?
- 15.6.6.22: Will Proxy be deprecated for use with connection pooling once MySQL 6.x comes out? Or will 6.x integrate proxy more deeply?
- 15.6.6.23: We've looked at using MySQL Proxy but we're concerned about the alpha status - when do you think the proxy would be considered production ready?

- 15.6.6.24: Will the proxy road map involve moving popular features from lua to C? For example Read/Write splitting
- 15.6.6.25: Are these reserved function names (for example, error_result) that get automatically called?
- 15.6.6.26: Can you explain the status of your work with `memcached` and MySQL Proxy?
- 15.6.6.27: Is the MySQL Proxy an API ?
- 15.6.6.28: Is there any big web site using MySQL Proxy ? For what purpose and what transaction rate have they achieved.
- 15.6.6.29: So the authentication when connection pooling has to be done at every connection? What's the authentication latency?
- 15.6.6.30: Is it possible to use the MySQL proxy w/ updating a Lucene index (or Solr) by making TCP calls to that server to update?
- 15.6.6.31: Isn't MySQL Proxy similar to what is provided by Java connection pools?
- 15.6.6.32: Are there tools for isolating problems? How can someone figure out if a problem is in the client, in the db or in the proxy?
- 15.6.6.33: Can you dynamically reconfigure the pool of MySQL servers that MySQL Proxy will load balance to?
- 15.6.6.34: Given that there is a `connect_server` function, can a Lua script link up with multiple servers?
- 15.6.6.35: Adding a proxy must add latency to the connection, how big is that latency?
- 15.6.6.36: In the quick poll, I see "Load Balancer: read-write splitting" as an option, so would it be correct to say that there are no scripts written for Proxy yet to do this?
- 15.6.6.37: Is it "safe" to use `LuaSocket` with proxy scripts?
- 15.6.6.38: How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?
- 15.6.6.39: Do you have make one large script and call at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?

Questions and Answers

15.6.6.1: Is the system context switch expensive, how much overhead does the lua script add?

Lua is fast and the overhead should be small enough for most applications. The raw packet-overhead is around 400 microseconds.

15.6.6.2: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.

Just specify the path to the socket:

```
--proxy-backend-addresses=/path/to/socket
```

However it appears that `--proxy-address=/path/to/socket` does not work on the front end. It would be nice if someone added this feature.

15.6.6.3: Can I use MySQL Proxy with all versions of MySQL?

MySQL Proxy is designed to work with MySQL 5.0 or higher, and supports the MySQL network protocol for 5.0 and higher.

15.6.6.4: If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?

MySQL Proxy can live on any box: application, db or its own box. MySQL Proxy uses comparatively little CPU or RAM, so additional requirements or overhead is negligible.

15.6.6.5: Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?

You can run the proxy on the application server, on its own box or on the DB-server depending on the use-case

15.6.6.6: Can MySQL Proxy handle SSL connections?

No, being the man-in-the-middle, Proxy can't handle encrypted sessions because it cannot share the SSL information.

15.6.6.7: In load balancing, how can I separate reads from writes?

There is no automatic separation of queries that perform reads or writes to the different backend servers. However, you can specify to `mysql-proxy` that one or more of the 'backend' MySQL servers are read only.

```
$ mysql-proxy \
--proxy-backend-addresses=10.0.1.2:3306 \
--proxy-read-only-backend-addresses=10.0.1.3:3306 &
```

15.6.6.8: What is the limit for `max-connections` on the server?

Around 1024 connections the MySQL Server may run out of threads it can spawn. Leaving it at around 100 is advised.

15.6.6.9: As the script is re-read by proxy, does it cache this or is it looking at the file system with each request?

It looks for the script at client-connect and reads it if it has changed, otherwise it uses the cached version.

15.6.6.10: With load balancing, what happen to transactions ? Are all queries sent to the same server ?

Without any special customization the whole connection is sent to the same server. That keeps the whole connection state intact.

15.6.6.11: Can I run MySQL Proxy as a daemon?

Starting from version 0.6.0, the Proxy is launched as a daemon by default. If you want to avoid this, use the `-D` or `--no-daemon` option. To keep track of the process ID, the daemon can be started with the additional option `--pid-file=file`, to save the PID to a known file name. On version 0.5.x, the Proxy can't be started natively as a daemon

15.6.6.12: What about caching the authorization info so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?

There is an option that provides this functionality `--proxy-pool-no-change-user`.

15.6.6.13: Would the Java-only connection pooling solution work for multiple web servers? With this, I'd assume you can pool across many web servers at once?

Yes. But you can also start one proxy on each application server to get a similar behavior as you have it already.

15.6.6.14: Could MySQL Proxy be used to capture passwords?

The MySQL network protocol does not allow passwords to be sent in clear-text, all you could capture is the encrypted version.

15.6.6.15: Can MySQL Proxy be used on slaves and intercept binlog messages?

We are working on that. See http://jan.kneschke.de/2008/5/30/mysql-proxy-rbr-to-sbr-decoding for an example.

15.6.6.16: MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?

Se your `max-connections` settings. By default the setting is 150, the proxy can handle a lot more.

15.6.6.17: How does MySQL Proxy compare to DBSlayer ?

DBSlayer is a REST->MySQL tool, MySQL Proxy is transparent to your application. No change to the application is needed.

15.6.6.18: I currently use SQL Relay for efficient connection pooling with a number of apache processes connecting to a MySQL server. Can MySQL proxy currently accomplish this. My goal is to minimize connection latency while keeping temporary tables available.

Yes.

15.6.6.19: The global namespace variable example with quotas does not persist after a reboot, is that correct?

Yes. if you restart the proxy, you lose the results, unless you save them in a file.

15.6.6.20: I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.

This issue is fixed in version 0.7.0.

15.6.6.21: If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?

Yes, MySQL Proxy can listen on any port. Providing none of the MySQL servers are listening on the same port.

15.6.6.22: Will Proxy be deprecated for use with connection pooling once MySQL 6.x comes out? Or will 6.x integrate proxy more deeply?

The logic about the pooling is controlled by the lua scripts, you can enable and disable it if you like. There are no plans to embed the current MySQL Proxy functionality into the MySQL Server.

15.6.6.23: We've looked at using MySQL Proxy but we're concerned about the alpha status - when do you think the proxy would be considered production ready?

We are on the road to the next feature release: 0.7.0. It will improve the performance quite a bit. After that we may be able to enter the beta phase.

15.6.6.24: Will the proxy road map involve moving popular features from lua to C? For example Read/Write splitting

We will keep the high-level parts in the Lua layer to be able to adjust to special situations without a rebuild. Read/Write splitting sometimes needs external knowledge that may only be available by the DBA.

15.6.6.25: Are these reserved function names (for example, error_result) that get automatically called?

Only functions and values starting with `proxy.*` are provided by the proxy. All others are provided by you.

15.6.6.26: Can you explain the status of your work with `memcached` and MySQL Proxy?

There are some ideas to integrate proxy and `memcache` a bit, but no code yet.

15.6.6.27: Is the MySQL Proxy an API ?

No, MySQL Proxy is an application that forwards packets from a client to a server using the MySQL network protocol. The MySQL proxy provides a API allowing you to change its behavior.

15.6.6.28: Is there any big web site using MySQL Proxy ? For what purpose and what transaction rate have they achieved.

Yes, gaiaonline. They have tested MySQL Proxy and seen it handle 2400 queries per second through the proxy.

15.6.6.29: So the authentication when connection pooling has to be done at every connection? What's the authentication latency?

You can skip the round-trip and use the connection as it was added to the pool. As long as the application cleans up the temporary tables it used. The overhead is (as always) around 400 microseconds.

15.6.6.30: Is it possible to use the MySQL proxy w/ updating a Lucene index (or Solr) by making TCP calls to that server to update?

Yes, but it isn't advised for now.

15.6.6.31: Isn't MySQL Proxy similar to what is provided by Java connection pools?

Yes and no. Java connection pools are specific to Java applications, MySQL Proxy works with any client API that talks the MySQL network protocol. Also, connection pools do not provide any functionality for intelligently examining the network packets and modifying the contents.

15.6.6.32: Are there tools for isolating problems? How can someone figure out if a problem is in the client, in the db or in the proxy?

You can set a debug script in the proxy, which is an exceptionally good tool for this purpose. You can see very clearly which component is causing the problem, if you set the right breakpoints.

15.6.6.33: Can you dynamically reconfigure the pool of MySQL servers that MySQL Proxy will load balance to?

Not yet, it is on the list. We are working on a administration interface for that purpose.

15.6.6.34: Given that there is a `connect_server` function, can a Lua script link up with multiple servers?

The proxy provides some tutorials in the source-package, one is `examples/tutorial-keepalive.lua`.

15.6.6.35: Adding a proxy must add latency to the connection, how big is that latency?

In the range of 400microseconds

15.6.6.36: In the quick poll, I see "Load Balancer: read-write splitting" as an option, so would it be correct to say that there are no scripts written for Proxy yet to do this?

There is a proof of concept script for that included. But its far from perfect and may not work for you yet.

15.6.6.37: Is it "safe" to use `LuaSocket` with proxy scripts?

You can, but it is not advised as it may block.

15.6.6.38: How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?

Connection Pooling is just one use-case of the MySQL Proxy. You can use it for a lot more and it works in cases where you can't use DBCP (like if you don't have Java).

15.6.6.39: Do you have make one large script and call at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?

You can just change the script and the proxy will reload it when a client connects.

Chapter 15. MySQL Enterprise Monitor

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

The MySQL Enterprise Monitor serves as an automated assistant for MySQL database administrators. This service is designed to help administrators with their day-to-day tasks by monitoring MySQL servers and identifying potential problems. These features are designed to save the database administrator's time and effort by providing the information you need through a simplified interface.

An extension of existing MySQL Enterprise services, MySQL Enterprise Monitor monitors enterprise database environments and provides expert advice on how customers can tighten security and optimize the performance and uptime of their MySQL servers.

MySQL Enterprise Monitor helps administrators:

- Intelligently stay up to date with releases and bug fixes
- Know what's going on with their system
- Manage day-to-day database maintenance tasks
- Improve the performance of their system
- Manage and prevent crises

The MySQL Enterprise Monitor was designed to tackle the job of managing the performance of any number of MySQL database servers, regardless of their physical or geographical location. Although MySQL Enterprise Monitor can easily track just a handful of MySQL servers, the service is specifically designed to greatly curtail the time it takes to get a handle on the availability and performance levels of many database servers at once.

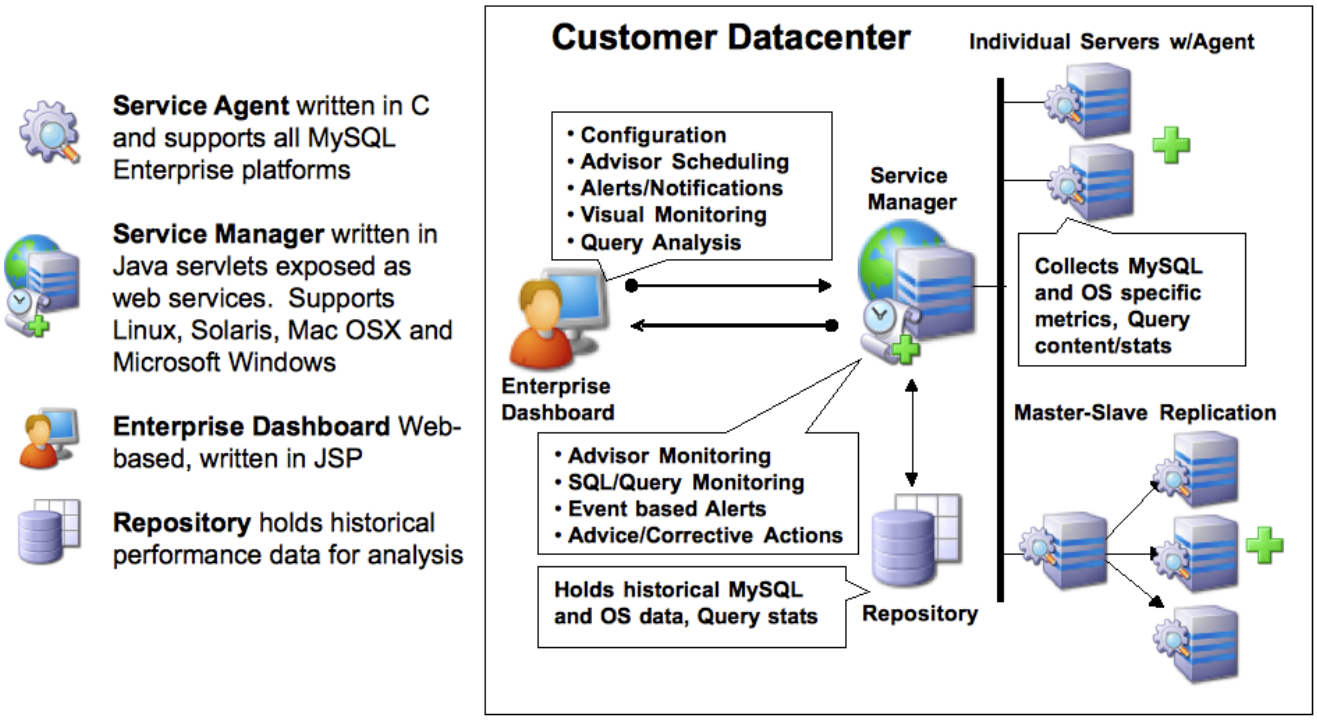
The MySQL Enterprise Monitor does this by providing an web-based interface—called the Enterprise Dashboard—that serves as the portal for viewing information about your MySQL database servers. MySQL professionals can manage all their servers by group or individually if need be.

The Enterprise Dashboard web interface does not have to be installed on individual desktops, but is instead available from a centrally located machine that serves as the main location for the Monitoring and Advisory service.

15.1. An Overview of the Service

The MySQL Enterprise Monitor is a collection of components that work together to monitor and help administer your MySQL server installations. This service includes server management agents, advisors, and a central MySQL Enterprise Service Manager, all working in tandem with the MySQL Enterprise to keep your MySQL servers secure and up to date. All of this is controlled through the MySQL Enterprise Dashboard—a lightweight web-based interface that gives you complete control of your MySQL servers from any location.

Figure 15.1. MySQL Enterprise Monitor Architecture



The service is made up of a number of components, including the Monitor Agent (MySQL Enterprise Monitor Agent), the Service Manager (MySQL Enterprise Service Manager), the Enterprise Dashboard, the Repository and the Advisors.

15.1.1. The Service Architecture

The MySQL Enterprise Monitor is powered by a distributed web-based application that is deployed within the confines of the corporate firewall. The Enterprise Dashboard provides the interface to the server data, advisor notifications, live information and communication with the MySQL Enterprise Update Service.

Subscribers are kept up to date about the latest releases of the MySQL server or issues that may affect their specific implementation of MySQL by using the MySQL Enterprise Update Service. This same mechanism is used to notify MySQL Enterprise Monitor users of updates to the application or to the MySQL Advisors and Rules. The various components are described below.

- **Monitor Agent**

  Monitor Agents are the foot soldiers of the MySQL Enterprise Monitor; they monitor each MySQL server. Running as a Windows service or Unix daemon, the Agent uses a combination of MySQL specific commands, SQL queries, and custom scripts to collect and report MySQL server or operating system (OS) specific data. The Monitor Agent initiates a “heartbeat” to the Service Manager on a regular basis to ensure specific MySQL server and OS level data collections are current.

  In the overall architecture, the Monitor Agent is the only component of the MySQL Enterprise Monitor that establishes or maintains a connection with the monitored MySQL Server. As with any MySQL client, the Monitor Agent is authenticated on the monitored MySQL server and requires a user name and password to establish a connection.

  In addition, the MySQL Enterprise Monitor Agent also provides a proxy service that allows for information about queries to be captured and reported as part of the Query Analyzer functionality. The MySQL Enterprise Monitor Agent accepts client connections and forwards the SQL statements on to the server and returns the results. In the background, the agent is collecting information about the query execution, row counts, times and other data so that queries and their execution can be monitored.

- **Service Manager**

  The Service Manager is the heart and soul of the MySQL Enterprise Monitor. It is built on a collection of Java services hosted on a single Windows or Unix server. The Service Manager interacts with all of the Monitor Agents under its domain to collect MySQL server and OS level data for each of the monitored MySQL servers.

The Service Manager performs many duties including:

- Enterprise Dashboard, the main interface to the MySQL Enterprise Service Manager.
- Autodiscovery of monitored MySQL Servers.
- Creation and management of Monitor Agent tasks.
- Storage of data collections from Monitor Agents.
- Monitoring of key MySQL server and OS level metric data collections.
- Reporting MySQL best practice events and violations.
- Providing MySQL expert advice for MySQL best practice violations.
- Autodiscovery of replication topology (Not available for all subscription levels)

- **The Repository**

  The Repository is built on MySQL 5.0.*x* and is used to store MySQL server and OS level data collections for each of the monitored MySQL Servers. This information is used by the Service Manager to evaluate and report the health and status of the monitored MySQL environment(s).

- **The Enterprise Dashboard**

  The MySQL Enterprise web client provides the graphical user interface (GUI) for the MySQL Enterprise Monitor. This interface is the primary means of monitoring the state of your MySQL servers, identifying rule violations and providing advice on how best to address and correct any underlying issues.

  This interface also provides an easy means of configuring advisors, adding users, creating notification groups, and receiving updates from MySQL Enterprise.

15.1.2. Service Features

The key features of the MySQL Enterprise Monitor can be summarized as follows:

- Group-level or Server-level management options
- Enterprise Dashboard for managing all MySQL Servers from a consolidated console
- Monitoring page for “at a glance” global health check of key systems
- MySQL-provided Advisors and Advisor Rules for enforcing MySQL Best Practices
- Advisor Rule Scheduling for unattended operations
- Customizable Thresholds and Alerts for identifying Advisor Rule violations
- User-Defined Advisor Rules
- Event/Alert History browser for researching advisor-specific events and annotations
- Query Analyzer functionality allowing you to monitor the execution times, row counts and other data about queries executed on your MySQL server.

These features are presented through the MySQL Enterprise Dashboard which is made up of six main pages:

- The **MONITOR** page comprises:
  - The **SERVER TREE**: Easily navigate monitored servers

  - The **GRAPHING**: This capability is built in so you can quickly assess critical functions such as activity, performance metrics, and number of connections
  - The **HEAT CHART**: Color-coded buttons provide key operating system and database metrics
- The **ADVISORS** page

  This page shows the advisors that are currently scheduled. There are advisors for a variety of topics such as security and indexing. Users can add, edit, or create their own advisors.
- The **EVENTS** page

  This page shows rule violations, indicating the server, severity, and time of occurrence. A number of filter options are available, allowing various views of events.
- The **GRAPHS** page

  Use this page to view all the available graphs and to adjust the scale of the graphs, for a more or less detailed view as the situation requires.
- The **QUERY ANALYZER** page
- The **REPLICATION** page

  Use this page to keep track of your masters and their slaves (Not available for all subscription levels)
- The **SETTINGS** page

  On this page you configure servers, users, email addresses, and notification groups. Entering a user name and password for MySQL Enterprise provides automatic updates.

15.1.3. Security

Using the Tomcat/Apache web server for the user interface allows an administrator to configure the web server to meet any security regulations. The MySQL Enterprise Monitor architecture is designed to be as secure as possible, even when monitoring systems outside of the local network.

Communications between the MySQL Enterprise Monitor Agent and MySQL Enterprise Service Manager can be protected by Secure Socket Layer (SSL) encryption and server and agent can use SSL certificates to provide authentication and prevent spoofing.

The MySQL Enterprise Monitor Agent is like a web browser — it is an HTTP client application that initiates all communication with the MySQL Enterprise Service Manager. If the server requires action from the agent, it must wait until the agent next initiates contact and sends its request in a response. This means you do not need to open an inbound port on the machine on which the agent is running because it does not listen for requests. However, an outbound port must be open for the agent to contact the MySQL Enterprise Service Manager.

As an additional security feature, each Agent can have a separate Advisory Service login which minimizes exposure should any one agent be compromised.

15.2. Conventions Used in This Document

This document uses certain typographical conventions:

- `Text in this style` is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”
- **`Text in this style`** indicates input that you type in examples.
- `Text in this style` indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command line client program) and `mysqld` (the MySQL server executable).
- *`Text in this style`* is used for variable input for which you should substitute a value of your own choosing.

- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”
- Character sequences are written like this: “To specify a wildcard, use the ‘`%`’ character.”
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell or from the command line in Windows:

```
shell> type a shell command here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Sometimes, what appears on one line in a console window cannot be represented in the documentation on a single line. In cases such as this the character ‘`»`’ is used. For example:

```
Please specify the directory where the MySQL Enterprise Monitor »
 will be installed.
```

Where Unix commands are concerned, the continuation character ‘`\`’ is used. Doing this allows commands to be copied and pasted to the command line verbatim. For example:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent -f \
 /opt/mysql/enterprise/agent/etc/mysql-monitor-agent.ini
```

SQL keywords are not case sensitive and may be written in either case. This document uses uppercase.

In syntax descriptions, square brackets (‘`[`’ and ‘`]`’) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (‘`|`’). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (‘`[`’ and ‘`]`’):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (‘`{`’ and ‘`}`’):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (`...`) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `INSERT ... SELECT` is shorthand for the form of `INSERT` statement that is followed by a `SELECT` statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple *`reset_option`* values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
```

```
shell> ./configure
```

Throughout this document the term ‘Unix’ is used to describe any Unix or Unix-like operating system. For an up-to-date list of operating systems supported by the MySQL Enterprise Monitor please see the http://www.mysql.com/products/enterprise/.

15.3. Installation and Upgrades

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

This chapter describes the process of installing the MySQL Enterprise Monitor on all operating systems. A working installation requires the installation of a MySQL Enterprise Service Manager, the MySQL Enterprise Advisors and one or more MySQL Enterprise Monitor Agents. Simply described, the agent inspects the MySQL server it is monitoring, reports to the Service Manager, and the results are interpreted by the advisors and displayed in the MySQL Enterprise Dashboard for viewing in a web browser.

One Monitor Agent is installed for each MySQL server that is being monitored. The Monitor Agent usually runs on the same machine that hosts the monitored MySQL server but it may run on any machine that has access to both the monitored MySQL server and the MySQL Enterprise Dashboard. The agent reports its findings to the Service Manager and these results are interpreted by Advisors and displayed in the dashboard. The end user opens a web browser to view the information presented in the dashboard. The Service Manager and dashboard run on the same machine and both have access to a local MySQL server installed as part of the MySQL Enterprise Monitor. This server is known as the repository and provides storage for the data provided by the agent.

Installation is a three step process:

1. Install and start the Service Manager on the monitoring system. See Section 15.3.2, “Service Manager Installation”.
2. Configure the Service Manager, see Section 15.3.3, “Monitor Agent Installation”.
3. Start the MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent instances, and then use the MySQL Enterprise Dashboard to install the Advisors and complete the configuration and installation. See Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”.

Depending on your configuration and environment, you will need to download a number of different components and files from MySQL Enterprise website available on the download page. These include:

- MySQL Enterprise Service Manager and MySQL Enterprise Dashboard for the platform that you intend to execute the MySQL Enterprise Service Manager on. These are named `mysqlmonitor-2.1.0.1096-linux-x86_64-installer.bin`, with the appropriate version and platform name. If you are performing an upgrade, download the upgrade installer, named `mysqlmonitor-2.1.0.1096-linux-x86_64-update-installer.bin`.
- One or more MySQL Enterprise Monitor Agent, one for each MySQL Server that you want to monitor. You should download an installer package for the right platform for the MySQL server you want to manage. Agent installers are available with the name `mysqlmonitoragent-2.1.0.1093-linux-debian3.1-powerpc-installer.bin`. Upgrade installers to update an existing MySQL Enterprise Monitor Agent installation are named `mysqlmonitoragent-2.1.0.1093-linux-debian3.1-powerpc-update-installer.bin`.
- *Optional*

  A product key file for MySQL Enterprise Service Manager. If your MySQL Enterprise Service Manager has internet connectivity, your product key can be downloaded automatically during the initial phase of configuration directly from the MySQL Enterprise website. For more information, see Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”.
- *Optional*

  An advisor bundle equal to the level of your MySQL Enterprise subscriptiion (Platinum, Gold, or Silver), which is required for MySQL Enterprise Service Manager. If your MySQL Enterprise Service Manager has internet connectivity, your advisor bundle can be downloaded automatically during the initial phase of configuration directly from the MySQL Enterprise website. For more information, see Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”.

For information on the installation requirements for different platforms, see Section 15.12.3, “Installation Requirements”.

15.3.1. User Roles

Prior to installation you will need to have at hand credentials for access to the MySQL server you plan to monitor and also your MySQL Enterprise credentials. *During* installation and when first logging in, you will set up a variety of users with different roles and credentials. This can become confusing. This section outlines the various users associated with the MySQL Enterprise Monitor and gives a brief description of their roles.

15.3.1.1. Existing Users

The **MySQL Enterprise user**: These are the credentials you use to log in to the MySQL Enterprise web site. You will need them in order to acquire the Advisor files and receive updates and, if necessary, acquire a product key.

The **MySQL user**: For Monitor Agents to report the status of a MySQL server they must have privileges on that server. To perform all functions an agent must have `SHOW DATABASES`, `REPLICATION CLIENT`, `SUPER`, `CREATE`, and `SELECT` privileges. In short, the Monitor Agent needs to have read access to all data. Details about this account are given in Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”.

15.3.1.2. User Created During Installation

The **Repository user**: This user is the only user in the `user` table in the `mysql` database in the bundled MySQL server. To avoid confusion with monitored MySQL servers, this server is referred to throughout this document as the `repository`. The repository user can log in from `localhost` using the password specified during installation and has all privileges on all databases. These credentials are used to create the repository and its tables and to record data in them. During installation the default value for the user name for this role is `service_manager`. No default password is specified. You can use these credentials to manage the repository from the command line or when using a program such as MySQL Administrator.

During installation the file `configuration_report.txt` is created. Reference this file for the credentials of the repository manager. After the MySQL Enterprise Service Manager is installed, look for this file in the following directories:

- Windows: `C:\Program Files\MySQL\Enterprise\Monitor`
- Unix: `/opt/mysql/enterprise/monitor`
- Mac OS X: `/Applications/mysql/enterprise/monitor`

15.3.1.3. Users Created on First Log-in

The **Root user**: This user is the administrator of the dashboard. The first time you log in to the dashboard you must log in as this user. The default user name for this user is `admin`. There is no default password for this user.

The **Agent user**: The Monitor Agent needs to report the status of the MySQL server it is monitoring. For this reason it needs to log in to the dashboard. The default user name for this user is `agent`. There is no default password for this user.

> **Note**
>
> The Monitor Agent has two roles in the MySQL Enterprise Monitor; it must have access to the dashboard and to the MySQL server it is monitoring. For a description of the agent as a MySQL user see Section 15.3.1.1, “Existing Users”.

15.3.2. Service Manager Installation

The MySQL Enterprise Service Manager is the core element of the MySQL Enterprise Monitor. The installation process for this element is completely self-contained, but the installation includes the following components:

- Apache Tomcat
- MySQL Server
- Java VM

> **Note**
>
> After installation you can determine the version number of the various components by entering `http://server_name:18080/main?command=list_versions` into the web browsers address bar.

During installation, versions of MySQL and Tomcat will be installed onto the machine. The installer automatically provides default network ports that are different from standard installation for these applications. You can change the ports during installation.

During installation, default values are shown for user names and ports. This is for your convenience only; you may choose different values. The installer detect ports that are already in use and allows you to select different ports.

> **Warning**
>
> The MySQL Enterprise Service Manager version 2.0 requires agents using 2.0 or higher.

All the installations share the same basic configuration parameters that you will be asked to confirm during installation. Before you start your installation, please review the section on these common paramaters, then proceed to section specific to your installation platform. For details of the common parameters, see Section 15.3.2.1, “Service Manager Installation Common Parameters”. For information on installation under Windows, see Section 15.3.2.2, “Service Manager Installation on Windows”, for Mac OS X see Section 15.3.2.3, “Service Manager Installation on Mac OS X”, and for Unix/Linux, see Section 15.3.2.4, “Service Manager Installation on Unix”.

15.3.2.1. Service Manager Installation Common Parameters

All installations of the Service Manager install the Tomcat and MySQL applications using the same basic set of parameters. The defaults provided by the installation process are designed to be unique so that they do not interfere with existing installations of either product. However, you should check these parameters before installation to ensure that you do not experience any problems.

The common parameters are divided into those applying to the Tomcat server, and the MySQL server (Repository Configuration):

- **Tomcat Server Options**
  - Tomcat Server port: The default port that the Tomcat server will use when listening for connections. If you change this option, then the port that you need to use when connecting to the Service Manager must be modified accordingly. The default value is 18080.

    > **Note**
    >
    > If you are not currently running a web server on port 80 you may find it more convenient to use the well known port rather than `18080`. Since port `80` is the default for a web server, you can then open the dashboard without specifying a port.

  - Tomcat Shutdown port: The port used by the management scripts that is used to shut the Tomcat server down when you need to stop the Service Manager. The default value is 18005.
  - Tomcat SSL Port: The standard port used to connect to the Service Manager when you want to use Secure Sockets Layer (SSL) encrypted communication. The default value is 18443.
- **Repository Configuration (MySQL Server)**
  - Repository Username: The user name created and used to store information within the MySQL server to hold the information used by the Service Manager. In normal use, you should not need to use or modify this information, but it may be required if you have a support issue. The default value is `service_manager`.
  - Repository User password: The password to be used for the Repository Username. This should be set to a secure password so that the repository data is secure.

The information that you configure during installation will always be recorded within the `configuration_report.txt` file within the installation directory for the Service Manager.

> **Caution**
>
> Because the information stored within the `configuration_report.txt` file is in plain text, the Repository user name and password information are also exposed within this file. Make sure that the installation directory and file are secure that they can only be accessed by those users who would need to use the information.

15.3.2.2. Service Manager Installation on Windows

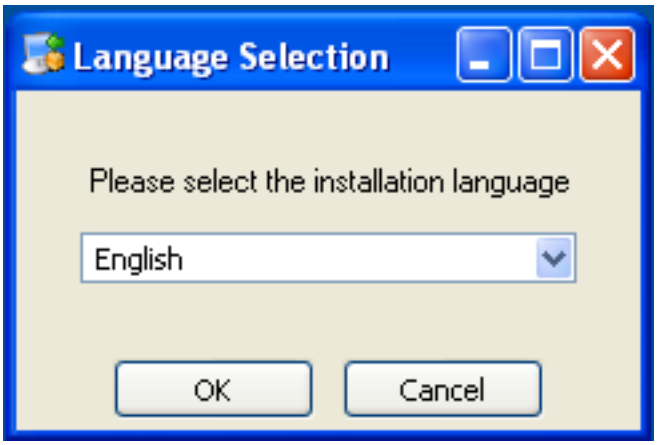
On Windows the installation modes are `win32` and `unattended` only. `unattended` mode is especially useful if you are doing multiple installations. For more information on this topic see Section 15.3.4, “Unattended Installation”.

> **Note**
>
> In order to install the Service Manager as a Windows service, you must do the installation as a privileged user.
>
> On Windows Vista or later, if user account control is on, an operating system dialog box requests confirmation of the installation.

To install the Service Manager on Windows, find the executable file named `mysqlmonitor-`*`version`*`-windows-installer.exe` (where *`version`* represents the three-part version number).

1. Double-click the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

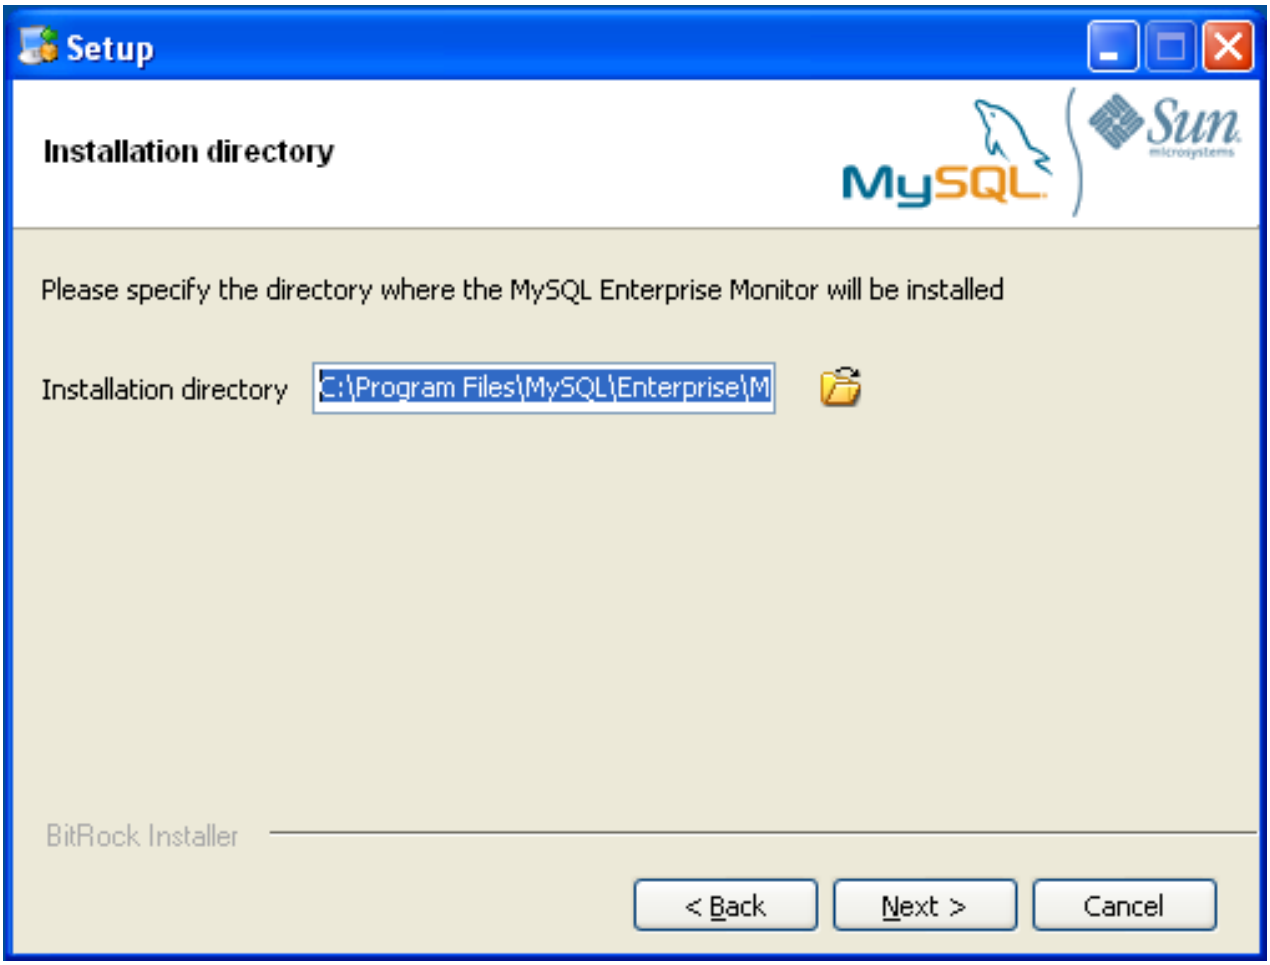
Figure 15.2. MySQL Enterprise Monitor: Installing Monitor on Windows: Language Selection



2. With the installation language selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to continue.

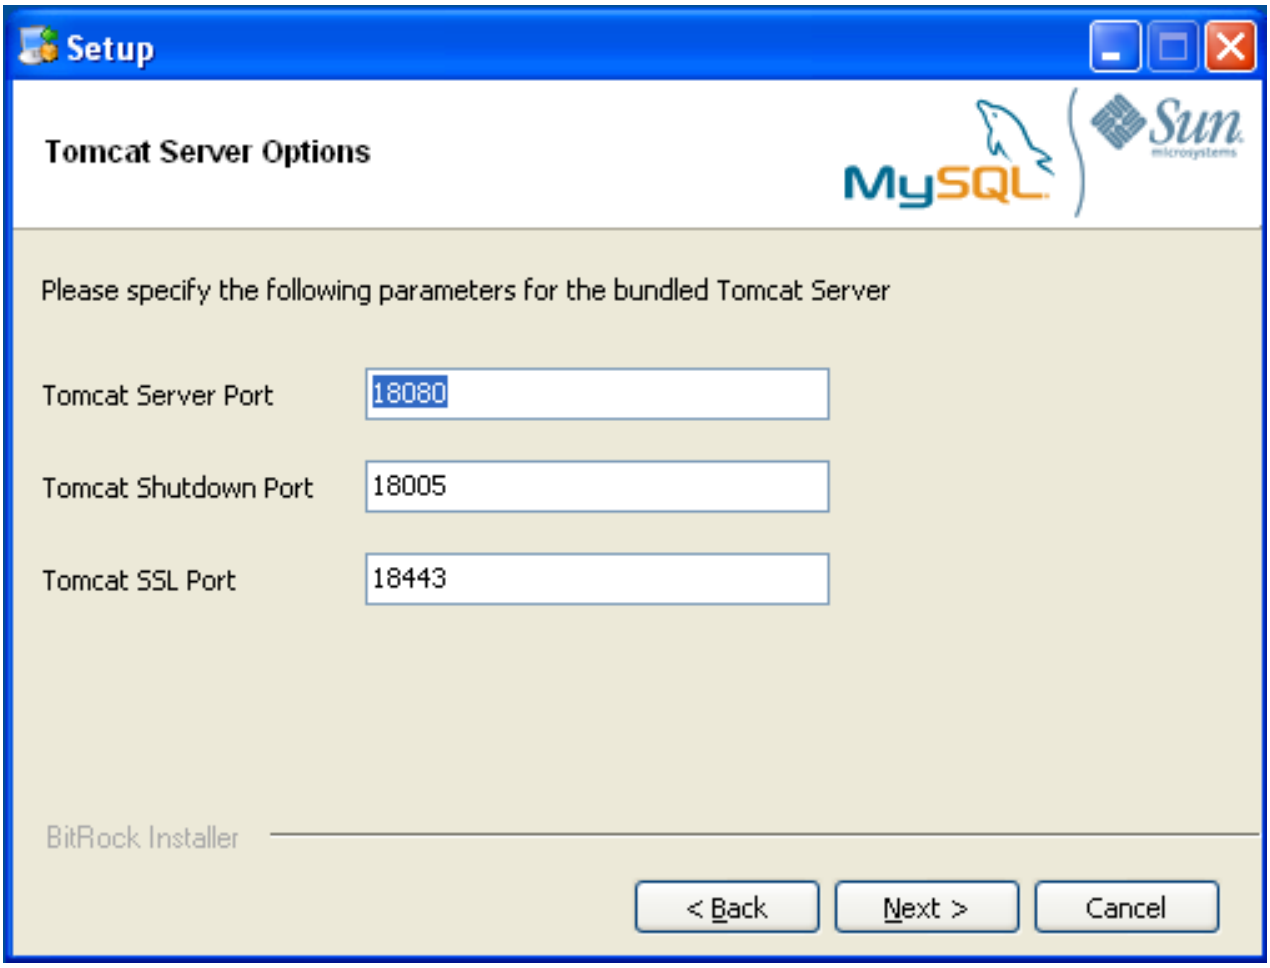
3. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Windows the directory is `C:\Program Files\MySQL\Enterprise\Monitor`. You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

Figure 15.3. MySQL Enterprise Monitor: Installing Monitor on Windows: Installation Directory



4. Configure the options that set the network ports used by the Tomcat server. For more information, see Section 15.3.2.1, "Service Manager Installation Common Parameters". Click NEXT to continue.

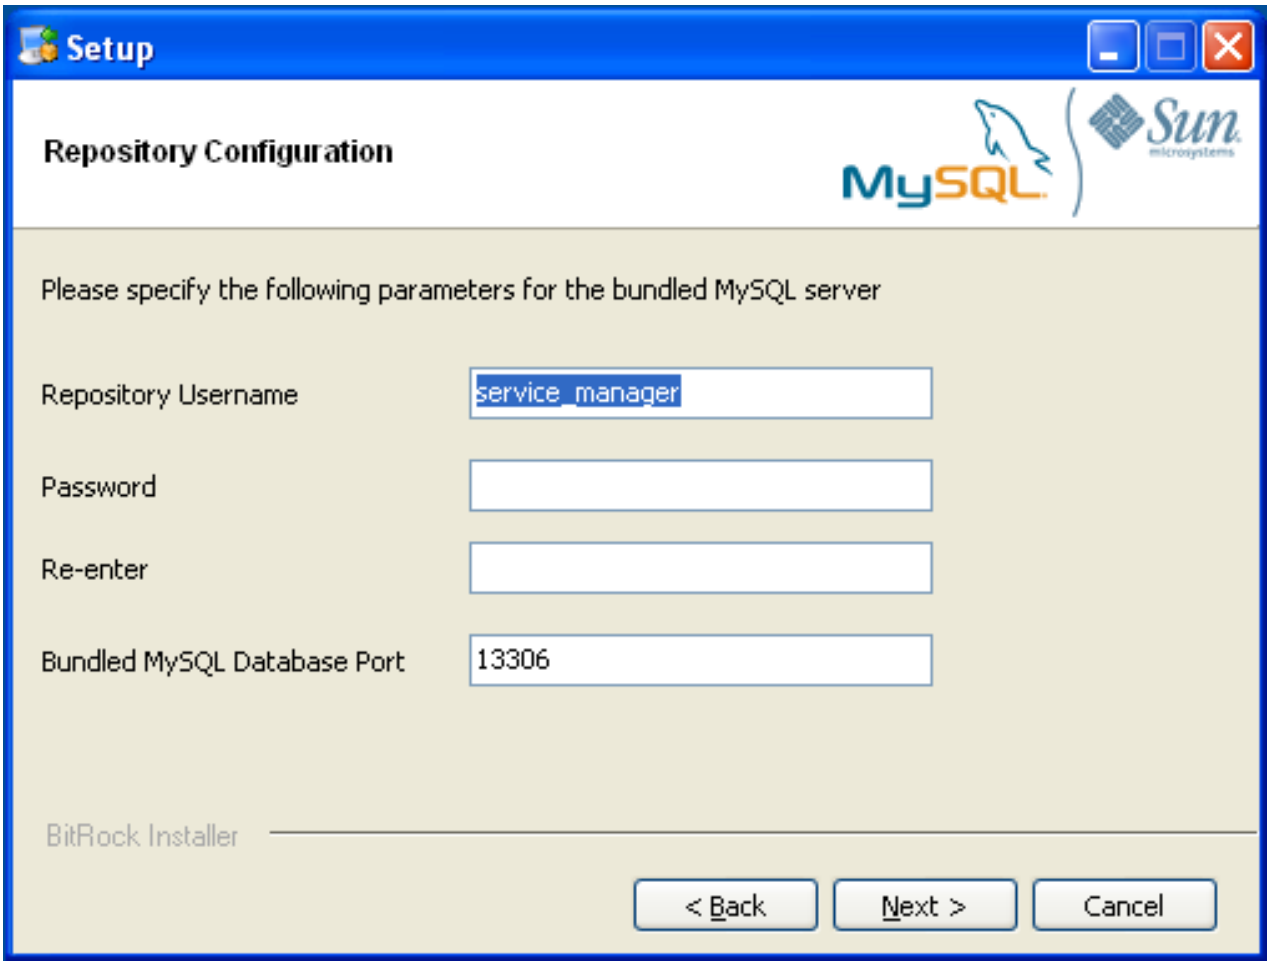
Figure 15.4. MySQL Enterprise Monitor: Installing Monitor on Windows: Tomcat Server Options



5. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see Section 15.3.2.1, "Service Manager Installation Common Parameters". Click NEXT to continue.

> **Note**
>
> If the Windows firewall is enabled you will be asked to unblock ports for Apache/Tomcat and the MySQL server.

Figure 15.5. MySQL Enterprise Monitor: Installing Monitor on Windows: Repository Configuration



6. You will be provided with information and a warning about the configuration options and how they are stored in the `configuration_report.txt` file, and it's location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.

7. You should now be prompted to start the installation process. Click NEXT to continue.

8. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.

9. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to login to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and clock FINISH.

For instructions on starting the MySQL Enterprise Monitor services under Windows, see Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”.

15.3.2.3. Service Manager Installation on Mac OS X

On Mac OS X there are three installation modes `osx`, `text`, and `unattended`. For more information on this topic see Section 15.3.4, “Unattended Installation”. The `text` mode installation for Mac OS X is identical to `text` installation under Unix. For `text` mode installation instructions see Section 15.3.2.4, “Service Manager Installation on Unix”.

Installing the MySQL Enterprise Service Manager on Mac OS X requires an existing installation of Java. The minimum required version is 1.5.0_7. If this version is not installed on your machine you can download it from Apple. This version of Java requires Mac OS X version 10.4.5 as a minimum, so you may need to upgrade your operating system in order to install it.

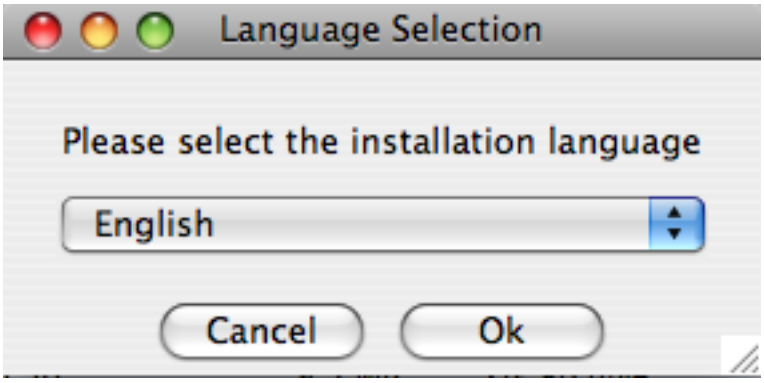
For reasons of backward compatibility, Mac OS X is usually installed with multiple versions of Java. When installing in `osx` mode, version 1.5.0_7 must be the default version. Upon installation, Java 1.5.0_7 sets itself as the default so this is usually not a problem.

If you have changed the default you can reset it or you may install the MySQL Enterprise Service Manager in `text` mode, setting the environment variables to point to the correct version of Java. To install in `text` mode, find the `installbuilder` file in the `Contents/MacOS` directory immediately below the `mysqlmonitor-version-osx-installer.app` directory. Installing the MySQL Enterprise Service Manager in `text` mode is identical to the procedure described in Section 15.3.2.4, "Service Manager Installation on Unix" with the minor differences noted above.

To install using the GUI (`osx`) installation, follow these instructions:

1. Double-click the MySQL Monitor installer. You should be presented with the Language Selection prompt. Select the language to use for the installer and then click OK.

Figure 15.6. MySQL Enterprise Monitor: Installing Monitor on OS X: Language Selection



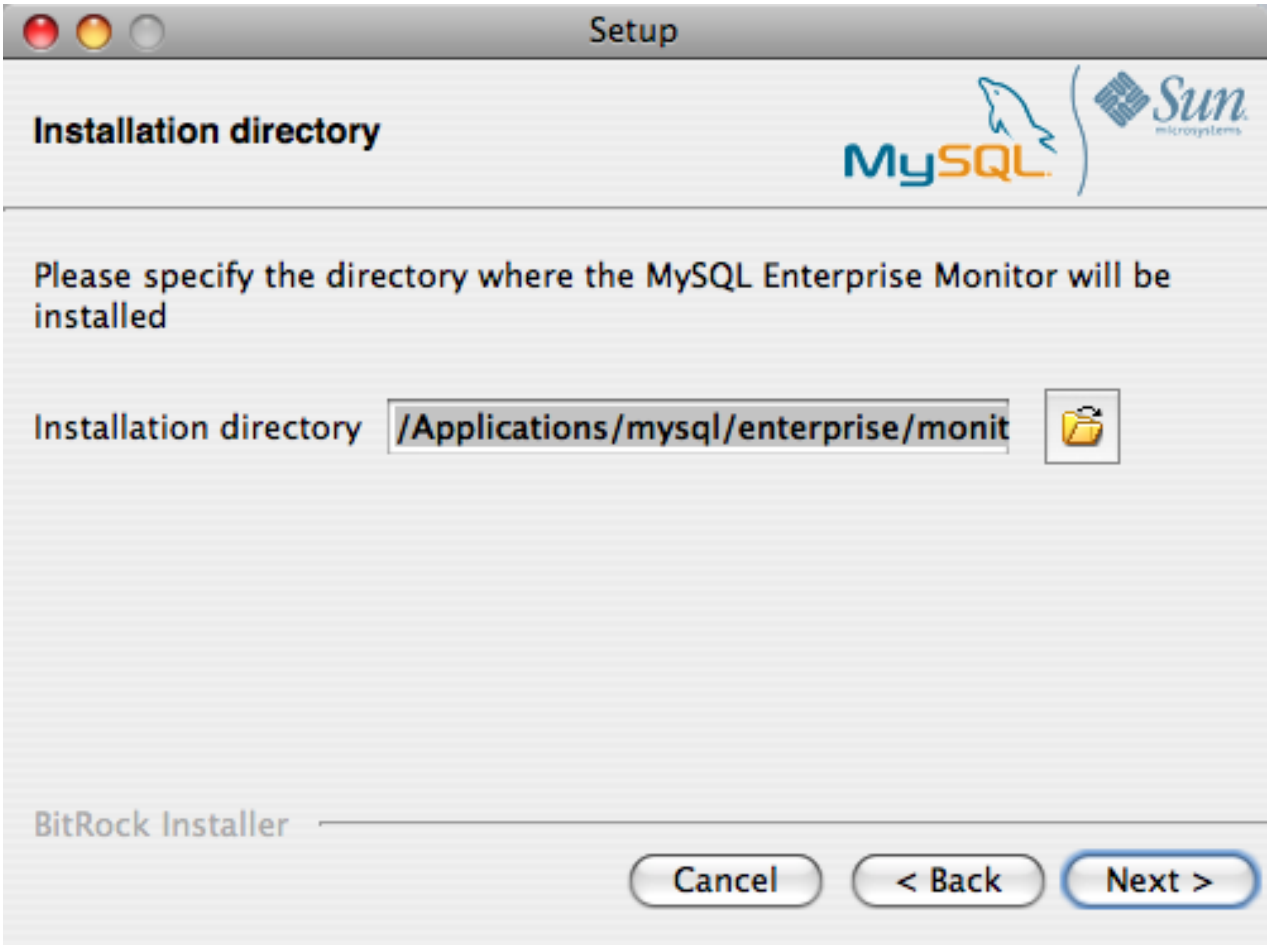
2. If you have multiple Java installations on your machine, you will be asked to choose which Java to use with your MySQL Enterprise Service Manager installation. Choose the Java version you want to use (1.5.0 or later is required), and click OK.

Figure 15.7. MySQL Enterprise Monitor: Installing Monitor on OS X: Java Selection

3. With the installation language and Java version selected, the remainder of the installation sets up the installation location and the main configuration parameters required by MySQL Enterprise Service Manager. Click NEXT to contintue.

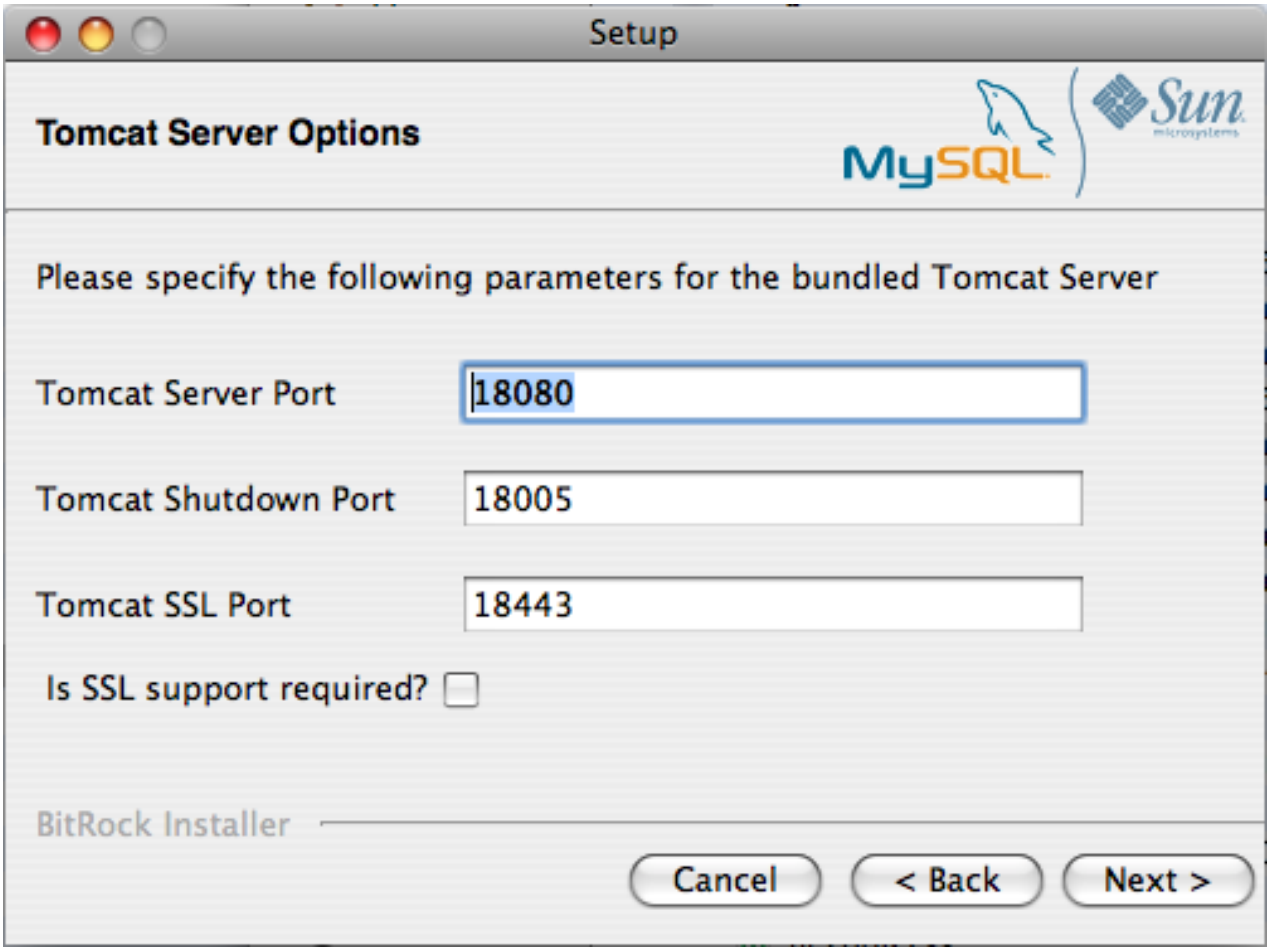
4. Select the installation directory where you want the MySQL Enterprise Service Manager components installed. By default on Mac OS X the directory is `/Applications/mysql/enterprise/monitor`. You click the button next to the installation directory field to select a directory using the File chooser, or type the directory manually. Click NEXT to continue.

Figure 15.8. MySQL Enterprise Monitor: Installing Monitor on OS X: Installation Directory



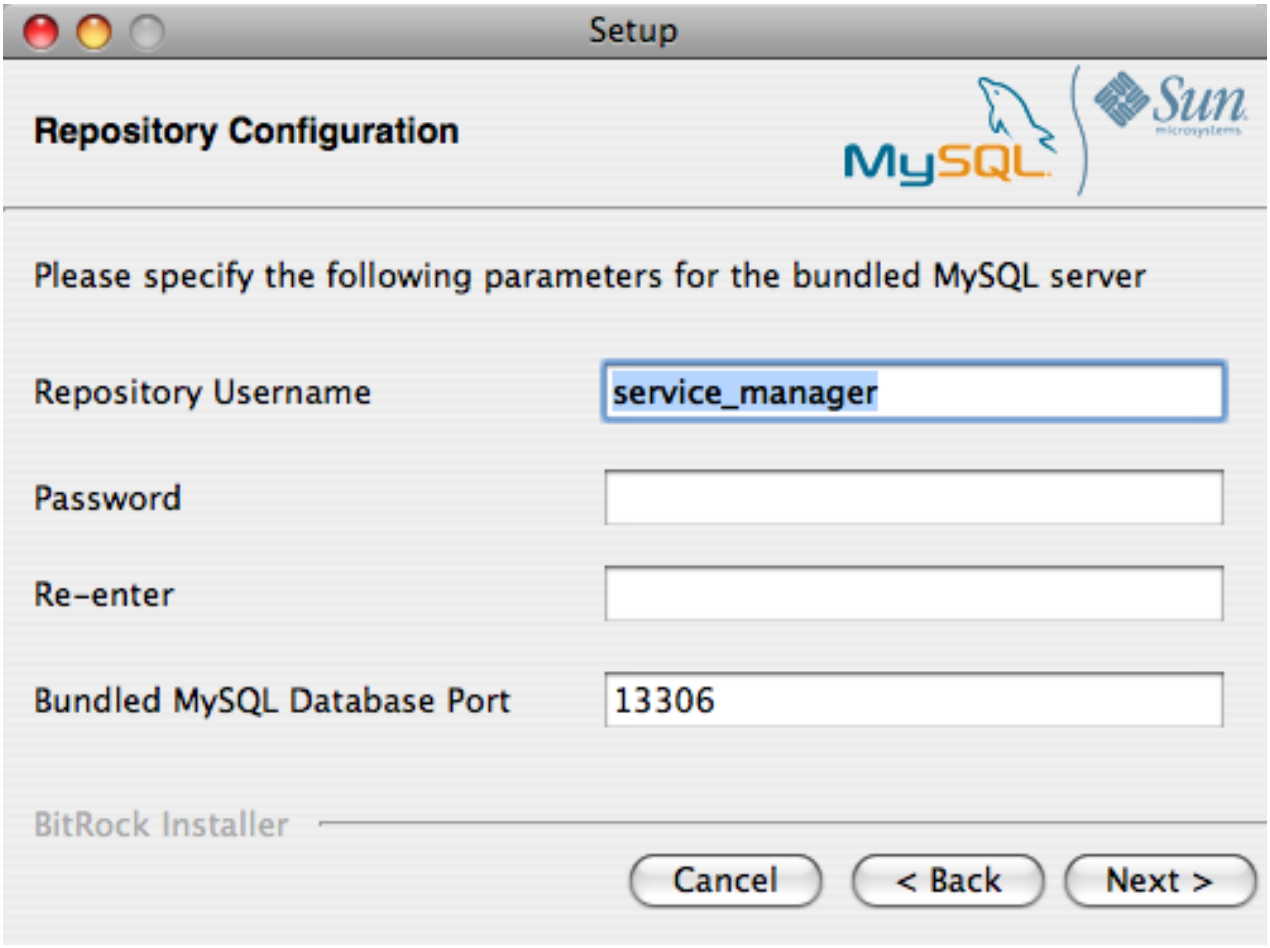
5. Configure the options that set the network ports used by the Tomcat server. For more information, see Section 15.3.2.1, "Service Manager Installation Common Parameters". Click NEXT to continue.

Figure 15.9. MySQL Enterprise Monitor: Installing Monitor on OS X: Tomcat Server Options



6. Configure the repository settings, setting the user name, password and port used to communicate with the bundled MySQL server that will be used to store the information and statistics for your installation. For more information, see Section 15.3.2.1, "Service Manager Installation Common Parameters". Click NEXT to continue.

Figure 15.10. MySQL Enterprise Monitor: Installing Monitor on OS X: Repository Configuration



7. You will be provided with information and a warning about the configuration options and how they are stored in the `configuration_report.txt` file, and it's location. Take a note of the full path to this file in case you need to look up the information later. Click NEXT to continue.

8. You should now be prompted to start the installation process. Click NEXT to continue.

9. Once the installation has been completed, you will be provided with the information on how to uninstall MySQL Enterprise Service Manager. Click NEXT to continue.

10. To complete the installation and set up your MySQL Enterprise Service Manager, you will need to login to the Dashboard. You can do this automatically by checking the box on the final window before clicking FINISH. This checkbox is selected by default. If you do not want to run the Dashboard at this time, uncheck the box and clock FINISH.

Your installation should now be complete. To continue with the configuration of MySQL Enterprise Service Manager, see Section 15.3.2.7, "MySQL Enterprise Service Manager Configuration Settings and Advisor Installation".

15.3.2.4. Service Manager Installation on Unix

To install the Service Manager find the file named `mysqlmonitor-version-installer.bin` (where *`version`* indicates the version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitor-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/monitor`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/user_name/mysql/enterprise/monitor/` directory.

What follows describes installation from the command line. You may install the Service Manager graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Service Manager in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see Section 15.3.4, “Unattended Installation”.

1. Begin installation by typing:

```
shell> ./mysqlmonitor-version-installer.bin
```

2. First choose the language for the installation:

```
Language Selection

Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

3. Throughout the installation process you will be asked the configuration questions for different options. Default values are shown between square brackets; to use the default press **Enter**. Otherwise, enter the new value and press **Enter**:

   First, select the directory where you want MySQL Enterprise Service Manager to be installed. The default is `/opt/mysql/enterprise/monitor/`. Make sure that the location you choose has enough space to hold the installation files and the database information that will be created when MySQL Enterprise Service Manager is running.

```
Please specify the directory where the MySQL Enterprise Service Manager
 will be installed.

Installation directory [/opt/mysql/enterprise/monitor/]:
```

4. Now set the Tomcat Server options. For more details on these parameters, see Section 15.3.2.1, “Service Manager Installation Common Parameters”.

```
-------------------------------------------------------------------------------
Tomcat Server Options

Please specify the following parameters for the bundled Tomcat Server

Tomcat Server Port [18080]:

Tomcat Shutdown Port [18005]:

Tomcat SSL Port [18443]:
```

   You will also be asked if SSL support is required. SSL support allows your agents and monitor to communicate with each other using SSL. Using SSL means that the data exchanged by the agent and MySQL Enterprise Service Manager are secure and can be used to monitor servers securely, or to monitor agents over a public connection.

   You can enable SSL by pressing **Y** when prompted during installation:

```
Is SSL support required?           [y/N]:
```

5. Set the repository (embedded MySQL server) configuration options. For more details on these parameters, see Section 15.3.2.1, “Service Manager Installation Common Parameters”.

```
-------------------------------------------------------------------------------

Repository Configuration

Please specify the following parameters for the bundled MySQL server

Repository Username  [service_manager]:

Password :

Re-enter :

Bundled MySQL Database Port [13306]:
```

6. Before the final installation process, you will provided with the location of the file that contains a copy of all of the settings. Be sure to follow the instructions and store this report in a secure location. There is no password recovery feature.

```
------------------------------------------------------------------------------

Configuration Report

Note:

The settings you specified will be saved here:

/opt/mysql/enterprise/monitor/configuration_report.txt

IMPORTANT: This configuration report includes passwords stored in plain text; it
is intended to help you install and configure your agents. We strongly advise
you to secure or delete this text file immediately after installation.

Press [Enter] to continue :
```

7. You you will now be asked to confirm the installation process.

```
Setup is now ready to begin installing MySQL Enterprise Monitor
 on your computer.

Do you want to continue? [Y/n]: Y

Please wait while Setup installs MySQL Enterprise Monitor
 on your computer.
```

   The installation process may take a few minutes to complete. Upon completion you should see:

```
Completed installing files

Setup has completed installing MySQL Enterprise files on your computer

Uninstalling the MySQL Enterprise files can be done by invoking:

/opt/mysql/enterprise/monitor/uninstall

To complete the installation, launch the MySQL Enterprise Dashboard and complete
the initial setup and product activation information. Refer to the readme file
for additional information and a list of known issues.

Press [Enter] to continue :
```

8. Finally, you will be given the opportunity to read a supplied `Readme` file that is supplied with the installation. The `Readme` contains important information about how to use and start your MySQL Enterprise Service Manager.

```
------------------------------------------------------------------------------

Setup has finished installing MySQL Enterprise Monitor on your computer.

View Readme File [Y/n]: n
```

   Once the `Readme` file has been displayed, or if you did not elect to read the file, the installation provides information about how to continue with your installation.

```
Info: To access the MySQL Enterprise Monitor please visit the
following page: http://localhost:18080/Auth.action

Press [Enter] to continue :
```

The Enterprise Dashboard will not start up automatically if you perform a `text` mode installation. For more information on starting and stopping MySQL Enterprise Service Manager, see Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”.

15.3.2.5. Starting/Stopping the MySQL Enterprise Monitor Service on Windows

You can choose to start up the MySQL Enterprise Service Manager on installation. The installed services are called:

- MySQL Enterprise Tomcat
- MySQL Enterprise MySQL

You can stop or start the services from the Microsoft Management Console Services window. Look for the `MySQL Enterprise Tomcat` and the `MySQL Enterprise MySQL` entries.

> **Note**
>
> On Windows Vista or later, starting these services requires administrative privileges—you must be logged in as an administrator. To start or stop a service right-click it and choose the RUN AS ADMINISTRATOR menu option. The same restriction applies to using the menu options discussed in the following and to starting the services from the command line. To open an administrator `cmd` window right-click the `cmd` icon and choose the RUN AS ADMINISTRATOR menu option.

To start or stop a service, right-click it and choose from the options in the pop-up menu.

There is also a menu entry for starting and stopping the services. Navigate to the `Program`, `MySQL`, `MySQL Enterprise Monitor`, `Services` entry to stop or start the services.

You can also stop or start a service from the command line. To start the Tomcat service type:

```
shell> sc start MySQLEnterpriseTomcat
```

or:

```
shell> net start MySQLEnterpriseTomcat
```

To stop this service type:

```
shell> sc stop MySQLEnterpriseTomcat
```

or:

```
shell> net stop MySQLEnterpriseTomcat
```

In similar fashion, you may stop or start the MySQL server from the command line. The service name is `MySQLEnterpriseMySQL`.

You may also start, stop, and restart a specific service or both services using the `mysqlmonitorctl.bat` file. To execute this file, go to the command line and navigate to the `C:\Program Files\MySQL\Enterprise\Monitor` directory. Typing **`mysqlmonitorctl.bat help`** produces the following output:

```
usage: mysqlmonitorctl.bat help
       mysqlmonitorctl.bat (start|stop|restart|install|uninstall)
       mysqlmonitorctl.bat (start|stop|restart) tomcat
       mysqlmonitorctl.bat (start|stop|restart) mysql

help       - this screen
start      - start the service(s)
stop       - stop the service(s)
restart    - restart or start the service(s)
install    - install the service(s)
uninstall  - uninstall the service(s)
```

To stop a specific service, pass the argument `tomcat` or `mysql` in addition to the status change argument. If you wish to change the status of both services, do not specify a service name. You may also uninstall the services using this batch file.

Configuration of the dashboard begins immediately after the Service Manager is installed. To continue a Windows installation skip the next section and go to Section 15.3.2.7, “MySQL Enterprise Service Manager Configuration Settings and Advisor Installation”.

15.3.2.6. Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X

The services incorporated into the MySQL Enterprise Service Manager are:

- The MySQL Server
- The Apache/Tomcat Server

Should you need to stop, start, or restart the MySQL Enterprise Service Manager call the `mysqlmonitorctl.sh` file located in the `/opt/mysql/enterprise/monitor/` directory on Unix or the `/Applications/mysql/enterprise/monitor/` on Mac OS X. To see all the available options navigate to the appropriate directory and type:

```
shell> /opt/mysql/enterprise/monitor/mysqlmonitorctl.sh help
```

Executing this script produces the following output:

```
usage: ./mysqlmonitorctl.sh help
./mysqlmonitorctl.sh (start|stop|status|restart)
./mysqlmonitorctl.sh (start|stop|status|restart) mysql
./mysqlmonitorctl.sh (start|stop|status|restart) tomcat

help       - this screen
start      - start the service(s)
stop       - stop  the service(s)
restart    - restart or start the service(s)
status     - report the status of the service
```

Using this script you can stop, start, or restart all the Service Manager components. To do this make a call to `mysqlmonitorctl.sh start` from your start-up script.

To start the service:

```
shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql  started
nohup: redirecting stderr to stdout
Starting mysqld daemon with databases from /opt/mysql/enterprise/monitor/mysql/data/
Using CATALINA_BASE:   /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME:   /opt/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /opt/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME:       /opt/mysql/enterprise/monitor/java
```

If you try to start the service and it is already running, you will be warned that the services are already running:

```
shell> ./mysqlmonitorctl.sh start
./mysqlmonitorctl.sh : mysql  (pid 18403) already running
./mysqlmonitorctl.sh : tomcat  (pid 18480) already running
```

To stop the service:

```
shell> ./mysqlmonitorctl.sh stop
Using CATALINA_BASE:   /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_HOME:   /Applications/mysql/enterprise/monitor/apache-tomcat
Using CATALINA_TMPDIR: /Applications/mysql/enterprise/monitor/apache-tomcat/temp
Using JRE_HOME:       /System/Library/Frameworks/JavaVM.framework/Versions/1.5.0/Home
Stopping tomcat service .. [ OK ]
STOPPING server from pid file /Applications/mysql/enterprise/monitor/mysql/data/mysqld.pid
090209 15:37:09  mysqld ended
```

The `restart` command is equivalent to executing a `stop` and then `start` operation.

This script can also be used to check the status of the Tomcat web server or the MySQL repository.

```
shell> ./mysqlmonitorctl.sh status
MySQL Network MySQL is running
MySQL Network Tomcat is running
```

Configuration of the dashboard begins immediately after the MySQL Enterprise Service Manager is installed.

15.3.2.7. MySQL Enterprise Service Manager Configuration Settings and Advisor Installation

The Enterprise Dashboard is the web-based interface to the Service Manager so the procedure for starting the dashboard is identical for all platforms. From the dashboard you can configure the settings necessary for receiving updates from MySQL Enterprise and for the initial installation of the Advisors.

If you installed the Service Manager using a graphical interface, you have the option of launching the dashboard on the final installation screen (as long as the LAUNCH MYSQL ENTERPRISE MONITOR NOW checkbox is checked).

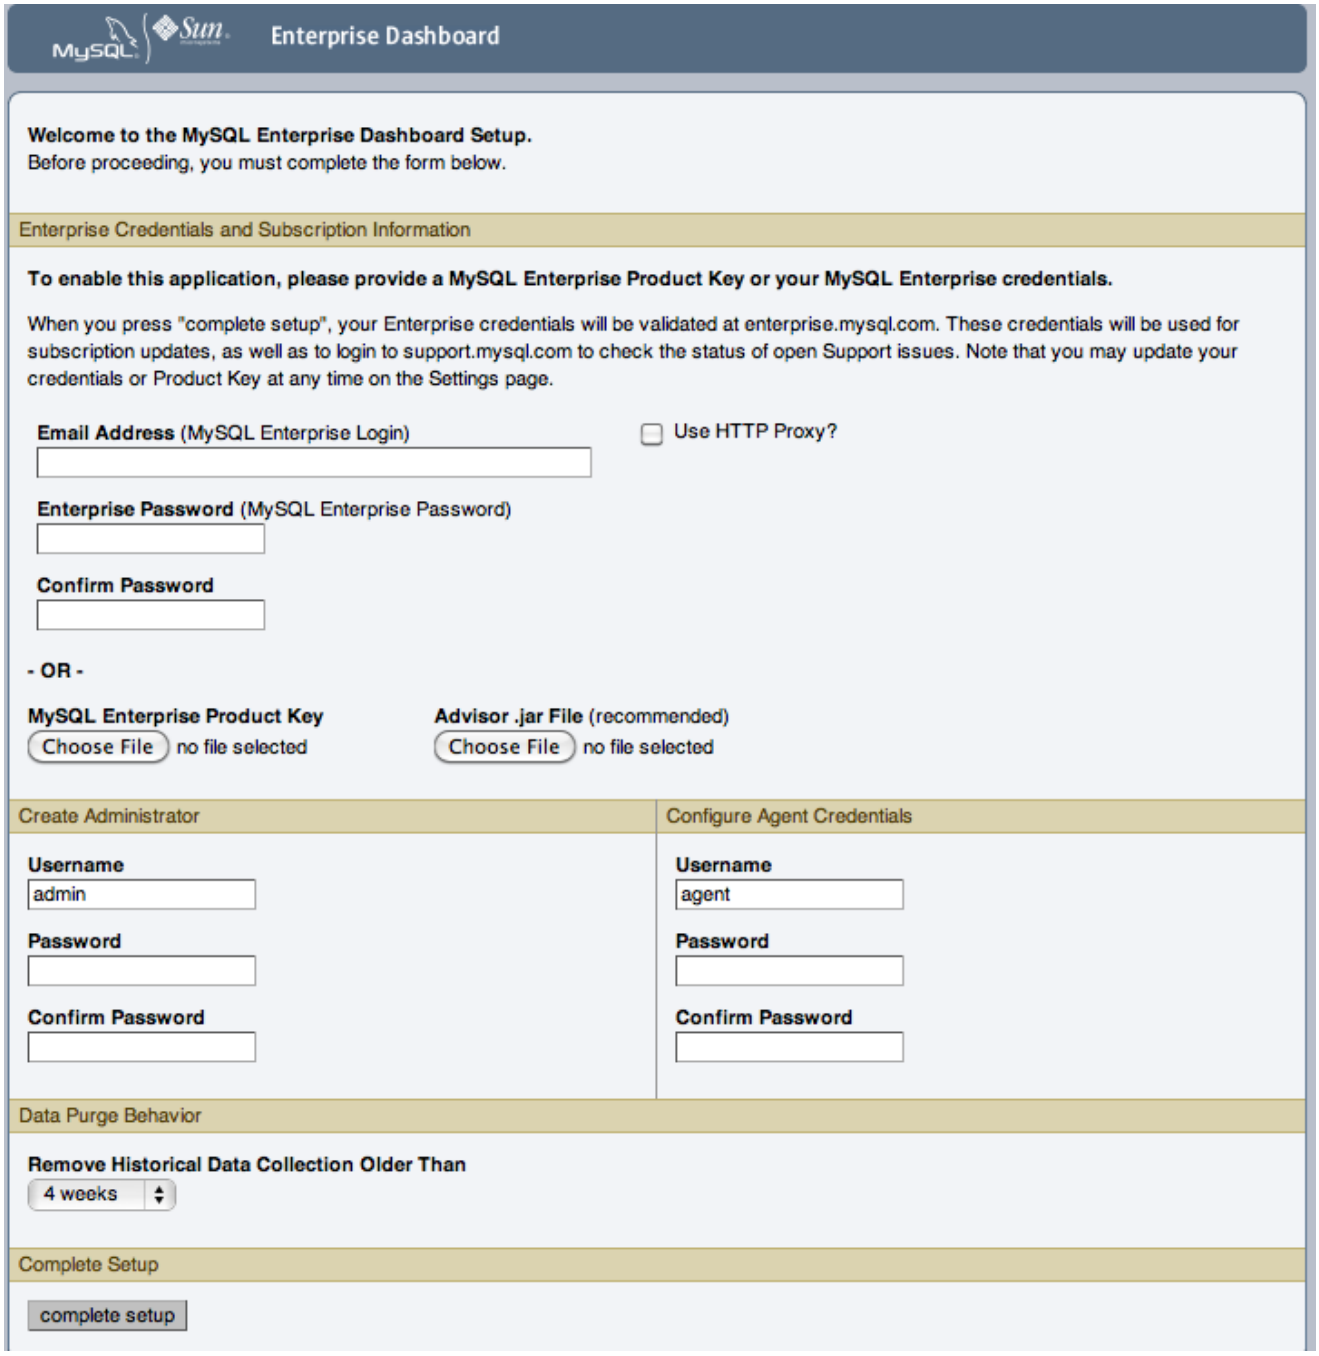
Otherwise, you can view the dashboard by typing `http://localhost:18080/Auth.action` into the address bar of your web browser. If you are unsure of the host name and port to use, check the `configuration_report.txt` file.

Under Windows it is also possible to open the dashboard by choosing the `MySQL` menu item and finding the `MySQL Enterprise Monitor` entry. Under this entry choose `Start Service Manager`.

15.3.2.7.1. Initial Dashboard Log-In

If this is the first time that you have attempted to log in to the dashboard you should see a screen similar to the following:

Figure 15.11. MySQL Enterprise Monitor: Initial Dashboard Log-In



Use this screen to perform the following tasks:

- Install the Advisors
- Set up your MySQL Enterprise credentials
- Create a user name and password for the dashboard administrator
- Create a user name and password for the Monitor Agent

If you have been provided with a `MySQL Enterprise Product Key` and an Advisors file click the BROWSE button and locate these files. The advisor file bears the name, `AdvisorScript-version.jar` and the product key, `Subscription-level_date.xml`. If you do not allow Internet access from the dashboard you must install the advisors in this way. It is strongly recommended that you install the Advisors at this point, but you may do so later. For instructions on doing this see, Section 15.3.2.7.3, "Installing Advisors After Initial Log-in". If the product key that you provide is invalid a notification appears and you will be unable to import the advisors.

> **Note**
>
> If you are activating the MySQL Enterprise Monitor using a product key do*not* enter your MySQL credentials; entering both produces an error message.

If you have Internet access from the dashboard, activate MySQL Enterprise Monitor by supplying your MySQL Enterprise credentials. Enter your email address as the `MySQL Enterprise Login` and enter and confirm your MySQL Enterprise password. If you specify incorrect credentials, you receive the error message, "Unable to connect to verify credentials."

In the **CREATE ADMINISTRATOR** section of this screen, enter credentials for the dashboard administrator. This creates the `root user` described in Section 15.3.1.3, "Users Created on First Log-in". Make note of the user name and password as these credentials are required for any future login.

In the **CONFIGURE AGENT CREDENTIALS** section of this screen enter the credentials for the agent. This is the `agent user` also described in Section 15.3.1.3, "Users Created on First Log-in". The agent needs to log in in order to report its findings. Make note of the agent's credentials; this information is required when installing the agent.

When all the settings have been specified, click the COMPLETE SETUP button. If you log in successfully you should see a message displaying the number of graphs and advisors that have been imported. This number varies depending upon your subscription level.

If importation of the advisor files fails, you will see the message:

```
Unable to import Advisor Jar. You may download the jar
manually from the Enterprise Portal and import it from the 'Check For Updates' page.
```

In this case you may download the advisor file from the Enterprise website and install it as described in Section 15.3.2.7.3, "Installing Advisors After Initial Log-in".

15.3.2.7.2. Setting the Timezone and Locale

If this is the first time that you have launched the dashboard you are asked to set your time zone and locale. Choose the appropriate values from the drop-down list boxes. Setting the time zone ensures that you have an accurate time reference for any notifications from the MySQL Enterprise Advisors.

> **Warning**
>
> It is especially important that the time zone be set correctly as this may also affect the way the graphs display. For this reason, also ensure that the time reported by the operating system is correct. To change the time zone or locale see Section 15.5.2, "User Preferences".
>
> The locale chosen determines the user's default language when logging in to the Dashboard. Note that this will override the default browser settings whenever this specific user logs in.

After specifying your time zone and locale, the dashboard opens on the `Monitor` page. For a detailed examination of the `Monitor` Screen see, Section 15.4, "MySQL Enterprise Dashboard".

15.3.2.7.3. Installing Advisors After Initial Log-in

The Advisors interpret the data sent by the Monitor Agents and display the results in the dashboard. A minimal set of Advisors are preinstalled with the Service Manager. To obtain the full set of Advisors and get the most value from the MySQL Enterprise Monitor, you must download Advisors from MySQL Enterprise.

If you did not install the Advisors when you first logged in to the MySQL Enterprise Dashboard, open the dashboard, find the `Advisors` tab, and choose the `Check for Updates` link. Doing this downloads the latest version of the Advisors from the MySQL Enterprise web site. In order to install the advisors in this fashion you must specify your MySQL Enterprise credentials. Find instructions for doing this in Section 15.5.1, "Global Settings".

If you do not allow Internet access from the dashboard, you must install the Advisors from a local file. To do this you need an advisor

file bearing the name, `AdvisorScript-version.jar`. If you don't already have this file, you can find it on the MySQL Enterprise downloads page. Download the Advisors file to a location that is accessible from the dashboard. Use the BROWSE button to find the Advisors file and then choose IMPORT to load the advisors.

15.3.2.7.4. Upgrading and Updating Advisors

The process for upgrading advisors is exactly the same as the initial installation. Advisors are updated by choosing the UPDATE button on the `Check for Updates` page. If you do not have Internet access from the dashboard you can import the Advisors from a local file as described in Section 15.3.2.7.3, "Installing Advisors After Initial Log-in".

> **Note**
>
> You may choose to upgrade your MySQL Enterprise Monitor subscription level at any time.

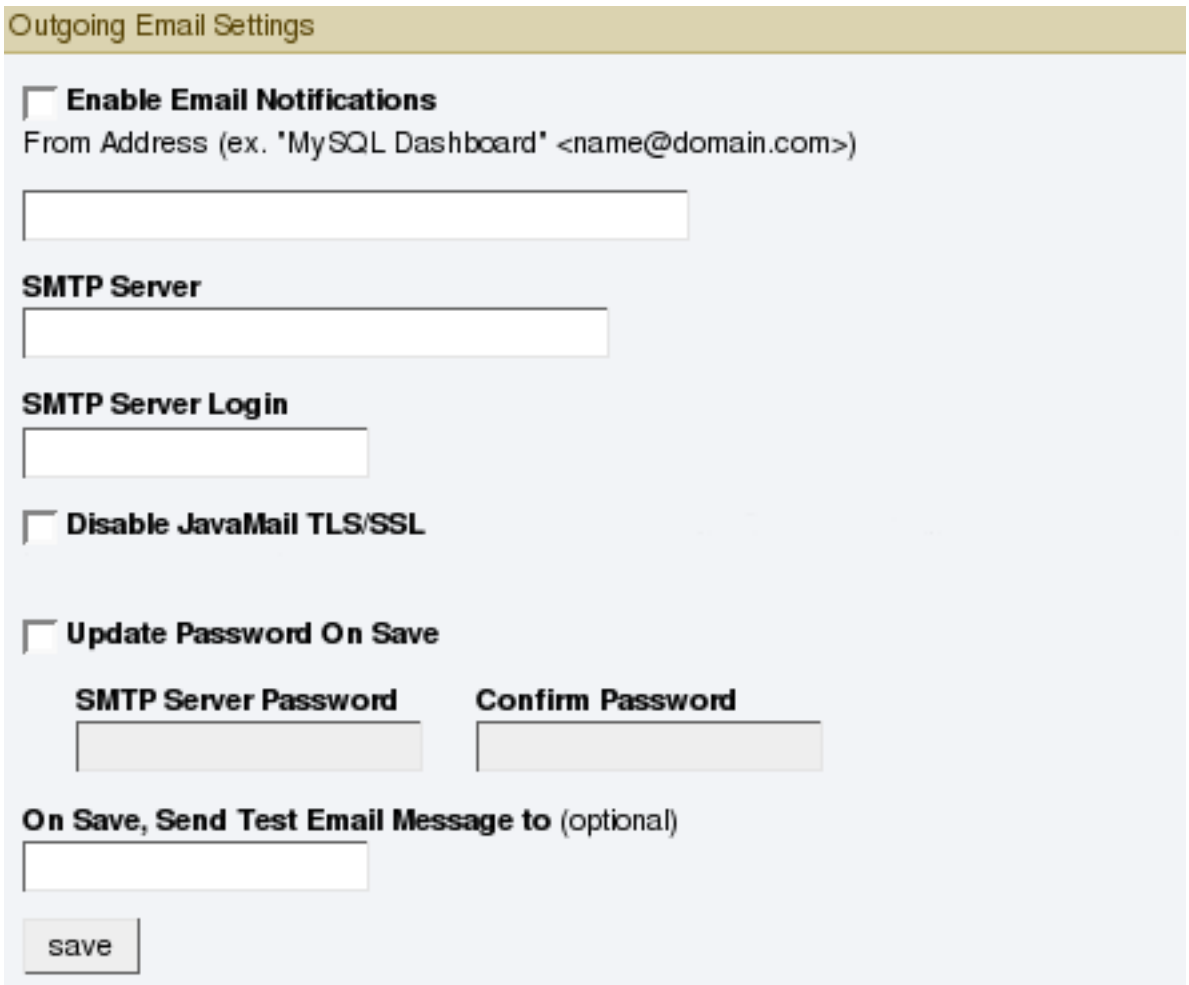
15.3.2.7.5. Outgoing Email Settings

Alert notification via email is a key component of the MySQL Enterprise Monitor Advisor solution. For this reason you may want to immediately configure an SMTP account for at least one recipient.

To do this choose the `Settings` tab and go to the `Global Settings` screen by clicking the appropriate link. Here you can configure the email settings. These settings apply to the currently logged-in user.

Find the `Outgoing Email Settings` on the left of this page.

Figure 15.12. MySQL Enterprise Monitor: Outgoing Email Settings



Ensure that the Enable Email Notifications checkbox is checked and enter information as appropriate.

The default value for the SMTP port is 25. If your mail server runs on a different port simply specify it, separating it from the server name using a colon. For example, if your mail server runs on port 587 enter *email.myserver.com*:587 into the **SMTP SERVER** text box.

> **Note**
>
> An email server must be available for sending email alerts.
>
> The SMTP client uses Transport Layer Security (TLS) if the SMTP server supports it.
>
> If your SMTP server incorrectly indicates that it supports TLS, check the **DISABLE JAVAMAIL TLS/SSL** check box.

The email settings page is dealt with in more detail in Section 15.5, "The Settings Page".

15.3.3. Monitor Agent Installation

A MySQL Enterprise Monitor Agent monitors a MySQL server and sends data to the Advisors. These data are interpreted and displayed in the dashboard. The Monitor Agent is installed on all platforms using the steps described in the next section.

> **Warning**
>
> The MySQL Enterprise Service Manager version 2.0 or higher requires agents with a version number of 2.0 or higher.

15.3.3.1. Creating a MySQL User Account for the Monitor Agent

Before setting up an agent to monitor a MySQL server you need to ensure that there is a user account for the agent on that server.

The privileges required for this user account vary depending on the information you wish to gather using the MySQL Enterprise Monitor Agent. The following privileges allow the Monitor Agent to perform its assigned duties without limitation:

- SHOW DATABASES: Allows the MySQL Enterprise Monitor Agent to gather inventory about the monitored MySQL server.
- REPLICATION CLIENT: Allows the MySQL Enterprise Monitor Agent to gather Replication master/slave status data. This privilege is only needed if the MySQL Replication Advisor Rules are employed.
- SELECT: Allows the MySQL Enterprise Monitor Agent to collect statistics for table objects.
- SUPER: Allows the MySQL Enterprise Monitor Agent to execute SHOW ENGINE INNODB STATUS in order to collect data about InnoDB tables. This privilege is also required to obtain replication information using SHOW MASTER STATUS.
- PROCESS: When monitoring a MySQL server running MySQL 5.1.24 or above with InnoDB, the PROCESS privilege is required to execute SHOW ENGINE INNODB STATUS.
- INSERT: Required to create the UUID required by the agent.
- CREATE: Allows the MySQL Enterprise Monitor Agent to create tables. During discovery, the agent creates the table inventory within the mysql database that is used to the UUID for the server. Without this table, the agent cannot determine the UUID of the server and therefore use this when sending information to MySQL Enterprise Service Manager.

For example, the following GRANT statement will give the agent the required SELECT, REPLICATION CLIENT, SHOW DATABASES and SUPER rights:

```
GRANT SELECT, REPLICATION CLIENT, SHOW DATABASES, SUPER, PROCESS
  ON *.*
  TO  'mysqluser'@'localhost'
  IDENTIFIED BY 'agent_password';
```

For security reasons, you may wish to limit the CREATE and INSERT privileges to the agent so that it can only create tables within the mysql database:

```
GRANT CREATE, INSERT
  ON mysql.*
```

```
  TO  'mysqluser'@'localhost'
  IDENTIFIED BY 'agent_password';
```

To enable replication discovery to work, you should also grant the `SELECT` privilege on the `mysql.inventory` table for each user with replication privileges on the corresponding replication master. This is required to let the MySQL Enterprise Monitor Agent read the replication master UUID. For example:

```
GRANT SELECT
  ON mysql.inventory
  TO  'replicationuser'@'%'
  IDENTIFIED BY 'replication_password';
```

> **Note**
>
> You should perform this step *after* after having run the agent on the corresponding MySQL server to ensure that the `mysql.inventory` table has been correctly created. You can do this by running the agent, shutting the agent down, running the above `GRANT` statement, and then restarting the agent.

If the agent is unable to access the information from the table then a warning containing this information will be written to the agent log.

> **Note**
>
> You may want to disable logging for the grant statement to prevent the grant information being replicated to the slaves. If this is the case, execute the statement `SET SQL_LOG_BIN=0` before you execute the above `GRANT` statement.

In a typical configuration, the agent runs on the same machine as the MySQL server it is monitoring so the host name will be *`localhost`*. However, this will change if the agent is running on a machine other than the one that hosts the monitored MySQL server. In this case, change *`localhost`* to the appropriate value. For more information about remote monitoring see Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”.

15.3.3.2. Installing the Agent on Microsoft Windows

To install the MySQL Enterprise Monitor Agent on Windows, double-click the `mysqlmonitoragent-`*`version`*`-windows-installer.exe` (where *`version`* indicates the three-part version number) installer.

> **Note**
>
> In order to install the agent as a Windows service, you must do the installation as a privileged user.
>
> On Windows Vista or later, if user account control is on, an operating system dialog box requests confirmation of the installation.

You may also install the Monitor Agent in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see, Section 15.3.4, “Unattended Installation”.

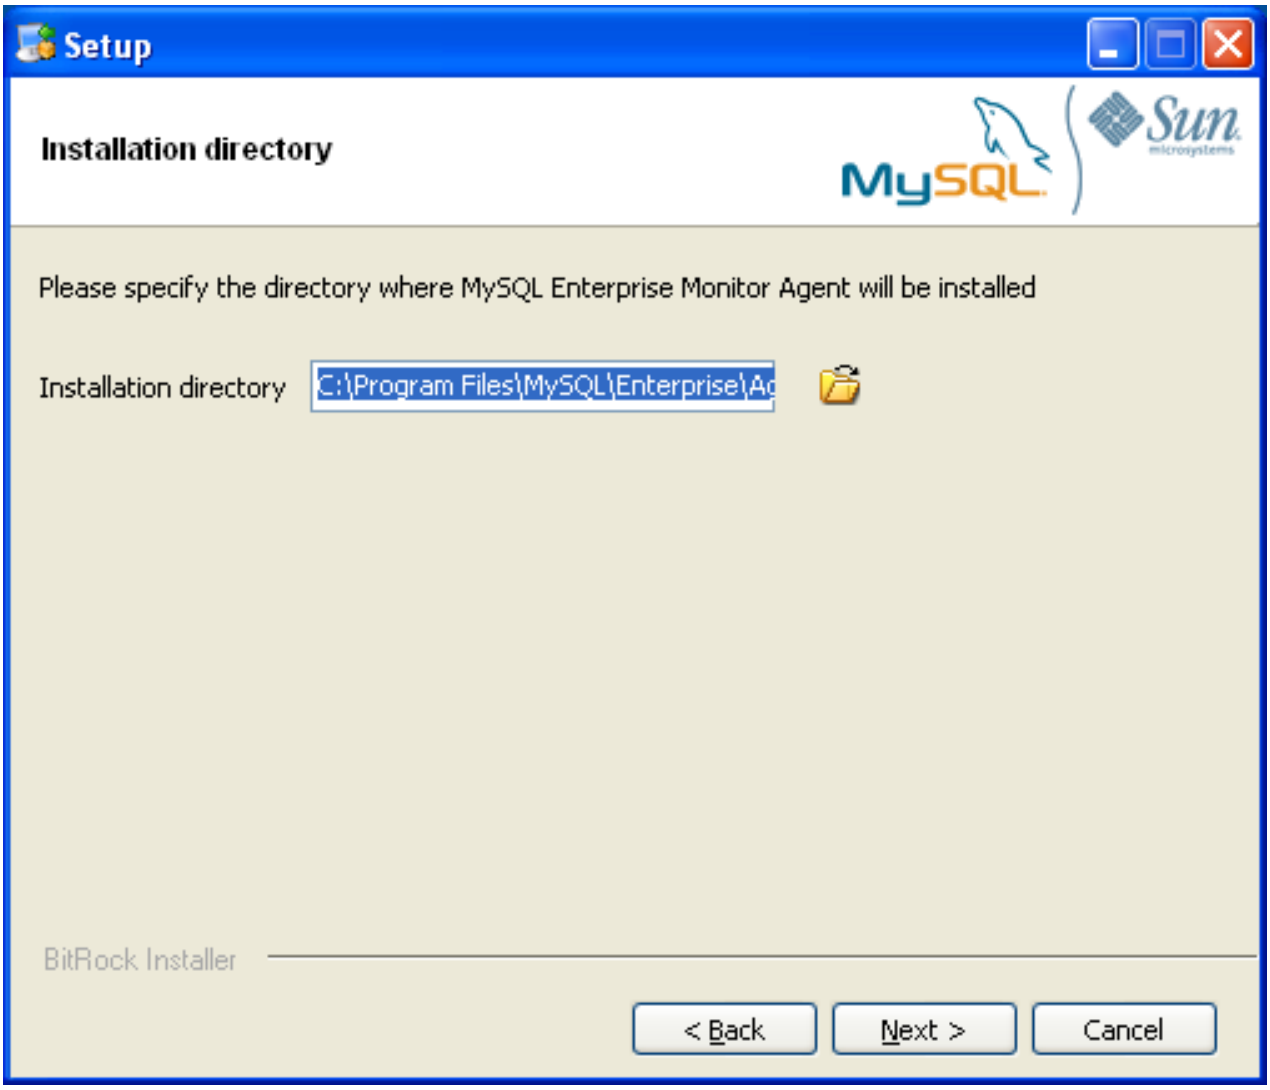
1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

Figure 15.13. MySQL Enterprise Monitor: Installing Agent on Windows: Language Selection

2. Click NEXT to start the installation process.

3. Select the installation directory. The default installation directory is `C:\Program Files\MySQL\Enterprise\Agent`. Select the installation directory, or type the new directory location. Click NEXT to continue the installation process.

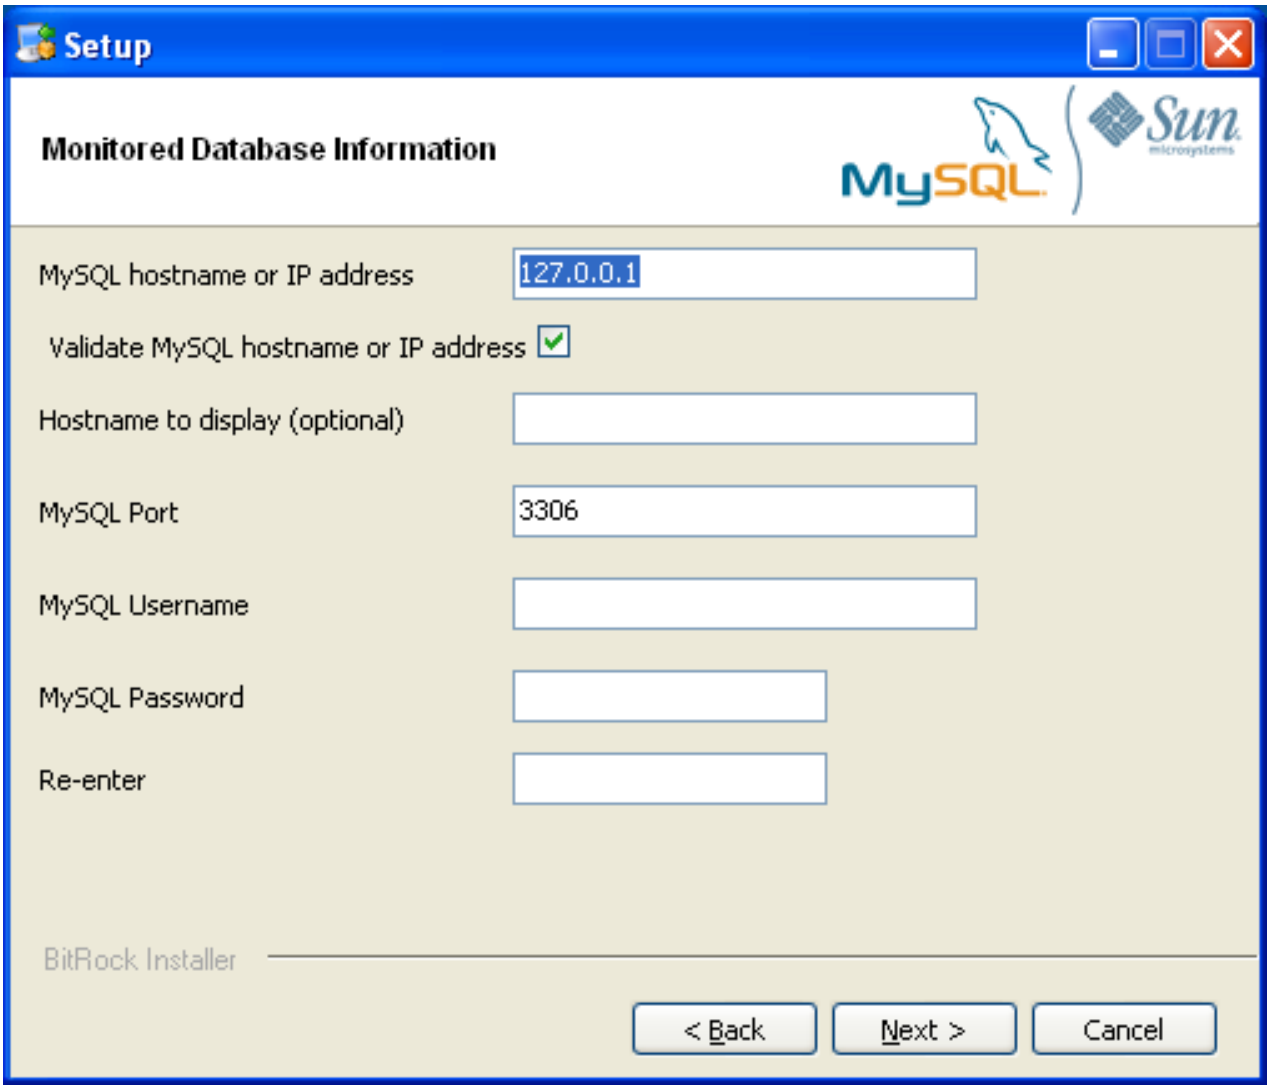
Figure 15.14. MySQL Enterprise Monitor: Installing Agent on Windows: Installation Directory



4. You need to specify the information about the MySQL server that you want to monitor. You must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MYSQL HOST NAME OR IP ADDRESS** checkbox is selected.

> **Note**
>
> Currently, on Windows, the monitor agent only includes support for connecting to the server to be monitored via TCP/IP, so if the server has been started with `--skip-networking` it cannot be monitored.
>
> If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the monitor agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if "localhost" is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

Figure 15.15. MySQL Enterprise Monitor: Installing Agent on Windows: Monitored Database Information



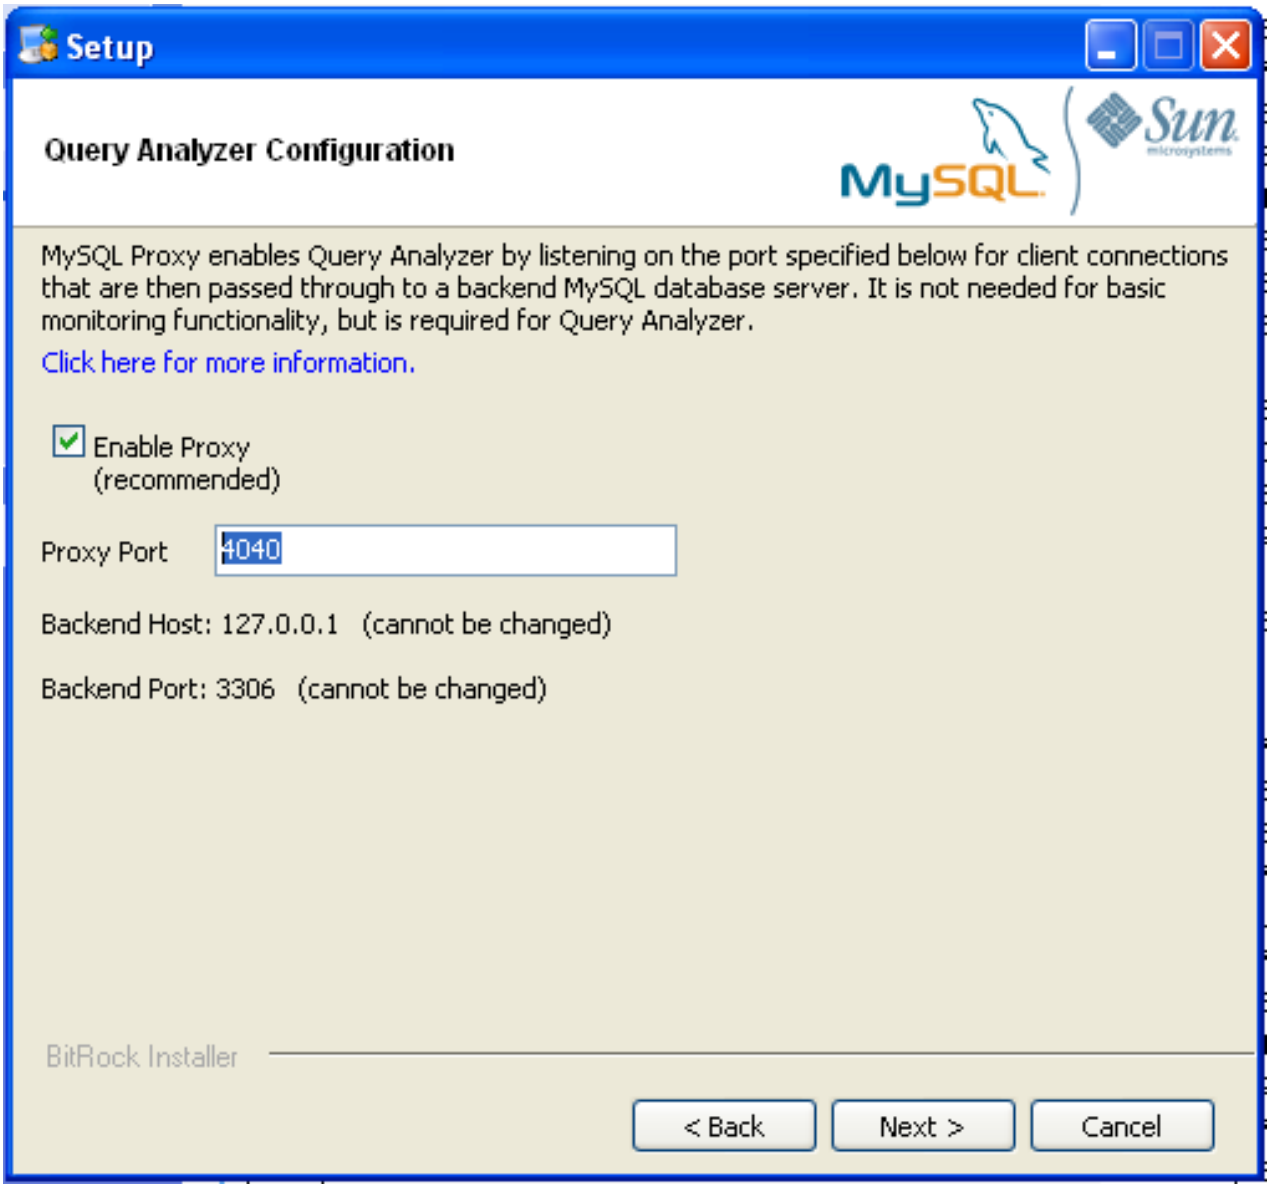
Click NEXT to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analyzer. For more information on Query Analyzer, see Section 15.10, "The Query Analyzer Page".

   When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections.

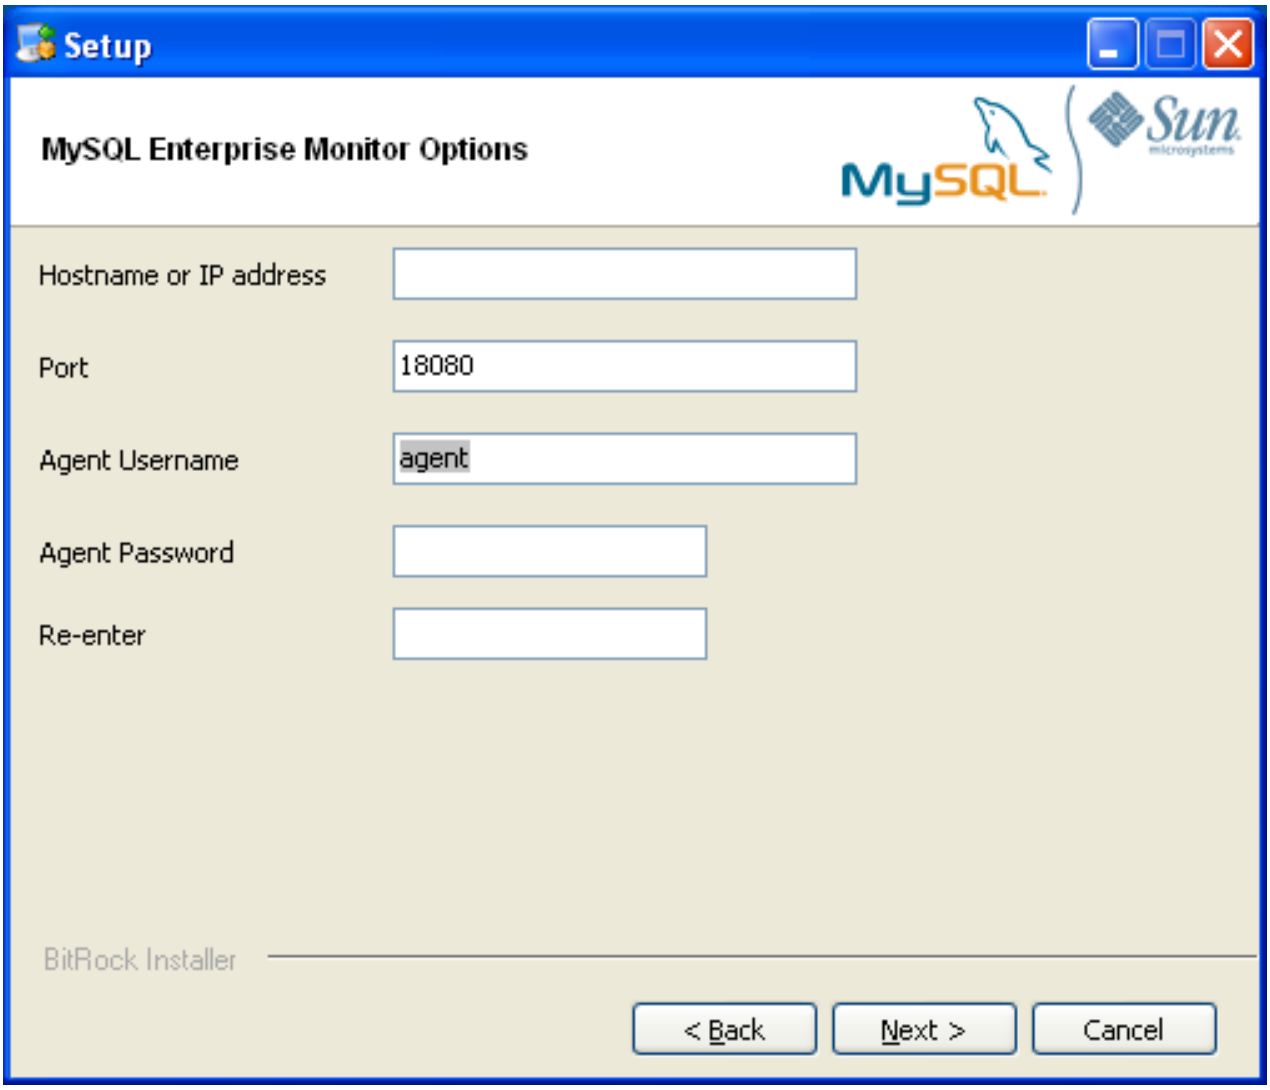
   The default port is 6446.

Figure 15.16. MySQL Enterprise Monitor: Installing Agent on Windows: Query Analyzer Configuration



6. The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

Figure 15.17. MySQL Enterprise Monitor: Installing Agent on Windows: MySQL Enterprise Service Manager Options



7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.

8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.

9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.

10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

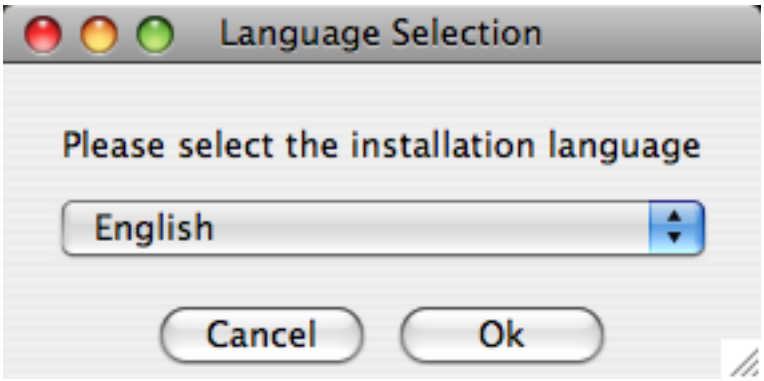
Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see Section 15.3.3.5.1, "Starting/Stopping the Agent on Windows".

15.3.3.3. Installing the Agent on Mac OS X

To install the MySQL Enterprise Monitor Agent on Mac OS X, decompress the `mysqlmonitoragent-`*`version`*`-installer.app.zip` and then run the `mysqlenterpriseagent-`*`version`*`-installer` application.

1. First, select the language for the MySQL Enterprise Monitor Agent installation. Click OK to continue installation.

Figure 15.18. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Language Selection



2. Click NEXT to start the installation process.

3. Select the installation directory. The default installation directory is `/Applications/mysql/enterprise/agent`. Select the installation directory, or type the new directory location.

   You also need to select the method that the agent will use to communicate with the MySQL server. You can choose either to use a TCP/IP (network) connection, or a Socket (local) connection. Choose the connection method, and click NEXT.

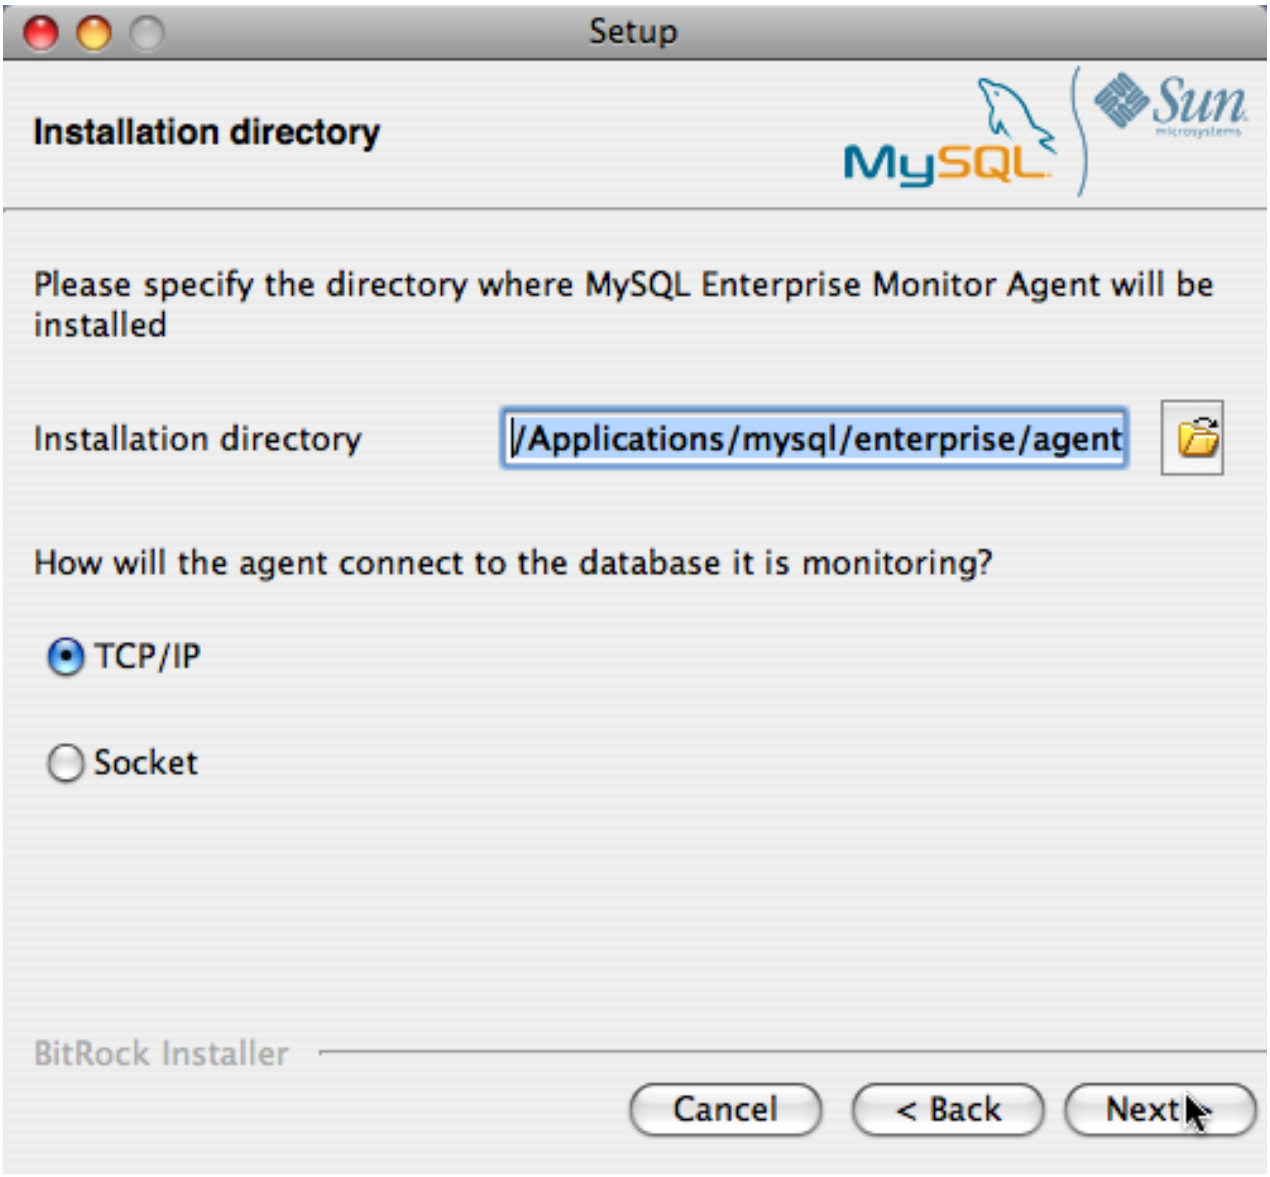
   Note

   The monitor agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects via the MySQL socket by default on Unix, if the hostname “localhost” is specified.

   If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it via TCP/IP, as the server will not listen for TCP/IP connections. In this case the monitor agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to Section 15.3.3.6.2, “MySQL Server (`agent-instance.ini`) Configuration”.

   If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the monitor agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

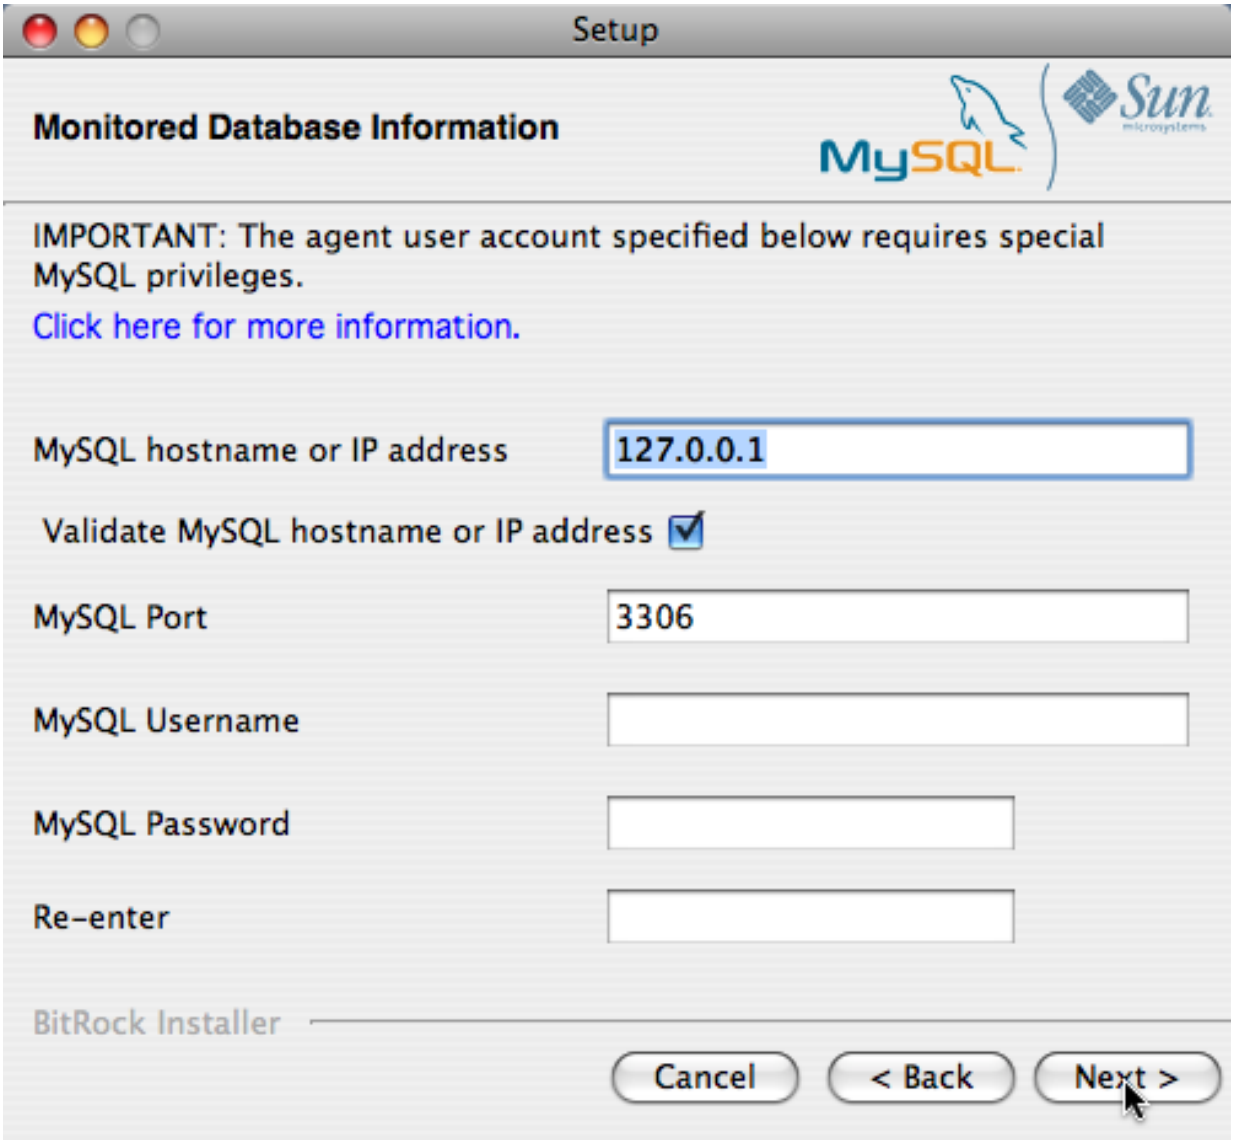
Figure 15.19. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Installation Directory



4. You need to specify the information about the MySQL server that you want to monitor. The configuration information you enter will depend on the connection method selected in the previous screen.

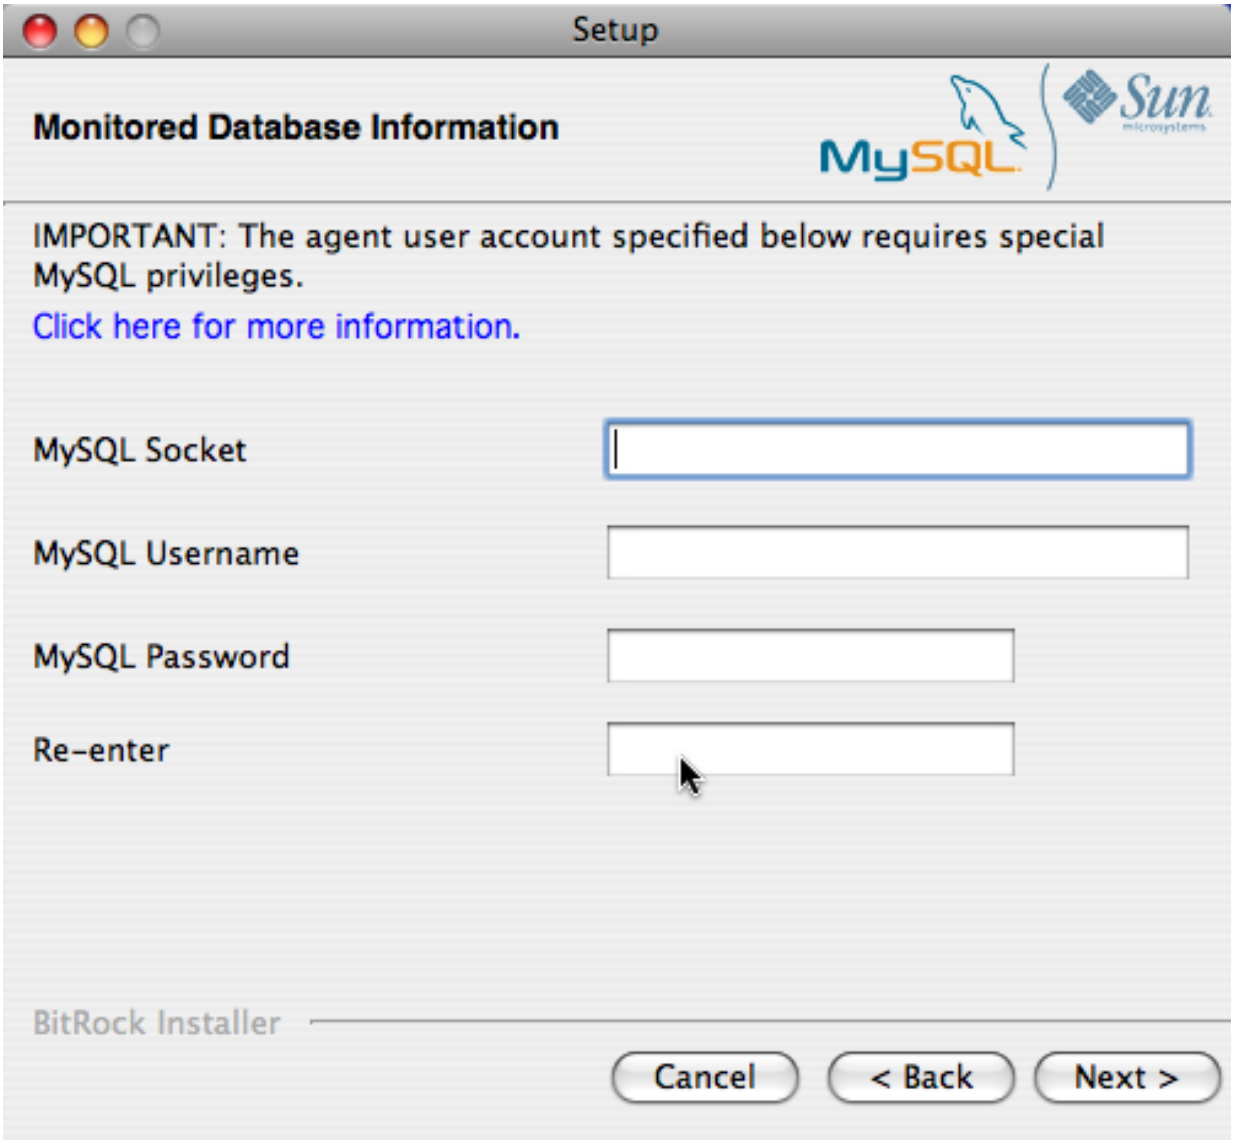
   - If you chose TCP/IP as the connection method, you must enter the IP address or host name of the host you want to monitor, and the port, user name and password that you will use to connect to the MySQL server. If you want to confirm that the MySQL server is currently reachable using the information, ensure that the **VALIDATE MYSQL HOST NAME OR IP ADDRESS** checkbox is selected.

Figure 15.20. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Monitored Database Information



- If you chose Socket as the connection method, you must enter the full path name to the Unix socket created by your MySQL server, and the user name and password that will be used to authenticate with the server. Typical values include `/tmp/mysql.sock` and `/var/mysql/mysql.sock`.

Figure 15.21. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Monitored Database Information

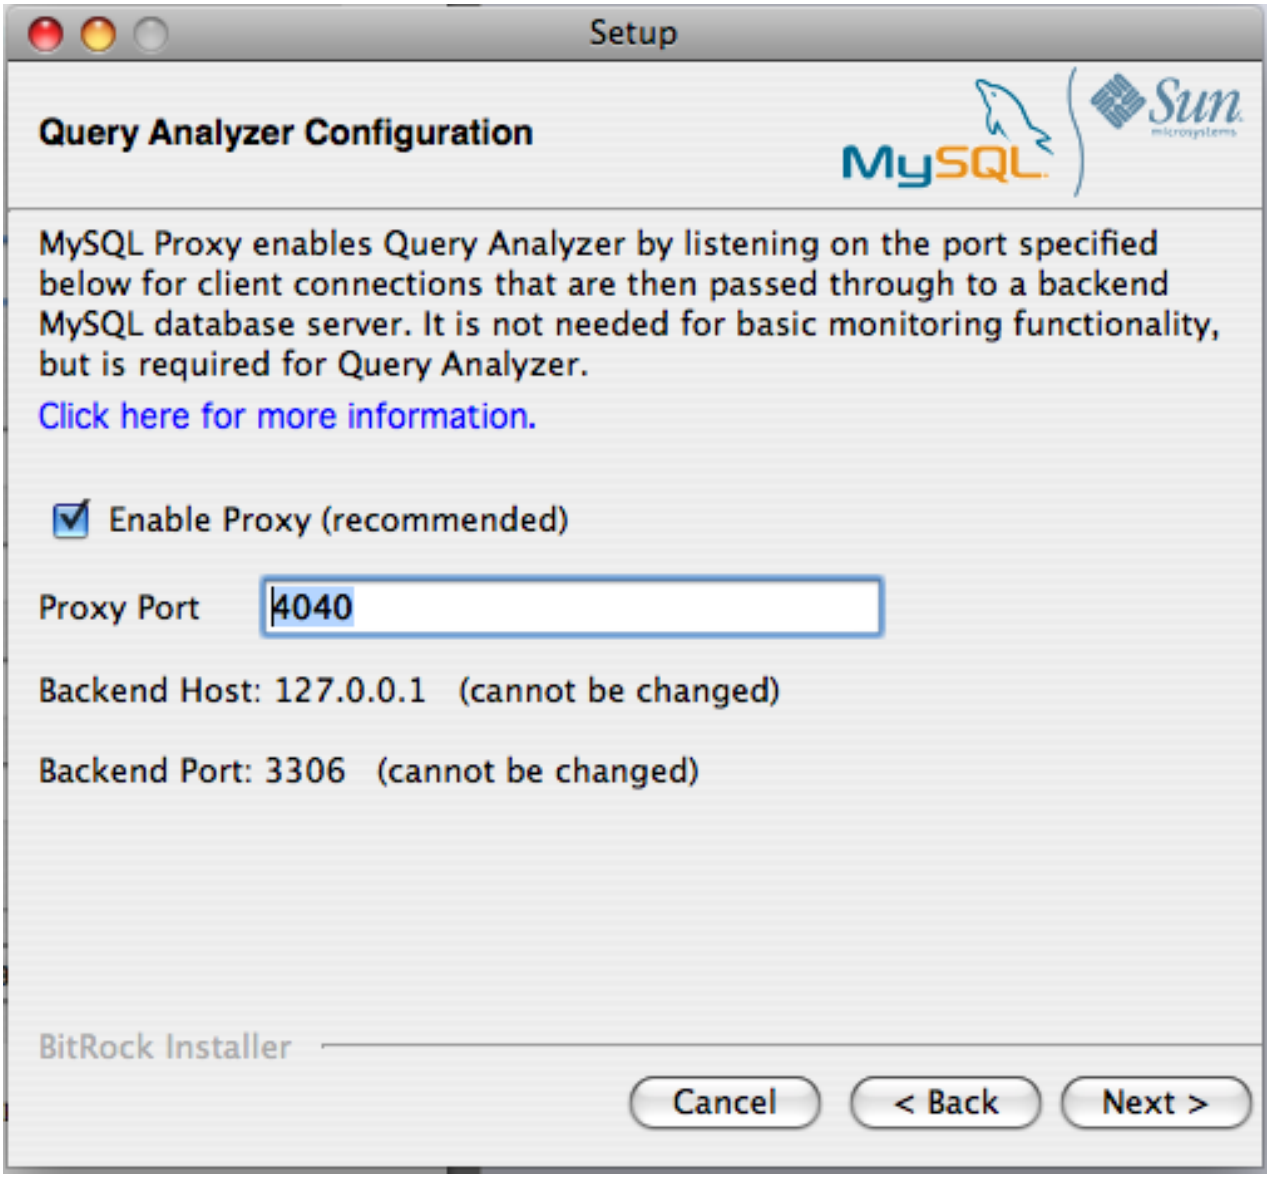


Click NEXT to continue the installation.

5. If you want to use Query Analyzer, then you need to enable the MySQL Enterprise Monitor Agent Proxy. The Proxy is enabled by default. If you disable the Proxy during installation, you will need to enable it later before you are able to use Query Analyzer. For more information on Query Analyzer, see Section 15.10, "The Query Analyzer Page".

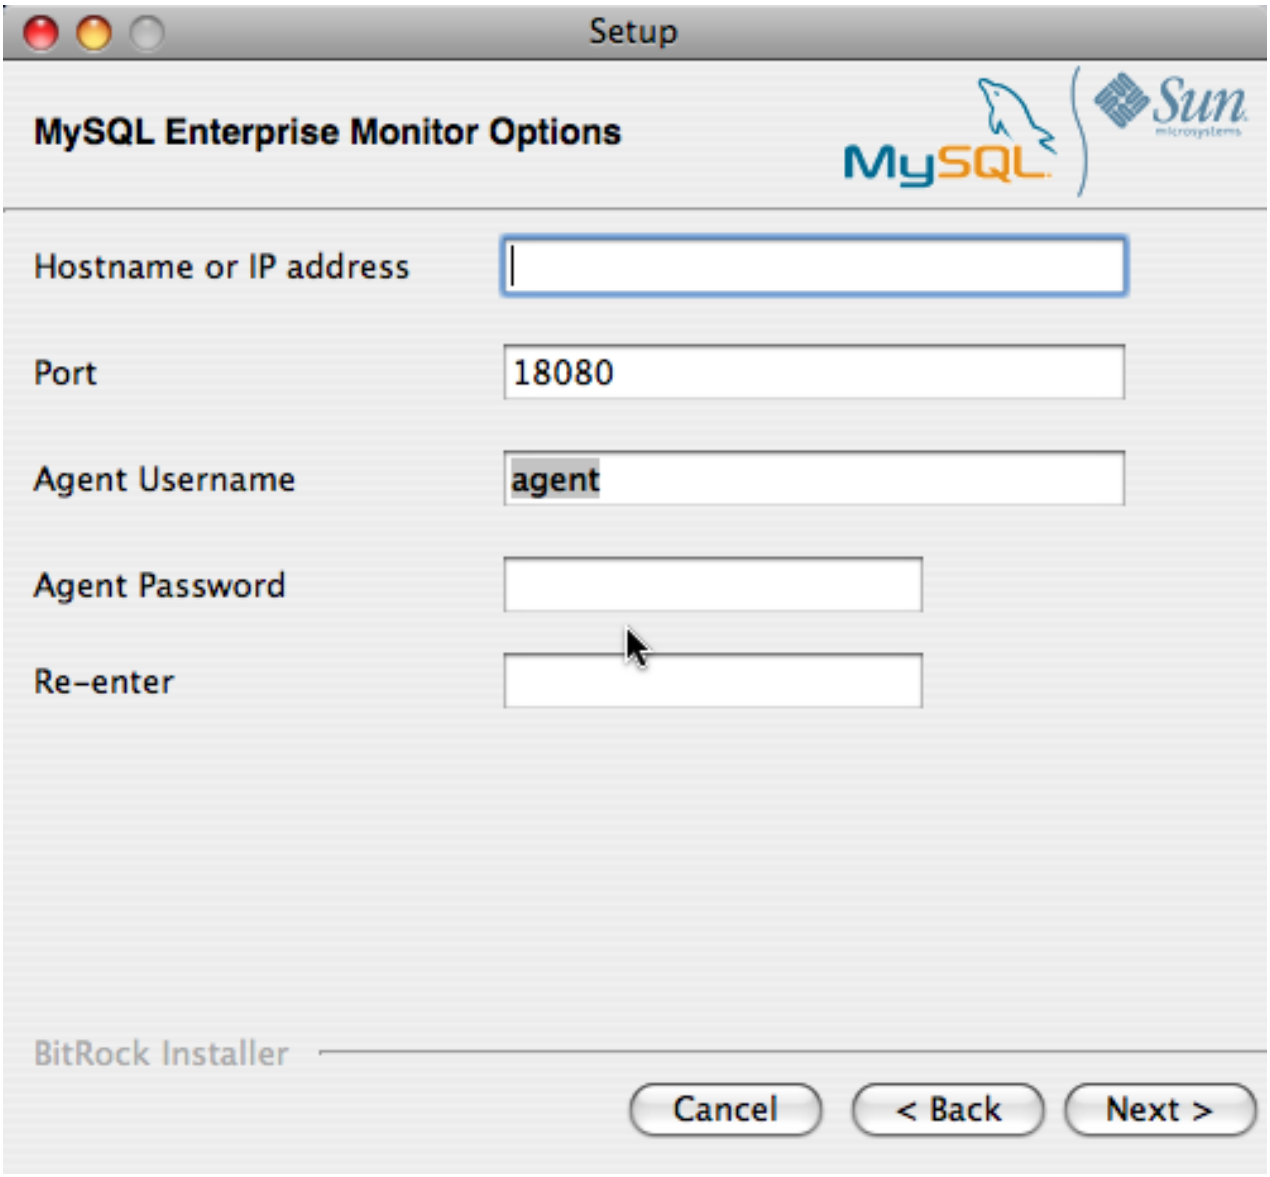
   When Proxy is enabled, MySQL Enterprise Monitor Agent listens on a network port for client applications, and forwards the connections to the backend MySQL server. You can change the port number that MySQL Enterprise Monitor Agent listens for connections The default port is 6446.

Figure 15.22. MySQL Enterprise Monitor: Installing Agent on Mac OS X: Query Analyzer Configuration



6. The MySQL Enterprise Service Manager that you want to use must be configured during installation. The host name, port and agent authentication information must be entered. If you have already installed MySQL Enterprise Service Manager then you can locate the information in the installation report file created during installation. Enter the required information and then click NEXT to continue.

Figure 15.23. MySQL Enterprise Monitor: Installing Agent on Mac OS X: MySQL Enterprise Service Manager Options



7. You will be provided with a Configuration Report containing the information that you have entered during the installation. Check the information provided in the report. If you see a problem, use BACK to go back to the configuration screen and change the information. If the information is correct, click NEXT to continue.

8. You are given a final opportunity to change the installation parameters. Click NEXT to start the installation process.

9. Once the agent has been installed, you will get a confirmation message. Click NEXT to finalize the installation.

10. You can start the MySQL Enterprise Monitor Agent automatically now the installation has been completed. To allow the agent to be started, leave the checkbox selected. To start the agent separately, uncheck the checkbox. Click FINISH to exit the installation.

Once the Monitor Agent is installed, it needs to be started. For information on how to start and stop the Agent, see Section 15.3.3.5.2, "Starting/Stopping the Agent on Mac OS X".

15.3.3.4. Installing the Monitor Agent on Unix

As a prerequisite for installing the MySQL Enterprise Monitor Agent on Linux systems you must have the Linux Standards Base (LSB)

initialization functions installed.

> **Note**
>
> You can check the existence of the LSB components by looking for an LSB package within your Linux package management environment. For example, on RedHat and other RPM-based distributions:
>
> ```
> shell> rpm -qa | grep -i lsb
> redhat-lsb-3.1-19.fc8.x86_64
> ```
>
> Under Debian/Ubuntu:
>
> ```
> shell> dpkg -l|grep -i lsb
> ii  lsb-base                                3.2-20ubuntu4
>     Linux Standard Base 3.2 init script function
> ii  lsb-release                             3.2-20ubuntu4
>     Linux Standard Base version reporting utilit
> ```
>
> Alternatively, you can use the `lsb_release` command. Existence of this command normally indicates that the current distribution is LSB compliant.

To install the agent navigate to the directory that contains the file, `mysqlmonitoragent-`*`version`*`-installer.bin` (where *`version`* indicates the three-part version number, the OS, and the architecture). Ensure that this file is executable by typing:

```
shell> chmod +x mysqlmonitoragent-version-installer.bin
```

To install to the default directory (`/opt/mysql/enterprise/agent`) you need to be logged in as `root`. Installing as an unprivileged user installs to the `/home/`*`user_name`*`/mysql/enterprise/agent` directory.

> **Note**
>
> If you install the agent as an unprivileged user, it will not automatically start up on rebooting.

What follows describes installation from the command line. You may install the Monitor Agent graphically by running the installer from within a windows manager. In both cases the steps are identical. You may also install the Monitor Agent in `unattended` mode. This is especially useful if you are doing multiple installations. For more information on this topic see Section 15.3.4, “Unattended Installation”.

Begin installation from the command line by typing:

```
shell> ./mysqlmonitoragent-version-installer.bin --mode text
```

The various options are shown in what follows. Default values are indicated by square brackets; to select them press ENTER. Otherwise enter a value of your choosing.

1. First, you must select the Language you want to use during the installation process:

   ```
   Language Selection

   Please select the installation language
   [1] English
   [2] Japanese
   Please choose an option [1] :
   ```

2. Next, specify the directory where you want the agent installed:

   ```
   -------------------------------------------------------------------------------
   Welcome to the MySQL Enterprise Monitor Agent Setup Wizard.

   -------------------------------------------------------------------------------
   Please specify the directory where MySQL Enterprise Monitor Agent will be installed

   Installation directory [/opt/mysql/enterprise/agent]:
   ```

3. Specify the MySQL server that you want to monitor. First, you must specify whether you want to use a TCP/IP or socket-based connection to communicate with the MySQL Server:

```
How will the agent connect to the database it is monitoring?

[1] TCP/IP
[2] Socket
Please choose an option [1] :
```

If you select TCP/IP, then you will be asked to enter the TCP/IP address and port number:

```
--------------------------------------------------------------------------------
Monitored Database Information

IMPORTANT: The agent user account specified below requires special MySQL privileges.

Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights

MySQL hostname or IP address [127.0.0.1]:

Validate MySQL hostname or IP address [Y/n]:

MySQL Port [3306]:
```

If you select Socket, then you will be asked to provide the path name to the MySQL socket. Typical values are `/tmp/mysql.sock`, `/var/lib/mysql.sock`, or `/var/run/mysql.sock`.

```
--------------------------------------------------------------------------------
Monitored Database Information

IMPORTANT: The agent user account specified below requires special MySQL privileges.

Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-install.html#mem-agent-rights

MySQL Socket []:
```

> **Note**
>
> The monitor agent always associates “localhost” with the TCP/IP address 127.0.0.1, not the MySQL socket. This is in contrast to the MySQL Command Line Tool, which connects via the MySQL socket by default on Unix, if the hostname “localhost” is specified.
>
> If the MySQL server you wish to monitor has been started with the `--skip-networking` command option then you will not be able to connect to it via TCP/IP, as the server will not listen for TCP/IP connections. In this case the monitor agent will need to be configured to use the MySQL socket. This can be done during installation by selecting “socket” rather than “TCP/IP” and then specifying the MySQL socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, for further information on this refer to Section 15.3.3.6.2, “MySQL Server (`agent-instance.ini`) Configuration”.
>
> If the MySQL server to be monitored has been started using the command option `--bind-address` then the server will only listen for connections on the IP address specified, that is, the IP address of the MySQL server. If the monitor agent has been started using TCP/IP networking and the default address of 127.0.0.1 it will not be able to connect to the server to be monitored. Also, if “localhost” is specified as the host name during agent configuration, a connection will not be established, as the server will be listening for connections on the address specified with the `--bind-address` option, not 127.0.0.1.

4. Specify the user credentials for the MySQL server that you want to monitor:

```
MySQL Username []: service_agent

MySQL Password :

Re-enter :
```

5. Select whether you want to enable Query Analyzer. If you disable the Query Analyzer during installation, you will need to manually edit the configuration file to re-enable the Query Analyzer functionality. If you enable Query Analyzer (Proxy), you must specify the port on which the agent will listen for queries.

```
------------------------------------------------------------------------------
Query Analyzer Configuration

MySQL Proxy enables query monitoring and analysis by listening on a specified port for client connections that are the

Click here for more information.
 [Y/n]:

Enable Proxy (recommended) [Y/n]:

Proxy Port [6446]:

Backend Host: 127.0.0.1   (cannot be changed)

Backend Port: 3306   (cannot be changed)
```

For more information on enabling Query Analyzer if you disabled it during installation, see Section 15.10, “The Query Analyzer Page”.

6. Enter the details of the MySQL Enterprise Service Manager that you want to use with this agent. The configuration information required is available within the installation report generated when you installed MySQL Enterprise Service Manager

```
------------------------------------------------------------------------------

MySQL Enterprise Monitor Options

Hostname or IP address []: 192.168.0.197

Tomcat Server Port [18080]:

Tomcat SSL Port [18443]:
```

The agent and MySQL Enterprise Service Manager support using SSL for communication. If you want to enable SSL communication between the agent and the MySQL Enterprise Service Manager, you must reply **Y** to the following question.

```
Use SSL? [y/N]:

Agent Username [agent]:

Agent Password :

Re-enter :

------------------------------------------------------------------------------
```

7. Before installation starts, you will be provided with a summary of the installation settings that you have specified:

```
Here are the settings you specified:

Installation directory: /opt/mysql/enterprise/agent

Monitored MySQL Database:
-------------------------
Hostname or IP address: 127.0.0.1
Port: 3306
MySQL username: mysql_user
MySQL password: password

Query Analyzer Configuration
-------------------------
Proxy Enabled: yes
Proxy Port: 6446

MySQL Enterprise Manager:
-----------------------------

Hostname or IP address: 192.168.0.197

Tomcat Server Port: 18080
Tomcat SSL Port: 18443
Use SSL: 0
Agent username: agent

Press [Enter] to continue :
```

```
-------------------------------------------------------------------------------

Setup is now ready to begin installing MySQL Enterprise Monitor Agent on your computer.

Do you want to continue? [Y/n]: y
```

8. The installer will copy the necessary files and create the configuration file required to run the agent:

```
-------------------------------------------------------------------------------
Please wait while Setup installs MySQL Enterprise Monitor Agent on your computer.

 Installing
 0% _______________ 50% _______________ 100%
 ########################################

-------------------------------------------------------------------------------
Info to start MySQL Agent

The MySQL agent was successfully installed. To start the MySQL Agent please
invoke:
/opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
Press [Enter] to continue :

-------------------------------------------------------------------------------
Setup has finished installing MySQL Enterprise Monitor Agent on your computer.
```

9. Finally, you can read the supplied `README` file when prompted. The file is provided within the `share/doc/README_en.txt` file within the agent installation directory if you would like to read this file separately.

For information on starting the agent, see Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”.

15.3.3.5. Starting/Stopping the MySQL Enterprise Monitor Agent

The MySQL Enterprise Monitor Agent can be started and stopped at any time. When not running, information about the current status of your server will not be available, and MySQL Enterprise Service Manager will provide a warning if an agent and the MySQL server that it monitors is unavailable.

> **Warning**
>
> If you are using Query Analyzer, then turning off the agent will prevent your applications from communicating with the MySQL server. See Section 15.10, “The Query Analyzer Page”.

15.3.3.5.1. Starting/Stopping the Agent on Windows

You have the option of starting the Monitor Agent from the final installation screen. Otherwise you can do this by going to the `Start Menu` and under `Programs` find `MySQL` and then the `MySQL Enterprise Monitor Agent` entry. Simply select the `Start MySQL Enterprise Monitor Agent` option.

> **Note**
>
> On Windows Vista or later, starting the agent requires administrative privileges—you must be logged in as an administrator. To start or stop the agent right-click the menu item and choose the RUN AS ADMINISTRATOR menu option. The same restriction applies to starting the agent from the command line. To open an administrator `cmd` window right-click the `cmd` icon and choose the RUN AS ADMINISTRATOR menu option.

> **Warning**
>
> To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, Section 15.3.3.7, “Troubleshooting the Agent”.

Alternately, you can start the agent from the command line by entering:

```
shell> sc start MySQLEnterpriseMonitorAgent
```

or:

```
shell> net start MySQLEnterpriseMonitorAgent
```

You can also start the agent by issuing the command, `agentctl.bat start`. Stop the agent by passing the argument, `stop`. This batch file is found in the `Agent` directory.

For confirmation that the service is running you can open the Microsoft Management Console Services window. To do this go to the Control Panel, find `Administrative Tools` and click the link to `Services`. Locate the service named `MySQL Enterprise Monitor Agent` and look under the **STATUS** column.

You may also start the agent from this window rather than from the `Start` menu or the command line. Simply right-click `MySQL Enterprise Monitor Agent` and choose `Start` from the pop-up menu. Starting the agent from this window opens an error dialog box if the agent cannot connect to the MySQL server it is monitoring. No error is displayed if the agent is unable to connect to the MySQL Enterprise Service Manager.

The pop-up menu for starting the agent also offers the option of stopping the agent. To stop the agent from the command line you only need type:

```
shell> sc stop MySQLEnterpriseMonitorAgent
```

or:

```
shell> net stop MySQLEnterpriseMonitorAgent
```

> **Note**
>
> `MySQLEnterpriseMonitorAgent` is the default name of the Monitor Agent service. If you have added an additional agent as described in Section 15.3.3.6.2, "MySQL Server (`agent-instance.ini`) Configuration", replace `MySQLEnterpriseMonitorAgent` with the appropriate agent name.

15.3.3.5.2. Starting/Stopping the Agent on Mac OS X

The script to start the agent on Mac OS X is located in the `/Applications/mysql/enterprise/agent/etc/init.d` directory. To start the agent navigate to this directory and at the command line type:

```
shell> ./mysql-monitor-agent start
```

To stop the agent, use the `stop` command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file.

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /Applications/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see Section 15.3.3.7, "Troubleshooting the Agent".

Installation creates the directory `/Applications/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the monitor agent, navigate to the `/Applications/mysql/enterprise/agent/etc/init.d` directory and execute **`mysql-monitor-agent`** `help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/Applications/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /Applications/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in Section 15.3.3.6.2, "MySQL Server (`agent-instance.ini`) Configuration", and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command **`./mysql-monitor-agent status`**.

> **Warning**
>
> To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, Section 15.3.3.7, "Troubleshooting the Agent".

15.3.3.5.3. Starting/Stopping the Agent on Unix

When installation is finished, you can start the monitor agent from the command line by typing:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

For a non-`root` installation the command would be:

```
shell> /home/<user name>/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start
```

To stop the agent, use the `stop` command:

```
shell> ./mysql-monitor-agent stop
```

If the agent cannot be stopped because the `pid` file that contains the agent's process ID cannot be found, you can use `kill` to send a `TERM` signal to the running process:

```
shell> kill -TERM PID
```

If you are running more than one agent on a specific machine, you must also specify the path to the `ini` file when you are stopping the agent. Executing `mysql-monitor-agent stop` without an `ini` file will only stop the agent associated with the default `ini` file. Likewise, when checking the status of an agent specify its `ini` file.

To verify that the agent is running use the following command:

```
shell> ./mysql-monitor-agent status
```

The resulting message indicates whether the agent is running or not. If the agent is not running, use the following command to view the last ten entries in the agent log file:

```
shell> tail /opt/mysql/enterprise/agent/log/mysql-monitor-agent.log
```

For further information on troubleshooting the agent see Section 15.3.3.7, "Troubleshooting the Agent".

Installation creates the directory `/opt/mysql/enterprise/agent` with the settings stored in the `mysql-monitor-agent.ini` file located directly below this directory in the `etc` directory. The `log` directory is also located immediately below the `agent` directory.

To see all the command-line options available when running the monitor agent, navigate to the `/opt/mysql/enterprise/agent/etc/init.d` directory and execute **`mysql-monitor-agent`** `help`. You should see the message:

```
Usage: ./mysql-monitor-agent {start|stop|restart|status} [ini-file-name]
```

The `ini-file-name` option only needs to be used if the `ini` file is not installed to the default location or you have changed the name of the `ini` file. You will need to use this option if you are installing more than one agent on the same machine. Pass the full path to the `ini` file. For example, after navigating to the `/opt/mysql/enterprise/agent/etc/init.d` directory, issue the command:

```
shell> ./mysql-monitor-agent start /opt/mysql/enterprise/agent/etc/new-mysql-monitor-agent.ini
```

If you installed the agent as `root`, on reboot the `mysql-monitor-agent` daemon will start up automatically. If you installed the agent as an unprivileged user, you must manually start the agent on reboot or write a script to perform this task. Likewise, if you have added an additional agent as described in Section 15.3.3.6.2, "MySQL Server (`agent-instance.ini`) Configuration", and you wish to start this agent on reboot, create a system initialization script appropriate to your operating system. To determine whether the agent is running or not navigate to the `init.d` directory and issue the command **`./mysql-monitor-agent status`**.

> **Warning**
>
> To report its findings, the agent needs to be able to connect to the dashboard through the port specified during installation. The default value for this port is `18080`; ensure that this port is not blocked. If you need help troubleshooting the agent installation see, Section 15.3.3.7, "Troubleshooting the Agent".

15.3.3.6. Advanced Agent Configuration

The MySQL Enterprise Monitor Agent is configured through files located within the `etc` directory within the directory where you installed the agent.

Configuration is stored in multiple files, according to a predetermined file and directory layout. The primary configuration file contains specific information about the agent and how the agent communicates with MySQL Enterprise Service Manager. The main configuration is located within the `mysql-monitor-agent.ini` file.

Additional configuration files contain information about the MySQL server that is being monitored. You can configure which directory is used for storing this information within the `mysql-monitor-agent.ini` file. The default location is the `etc/instances` directory within the MySQL Enterprise Monitor Agent directory.

The server you want to monitor should have a directory within the specified location, optionally using the name of the server you are monitoring, and within that directory, an `agent-instance.ini` file. This file contains the configuration information for connecting to the MySQL server, including the host name, port, user credentials and display name.

You can see an example of the file layout of the `etc` directory:

```
.
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

For more information on the configuration of the `mysql-monitor-agent.ini` file, see Section 15.3.3.6.1, "MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration". For details on the content of the individual MySQL instance configuration files, see Section 15.3.3.6.2, "MySQL Server (`agent-instance.ini`) Configuration".

15.3.3.6.1. MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration

The `mysql-monitor-agent.ini` files contains the base configuration information for the MySQL Enterprise Monitor Agent. The file sets the core information about the supported functionality for the entire agent.

You can see a sample of the configuration file below:

```
# WARNING - the UUID defined below must be unique for each agent.
#
# To use this .ini file as a template for configuring additional
```

```
# agents, do not simply copy and start a new agent without first
# modifying the UUID.
#
# Refer to the documentation for more detailed information and
# instructions.
#
# Version: 20080718_230416_r7011

[mysql-proxy]

plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor-server:18080/heartbeat
mysqld-instance-dir= etc/instances
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script        = share/mysql-proxy/quan.lua

agent-uuid = 8770ead5-3632-4b29-a413-4a7c92437e26
log-file = mysql-monitor-agent.log
pid-file=/Applications/mysql/enterprise/agent/mysql-monitor-agent.pid
```

> **Note**
>
> Do not copy the agent configuration information from one machine to another without changing the `agent-uuid`. Each agent instance must have a unique agent id.

The main configuration information must be located within the `[mysql-proxy]` section of the configuration file. The main configurable parameters within this file are:

- `plugins`: Configures the plugins to be used by the agent. When monitoring servers you must have the `agent` plugin configured. If you want to support Query Analyzer then you must also have the `proxy` module enabled. Plugins should be specified as a comma separated list of plugin names.

  If you selected to support Query Analyzer during installation of the agent, the default value will be `proxy,agent`. If you disabled Query Analysis during installation, the default value will be `agent`.

- `log-level`: Sets the logging level of the agent. The default level is `critical`.

  Valid values for `log-level` are as follows:

  - `debug`: Provides detailed information about what the agent is doing and the information being provided by the agent to the MySQL Enterprise Service Manager.
  - `critical`: Lists critical messages highlighting problems with the agent.
  - `error`: Lists error messages.
  - `warning`: Provides only warning messages generated by the agent.
  - `message`: Provides information about the agent and basic processing information.
  - `info`: Provides messages used for informational purposes.

  > **Warning**
  >
  > Be careful when setting the `log-level` to `debug`. Doing this will rapidly increase the size of your `mysql-monitor-agent.log` file. To avoid disk space problems, put the log files on a different drive from your MySQL server and the MySQL Enterprise Dashboard.
  >
  > It is strongly recommended that you use a `log-level` of `critical` or `error` in a production server. Use the higher-levels to provide more detailed information only for debugging problems with your agent.
  >
  > Under Windows, if you restart the agent from the command line after setting the `log-level` to `debug`, extensive debug information is displayed to the console as well as to the log file.

- `agent-mgmt-hostname`: Sets the URL to use when reporting information. This value will be automatically set to your MySQL Enterprise Service Manager during installation.

- `mysqld-instance-dir`: Sets the directory where the configuration files that specify the MySQL servers to be monitored can be located.
- `agent-item-files`: Sets the information that is provided up to the MySQL Enterprise Service Manager when the agent is reporting status information. You should leave this item with the default setting of the `share/mysql-proxy/items/quan.lua` (which provides Query Analyzer data) and `share/mysql-proxy/items/items-mysql-monitor.xml` (which provides the core agent monitoring data).
- `proxy-address`: Sets the address and/or port number for the proxy to listen to for connections. The setting is used when employing Query Analysis as the address/port that you must configure your application to use in place of your normal MySQL server. By default this item is set during installation.

  The default value is 6446. If you want to support a different local host name/IP address and port, specify the host name and the port number, separated by a colon.
- `proxy-backend-addresses`: Sets the host name and port number to be used when communicating the backend MySQL server when employing query analyzer. This is the MySQL server where packets from the client are sent when communicating with the proxy on the host name/port set by the `proxy-address`.
- `proxy-lua-script`: Sets the Lua script to be used by the proxy when forwarding queries. To use Query Analyzer, this parameter should be set to `share/mysql-proxy/quan.lua`. This is the default value.
- `agent-uuid`: Sets the UUID (Universally Unique ID) of the agent. This value should be unique for all agents communicating with the same server, as the UUID is used to uniquely ID the agent within MySQL Enterprise Service Manager

  If you are setting up multiple hosts and copying the configuration between hosts, make sure that the `agent-uuid` is unique. You can have the agent create a new UUID by leavig this configuration property blank.
- `log-file`: Sets the location of the log file used to record information about the agent when it is running. If you do not specify a full path name, then the log file location is considered to be relative to the installation directory of the agent.
- `pid-file`: Sets the location of the file used to record the Process ID of the agent. This is used by the script that shuts down the agent to identify the process to be shutdown. The default value is the `mysql-monitor-agent.pid` file within the base installation directory as created by the agent installer.

15.3.3.6.2. MySQL Server (`agent-instance.ini`) Configuration

For the MySQL server that you want to monitor, you must create an `agent-instance.ini` within the directory specified by the `mysqld-instance-dir` configuration parameter within the main `mysql-monitor-agent.ini` file.

The `agent-instance.ini` file contains the host name and user credentials for connecting to the MySQL server that you want the agent to monitor. The format of the file is as follows:

```
# To use this .ini file as a template for configuring additional
# instances to monitor, do not simply copy and start a new agent
# without first modifying the displayname.
#
# Refer to the documentation for more detailed information and
# instructions.
#
# Version: 20080718_230416_r7011

[mysqld]
hostname = 127.0.0.1
port     = 3306
user     = root
password =
```

The individual configuration parameters can be defined as follows:

- `hostname`: The host name of the MySQL server that you want to monitor.
- `port`: The TCP/IP port of the MySQL server that you want to monitor.
- `user`: The user to use when connecting to the MySQL server that you want to monitor.
- `password`: The corresponding password to use when connecting to the MySQL server that you want to monitor.

It is also possible to configure the agent to use sockets. This can be done during installation by selecting “socket” rather than “TCP/IP” from the menu and then specifying the socket name. This can also be configured after installation by editing the `agent-instance.ini` configuration file, and adding the line:

```
socket = /full/path/to/mysql.sock
```

15.3.3.6.3. Monitoring Multiple MySQL Servers

You can monitor multiple MySQL servers (either on the same machine, or across different machines) using two different methods:

- By using a single agent instance to monitor multiple MySQL servers. You can use this method if you want to monitor multiple servers, but do not want or need to support Query Analysis on the additional servers.
- By using multiple copies of the MySQL Enterprise Monitor Agent to monitor each server individually. Using this method requires additional overhead to monitor each server, while also allowing you to supply Query Analyzer data.

Using a Single Agent Instance

> **Warning**
>
> Do not use the single agent instance method if you want to use Query Analyzer. If you set your application to use the proxy port provided by the single instance then the queries may not be directed to the correct server. Using Query Analyzer, the proxy, and the single agent instance method is not supported.

> **Warning**
>
> When using the single agent instance method, the agent will attempt to determine the right information about the backend server that it is monitoring in order to use the information when applying rule and advisor information. Currently, this operation is performed for only one of the servers in the list of configured servers. If the servers being monitoring are using different MySQL versions then the rules applied to the servers may be incorrect, and you could get wrong or misleading advice about issues or problems on a given server.

To use a single agent to monitor multiple instances, you can create additional directories and configuration files within the `instances` directory for the agent. For example, you can see the default structure of the agent configuration directory:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./mysql-monitor-agent.ini
```

Within the `instances` directory, you can add further directories, one for each monitored server. Each additional directory must have a suitable `agent-instance.ini` file containing the connection information for the new MySQL server instance. For example, the following structure demonstrates an agent monitoring four MySQL servers:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances/mysql2
./instances/mysql2/agent-instance.ini
./instances/mysql-rep
./instances/mysql-rep/agent-instance.ini
./instances/mysql-backup
./instances/mysql-backup/agent-instance.ini
./mysql-monitor-agent.ini
```

To add another MySQL monitored server, follow these steps:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”.
2. Copy an existing configuration directory and configuration files to the new directory:

```
shell> cp -R etc/instances/agent etc/instances/mysql2
```

3. Edit the configuration file within the new directory, for example `mysql2/agent-instance.ini`, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.

4. Restart the agent:

```
shell> mysql-monitor-agent restart
```

Using Multiple Agent Instances

To use multiple agents to monitor multiple MySQL servers you need to create a new configuration structure for both the agent and the MySQL server instances you need to monitor, including the binaries and configuration files, and then update the configuration to set the corresponding parameters to monitor the new server. Using this method allows you to enable query analyis by redirecting requests to the target server using the built-in proxy service within the agent.

For example, the directory structure below shows the configuration directory for two agents monitoring a single MySQL server each:

```
./init.d
./init.d/mysql-monitor-agent
./instances
./instances/agent
./instances/agent/agent-instance.ini
./instances-second/agent
./instances-second/agent/agent-instance.ini
./mysql-monitor-agent.ini
./mysql-second-agent.ini
```

The `mysql-monitor-agent.ini` file contains the configuration for the first agent, with the MySQL servers monitored defined within the `instances` directory. The `mysql-second-agent.ini` file contains the configuration information for the second agent, with the MySQL servers monitor defined within the `instances-second` directory.

To set up multiple agents:

1. Make sure that the MySQL instance that you want to monitor has a suitable user to use for connecting to the server. For more information, see Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”.

2. You need to generate a new UUID for the new agent:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
ee9296d7-f7cd-4fee-8b26-ead884ebf398
2009-03-05 11:49:37: (critical) shutting down normally
```

   Keep a record of the UUID to update the configuration file.

   Note, the agent should not be running when the UUID is generated.

3. Copy the main agent configuration file, which is by default in `/opt/mysql/enterprise/agent/etc/mysql-monitor-agent.ini`:

```
shell> cp mysql-monitor-agent.ini mysql-second-agent.ini
```

4. Edit the new configuration file, changing the following settings:

   - Change the `mysqld-instance-dir` to the new directory that will contain the individual MySQL server configuration files.
   - Change the `proxy-address` to a different value than the first agent configuration.
   - Change the `proxy-backend-addresses` to specify the IP address and MySQL port number for the MySQL server.
   - Change the `agent-uuid` to the new value obtained in an earlier step.
   - Change the `log-file` parameter to specify a different file to use when logging errors and problems. You cannot log to the same file from two different agents.

- Change the `pid-file` parameter to specify the file that will be used to store the process ID of the agent.

5. Copy an existing configuration directory and configuration files to the new directory:

```
shell> cp -R etc/instances etc/instances-second
```

6. Edit the configuration file, `instances/second/agent/agent-instance.ini` within the new directory, and set the `user`, `password` and either the `hostname` and `port`, or `socket` parameters.

7. With multiple instances, you must start each agent individually, specifying the location of the main configuration file. For example, to start the original (default) service:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-monitor-age
```

   To start the second instance:

```
shell> /opt/mysql/enterprise/agent/etc/init.d/mysql-monitor-agent start /opt/mysql/monitor/agent/etc/mysql-second-agen
```

15.3.3.6.4. Configuring an Agent to Monitor a Remote MySQL Server

Typically, the agent runs on the same machine as the MySQL server it is monitoring. Fortunately, this is not a requirement. If you want to monitor a MySQL server running on an operating system for which there is no agent available, you can install the agent on a machine other than the one hosting the MySQL server.

The process for installing an agent to monitor a MySQL server on a remote machine is identical to the process described in Section 15.3.3, “Monitor Agent Installation”. Follow the directions given there, being careful to specify the correct IP address or host name for the MySQL Enterprise Service Manager and likewise for the MySQL server—since the agent is not running on the same machine as the MySQL server, it cannot be the default, `localhost`.

Don't forget that the agent must be given rights to log in to the MySQL server from a host other than `localhost` and that the port used by the MySQL server, typically `3306` must be open for remote access. For more information about the database credentials required by agents see, Section 15.3.3.1, “Creating a MySQL User Account for the Monitor Agent”.

The agent also needs to be able to log in to the MySQL Enterprise Service Manager, typically using port `18080`, so ensure that the appropriate port is open.

> **Note**
>
> Remote agents do not report the OS information for either the host or the agent.
>
> If your subscription level entitles you to replication autodiscovery, do **not** use remote monitoring with replication slaves or masters. The agent must be installed on the same machine as the server you are monitoring in order for discovery to work properly. For more information, see Section 15.11, “The Replication Page”.

15.3.3.6.5. Monitoring Outside the Firewall with an SSH Tunnel

If you run an SSH server on the machine that hosts the MySQL Enterprise Service Manager and an SSH client on the machine that hosts the agent, you can create an SSH tunnel so that the agent can bypass your firewall. First, you need to make an adjustment to the `hostname` value specified in the `[mysql-proxy]` section of the `.ini` file. (For more information about the contents and location of the `.ini` file see Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration”.) Stop the agent and change the `hostname` value as shown in the following:

```
hostname = http://agent_name:password@localhost:18080/heartbeat
```

Replace the `agent_name` and `password` with suitable values. Likewise replace port `18080` if you are not running the dashboard on this port. Use `localhost` for the host name, since the agent is connecting through an SSH tunnel.

Next, execute the following command on the machine where the agent is running:

```
shell> ssh -L 18080:Dashboard_Host:18080 -l user_name -N Dashboard_Host
```

When prompted, enter the password for *`user_name`*.

If you are not running the MySQL Enterprise Service Manager on port `18080`, substitute the appropriate port number. Likewise, replace `Dashboard_Host` with the correct value. `user_name` represents a valid operating system user on the machine that hosts the MySQL Enterprise Service Manager.

Be sure to restart the agent so that the new value for the `hostname` takes effect. For instructions on restarting the agent see:

- Under Windows see, Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”.
- Under Unix see, Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”.
- Under Mac OS X see, Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”.

15.3.3.6.6. Generating a new UUID

For MySQL Enterprise Monitor to operate correctly, each agent must have a unique UUID in order to uniquely identify the agent with the MySQL Enterprise Service Manager.

> **Warning**
>
> Ensure that you do not reuse or duplicate a UUID. Running two agents with the same identification number yields unpredictable results

In Unix go to the command line and type:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

In Mac OS X go to the command line and type:

```
shell> /Applications/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
```

This should display a line similar to the following:

```
ee9296d7-f7cd-4fee-8b26-ead884ebf398
```

Paste this line into the `[mysql-proxy]` section of the `mysql-monitor-agent.ini` file for the `agent-uuid` parameter:

```
[mysql-proxy]
...
agent-uuid=ee9296d7-f7cd-4fee-8b26-ead884ebf398
```

In Windows, go to the command line and change to the MySQL Enterprise Monitor Agent installation directory and update the UUID by executing `mysql-monitor-agent -uf mysql-monitor-agent-3307.ini`. For example:

```
C:\> cd C:\Program Files\MySQL\Enterprise\Agent
C:\> mysql-monitor-agent -uf mysql-monitor-agent.ini (or your .ini file name)
```

This updates the configuration file directly with the new UUID.

15.3.3.7. Troubleshooting the Agent

The first step in troubleshooting the agent is finding out whether it is running or not. To do this see:

- Windows: Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”
- Unix: Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”
- Mac OS X: Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”

If incorrect credentials are specified for the agent login to the MySQL server that it is monitoring, then the agent will not run on start-up. Log in to the monitored MySQL server and check the agent's credentials. Compare the values of the `Host`, `User`, and `Password` fields in the `mysql.user` table with the values shown in the `[mysqld]` section of the `etc/instances/mysql/agent-instance.ini`. If incorrect credentials are specified in the `ini` file, simply correct them and restart the agent. Remember, changes to the `ini` file do not take effect until the agent is restarted.

The agent will not start up if incorrect credentials are specified for the service manager login. Using incorrect credentials for logging in to the service manager creates an entry in the agent log file. For the location of this log file see Agent Log and PID Files.

If the agent starts up but no server appears in the dashboard, check the `hostname` specified in the `[mysql-proxy]` portion of the `mysql-monitor-agent.ini` file. Incorrect credentials, IP address, or port will all cause the MySQL server to fail to appear in the dashboard. Also, ensure that the port specified in this file is not blocked on the machine hosting the MySQL Enterprise Service Manager.

An easy way to confirm that the agent can log in to the service manager is to type **`http://Dashboard_Host:18080/heartbeat`** into the address bar of your web browser, substituting the appropriate host name and port. When the HTTP authentication dialog box opens, enter the agent user name and password. If you log in successfully, you should see the following message:

```
<exceptions>
<error>E1031:  Agent payload parameter NULL.</error>
</exceptions>
```

> **Note**
>
> Despite the fact that the preceding listing shows an error, you have logged in successfully. This error appears *because* you have logged in but with no “payload”.

If you can log in successfully in the way described above and the agent is running, then there are errors in the `mysql-monitor-agent.ini` file. Compare the host name, port, agent name, and password found in the `ini` file with the values you entered into the address bar of your web browser.

If HTTP authentication fails then you are using incorrect credentials for the agent. Attempting to log in to the service manager using incorrect credentials creates an entry in the agent log file. For the location of this log file see Agent Log and PID Files.

If no HTTP authentication dialog box appears, and you are unable to connect at all, then you may have specified an incorrect host name or port. Confirm the values you entered against those described as the `Application hostname and port:` in the `configuration_report.txt` file. Failure to connect could also indicate that the port is blocked on the machine hosting the MySQL Enterprise Service Manager.

To check if a blocked port is the problem, temporarily bring down your firewall. If the agent is then able to connect, open up the port specified during installation and restart the agent. If necessary you can monitor outside the firewall using an SSH tunnel. For more information, see Section 15.3.3.6.5, “Monitoring Outside the Firewall with an SSH Tunnel”.

You can also check the agent error log file to help determine any problems. An error such as the following might indicate a blocked port:

```
(critical) connection to  merlin-server
'http://agent:test@172.11.1.1:18080/heartbeat' failed:
"connect() timed out!" error.
```

For the location of the agent error log file see, Agent Log and PID Files.

Setting the `log-level` entry in your `ini` file is also a good debugging technique. For more information on this subject see, Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration”.

Running the agent from the command line sometimes displays errors that fail to appear in the log file or on the screen when the agent is started from a menu option. To start the agent from the command line see the instructions given at the start of this section.

If you have more than one agent running on the same machine, the `UUID` must be unique and the `log-file` and `pid-file` values must be different. For more information, see Section 15.3.3.6.2, “MySQL Server (`agent-instance.ini`) Configuration”.

If the agent is not running on the same machine that hosts the MySQL server it is monitoring, then you must ensure that the correct `host` is specified for the agent account. The correct port, typically 3306, must also be open for remote login. For more information about remote monitoring see, Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”.

If the MySQL Enterprise Monitor Agent has been ungracefully terminated and restarted (for example after being terminated using

`kill`), then you may see a `DuplicateAgentUuidException` error until the original registration of the previous instance of the agent has expired.

15.3.4. Unattended Installation

It is possible to install the MySQL Enterprise Monitor without any direct user interaction. This is done by passing the command-line option `--mode unattended` to the installation file.

Using this mode and other command-line parameters means the user will not be prompted for input during installation. This is especially useful when doing multiple installations of the MySQL Enterprise Monitor.

However, rather than passing numerous parameters from the command line, it is usually more convenient to save your options in a text file and invoke the installer using the `optionfile` option. This is a more reusable and less error-prone solution.

Before attempting an unattended installation, it is recommended that you install the MySQL Enterprise Monitor interactively at least once. Failing this, as a minimum, read the regular installation instructions since some tasks still remain after an unattended installation; you must configure the MySQL Enterprise settings, import the advisors, and start up all the services/daemons.

15.3.4.1. Command-Line Options

To view the available options for the monitor installer or for the agent installer, at the command line type the executable file name along with the `--help` option.

On each platform, for each installer, the installer supports a number of different installation modes. Some of these are unique to an individual platform, others are available on all platforms. The table below summarizes the different options available for each platform.

Platform	Default Mode	win32	gtk	xwindow	osx	text	unattended
Windows	win32	Y	N	N	N	N	Y
Unix	gtk	N	Y	Y	N	Y	Y
Linux	gtk	N	Y	Y	N	Y	Y
Mac OS X	win32	N	N	N	Y	Y	Y

15.3.4.1.1. MySQL Enterprise Service Manager Options

The following listing shows the command line options for the MySQL Enterprise Service Manager.

```
--help                          Display the list of valid options

--version                       Display product information

--optionfile <optionfile>       Installation option file

                                Default:

--mode <mode>                   Installation mode
                                Default: win32
                                Allowed: win32 unattended

--debugtrace <debugtrace>       Debug filename
                                Default:

--installer-language <installer-language> Language selection
                                Default:
                                Allowed: en  jp

--installdir <installdir>       Installation directory
                                Default:/opt/mysql/enterprise/monitor/

--tomcatport <tomcatport>       Tomcat Server Port
                                Default: 18080

--tomcatshutdownport <tomcatshutdownport> Tomcat Shutdown Port
                                Default: 18005

--tomcatsslport <tomcatsslport>Tomcat SSL Port
                                Default: 18443

--usessl <usessl>               Should communication between the Dashboard »
                                       and Service Manager be encrypted?
                                Default: 0
```

```
--adminuser <adminuser>        Repository Username
                               Default: service_manager

--adminpassword <adminpassword>Password
                               Default:

--dbport <dbport>              Bundled MySQL Database Port
                               Default: 13306
```

The options and their effect on installation are detailed below:

- `--help`

  Display the list of valid options.

- `--version`

  Display product and version information.

- `--optionfile`

  The path to the option file containing the information for the installation.

- `--mode`

  The installation mode to be used for this installation.

- `--debugtrace`

  The filename to be used for a debug trace of the installation.

- `--installer-language`

  The installer language; supported options are `en` for English and `jp` Japanese.

- `--installdir`

  The installation directory for MySQL Enterprise Service Manager.

  The default on Windows is `C:\Program Files\MySQL\Enterprise\Monitor`

  The default on Unix is `/opt/mysql/enterprise/monitor/`

  The default on Mac OS X is `/Applications/mysql/enterprise/monitor/`

- `--tomcatport`

  The MySQL Enterprise Service Manager port;

  The default is 18080.

- `--tomcatshutdownport`

  The MySQL Enterprise Service Manager Tomcat shutdown port.

  The default is 18005.

- `--tomcatsslport`

  The MySQL Enterprise Service Manager SSL port.

  The default is 18443.

- `--usessl`

  Enable support for SSL communication between the MySQL Enterprise Monitor Agent and MySQL Enterprise Service Manager.

The default is 0.

- `--adminuser`

  The MySQL Enterprise Service Manager user name.

  The default is `service_manager`.

  > **Warning**
  >
  > The repository user name and password are stored in unencrypted form in the `config.properties` file. To locate this file on your operating system see The `config.properties` File.

- `--adminpassword`

  The MySQL Enterprise Service Manager password.

- `--dbport`

  The TCP/IP port for the Bundled MySQL database.

  The default is 13306.

15.3.4.1.2. MySQL Enterprise Monitor Agent Options

To view all the options available for an unattended *agent* installation, invoke the agent installer file passing in the `help` option. (Under Windows you must redirect the output to a file. You should see a listing similar to the following:

> **Note**
>
> The exact options may vary depending on the operating system on which you are executing the installer.

```
Usage:

 --help                          Display the list of valid options

 --version                       Display product information

 --optionfile <optionfile>       Installation option file
                                 Default:

 --unattendedmodeui <unattendedmodeui> Unattended Mode UI
                                 Default: none
                                 Allowed: none minimal minimalWithDialogs

 --mode <mode>                   Installation mode
                                 Default: osx
                                 Allowed: osx text unattended

 --debugtrace <debugtrace>       Debug filename
                                 Default:

 --installer-language <installer-language> Language selection
                                 Default:
                                 Allowed: en ja

 --installdir <installdir>       Installation directory
                                 Default:

 --mysqlconnmethod <mysqlconnmethod>
                                 Default: tcpip
                                 Allowed: tcpip socket

 --mysqlhost <mysqlhost>         MySQL hostname or IP address
                                 Default: 127.0.0.1

 --checkmysqlhost <checkmysqlhost> Validate MySQL hostname or IP address
                                 Default: yes

 --mysqlport <mysqlport>         MySQL Port
                                 Default: 3306

 --mysqlsocket <mysqlsocket>     MySQL Socket
                                 Default:

 --mysqluser <mysqluser>         MySQL Username
```

```
                                Default:

--mysqlpassword <mysqlpassword> Password for mysql user
                                Default:

--enableproxy <enableproxy>     Enable Proxy (recommended)
                                Default: 1

--proxyport <proxyport>         Proxy Port
                                Default: 6446

--managerhost <managerhost>     Hostname or IP address
                                Default:

--managerport <managerport>     Tomcat Server Port
                                Default: 18080

--managersslport <managersslport> Tomcat SSL Port
                                Default: 18443

--usessl <usessl>               Use SSL?
                                Default: 0

--agentuser <agentuser>         Agent Username
                                Default: agent

--agentpassword <agentpassword> Agent Password
                                Default:

--proxyuser <proxyuser>         User Account
                                Default: root
```

The options and their effect on installation are detailed below:

- `--help`

  Display the list of valid options

- `--version`

  Display product information, including the version number of the installer.

- `--optionfile <optionfile>`

  Specify the location of an option file containing the configuration options for this installation.

- `--unattendedmodeui <unattendedmodeui>`

  The UI elements to use when performing an unattended installation. The options are `none`, show now UI elements during the installation; `minimal`, show minimal elements during installation; `minimalWithDialogs`, show minimal UI elements, but include the filled-dialog boxes.

  The default is `none`.

- `--mode <mode>`

  Specify the installation mode to use for this installation.

- `--debugtrace <debugtrace>`

  Set the filename to use when recording debug information during the installation.

- `--installer-language <installer-language>`

  Set the language to be used for the installer.

- `--installdir <installdir>`

  Specify the directory where the software will be installed.

  The default on Windows is `C:\Program Files\MySQL\Enterprise\Agent`

  The default on Unix is `/opt/mysql/enterprise/agent/`

The default on Mac OS X is `/Applications/mysql/enterprise/agent/`

- `--mysqlconnmethod <mysqlconnmethod>`

  Specify the connection method to use to connect to MySQL.

  Options are `tcpip` and `socket`.

  The default is `tcpip`.

- `--mysqlhost <mysqlhost>`

  MySQL hostname or IP address

  The default is 127.0.0.1.

- `--checkmysqlhost <checkmysqlhost>`

  Validate the MySQL hostname or IP address

  The default is `yes`.

- `--mysqlport <mysqlport>`

  Specify the TCP/IP port to use when connecting to MySQL.

  The default is 3306.

- `--mysqlsocket <mysqlsocket>`

  Specify the filename of the MySQL socket to use when communicating with the monitored MySQL instance.

- `--mysqluser <mysqluser>`

  Specify the username to use when connecting to the MySQL instance.

- `--mysqlpassword <mysqlpassword>`

  Specify the password to use when connecting to the MySQL instance.

- `--enableproxy <enableproxy>`

  Enable the Proxy. This is recommended and is required if you want to use Query Analyzer.

  The default is 1 (use the proxy).

- `--proxyport <proxyport>`

  Specify the TCP/IP port to use for the proxy interface.

  The default is 6446.

- `--managerhost <managerhost>`

  The hostname or IP address of the MySQL Enterprise Service Manager.

- `--managerport <managerport>`

  The port number of the MySQL Enterprise Service Manager.

  The default is 18080.

- `--managersslport <managersslport>`

  The port number of the MySQL Enterprise Service Manager for SSL-based communication

The default is 18443.

- `--usessl <usessl>`

  Specifies whether SSL should be used to communicate with the MySQL Enterprise Service Manager.

- `--agentuser <agentuser>`

  Specify the agent username to be used when communicating with the MySQL Enterprise Service Manager.

- `--agentpassword <agentpassword>`

  Specify the agent password to be used when communicating with the MySQL Enterprise Service Manager.

- `--proxyuser <proxyuser>`

  The user account for the proxy server.

  The default is `root`.

15.3.4.2. Unattended Windows Installation

For unattended installation on Windows, create an option file named `options.server.txt`. The following is an example of what the contents of an option file might be.

```
debugtrace=C:\Program Files\MySQL\Enterprise\install.debugtrace.log
mode=unattended
installdir=C:\Program Files\MySQL\Enterprise
tomcatport=8080
tomcatshutdownport=8005
tomcatsslport=8443
adminpassword=myadminpassword
dbport=3300
```

This file identifies a directory and file name for a log file, sets the `mode` to `unattended`, and uses the `installdir` option to specify an installation directory. The meaning of the other options is fairly self-evident.

> **Note**
>
> Set the `installdir` and `debugtrace` options to values appropriate to your locale and operating system.
>
> The only options that must be specified in an option file when installing the MySQL Enterprise Service Manager are `mode` (if not specified at the command line), `installdir`, and `adminpassword`.
>
> Check the options in your option file closely before installation; no warnings will be issued if there are errors.

Ensure that the monitor installer file and the options file are in the same directory and, if you saved the options file as `options.server.txt`, you can invoke an unattended installation from the command line by typing:

```
C:\ mysqlmonitor-version-windows-installer.exe --optionfile options.server.txt
```

You can install the MySQL Enterprise Monitor Agent in exactly the same fashion. Create an agent option file and call the agent installer using the `optionfile` option.

As a minimum for the agent installation, you must specify the `mode` (if not specified at the command line), `mysqluser`, `installdir`, `mysqlpassword`, `installdir`, `managerhost`, and `agentpassword` options. Create a file containing these values and use it with the `optionfile` option for unattended agent installation.

If you wish, you can create one script that calls both the Service Manager and the Monitor Agent programs passing appropriate `optionfile` options.

15.3.4.3. Unattended Unix and Mac OS X Installation

For unattended installation on Unix, create an option file named `options.server.txt`. The following is an example of what the contents of an option file might be for installation on Unix.

```
debugtrace=/opt/mysql/enterprise/install.debugtrace.monitor.log
mode=unattended
installdir=/opt/mysql/enterprise/monitor
tomcatport=8080
tomcatshutdownport=8005
tomcatsslport=8443
adminpassword=myadminpassword
dbport=3300
```

This file identifies a directory and file name for a log file, sets the `mode` to `unattended`, and uses the `installdir` option to specify an installation directory. The meaning of the other options is fairly self-evident.

> **Note**
>
> Set the `installdir` and `debugtrace` options to values appropriate to your locale and operating system.
>
> The only options that must be specified in an option file when installing the MySQL Enterprise Service Manager are `mode` (if not specified at the command line), `installdir`, and `adminpassword`.
>
> Check the options in your option file closely before installation; no warnings will be issued if there are errors.

Ensure that the monitor installer file and the options file are in the same directory and, if you saved the options file as `options.server.txt`, you can invoke an unattended installation from the command line by typing:

```
shell> mysqlmonitor-version-installer.bin --optionfile options.server.txt
```

You can install the MySQL Enterprise Monitor Agent in exactly the same fashion. Create an agent option file and call the agent installer using the `optionfile` option.

As a minimum for the agent installation, you must specify the `mode` (if not specified at the command line), `mysqluser`, `installdir`, `mysqlpassword`, and `agentpassword` options. Create a file containing these values and use it with the `optionfile` option for unattended agent installation.

If you wish, you can create one script that calls both the Service Manager and the Monitor Agent programs passing appropriate `optionfile` options.

> **Note**
>
> The Service Manager does not automatically start up on rebooting. For more information, see Bug#31676.

The procedure for unattended agent installation under Mac OS X is identical to the procedure under Unix.

15.3.4.4. Starting the Services

For instructions on starting the services needed by the MySQL Enterprise Service Manager see, Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows” for Windows and, Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X” for Unix and Mac OS X.

For instructions on starting the MySQL Enterprise Monitor Agent see:

- Windows: Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”
- Unix: Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”
- Mac OS X: Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”

If you wish, you can script the startup of these services.

15.3.5. Post-Installation Considerations

Depending upon how you plan to use the MySQL Enterprise Monitor, there are some tasks you may want to perform after installation. Find some suggestions in the following list:

- **Email settings**: Test email notification by deliberately triggering an alert.
- **Auto Startup**: On Unix systems, the MySQL Enterprise Service Manager does not automatically restart when the system is re-booted. You may wish to create a system initialization script appropriate to your operating system.
- **Log files**: Check the log files for any irregularities. For the locations of the various log files see Files Associated with The MySQL Enterprise Monitor.
- **Agent Log file rotation**: Implement log file rotation for the monitor agent.
- **Back up the repository**: For a back-up strategy suitable to your circumstances, see the MySQL reference manual documentation.
- **Configuration backup**: Back up the `mysql-monitor-agent.ini` file and the associated `instances` directory and contents.

  For more information about the `mysql-monitor-agent.ini` file see Section 15.3.3.6, “Advanced Agent Configuration”.
- **Configuration file**: Store the `configuration_report.txt` in a safe place. There is no mechanism for retrieving the password stored in this file.
- **Repository credentials**: The repository user name and password are stored in unencrypted form in the `config.properties` file. Take care to protect this file.
- **Disk management**: Remove installation files, and monitor the space used by the repository. Ensure that you have adequate disk space by regularly purging data. For more information, see Data Purge Behavior.
- **Firewall changes**: You may want to limit or expand access to the MySQL Enterprise Service Manager.
- **Open ports**: As with firewall changes, you may want to limit or expand access to the MySQL Enterprise Service Manager. The dashboard uses nonstandard ports, none of which are usually open by default.
- **Server upgrades**: See Section 15.3.6.3.1, “Upgrading the Monitored MySQL Server” for instructions on upgrading a server.
- **Repository access**: You may want to add other users.

15.3.6. Upgrading, Re-Installing or Changing Your Installation

You can upgrade MySQL Enterprise Monitor in a number of different ways:

- For instructions on upgrading your existing installation, see Section 15.3.6.1, “Upgrading MySQL Enterprise Monitor”.
- For more information on re-installing an existing installation, see Section 15.3.6.2, “Reinstalling MySQL Enterprise Monitor”.
- To change an existing installation, such as changing the monitored server, see Section 15.3.6.3, “Changing Your MySQL Enterprise Monitor Installation”.

15.3.6.1. Upgrading MySQL Enterprise Monitor

From time to time there may be updates to the MySQL Enterprise Service Manager or the MySQL Enterprise Monitor Agent. This section describes how to perform an update for either of these components.

You cannot use the update installers to change to a different operating system or chip architecture. For example, you cannot update a 32-bit Linux installation to a 64-bit version using an update installer—in cases such as this you must do a fresh installation.

The installation and configuration of MySQL Enterprise Monitor Agent must be standard before you start the installation. The update installer will not upgrade agents where you have changed or modified the filenames or directory layout of the installed agent, configuration files, or the startup files.

The name of the update file varies but it shows the target operating system and the version the update applies to. If a specific component is being updated it may also appear in the file name. For example, a file named *`mysqlenterprisemanager-2.0.0-windows-update-installer.exe`* would indicate a Windows update to MySQL Enterprise Service Manager version 2.0.0.

You may install an update in the same way that you initially installed the service manager or the agent; in `win32` or `unattended` mode on Windows in `gtk`, `text`, `xwindow`, or `unattended` mode on Unix and in `osx`, `text` , or `unattended` mode on OS X.

> **Warning**
>
> The method you use for upgrading MySQL Enterprise Monitor components will depend on the upgrade you are performing.
>
> - If you are upgrading between major versions (for example, from MySQL Enterprise Monitor 1.3 to merlin 2.0), you should shutdown the MySQL Enterprise Service Manager and each connected MySQL Enterprise Monitor Agent. Once you have shutdown each component, start by updating the MySQL Enterprise Service Manager, and then updating the MySQL Enterprise Monitor Agent on each monitored client.
> - If you are upgrading between the same major version, for example, MySQL Enterprise Monitor 2.0 to MySQL Enterprise Monitor 2.1, or a minor version, such as MySQL Enterprise Monitor 2.1.1 to MySQL Enterprise Monitor 2.1.2, you can shutdown only the component (agent, or server) you are updating. Using this method, you can perform a 'rolling' upgrade, where you shutdown a single MySQL Enterprise Monitor Agent, upgrade it to the latest agent version, and then restart the agent before moving on to the next monitored instance.

> **Important**
>
> The upgrade installer will overwrite `items-mysql-monitor.xml`. On Windows this file is found in the `C:\Program Files\MySQL\Enterprise\Agent\share\mysql-monitor-agent` directory and on Unix in the `/opt/mysql/enterprise/agent/share/mysql-monitor-agent` directory. You should back this file up if you have made any changes to it.

> **Warning**
>
> If you use the Upgrade installer to update MySQL Enterprise Service Manager and you have made any changes to the `my.cnf` within your MySQL Enterprise Service Manager installation, any changes will be lost. You should copy the existing `my.cnf` file before starting the upgrade installer.

Otherwise, updating is a fairly straightforward process. Run the installation file and choose the directory of your current installation and whether or not you wish to back up your current installation. The time required to complete the process varies depending upon the nature of the update.

If you chose to back up your current installation, a directory named `backup` will be created in the current installation directory. This directory will contain copies of the directory or directories that were replaced during the update. In cases where only specific files are replaced, the `backup` directory may contain only these files. If you are unhappy with the update simply overwrite the new files or directories with the originals found in the `backup` directory. Be sure to stop both the MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent before restoring the original files. You can delete or archive this directory when you are satisfied that the update was successful.

If you choose to back up your current installation, the installer checks that there is adequate disk space for your repository backup. If there is not enough space, you are given the option of choosing another location; you may also choose not to back up the repository.

To update your Advisors see, Section 15.3.2.7.4, “Upgrading and Updating Advisors”.

15.3.6.1.1. Upgrading from MySQL Enterprise Monitor 1.3 to 2.0

To upgrade your existing installation from MySQL Enterprise Monitor 1.3 to MySQL Enterprise Monitor 2.0, you need to upgrade both your MySQL Enterprise Service Manager and your MySQL Enterprise Monitor Agent on each machine that you are monitoring.

To perform the update process you must use an `update` installer. This ensures that your current configuration information is migrated to the new version of MySQL Enterprise Service Manager.

Before you start the migration, shutdown your MySQL Enterprise Service Manager and MySQL Enterprise Monitor Agent on each monitored host. Then install the updated MySQL Enterprise Service Manager application to migrate the configuration and data of the main application and repository. Once the new MySQL Enterprise Service Manager is running, you can start to update and migrate each agent.

For more information on upgrading your MySQL Enterprise Service Manager, see Section 15.3.6.1.1.1, “Upgrading to MySQL Enterprise Service Manager 2.0”. For more information on upgrading an MySQL Enterprise Monitor Agent, see Section 15.3.6.1.1.2,

"Upgrading to MySQL Enterprise Monitor Agent 2.0".

15.3.6.1.1.1. Upgrading to MySQL Enterprise Service Manager 2.0

Upgrading MySQL Enterprise Service Manager requires you to use on of the *update* installers. The update installer performs a number of operations during installation:

- A new database, required to support 2.0 functionality, is created.
- You core dashboard, user, and rule information is migrated from the old database to the new database.
- The core configuration parameters for the MySQL Enterprise Service Manager are migrated from MySQL Enterprise Monitor 1.3 are migrated to MySQL Enterprise Monitor 2.0.

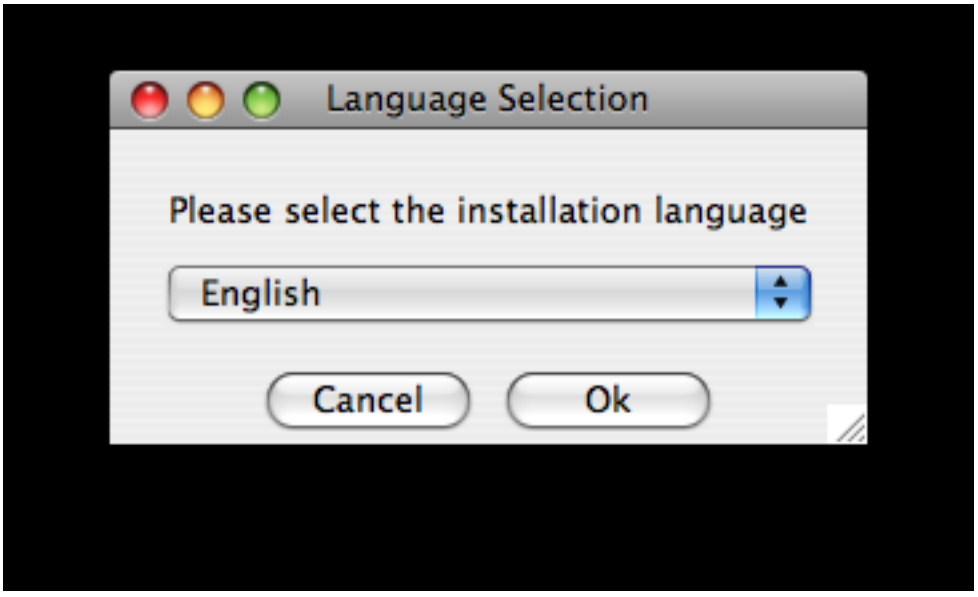
The installation of the new software using the update installer follows this basic sequence:

1. Request the installation language.
2. Confirm the location of the current MySQL Enterprise Service Manager installation.
3. Specify whether you want to keep a copy of the old server, application, and database files.
4. Configure the Tomcat server settings, including whether the new server should support SSL connections from agents.
5. If requested, the application and database information is backed up and upgraded, before the new application is installed.

The installation process is consistent for all platforms. A sample of the process for Max OS X has been provided below:

1. Double-click the update installer. The update installer will have `update` in the file name. For example, `mysqlmonitor-2.0.0.7101-osx-update-installer.app`.
2. Confirm the language you want to use when installing the software.

Figure 15.24. MySQL Enterprise Monitor: Server Update: Language Selection

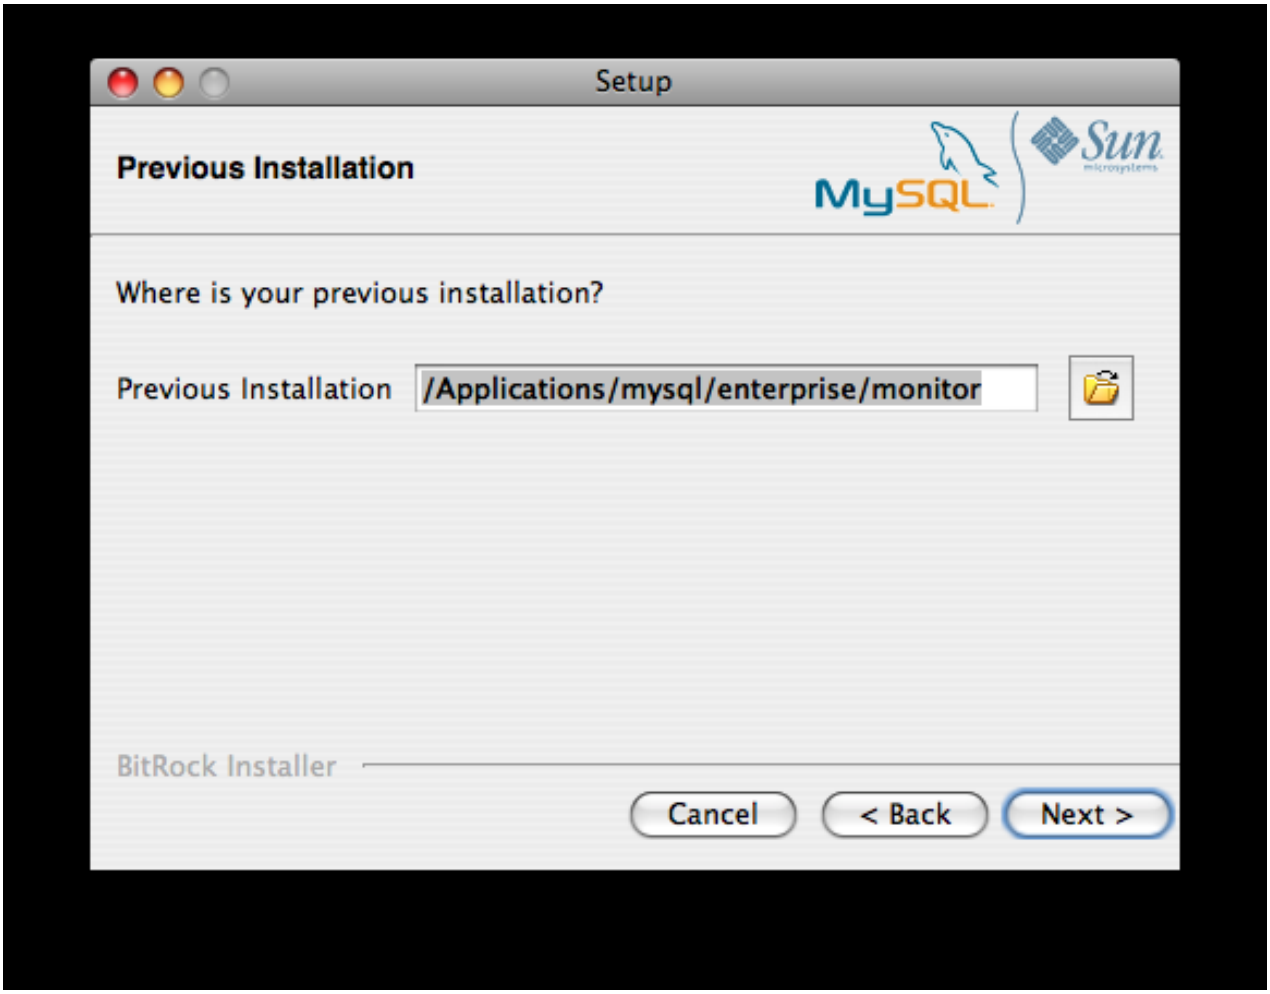


Click OK

3. You will be presented with an information screen showing the application you are installing. Click NEXT to continue.

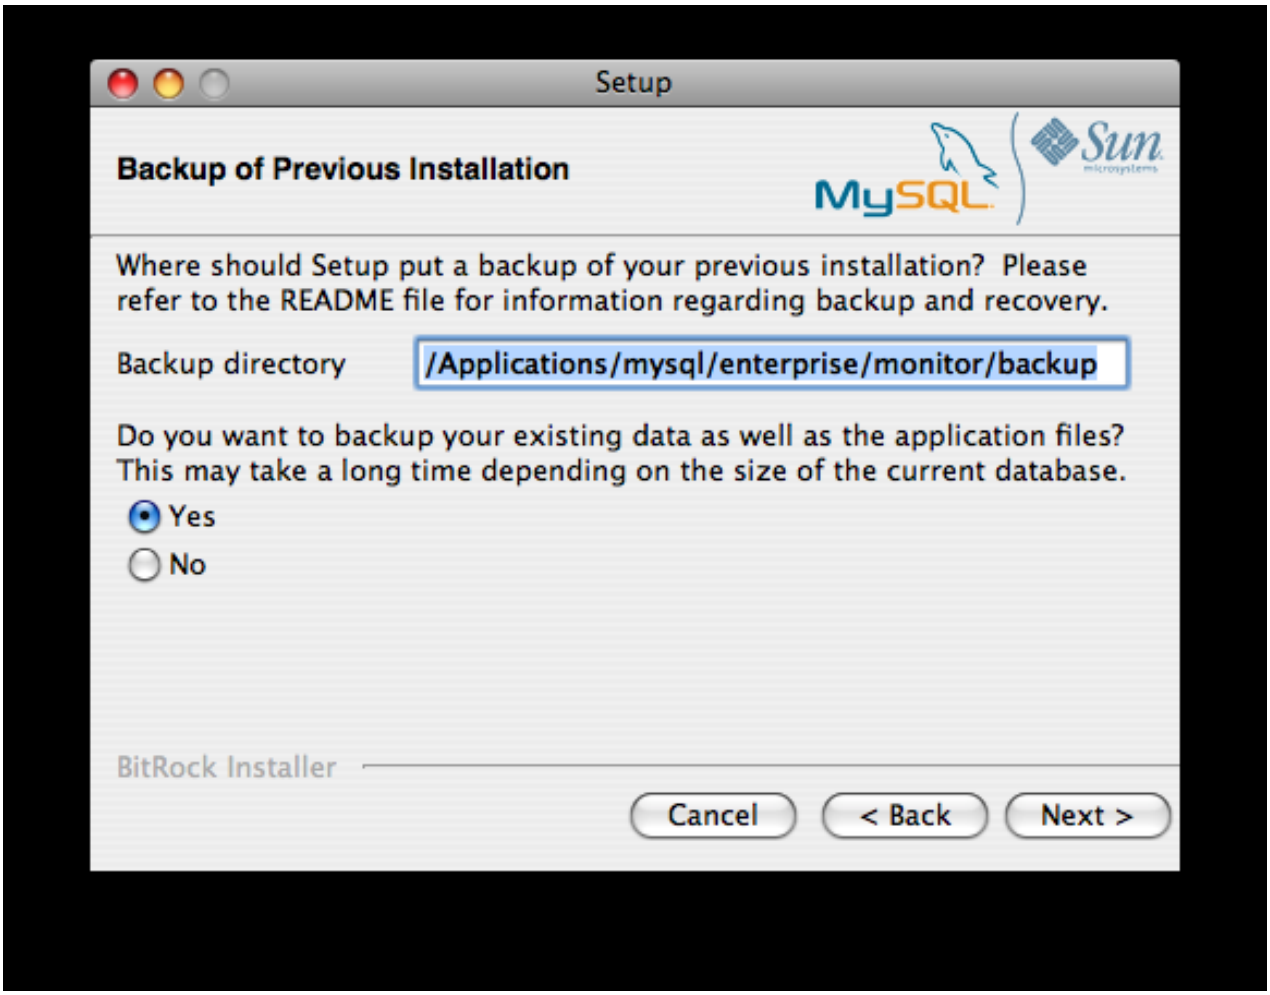
4. Specify, or locate, the previous installation of MySQL Enterprise Service Manager If you installed the server within the default location, the current version of the application should be located automatically.

Figure 15.25. MySQL Enterprise Monitor: Server Update: Previous Installation



5. The installer can keep a backup copy of your existing application, including keeping a complete backup of the data stored within your MySQL Enterprise Monitor repository database.

Figure 15.26. MySQL Enterprise Monitor: Server Update: Backup of Previous Installation



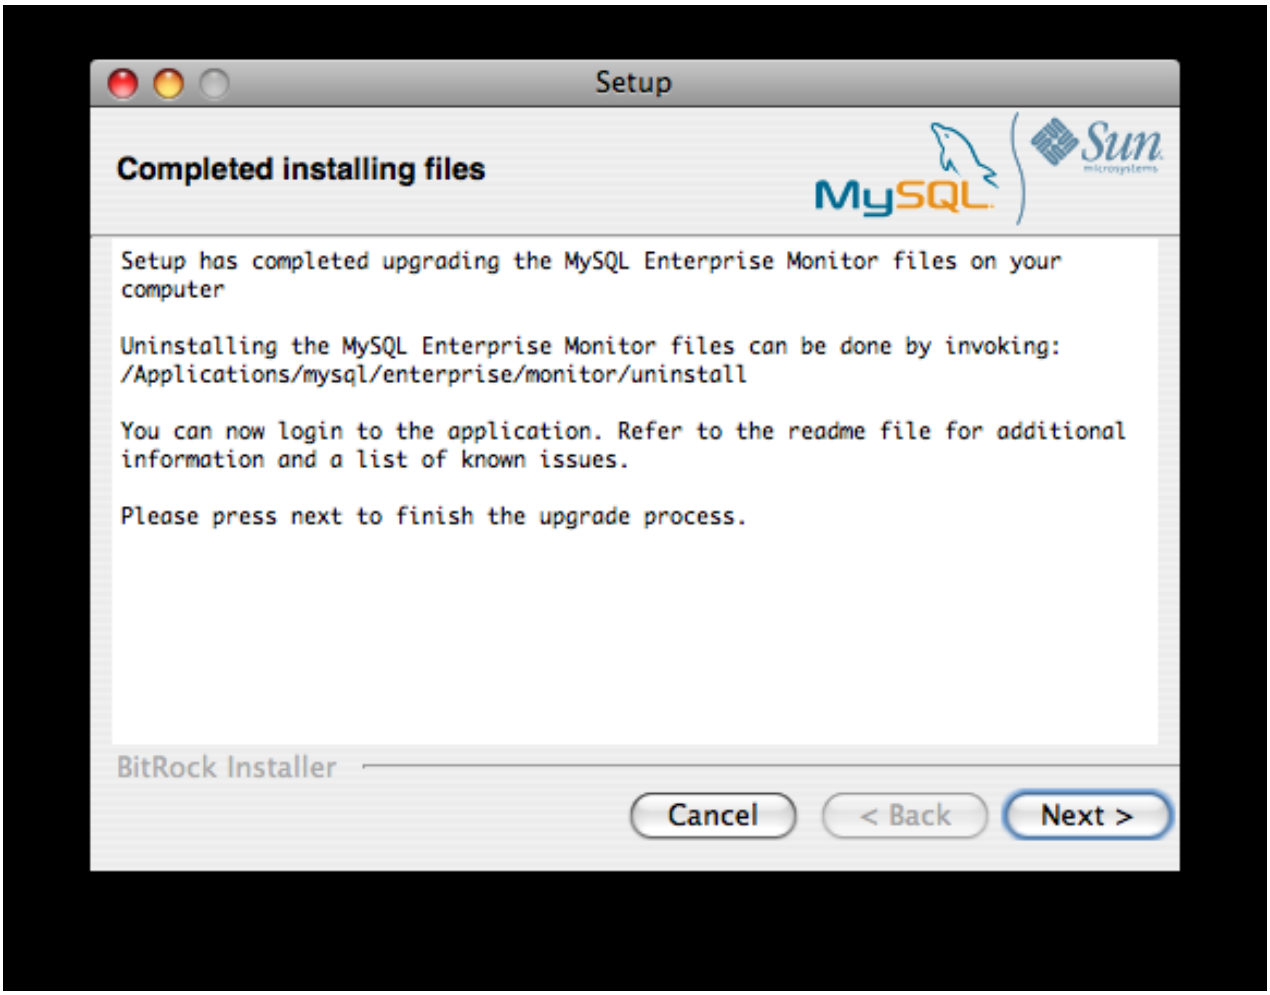
Specify the location of the backup (default is to use the `backup` directory within your installation directory). Note that backing up the database in addition to the main application will increase the installation time as the files have to be copied. The larger the size of your repository data, the longer the installation process will take.

6. Specify the Tomcat Server options. The Tomcat Server Port is the default port you will use to access the MySQL Enterprise Dashboard. If you want to support agents using SSL to communicate to MySQL Enterprise Service Manager, you must check the **Is SSL support required?**

7. Confirm that you want to continue the installation. Once installation has started, the backup of you existing application (and database) will start, although the process may take some time. Wait until the process completes.

8. Once the process has completed you will be provided with a notification of the installation process, including how to uninstall the application if you want to do so in the future. If any errors occurred, they will be reported here.

Figure 15.27. MySQL Enterprise Monitor: Server Update: Completed installing files

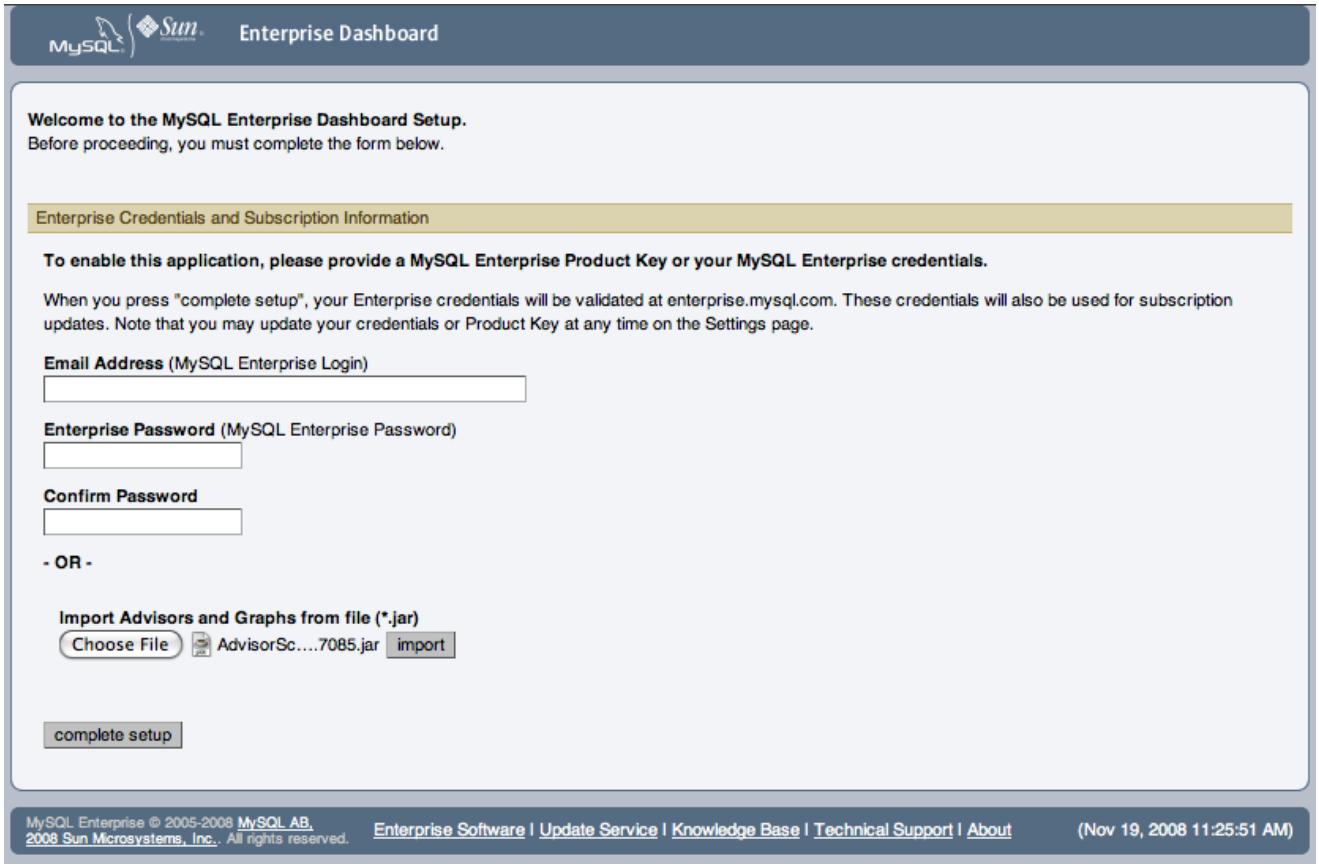


9. The installation has now completed. You can automatically start the MySQL Enterprise Service Manager and view the attached Readme file by ensuring the checkboxes on this page are selected.

10. You can now quit the installer.

Once the installation has completed, the first time you login to MySQL Enterprise Dashboard you will be asked to provide your login credentials, if they do not already exist in the server configuration, or to provide a copy of the Advisor jar suitable for your MySQL Enterprise Service Manager version.

Figure 15.28. MySQL Enterprise Monitor: Server Update: Final Setup



MySQL Enterprise Monitor has now been updated. You must update each of your agents to MySQL Enterprise Monitor Agent 2.0 to ensure that they are providing the correct information to MySQL Enterprise Service Manager

15.3.6.1.1.2. Upgrading to MySQL Enterprise Monitor Agent 2.0

To upgrade an agent you should use a `update` installer. This will migrate your configuration information, simplifying the upgrade process significantly.

> **Note**
>
> The agent log file, `mysql-monitor-agent.log`, if it exists, will be retained during the upgrade. A new log file, `mysql-monitor-agent.log` is used by MySQL Enterprise Monitor Agent 2.0.

The core sequence is the same on all platforms, the update process on Linux is shown below:

1. Start the update installer.

```
shell> ./mysqlmonitoragent-2.0.0.7101-linux-glibc2.3-x86-32bit-update-installer.bin
```

2. Set the language for the installation process.

```
Language Selection

Please select the installation language
[1] English
[2] Japanese
Please choose an option [1] :
```

3. Confirm or update the location of the installation directory of the previous version.

```
-------------------------------------------------------------------------------
```

```
Welcome to the setup wizard for the MySQL Enterprise Monitor Agent Update

-------------------------------------------------------------------------------
Please specify the directory that contains the previous installation of
the MySQL Enterprise Monitor Agent

Installation directory [/opt/mysql/enterprise/agent]:
```

4. Specify whether you want to create a backup of the current application and configuration information, and if so, where the backup directory should be created.

```
-------------------------------------------------------------------------------
Current installation backup

Do you want to create a backup during the update process?

Backup the current installation [Y/n]: Y

Backup directory [/opt/mysql/enterprise/agent/patchbackup]:
```

5. You will be asked whether you want to enable the Query Analyzer. The Query Analyzer enables you to monitor the execution stateistics for individual queries executed through your MySQL servers. To enable, you must specify the proxy port, MySQL server and MySQL server port that you want to use. If you do not enable Query Analyzer now, you can enable it later. See Section 15.10, “The Query Analyzer Page”.

```
-------------------------------------------------------------------------------
Query Analyzer Configuration

MySQL Proxy enables query monitoring and analysis by listening on the port
specified below for client connections that are then passed through to a
backend MySQL database server. It is not needed for basic monitoring
functionality, but is required for query monitoring and analysis.

Visit the following URL for more information:
https://enterprise.mysql.com/docs/monitor/2.0/en/mem-query-analyzer.html

Enable Proxy (recommended) [Y/n]:

Proxy Port []:

Backend Host: 127.0.0.1   (cannot be changed)

Backend Port: 3306   (cannot be changed)
```

6. You are now ready to complete the installation. Confirm that you want to continue.

```
-------------------------------------------------------------------------------
Setup is now ready to begin installing MySQL Enterprise Monitor Agent Update on your computer.

Do you want to continue? [Y/n]:

-------------------------------------------------------------------------------
Please wait while Setup installs MySQL Enterprise Monitor Agent Update on your computer.

 Installing
 0% _______________ 50% _______________ 100%
 ##############################################

-------------------------------------------------------------------------------
Setup has finished installing MySQL Enterprise Monitor Agent Update on your computer.

Restart MySQL Enterprise Monitor Agent now [Y/n]:

View Readme File [Y/n]: n
```

Before connecting your MySQL Enterprise Monitor Agent to your MySQL server you must update the grants for the MySQL Enterprise Monitor Agent. Connect to the MySQL server and run this statement to update the required grants:

```
GRANT CREATE, INSERT
  ON mysql.*
  TO  'mysqluser'@'localhost'
  IDENTIFIED BY 'agent_password';
```

Replacing the `mysqluser` and `agent_password` parameters with the values used for connecting your agent to your MySQL server.

Once the update agent has communicated with the MySQL Enterprise Service Manager the core information about the agent and the MySQL server it is monitoring will be migrated to the new data format required by MySQL Enterprise Service Manager 2.0. To migrate the existing stored data, see Section 15.12.9, “Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0”.

15.3.6.1.2. Upgrading to MySQL Enterprise Monitor 2.1

When upgrading to MySQL Enterprise Monitor 2.1 you should be aware of the following issues:

- During the upgrade process, if you had previously set a Query Analyzer data purge value that was greater than the standard data purge value, the historical data collection purge period will be set to the Query Analyzer purge period. This will be logged in the upgrade log with the following notice:

  ```
  getDataCollectionPurgeLifespan now: 4 weeks (was: 2 weeks)
  ```

15.3.6.1.3. Unattended MySQL Enterprise Monitor Update

The options available when performing an unattended MySQL Enterprise Service Manager update are as follows:

```
--help                          Display the list of valid options

--version                       Display product information

--optionfile <optionfile>       Installation option file
                                Default:

--mode <mode>                   Installation mode
                                (Windows)Default: win32
                                (Unix)Default: gtk
                                (Mac OS X)Default: osx
                                (Windows)Allowed: win32 unattended
                                (Unix)Allowed: gtk text xwindow unattended
                                (Mac OS X)Allowed: osx text unattended

--debugtrace <debugtrace>       Debug filename
                                Default:

--installer-language <installer-language> Language selection
                                 Default:
                                 Allowed: en  jp

--installdir <installdir>       Previous Installation
                                Default:

--createDataBackup <createDataBackup>

                                Default: 1

--backupDir <backupDir>         Backup directory
                                Default:
```

The options for an unattended update of the agent differ only in that the `createDataBackup` option is replaced by `createBackup`.

If you did not install the MySQL Enterprise Service Manager to the default directory the `installdir` option must be specified. `mode` must also be specified when performing an unattended update. Otherwise, performing an unattended update is identical to the process described in Section 15.3.4, “Unattended Installation”.

15.3.6.2. Reinstalling MySQL Enterprise Monitor

In some cases you may want to reinstall MySQL Enterprise Monitor rather than updating your current installation. To reinstall rather than update MySQL Enterprise Monitor follow these steps:

1. Stop all the Monitor Agents
2. Run the `uninstall` programs for both the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent
3. Begin the new installation

To stop the Monitor Agents see:

- Windows: Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”
- Unix: Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”
- Mac OS X: Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”

Instructions for removing the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent are given in Section 15.3.7, “Uninstalling the MySQL Enterprise Monitor”.

15.3.6.3. Changing Your MySQL Enterprise Monitor Installation

This section describes the best practices to employ when changing your MySQL Enterprise Monitor installation.

15.3.6.3.1. Upgrading the Monitored MySQL Server

When upgrading a monitored MySQL server first stop the agent. To stop the agent see:

- Windows: Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”
- Unix: Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”
- Mac OS X: Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”

Stop the MySQL server and perform the upgrade. For instructions on stopping and restarting the MySQL service under Windows see Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”.

To stop and restart the MySQL daemon under Unix and Mac OS X, see, Section 15.3.2.6, “Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X”.

Once the service/daemon is stopped you may upgrade your server. For instructions on upgrading your MySQL server see the reference manual pertaining to your server version. When the upgrade is complete restart the MySQL server.

> **Note**
>
> The agent's log file will show that the server was down.

15.3.6.3.2. Changing the Server That an Agent Monitors

You need not reinstall the MySQL Enterprise Monitor Agent in order to change the MySQL server that it monitors. It is possible to adapt an existing agent so that it monitors a different server.

To do this you must stop the monitor agent and then remove the server that it is monitoring. To stop the agent see:

- Windows: Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”
- Unix: Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”
- Mac OS X: Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”

For instructions on removing a server see, Section 15.5.3.3, “Removing a Server From the Dashboard”.

Once the agent is stopped and the server is removed from the Dashboard, changes may be made to the `mysql-monitor-agent.ini`, or the `agent-instance.ini` file within the agent `instances` instances directory. You can find the location of the directory by examining the content of the `mysql-monitor-agent.ini` and checking the value of the `mysqld-instance-dir` parameter.

If you want to make changes to the monitored MySQL server, edit the `agent-instance.ini` file. Change the `user`, `password`, `hostname`, and `port` values if required. For more information, see Section 15.3.3.6.2, "MySQL Server (`agent-instance.ini`) Configuration".

To change other settings, such as enabling proxy support (required for Query Analyzer), the management host, or the port number used by the agent, modify the `mysql-monitor-agent.ini` file. For more information, see Section 15.3.3.6.1, "MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration".

To restart the agent see:

- Windows: Section 15.3.3.5.1, "Starting/Stopping the Agent on Windows"
- Unix: Section 15.3.3.5.3, "Starting/Stopping the Agent on Unix"
- Mac OS X: Section 15.3.3.5.2, "Starting/Stopping the Agent on Mac OS X"

> **Note**
>
> If you are adapting an existing agent to monitor a remote server make sure that the agent has the credentials for remote access and that the port on the remote MySQL server instance is open. For more information, see Section 15.3.3.6.4, "Configuring an Agent to Monitor a Remote MySQL Server".
>
> If you experience difficulties starting the agent, check Section 15.3.3.7, "Troubleshooting the Agent".

Log in to the Dashboard and you should find your new server in the `All Servers` group.

15.3.6.3.3. Temporarily Suspending the Agent

In some situations you may need to bring down a monitored server. When this is necessary, it is good practice to stop the agent first—doing so will avoid generating a "Server is unreachable" event.

For instance, suppose you need to stop the server in order to do a backup. The steps to follow are:

1. Stop the agent
2. Stop the service/daemon
3. Perform the backup
4. Restart the service/daemon
5. Restart the agent

To stop or start the agent see:

- Windows: see Section 15.3.3.5.1, "Starting/Stopping the Agent on Windows"
- Unix: see Section 15.3.3.5.3, "Starting/Stopping the Agent on Unix"
- Mac OS X: see Section 15.3.3.5.2, "Starting/Stopping the Agent on Mac OS X"

To stop the MySQL service/daemon see the MySQL reference manual for your server version. You can find the manual online at http://dev.mysql.com/doc.

Follow these steps and there will be no "noise" associated with backing up your server. In contrast, if you leave the agent running while

bringing down the server, you will generate a “Server is unreachable” event.

As an alternative to stopping the agent, you can change the logic associated with a rule. For instance, you could alter the threshold of the rule “Server is unreachable”:

```
%server.reachable% == THRESHOLD
```

to:

```
%server.reachable% == THRESHOLD  && CURTIME() NOT BETWEEN '22:00:00' AND '23:00:00'
```

This would effectively blackout the rule between 10 and 11 pm, during which time you could perform a backup.

For more information about editing rules see Section 15.7.3, “Editing Built-in Rules”. To blackout all events associated with a specific server or group of servers see Section 15.7.7, “Advisor Blackout Periods”.

15.3.7. Uninstalling the MySQL Enterprise Monitor

Removal of the MySQL Enterprise Monitor requires removal of the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent Service. In some circumstances, when running multiple agents on one machine for instance, you may not want to remove the entire MySQL Enterprise Monitor Agent Service but only a single monitored server.

15.3.7.1. Removing the MySQL Enterprise Monitor: Windows

Removing the MySQL Enterprise Service Manager

Remove the MySQL Enterprise Service Manager by going to the `Control Panel` and choosing `Add or Remove Programs`. Find the entry for `MySQL Enterprise Monitoring and Advisory Service` and remove it. During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to reinstall the MySQL Enterprise Monitor.

If you are not saving existing data, after MySQL Enterprise Service Manager has been removed you may delete the `C:\Program Files\MySQL\Enterprise\Monitor` directory.

> **Warning**
>
> If you chose not to remove existing data and log files when uninstalling MySQL Enterprise Service Manager do **not** remove the `C:\Program Files\MySQL\Enterprise\Monitor` directory. Doing so will delete these files.

If you added the Tomcat/Apache web server to the list of Windows firewall exceptions, remove this service by opening the `Windows Firewall` from the `Control Panel`. Choose the `Exceptions` tab and delete the `Tomcat/Apache` entry.

Removing MySQL Enterprise Monitor Services Only

When the MySQL Enterprise Service Manager is installed, the Tomcat/Apache and MySQL server services are started. It is possible to remove these services without also removing your MySQL Enterprise Service Manager installation. For more information about these services see, Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”.

Do this by finding the `MySQL Enterprise Monitor` menu option and choosing `Services` and then `Uninstall MySQL Enterprise Monitor Services`. This will remove all the services associated with MySQL Enterprise Service Manager.

You can confirm that these services have been removed by checking services in the Microsoft Management Console Services window.

If you wish to reinstall these services you can do this by using the `Install MySQL Enterprise Monitor Services` menu option.

It is also possible to remove services using the `mysqlmonitorctl.bat` file found in the `C:\Program Files\MySQL\Enterprise\Monitor` directory. To see the available options, go to the command line and type: **`myqlnet-workctrl help`**. This batch file is discussed in more detail in Section 15.3.2.5, “Starting/Stopping the MySQL Enterprise Monitor Service on Windows”.

Removing the Monitor Agent

To remove the Monitor Agent itself, open the `Control Panel` and choose `Add or Remove Programs`. Find the entry for

`MySQL Enterprise Monitor Agent` and remove it. This will execute the uninstall program located in the `C:\Program Files\MySQL\MySQL\Enterprise\Agent` directory.

> **Warning**
>
> If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** remove the `MySQL Enterprise Monitor Agent` entry from the `Add or Remove Programs` menu. To remove a single agent see Removing a Single Agent [1416]

After removing the Monitor Agent you may also need to remove the directories, `C:\Program Files\MySQL\Enterprise` and `C:\Program Files\MySQL\Enterprise\Agent`.

Removing the Monitor Agent in this fashion will remove the default service. However, if you are running additional Monitor Agents as described in Section 15.3.3.6.2, “MySQL Server (`agent-instance.ini`) Configuration”, you will have to remove those agents manually. See the next section for instructions on doing this.

Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** remove the `MySQL Enterprise Monitor Agent` entry from the `Add or Remove Programs` menu. To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a service
4. Remove/Archive the associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see, Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”.

You can confirm the location of the agent log files by checking the `ini` file. For more information on this topic see Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration”.

Go to the command line and remove the MySQL Enterprise Monitor Agent as a Windows service by typing:

```
shell> sc delete AgentName
```

You can confirm that the agent has been removed by checking the Microsoft Management Console Services window. There should no longer be an entry for the removed agent.

You should also remove or archive any log or configuration files associated with this agent. If you have installed any additional agents, remove them in the same fashion.

15.3.7.2. Removing the MySQL Enterprise Monitor: Unix

Removing the MySQL Enterprise Service Manager

To remove the MySQL Enterprise Service Manager, find the `uninstall` file in the `/opt/mysql/enterprise/monitor` directory.

Execute this file by typing:

```
shell> ./uninstall
```

During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to reinstall the MySQL Enterprise Monitor.

If you are not saving existing data, after uninstalling the MySQL Enterprise Service Manager you may remove the `/opt/mysql/enterprise/monitor` directory.

> **Warning**

If you chose not to remove existing data and log files when uninstalling the MySQL Enterprise Monitor do **not** remove the `/opt/mysql/enterprise/monitor` directory; doing so will delete these files.

On Red Hat Enterprise Linux 4 and Fedora Core 4, the uninstall script may not stop the Tomcat server. Do this manually if necessary. To do this see, Section 15.3.2.6, "Starting/Stopping the MySQL Enterprise Monitor Service on Unix and Mac OS X".

There may be other Java processes running on your system. Be careful not to accidentally stop them.

On some Unix platforms, inluding HP-UX, you may have to manually delete the `uninstall` application and the installation directory after you have execute the uninstall process.

Removing the Monitor Agent

Prior to removal of the Monitor Agent Service you should stop any agents. Do this by changing to the `init.d` directory and issuing the command, `./mysql-monitor-agent stop`.

You will find the `uninstall` file in the `/opt/mysql/enterprise/agent` directory. Execute this file by navigating to this directory and typing:

```
shell> ./uninstall
```

After uninstalling the Monitor Agent you may remove the `/opt/mysql/enterprise/agent` directory.

Removing the Monitor Agent in this fashion will remove the default service, and all the configuration files for different instances.

Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do **not** run the uninstall program. To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a service
4. Remove/Archive associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see Section 15.3.3.5.3, "Starting/Stopping the Agent on Unix".

You can confirm the location of the agent log files by checking the `ini` file. For more information on this topic see Section 15.3.3.6.1, "MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration".

You may then remove the agent as a daemon by removing its entry in the `init.d` directory. You should also remove or archive any log or configuration files associated with this agent.

If you have installed any additional agents, remove them in the same fashion.

15.3.7.3. Removing the MySQL Enterprise Monitor Mac OS X

Removing the MySQL Enterprise Service Manager

To remove the MySQL Enterprise Service Manager, run the `uninstall.app` located in the `/Applications/mysql/enterprise/monitor/` directory, or the root directory of your MySQL Enterprise Service Manager installation.

During the uninstall process you will be given the option of saving existing data and log files. Choose this option if you plan to reinstall the MySQL Enterprise Monitor.

If you are not saving existing data, after uninstalling the MySQL Enterprise Service Manager you may remove the `/Applications/mysql/enterprise/monitor` directory.

Warning

If you chose not to remove existing data and log files when uninstalling the MySQL Enterprise Monitor do not remove the /Applications/mysql/enterprise/monitor directory; doing so will delete these files.

Removing the Monitor Agent

Prior to removal of the MySQL Enterprise Monitor Agent you should stop any agents. Do this by changing to the `init.d` directory and issuing the command:

```
shell> ./mysql-monitor-agent stop
```

Run the `uninstall.app` file located in the `/Applications/mysql/enterprise/agent` directory.

After uninstalling the MySQL Enterprise Monitor Agent you may remove the `/Applications/mysql/enterprise/agent` directory.

Removing the MySQL Enterprise Monitor Agent in this fashion will remove the default service, and all the configuration files for different instances.

Removing a Single Agent

If you are running more than one agent on the same machine and wish to remove only one of the agents, do not run the uninstall program.

To remove a single agent and leave other agents intact follow these steps:

1. Stop the agent
2. Confirm the location of the log files
3. Remove the agent as a daemon
4. Remove/Archive associated files

It is best to stop the agent before removing it; for instructions on stopping an agent see Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”.

You can confirm the location of the agent log files by checking the ini file. For more information on this topic see Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration”.

You may then remove the agent as a daemon by removing its entry in the `init.d` directory.

You should also remove or archive any log or configuration files associated with this agent.

If you have installed any additional agents, remove them in the same fashion.

15.4. MySQL Enterprise Dashboard

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

The purpose of the MySQL Enterprise Dashboard is to provide you with information about your MySQL servers. It provides a list of the latest MySQL Enterprise Advisor reports, server status information, MySQL Enterprise alerts, and updated views of monitored MySQL servers. The `Monitor` screen gives a quick overview of the status of your MySQL servers.

The MySQL Enterprise Dashboard interface is provided through a standard web browser. For more details on the supported browsers, see Section 15.12.2, “Supported Browsers”.

You can open the Dashboard and connect to the MySQL Enterprise Dashboard either using the standard HTTP protocol, or using an SSL connection (HTTPS). By default, you can connect to MySQL Enterprise Dashboard using `http://host:18080`, where `host` is the hostname or IP address of the MySQL Enterprise Service Manager. The default SSL URL is `http://host:18443`. These values can be overridden during installation. You can check the configured values by looking at the `configuration_report.txt`

file within your installation directory.

> **Note**
>
> If you are connecting using SSL, the built-in certificate has been self-signed and may be highlighted as 'unsafe' within the browser on initial connection. You should add an exception for the certificate on this server to prevent problems accessing the site.

The Monitoring page provides an instant health check for all of the MySQL servers across the enterprise.

From this page users can:

- View monitoring data and all critical MySQL Advisor Rule violations for all or selected servers.
- Close and annotate MySQL Advisor Rule violations.
- Quickly determine if there is a Monitor Agent that is not communicating with the Service Manager.
- Quickly determine if there is a server that is in trouble or completely down.
- View indicator value graphs for key MySQL and operating system (OS) level metrics. Graph presentation will default to a thumbnail view but will open into a larger image upon being clicked.

The monitored server or servers are displayed in a tab on the left known as the `Server Tree`. You can navigate to a number pages that provide more detailed information. These pages include:

- `Monitor`: The overview page providing you with a quick summary of the servers, their status, events, availability and load. The remainder of this chapter details the contents of this page.
- `Advisors`: Shows the various advisors configured in your installation and allows you to schedule their execution on different servers, apply and manage rules and manage the advisor installation itself. For more information, see Section 15.7, “The Advisors Page”.
- **EVENTS**: Provides an interface into the event system that highlights specific issues and problems on your monitored servers. For more information on using Events, see Section 15.8, “The Events Page”.
- `Query Analyzer`: Interfaces to the query monitoring system that can be used to monitor and track the individual queries that are being executed on a system and help to highlight problem queries that may need optimization or that may be affecting server load. For more information, see Section 15.10, “The Query Analyzer Page”.
- `Graphs`: Enables you to view and configure a number of individual graphcs covering a range of different statistics. For more details on how to view and use these graphs, see Section 15.9, “The Graphs Page”.
- `Replication`: Provides information on the status and structure of your servers that are using replication. This page is only available if you have a suitable subscription level. For more information, see Section 15.11, “The Replication Page”.
- `Settings`: Controls the settings for the server, including email configuration, passwords, and server and user management. For more information, see Section 15.5, “The Settings Page”.

Graphs are shown in the center of the page beneath the tabs. If applicable, you'll also find a list of critical events.

On the right is the color-coded `Heat Chart`, showing the advisors that are installed by default. The `Heat Chart` shows the most important advisors, allowing a quick overview of the state of your servers. You may open the `Heat Chart` in its own window by clicking the `Standalone Heat Chart` link. If applicable, you'll also find a list of critical events.

The `Show/Hide Legend` link toggles display of the key to the icons used in the `Heat Chart`.

> **Note**
>
> Find colorblind-accessible icons in the `alternate` directory. On Linux this directory is immediately below the `/monitor/apache-tomcat/webapps/ROOT/web/resources/images/` directory. These images are stored in the same directory on Windows. To use them, backup the originals and then copy and paste the alternate set into the `images` directory.

If a specific server is selected in the Server Tree details about this server are shown beneath the legend in the Meta Info area. The information shown in this area is the host name, the MySQL version number, the number of scheduled rules, the operating system, and the CPU.

The Meta Info section also shows how long the agent has been running, when it last contacted the MySQL server it is monitoring, and the last time the agent contacted the dashboard. Mouse over the date shown beside **UP SINCE** and a pop-up box displays the time that has elapsed since the server instance was last started. You can also mouse over the **LAST MYSQL CONTACT** and the **LAST AGENT CONTACT** dates.

> **Note**
>
> In the case of remote monitoring, the agent runs on a different machine than the MySQL server that it is monitoring. The Hostname, MySQL, and Rules information applies to the system being monitored. The OS and CPU information applies to the machine on which the agent is running. For more information about remote monitoring see, Section 15.3.3.6.4, "Configuring an Agent to Monitor a Remote MySQL Server".

The top of the screen shows the refresh cycle and Help and Log Out links. Click the Help link to open the documentation in a separate browser window. Choose Log Out if you wish to leave the Dashboard or to log in as a different user. Different refresh rates are available from the drop-down listbox.

In the footer are external links to MySQL Enterprise and information about the current user. Users can remain connected to the Dashboard and update their subscription, use the Enterprise Knowledge Base, and contact technical support. Your subscription information is also displayed here, showing the number of days remaining and the number of licenses. The number of licenses indicates to the number of machines that may be monitored; any number of MySQL servers may be running on a specific machine.

The footer also contains a link to the Settings page. If your subscription is current it reads **SUBSCRIPTION IS UP-TO-DATE. MORE INFO.....** For more information about the Settings page see Section 15.5.7, "The Product Information Screen".

15.4.1. The Server Tree

The tab on the left displays the Server tree. By default the first group of servers is selected. This selection determines the information shown on the Monitor page.

If a server group is selected, the information presented on the Monitor page is aggregate information for this group; if only one server is selected the information applies to that server only.

Change your server selection and the information shown in the graphs and in the Heat Chart changes.

> **Note**
>
> For more information about server groups see, Section 15.5.3.2, "Grouping Servers".

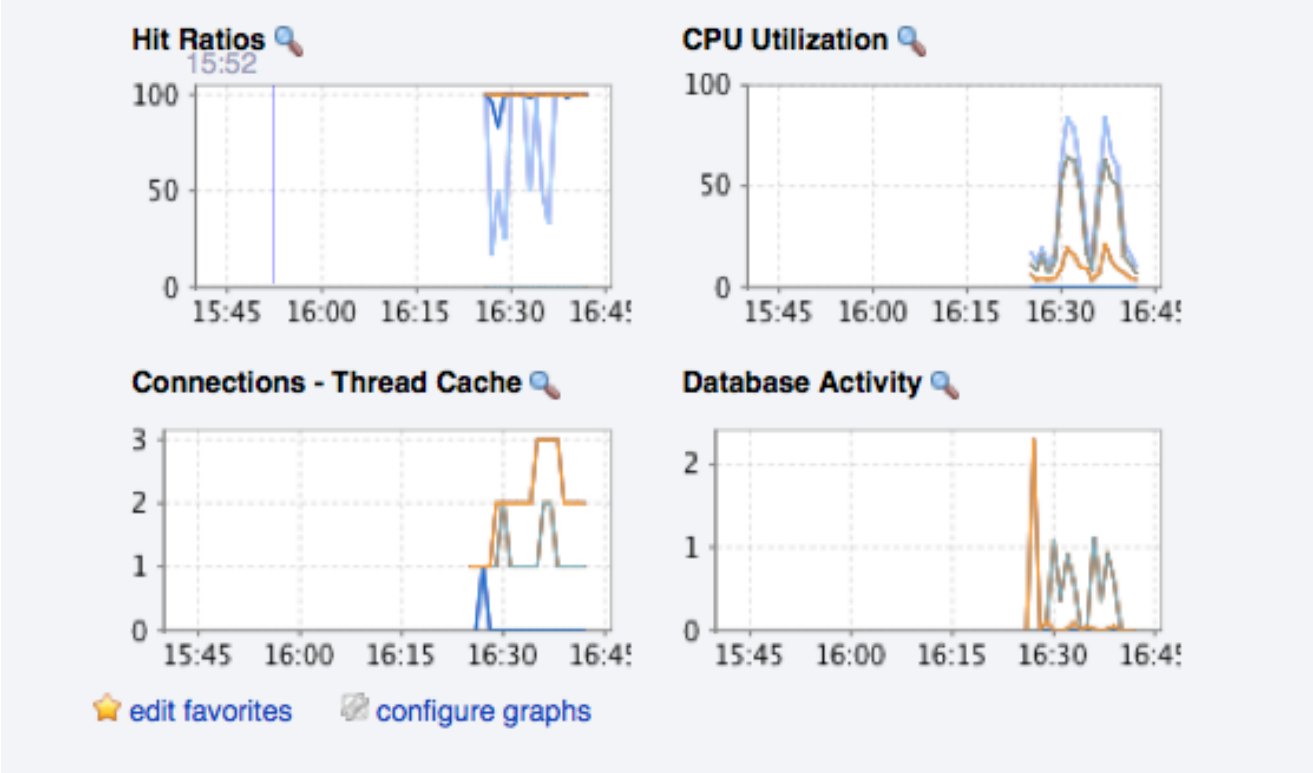
The individual server, or server group, selected in the Server Tree also determines what information appears when the Advisors tab or the **EVENTS** tab is selected.

The Server Tree presents an easy way to navigate to different groups or to specific servers.

15.4.2. The Server Graphs and Critical Events

The center of the Monitor page gives a visual representation of the state of your servers.

Figure 15.29. MySQL Enterprise Dashboard: The Graphs Screen



The graphs present information about the currently selected server or server group. The default graphs show the hit ratios, CPU utilization, connections, and database activity for a specific interval.

Graphs also provide an entry point for examining the operations on a server in relation to the queries that were being on the server at the time. The plots of the graph are correlated with the queries that are being executed at that time, enabling you to monitor your server usage more effectively. By clicking and dragging on a graph you can zoom in on the graph content and then view the queries that were being executed during the specified period in order to gain a better insight into the operation of your servers. This information is only available if you have configured query analysis, and have enabled query analysis for the servers you are monitoring. For more information, see Section 15.10, “The Query Analyzer Page”.

To set the interval click the `configure graphs` link immediately below the graphs. This opens a dialog box where you can choose the default interval for the x-axis of the graphs. Defining a shorter or longer interval gives you a shorter or longer term view of server activity. The thumbnail and full-size graph dimensions can also be adjusted from this dialog box. Save any changes that you have made and the values chosen will be the defaults whenever you log in.

You can also choose the default graphs shown on the `Monitor` page. To do this click the `edit favorites` link and choose the graphs you want from the drop-down list box. To choose contiguous graphs, hold down the **Shift** key and click the desired graphs. For a noncontiguous selection, click the desired graphs while holding down the **Ctrl** key. The maximum number of graphs that can be displayed on the `Monitor` page is six. Save your changes and these will be the default graphs whenever you log in.

Color coding helps distinguish different aspects of each graph. With `Database Activity` for example, you can readily distinguish `SELECT` statements from database insertions.

Clicking a graph opens a detailed view with **Graph Display** and **Configure** tabs. Choose the `Configure` tab to temporarily change the way that a graph displays. Changes made from this tab only apply to the standalone graph while it is open. Persistent changes are made as described above.

Dismiss the enlarged graph by clicking the HIDE button.

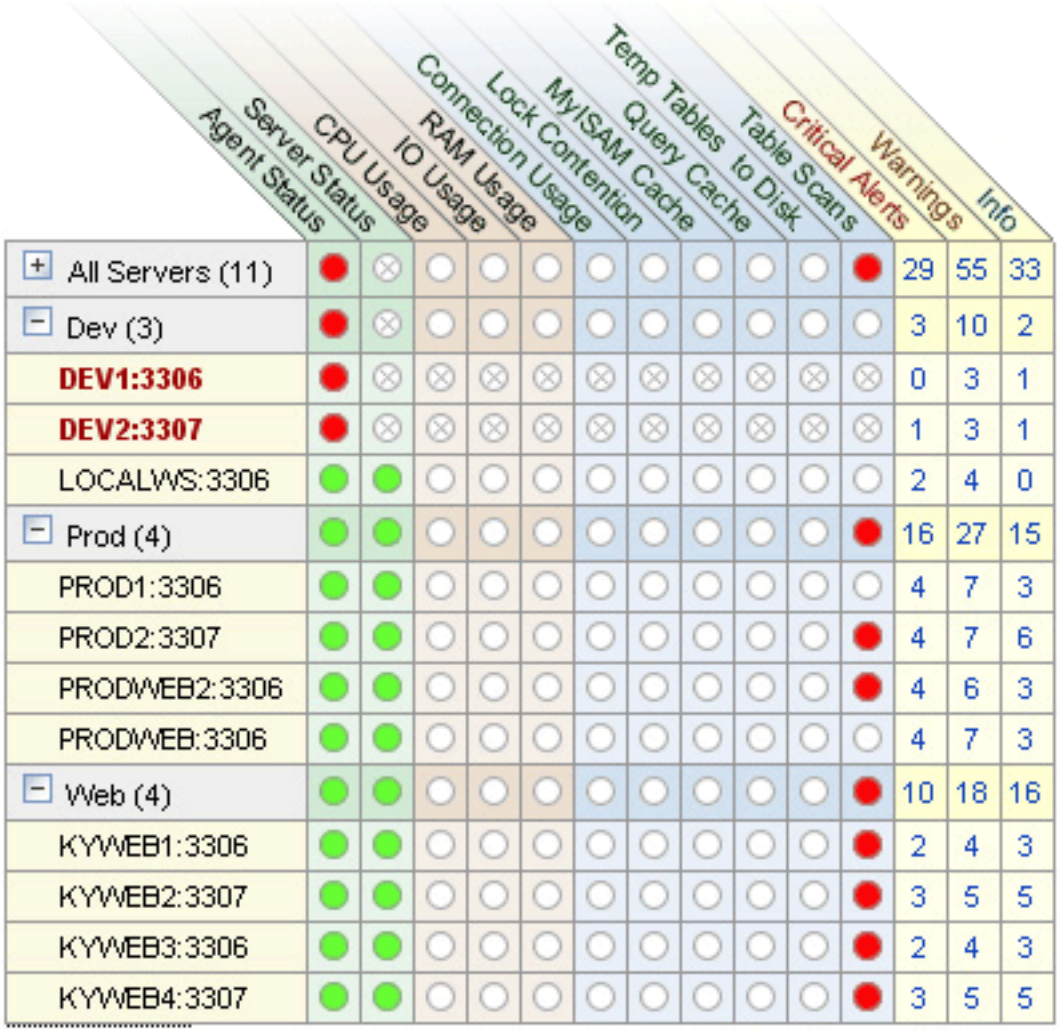
Alerts from the event system will be displayed immediately below the charts. For more information on the events display, see Section 15.8, “The Events Page”.

15.4.3. The Heat Chart

The `Heat Chart` is found on the right side of the `Monitor` page and shows the status of critical rules. Monitored servers are organized by groups. To view the status of a specific server, click the + button next to the appropriate server group.

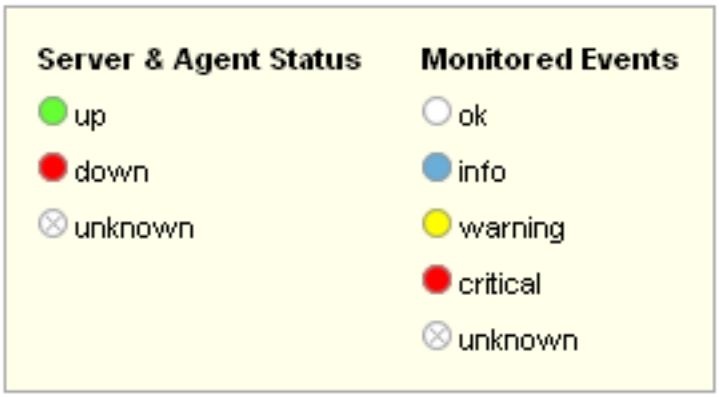
Whenever a new agent contacts the Service Manager for the first time, all the rules in the Heat Chart Advisor are automatically activated. These Advisors monitor the status of the server and agent, critical operating system indicators, and important events related to your MySQL servers. An example follows.

Figure 15.30. MySQL Enterprise Dashboard: The Heat Chart



To interpret the Heat Chart see the following legend.

Figure 15.31. MySQL Enterprise Dashboard: The Heat Chart Legend



The status `unknown` will typically apply when an agent is down and can no longer report the status of the server that it is monitoring. The status `unknown` may also apply if the data collection that should be collected is not available on the server being monitored.

You may open the Heat Chart in its own browser window by clicking the `Standalone Heat Chart` link immediately below the `Heat Chart` on the left. If you like, the refresh rate can be set to a different rate than the setting on the `Monitor` page.

In addition to showing the most important advisors, the `Heat Chart` also has columns that display the number of critical, warning, and informational alarms. Clicking the hyperlink in any one of these columns takes you to the `Event` screen, which gives more detailed information. For more information about events see, Section 15.8, "The Events Page".

When the Dashboard is first installed no notification groups are associated with the Advisors shown in the Heat Chart. For more information on this topic see, Section 15.3.2.7.3, "Installing Advisors After Initial Log-in" and, Section 15.5.5, "Manage Notification Groups".

15.5. The Settings Page

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

Upon initial installation you may have configured your MySQL Enterprise credentials and also outgoing email settings. This section explores the configuration settings in more detail, and also shows how to manage servers, users, notification groups, Simple Network Management Protocol (SNMP) traps, log files, and the product information screen.

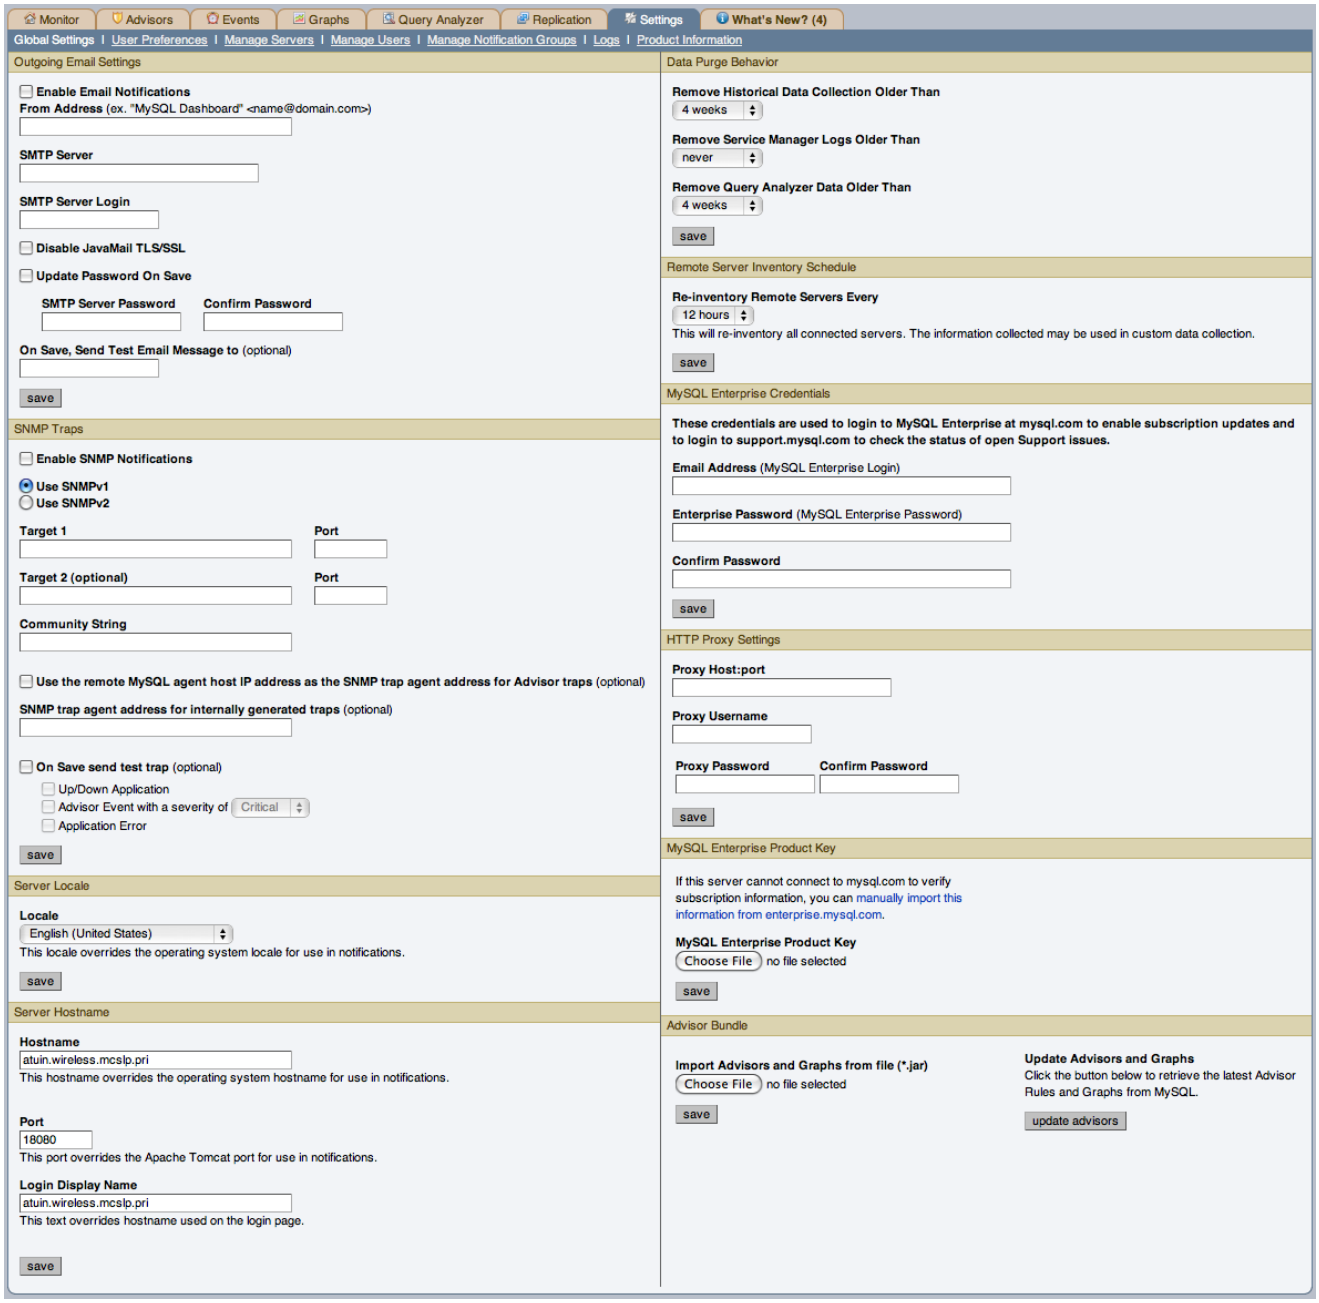
Knowledge of server management is a prerequisite for properly configuring advisors—the subject of Section 15.7, "The Advisors Page".

To get to the `Settings` page open the Dashboard and choose the `Settings` tab.

15.5.1. Global Settings

The **GLOBAL SETTINGS** control the main confirguration parameters for the entire MySQL Enterprise Monitor system, including your email notifications, data purge, and Enterprise website credentials.

Figure 15.32. MySQL Enterprise Dashboard: Settings



The **GLOBAL SETTINGS** page is divided into a number of different sections:

- **OUTGOING EMAIL SETTINGS**

  Configures the settings for email notifications by MySQL Enterprise Service Manager. You must configure the **FROM ADDRESS** **SMTP SERVER** settings. If your server requires authorization, complete the necessary server login details, and whether SSL is required.

  You can test your configuration immediately by adding an email address to the **ON SAVE, SEND TEST EMAIL MESSAGE TO** box.

  For more information about `Outgoing Email Settings` see, Section 15.3.2.7.5, “Outgoing Email Settings”.

- **SNMP TRAPS**

The **SNMP TRAPS** section of the **GLOBAL SETTINGS** tab allows you to enable Simple Network Management Protocol so that your Network Management System (NMS) can handle events created by the MySQL Enterprise Monitor. SNMP notifications are off by default. You can enable them by clicking the **ENABLE SNMP NOTIFICATIONS** checkbox.

MySQL Enterprise Service Manager includes support for both SNMPv1 and SNMPv2. You can select the SNMP version to use by clicking the corresponding **USE SNMPV1** or **USE SNMPV2** radio button.

In the **TARGET 1** or **TARGET 2** text box enter the IP address or hostnames of your NMS listeners. The port number defaults to the well-known SNMP port, `162`. If you are not using this port, enter the port that your Network Management System is listening on.

Enter the appropriate community string in the `Community String` text box. The default value for this string is `public`.

For the trap address for Advisor traps, you can optionally elect to use the address of the agent that triggered the alert, rather than the address of the MySQL Enterprise Service Manager. To do this, click the **USE THE REMOTE MYSQL AGENT HOST IP ADDRESS AS THE SNMP TRAP AGENT ADDRESS FOR ADVISOR TRAPS**. For internally generated SNMP traps (i.e. with MySQL Enterprise Service Manager) you can also specify an alternate address by putting the IP address in the **SNMP TRAP AGENT ADDRESS FOR INTERNALLY GENERATED TRAPS** box.

To ensure that the target you have specified is valid, check the `On Save, Send Test Trap` check box. The remaining check boxes help you to configure how your NMS responds to MySQL Enterprise Monitor. Check the **UP/DOWN APPLICATION** check box to configure NMS for starting up or shutting down the MySQL Enterprise Monitor. For configuration of advisor events choose a level of severity and check the **ADVISOR EVENT WITH THE SEVERITY OF *CRITICAL*** check box. Finally, choose the **APPLICATION ERROR** check box to configure NMS to support application error traps. Be sure to save your settings before exiting.

If you wish to enable SNMP traps globally, check the `Enable SNMP Notifications` checkbox. To enable SNMP traps only for specific rules run against specific servers or server groups leave this checkbox unchecked—enabling specific SNMP traps is done as rules are scheduled. For instructions on doing this see Section 15.7.2, “Scheduling Rules”.

The Management Information Base (MIB) file associated with SNMP trapping is called `MONITOR.MIB`. For the location this file see The Management Information Base (MIB) File.

> **Note**
>
> The MIB file supplied with MySQL Enterprise Service Manager is not directly compatible with OpenNMS. For a sample of the modifications that need to be made, please see the comments for Bug#41714.

- **SERVER LOCALE**

  The `Server Locale` setting determines the language of notification for the following items:

  - Email notifications
  - SNMP traps
  - The naming conventions for shared resources such as a replication group name prefix

  The initial value in this drop down list box is the locale for the OS on which the Dashboard is running.

- **SERVER HOSTNAME**

  You can alter the hostname and port used to identify the MySQL Enterprise Service Manager when reporting notifications. This can be useful if the server hostname, and the hostname you want to use when connecting to your MySQL Enterprise Service Manager

  > **Note**
  >
  > Only change the **PORT** setting if you have altered or redirected the original port used when installing MySQL Enterprise Service Manager. Entering the incorrect information will not affect the accessibility of your system, except when clicking links within the notification messages.

  You can also alter the name for the server displayed in the login page by changing the value in the **LOGIN DISPLAY NAME**. You may want to use this to display an organizational or divisional title, rather than the hostname, of the MySQL Enterprise Service Manager.

- **DATA PURGE BEHAVIOR**

The `Data Purge Behavior` section of the `Global Preferences` page lets you remove old log files and also old data from the repository. The default purge interval is `28 days`. If you wish to purge data, change this setting by choosing from the drop-down list. Choosing `52 weeks`, for example, will remove all data that is older than a year.

> **Warning**
>
> Purging data will permanently remove information from the repository. Since events are derived from data contained in the repository, they will be purged along with the data.
>
> Ensure that there is adequate disk space for the repository. If you are monitoring numerous servers and running many rules the size of the repository can increase rapidly. Choose purge behavior accordingly.
>
> The default value for purging, `never`, is the safest option. However, please choose a purge setting that makes sense for your environment.

> **Note**
>
> The purge process is started approximately once every minute. If you change the purge duration from a larger timespan to a smaller one, the data may start to be purged immediately.

You can configure the data purge behavior for a number of different systems individually:

- **Remove Historical Data Collection Older Than** configures the duration that the main data about your servers is retained. This includes all data collections, including CPU, memory and connections and activity statistics.
- **Remove Service Manager Logs Older Than** configures the duration that the main MySQL Enterprise Service Manager logs are retained.
- **Remove Query Analyzer Data Older Than** configures the duration that the query analyzer statistics and information about individual queries is retained.

Notes for setting purge behavior:

- Purging can be carried out manually by enabling the `innodb_file_per_table` for the repository database and then using an `OPTIMIZE TABLE` operation to reclaim space from deleted rows in the table.
- If you set the purge value to a very low timespan value when the previous setting was quite high then the space used for the data that was purged will not be reclaimed from the InnoDB tablespaces. You can do this by running `OPTIMIZE TABLE` on the MySQL tables for MySQL Enterprise Service Manager to reclaim the space from the purged rows.
- You cannot set the Query Analyzer purge period to a value greater than historical data collection purge period. If you attempt to do so you will get a warning: `An invalid Query Analyzer data life span was given. Value may not be larger than data life span.`.

- **REMOTE SERVER INVENTORY SCHEDULE**

  MySQL Enterprise Monitor keeps track of all the databases and tables in a server, as well as the amount of RAM, disk space, and other items. A re-inventory updates this information in case you have added or dropped databases and tables. Depending upon the configuration of your system, this operation can tax resources. If you are monitoring many remote servers this is an operation you may want to perform in off-peak hours only.

- **MYSQL ENTERPRISE CREDENTIALS**

  You can specify the credentials for logging into the MySQL Enterprise Website. These should match the user name and password that you have registered with MySQL for your enterprise subscription.

  > **Note**
  >
  > Only administrators can change the `MySQL Enterprise Credentials` section or enter a product key; for other users, this section does not show up in the interface. For more information about different users and their rights see Section 15.5.4, “Managing Users”. Specifying incorrect credentials results in the error message, “Your credentials do not appear to be valid.”

- **HTTP PROXY SETTINGS**

You may want to update your HTTP Proxy Settings if your MySQL Enterprise Service Manager is not directly connected to the internet. The proxy settings will be used when updating the information within the What's New page and when accessing the MySQL Enterprise Website for authentication of your license and product key information. For more information, see Section 15.6, "The What's New Page".

- **MySQL Enterprise Product Key**

  You may update your `MySQL Enterprise Product Key`. If you do not have access to the Internet from the Dashboard, this provides an alternate way to update or activate the MySQL Enterprise Monitor.

  To enter your product key first download it from the MySQL Enterprise website. Copy the key to a location accessible from the Dashboard. Use the BROWSE button to locate the key and then press the SAVE button.

  If you wish to switch from using your MySQL Enterprise credentials to using a product key to update MySQL Enterprise Monitor, you must first clear your credentials. Do this by removing the email address from the **MySQL Enterprise Credentials** section and then clicking the SAVE button. You may then enter and save your MySQL Enterprise product key.

  > **Note**
  >
  > Only administrators can change the `MySQL Enterprise Credentials` section or enter a product key; for other users, this section does not show up in the interface. For more information about different users and their rights see Section 15.5.4, "Managing Users". Specifying incorrect credentials results in the error message, "Your credentials do not appear to be valid."

- **Advisor Bundle**

  You can update your Advisor Bundle and the associated rules and graphs by importing a new Advisor Bundle. To update your Advisor Bundle using a bundle file that you have previous downloaded:

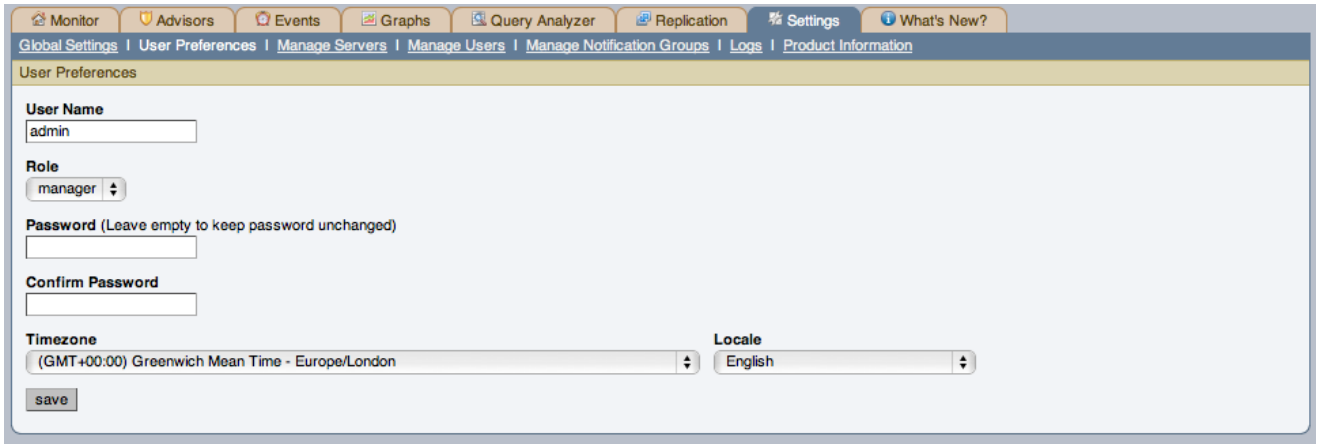
  1. Click CHOOSE FILE and locate your Advisor Bundle on your computer.
  2. Click SAVE to upload the updated bundle and validate the contents.

  To update the Advisor Bundle automatically from the MySQL Enterprise Website using your existing MySQL Enterprise Credentials, click the UPDATE ADVISORS button.

15.5.2. User Preferences

On this page users can change their passwords, user names, and locale information.

Figure 15.33. MySQL Enterprise Dashboard: User Preferences



Change your password by entering a new value into the **Password** text box. To change your user name enter a new value into the **Username** text box. Click the SAVE USER PROPERTIES button to commit this change.

You may also adjust your time zone and locale information from this page. The settings on this page apply only to the user who is currently logged in.

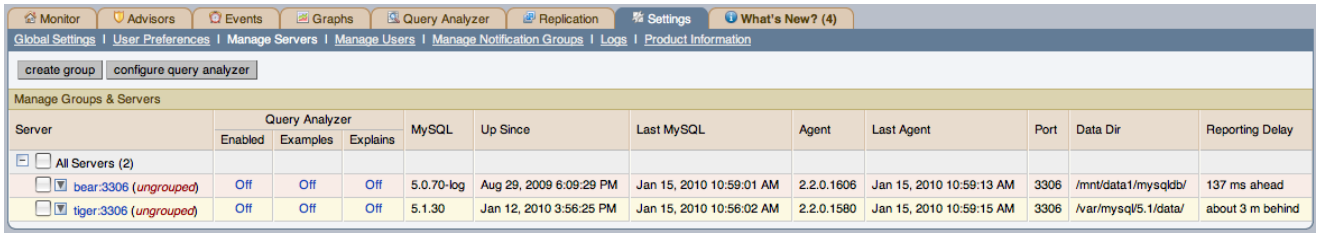
The MySQL Enterprise Service Manager determines the default value for the locale by looking at your browser settings. Changing this value, determines the language setting for any future logins to the Dashboard, overriding your browser settings.

> **Note**
>
> Be sure to set the correct time zone so that alerts are time stamped correctly.
>
> This setting applies only to the specific user.

15.5.3. Manage Servers

To help with server management, the Service Manager supports the logical grouping of MySQL servers. This allows you to group servers in any fashion you choose. For example, you can manage servers according to purpose. You can group servers by whether the servers handle Internet or intranet data, by whether they power finance or HR applications, or, if you prefer, you may organize them by physical location rather than by functionality.

Figure 15.34. MySQL Enterprise Dashboard: Manage Servers



For a server to appear in the Dashboard there must be an agent monitoring it. If you wish to add a server to the Dashboard follow the procedure for installing an agent found at Section 15.3.3, “Monitor Agent Installation”. Instructions for adding a remote server are found at Section 15.3.3.6.4, “Configuring an Agent to Monitor a Remote MySQL Server”.

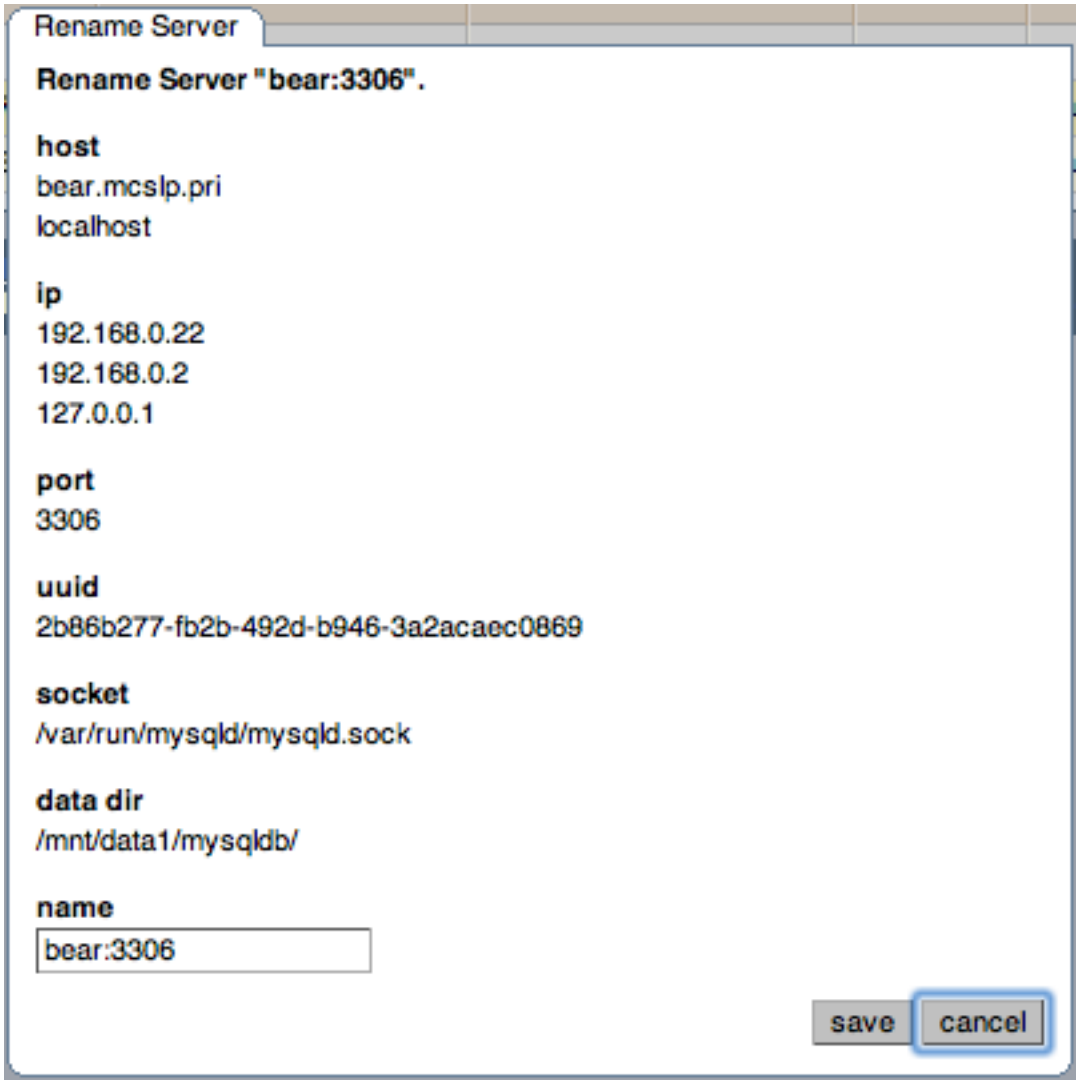
The **MANAGE SERVERS** panel also allows you control the Query Analyzer and Data Migration. For more information, see Section 15.10.7, “Query Analyzer Settings” and Section 15.12.9, “Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0”.

> **Note**
>
> The **ALL SERVERS** group is built in and every monitored server is a member of this group.

15.5.3.1. Renaming a Server

You can rename an existing server without losing the current historical data or configuration information. Renaming the server also allows you to modify the name of the server to be more descriptive according to the server's role within your organization. For example, you may want to rename a server from the default host name to include the department and application for the MySQL server.

Figure 15.35. MySQL Enterprise Dashboard: Server Renaming



> **Note**
>
> Renaming a server using the **MANAGE SERVERS** tab overrides all other settings, including changes made within the agent configuration.

15.5.3.2. Grouping Servers

All monitored servers are automatically included in the top level server grouping, **ALL SERVERS**. Other server groupings are replication groups or user-defined groups.

You can create a user-defined group by clicking the **MANAGE SERVERS** link. Add a group name and then click the CREATE GROUP button. The new group will be displayed immediately.

Replication groups are automatically discovered by MySQL Enterprise Monitor and in this respect differ from user-defined groups. For more information about replication groups see Section 15.11, "The Replication Page". However, like user-defined groups you can edit the name of a replication group and add other servers to it.

To add to a group, select the `add to group` link. Choose the server or servers you wish to add and then complete the operation by choosing the ADD TO GROUP button. You can add a server to a group even if the agent is down.

To remove a server from a group expand the server group tree and click the `remove from group` link. To delete a server altogether see Section 15.5.3.3, "Removing a Server From the Dashboard".

> **Note**
>
> Slaves removed from a replication group will be rediscovered and re-added to that group.

To delete an group, you can use the **DELETE GROUP** link. This will delete the group and remove the servers from being part of the deleted group.

> **Warning**
>
> You cannot delete automatically created groups, such as those built during replication discovery, unless the group is empty. If the group is not empty, you will get a error.

There are three ways to modify an existing group; by renaming it, adding to it, or removing it. Select the `rename` link to change the name of a group and `add to group` to add servers. Deleting a group simply requires clicking the `remove all from group` link. This removes the server group but has no effect on individual servers.

15.5.3.3. Removing a Server From the Dashboard

If you no longer wish to monitor a MySQL server you can remove it from the Dashboard. There is no provision for deleting an active server from the Dashboard—to remove a server you must make it inactive by stopping the agent.

For instructions on stopping an agent see:

- Windows: Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”
- Unix: Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”
- Mac OS X: Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”

Once the agent is stopped you may delete the monitored server. Deleting a server simply means that it will no longer show up in the Dashboard.

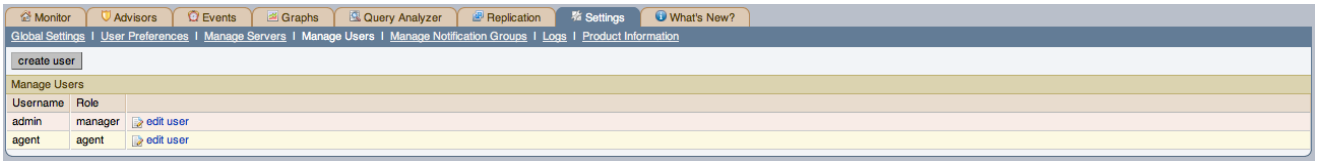
Remove a server by choosing the SETTINGS tab and then the **MANAGE SERVERS** link. Find the server you wish to remove and delete it by clicking the DELETE link within the pop-up menu. Deleting a server from the **ALL SERVERS** group or from any other group will remove it from the Dashboard entirely.

> **Note**
>
> A DELETE link will not be available for an active server. You must stop the agent before this link will appear.
>
> You may remove a server from any group at any time. Removing the last server from a group also removes that group.

15.5.4. Managing Users

The **MANAGE SERVERS** panel allows to create, delete and manage individual users that have access to MySQL Enterprise Service Manager

Figure 15.36. MySQL Enterprise Dashboard: Manage Users



To log in to the Dashboard a user account is required. There are three types of users with varying privileges; Administrators, Database Administrators, and Agents. The `Administrator` can create additional users and differs from a `DBA` in this respect. For this reason the `Manage Users` does not display if a DBA user logs in. Additionally, only administrators can change the MySQL Enterprise Credentials section or enter a product key on the `Global Settings` page. These sections do not appear when DBA users log in. For more information on this subject see Section 15.5.1, “Global Settings”. The `Agent` account simply allows the MySQL Enterprise Mon-

itor Agent to communicate with the Dashboard. There is no need for more than one agent account but defining an account for each server that is monitored can be an advantage since this minimizes exposure should any one agent be compromised. You cannot log in to the Dashboard using the agent's credentials.

When the Dashboard is first launched there are two default users, `Administrator` and `Agent`, both created during installation. Their default user names are respectively, `admin` and `agent`. The Administrator defined during installation as having the root role is unique; this user cannot be deleted.

If you are logged in as an `Administrator`, you can add a new user by choosing the `Manage Users` link from the `Settings` page. To create a user click the CREATE USER button, select a role for the user, and enter a user name and password.

When a new user first logs in, a dialog box opens requesting time zone and locale information. This information may be changed later from the `User Preferences` page. For more information, see Section 15.5.2, “User Preferences”.

If you installed the Advisors through the Dashboard you should have already configured the settings for the root role user. (See Section 15.5.1, “Global Settings” and following for more information about this topic.)

> **Warning**
>
> To receive MySQL Enterprise and Advisor updates configure the MySQL Enterprise settings for at least one user. The MySQL Enterprise settings were set up on the first login to the Dashboard. For information on changing these settings see, Section 15.5.1, “Global Settings”.

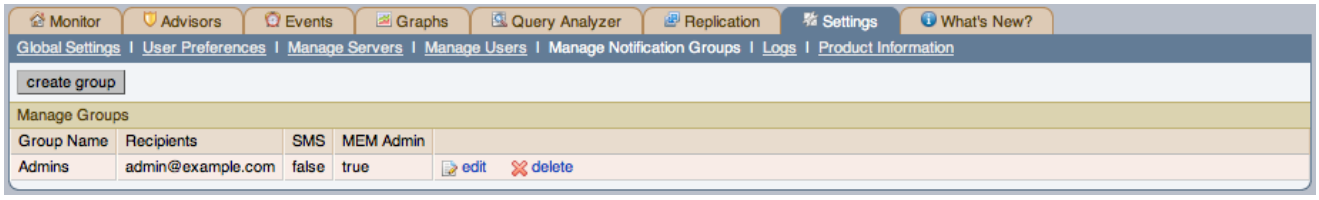
To edit an existing user's information, select the `Manage Users` link, then select the user you wish to edit. Make your desired changes in the fields provided and then save your changes.

To delete an existing user, merely select the `delete` link.

15.5.5. Manage Notification Groups

The **MANAGE NOTIFICATION GROUPS** panels allows you to create and manage the notification groups used when different notifications and warnings are distributed.

Figure 15.37. MySQL Enterprise Dashboard: Manage Notification Groups

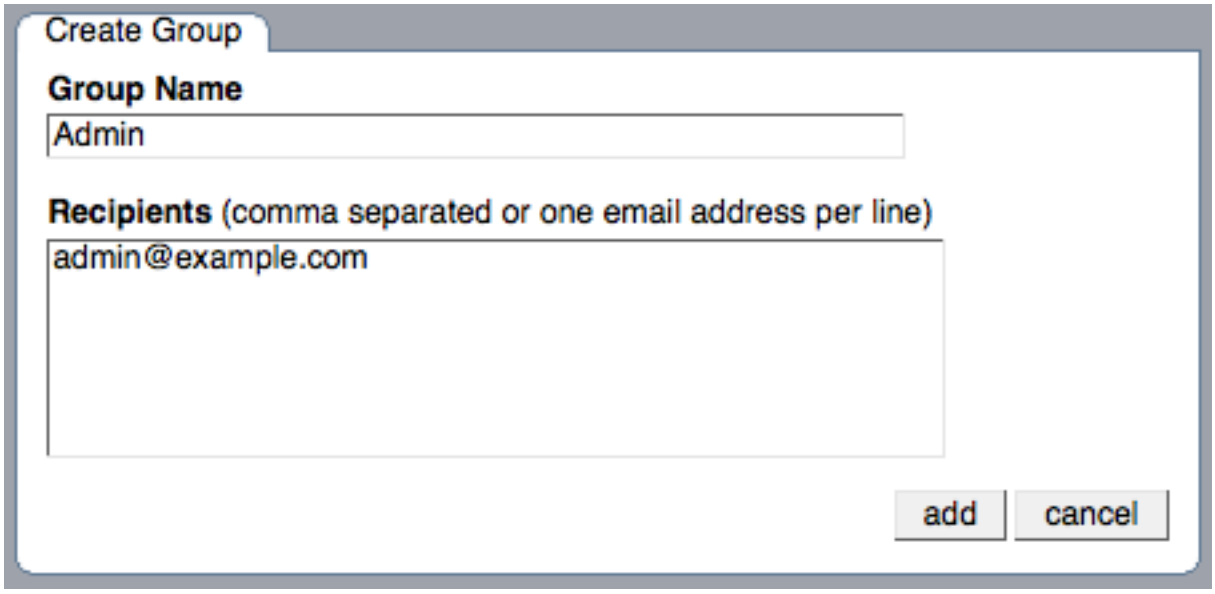


Notification groups are collections of users who should be notified when advisor alerts occur. These users may have login credentials for the Dashboard but this is not a requirement.

You can create a group by clicking the `create group` link. Specify a group name and add recipients. When adding a user an email address must be specified. If you are adding multiple users separate them with commas.

To modify an existing notification group, select the `edit` link next to the group name. Deleting a group simply requires clicking the `delete` link.

Figure 15.38. MySQL Enterprise Dashboard: Edit Notification Groups



If a rule triggers an alarm, an email will be sent to the members of the notification group specified when the rule was scheduled. For more information about scheduling rules see Section 15.7.2, "Scheduling Rules".

To use this group for notification using the SMS interface, select the checkbox next to **SMS**. This will force the messages to be encoded suitable for sending using SMS. Messages will be sent using the configured SMS service.

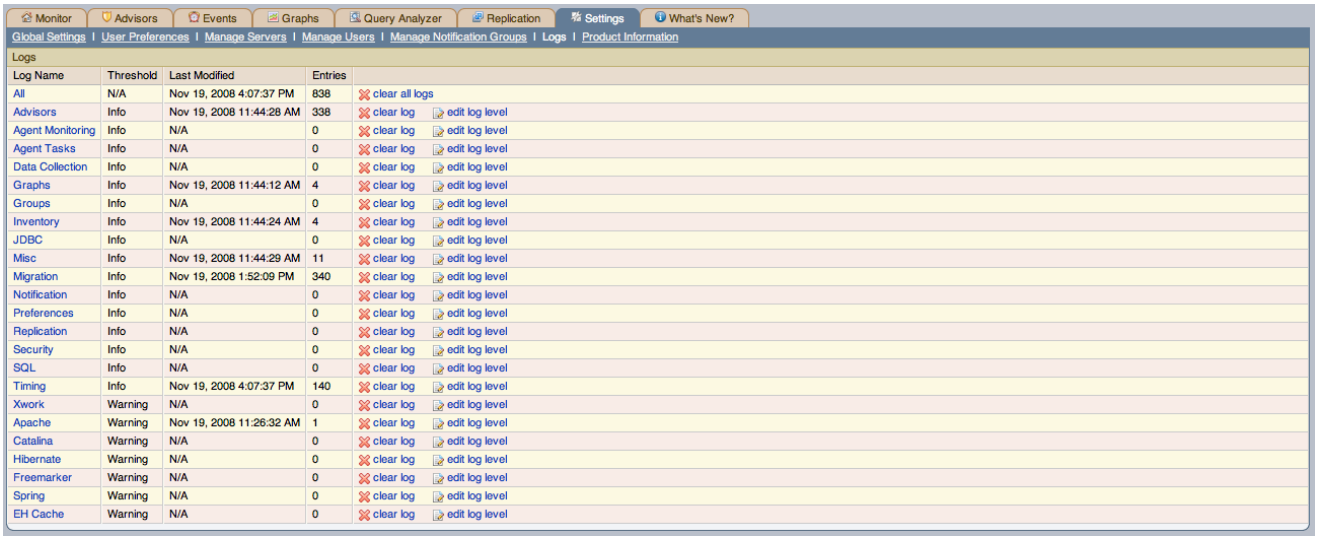
You can also optionally select a notification group to be used when sending critical error messages (such as MySQL Enterprise Monitor Agent or MySQL Enterprise Service Manager failures) by selecting the checkbox next to **MEM ADMIN**.

> **Note**
>
> You should ensure that there is a mail server available for sending out alerts and that there is an account configured for receiving any alerts that are created. For SMS messages, you must ensure that you have configured your SMS service settings.

15.5.6. Logs

Use the `Logs` link to inspect the various log files associated with the MySQL Enterprise Service Manager. The following image is an example of this screen.

Figure 15.39. MySQL Enterprise Dashboard: Logs



The various categories of logs are shown in alphabetical order. The most recent changes to each log are shown in the **LAST MODIFIED** column. The number of entries in any specific log is shown under the **ENTRIES** column.

To view detailed information click the `Log Name`. This will open a separate browser window showing the date, time, alert type, and accompanying message.

On this screen you can filter log information in a couple of ways; by the message type and by time period .

To filter by message type select from the options in the **LEVEL** drop-down box. These are, in order of decreasing severity:

- All
- Error
- Warning
- Information
- Trace
- Debug

You can also adjust the number of items that appear on each page.

Press the `clear all logs` link to remove all log entries. To remove entries of a specific kind click the `clear logs` link associated with the specific log you would like to remove. A confirmation dialog box allows you to back out of this operation and avoid accidentally removing log information.

To clear log files of a specific age see the `Data Purge Behavior` section of the `Global Preferences` page. For more information on this topic see Data Purge Behavior [1425].

Use the `edit log level` link to change the type of error logged. The value selected from the `Edit Log Level` dialog box determines what appears under the **THRESHOLD** column (second from the left in Data Purge Behavior [1425]).

Selecting `Error` from the list box will create the least number of log entries and `Debug` the most. Choosing `None` turns off logging altogether.

It is also possible to download a compressed version of all the log files. For more information, see Section 15.5.7, “The Product Information Screen”.

15.5.7. The Product Information Screen

Use the `Product Information` link to view detailed information about your subscription level and contract status.

- **Subscription Warnings**

  The **SUBSCRIPTION WARNINGS** section contains information unique to your subscription. Information provided here will relate to your subscription settings and the servers currently being monitored. For more information, see Section 15.5.7.1, "Subscription Warning".

- **Contract Status**

  The **CONTRACT STATUS** section displays the subscription level, expiration date, contract number, the number of servers supported, and your MySQL Enterprise user name. The **SUBSCRIPTION LEVEL** section gives more detailed information, including features and any restrictions that may apply. You may update your subscription at any time by clicking the UPDATE button.

- **Subscription Information**

  The **SUBSCRIPTION INFORMATION** section contains detailed information about your subscription level and the numbger of hosts currently monitored within your subscription level.

- **Enterprise Dashboard Server Info**

  The **ENTERPRISE DASHBOARD SERVER INFO** section provides detailed information about the running of your MySQL Enterprise Service Manager, including information about the Java environment, hostname and version information.

  The section also includes detailed information about the current status of your MySQL Enterprise Service Manager, showing information on the agents, rules, and outstanding status of the various components. The information provded in this section is listed below:

  - **PENDING HEARTBEATS**
  - **PROCESSED HEARTBEATS**
  - **PENDING JOBS**
  - **NUMBER OF AGENTS**
  - **MONITORED MYSQLD INSTANCES**
  - **BUILD VERSION**
  - **ADVISOR VERSION**
  - **NUMBER OF RULES**
  - **NUMBER OF GRAPHS**
  - **LAST SUCCESSFUL EMAIL**
  - **LAST EMAIL FAILURE**
  - **LAST FAILURE MESSAGE**

  You can monitor the status of the email messages sent by MySQL Enterprise Service Manager by looking at the values of the **LAST SUCCESSFUL EMAIL** and **LAST EMAIL FAILURE** sections. Any failure by MySQL Enterprise Service Manager to send an email will be reported, with the failure date recorded in **LAST EMAIL FAILURE**. You can examine the **LAST FAILURE MESSAGE** field to determine the precise reason for the failure.

- **Readme**

  The **README** section contains a copy of the text `Readme` file provided with each release, and provides release specific information about your MySQL Enterprise Service Manager installation.

- **Diagnostic Report**

  The page includes a hyperlink, **DOWNLOAD DIAGNOSTIC REPORT**. Click this link to download a compressed version of the MySQL

Enterprise Service Manager log files. All the log files found on the Logs page (for more information about logs see Section 15.5.6, “Logs”) are contained in this file. It also contains the Java properties file, the monitored MySQL servers property file, information about the status of the JDBC connection and Java threads, and the subscription.xml file. This report is especially useful for debugging the MySQL Enterprise Service Manager and the MySQL Enterprise Monitor Agent.

15.5.7.1. Subscription Warning

The Subscriptions Warning section on the product information page displays any warnings relative to your subscription. For example, if your subscription has expired you may receive a message such as the following:

```
Your Subscription Needs to be Updated
* Your Platinum subscription expired 3 days ago on Feb 14, 2008 11:59:59 PM.
If the subscription information on this page is not current, you can
update it by going to the Enterprise Monitor Global Settings page and
providing MySQL Enterprise credentials or by importing a new product
key that you downloaded from http://www.mysql.com/enterprise/download.php.
To update or renew your subscription, please contact your MySQL
Account Representative at sales@mysql.com or visit
http://www.mysql.com/about/contact/renew.html.  After the update or
renewal is complete you can then follow the above instructions for
updating your subscription.
```

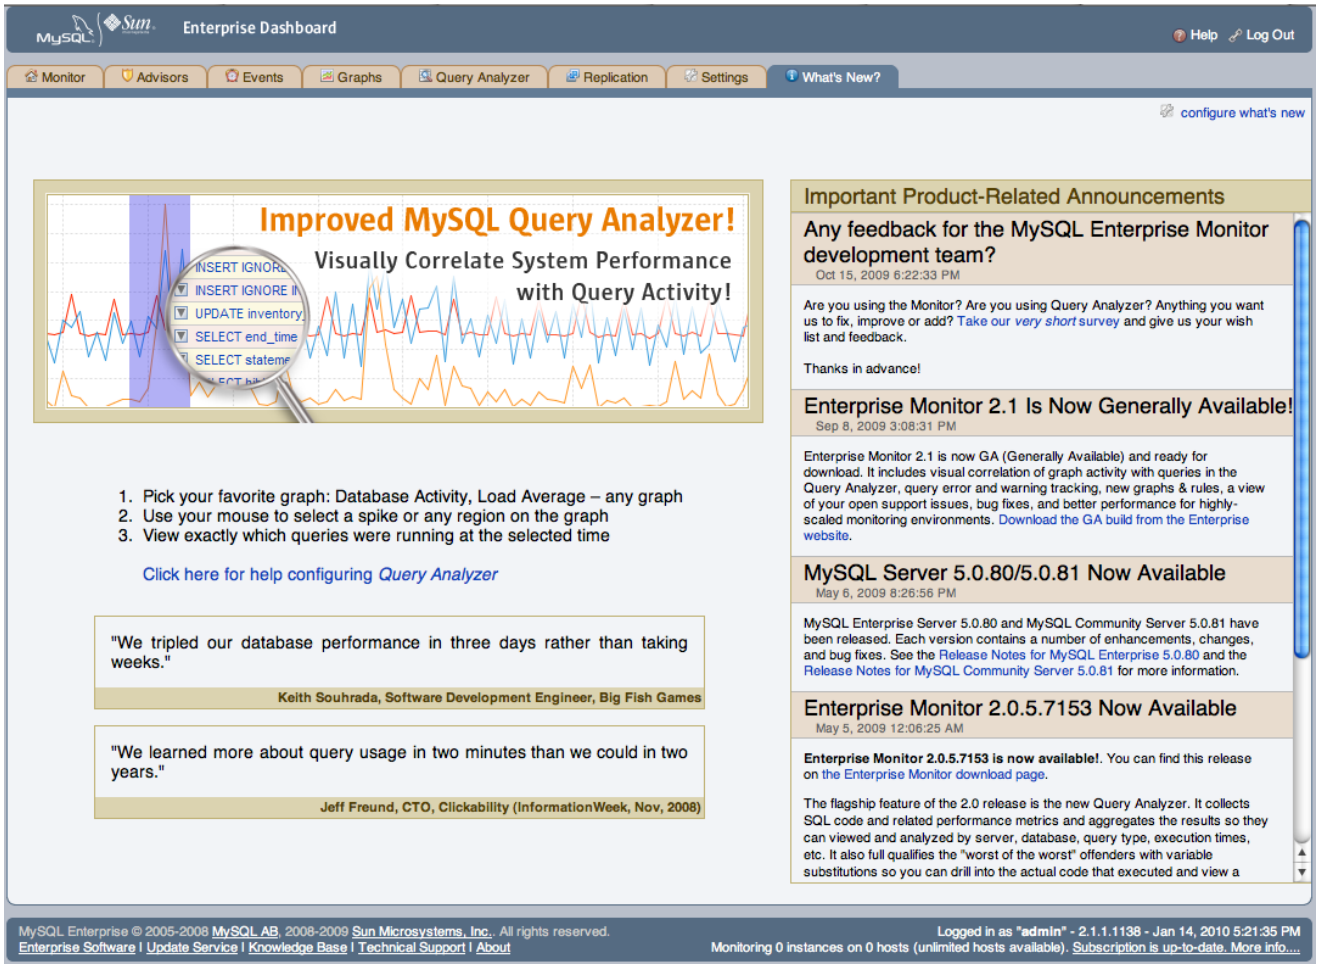
Follow these instructions to update your subscription. If you see this message and your subscription has already been updated, simply click the UPDATE button in the **CONTRACT STATUS** section of this page. This should update your subscription and remove the warning.

> **Note**
>
> After updating your subscription remember to also update your advisors. For instructions on doing this see Section 15.7.1, “Installing and Updating Advisors”.

15.6. The What's New Page

The What's New Page provides a simplified interface for providing updates and news related to your MySQL Enterprise Subscription. By default, the information is automatically updated every hour. To disable the updates, or force an update, see Section 15.6.1, “Setting What's New Configuration”.

Figure 15.40. The What's New Tab



The **WHAT'S NEW** page is divided into three main sections:

- The area on the left-hand side of the page is used to provide information about the major new features and functionality in MySQL Enterprise Monitor.
- **OPEN SUPPORT ISSUES** provides a quick interface to the list of currently open issues with MySQL Support as identified through the MySQL Enterprise and Support websites. Issues that are currently marked in the system as *Waiting On Customer* are also added to the main MySQL Enterprise Dashboard above the Heat Chart.

  To use the Open Support Issues functionality, you must have set your MySQL Enterprise credentials within MySQL Enterprise Dashboard. For more information, see Section 15.5.1, “Global Settings”.
- **IMPORTANT PRODUCT RELEASE ANNOUNCEMENTS** provides a list of news items from the news feed provided on the MySQL Enterprise website. The news feed will contain important information, including, but not limited to:

  - New releases of MySQL Products, including MySQL Server and MySQL Enterprise Monitor.
  - End-of-life and support changes.
  - Urgent errors and notifications.

  When items are new (unread), they will be indicated with a star icon. Unread items on the What's New page will also be notified with a number in the tab title within the main Dashboard. Items are automatically marked as read when you visit the What's New page.

  The announcements information is made available in two ways, using either a connection to the MySQL Enterprise website, when

the information will be updated at a set interval, or through information included with the MySQL Enterprise Advisor bundles.

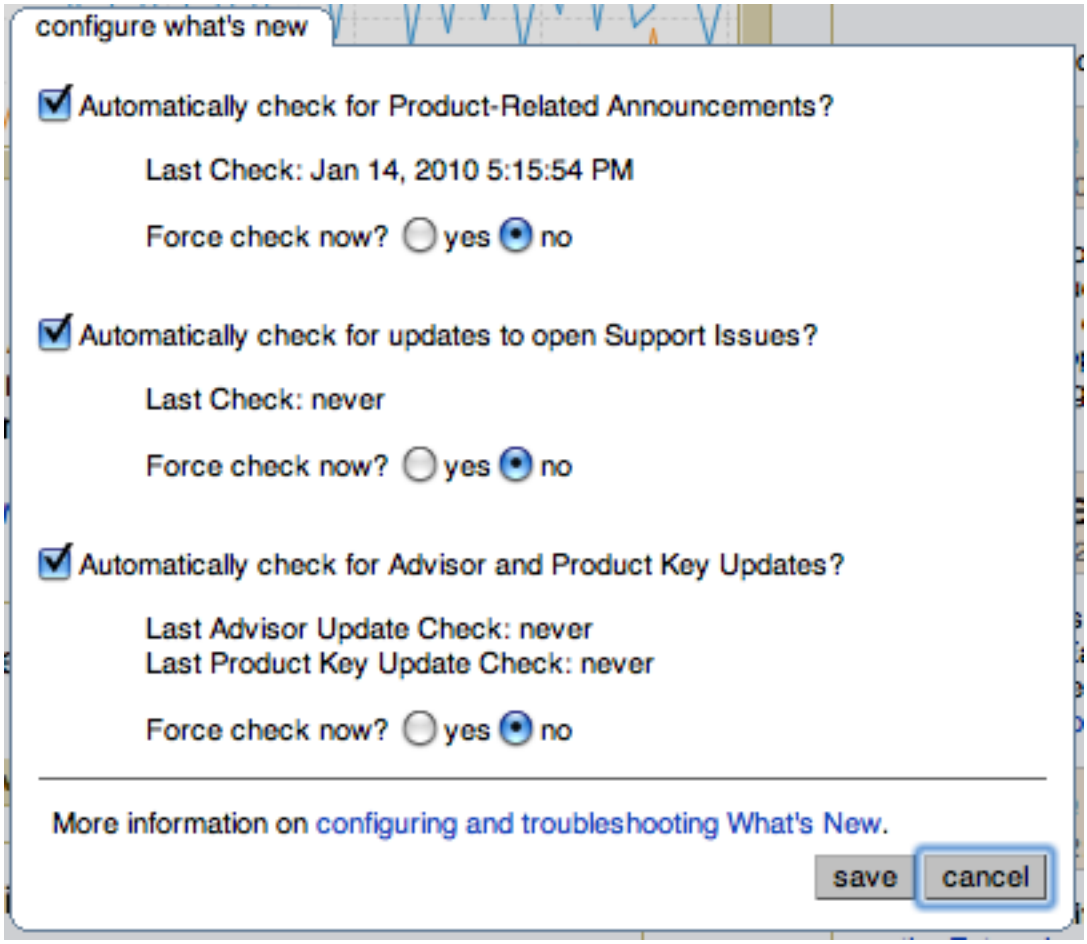
> **Note**
>
> To use poll the MySQL Enterprise site directly your MySQL Enterprise Service Manager must have access to the MySQL Enterprise website. If your MySQL Enterprise Service Manager is not directly connected to the Internet, you can set an HTTP Proxy to be used to access the information. For more information on configuring an HTTP Proxy, see Section 15.5.1, “Global Settings”.

> **Note**
>
> You can disable the display of your open Support issues and product notifications by using the CONFIGURE WHAT'S NEW link on the **WHAT'S NEW** page. For more information, see Section 15.6.1, “Setting What's New Configuration”.

15.6.1. Setting What's New Configuration

You can configure the operation and forcibly update the information on the What's New page by clicking the CONFIGURE WHAT'S NEW button at the top-right of the What's New page.

Figure 15.41. What's New Configuration



The configurable options are:

- **AUTOMATICALLY CHECK FOR NEW ANNOUNCEMENTS?**

  To disable the New Announcements updates, deselect the checkbox. Updates are enabled by default.

  The last time an update of the New Announcements information was successfully executed is displayed below the title.

  You can force an update of the New Announcements information by selecting the YES radio button next to **FORCE CHECK NOW?**. A check will be executed when you click the SAVE button to close the configuration dialog.

- **AUTOMATICALLY CHECK TO SUPPORT ISSUES?**

  To disable the Support Issues updates, deselect the checkbox. Updates are enabled by default.

  The last time an update of the Support Issues information was successfully executed is displayed below the title.

  You can force an update of the Support Issues information by selecting the YES radio button next to **FORCE CHECK NOW?**. A check will be executed when you click the SAVE button to close the configuration dialog.

- Automatically check for Advisor and Product Key Updates?

  The MySQL Enterprise Service Manager can automatically look for changes to your MySQL Enterprise Advisor and product key information by polling the MySQL Enterprise website.

  To disable the Advisor and Product key updates, deselect the checkbox. Updates are enabled by default.

  You can force a check for updates to the Advisor and Product key information by selecting the YES radio button next to **FORCE CHECK NOW?**. A check will be executed when you click the SAVE button to close the configuration dialog.

Click SAVE to save your settings. If you selected any system to force an update, the update will take place in the background. To cancel your changes, click CANCEL.

15.7. The Advisors Page

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

MySQL Enterprise Advisors are a series of scripts that gather information from your MySQL servers via the Service Manager and the Monitor Agents, analyze that information based on custom rules developed by MySQL AB, and then offer alerts and advice when necessary. As new rules are introduced, the MySQL Enterprise Advisors can be updated through the MySQL Enterprise website.

The MySQL Enterprise Advisors fall into the following categories:

- Administration
  - Better manage databases
  - Suggest improvements for smoother operation
- Heat Chart
  - Drive the status indicators in the Heat Chart
  - Identify up/down status and performance issues
- Performance
  - Identify potential performance bottlenecks
  - Make suggestions for improved database speed
- Replication

    - Identify replication bottlenecks
    - Improve replication design
- Schema
    - Identify schema changes
    - Find security loopholes
- Security
    - Protect MySQL servers
    - Find security loopholes

An advisor category provides a set of rules designed to enforce MySQL best practices for that specific category. Rules can be targeted to run at the individual server or group level and, upon rule violation, provide alerts and expert advice on how to address and correct a problem before it becomes a costly outage.

Individual rules are defined in the `items-mysql-monitor.xml` file. On Windows this file is found in the `C:\Program Files\mySQL\Enterprise\Agent\share\mysql-monitor-agent` directory and on Unix in the `/opt/mysql/enterprise/agent/share/mysql-monitor-agent` directory. Find below the rule for discovering a `root` account with no password.

```
<ITEM>
  <NAME>no_root_password</NAME>
  <FIELD>no_password</FIELD>
  <SCOPE>table</SCOPE>
  <CODE>
    <![CDATA[SELECT COUNT(*) AS no_password FROM mysql.user WHERE user='root' AND password='']]>
  </CODE>
  <NAMESPACE>mysql</NAMESPACE>
  <RETURNS>INTEGER</RETURNS>
  <SOURCE>table</SOURCE>
  <INSTANCE>mysql.user</INSTANCE>
</ITEM>
```

Your MySQL Enterprise subscription level determines which rules are available to you. Subscription levels are cumulative, meaning that higher MySQL Enterprise levels have access to all the rules of the lower levels.

When the Dashboard is first installed, the only rules that are scheduled are those that belong to the `Heat Chart` group.

Go to the Advisors screen by logging in to the Dashboard and choosing the `Advisors` tab.

15.7.1. Installing and Updating Advisors

Instructions for installing Advisors are given in Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”, and following. Principally, you need to configure your MySQL Enterprise login or enter your product key before you can update your Advisors.

If your MySQL Enterprise login is configured, you can download the latest Advisors by navigating to the `Advisors` page and finding the `Check for Updates` link. You can periodically update advisors in this way.

> **Note**
>
> If you do not have Internet access and cannot use the online update option you can manually import advisors. This process is described in Section 15.3.2.7.3, “Installing Advisors After Initial Log-in”.

15.7.2. Scheduling Rules

Once the MySQL Enterprise Advisors have been installed, you can configure which advisors you would like to run on a scheduled basis.

You can schedule rules by individual server or by group. This is done by first selecting the desired server or server group from the `Server` tree found on the left side of the screen. Next select the `Advisors` tab.

Opening the Advisors tab takes you to the Current Schedule page. If you have only just installed the MySQL Enterprise Monitor then you will only see the Heat Chart group of advisors. Clicking the + button will show all the rules in the Heat Chart group.

Clicking the + button beside any specific rule will show the servers that this rule is running on, its frequency, and its status. Initially, all the Heat Chart rules are enabled.

For a more complete description of a rule, click the rule's name. This opens a dialog box that gives detailed information about the rule.

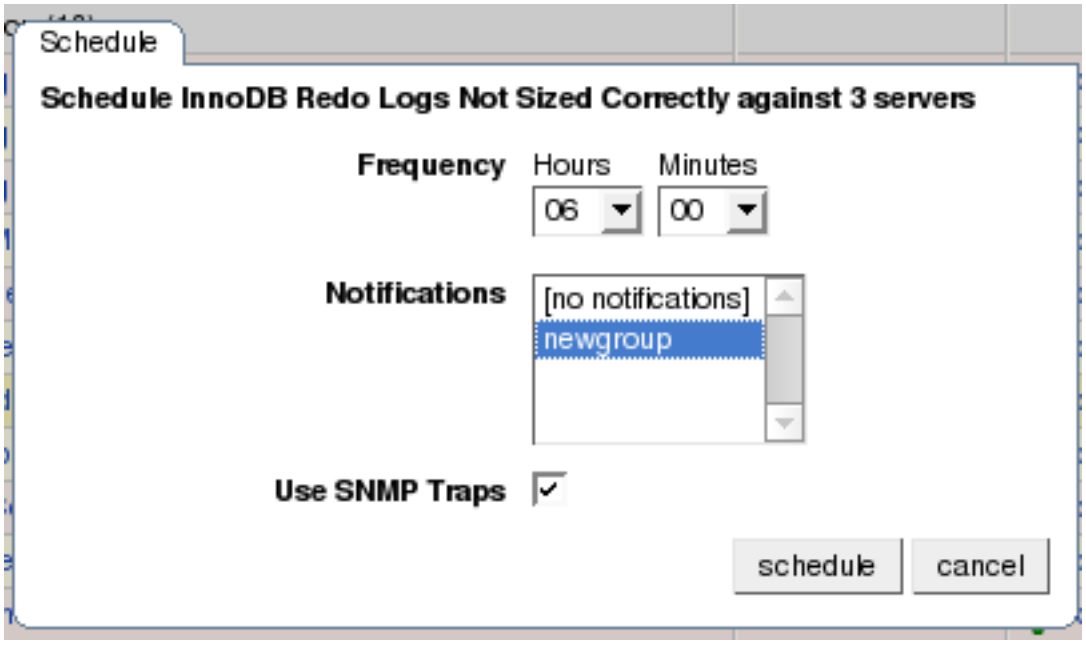
To view the advisors other than the Heat Chart group, select the Add to Schedule link. This will show all the advisors available for your subscription level.

Rules are grouped by functionality and displayed in alphabetic order. To expand a group click the + button to the left of the advisor name.

You may activate all the rules in a group by selecting the checkbox beside the group name. Once selected you may apply rules against a specific server or a group of servers. A message showing the group of servers or the specific server you have selected will display immediately below the SCHEDULE button. For example, if the All Servers group is selected in the server tree, then the message will read, “Schedule Advisors Against **All Servers**”.

To select a specific rule, expand the group tree by clicking the + button. Select the checkbox to the left of the rule you wish to schedule. Click SCHEDULE to display the following dialog box:

Figure 15.42. MySQL Enterprise Dashboard: Scheduling Dialog



The Schedule dialog box allows you to configure the following fields:

- Frequency: Dictates how often the rule will run. The default value for different rules varies but a rule can be set to run at any interval desired.

  > **Warning**
  >
  > Setting the frequency of a rule involves tradeoffs. Rule evaluation consumes system resources—CPU, memory, and disk space. While the amount consumed is small, if you run all the rules against dozens of servers on a very frequent basis, you may put a significant load on the Service Manager. So select an appropriate frequency. For example, unless you are stopping and restarting your servers frequently, rules that check server configuration variables probably don't need to run very often.
  >
  > Another consideration is that certain status variables increase monotonically until a server is restarted. Examples of these

are `Key_reads`, `Qcache_hits`, `Questions`, `Table_locks_waited`, and similar variables. The value returned by `SHOW STATUS` for these variables is the value since the server was started (or since the last `FLUSH STATUS` command), which is not very useful for performance tuning, especially if the server has been running for an extended period of time. For performance tuning it is much better to know the change in state (for example, delta) of these values over the last 10 minutes, 1 hour, or whatever time frame is appropriate for your application. The frequency at which you schedule a rule is the time frame used to calculate the delta values of these variables, and it is the delta that is used in expression evaluation, not the absolute value. Consequently, select a frequency that is appropriate for the metrics being used in the expression.

- `Notifications`: A listbox of users and/or notification groups who will be emailed when an advisor reaches an alert level. Single or multiple selections are allowed. For instructions on setting up notification groups see, Section 15.5.5, "Manage Notification Groups".

Set the frequency, identify whomever you wish to notify, and click SCHEDULE to schedule the advisor. Upon completion, you should see the message, `Successfully scheduled`.

If you haven't set up global SNMP traps and would like your Network Management System (NMS) to handle events related to a specific rule then check the `Use SNMP Traps` checkbox. For more information about Simple Network Management Protocol (SNMP) see Simple Network Management Protocol (SNMP) Traps.

Scheduling rules using the checkbox and the SCHEDULE button is an effective way to schedule multiple rules. To schedule a single rule you may also use the `schedule` link.

When scheduling more than one rule, you have the option of selecting a checkbox to use the default frequency of each rule or you may choose a frequency that will apply to all selected rules. When customizing the frequency, take care that you choose a value that is appropriate to all the rules selected.

Note

If the agent does not have the `SUPER` privilege and InnoDB-related rules are scheduled, a warning will appear in the `DataCollection` log. This also occurs if `mysqld` is started with the `skip-innodb` option. For more information about agent rights see Section 15.3.3.1, "Creating a MySQL User Account for the Monitor Agent".

15.7.2.1. Heat Chart Notifications

It is particularly important that `Notifications` be set for the `Heat Chart` group of rules. This is easily done from the `Current Schedule` page by clicking the + button beside a rule and then clicking a server.

Doing this opens a window with three tabs—`Overview`, `Settings`, and `Advanced`.

The `Overview` tab shows which advisor group a rule belongs to, a description of its purpose, and a link to the history of this alert.

In the `Settings` tab you can adjust the frequency of this rule and also specify a notification group. To select more than one contiguous group press the `Shift` key and click the desired groups. (Some web browsers may require that you drag your selection.) Noncontiguous selections are made by holding down the `Control` key and clicking the desired groups.

If you haven't set up global SNMP traps and would like your Network Management System (NMS) to handle events related to a specific rule then check the `Use SNMP Traps` checkbox. For more information about Simple Network Management Protocol (SNMP) see Simple Network Management Protocol (SNMP) Traps.

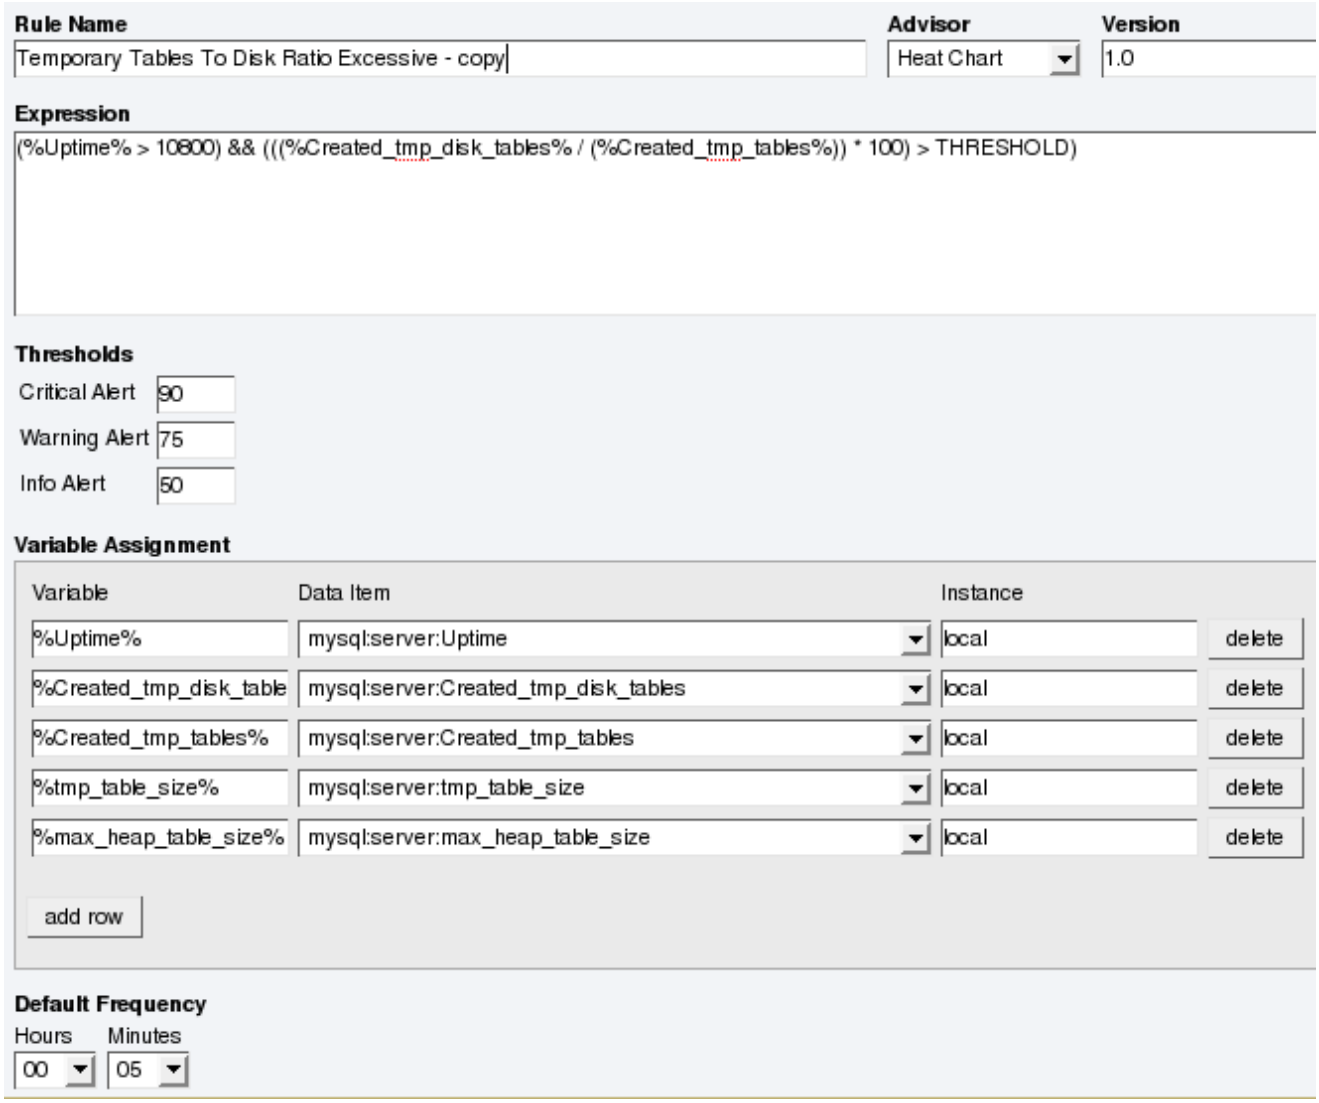
The `Advanced` tab gives detailed information about how this rule is implemented.

15.7.3. Editing Built-in Rules

The frequency and thresholds defined for a rule are default recommendations. To edit these properties choose the `Create/Edit Rule` link.

The following image shows the screen used to edit rules:

Figure 15.43. MySQL Enterprise Dashboard: Editing Rules



Beside the rule name is the `Advisor` drop-down list box, used for setting the advisor group. This list box shows existing groupings and any you may have added. The `Expression` textarea shows the advisor rule, `Variable Assignment` the data item associated with variable(s) used in the rule and `Thresholds` determines when to trigger each alert type.

The three levels of `Thresholds` are `Info Alert`, `Warning Alert`, and `Critical Alert` indicating increasing levels of severity. Levels can be triggered by the expression result being equal to a certain value, greater than a certain value, or less than a certain value.

The data items that variables are associated with are operating system (OS) properties such as available RAM or MySQL characteristics such as the InnoDB buffer pool. To see all available data items drop down the `Data Item` list box. For a listing of these data items see Data Collection Items.

In Figure 15.43, “MySQL Enterprise Dashboard: Editing Rules” the drop-down `Data Item` list box within the `Variable Assignment` frame shows the various MySQL server status or operating system specific variables that may be used in expressions. The text boxes below `Thresholds` define the levels at which informational, warning, or critical alerts are issued.

To lower the threshold for an informational alert, simply increase the number given in the `Info Alert` text box.

When a data item can apply to multiple objects, you need to specify which instance to use for that item, hence the `Instance` text box. In almost all cases this should be set to `local`. The exceptions are as follows:

- For CPU-related items set **INSTANCE** to `cpu0`. Additional CPUs on a system are referred to as `cpu1, cpu2` and so on.
- There can be multiple disks mounted on a system. To refer to a specific drive set **INSTANCE** to the name of of the mounted drive. On Windows this would be `C:, D:`, and so on. On Unix systems, use whatever is valid for the `df` command.
- For RAM-related items set **INSTANCE** to `mem`.
- Where there are table-specific variables, the database name and table name must be specified in the **INSTANCE** text box. This topic is discussed in detail in what follows.

> **Note**
>
> It is not possible to have a data item that is unrelated to an instance. This raises the error, `You must map "<variable>" to an instance`, and you will be unable to save the rule.

An agent can only collect data from one MySQL server, so the `instance` entry for a variable in a rule does not need to specify which MySQL server to use; no matter how many servers are being monitored there is always a one-to-one relationship between an agent and its monitored server.

However, on one server there may be multiple occurrences of a variable. For example, there are multiple possible occurrences of table-specific variables such as `Avg_row_length` because there can be multiple databases and tables defined in a MySQL server. In this case, the "instance" refers to the database and table that a data item should be associated with, specified in the form *`databasename.tablename`*. So, for example, if you want to reference the `Avg_row_length` of the `mysql` database `user` table in an expression, select the `mysql:tablestatus:Avg_row_length` from the **DATA ITEM** list box and specify `mysql.user` in the **INSTANCE** text box.

On the other hand, in the case of a global server variable, there is only one possible target. For example, there can only be one instance of `delay_key_write` because this variable is global and applies to the server as a whole. In this case specify `local` in the **INSTANCE** text box.

To save your changes click the SAVE button at the bottom of the page.

> **Note**
>
> You can change only the thresholds and the frequency of built-in rules. So that rules function properly when updated, other changes are prohibited.
>
> Should you wish to make other changes to a built-in rule, copy it and modify it as desired.

You can edit a rule even if it is currently scheduled. Your changes will not be overwritten when new rules are imported using the `Check for Updates` link.

15.7.4. Creating Advisors and Rules

In addition to using and editing the advisors and rules provided by MySQL Enterprise, users can create their own advisors and rules to meet their own unique needs. To do this go to the `Advisors` page and choose the `Create/Edit Rule` link.

15.7.4.1. Creating Advisors

Similar existing rules are grouped together in advisor groups.

The built-in advisors are:

- Administration
- Heat Chart
- Performance
- Replication
- Schema

- Security

The ability to create your own advisor group allows you to create groupings suitable to your circumstances.

You can create your own grouping by simply clicking the CREATE ADVISOR button. Enter an appropriate name and click the ADD button. The newly created group will appear in the `Advisor` column.

The newly created advisor is added to the list box of advisors shown in Figure 15.43, "MySQL Enterprise Dashboard: Editing Rules". You can now use this category of advisors when you create a new rule.

15.7.4.2. Overview of Rule Creation

Rules are created using the same screen seen in Figure 15.43, "MySQL Enterprise Dashboard: Editing Rules". To begin creating a rule from scratch, click the CREATE RULE button. However, the simplest way to create a new rule is to copy an existing one. Unlike editing an existing rule, when you copy a rule, every element of that rule is editable.

You can change the rule name, the advisor group that a rule belongs to and you can set your own version number. In Figure 15.43, "MySQL Enterprise Dashboard: Editing Rules", you have already seen how the threshold and frequency of a rule may be altered.

Most importantly you can alter a rule's expression. Expressions are the core of a MySQL Enterprise Advisor and are used to define the scenario being monitored. An expression can be as simple as a single server parameter or can be quite complex, combining multiple parameters with various mathematical operations.

An expression has two main characteristics:

- An expression defines a situation where a best practice is not being followed
- The result of an expression must always be 1 or 0 (that is, true or false)

If an expression evaluates to true for a specific server, an alarm is raised, indicating that a best practice is not being followed. If an expression evaluates to false no alarm is raised because the best practice is indeed being followed.

For example, if having binary logging enabled is considered a best practice for a production server (which we believe it is), then this best practice is being violated if `log_bin` is `OFF`. Consequently, the expression for the "Binary Logging Not Enabled" rule is "%log_bin% == OFF". If this evaluates to 1, an alarm is raised because the best practice is not being followed.

An expression is made up of one or more variables and zero or more mathematical operators. The MySQL Enterprise Monitor uses the MySQL database server's expression parser and evaluator For a complete list of operators and functions see Chapter 11, *Functions and Operators*. For a complete list of the built-in variables used when creating rules see Section 5.1.1, "Server Option and Variable Reference".

Creating an expression is dependent on variables defined in the **VARIABLE ASSIGNMENT** frame. This frame links variables used in the expression field with data gathered from the target MySQL server instance—server status variables, operating system status information, and table information. Variable names are associated with elements in the **DATA ITEM** drop-down list. If you need to define more than one variable simply click the ADD ROW button. For a complete listing of the data collection items used in creating rules see Data Collection Items.

The remaining fields determine the information that displays in a notification email or the informational pop-up window associated with each advisor.

> **Note**
>
> When saving a new rule ensure that you do not duplicate the name of an existing rule.

15.7.4.3. Variables

When an expression is evaluated variables get replaced by values. For example, part of the expression for the "MyISAM Key Cache Has Sub-Optimal Hit Rate" rule calculates the hit rate as follows:

```
100-((%Key_reads% / %Key_read_requests%)*100)
```

If the current value of `%Key_reads%` is 4522 and the current value of `%Key_read_requests%` is 125989, the hit ratio assesses to 96.4%:

```
100 -((4522 / 125989) * 100)
```

By convention, the Advisors supplied by MySQL use '%' as the delimiter, for example, %Key_reads%. This makes variables more readily identifiable.

In addition to being used in an expression, variables may also be used in the Description, Advice, Action, and Links attributes of a rule. This allows you to report the current value of an expression.

For instance, you can add the message, "The current value of Key_reads is %Key_reads%." to the Advice text box. When this is displayed on the screen, the value of %Key_reads% is substituted into the text. Supposing %Key_reads% has a value of 4522, the message becomes "The current value of Key_reads is 4522."

15.7.4.4. Thresholds

Each expression has a threshold value that triggers an alert. The THRESHOLD keyword is used to associate that value with an alert level—either an Info, Warning, or Critical alert.

For example, the expression for the performance advisor, "Thread Cache Size May Not Be Optimal", is:

```
100-((%Threads_created% / %Connections%) * 100) < THRESHOLD
```

The THRESHOLD is set at 95% for an Info level alert, 85% for a Warning alert, and 75% for a Critical alert; producing alerts of three different levels.

Expressions can be quite simple. The expression for "Binary Logging Not Enabled" (one of the Administration alerts) is:

```
%log_bin% == THRESHOLD
```

When the result is OFF, only one alert is triggered—a Warning level alert. In this situation you might think we could just use the expression %log_bin% == "OFF". However, doing this would not test binary logging against a threshold so would not result in an alert.

When you create an expression, think carefully about the conditions under which it should be evaluated and the conditions under which it should not. For example, the expression for the "MyISAM Key Cache Has Sub-Optimal Hit Rate" rule is:

```
(%Uptime% > 10800) && (%Key_read_requests% > 10000) »
 && (100-((%Key_reads% / %Key_read_requests%) * 100) < THRESHOLD)
```

The essence of the rule is really: (100-((%Key_reads% / %Key_read_requests%) * 100) < THRESHOLD). However, when a server is first starting up, it may take a while to reach a state that is representative of normal operations. For example, the key cache and the query cache may need some period of time before they have cached typical application data as opposed to start-up and initialization data. In this case, the first part of the expression, (%Uptime% > 10800), holds off evaluating this expression until the system has been running for 10800 seconds (3 hours).

In addition, if some part of the system is not heavily used an alert may be triggered based on limited data. For example, if your application does not use the MyISAM storage engine, the "MyISAM Key Cache Has Sub-Optimal Hit Rate" rule may be triggered based on very limited use of other MyISAM tables such as the mysql.user table. For this reason, this advisor has a second part—(%Key_read_requests% > 10000)—meaning the rule won't be evaluated unless there is plenty of activity associated with the key cache.

In other circumstances, there may be periods of time during which you don't want a rule to be evaluated—a blackout period. For example, the expression for the "Slave Too Far Behind Master" rule is: %Seconds_Behind_Master% > THRESHOLD. However, suppose you run a backup process between 6 and 7 pm on a replication slave, and it's normal for that slave to get behind the master by an amount more than the THRESHOLD during that time. In that case you don't want to receive an alert because the rule violation is expected. You can achieve this by adding the following to the expression: && CURTIME() NOT BETWEEN '18:00:00' AND '19:00:00' In essence, this means "don't trigger an alert between 18:00:00 and 19:00:00 (6 pm and 7 pm)".

15.7.4.5. Using Strings

String values may appear in the Expression or the Thresholds text boxes. In both cases, they must be enclosed within quotation marks. For example, the expression for the "Slave I/O Thread Not Running" rule is:

```
(%Slave_running% == "ON") && (%Slave_IO_Running% != THRESHOLD)
```

In similar fashion the `Critical Alerts` threshold text box is set to a value of `"Yes"`.

When the expression is evaluated, either `"OFF"` or `"ON"` will be substituted for `%Slave_running%`, and `"Yes"` or `"No"` for `%Slave_IO_Running%`, depending on the state of your system. If the slave is running but the I/O thread is not, the expression then becomes:

```
("ON" == "ON") && ("No" != "Yes")
```

Without quotation marks this expression would not evaluate to `TRUE` as it should.

> **Note**
>
> So that it is interpreted properly, the `==` operator is converted to `=` before being passed to the MySQL expression parser.

15.7.4.6. Wiki Format

When editing or defining a rule, the text entered in the `Problem Description`, `Advice`, `Recommended Action`, and `Links and Further Reading` text boxes may be formatted in Wiki format. This allows you to format text and add hyperlinks when creating or editing your own rules.

Find a brief introduction to using Wiki formatting in the following table.

Table 15.1. MySQL Enterprise Monitor: Wiki Formatting

Example	Description
__*bold*__	boldface text
~~*italic*~~	italicize text
\\	create a line break
\\ \\	create a double line break
G	create a backslash
**item 1*	create a bulleted list item
#*item 1*	create a numbered list item
_	use the '\' to escape special characters
{moreInfo:name|url}	create a hyperlink

So the following Wiki text:

```
Replication is a __very nice feature__ of MySQL.  Replication can be very
useful for solving problems in the following areas:
* Data Distribution
* Load Balancing
* Backup and Recovery
You can check replication status and start a slave using the following
commands: SHOW SLAVE STATUS \\\\G\\START SLAVE;
{moreInfo:MySQL Manual: Replication
      FAQ|http://dev.mysql.com/doc/refman/5.0/en/replication-faq.html}
```

Would be translated into the following HTML markup:

```
Replication is a <b>very nice feature</b> of MySQL.  Replication can be very
useful for solving problems in the following areas:
<ul>
  <li>Data distribution</li>
  <li>Load Balancing</li>
  <li>Backup and recovery</li>
</ul>You can check replication status and start a slave with the following
commands: SHOW SLAVE STATUS \G;<br/>START SLAVE;
<a href="../mysql-monitor-common/http://dev.mysql.com/doc/refman/5.0/en/replication-faq.html"
  target="_blank" >MySQL Manual: Replication FAQ</a>
```

To find out more about this format go to the wikipedia.org web site.

15.7.4.7. Creating a New Rule: An Example

This section documents the steps required to create a rule. Before attempting to create a rule, please review the preceding sections of this chapter.

This example creates a rule that checks the number of rows in a table. Having 50,000 rows in this table is deemed to warrant a critical alert. Lesser numbers are assigned to informational and warning level alerts.

Begin by navigating to the `Advisors` tab and clicking the `manage rules` link. Then choose the CREATE RULE button.

Create your custom rule by following these steps:

1. Using the `Rule Name` text box, give the rule an appropriate name. Something such as "Excessive number of records in *`table_name`* table", may be appropriate.
2. From the `Advisor` drop down list box choose an advisor group for your rule. The `Administration` group of rules might be suitable but if you wish, create your own group of advisors. For instructions on doing this see Section 15.7.4.1, “Creating Advisors”.
3. Enter the following expression in the **EXPRESSION** text area: '%*`table_name`*_num_rows% > THRESHOLD'. Replace *`table_name`* with the name of the table you wish to monitor. Note that the variable `%`*`table_name`*`_num_rows%` has not yet been defined.
4. Set the Thresholds.
   a. Set the `Critical Alert` level to `50000`.
   b. Set the `Warning Alert` level to `10000`.
   c. Set the `Info Alert` level to `5000`.
5. Define your variable in the `Variable Assignment` frame.
   a. In the `Variable` text box enter `'%`*`table_name`*`_num_rows%`, the variable used in the `Expression` text box
   b. In the `Data Item` drop down list box find and select the `mysql:table:numrows` entry. (For a description of all the data items available see Data Collection Items.)
   c. In the `Instance` text box enter *`database_name.table_name`*.
6. Add appropriate entries for the `Problem Description`, the `Advice`, and the `Links` text areas. If you wish, use Wiki markup for these text areas. See Section 15.7.4.6, “Wiki Format” for more information. Note that you can also reference the `'%`*`table_name`*`_num_rows%` variable in these text areas. For example, you can display the current number of rows with a message such as '*`table_name`* currently has %*`table_name`*_num_rows% rows.'
7. Save the rule.

Once the rule is created it needs to be scheduled against the server that contains the database table you wish to monitor. For instructions on scheduling rules see Section 15.7.2, “Scheduling Rules”.

15.7.5. Creating a Custom Data Collection Item

Section 15.7.4.7, “Creating a New Rule: An Example” shows how to create a custom rule and Data Collection Items shows the data items that can be used in rule creation. However, in some circumstances you may want to create a rule that uses a custom data collection item.

You can create additional custom data collection items by editing the `share/mysql-proxy/items/custom.xml` custom rule file added during installation. The `custom.xml` is installed automatically, but is not affected when running an upgrade installation. The rules file is listed last in the `agent-item-files` configuration parameter, which means that any rules and data collection items added to this file will supercede the standard data collection definitions.

Once you have made changes to the `custom.xml`, you must restart the agent to load the custom definitions.

15.7.5.1. Modifying the Custom Data Item XML File

As an example, this section shows how to create a data item for monitoring the amount of free InnoDB tablespace. You can have multiple items in your `custom.xml` file, just specify additional `class` entries. A sample entry is provided in the `custom.xml` file that is included during installation. You can replace, or add the following definition to the file:

```
<?xml version="1.0" encoding="utf-8"?>
<classes>
  <class>
    <classname>innodb_min_free</classname>
    <namespace>mysql</namespace>
    <query><![CDATA[SELECT MIN(substring_index(substring_index(table_comment," ",3)," ",-1)/1024/1024)
      as Free FROM INFORMATION_SCHEMA.TABLES WHERE engine = 'InnoDB']]></query>
  </class>
</classes>
```

After saving the file, ensure that the `agent-item-files` parameter within the configuration includes the `custom.xml` file. For example:

```
[mysql-proxy]
 ...
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml,»
      share/mysql-proxy/items/agent-allocation-stats.lua,share/mysql-proxy/items/custom.xml
 ...
```

For this change to take effect you must restart the agent. To do this see:

- Windows: Section 15.3.3.5.1, “Starting/Stopping the Agent on Windows”
- Unix: Section 15.3.3.5.3, “Starting/Stopping the Agent on Unix”
- Mac OS X: Section 15.3.3.5.2, “Starting/Stopping the Agent on Mac OS X”

Once the agent has restarted, you will find the new data item in the `Data Item` drop down list box on the `Rule Definition` page. Its fully qualified name is `mysql:table:innodb_min_free`.

15.7.6. Disabling and Unscheduling Rules

In some circumstances you may no longer wish to apply a rule against a specific server or group of servers and in other circumstances you may want to suspend a rule for a short length of time. With this in mind, it is possible to disable or unschedule a rule.

To disable or unschedule an advisor choose the `Current Schedule` screen of the `Advisors` tab.

Rules may be disabled or unscheduled using the buttons on the upper or lower left of the screen. You may also change a rule by clicking the `enabled` or `unschedule` hyperlink to the right of a rule. The buttons are particularly useful when you are altering more than one rule.

To no longer run a rule against a specific server, expand the advisor group and the specific rule by clicking the + button. You may then click the UNSCHEDULE button. When the dialog window opens, choose the UNSCHEDULE button and that rule will no longer be applied. If you wish to back out of the operation choose CANCEL. If, at a later date, you wish to institute this rule again, you may do so from the `Add to Schedule` page.

If you want to suspend a rule temporarily, use the DISABLE button and follow the same process you would for unscheduling. Once a rule is disabled the link under the status column changes to red and reads `disabled`. When a rule is disabled, data is no longer collected for that rule. A disabled rule is easily re-enabled by clicking the `disabled` link or by using the ENABLE button.

Multiple rules may be altered for one or more servers by selecting the appropriate checkbox and then clicking the UNSCHEDULE, ENABLE, or DISABLE button.

> **Note**
>
> Rules associated with the heat chart cannot be disabled or unscheduled as they are required by MySQL Enterprise Monitor.

15.7.7. Advisor Blackout Periods

Database servers require regular maintenance and during these periods you may wish to stop Monitor Agents from reporting their findings. During a blackout period rules are not evaluated and notifications are put on hold but Monitor Agents continue to collect data . In this respect blacked-out rules differ from disabled rules; data continues to be collected and stored in the repository.

Blackout periods are enabled by entering the following URL into the address bar of your browser, substituting the appropriate host name, port and server name:

```
http://localhost:18080/rest?command=blackout »
 &server_name=SuSE:3306&blackout_state=true
```

If you are unsure of the host name and port to use, check the `configuration_report.txt` file. Be sure to specify the correct port for the Tomcat server. Specify the server you wish to blackout using the name that appears in the Server Tree, being sure to include a colon and port number as shown in the preceding example.

An HTTP authentication dialog box requesting your Dashboard user name and password will open. Specify the administrator's credentials. The default user name is `admin`; use the password you specified when you initially logged in to the Dashboard.

You can also blackout a server group by entering the following URL into the address bar of your browser, substituting the appropriate host name, and server group name:

```
http://localhost:18080/rest?command=blackout »
 &group_name=Finance&blackout_state=true
```

When the HTTP authentication dialog box opens, enter the administrator's credentials.

You can confirm that a server is blacked out by looking at the server name in the Dashboard; the name of a blacked out server is greyed.

To reactivate the blacked-out server or server group, use the appropriate URL and query string, changing the `blackout_state=true` name/value pair to `blackout_state=false`. Again, this must be done by a user with administrative privileges.

> **Note**
>
> Restarting MySQL Enterprise Monitor will **not** reactivate a blacked out server.

15.7.7.1. Scripting Blackouts

Rather than opening your web browser and blacking out a server by typing entries into the address bar, you can write a script to achieve the same effect. This section documents a sample blackout script that can be run from the command line.

Create the following file and save it as `blackout.pl`.

```
#!/usr/bin/perl
use LWP 5.64;
# USAGE: blackout.pl servicemanager:18080 admin password servername:3306 true
# $ARGV[0] = management server hostname:port
# $ARGV[1] = management server username
# $ARGV[2] = management server password
# $ARGV[3] = mysqld managed instance server name and port
# $ARGV[4] = blackout state (true/false)
my $browser = LWP::UserAgent->new;
$browser->credentials(
  $ARGV[0],
  '',
  $ARGV[1],
  $ARGV[2]
);
my $url = URI->new('http://'.$ARGV[0].'/rest');
$url->query_form( # And here the form data pairs:
  'command' => 'blackout',
  'server_name' => $ARGV[3],
  'blackout_state' => $ARGV[4]
);
my $response = $browser->post( $url );
if (!$response->is_success) {
  die $response->status_line . "\n";
}
```

> **Note**

Windows users can omit the shebang line.

On Unix systems use the `chmod +x blackout.pl` command to make the file executable.

At the command line enter **`blackout.pl servicemanager:18080 admin password servername:3306 true`**.

If you are unsure of the host name and port to use, check the `configuration_report.txt` file. Be sure to specify the correct port for the Tomcat server. Specify the server you wish to blackout using the name that appears in the Server Tree, being sure to include a colon and port number as shown in the preceding example. Make sure that the user you specify is a "manager". Specifying a user with "dba" rights only will not black out a server and no error will be displayed.

You can confirm that a server is blacked out by looking at the server name in the Dashboard; the name of a blacked out server is greyed. To end the blackout, run the same script, changing the final argument to `false`.

Note

Restarting MySQL Enterprise Monitor will **not** reactivate a blacked out server.

15.8. The Events Page

Note

MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

Once an advisor has been scheduled, it will run at set intervals. If it finds nothing of interest no alerts or emails will be created.

Events are defined using a number of different levels according to the severity of the alert. The seven levels are

- **Failure**: Indicates a failure for the given rule or event. Usually this indicates that the rule on which the event is based has failed, probably due to a typo or other error. Occasionally it can indicate a failure to retrieve the required information for a given rule.
- **Critical**: The event is critical and requires immediate attention. Critical events normally indicate that a serious problem has, or is about, to occur. You should examine the event and determine the cause and fix it as soon as possible.
- **Warning**: The event is a warning of something that you should be aware of, but which is not affecting the operation of your server.
- **Info**: The event is for informational purposes. Info events are used to indicate issues that do not affect the operation of your server, but which may highlight a minor configuration or other issue.
- **Success**: The rule has executed successfully with no issues. This is used to indicate that the result of the rule is OK and is used to indicate when an event that was previously in a Critical or Failure state has returned to normal.
- **Unknown**: Indicates when the current state of the event/rule is currently unknown. This state can be issued when the current status of the event cannot be determined.
- **Closed**: The issue has been corrected and marked closed.

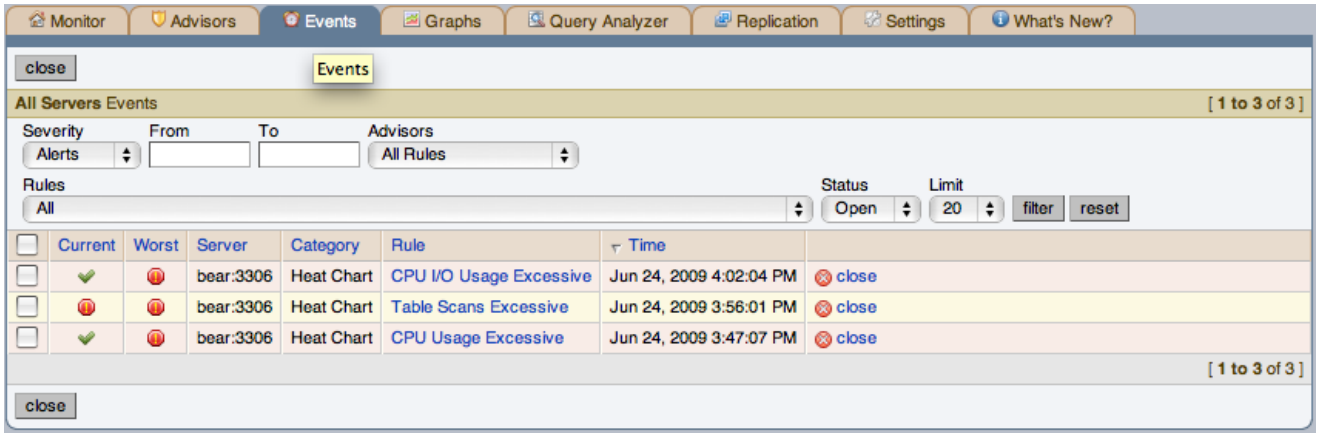
For convenience, the event states are also represented by icons, as defined in the table below. The table also shows the relative level of the alert from the highest (Critical) to the lowest (unknown). The order represented here is used when identifying when an event has transitioned between levels (for example, from Success to Critical), hence triggering a notification, and when sorting events based on their current state.

Icon	Description
	An octagonal red icon indicates a critical alert.
	A triangular yellow icon a warning.
	A conversation bubble an informational alert.
	A green tick beside an event indicates that the rule has run successfully and no alert created.
	A question mark icon indicates that the status of the rule is unknown.

When alerts are triggered, they appear on the **EVENTS** screen. Alerts also appear on the `Monitor` screen in order of severity. The notification group or groups associated with a specific rule receive email notification when an alert is triggered. For more information about creating notification groups see Section 15.5.5, "Manage Notification Groups".

To view open events, click the **EVENTS** tab. The tree-view on the left determines which server or server group these events belong to. Open events are shown in tabular format.

Figure 15.44. MySQL Enterprise Dashboard: Events Screen



The event table has the following columns:

- **CURRENT**: An icon indicating the current severity of the alert
- **WORST**: An icon indicating the worst severity recorded for this alert
- **SERVER**: The name of the server the alert applies to
- **ADVISOR**: The category of the advisor
- **RULE**: A short description of the rule that has been violated
- **TIME**: The approximate time the event occurred
- **STATUS**: The status of the event
- **UNNAMED COLUMN**: Provides a link to the `Close` dialog box

By default, all events are shown but the list of events can be filtered using the form displayed above the event list. The options include filtering by:

- Severity
- Date (using a range with From/To)
- Advisor group
- Specific rule
- Status

Choose the options you are interested in and click the FILTER button to refresh the display. You may limit the number of items that appear on a page by choosing a different value from the **LIMIT** drop down listbox.

The drop down list box showing severity has the options: `All`, `Alerts`, `Critical`, `Warning`, `Info`, `Success`, and `Unknown`. Selecting the option `All` shows all alerts and also those rules that have run successfully.

A successful rule is one that has not been violated and is indicated by a green tick icon.

The `Alerts` shows only those rules that have been violated.

Columns can be sorted by clicking the individual column headings. The alerts shown in Figure 15.44, "MySQL Enterprise Dashboard: Events Screen".

The server shown in Figure 15.44, "MySQL Enterprise Dashboard: Events Screen", is filtered for `All`. Typically, when filtering by severity you would choose `Alerts` and, if you see a `Critical`, `Warning`, or `Info` alert, use the `All` filter to see when the rule last ran successfully. This may assist in determining the cause of the alert.

Besides filtering for severity, you can also choose to filter for a specific time period using the `From` and `To` text boxes. You also have the choice of filtering by specific rules or categories of rules. The `Status` drop-down list box let's you choose `All`, `Open`, or `Closed` events. To avoid excessive scrolling, you can also limit the number of events that show on a specific page.

For more information about an alert, click the rule name. A pop-up window will appear showing a description of the alert and the exact time of occurrence. This pop-up windows provides links to useful resources and advice for resolution. You can also view the exact expression that generated the event.

15.8.1. Closing an Event

After determining what action to take, events should be closed.

To resolve an individual alert click the `close` link in the **OPERATIONS/NOTES** column. Document the resolution using the `Notes` text area and choose the CLOSE EVENT(S) button.

To close a number of alerts simultaneously, select the checkbox beside the alerts you wish to close and then click the CLOSE button to the lower or upper left side of the screen.

Once an event has been closed it appears on the **EVENTS** screen showing a `resolution notes` link. Click this link to review the notes. Events that have been closed are saved in the Repository. If you wish to view closed events filter the display by choosing `Closed` from the **STATUS** drop-down box.

15.8.2. Notification of Events

If you have created notification groups and then configured individual rules to send their notification to one or more groups then the notification works as follows:

- Notification of an event takes place when a rule is executed and the severity level for a given rule changes. For example, if during execution of a rule, the result of the rule goes from severity level `Success` to `Critical`, the configured notification groups will get one email with the detail of the event and current status.
- If the status of the event has not changed when the rule is next executed, no new email is sent.

  This is true whether the rule is executed as part of it's normal schedule or execution of the rule has been explicitly requested.

SNMP notifications are sent each time a given rule is executed, irrespective of the current or returned state.

15.9. The Graphs Page

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

Navigate to the `Graphs` page by choosing the **GRAPHS** tab.

By default four graphs are displayed on the `Monitor page`. These graphs present information about the currently selected server or server group, showing the hit ratios, CPU utilization, connections, and database activity. Color coding helps distinguish different aspects

of each graph.

From the Monitor page you can make permanent or temporary changes to the way a graph is displayed. For example, you can choose to display the last hour's activity or you can choose to view a specific period of time.

Persistent changes to the way the graphs display are only made from the Monitor page. You can set the size of the thumbnails and the full-sized graphs and you can also set their refresh interval. For more information, see Section 15.4.2, "The Server Graphs and Critical Events". As with the Monitor page, the data shown in the graphs is determined by the server or group of servers selected in the server tree.

The Graphs page shows all the available graphs and provides the capability of adjusting the scale of the graphs, allowing a more or less detailed view as the situation requires. To ensure that you have the latest versions of the various graphs click on the **CHECK FOR UPDATES** link on the top left of this page.

All graphs support the ability to drag and select a specific area of the graph. When you select an area of the graph, the display changes to the **QUERY ANALYZER** tab and displays the queries that were being executed during the selected time period. You can also zoom into the graph by selecting specific time periods. For more information on using the graphs to monitor the execution of specific queries, see Section 15.10.3, "Using Graphs to Identify Queries".

15.9.1. Displaying Graphs

The total number of graphs varies depending upon your subscription level. The four graphs that appear by default on the Monitor page are:

- Hit Ratios
- Database Activity
- Connections
- CPU Utilization

When the Graphs page is first opened, no graphs are visible. To view a graph click the + button on the left or, to view all graphs, use the EXPAND ALL button.

The larger size of graphs is the primary reason for viewing graphs on the Graphs page rather than on the Monitor page. Additionally, you can only show a maximum of six graphs on the Monitor page; the remaining graphs can only be viewed from the Graphs page.

15.9.2. Setting an Interval

Change the interval for a graph by choosing values from the **HOURS** and **MINUTES** drop-down list boxes. If necessary adjust the width and height of the graph and then click the UPDATE button. The changes to the time span apply to all the graphs on the Graphs page but have *no* effect on the graphs on the Monitor page.

To change the graphs both here and on the Monitor page use the configure graphs link on the top right. This opens a dialog box for setting the default interval for the x-axis. Save any changes that you have made and the values chosen will be the defaults whenever you log in. You can also change the defaults from the Monitor page as described in Section 15.4.2, "The Server Graphs and Critical Events"; defaults for other users will be unchanged.

Use the RESET button to restore the default value for the interval. Doing this will also reset the default size of the graphs.

15.9.3. Setting a Time Span

Setting a graph to display a time span gives you a historical perspective on server activity. You may want to know what was happening at a specific point in time or you may wish to look at an extended period in order to determine patterns or trends. Changing the time span gives you the flexibility to do this.

In the **TIME DISPLAY** drop-down list box select the From/To option. Choosing this option updates the display to include **TO** and **FROM** text boxes.

Set the date you wish to start viewing from by manually entering the date in year, month, and day format (2007-03-14). However, it is much easier to click the calendar icon and choose a date from the drop-down calendar. Enter a terminating date in the same way. If you

wish, you may also choose the specific time of day by selecting the hour and minute.

If necessary adjust the width and height of the graph and then click the UPDATE button. The changes to the time span apply to all the graphs on the `Graphs` page but have *no* effect on the graphs on the `Monitor` page. You cannot change the time span of the graphs that appear on the `Monitor` page. Changes apply only to the current user; defaults for other users will be unchanged.

Use the RESET button to cancel your changes.

15.10. The Query Analyzer Page

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

Query Analyzer enables you to monitor the statements being executed on a monitored server and retrieve information about the query, number of executions and the execution times of each query. Queries are normalized, so that the unique data defined within each query has been removed. By removing the data specific elements of the queries, the generic queries can be counted and identified more easily.

> **Important**
>
> MySQL Query Analyzer is designed to gather query performance information from a variety of sources. Query Analyzer uses a new agent plug-in to proxy your queries and collect performance data that is then transmitted to the Enterprise Monitor. This is a new role for the Agent: it is no longer just monitoring, it is now *optionally* between your MySQL client application and the mysql server.
>
> Depending upon your system load, it is possible to overload the proxy or have the proxy/agent consume system resources needed by mysql itself. In particular, the memory needed by the MySQL Agent for basic monitoring is fairly small and consistent and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example `EXPLAIN`s being processed plus the network bandwidth required to send this query performance data to the Service Manager. In general, the amount of memory used for the Query Analyzer is well-bounded, but under heavy load or, in some cases under older versions of linux, RAM usage by Query Analyzer may be too high for your environment and load.
>
> Therefore we advise you to use this release of Query Analyzer extensively in development, test and stage environments under load for an extended period of time before considering usage in a production environment. For all deployments:
>
> 1. Carefully monitor the Agent's resource consumption using the new graph **MEMORY USAGE - AGENT** graphs available on the **GRAPH** tab. You can also add an SMTP or SNMP notification to the new Heat Chart rule **MYSQL AGENT MEMORY USAGE EXCESSIVE**.
> 2. If the amount of memory consumed is too high, consider sampling queries during nonpeak hours or monitoring only a subset of queries on this system.
>
> If you experience any problems with Query Analyzer, we're interested in working with you closely and quickly to resolve them. Please open a Support issue right away. We're already working hard on optimizing Agent/proxy RAM usage and are planning a series of rapid releases to quickly distribute these and other improvements to you.

Query Analyzer works by intercepting the SQL statements that your MySQL client application sends to the MySQL server. Instead of connecting direct to the MySQL Server, queries are routed through the MySQL Enterprise Monitor Agent, the agent/proxy forwards the queries on to the server and sends the replies back to the client application as normal. In addition to forwarding the queries, the agent/proxy will also normalize the queries and then supply the execution information about each query to the monitor. The forwarding functionality is provided by the same module that supports the MySQL Proxy application. For information on MySQL Proxy, see Section 14.6, “MySQL Proxy”.

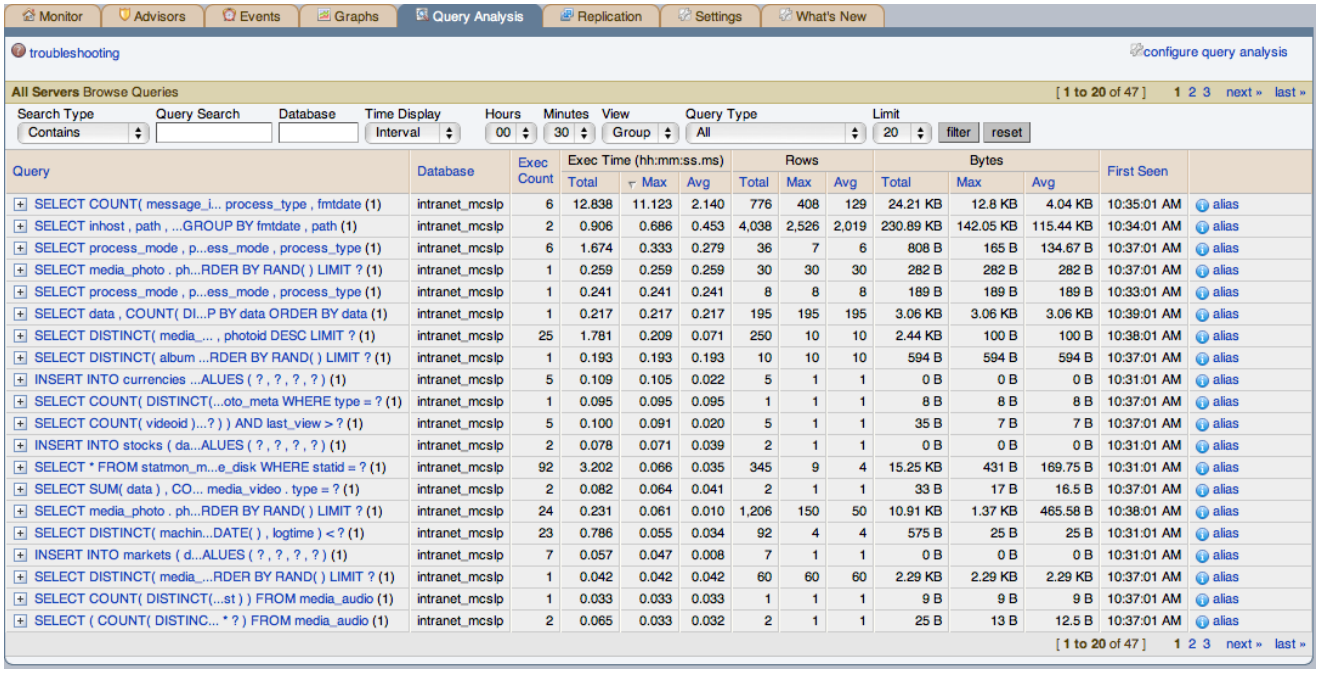
> **Important**
>
> The MySQL Proxy component, and Query Analyzer, require that clients connecting through MySQL Enterprise Monitor Agent are using MySQL 5.0 or later. Clients that use the library provided with MySQL 4.1 or earlier will not work with MySQL Enterprise Monitor Agent.

Once your MySQL client application has been configured to communicate via the MySQL Enterprise Monitor Agent, queries will be monitored and the simplified queries, without the query specific data, will be sent to the MySQL Enterprise Monitor Agent.

There are a number of different ways that you can enable Query Analysis. For more information on the different options, see Section 15.10.1, “Enabling Query Analyzer”.

To analyse the queries captured by the agent/proxy, change to the `Query Analyzer` page. You can see an example of the table on that page in the figure below.

Figure 15.45. MySQL Enterprise Dashboard: Query Analyzer



The main Query Analyzer table provides the summary information for all of the queries executed via the agent/proxy. The table will track all the queries submitted to the server via the agent/proxy. The table will show a maximum of 20 rows, and you can page through the list of queries by using the page numbers, or the **NEXT**, **PREVIOUS**, **FIRST**, and **LAST** buttons. To filter the list of queries that are displayed, or to change the number of queries, see Section 15.10.4, “Filtering Query Analyzer Data”.

Each row within the table provides the statistical information for one normalized query statement. If you have configured multiple agent/proxies to accept and forward queries to different servers, then you can expand the server view. The summary information displayed is different depending on whether you have selected a server group or an individual server.

If you have selected a server group, then the information displayed is aggregated from across the entire group. The same query executed on multiple servers will show average, total and minimum/maximum information for that query across all the servers. If you select an individual server, then only queries executed on that server are included within the table.

For each row, the following columns are populated according to the selected filtering options. For example, if the filter have been configured to show queries within the last 30 minutes (**INTERVAL**), then only queries executed during that time will be displayed, and the corresponding statistics, such as execution times, rows returned and bytes returned will be according to that 30 minute timespan.

- **QUERY**: The normalized version of the query. Normalization removes the query-specific data so that different queries with different data parameters are identified as the same basic query.

  The information is shown as one query per row. Each query row is expandable, and can be expanded to show the execution times for individual servers for that query.

- **DATABASE**: The default database in use at the time of the query. The database name may not match the database used within the query if you have have explicitly stated the database name in the query.

- **EXEC COUNT**: The number of times that the query has been executed.
- **EXEC TIME**: The execution time for all the matching queries. This is the time, for every invocation of the corresponding query, as calculated by comparing the time when the query was submitted and when the results were returned by the server. Times are expressed in HH:MM:SS.MS (hours, minutes, seconds, and milliseconds).

  The **EXECUTION** column is further subdivided into the following columns:

  - **COUNT**: The total number of executions.
  - **TOTAL**: The cumulative execution time for all the executions of this query.
  - **MAX**: The maximum execution time for an execution of this query.
  - **AVG**: The average execution time for the execution of this query.

  When looking at the information provided in this query, you should consider comparing the average and maximum execution times to see if there was a problem on a specific server or during a specific time period when the query took place, as this may indicate an issue that needs to be investigated. For more information, see Section 15.10.5, "Using Query Analyzer Data".

  > **Note**
  >
  > Due to limitations in the counters used for monitor queries on Windows, the time reported for short queries may be reported 0.000. This will be fixed in a future release.

- **ROWS**: The rows returned by the query. The column is sub-divided into the following columns:
  - **TOTAL**: The sum total number of rows returned by all executions of the query.
  - **MAX**: The maximum number of rows returned by a single execution of the query.
  - **AVG**: The average number of rows returned by all executions of the query.
- **BYTES**: The number of bytes returned by each query. The column is sub-divided into the following columns:
  - **TOTAL**: The sum total bytes returned by all executions of the query.
  - **MAX**: The maximum number of bytes returned by a single execution of the query.
  - **AVG**: The average number of bytes returned by all executions of the query.
- **FIRST SEEN**: The first time the query was seen within the given filter conditions.

You can sort the list of queries by clicking the column name. The direction of the sort (highest to lowest, or lowest to highest) is indicated by a triangle next to the currently selected column. The default is to sort the list of queries by the Total Execution time.

15.10.1. Enabling Query Analyzer

There are three different ways of enabling query analyzer:

- Change your MySQL client application to talk to the Proxy port you configured during installation. This requires changing your MySQL client application code, and may require that you stop and restart your MySQL client application , but does not require any changes to your MySQL server. For more information, see Section 15.10.1.1, "Enabling Query Analyzer by Changing the MySQL Client Application".
- Change your MySQL server to listen on a different port, and configure the Agent/proxy to listen on the original MySQL server port. This does not require any changes to your MySQL client application , but will require shutting down and restarting your MySQL server, which may affect your cache and performance. For more information, see Section 15.10.1.2, "Enabling Query Analyzer by Changing MySQL Server".
- Use IP tables to redirect the network packets to the agent/proxy.

> **Important**

MySQL Query Analyzer is designed to gather query performance information from a variety of sources. Query Analyzer uses a new agent plug-in to proxy your queries and collect performance data that is then transmitted to the Enterprise Monitor. This is a new role for the Agent: it is no longer just monitoring, it is now *optionally* between your MySQL client application and the mysql server.

Depending upon your system load, it is possible to overload the proxy or have the proxy/agent consume system resources needed by mysql itself. In particular, the memory needed by the MySQL Agent for basic monitoring is fairly small and consistent and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example `EXPLAIN`s being processed plus the network bandwidth required to send this query performance data to the Service Manager. In general, the amount of memory used for the Query Analyzer is well-bounded, but under heavy load or, in some cases under older versions of linux, RAM usage by Query Analyzer may be too high for your environment and load.

Therefore we advise you to use this release of Query Analyzer extensively in development, test and stage environments under load for an extended period of time before considering usage in a production environment. For all deployments:

1. Carefully monitor the Agent's resource consumption using the new graph **MEMORY USAGE - AGENT** graphs available on the **GRAPH** tab. You can also add an SMTP or SNMP notification to the new Heat Chart rule **MYSQL AGENT MEMORY USAGE EXCESSIVE**.

2. If the amount of memory consumed is too high, consider sampling queries during nonpeak hours or monitoring only a subset of queries on this system.

If you experience any problems with Query Analyzer, we're interested in working with you closely and quickly to resolve them. Please open a Support issue right away. We're already working hard on optimizing Agent/proxy RAM usage and are planning a series of rapid releases to quickly distribute these and other improvements to you.

Note that you must have enabled Query Analyzer within the agent/proxy during installation. If you did not enable Query Analyzer during the installation of the agent/proxy, check the following elements within the main `mysql-monitor-agent.ini` configuration file:

- Add the `proxy` plugin to the `plugins` parameter:

```
plugins=proxy,agent
```

- Ensure that the `quan.lua` items file is enabled in the `agent-item-files` configuration property:

```
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
```

- Check and set the `proxy-address`, `proxy-backend-addresses`, and `proxy-lua-script` settings are configured:

```
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script        = share/mysql-proxy/quan.lua
```

For more information on these configuration options, see Section 15.3.3.6.1, “MySQL Enterprise Monitor Agent (`mysql-monitor-agent.ini`) Configuration”.

Note

The Query Analyzer functionality may show as being enabled on a server, even though the modules within MySQL Enterprise Monitor Agent may not have been enabled.

You may also need to make some additional changes to the security configuration on your server to ensure that queries are correctly reported to MySQL Enterprise Service Manager:

- You must ensure that each user configured within your MySQL client application that connects through the agent/proxy and is required to report query analyzer information is allowed to connect to the server from the host on which the agent/proxy is running. When the user connects to the agent/proxy, and the agent/proxy connects to the server the host of the agent/proxy will be used as the

identifying client host name during the connection.

> **Warning**
>
> Because the proxy is providing the immediate connectivity to the MySQL server, authentication must use the proxy hostname, not the client hostname.

To update your user credentials, you need to use the `GRANT` statement. For example:

```
mysql> GRANT SELECT,UPDATE,INSERT on database.* to 'user'@'localhost' IDENTIFIED BY 'password';
```

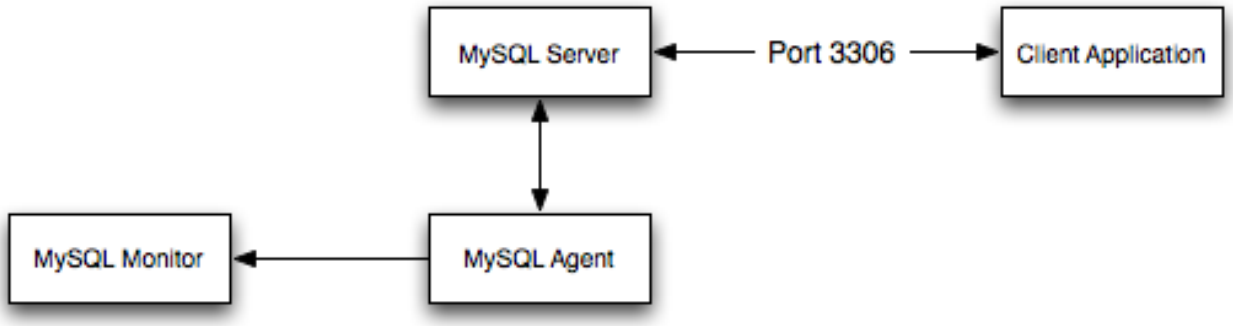
- The MySQL client application user must have `SELECT` privileges on the `mysql.inventory` table. This table contains the server UUID and is required to report the query analyzer data to the MySQL Enterprise Service Manager. To enable this, use the `GRANT` option:

```
mysql> GRANT SELECT on mysql.inventory to 'user'@'localhost' IDENTIFIED BY 'password';
```

15.10.1.1. Enabling Query Analyzer by Changing the MySQL Client Application

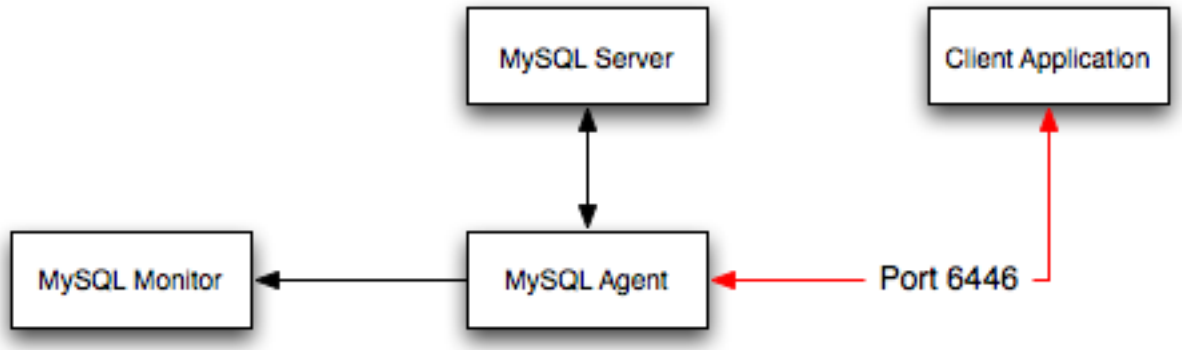
Generally, changing your MySQL client application is the easiest and recommended method. For example, given a typical structure like the one shown in the figure below, the client application would need to be modified so that it no longer communicated directly with the MySQL server, but to the agent/proxy.

Figure 15.46. MySQL Enterprise Dashboard: Standard Agent/Monitor Topology



You can see an example of the structure when communicating via the agent/proxy below.

Figure 15.47. MySQL Enterprise Dashboard: Query Analyzer Agent/Monitor Topology



To enable query analyzer within your MySQL client application:

1. Make sure that the MySQL Enterprise Service Manager and your MySQL Enterprise Monitor Agent are configured and running.
2. Confirm the configuration of your agent by examining the contents of the `etc/mysql-monitor-agent.ini` file within your installed Agent directory.

   Queries will be sent to the host specified in the `proxy-backend-addresses` parameter, and the agent will listen for connections to be redirected to the server on the host name and port configured in the `proxy-address` parameter.
3. Now modify your MySQL client application to communicate with the address specified in the `proxy-address` parameter.

   Alternatively, if you do not want to modify your application directly, you can use iptables or firewall rules to redirect queries from the original host/port combination to the agent's port.

   Because connections to the MySQL server will be coming from the agent/proxy, not the original host, the user credentials used must be have a suitable `GRANT` statement for connections from `localhost`, or the host on which the agent/proxy is executing. The user name and password information will be passed on directly through the agent/proxy from the client to the server.
4. Confirm that your MySQL client application still operates normally. There should be no difference between communicating directly with the MySQL server and communicating via the agent/proxy.

Note

If you are using the `mysql` client to connect to the agent/proxy and your backend servers, make sure that you are communicating with the proxy over the right port. By default, if you specify `localhost` as the host name, then `mysql` will connect using the local Unix domain socket, rather than the TCP/IP socket.

You can enforce `mysql` to use the right port either by explicitly requesting the protocol type, or by using the IP address rather than `localhost`. For example, both of these command lines will start the client using the right protocol:

```
shell> mysql --port=6446 --protocol=tcp
shell> mysql --port=6446 --host=127.0.0.1
```

Note

It is recommended that you use one agent/proxy per MySQL server instance. The agent/proxy is not able to forward queries to multiple MySQL server backends.

15.10.1.2. Enabling Query Analyzer by Changing MySQL Server

When enabling Query Analyzer by changing the MySQL Server, you need to shutdown your server, edit the MySQL configuration file, and then restart MySQL. You will also need to change your Agent/proxy configuration so that the Agent/proxy is listening on the original MySQL TCP/IP port. To use this method:

1. Edit the `/etc/my.cnf` or other MySQL configuration file and change or add the `port` setting from it's current value (default 3306), to another value. For example:

   ```
   port                                    = 3307
   ```
2. Shutdown your MySQL Server.
3. Startup your MySQL Server and confirm that is running.
4. Edit your MySQL Enterprise Monitor Agent configuration so that the agent/proxy is listening for connections on the original MySQL port:

   ```
   proxy-address=:3306
   proxy-backend-addresses = 127.0.0.1:3307
   ```
5. Stop and restart MySQL Enterprise Monitor Agent.

You should now be able to connect to your MySQL server through the MySQL Enterprise Monitor Agent by connecting on the original port:

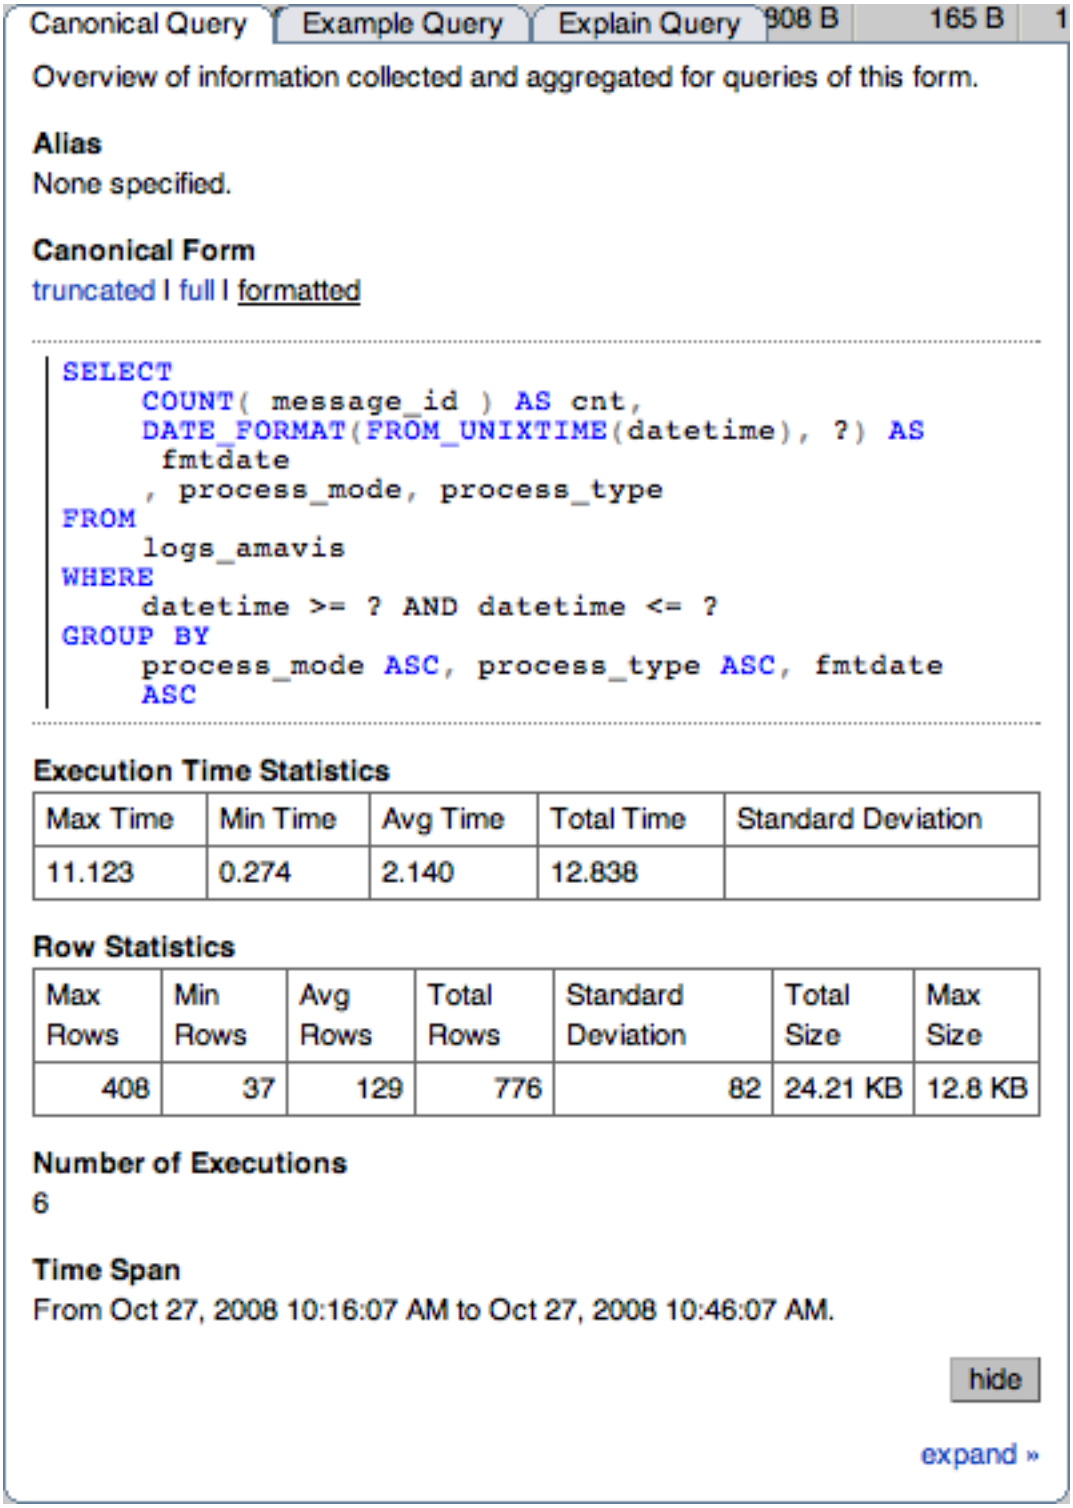
```
shell> mysql --host=127.0.0.1
```

15.10.2. Getting Detailed Query Information

If you click an individual query, a pop-up window will provide more detailed information about the individual query. You can see an example of this in the figure below. The available tabs within this window will depend on whether you have configured the more detailed query information. By default, you will always be provided the Summary Details page. If enabled, you may also view Example Details, which provide more detailed data about a specific query, including the data and parameters submitted. In addition, you may also enable Example Explain, which provides you with the ability to remotely execute an `EXPLAIN` statement with the specified query and view the resulting information.

- The **Canonical Query** tab:

Figure 15.48. MySQL Enterprise Dashboard: Canonical Query Tab for a Query



In addition to the summary information given in the table, you will get detailed execution statistics, including the minimum time, maximum time, average time, total time and the standard deviation. The standard deviation will enable you to determine whether a particular invocation of a query is outside the normal distribution of times for the given query.

Row statistics provide more detailed contents on the maximum, minimum, average, total, and standard deviation for the number of

rows returned by the query, and the total size and maximum size of the data returned. The time period for the total and average figures is shown under the Summary Time Span.

The detailed view for a query also provides three different views of the query. The `truncated` version is a shortened version of the query. The `full` version of the query is the entire query statement. Normalization removes the constants from the individual queries so that queries following the same logical structure are identified as the same basic query.

To close the query detail window, click the HIDE button.

To simplify the identification of a given query, you can create a query alias. The alias will be used in place of the normalized query text within the Query Analyzer table. To create an alias for a query, click the CREATE ALIAS link against the query. The maximum length for a query alias is 255 characters.

- The **Example Query** tab:

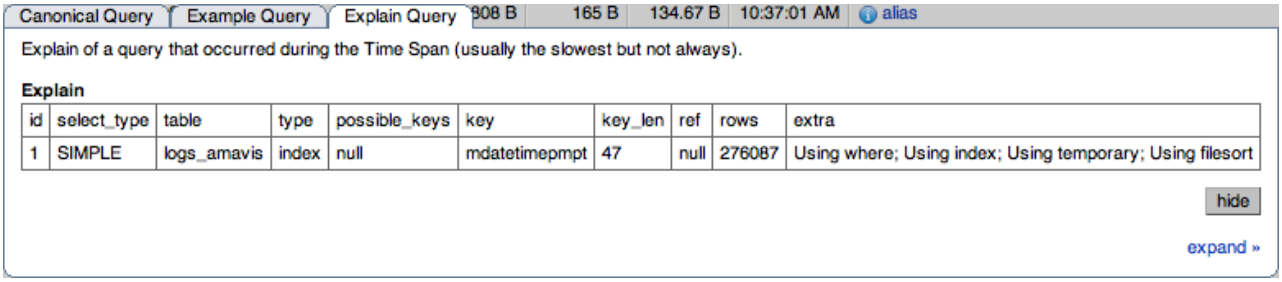
Figure 15.49. MySQL Enterprise Dashboard: Example Query Tab for a Query

The Example Details tab provides detailed information about the most expensive query executed, as determined by the execution time.

In addition to the full query, with data, that was executed, the tab shows the execution time, data, user, thread ID, client host and execution host for the given query.

- The **Explain Query** tab:

Figure 15.50. MySQL Enterprise Dashboard: Explain Query Tab for a Query



The Example Explain tab enables you to view the output from running the query with the `EXPLAIN` prefix. For more information, see Section 12.8.2, "`EXPLAIN` Syntax".

15.10.3. Using Graphs to Identify Queries

The MySQL Enterprise Dashboard supports correlated graphs so that you can compare the graphed execution parameters, such as the server load, thread statistics, or RAM usage, against the queries that were being executed by the server or servers being monitored at that time.

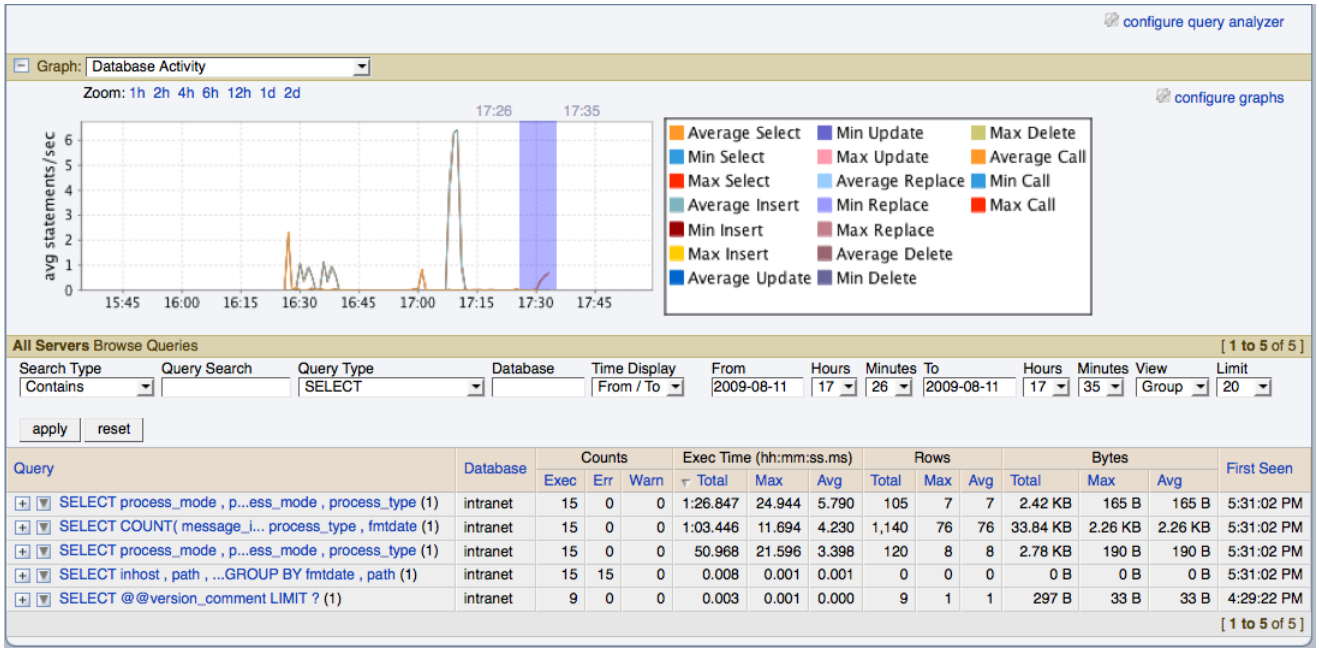
You can use the correlated graphs in two different ways:

- By dragging and selecting an area on a graph as displayed within the **MONITOR** over view tab, or the **GRAPHS** tab of the MySQL Enterprise Dashboard. When using either of these two tabs, you can drag and select any region on a displayed graph, and the display will change to the **QUERY ANALYZER** tab, displaying the corresponding zoomed graph, and the associated queries being executed during the selected period.
- You can select a graph to be displayed within the **QUERY ANALYZER** tab. Open the **GRAPH** section, and use the pop-up list to select the graph to be displayed. You can see an example of this in Figure 15.51, "MySQL Enterprise Dashboard: Correlated Graphs".

When using the correlated graphs, selecting an area within the graph will set the start and end time within the query filtering selection. You can combine with other filtering options, such as the **QUERY TYPE**, to zero-in on the queries that you want to examine.

To use the graphs in this manner, select a starting point and click, while holding down the button, drag a selection area to set the time-range for the query display. The time range that you have selected will be displayed above the graph as you select the area.

Figure 15.51. MySQL Enterprise Dashboard: Correlated Graphs



You can also explicitly zoom in an out of the displayed graph by using the links next to the **ZOOM** label. You can select to show just an hour of the graph material, or larger ranges up to two days. At all times, the area on the graph highlighted in blue is the actual date/time range selected within the list of analyzed queries.

For more information on filtering your queries, see Section 15.10.4, “Filtering Query Analyzer Data”.

15.10.4. Filtering Query Analyzer Data

You can filter the queries shown within the Query Analyzer table by using the form at the top of the table. The different fields of the form are used to specify the parameters for the filter process. Once you have specified a filter, all the queries and related statistics shown within the Query Analyzer table are displayed in relation to the filter settings. For example, by default, the filter settings show the queries for the last 30 minutes. All the statistics shown are relative to the last 30 minutes, including average, maximum and execution counts.

The filter fields are:

- **SEARCH TYPE** and **QUERY SEARCH** support text searching of the normalized query. For the search type you can specify either a basic text match, or a regular expression match. In addition to the basic text match, you can also search for a query that does not contain a particular string. For regular expression searches, you can specify whether the regular expression should match, or not match (negative regexp) the queries. Regular expressions are parsed using the standard MySQL `REGEXP()` function. For more information, see Section 11.5.2, “Regular Expressions”.

  > **Note**
  >
  > The search is performed against the canonical version of the query. You cannot search against specific text or values within the parameters of the query itself.

- **DATABASE**: Limit the queries to those executed within a specific database. The database match is performed using the `LIKE` match from the MySQL database, hence you can use the `%` and `_` characters to multiple and single character matches. For more information, see Section 3.3.4.7, “Pattern Matching”.

- The **TIME DISPLAY** menu selects whether the time selection for filtering should be based on the time **INTERVAL** (only queries recorded within the displayed time period are shown, using the **HOURS** and **MINUTES** pop-up), or whether the selection should be based on a time period (**FROM/TO**), where you can select the time range to be displayed.

  Using the **INTERVAL** mode shows queries within the given time period from the point the graph was updated. For example, if you select 30 minutes, then the queries shown were captured within the last 30 minutes. If you updated the display at 14:00, then the queries displayed would have been captured between 13:30 and 14:00. Using interval mode limits the timespan for the filter selec-

tion to a maximum of 23 hours and 59 minutes.

Using the **FROM/TO** mode enables you to show queries between specific dates and times. Using this mode you can show only the queries received during a specific time span, and you can display the query history for a much longer time period, for as long as you have been recording query analysis information.

- The **VIEW** selection determines whether the information should be returned on a group basis, where an aggregate of the same query executed on all monitored servers is shown, or on a **SERVER** basis, where queries are summarized by individual server. If the latter option has been selected, the table includes an additional column showing the server.
- **QUERY TYPE** lets you select the type of query on which to filter queries. Selecting **ALL** will show all queries. Additional query types you can select include `SELECT`, `INSERT`, `UPDATE` and other main SQL query types.
- **LIMIT** specifies the number of queries to be displayed within each page.

When you have set your filter parameters, you can update the Query Analysis display by clicking the FILTER button. To reset the fields to the default settings click the RESET button.

15.10.5. Using Query Analyzer Data

The information provided by Query Analyzer can be complex to understand and resolve into simple targets and resolutions for your MySQL client application. The information can be used in different ways to find problems in your queries or your servers, or both. Provided below are some tips on how to get the best out of the Query Analyzer interface, and how to identify different queries and problems based on the information shown by the Query Analyzer system.

First, consider the information provided by individual columns by your queries. In particular, the following columns can highlight specific problems with your queries or database server:

- **Execution Count**: High execution counts, especially for a query that you expect to be executed very rarely, may indicate that your MySQL client application is either running a simple query to frequently, or may be running a query multiple times that could otherwise be cached. You should pay particular attention to queries where the execution count increases significantly in a short period of time compared to the normal execution rate.

  How to find: Use the sort feature to sort the queries by execution count.
- **New queries**: New queries appearing in the Query Analyzer tab, especially if they appear after other queries have been in the display for a number of hours or days may indicate a number of issues:
- **Execution times**: Long execution times, and a long max execution time compared to the average execution time may indicate a problem with a specific query and specific parameters.

  How to find: Use the sort feature to sort the queries by execution count.

You can also use the filtering and sort options to get specific information about potential problem queries.

15.10.6. Troubleshooting Query Analyzer

If you are having trouble with Query Analyzer, either because the information is not being shown or the full range of queries that you expect are not appearing in the Query Analyzer page then there are a number of systems you can check.

To confirm that your system is correctly configured for Query Analysis, check the following:

- Confirm that the agent is running by checking the Agent log and the status of the server within MySQL Enterprise Service Manager
- Check the configuration of the agent. You must confirm the following:
  - The `plugins` parameter within the main configuration file, `mysql-monitor-agent.ini`, must contain the `proxy` plugin:

    ```
    plugins=proxy,agent
    ```

- The `agent-item-files` parameter within the main configurationfile, `mysql-monitor-agent.ini`, must specify the `share/mysql-proxy/items/quan.lua` script:

```
agent-item-files = share/mysql-proxy/items/quan.lua, »
     share/mysql-proxy/items/items-mysql-monitor.xml
```

- The proxy configuration parameters must point to the MySQL server where you want your queries to be sent. For example, if you are running your agent on the same host as your MySQL server then you might have the following lines in your `mysql-monitor-agent.ini` file:

```
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script        = share/mysql-proxy/quan.lua
```

  The above configuration can means:

  - The agent/proxy will listen on the current machine, using port 6446 (`proxy-address`).
  - The agent/proxy will send all queries received on to the host `127.0.0.1` on port `3306` (the standard MySQL port), as per the `proxy-backend-addresses` parameter.

You can see a sample complete configuration file (`mysql-monitor-agent.ini`), using the `127.0.0.1` as the MySQL backend server, and reporting to a MySQL Enterprise Service Manager called `monitor`:

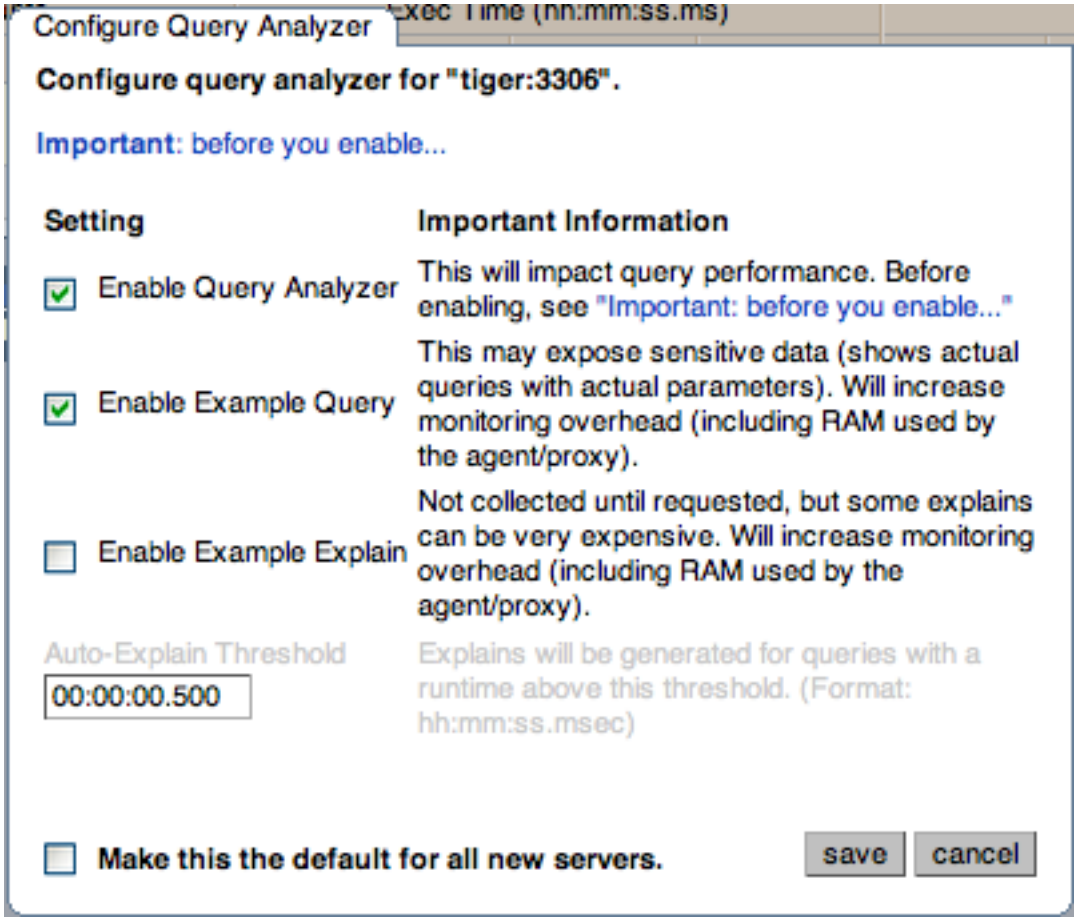
```
[mysql-proxy]
plugins=proxy,agent
agent-mgmt-hostname = http://agent:password@monitor:18080/heartbeat
mysqld-instance-dir= etc/instances
agent-item-files = share/mysql-proxy/items/quan.lua,share/mysql-proxy/items/items-mysql-monitor.xml
proxy-address=:6446
proxy-backend-addresses = 127.0.0.1:3306
proxy-lua-script        = share/mysql-proxy/quan.lua
agent-uuid = a3113263-4993-4890-8235-cadef9617c4b
log-file = mysql-monitor-agent.log
pid-file=/opt/mysql/enterprise/agent/mysql-monitor-agent.pid
```

- Confirm that you can connect through the agent proxy to your backend MySQL server. You can do this by checking with the MySQL client. You must specify the same options as you would if you were connecting to the original server, including specifying the same user and password information:
- Check that your MySQL client application is configured to use the configured proxy port, instead of the real MySQL port when sending queries.
- Confirm that Query Analyzer enabled for your host. For more information, see Section 15.10.7, “Query Analyzer Settings”.

15.10.7. Query Analyzer Settings

There are a number of settings related to the Query Analyzer data. You can configure the query analyzer operation by using the **CONFIGURE QUERY ANALYZER** link within the **QUERY ANALYZER** tab, or through the CONFIGURE QUERY ANALYZER button within the **MANAGE SERVERS** tab within the **SETTINGS** tab. Both methods provide you with the same dialog:

Figure 15.52. MySQL Enterprise Dashboard: Query Analyzer Configuration



Through either solution, the configuration options that you select are applied to the individual server or server group selected within the **SERVERS**navigation panel.

There are three configuration options available through either method:

- **ENABLE QUERY ANALYZER** configures whether query analyzer should be enabled for this server or server group. If selected, query analyzer will be enabled. To disable, delect the check box.

  If Query Analyzer has been enabled, then you can additional configure the Example Query function by selecting the **ENABLE EXAMPLE QUERY** checkbox. Enabling this option provides an additional tab when you open the **CANONICAL QUERY** window when clicking a query.

- **ENABLE EXAMPLE QUERY** allows the Query Analyzer to display more information about individual queries. When enabled, queries and their data items (rather than the canonical form shown by default) will be provided. Enabling this option may expose the full query statements and therefore may present a security issue.

  With the **EXAMPLE QUERY** option enabled, an additional tab within the query summary details is made available. For more information, see Section 15.10.2, “Getting Detailed Query Information”.

  If you have enabled **EXAMPLE QUERY**, then you can additional enable **EXAMPLE EXPLAIN**, To enable this tab, select the **ENABLE EXAMPLE EXPLAIN** checkbox.

- **ENABLE EXAMPLE EXPLAIN** provides another tab when viewing a query where you can view the output from `EXPLAIN` output from MySQL for the selected query. This will show the full query and how the query was executed within the servers.

  When the `EXPLAIN` functionality has been enabled, the **AUTO-EXPLAIN THRESHOLD** controls when the `EXPLAIN` output for a query is triggered. Queries that take longer than the **AUTO-EXPLAIN THRESHOLD** will have the `EXPLAIN` output generated and stored in the database to be display in the **EXAMPLE EXPLAIN** tab.

Enabling this option may add overhead to the execution of your server, as the server will run an `EXPLAIN` statement each time it identifies a long running query. For more information, Section 15.13, "MySQL Enterprise Monitor Frequently Asked Questions".

To enable or disable query analyzer for an individual server, go to the **SETTINGS** page and click the MANAGE SERVERS link. To configure all the properties, click the **CONFIGURE QUERY ANALYZER** link next to server you want modify.

Alternatively, for each server, the **QUERY ANALYZER** column shows the current setting, On or Off, and whether the **EXAMPLE** and **EXPLAIN** functionality is enabled. To change any setting, click the current status to toggle between the On/Off position.

To disable or enable Query Analyzer for the selected servers, use the DISABLE QUERY ANALYZER or `enable query analyzer` buttons within the **SETTINGS** page. You must have selected one or more servers from the list of available servers before selecting these buttons.

You can use the options that you have just selected as the default for all new servers that register with MySQL Enterprise Service Manager by using select the **MAKE THIS THE DEFAULT FOR ALL NEW SERVERS** checkbox. By default, when a new server registers with MySQL Monitor, the server is automatically configured to supply Query Analyzer data. This can have impact on the performance of your monitor and agent as it increases the amount of information supplied to the MySQL Monitor.

Configuration of Query Analyzer occurs through the CONFIGURE DEFAULTS button from within the **QUERY ANALYZER** page.

15.11. The Replication Page

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

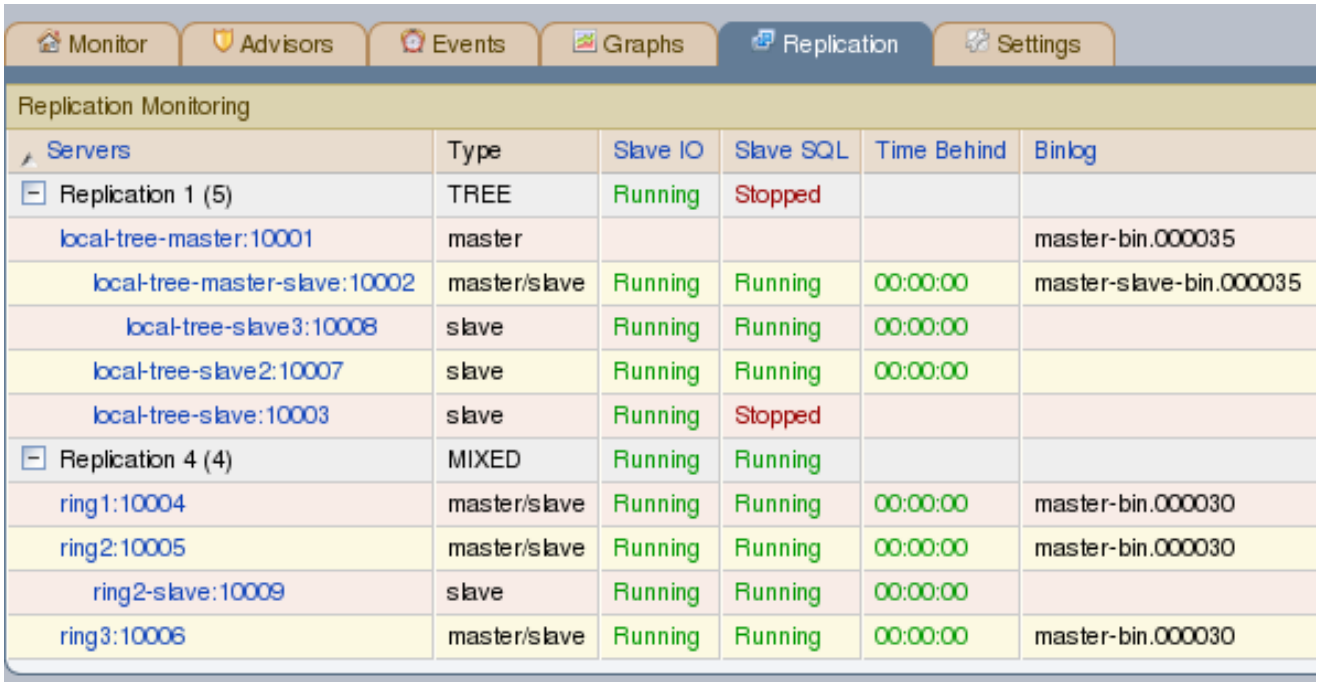
Navigate to the `Replication` page by choosing the **REPLICATION** tab. This page provides a quick summary view of the state of your replication servers or, if you wish, you can drill down and determine specifics about any master or slave.

> **Note**
>
> Servers, whether masters or slaves, must be monitored in order for them to appear on this page.

> **Note**
>
> There will be no `Replication` page if your subscription level does not support this feature.

The `Replication` page groups all master servers with their slaves. Masters and their slaves are autodiscovered and a grouping is created. This grouping shows up on the replication page and also in the `Heat Chart` on the `Monitor` page. Scans run on a five minute interval, so depending upon the order of discovery, it can take as long as 2 polling intervals to create a complete group.

Figure 15.53. MySQL Enterprise Dashboard: Replication Groups



Servers	Type	Slave IO	Slave SQL	Time Behind	Binlog
Replication 1 (5)	TREE	Running	Stopped		
local-tree-master:10001	master				master-bin.000035
local-tree-master-slave:10002	master/slave	Running	Running	00:00:00	master-slave-bin.000035
local-tree-slave3:10008	slave	Running	Running	00:00:00	
local-tree-slave2:10007	slave	Running	Running	00:00:00	
local-tree-slave:10003	slave	Running	Stopped		
Replication 4 (4)	MIXED	Running	Running		
ring1:10004	master/slave	Running	Running	00:00:00	master-bin.000030
ring2:10005	master/slave	Running	Running	00:00:00	master-bin.000030
ring2-slave:10009	slave	Running	Running	00:00:00	
ring3:10006	master/slave	Running	Running	00:00:00	master-bin.000030

Discovery events are logged to the `Replication` log. To view this log navigate to the `Settings` page and choose the **LOGS** link. View all replication-related events by clicking the **REPLICATION** link. This log can be a useful tool should you need to debug the replication topology discovery process.

> **Warning**
>
> The agent must be installed on the same machine as the server you are monitoring in order for discovery to work properly. Do **not** use remote monitoring.

Replication groups can be managed from the `Manage Servers` page in the same way as other groups. However, any slaves removed from a server group will automatically be restored to that group. It is also possible to add nonslaves to a replication grouping. For more information about server groupings see Section 15.5.3.2, “Grouping Servers”.

15.11.1. Replication Page Details

Choose a value from the **REFRESH** drop-down list box to set the rate at which information is updated. This refresh rate applies only to the information presented on this page: It is independent of the rate set for the `Monitor` page.

The following columns describe replication servers and their slaves:

- Servers: Displays the group name and any master servers and slaves
- Type: Indicates the topology of a server group or in the case of individual servers, whether a server is a master, a master/slave, or a slave
- Slave IO: Reports the status of the slave I/O thread
- Slave SQL: Reports the status of the slave SQL thread
- Seconds Behind: The number of seconds the slave is behind the master. This column is blank if a server is a master.
- Binlog: The binary log file name
- Binlog Pos: The current position in the binary log file
- Master Binlog: The master binary log file name

- Master Binlog Pos: The current position in the master binary log file
- Last Error: The most recent error
- Unlabeled Column: Use the **RENAME GROUP** link on the server group line to edit the server group name

Levels of indentation in the `Servers` column show the relationship between master servers and their slaves. Most column headings are active links that allow you to change the order of display by clicking the header. Sorting works differently for different column groupings. Click the `Seconds Behind` header to order servers by the number of seconds they are behind their master. However, in all cases, the server topology is respected. For example, in a `TREE` topology, ordering occurs within branches only.

If the agent is down, servers show in bold red in the `Servers` column. The `Slave IO` and the `Slave SQL` columns display `stopped` in red text if these threads are not running. If an agent is down, italics is used to display the last know status of the I/O or SQL threads.

Clicking a master server opens a dialog box that displays information about the server. The information shown includes:

- The number of slave servers
- The binary log file name
- The binary log position
- Which databases are replicated and which not

The dialog box also includes a link that allows the user to hide or show the slave servers.

Clicking a slave server opens a dialog window showing extensive information about the slave.

15.12. MySQL Enterprise Monitor Reference

This appendix contains reference information for MySQL Enterprise Monitor.

15.12.1. MySQL Enterprise Monitor Limitations

The following list provides information on known limitations within MySQL Enterprise Monitor

- The maximum size for data stored within the `mysql.inventory` table is 64 bytes.
- The MySQL Enterprise Monitor Agent when operating for Query Analyzer as a proxy cannot handle queries greater than 16MB.
- The MySQL Enterprise Monitor Agent when operating for Query Analyzer as a proxy does not support clients using the MySQL protocol older than MySQL 5.0.
- The MySQL Enterprise Monitor Agent when operating for Query Analyzer as a proxy does not support clients affects the authentication of clients. As the proxy is the real client connecting to the backend MySQL server, authentication should use the hostname of the proxy, not the original client.
- When viewing the graphs generated by MySQL Enterprise Service Manager, the fonts used for the graphs may not be displayed properly if the required font is missing.

  You can specify a custom font by setting a custom property within the embedded MySQL Server to a known working font. To do this, connect to your embedded MySQL sever using the information provided by the `configuration_report.txt` file. Once connected, execute the following statment:

  ```
  mysql> INSERT INTO map_entries VALUES (1,'Helvetica','graph.font');
  ```

  Replacing `Helvetica` with the font you want to use.

  The font used for graph rendering will be selected as follows, in this order:

  1. The user override value.

2. The MySQL Enterprise Service Manager default of Arial.
3. The graph engine default of SansSerif.

- It is not possible to monitor more than one MySQL Enterprise Dashboard instance hosted on the same machine simultaneously within the same browser, even if each MySQL Enterprise Dashboard uses a different port for access. The effect of this limitation may be more significant on certain browsers.
- When monitoring multiple MySQL instances with one MySQL Enterprise Monitor Agent, if any of the MySQL instances are down at the point when the agent is started, the agent will not attempt to reconnect to the servers. This could lead to indications that MySQL instances were down when in fact they were running and available. To avoid this problem, ensure all of the monitored instances are available before starting the agent.

15.12.2. Supported Browsers

The MySQL Enterprise Dashboard is known to work within the following browser environments:

- Microsoft Internet Explorer 7.x, 8.x

  Note

  MySQL Enterprise Dashboard is not compatible with the **COMPATIBILITY VIEW** option within Internet Explorer 8.x. Please make sure this option is disabled before using MySQL Enterprise Dashboard
- Safari 3.2, 4.x
- Firefox 3.0, 3.5

The MySQL Enterprise Dashboard is known *not* to work within the following browser environments:

- Microsoft Internet Explorer 6.x
- Opera
- Google Chrome

15.12.3. Installation Requirements

The Service Manager is available for Windows, Mac OS X, and a variety of Unix and Linux operating systems. In most cases, the standard operating system and packages are supported without further libraries and modules. All the required components are installed automatically.

- **Mac OS X Notes**
  - The Mac OS X Service Manager is only supported on Intel architecture. However, the Mac OS X agent is supported for both Intel and the PowerPC.
  - Installation requires approximately 450MB of disk space for MySQL Enterprise Service Manager
- **Windows Notes**
  - Installation requires approximately 260MB of disk space for MySQL Enterprise Service Manager
- **Unix/Linux Notes**
  - Installation requires approximately 450MB of disk space for MySQL Enterprise Service Manager
  - On FreeBSD, you must have `bind8` installed.

> **Note**
>
> Disk-space usage requirements are approximate for the base application. During usage, the service manager records detailed information about your MySQL servers and environment, and disk space usage will increase with time to record this historical data. You can control how long information is stored once the service manager has been installed.

The minimum recommended requirements for the service manager are at least a 2GHz CPU, with two or more CPU cores, and at least 2GB of RAM. If you are monitoring a large number of services, then there will be an increased load on the server manager. Running the service manager on a machine that is already running other tasks is only recommended if you are monitoring a small number of agents. For monitoring five or more agents simultaneously, you should dedicate a machine to the process. For more information, see Section 15.12.5, “Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations”.

The Monitor Agent is available for a wide range of operating systems. For an up-to-date list please see the http://www.mysql.com/products/enterprise/. The agent can be used to monitor any MySQL server from version 4.0.x through 6.0.x.

Production support is not currently available for MySQL Enterprise Monitor (Service Manager component) in virtualized environments.

15.12.4. Creating a new SSL KeyStore

The SSL certificate that is provided with the server during installation is a sample certificate only. If you want to use SSL for communicating with your MySQL Enterprise Service Manager and MySQL Enterprise Dashboard you should replace the supplied certificate with your own certificate.

The certificate keystore is located in the `apache-tomcat/conf/myKeyStore` file within your MySQL Enterprise Service Manager installation.

To create a new, self-signed, certificate, use the `keytool` command (provided with Java SE Security) to create a new certificate file:

```
shell> keytool -genkey -alias tomcat -keyalg RSA -validity 1825 -keystore newKeystore
```

You will be prompted to fill in the certificate information and to provide a unique password for the certificate.

The `-validity` specifies the length of the certificate created, specified in days. The `-alias` is required to ensure that the certificate is associated with `tomcat`.

Once you have created the new keystore, you should shutdown MySQL Enterprise Service Manager, copy the new keystore file to `apache-tomcat/conf/myKeyStore` and restart MySQL Enterprise Service Manager.

If you have an existing certificate that you would like to import into your keystore, you need to import the certificate using the following command:

```
shell> keytool -import -alias tomcat -keystore newKeystore -file public.pem
```

For more information on using SSL certificates in Tomcat see Apache Tomcat 6.0: SSL Configuration HOW-TO.

15.12.5. Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations

Running MySQL Enterprise Service Manager places a reasonable load on your system, and this load increases linearly as you add more agents monitoring more servers. Ideally, you should use a dedicated machine for MySQL Enterprise Service Manager, rather than running it alongside other applications and services.

Minimum System Requirements

- 2 or more CPU cores
- 2 or more GB of RAM
- Disk I/O subsystem applicable for a write-intensive database

Recommended System Requirements (if monitoring 100 or more MySQL servers)

- 4 or more CPU cores
- 8 or more GB of RAM
- Disk I/O subsystem applicable for a write-intensive database (RAID10, RAID 0+1)

15.12.6. MySQL Enterprise Monitor Agent Reference

The MySQL Enterprise Monitor Agent supports the following configurable options:

Table 15.2. `mysql-monitor-agent` Help Options

Format	Config File	Description	Introduction	Deprecated	Removed
--help		Show help options			
--help-admin		Show options for the admin-module			
--help-agent		Show agent options			
--help-all		Show all help options			
--help-monitor		Show monitor options			
--help-proxy		Show options for the proxy-module			

Table 15.3. `mysql-monitor-agent` Admin Options

Format	Config File	Description	Introduction	Deprecated	Removed
--admin-address	admin-address	Defines the listening address and poirt for the admin module			
--admin-lua-script	admin-lua-script	Script to execute by the admin module			
--admin-password	admin-password	Password for authentication for admin module			
--admin-username	admin-username	Username for authentication for admin module			
--proxy-address	proxy-address	Listening address:port of the proxy server			

Table 15.4. `mysql-monitor-agent` Agent Options

Format	Config File	Description	Introduction	Deprecated	Removed
--agent-collector-plugins	agent-collector-plugins	Load the specified collector plugins			
--agent-force-uncorking	agent-force-uncorking	Forcibly turn off corking (randomization of data collection intervals)	2.1.0		
--agent-generate-uuid	agent-generate-uuid	Generate a UUID for use with the agent-uuid			
--agent-heartbeat-interval	agent-heartbeat-interval	The interval for generating heartbeat operations			

Format	Config File	Description	Introduction	Deprecated	Removed
--agent-host-id	agent-host-id	The host ID for the agent			
--agent-host-id-commandline	agent-host-id-commandline	The command to use to generate the agent host id			
--agent-hostname	agent-hostname	Hostname of the agent host			
--agent-item-files	agent-item-files	List of data items for additional collections			
--agent-max-response-size	agent-max-response-size	Maximum response size for agent data	2.1.0		
--agent-mgmt-hostname	agent-mgmt-hostname	URL of the management server			
--agent-run-os-tests	agent-run-os-tests	Run the operating system tests and shutdown			
--agent-sync-attempts	agent-sync-attempts	Synchronize the attempts to connect at resync			
--agent-track-alloc	agent-track-alloc	Enable the tracking of the allocation sizes			
--agent-uuid	agent-uuid	UUID of this agent			

Table 15.5. `mysql-monitor-agent` Monitor Options

Format	Config File	Description	Introduction	Deprecated	Removed
--monitor-interval	monitor-interval	Interval for executing queries against the backend			
--monitor-lua-script	monitor-lua-script	Script filename for the monitor			
--monitor-password	monitor-password	Set the password for the monitored MySQL Server			
--monitor-username	monitor-username	Set the username for the monitored MySQL Server			

Table 15.6. `mysql-monitor-agent` Proxy Options

Format	Config File	Description	Introduction	Deprecated	Removed
--no-proxy	no-proxy	Don't start the proxy module			
--proxy-backend-addresses	proxy-backend-addresses	Address:port of the remote MySQL server			
--proxy-fix-bug-25371	proxy-fix-bug-25371	Enable the fix for Bug#25371 (for mysqld > 2.0.0.12) for older libmysql versions			
--proxy-lua-script	proxy-lua-script	Filename for Lua script for proxy operations			

Format	Config File	Description	Introduction	Deprecated	Removed
--proxy-pool-no-change-user	proxy-pool-no-change-user	Don't use the protocol CHANGE_USER to reset the connection when coming from the connection pool			
--proxy-read-only-backend-addresses	proxy-read-only-backend-addresses	Address:port of the remote MySQL server (read only)			
--proxy-skip-profiling	proxy-skip-profiling	Disabled profiling of queries			

Table 15.7. `mysql-monitor-agent` Application Options

Format	Config File	Description	Introduction	Deprecated	Removed
--basedir	basedir	Specify the base directory to prepend to paths in the config			
--daemon	daemon	Start in daemon-mode			
--defaults-file	defaults-file	Specify the configuration file			
--keepalive	keepalive	Try to restart the proxy if a crash occurs			
--log-back-trace-on-crash	log-back-trace-on-crash	Try to invoke the debug and generate a backtrace on crash			
--log-file	log-file	Specify the file for logging error messages			
--log-level	log-level	Logging level			
--log-use-syslog	log-use-syslog	Log errors to syslog			
--lua-cpath	lua-cpath	Set the LUA_CPATH			
--lua-path	lua-path	Set the LUA_PATH			
--max-open-files	max-open-files	Specify the maximum number of open files to support			
--pid-file	pid-file	PID file to store the process ID (when in daemon mode)			
--plugin-dir	plugin-dir	Path to the plugin files			
--plugins	plugins	List of plugins to load			
--user	user	Specify the user to use when running mysql-monitor-agent			
--version	version	Show the version information			

- `--help`

Command-Line Format	`--help`

Show available help options.

- `--help-all`

Command-Line Format	`--help-all`

Show all help options.

- `--help-admin`

Command-Line Format	`--help-admin`

Show options for the admin-module.

- `--help-proxy`

Command-Line Format	`--help-proxy`

Show options for the proxy-module.

- `--help-monitor`

Command-Line Format	`--help-monitor`

Show options for the monitor module.

- `--help-agent`

Command-Line Format	`--help-agent`

Show options for the agent module.

- `--admin-address=host:port`

Command-Line Format	`--admin-address`	
Config-File Format	`admin-address`	
	Permitted Values	
	Type	`string`
	Default	`:4041`

Specify the host name (or IP address) and port for the administration port. The default is `localhost:4041`.

- `--admin-lua-script=script`

Command-Line Format	`--admin-lua-script`	
Config-File Format	`admin-lua-script`	
	Permitted Values	
	Type	`filename`
	Default	

Specify the script to use for the administration module for the proxy.

- `--admin-password=pass`

Command-Line Format	`--admin-password`

Config-File Format	admin-password	
	Permitted Values	
	Type	string
	Default	

Define the password to use to authenticate users wanting to connect to the administration module of mysql-monitor-agent. The administration module uses the MySQL protocol to request a username and password for connections.

- --admin-username=user

Command-Line Format	--admin-username	
Config-File Format	admin-username	
	Permitted Values	
	Type	string
	Default	root

Define the username to use to authenticate users wanting to connect to the administration module of mysql-monitor-agent. The default username is root. The administration module uses the MySQL protocol to request a username and password for connections.

- --agent-collector-plugins=user

Command-Line Format	--agent-collector-plugins	
Config-File Format	agent-collector-plugins	
	Permitted Values	
	Type	numeric
	Default	collect_lua

A comma-separated list of the plugins to be used and loaded by the agent and used to provide collector items.

- --agent-force-uncorking

Version Introduced	2.1.0
Command-Line Format	--agent-force-uncorking
Config-File Format	agent-force-uncorking

Forcibly turn off the corking of responses sent to MySQL Enterprise Service Manager. The corking mechanism tries to randomize the collection intervals of data sent up to the server to prevent flooding the server with information.

The frequency of collecting the data is not modified by this setting.

- --agent-generate-uuid

Command-Line Format	--agent-generate-uuid
Config-File Format	agent-generate-uuid

Regenerates a UUID for the agent. You can use this to generate a new UUID if you have copied configuration information for an agent from one machine to another. To use:

```
shell> /opt/mysql/enterprise/agent/bin/mysql-monitor-agent --agent-generate-uuid
ee9296d7-f7cd-4fee-8b26-ead884ebf398
2009-03-05 11:49:37: (critical) shutting down normally
```

For more information, see Section 15.3.3.6.3, “Monitoring Multiple MySQL Servers”.

- `--agent-heartbeat-interval=#`

Command-Line Format	`--agent-heartbeat-interval`	
Config-File Format	`agent-heartbeat-interval`	
	Permitted Values	
	Type	`numeric`
	Default	`3`

Specify the heartbeat interval. The agent sends heartbeat messages to MySQL Enterprise Service Manager to indicate that it is alive and still running and monitoring servers. The MySQL Enterprise Service Manager uses this information to help identify when an agent is available or not.

- `--agent-host-id=HOSTID`

Command-Line Format	`--agent-host-id`
Config-File Format	`agent-host-id`

Define the agent host id. The host id should be a unique identifier for the host on which the agent is running, and is different to the agent UUID. You can override the host ID for use within HA environments where you have two identical agent configurations, one on a live server, and one on a backup server to be brought into use if the primary server fails. The host ID is used to identify the host by the server, and during failover you want the host ID to remain constant as you monitor either the original or failover (replacement) server.

- `--host-id-commandline`

Command-Line Format	`--agent-host-id-commandline`
Config-File Format	`agent-host-id-commandline`

Specify the command line to generate the host ID. By default, the host ID is generated by using a variety of methods configured for a specific platform, including using SSH keys and embedded host ID information. You can replace this with an alternative command-line

- `--basedir`

Command-Line Format	`--agent-hostname`
Config-File Format	`agent-hostname`

Override the automatically determined hostname. You can use this to specify an alternate hostname for the agent. This can be useful if your host has multiple hostnames and you want the machine identified by a specific hostname.

- `--agent-item-files`

Command-Line Format	`--agent-item-files`
Config-File Format	`agent-item-files`

A comma separated list of the item files used to load data items that are then collected and sent to MySQL Enterprise Service Manager. For more information, see Section 15.7.5, “Creating a Custom Data Collection Item”.

- `--agent-max-response-size`

Version Introduced	2.1.0
Command-Line Format	`--agent-max-response-size`

Config-File Format	agent-max-response-size	
	Permitted Values	
	Type	numeric
	Default	65536

Specify the maximum size of the response packet sent to MySQL Enterprise Service Manager

- `--agent-mgmt-hostname`

Command-Line Format	--agent-mgmt-hostname
Config-File Format	agent-mgmt-hostname

Set the URL of the MySQL Enterprise Service Manager where collected data is sent. The URL should include the username and password for the agents, for example: `http://agent:password@memserver:18080/heartbeat`.

> **Note**
>
> If you have the `http_proxy` environment variable configured within your environment, you should add the value of `agent-mgmt-hostname` to the `no_proxy` variable to ensure that data is correctly transmitted to MySQL Enterprise Service Manager and not redirected through the configured proxy address.

- `--agent-run-os-tests`

Command-Line Format	--agent-run-os-tests
Config-File Format	agent-run-os-tests

Runs the internal operating system tests, and then exits. Using this option will generate a large body of information about the various operating system information that can be collected about the host. You can use this to determine whether the agent is collecting the right amount, quantity and quality of information to the server.

A truncated sample of the output is provided below:

```
2010-01-22 16:15:45: (critical) MySQL Monitor Agent 2.1.1.1138 started.
sigar-test-all.c.128 ():
  pid = 1353
sigar-test-all.c.110 ():
  mem.ram = 6080,
  mem.total = 6374154240,
  mem.used = 3356090368,
  mem.free = 3018063872,
  mem.actual_free = 3018063872,
  mem.actual_used = 3356090368
sigar-test-all.c.143 ():
  swap.total = 28523896832,
  swap.used = 710623232,
  swap.free = 27813273600
sigar-test-all.c.169 ():
  cpu.user = 24544920,
  cpu.sys = 136764840,
  cpu.nice = 0,
  cpu.idle = 1234759920,
  cpu.wait = 0,
  cpu.total = 349015500
sigar-test-all.c.194 ():
[0]
  cpu.user = 8516770,
  cpu.sys = 56838970,
  cpu.nice = 0,
  cpu.idle = 283667220,
  cpu.wait = 0,
  cpu.total = 349022960
[1]
  cpu.user = 6130420,
  cpu.sys = 12671090,
  cpu.nice = 0,
...
```

- `--agent-sync-attempts`

Command-Line Format	`--agent-sync-attempts`
Config-File Format	`agent-sync-attempts`

Attempt to synchronise with the server during the resynchronization.

- `--basedir`

Command-Line Format	`--agent-track-alloc`
Config-File Format	`agent-track-alloc`

Track the memory allocation in the various modules of the agent to help monitor the memory usage.

- `--basedir`

Command-Line Format	`--agent-uuid`	
Config-File Format	`agent-uuid`	
	Permitted Values	
	Type	`string`

Specify the agent UUID. A UUID is automatically generated for each agent during installation, with the UUID automatically added to the configuration. You can generate a new UUID using the `agent-generate-uuid` command line option.

- `--basedir`

Command-Line Format	`--basedir`	
Config-File Format	`basedir`	
	Permitted Values	
	Type	`filename`

Specify a base directory that will be prepended to all other filename configuration options. The base name should be an absolute (not relative) directory. If you specify a relative directory, `mysql-monitor-agent` will generate an error during startup.

- `--defaults-file`

Command-Line Format	`--defaults-file`
Config-File Format	`defaults-file`

Specify a file to use as the file with configuration information. If not specified, configuration options are only taken from the command line.

- `--event-threads=#`

Command-Line Format	`--event-threads`	
Config-File Format	`event-threads`	
	Permitted Values	
	Type	`numeric`
	Default	`1`

Specify the number of event threads reserved to handle incoming requests.

- `--keepalive`

Command-Line Format	`--keepalive`
Config-File Format	`keepalive`

Creates a process surrounding the main `mysql-monitor-agent` which will attempt to restart the true `mysql-monitor-agent` process in thr event a crash or other failure.

- `--log-backtrace-on-crash`

Command-Line Format	`--log-backtrace-on-crash`
Config-File Format	`log-backtrace-on-crash`

Logs the backtrace to the error log and tries to initialize the debugger in the event of a failure.

- `--log-file=filename`

Command-Line Format	`--log-file`	
Config-File Format	`log-file`	
	Permitted Values	
	Type	`filename`

Specify the name of a file to be used to record log information.

- `--log-file=filename`

Command-Line Format	`--log-level`	
Config-File Format	`log-level`	
	Permitted Values	
	Type	`enumeration`
	Valid Values	`error`, `warning`, `info`, `message`, `debug`

The log level to be used when outputting error messages. The specification will output that level (or lower) of a given error message. For example, `message` will also output `info`, `warning`, and `error` messages.

- `--log-use-syslog`

Command-Line Format	`--log-use-syslog`
Config-File Format	`log-use-syslog`

Causes errors to be sent to the syslog (Unix/Linux only).

- `--lua-cpath=path`

Command-Line Format	`--lua-cpath`	
Config-File Format	`lua-cpath`	
	Permitted Values	
	Type	`filename`

Specify the `LUA_CPATH` to be used when loading compiled modules or libraries for Lua scripts.

- `--lua-path=path`

Command-Line Format	`--lua-path`	
Config-File Format	`lua-path`	
	Permitted Values	
	Type	`filename`

Specify the `LUA_CPATH` to be used when loading modules for Lua.

- `--max-open-files=#`

Command-Line Format	`--max-open-files`	
Config-File Format	`max-open-files`	
	Permitted Values	
	Type	`numeric`

The maximum number of open files and sockets supported by the `mysql-monitor-agent` process. You may need to increase this with certain scripts.

- `--monitor-interval=#`

Command-Line Format	`--monitor-interval`	
Config-File Format	`monitor-interval`	
	Permitted Values	
	Type	`numeric`
	Default	`1`
	Min Value	`1`

Execute queries against the backends at this interval. The default is 1.

- `--monitor-lua-script=SCRIPT`

Command-Line Format	`--monitor-lua-script`	
Config-File Format	`monitor-lua-script`	
	Permitted Values	
	Type	`string`

Filename of the Lua script to use for the monitor module.

- `--monitor-password=PASS`

Command-Line Format	`--monitor-password`	
Config-File Format	`monitor-password`	
	Permitted Values	
	Type	`string`

The password for the monitoring user account.

- `--monitor-username=USER`

Command-Line Format	--monitor-username	
Config-File Format	monitor-username	
	Permitted Values	
	Type	string
	Default	monitor

The username for the monitoring user account.

- --no-proxy

Command-Line Format	--no-proxy
Config-File Format	no-proxy

Disable the proxy module.

- --plugin-dir=path

Command-Line Format	--plugin-dir	
Config-File Format	plugin-dir	
	Permitted Values	
	Type	filename

The directory to use when loading plugins for mysql-monitor-agent.

- --plugins=plugin,...

Command-Line Format	--plugins	
Config-File Format	plugins	
	Permitted Values	
	Type	string

A comma-separated list of the plugins to be loaded.

- --proxy-address=host:port

Command-Line Format	--proxy-address	
Config-File Format	proxy-address	
	Permitted Values (>= 2.1.0)	
	Type	string
	Default	:6446

The listening host name (or IP address) and port of the proxy server. The default is :6446 (all IPs on port 6446).

- --proxy-read-only-backend-addresses=host:port

Command-Line Format	--proxy-read-only-backend-addresses	
Config-File Format	proxy-read-only-backend-addresses	
	Permitted Values	
	Type	string

The listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.

- `--proxy-backend-addresses=host:port`

  The host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.

- `--proxy-pool-no-change-user`

Command-Line Format	`--proxy-pool-no-change-user`
Config-File Format	`proxy-pool-no-change-user`

  Disables the use of the MySQL protocol `CHANGE_USER` when reusing a connection from the pool of connections specified by the `backend-addresses` list.

- `--proxy-skip-profiling`

  disables profiling of queries (tracking time statistics). The default is for tracking to be enabled.

- `--proxy-fix-bug-25371`

Command-Line Format	`--proxy-fix-bug-25371`
Config-File Format	`proxy-fix-bug-25371`

  Gets round an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.

- `--proxy-lua-script=file`

Command-Line Format	`--proxy-lua-script`	
Config-File Format	`proxy-lua-script`	
	Permitted Values	
	Type	`filename`

  specify the Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while `mysql-monitor-agent` is running then the updated content will automatically be used when a new connection is made.

- `--daemon`

Command-Line Format	`--daemon`
Config-File Format	`daemon`

  Starts the proxy in daemon mode.

- `--pid-file=file`

Command-Line Format	`--pid-file`	
Config-File Format	`pid-file`	
	Permitted Values	
	Type	`filename`

Sets the name of the file to be used to store the process ID.

- `--user=user`

Command-Line Format	`--user`	
Config-File Format	`user`	
	Permitted Values	
	Type	`string`

Run `mysql-monitor-agent` as the specified `user`.

- `--version`

Command-Line Format	`--version`
Config-File Format	`version`

Show the version number.

15.12.7. Configuring Tomcat Parameters

The parameters for the Tomcat hosting system used to support MySQL Enterprise Service Manager and MySQL Enterprise Dashboard can have an affect on the performance of the system.

The default settings for Java for Tomcat are as follows:

Initial heap size	-Xms	768MB
Maximum heap size	-Xmx	768MB
Java stack size	-Xss	128MB

You can change these parameters to higher values,by editing the `JAVA_OPTS` setting within the corresponding platform script.

- On Unix/Linux and Mac OS X

  Edit the values within `apache-tomcat/bin/setenv.sh` file within your MySQL Enterprise Service Manager directory. You should avoid setting maximum figures higher than the physical memory of your system as this may reduce, rather than increase the performace.

  If you change these parameters, you will need to shutdown and restart MySQL Enterprise Service Manager for the changes to take effect.

- Windows

  Edit the `JAVA_OPTS` settings within the `apache-tomcat/bin/setenv.bat` file.

  To enable the changes, you must re-install your service. To do this, shutdown your MySQL Enterprise Service Manager service and then reinstall the service by running:

```
shell> mysqlmonitorctl.bat uninstall
shell> mysqlmonitorctl.bat install
```

On all platforms, changes to the `JAVA_OPTS` using the above methods should be retained over an upgrade of the MySQL Enterprise Service Manager service.

If you change these parameters, you must restart MySQL Enterprise Service Manager for the changes to take effect.

15.12.8. Backing up MySQL Enterprise Service Manager

If you want to backup the data stored within your MySQL Enterprise Service Manager, you can use any of the typical backup solutions, such as `mysqldump`, to save your data. All you need to backup the information is host name, user name and password details that were set during the installation of the MySQL Enterprise Service Manager

You can locate this information by examining the contents of the `configuration_report.txt` file that was generated when MySQL Enterprise Service Manager was installed. A scample of the file is provided below:

```
MySQL Enterprise Monitor (Version 2.0.0.7088 : 20081031_152749_r7088)
Here are the settings you specified:
Application hostname and port: http://127.0.0.1:18080
Tomcat Ports: 18080 - 18443 (SSL)
MySQL Port : 13306
Repository Credentials (bundled MySQL):
---------------------------------------
service_manager/Password
Use the following command to login to the MySQL Enterprise Monitor database:
mysql -uservice_manager -pPassword -P13306 -h127.0.0.1
```

The last line provides the information about how to connect to the server using the standard `mysql` command line client.

All the MySQL Enterprise Monitor repository information, including your configuration, rule and historical data is stored within the `mem` database.

To backup this information using `mysqldump` you might use the following command:

```
shell> mysqldump --single-transaction »
-uservice_manager -pPassword -P13306 -h127.0.0.1 mem >mem.dump
```

The above command would create a file, `mem.dump`, containing all of the MySQL Enterprise Monitor data.

To ensure consistency in a recovery situation, you may also want to backup the agent configuration and metadata stored on each monitored MySQL server. To do this:

- Backup the configuration files of each agent. You should keep a copy of the `etc` directory for each agent. This directory contains the main configuration file, `mysql-monitor-agent.ini`, and the configuration information for each server being monitored, which is stored within the `etc/instances` directory.
- On each server being monitored, retain a copy of the `mysql.inventory` table, which contains the unique ID of the MySQL server.

15.12.9. Migrating 1.3.x Historical Data to MySQL Enterprise Monitor 2.0

You can migrate the data generated during a MySQL Enterprise Monitor 1.3.x installation using the Data Migration functionality of the **SERVER CONFIGURATION** panel.

To use the data migration feature, you must have installed MySQL Enterprise Service Manager using an *update* installer. The update installer performs the initial migration of your configuration, rules, schedule, and events data. The historical data is not migrated until you explicitly request the migration of information within the **MANAGE SERVERS** section of the **SETTINGS** panel.

Data migration works on a single server, allowing you to select on which servers you want to migrate information. The migration is subject to the following:

- You must elect to migrate the data from each server individually.
- Migration takes approximately 5-6 hours, for each month, for each server. Therefore, if you have six months of data on 10 servers it could take between 300 and 360 hours (15 days) to migrate all of your historical data one server at a time.
- To limit the data migration, set the **DATA PURGE BEHAVIOR** within the **SETTINGS** page. Only data more recent than the specified purge period will be migrated. Data older than the purge period will be ignored.
- To prevent performance issues, migrate only one or a small number of servers concurrently.
- You can start and stop the migration of the data at any time. As a general guide, you should avoid stopping the data migration pro-

cess and allow it to complete unless:

- Run out of disk space.
- MySQL Enterprise Service Manager becomes too slow and unresponsive.
- Migration never completes.

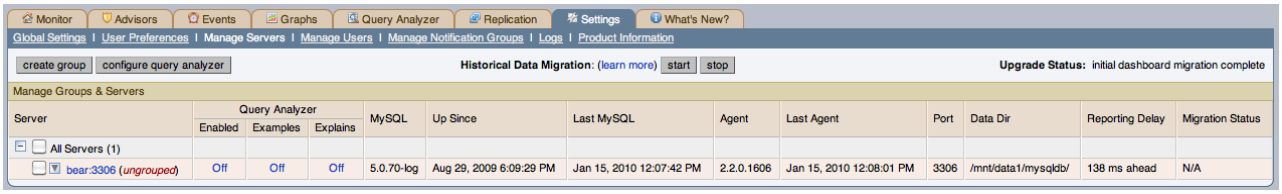
With the last item, where the migration never completes, occasionally there are some aspects of the data that cannot be migrated successfully. This will prevent the migration process completing, but does not affect the conversion of any data that could be migrated.

Starting Historical Data Migration

To start data migration:

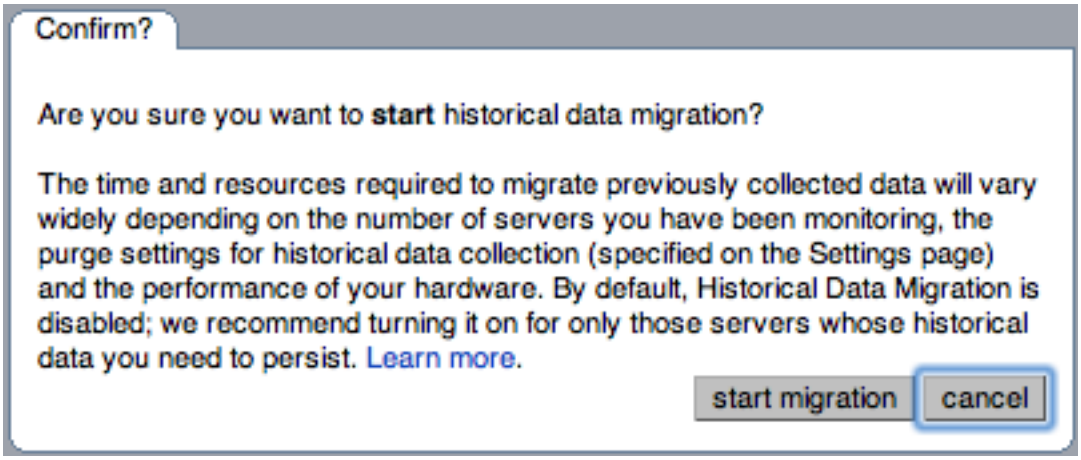
- Switch to the **MANAGE SERVERS** display of the **SETTINGS** panel within MySQL Enterprise Dashboard.
- Ensure that the data migration functionality has been enabled. The START and STOP buttons next to **HISTORICAL DATA MIGRATION** will be visible.

Figure 15.54. MySQL Enterprise Monitor: Historical Data Migration Availability



- Select the servers you want to migrate by using the checkbox next to each server name. You can select one or more servers to migrate. Servers that are suitable for migration will show their migration status within the **MIGRATION STATUS** columnn. If the server is not able to be migrated, `N/A` will be shown.
- Click START next to **HISTORICAL DATA MIGRATION**.
- You will be presented with a confirmation dialog box. To start the migration, click START MIGRATION. To cancel migration, click CANCEL.
- The servers that have been selected for migration will show `Queued for Migration` in the **MIGRATION STATUS** column.

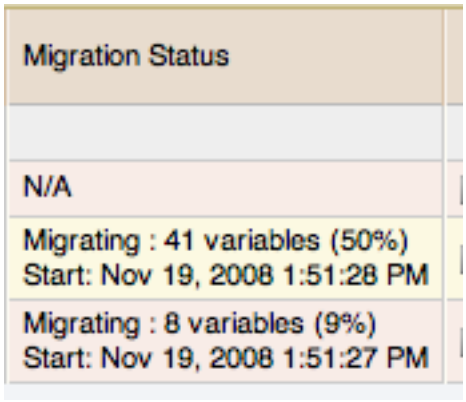
Figure 15.55. MySQL Enterprise Monitor: Confirming Historical Data Migration



Monitoring Historical Data Migration

You can check the migration status of any individual server by examining the **MIGRATION STATUS** column for each server. You can see an example of the migration status below.

Figure 15.56. MySQL Enterprise Monitor: Historical Data Migration Progress



Note that the migration status is shown according to the state of migration at the time the page was loaded. The actual migration continues in the background, and the current state may not match the state of the migration at the time it is viewed.

Servers showing `Done` in the **MIGRATION STATUS** column have already completed their migration.

You can check the overall migration status by examining the **UPGRADE STATUS** display.

Stopping Historical Data Migration

You can stop the migration process for any server that is still migrating data. The migration can be restarted at any time without causing any problems.

To stop the historical data migration:

1. Select the servers you want to stop migrating by using the checkbox next to each server name. You can select one or more servers to stop migrating.
2. Click STOP next to **HISTORICAL DATA MIGRATION**.

Confirmation that the migration has been stopped will be provided. If migration has already completed, you will be notified.

Removing Old Data

Once data migration has been completed for all the servers you want to migrate, you may want to delete or remove access to the old data within your MySQL Enterprise Monitor repository. Data for MySQL Enterprise Monitor 1.3 was stored in a database called `merlin` within the MySQL repository. Data for MySQL Enterprise Monitor 2.0 is stored within a database called `mem`.

To create a backup of the old information, use `mysqldump`:

```
shell> mysqldump -uservice_manager -pPassword -P13306 -h127.0.0.1 merlin >data-1.3.sql
```

The above will create a file, `data-1.3.sql` containg all of the MySQL Enterprise Monitor 1.3 information.

If you remove access to the old data, then the data migration options for old servers will be removed from the **MANAGE SERVERS** panel within MySQL Enterprise Service Manager. To remove access, you need to `REVOKE` access to the `merlin` database:

```
mysql& REVOKE ALL on merlin.* FROM 'service_manager';
```

Note that revoking access to the old data will not reclaim any of the disk space used by the old data.

To delete the data from the database and free up the space being used by the historical information, `DROP` the `merlin` database:

```
mysql& DROP DATABASE merlin;
```

Once all the data has been migrated you can hide the migration user interface by clicking the HIDE MIGRATION INTERFACE button.

15.12.10. Regular MySQL Enterprise Monitor Maintenance

MySQL Enterprise Monitor is generally self managing and does not need excessive maintenance. You should, however, be aware of certain maintenance tasks that you can automate or will need to manually perform to keep your MySQL Enterprise Monitor running efficiently.

- Make sure you have set the purge interval for your data to an appropriate value according to duration and history of data that you want to keep. For more information, see Data Purge Behavior.
- Check, and delete, the contents of the temporary directory with your MySQL Enterprise Service Manager installation directory.

15.12.11. Advisor/Graph Reference

Basic

- **Advisors**
  - Agent Host Time Out of Sync Relative to Dashboard
  - CPU I/O Usage Excessive
  - CPU Usage Excessive
  - Connection Usage Excessive
  - Lock Contention Excessive
  - MyISAM Key Cache Has Sub-Optimal Hit Rate
  - MySQL Agent Not Communicating With Database Server
  - MySQL Agent Not Reachable
  - MySQL Server Not Reachable
  - Query Cache Has Sub-Optimal Hit Rate
  - RAM Usage Excessive
  - Table Scans Excessive
  - Temporary Tables To Disk Ratio Excessive
- **Graphs**
  - CPU Utilization
  - Connections
  - Database Activity
  - Hit Ratios

Silver

- **Advisors**
  - 32-Bit Binary Running on 64-Bit AMD Or Intel System
  - Account Has An Overly Broad Host Specifier
  - Account Has Global Privileges
  - Account Has Old Insecure Password Hash
  - Account Has Strong MySQL Privileges
  - Attempted Connections To The Server Have Failed
  - Binary Logging Is Limited
  - Binary Logging Not Enabled
  - Binary Logging Not Synchronized To Disk At Each Write
  - CREATE TABLE LIKE Does Not Require Any Privileges On Source Table
  - Database May Not Be Portable Due To Identifier Case Sensitivity
  - Date-Handling Bugs Can Crash The Server
  - Default Value Being Used For max_prepared_stmt_count
  - Disabling Next-Key Locking In InnoDB Can Crash The Server
  - Event Scheduler Disabled
  - Excessive Percentage Of Attempted Connections To The Server Have Failed
  - General Query Log Enabled
  - Improper key_cache_block_size Setting Can Corrupt MyISAM Tables
  - In-Memory Temporary Table Size Limited By Maximum Heap Table Size
  - Incorrect InnoDB Flush Method On Windows Using MySQL Version 4.1.9
  - InnoDB Tablespace Cannot Automatically Expand
  - InnoDB Transaction Logs Not Sized Correctly
  - Insecure Password Authentication Option Is Enabled
  - Insecure Password Generation Option Is Enabled
  - Key Buffer Size Greater Than 4 GB
  - LOCAL Option Of LOAD DATA Statement Is Enabled
  - Malformed Password Packet In Connection Protocol Can Crash Server
  - Maximum Connection Limit Nearing Or Reached
  - Missing Security Improvements In GRANT Options
  - Multi-Byte Encoding Processing Can Lead To SQL Injection
  - Multiple Threads Used When Repairing MyISAM Tables
  - MySQL Agent Memory Usage Excessive
  - MySQL Server Has Been Restarted

- Next-Key Locking Disabled For InnoDB But Binary Logging Enabled
- No Limit On Total Number Of Prepared Statements
- No Value Set For myisam-recover
- Non-Authorized User Has DB, Table, Or Index Privileges On All Databases
- Non-Authorized User Has GRANT Privileges On All Databases
- Non-Authorized User Has Server Admin Privileges
- Query Cache Not Available
- Root Account Can Login Remotely
- Root Account Without Password
- Row-based Replication Broken For UTF8 CHAR Columns Longer Than 85 Characters
- Security Alterations Detected: User Privileges Granted
- Security Alterations Detected: User Privileges Revoked
- Security Alterations Have Been Detected
- Security Risk with BINLOG statement
- Server Contains Default "test" Database
- Server Has Accounts Without A Password
- Server Has Anonymous Accounts
- Server Includes A Root User Account
- Stored Routine Runs In Definer"s Rather Than Caller"s Security Context
- Symlinks Are Enabled
- Table Cache Set Too Low For Startup
- Use Of View Overrides Column Update Privileges On Underlying Table
- User Can Gain Privileges By Running Stored Routine Declared Using SQL SECURITY INVOKER
- User Has Rights To Database That Does Not Exist
- User With Only ALTER Privilege On Partitioned Table Can Obtain SELECT Privilege Information
- Users Can View All Databases On MySQL Server
- XA Distributed Transaction Support Enabled For InnoDB

- **Graphs**

  - Sort Activity
  - Table Lock Wait Ratio
  - Table Locks

Advisors

- **32-Bit Binary Running on 64-Bit AMD Or Intel System**

The chip architecture and operating system installed on a machine both impact the performance of software running on the system. While it is possible to run 32-bit software on many 64-bit systems, in general, software built to run on a 64-bit system will run better on such a system than software built to run on a 32-bit system.

Default frequency 06:00:00

- **AUTO_INCREMENT Field Limit Nearly Reached**

  Many applications need to generate unique numbers and sequences for identification purposes (e.g. customer IDs, bug or trouble ticket tags, membership or order numbers, etc). MySQL's mechanism for doing this is the AUTO_INCREMENT column attribute, which enables you to generate sequential numbers automatically.

  However, the range of numbers that can be generated is limited by the underlying data type. For example, the maximum value possible for a TINYINT UNSIGNED column is 255. If you try to generate a number that exceeds the maximum allowed by the underlying data type (e.g. by inserting a NULL value into the AUTO_INCREMENT column), you will trigger database errors and your application may not behave properly.

  Note that the primary purpose of AUTO_INCREMENT in MySQL is to generate a sequence of `positive` integers. The use of non-positive numbers in in an AUTO_INCREMENT column is unsupported, so you may as well define those columns to be UNSIGNED, which effectively doubles their allowable range.

  Default frequency 06:00:00

- **Account Has An Overly Broad Host Specifier**

  The MySQL server has user accounts with overly broad host specifiers. A MySQL account is identified by both a username and a hostname, which are found in the User and Host columns of the mysql.user table. The User value is the name that a client must supply when connecting to the server. The Host value indicates the host or hosts from which the user is allowed to connect. If this is a literal hostname, the account is limited to connections only from that host. If the hostname contains the '%' wildcard character, the user can connect from any host that matches the wildcard character and potentially from any host at all.

  From a security standpoint, literal host values are best and `%` is worst. Accounts that have Host values containing wildcards are more susceptible to attack than accounts with literal host values, because attackers can attempt to connect from a broader range of machines.

  For example, if an account has user and host values of `root` and `%` , it means that you can connect as the root user from `any` machine if you know the password. By contrast, if the host name is `localhost` or `127.0.0.1`, the attacker can only attempt to connect as the root user from the server host.

  Default frequency 00:05:00

- **Account Has Global Privileges**

  A MySQL server may have user accounts with privileges on all databases and tables (*.*). In most cases global privileges should be allowed only for the MySQL root user, and possibly for users that you trust or use for backup purposes. Global privileges such as `DROP, ALTER, DELETE, UPDATE, INSERT,` and `LOCK TABLES` may be dangerous as they may cause other users to be affected adversely.

  Default frequency 00:05:00

- **Account Has Old Insecure Password Hash**

  Prior to MySQL 4.1, password hashes computed by the PASSWORD() function were 16 bytes long. As of MySQL 4.1 (and later), PASSWORD() was modified to produce a longer 41-byte hash value to provide enhanced security.

  Default frequency 06:00:00

- **Account Has Strong MySQL Privileges**

  Certain account privileges can be dangerous and should only be granted to trusted users when necessary. For example, the FILE privilege allows a user to read and write files on the database server (which includes sensitive operating system files), the PROCESS privilege allows currently executing statements to be monitored, and the SHUTDOWN privilege allows a user to shut down the server. In addition, the GRANT privilege allows a user to grant privileges to others.

  Default frequency 00:05:00

- **Agent Host Time Out of Sync Relative to Dashboard**

  To maintain data consistency and to facilitate day-to-day system management operations, which often require comparing logs, files, and timestamps across servers, it is important that the server clocks across all your systems and data centers be synchronized with respect to each other relative to UTC time (which takes timezones into account). When the clock on one server is minutes or hours behind another server, any timestamps created in the databases or on the file systems of those two servers will differ by that amount. Thus if you depend on timestamps to test the freshness of some data item, or if you are trying to diagnose a problem and need to compare timestamps across systems, your task will be more complicated due to this time difference.

  In addition, the data and graphs shown in the MySQL Enterprise Monitor Dashboard will be skewed by the difference in time between the machine hosting the Service Manager and the machines running the Agents. For example, if the time on an Agent machine is one hour behind the time on the Service Manager machine, the MySQL server that Agent is monitoring will appear to be down (see Bug#45937) and no data will appear in the graphs for that server for the first hour after the Agent is started.

  Default frequency 00:05:00

- **Attempted Connections To The Server Have Failed**

  Aborted connection attempts to MySQL may indicate an issue with respect to the server or network, or could be indicative of DoS or password-cracking attempts against the MySQL Server. The aborted-connects count is incremented when:

  - A client does not have privileges to access a database
  - A client uses the wrong password
  - A malformed packet is received
  - The connect_timeout variable is exceeded

  Default frequency 00:05:00

- **Binary Log File Count Exceeds Specified Limit**

  The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables replication as well as point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database. However, binary logs consume disk space and file system resources, and can be removed from a production server after they are no longer needed by the slaves connecting to this master server, and after they have been backed up.

  Default frequency 06:00:00

- **Binary Log Space Exceeds Specified Limit**

  The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables replication as well as point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database. However, binary logs consume disk space and can be removed from a production server after they are no longer needed by the slaves connecting to this master server, and after they have been backed up.

  Default frequency 06:00:00

- **Binary Log Usage Exceeding Disk Cache Memory Limits**

  When binary log usage exceeds the binary log cache memory limits, it is performing excessive disk operations. For optimal performance, transactions that move through the binary log should be contained within the binary log cache.

  Default frequency 00:05:00

- **Binary Logging Is Limited**

  The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database.

  Binary logging can be limited to specific databases with the `--binlog-do-db` and the `--binlog-ignore-db` options. However, if these options are used, your point-in-time recovery options are limited accordingly, along with your ability to review alterations made to your system.

Default frequency 06:00:00

- **Binary Logging Not Enabled**

  The binary log captures DML, DDL, and security changes that occur and stores these changes in a binary format. The binary log enables point-in-time recovery, preventing data loss during a disaster recovery situation. It also enables you to review all alterations made to your database.

  Default frequency 06:00:00

- **Binary Logging Not Synchronized To Disk At Each Write**

  By default, the binary log is not synchronized to disk at each write. If the server host, operating system, or MySQL server crash, there is a chance that the latest statements in the binary log are not written to disk. To prevent this, you can cause the binary log to be synchronized to disk after every Nth binary log entry using the `sync_binlog` global variable. 1 is the safest value, but also the slowest.

  Default frequency 06:00:00

- **CPU I/O Usage Excessive**

  CPU I/O usage should be low on a properly configured and well-tuned system. Excessive CPU I/O usage is often indicative of poor disk or network performance.

  Default frequency 00:01:00

- **CPU Usage Excessive**

  CPU usage should be low-to-moderate on a properly configured and well-tuned system. Excessive CPU usage can be indicative of many problems: insufficient RAM, fragmented disks, poorly-tuned queries, etc.

  Default frequency 00:01:00

- **CREATE TABLE LIKE Does Not Require Any Privileges On Source Table**

  Due to Bug#25578, a user who does not have any access to a database can still clone the structure of tables in that database. Knowing the structure of tables in a database may give a determined hacker insight that allows him or her to proceed with other exploits.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Connection Usage Excessive**

  Once the maximum connection limit for the MySQL server has been reached, no other user connections can be established and errors occur on the client side of the application.

  Default frequency 00:01:00

- **Data Flushed To Disk After Each SQL Statement**

  MySQL updates its data files on disk with the write() system call after every SQL statement and lets the operating system handle the synchronizing to disk. You can force MySQL to flush everything to disk after every SQL statement with the `--flush` option, however, this will have an adverse effect on performance.

  Default frequency 06:00:00

- **Database May Not Be Portable Due To Identifier Case Sensitivity**

  The case sensitivity of the underlying operating system determines the case sensitivity of database and table names. If you are using MySQL on only one platform, you don't normally have to worry about this. However, depending on how you have configured your server you may encounter difficulties if you want to transfer tables between platforms that differ in filesystem case sensitivity.

  Default frequency 06:00:00

- **Date-Handling Bugs Can Crash The Server**

  Two bugs related to date-handling operations can crash the server leading to potential Denial of Service (DoS) attacks:

  - STR_TO_DATE(1,NULL) caused a server crash (Bug#15828);
  - Invalid arguments to DATE_FORMAT() caused a server crash (Bug#20729).

    These bugs have been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Default Value Being Used For max_prepared_stmt_count**

  Prepared statements may increase performance in applications that execute similar statements more than once, primarily because the query is parsed only once. Prepared statements can also reduce network traffic because it is only necessary to send the data for the parameters for each execution rather than the whole statement.

  However, prepared statements consume memory in the MySQL server until they are closed, so it is important to use them properly and to limit the number of statements that can be open at any one time. The default value for max_prepared_stmt_count may not be appropriate for your application and environment.

  Default frequency 06:00:00

- **Disabling Next-Key Locking In InnoDB Can Crash The Server**

  Due to several bugs, the server could crash if next-key locking in InnoDB was disabled.

  These bugs have been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Event Scheduler Disabled**

  The Event Scheduler is a very useful feature when enabled. It is a framework for executing SQL commands at specific times or at regular intervals. Conceptually, it is similar to the idea of the Unix crontab (also known as a "cron job") or the Windows Task Scheduler.

  The basics of its architecture are simple. An event is a stored routine with a starting date and time, and a recurring tag. Once defined and activated, it will run when requested. Unlike triggers, events are not linked to specific table operations, but to dates and times. Using the event scheduler, the database administrator can perform recurring events with minimal hassle. Common uses are the cleanup of obsolete data, the creation of summary tables for statistics, and monitoring of server performance and usage.

  Default frequency 00:05:00

- **Excessive Disk Temporary Table Usage Detected**

  If the space required to build a temporary table exceeds either `tmp_table_size` or `max_heap_table_size`, MySQL creates a disk-based table in the server's tmpdir directory. Also, tables that have TEXT or BLOB columns are automatically placed on disk.

  For performance reasons it is ideal to have most temporary tables created in memory, leaving exceedingly large temporary tables to be created on disk.

  Default frequency 00:05:00

- **Excessive Number of Locked Processes**

  Depending on the circumstances, storage engines, and other factors, one process may be using or accessing a resource (e.g. a table or row) required by another process in such a way that the second process cannot proceed until the first process releases the resource. In this case the second process is in a "locked" state until the resource is released. If many processes are in a locked state it may be a sign of serious trouble related to resource contention, or a long running session that is not releasing currently held locks when it should have.

  Default frequency 00:01:00

- **Excessive Number of Long Running Processes**

Most applications and databases are designed to execute queries very quickly. If many queries are taking a long time to execute (e.g. more than a few seconds) it can be a sign of trouble. In such cases queries may need to be tuned or rewritten, or indexes added to improve performance. In other cases the database schema may have to be redesigned.

Default frequency 00:01:00

- **Excessive Number of Long Running Processes Locked**

  Most applications and databases are designed to execute queries very quickly, and to avoid resource contention where one query is waiting for another to release a lock on some shared resource. If many queries are locked and taking a long time to execute (e.g. more than a few seconds), it can be a sign of performance trouble and resource contention. In such cases queries may need to be tuned or rewritten, or indexes added to improve performance. In other cases the database schema may have to be redesigned.

  Default frequency 00:01:00

- **Excessive Percentage Of Attempted Connections To The Server Have Failed**

  Excess aborted connection attempts to MySQL may indicate an issue with respect to the server or network, or could be indicative of DoS or password-cracking attempts against the MySQL Server. The aborted-connects count is incremented when:

  - A client does not have privileges to access a database
  - A client uses the wrong password
  - A malformed packet is received
  - The connect_timeout variable is exceeded

  Default frequency 00:05:00

- **Flush Time Set To Non-Zero Value**

  If `flush_time` is set to a non-zero value, all tables are closed every flush_time seconds to free up resources and synchronize unflushed data to disk. If your system is unreliable and tends to lock up or restart often, forcing out table changes this way degrades performance but can reduce the chance of table corruption or data loss. We recommend that this option be used only on Windows, or on systems with minimal resources.

  Default frequency 06:00:00

- **General Query Log Enabled**

  The general query log is a general record of what mysqld is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to mysqld.

  However, the general query log should not be enabled in production environments because:

  - It adds overhead to the server;
  - It logs statements in the order they were received, not the order they were executed, so it is not reliable for backup/recovery;
  - It grows fast and can use a lot of disk space;
  - You cannot stop logging to the general query log without stopping the server (for versions previous to 5.1).

    You should use the binary log instead.

  Default frequency 06:00:00

- **INSERT ON DUPLICATE KEY UPDATE Bug May Break Replication**

  For INSERT ... ON DUPLICATE KEY UPDATE statements where some AUTO_INCREMENT values were generated automatically for inserts and some rows were updated, one auto-generated value was lost per updated row, leading to faster exhaustion of the range of the AUTO_INCREMENT column. Affected versions of MySQL include 5.0.24 to 5.0.34, and 5.1.12 to 5.1.17 (inclusive).

Because the original problem can affect replication (different values on master and slave), it is recommended that the master and its slaves be upgraded to the current version.

Default frequency 06:00:00

- **Improper key_cache_block_size Setting Can Corrupt MyISAM Tables**

  The server deducts some bytes from the key_cache_block_size option value and reduces it to the next lower 512 byte boundary. The resulting block size is not a power of two. Setting the key_cache_block_size system variable to a value that is not a power of two results in MyISAM table corruption.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **In-Memory Temporary Table Size Limited By Maximum Heap Table Size**

  If the space required to build a temporary table exceeds either `tmp_table_size` or `max_heap_table_size`, MySQL creates a disk-based table in the server's tmpdir directory. For performance reasons it is ideal to have most temporary tables created in memory, leaving exceedingly large temporary tables to be created on disk. Many DBAs configure `tmp_table_size` appropriately, but forget that `max_heap_table_size` also plays a role.

  Default frequency 06:00:00

- **Incorrect InnoDB Flush Method On Windows Using MySQL Version 4.1.9**

  If `innodb_file_per_table` is enabled and `innodb_flush_method` is not set to `unbuffered` on Windows when using MySQL Server version 4.1.9, MySQL may not start and you may see operating system error code 87.

  Default frequency 06:00:00

- **Indexes Not Being Used Efficiently**

  The target server does not appear to be using indexes efficiently. The values of Handler_read_rnd_next and Handler_read_rnd together - which reflect the number of rows read via full table scans - are high compared to the Handler variables which denote index accesses - such as Handler_read_key, Handler_read_next etc. You should examine your tables and queries for proper use of indexes.

  Default frequency 00:05:00

- **InnoDB Buffer Cache Has Sub-Optimal Hit Rate**

  Logical I/O is many times faster than physical I/O, and therefore a DBA should strive to keep physical I/O to a minimum. It is true that logical I/O is not free, and that the DBA should work to keep `all` I/O to a minimum, but it is best if most data access is performed in memory. When using InnoDB, most data access should occur in RAM, and therefore the InnoDB buffer cache hit rate should be high.

  Default frequency 00:05:00

- **InnoDB Buffer Pool Writes May Be Performance Bottleneck**

  For optimal performance, InnoDB should not have to wait before writing pages into the InnoDB buffer pool.

  Default frequency 00:05:00

- **InnoDB Doublewrite Buffer Enabled**

  InnoDB uses a novel file flush technique called *doublewrite*. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for fsync() operations.

  Doublewrite means that before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, during recovery InnoDB can find a good copy of the page from the doublewrite buffer.

  Default frequency 06:00:00

- **InnoDB Flush Method May Not Be Optimal**

  Different values for `innodb_flush_method` can have a marked effect on InnoDB performance. In some versions of GNU/Linux and Unix, flushing files to disk by invoking fsync() (which InnoDB uses by default) or other similar methods, can be surprisingly slow. If you are dissatisfied with database write performance, you might try setting the innodb_flush_method parameter to O_DIRECT or O_DSYNC.

  Default frequency 06:00:00

- **InnoDB Log Buffer Flushed To Disk After Each Transaction**

  By default, InnoDB's log buffer is written out to the log file at each transaction commit and a flush-to-disk operation is performed on the log file, which enforces ACID compliance. In the event of a crash, if you can afford to lose a second's worth of transactions, you can achieve better performance by setting `innodb_flush_log_at_trx_commit` to either 0 or 2. If you set the value to 2, then only an operating system crash or a power outage can erase the last second of transactions. This can be very useful on slave servers, where the loss of a second's worth of data can be recovered from the master server if needed.

  Default frequency 06:00:00

- **InnoDB Log Waits May Be Performance Bottleneck**

  For optimal performance, InnoDB should not have to wait before writing DML activity to the InnoDB log buffer.

  Default frequency 00:05:00

- **InnoDB Tablespace Cannot Automatically Expand**

  If the InnoDB tablespace is not allowed to automatically grow to meet incoming data demands and your application generates more data than there is room for, out-of-space errors will occur and your application may experience problems.

  Default frequency 06:00:00

- **InnoDB Transaction Logs Not Sized Correctly**

  To avoid frequent checkpoint activity and reduce overall physical I/O, which can slow down write-heavy systems, the InnoDB transaction logs should be approximately 50-100% of the size of the InnoDB buffer pool, depending on the size of the buffer pool.

  Default frequency 06:00:00

- **Insecure Password Authentication Option Is Enabled**

  Prior to MySQL 4.1, password hashes computed by the PASSWORD() function were 16 bytes long. As of MySQL 4.1 (and later), PASSWORD() was modified to produce a longer 41-byte hash value to provide enhanced security. However, in order to allow backward-compatibility with user tables that have been migrated from pre-4.1 systems, you can configure MySQL to accept logins for accounts that have password hashes created using the old, less-secure PASSWORD() function, but this is not recommended.

  Default frequency 06:00:00

- **Insecure Password Generation Option Is Enabled**

  Prior to MySQL 4.1, password hashes computed by the PASSWORD() function were 16 bytes long. As of MySQL 4.1 (and later), PASSWORD() was modified to produce a longer 41-byte hash value to provide enhanced security. In order to allow backward-compatibility with older client programs, you can configure MySQL to generate short (pre-4.1) password hashes for new passwords, however, this is not recommended.

  Default frequency 06:00:00

- **Key Buffer Size Greater Than 4 GB**

  To minimize disk I/O, the MyISAM storage engine employs a key cache (or key buffer) to keep the most frequently accessed index blocks in memory. However, prior to MySQL version 5.0.52 this key buffer is limited in size to 4 GB, `even on 64-bit operating systems`. If set to a larger value, mysqld may crash when it tries to increase the actual buffer beyond 4 GB. Note that key_buffer_size is limited to 4GB on both 32-bit and 64-bit Windows systems, even in MySQL version 5.0.52 and later.

  Default frequency 06:00:00

- **Key Buffer Size May Not Be Optimal For Key Cache**

  The key cache hit ratio represents the proportion of keys that are being read from the key cache in memory instead of from disk. This should normally be greater than 99% for optimum efficiency.

  Default frequency 00:05:00

- **Key Buffer Size May Not Be Optimal For System RAM**

  The target server does not appear to have sufficient memory devoted to the key cache. On a dedicated server, this cache is commonly about 25%-50% of total RAM.

  Default frequency 06:00:00

- **LOCAL Option Of LOAD DATA Statement Is Enabled**

  The LOAD DATA statement can load a file that is located on the server host, or it can load a file that is located on the client host when the LOCAL keyword is specified.

  There are two potential security issues with supporting the LOCAL version of LOAD DATA statements:

  - The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the LOAD DATA statement. Such a server could access any file on the client host to which the client user has read access.

  - In a Web environment where the clients are connecting from a separate web server, a user could use LOAD DATA LOCAL to read any files that the web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the web server, not the remote program being run by the user who connects to the web server.

  Default frequency 00:05:00

- **Lock Contention Excessive**

  Performance can be degraded if the percentage of table operations that have to wait for a lock is high compared to the overall number of lock requests. This can happen when using a table-level locking storage engine, such as MyISAM, instead of a row-level locking storage engine.

  Default frequency 00:05:00

- **Malformed Password Packet In Connection Protocol Can Crash Server**

  Due to Bug#28984, a malformed password packet in the connection protocol could cause the server to crash. This can lead to denial of service (DoS) attacks.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Maximum Connection Limit Nearing Or Reached**

  Once the maximum connection limit for the MySQL server has been reached, no other user connections can be established and errors occur on the client side of the application.

  Default frequency 00:05:00

- **Missing Security Improvements In GRANT Options**

  The GRANT statement is used to create MySQL user accounts and to grant rights to accounts. Due to bugs 15756 and 14385, rights may be granted erroneously in certain circumstances:

  - In grant table comparisons, improper use of a latin1 collation caused some hostname matches to be true that should have been false (Bug#15756).

  - GRANTs to users with wildcards in their host information could be erroneously applied to similar users with the same username and similar wildcards. For example, a privilege granted to foo@% is also applied to user foo@192.% (Bug#14385).

These bugs have been fixed in later versions of the MySQL server.

Default frequency 06:00:00

- **Multi-Byte Encoding Processing Can Lead To SQL Injection**

  Due to bug 8378, the server incorrectly parsed strings escaped with the mysql_real_escape_string() C API function. As a result, even when the character set-aware mysql_real_escape_string() function was used, SQL injection was possible.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Multiple Threads Used When Repairing MyISAM Tables**

  Using multiple threads when repairing MyISAM tables can improve performance, but it can also lead to table and index corruption as reported by several bugs (#11527, #11684, #18874). Even though these bugs have been fixed, this feature is still considered beta-quality, as noted in the manual.

  Default frequency 06:00:00

- **MyISAM Concurrent Insert Setting May Not Be Optimal**

  MyISAM uses table-level locking, which can adversely affect performance when there are many concurrent INSERT and SELECT statements because INSERTs will block all SELECTs until the INSERT is completed. However, MyISAM can be configured to allow INSERT and SELECT statements to run concurrently in certain situations.

  - If `concurrent_insert is set to 1` (the default), MySQL allows INSERT and SELECT statements to run concurrently `for MyISAM tables that have no free blocks in the middle` of the data file.
  - If `concurrent_insert is set to 2` (available in MySQL 5.0.6 and later), MySQL allows concurrent inserts `for all MyISAM tables`, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

    Note that setting concurrent_insert to 2 allows tables to grow even when there are holes in the middle. This can be bad for applications that delete large chunks of data but continue to issue many SELECTs, thus effectively preventing INSERTs from filling the holes.

  Default frequency 06:00:00

- **MyISAM Indexes Found with No Statistics**

  The MySQL optimizer needs index statistics to help make choices about whether to use indexes to satisfy SQL queries. Having no statistics or outdated statistics limits the optimizer's ability to make smart and informed access plan choices.

  Default frequency 12:00:00

- **MyISAM Key Cache Has Sub-Optimal Hit Rate**

  The key cache hit ratio represents the proportion of index values that are being read from the key cache in memory instead of from disk. This should normally be greater than 99% for optimum efficiency.

  Default frequency 00:05:00

- **MySQL Agent Memory Usage Excessive**

  The memory needed by the MySQL Agent for basic monitoring is fairly small and consistent, and depends on the number of rules you have enabled. However, when the Query Analyzer is enabled, the Agent can use significantly more memory to monitor and analyze whatever queries you direct through it. In this case, the amount of memory used depends on the number of unique normalized queries, example queries and example explains being processed, plus the network bandwidth required to send query data to the Service Manager. In general, the amount of memory used for the Query Analyzer is small and well-bounded, but under some circumstances it can become excessive, especially on older versions of Linux.

  Default frequency 00:01:00

- **MySQL Agent Not Communicating With Database Server**

  The MySQL Enterprise Service Agent must be able to communicate with the local MySQL database server in order to monitor the server and provide advice on enforcement of best practices.

  Default frequency 00:01:00

- **MySQL Agent Not Reachable**

  In order to monitor a MySQL server, a Service Agent must be running and communicating with the Service Manager. If the Agent cannot communicate with the Service Manager, the Service Manager has no way of knowing if the MySQL database server being monitored is running, and it cannot collect current statistics to properly evaluate the rules scheduled against that server.

  Default frequency 00:00:01

- **MySQL Server Has Been Restarted**

  To perform useful work, a database server must be up-and-running continuously. It is normal for a production server to run continuously for weeks, months, or longer. If a server has been restarted recently, it may be the result of planned maintenance, but it may also be due to an unplanned event that should be investigated.

  Default frequency 00:05:00

- **MySQL Server Not Reachable**

  To perform useful work, it must be possible to connect to the local MySQL database server. If the MySQL Enterprise Service Agent cannot communicate with the server, it is likely the server is not running.

  Default frequency 00:01:00

- **Next-Key Locking Disabled For InnoDB But Binary Logging Enabled**

  Next-key locking in InnoDB can be disabled, which may improve performance in some situations. However, this may result in inconsistent data when recovering from the binary logs in replication or recovery situations. Starting from MySQL 5.0.2, this option is even more unsafe than it was in version 4.1.x.

  Default frequency 06:00:00

- **No Limit On Total Number Of Prepared Statements**

  Due to Bug#16365, there is no limit to the number of prepared statements that can be open per connection. This can lead to a Denial Of Service (DoS) attack, as the server will crash with out-of-memory (OOM) errors when the amount of statements becomes very large.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **No Value Set For myisam-recover**

  The `myisam-recover` option enables automatic MyISAM crash recovery should a MyISAM table become corrupt for some reason. If this option is not set, then a table will be "Marked as crashed" if it becomes corrupt, and no sessions will be able to SELECT from it, or perform any sort of DML against it.

  Default frequency 06:00:00

- **Non-Authorized User Has DB, Table, Or Index Privileges On All Databases**

  Privileges such as SELECT, INSERT, ALTER, and so forth allow a user to view and change data, as well as impact system performance. Such operations should be limited to only those databases to which a user truly needs such access so the user cannot inadvertently affect other people's applications and data stores.

  Default frequency 01:00:00

- **Non-Authorized User Has GRANT Privileges On All Databases**

The GRANT privilege, when given on all databases as opposed to being limited to a few specific databases, enables a user to give to other users those privileges that the grantor possesses on all databases. It can be used for databases, tables, and stored routines. Such a privilege should be limited to as few users as possible. Users who do indeed need the GRANT privilege should have that privilege limited to only those databases they are responsible for, and not for all databases.

Default frequency 01:00:00

- **Non-Authorized User Has Server Admin Privileges**

  Certain privileges, such as SHUTDOWN and SUPER, are primarily used for server administration. Some of these privileges can have a dramatic effect on a system because they allow someone to shutdown the server or kill running processes. Such operations should be limited to a small set of users.

  Default frequency 01:00:00

- **Object Changed: Database Has Been Altered**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Database Has Been Created**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Database Has Been Dropped**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Function Has Been Created**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Function Has Been Dropped**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures or functions and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Index Has Been Created**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Index Has Been Dropped**

For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

Default frequency 00:10:00

- **Object Changed: Table Has Been Altered**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Table Has Been Created**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: Table Has Been Dropped**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changed: User Has Been Dropped**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when changes occur in a production environment with respect to database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Object Changes Detected**

  For development environments, changes to databases and objects may be a normal occurrence, but not for production environments. It is wise to know when any changes occur in a production environment with respect to any database structures and investigate the reasons for the changes.

  Default frequency 00:10:00

- **Prepared Statements Not Being Closed**

  Prepared statements may increase performance in applications that execute similar statements more than once, primarily because the query is parsed only once. Prepared statements can also reduce network traffic because it is only necessary to send the data for the parameters for each execution rather than the whole statement.

  However, prepared statements take time to prepare and consume memory in the MySQL server until they are closed, so it is important to use them properly. If you are not closing prepared statements when you are done with them, you are needlessly tying up memory that could be put to use in other ways.

  Default frequency 00:05:00

- **Prepared Statements Not Being Used Effectively**

  Prepared statements may increase performance in applications that execute similar statements more than once, primarily because the query is parsed only once. Prepared statements can also reduce network traffic because it is only necessary to send the data for the parameters for each execution rather than the whole statement.

  However, prepared statements take time to prepare and consume memory in the MySQL server until they are closed, so it is import-

ant to use them properly. If you are only executing a statement a few times, the overhead of creating a prepared statement may not be worthwhile.

Default frequency 00:05:00

- **Query Cache Has Sub-Optimal Hit Rate**

  When enabled, the query cache should experience a high degree of "hits", meaning that queries in the cache are being reused by other user connections. A low hit rate may mean that not enough memory is allocated to the cache, identical queries are not being issued repeatedly to the server, or that the statements in the query cache are invalidated too frequently by INSERT, UPDATE or DELETE statements.

  Default frequency 00:05:00

- **Query Cache Not Available**

  MySQL can cache the results of SELECT statements in memory so that they do not have to constantly be parsed and executed. If your application often runs the same queries over and over, caching the results can increase performance significantly. It's important to use a version or binary of MySQL that supports the query cache.

  Default frequency 06:00:00

- **Query Cache Not Enabled**

  Enabling the query cache can increase performance by 200% for queries that are executed often and have large result sets.

  Default frequency 00:05:00

- **Query Cache Potentially Undersized**

  When the Query Cache is full, and needs to add more queries to the cache, it will make more room in the cache by freeing the least recently used queries from the cache, and then inserting the new queries. If this is happening often then you should increase the size of the cache to avoid this constant "swapping".

  Default frequency 00:05:00

- **RAM Usage Excessive**

  A reasonable amount of free memory is required for a system to perform well. Without free memory, new processes and threads cannot start, and the operating system may do excessive paging (swapping blocks of memory to and from disk).

  Default frequency 00:01:00

- **Root Account Can Login Remotely**

  By default, MySQL includes a root account with unlimited privileges that is typically used to administer the MySQL server. If possible, accounts with this much power should not allow remote logins in order to limit access to only those users able to login to the machine on which MySQL is running. This helps prevent unauthorized users from accessing and changing the system.

  Default frequency 00:05:00

- **Root Account Without Password**

  The root user account has unlimited privileges and is intended for administrative tasks. Privileged accounts should have strong passwords to prevent unauthorized users from accessing and changing the system.

  Default frequency 00:05:00

- **Row-based Replication Broken For UTF8 CHAR Columns Longer Than 85 Characters**

  Due to Bug#37426, row-based replication breaks when CHAR() UTF8 fields with a length greater than 85 characters are used.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Security Alterations Detected: User Privileges Granted**

  For development environments, changes to database security privileges may be a normal occurrence, but for production environments it is wise to know when any security changes occur with respect to database privileges, and to ensure that those changes are authorized and required.

  Default frequency 00:05:00

- **Security Alterations Detected: User Privileges Revoked**

  For development environments, changes to database security privileges may be a normal occurrence, but for production environments it is wise to know when any security changes occur with respect to database privileges, and to ensure that those changes are authorized and required.

  Default frequency 00:05:00

- **Security Alterations Have Been Detected**

  For development environments, changes to database security privileges may be a normal occurrence, but for production environments it is wise to know when any security changes occur with respect to database privileges, and to ensure that those changes are authorized and required.

  Default frequency 00:05:00

- **Security Risk with BINLOG statement**

  Due to Bug#31611, any user can execute BINLOG statements, which effectively gives them the ability to execute any SQL statement regardless of the privileges associated with their user account (i.e. as given by the GRANT statement). This allows any connected user to get any privileges they want, edit any data they want, add and drop tables, etc.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Server Contains Default "test" Database**

  By default, MySQL comes with a database named `test` that anyone can access. This database is intended only for testing and should be removed before moving into a production environment. Because the default `test` database can be accessed by any user and has permissive privileges, it should be dropped immediately as part of the installation process.

  Default frequency 00:05:00

- **Server Has Accounts Without A Password**

  Accounts without passwords are particularly dangerous because an attacker needs to guess only a username. Assigning passwords to all accounts helps prevent unauthorized users from accessing the system.

  Default frequency 00:05:00

- **Server Has Anonymous Accounts**

  Anonymous MySQL accounts allow clients to connect to the server without specifying a username. Since anonymous accounts are well known in MySQL, removing them helps prevent unauthorized users from accessing the system.

  Default frequency 00:05:00

- **Server Includes A Root User Account**

  By default, MySQL includes a root account with unlimited privileges that is typically used to administer the MySQL server. There is no reason this account must be named 'root'. Accounts with this much power should not be easily discovered. Since the root account is well known in MySQL, changing its name helps prevent unauthorized users from accessing and changing the system.

  Default frequency 00:05:00

- **Server-Enforced Data Integrity Checking Disabled**

SQL Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. If no SQL modes are enabled this means there is no form of server-enforced data integrity, which means incoming data that is invalid will not be rejected by the server, but instead will be changed to conform to the target column's default datatype. Note, however, that beginning with MySQL 4.1, any client can change its own session SQL mode value at any time.

Default frequency 06:00:00

- **Server-Enforced Data Integrity Checking Not Strict**

  SQL Modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. There are many possible options that can be used in conjunction with each other to specify varying degrees of syntax and data validation checks the MySQL server will perform. However, to ensure the highest level of confidence for data integrity, at least one of the following should be included in the list: `TRADITIONAL, STRICT_TRANS_TABLES,` or `STRICT_ALL_TABLES`.

  Note, however, that beginning with MySQL 4.1, any client can change its own session SQL mode value at any time.

  Default frequency 06:00:00

- **Slave Detection Of Network Outages Too High**

  Slaves must deal with network connectivity outages that affect the ability of the slave to get the latest data from the master, and hence cause replication to fall behind. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout seconds`. You may want to decrease `slave_net_timeout` so the outages -- and associated connection retries -- are detected and resolved faster. The default for this parameter is 3600 seconds (1 hour), which is too high for many environments.

  Default frequency 06:00:00

- **Slave Error: Unknown or Incorrect Time Zone**

  In order to use time zone names in conjunction with certain statements, functions, and data types, you must configure the server to understand those names by loading information from the operating system's time zone files into a set of tables in the mysql database. However, while the MySQL installation procedure creates those time zone tables, it does not load them; they must be loaded manually after installation.

  Default frequency 00:05:00

- **Slave Execution Position Too Far Behind Read Position**

  When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. If the position from which the SQL thread is reading is way behind the position to which the I/O thread is currently writing, it is a sign that replication is getting behind and results of queries directed to the slave may not reflect the latest changes made on the master.

  Default frequency 00:05:00

- **Slave Has Been Stopped**

  If replication on a slave has been stopped, it means the slave is not retrieving the latest statements from the master and it is not executing those statements on the slave.

  Default frequency 00:01:00

- **Slave Has Experienced A Replication Error**

  When a slave receives updates from its master it must apply those updates locally so the data on the slave matches that on the server. If an error occurs while applying an update on a slave, the data on the slave may not match that on the master and it is an indication that replication may be broken.

  Default frequency 00:05:00

- **Slave Has Login Accounts With Inappropriate Privileges**

  Altering and dropping tables on a slave can break replication. Unless the slave also hosts non-replicated tables, there is no need for accounts with these privileges. As an alternative, you should set the `read_only` flag `ON` so the server allows no updates except

from users that have the SUPER privilege or from updates performed by slave threads.

Default frequency 06:00:00

- **Slave Has Problem Communicating With Master**

  Slaves must connect to a master to get the latest data from the master. If they cannot connect, or periodically have trouble connecting, replication may fall behind (i.e. the slave may not have the lastest data that was written to the master).

  Default frequency 00:05:00

- **Slave Has Stopped Replicating**

  If neither the slave I/O thread nor the slave SQL threads are running, it means the slave is not getting the latest statements from the master and it is not executing those statements on the slave, and thus replication has stopped entirely.

  Default frequency 00:01:00

- **Slave I/O Thread Not Running**

  The slave I/O thread is the thread that retrieves statements from the master's binary log and records them into the slave's relay log. If this thread isn't running, it means the slave is not able to retrieve the latest data from the master.

  Default frequency 00:01:00

- **Slave Not Configured As Read Only**

  Arbitrary or unintended updates to a slave may break replication or cause a slave to be inconsistent with respect to its master. Making a slave `read_only` can be useful to ensure that a slave accepts updates only from its master server and not from clients; it minimizes the possibility of unintended updates.

  Default frequency 06:00:00

- **Slave Relay Log Space Is Very Large**

  When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. After the SQL thread has executed all the updates in a relay log, the file is no longer needed and can be deleted to conserve disk space.

  Default frequency 06:00:00

- **Slave Relay Logs Not Automatically Purged**

  When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. After the SQL thread has executed all the updates in a relay log, the file is no longer needed and can be deleted to conserve disk space.

  Default frequency 06:00:00

- **Slave SQL Thread Not Running**

  The slave SQL thread is the thread that reads statements from the slave's relay log and executes them to bring the slave in sync with the master. If this thread isn't running, it means the slave is not able to apply the latest changes it has read from the master, and results of queries directed to the slave may not reflect the latest changes made on the master.

  Default frequency 00:01:00

- **Slave SQL Thread Reading From Older Relay Log Than I/O Thread**

  When a slave receives updates from its master, the I/O thread stores the data in local files known as relay logs. The slave's SQL thread reads the relay logs and executes the updates they contain. If the SQL thread is reading from an older relay log than the one to which the I/O thread is currently writing, it is a sign that replication is getting behind and results of queries directed to the slave may not reflect the latest changes made on the master.

  Default frequency 00:05:00

- **Slave Too Far Behind Master**

  If a slave is too far behind the master, results of queries directed to the slave may not reflect the latest changes made on the master.

  Default frequency 00:01:00

- **Slave Waiting To Free Relay Log Space**

  For slaves with limited disk space you can place a limit on how large the replication relay log can grow. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unprocessed relay logs. While this protects MySQL from filling up the disk, it means replication is delayed and the slave will fall behind the master.

  Default frequency 00:05:00

- **Slave Without REPLICATION SLAVE Accounts**

  If the master ever fails, you may want to use one of the slaves as the new master. An account with the REPLICATION SLAVE privilege must exist for a server to act as a replication master (so a slave can connect to it), so it's a good idea to create this account on your slaves to prepare it to take over for a master if needed.

  Default frequency 06:00:00

- **Slow Query Log Not Enabled**

  The slow query log can be used to identify queries that take a long time to complete.

  Default frequency 00:05:00

- **Stored Procedures Found With SELECT * Syntax**

  Best practices for SQL coding state that no query should be issued with SELECT *. Reasons include:

  - To ensure that only the necessary columns are returned from a SQL statement, the actual column names should be specifically entered. This cuts down on unwanted network traffic as only columns necessary for query satisfaction are present.
  - If the underlying table has columns added or removed, the query itself may malfunction if cursors or other such application objects are used.

  Default frequency 06:00:00

- **Stored Routine Runs In Definer''s Rather Than Caller''s Security Context**

  Due to bug 18630, a stored routine created by one user and then made accessible to a different user using GRANT EXECUTE could be executed by that user with the privileges of the routine's definer.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Symlinks Are Enabled**

  You can move tables and databases from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or to increase the speed of your system by spreading your tables to different disks.

  However, symlinks can compromise security. This is especially important if you run mysqld as root, because anyone who has write access to the server's data directory could then delete any file in the system!

  Default frequency 06:00:00

- **Table Cache Not Optimal**

  MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client threads having different states on the same table, the table is opened independently by each concurrent thread.

The table cache is used to cache file descriptors for open tables and there is a single cache shared by all clients. Increasing the size of the table cache allows mysqld to keep more tables open simultanously by reducing the number of file open and close operations that must be done. If the value of `Open_tables` is approaching the value of `table_cache`, this may indicate performance problems.

Default frequency 00:05:00

- **Table Cache Set Too Low For Startup**

  The table cache size controls the number of open tables that can occur at any one time on the server. MySQL will work to open and close tables as needed, however you should avoid having the table cache set too low, causing MySQL to constantly open and close tables to satisfy object access.

  If the table cache limit has been exceeded by the number of tables opened in the first three hours of service, then the table cache size is likely set too low.

  Default frequency 00:30:00

- **Table Lock Contention Excessive**

  Performance can be degraded if the percentage of table operations that have to wait for a lock is high compared to the overall number of lock requests. This can happen when using a table-level locking storage engine, such as MyISAM, instead of a row-level locking storage engine.

  Default frequency 00:05:00

- **Table Scans Excessive**

  The target server does not appear to be using indexes efficiently. The values of Handler_read_rnd_next and Handler_read_rnd together - which reflect the number of rows read via full table scans - are high compared to the sum of Handler variables which denote all row accesses - such as Handler_read_key, Handler_read_next etc. You should examine your tables and queries for proper use of indexes.

  Default frequency 00:05:00

- **Tables Found with No Primary or Unique Keys**

  A primary or unique key of a relational table uniquely identifies each record in the table. Except in very unusual circumstances, every database table should have one or more columns designated as the primary key or as a unique key, and it is common practice to declare one.

  Default frequency 12:00:00

- **Temporary Tables To Disk Ratio Excessive**

  If the space required to build a temporary table exceeds either `tmp_table_size` or `max_heap_table_size`, MySQL creates a disk-based table in the server's tmpdir directory. Also, tables that have TEXT or BLOB columns are automatically placed on disk.

  For performance reasons it is ideal to have most temporary tables created in memory, leaving exceedingly large temporary tables to be created on disk.

  Default frequency 00:05:00

- **Thread Cache Not Enabled**

  Each connection to the MySQL database server runs in its own thread. Thread creation takes time, so rather than killing the thread when a connection is closed, the server can keep the thread in its thread cache and use it for a new connection later.

  Default frequency 00:05:00

- **Thread Cache Size May Not Be Optimal**

  Each connection to the MySQL database server runs in its own thread. Thread creation takes time, so rather than killing the thread when a connection is closed, the server can keep the thread in its thread cache and use it for a new connection later.

Default frequency 00:05:00

- **Too Many Concurrent Queries Running**

  Too many active queries indicates there is a severe load on the server, and may be a sign of lock contention or unoptimized SQL queries.

  Default frequency 00:05:00

- **Use Of View Overrides Column Update Privileges On Underlying Table**

  Due to Bug#27878, by using a view, a user who only has privileges to update a given column of a table is able to update any column of that table, even though the view is defined with SQL SECURITY INVOKER. Also, use of a view could allow a user to gain update privileges for tables in other databases.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **User Can Gain Privileges By Running Stored Routine Declared Using SQL SECURITY INVOKER**

  Due to Bug#27337, if a stored routine was declared using SQL SECURITY INVOKER, a user who invoked the routine could gain privileges. For example, a user without the CREATE privilege on a certain database could gain that privilege after invoking a stored routine.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **User Has Rights To Database That Does Not Exist**

  When a database is dropped, user privileges on the database are not automatically dropped. This has security implications as that user will regain privileges if a database with the same name is created in the future, which may not be the intended result.

  Default frequency 00:05:00

- **User With Only ALTER Privilege On Partitioned Table Can Obtain SELECT Privilege Information**

  Due to Bug#23675, a user with only the ALTER privilege on a partitioned table could obtain information about the table that should require the SELECT privilege.

  This bug has been fixed in later versions of the MySQL server.

  Default frequency 06:00:00

- **Users Can View All Databases On MySQL Server**

  The SHOW DATABASES privilege should be granted only to users who need to see all the databases on a MySQL Server. It is recommended that the MySQL Server be started with the `--skip-show-database` option enabled to prevent anyone from using the SHOW DATABASES statement unless they have been specifically granted the SHOW DATABASES privilege.

  Note: If a user is granted any global privilege, such as CREATE TEMPORARY TABLES or LOCK TABLES, they are automatically given the ability to show databases unless the server is started with the --skip-show-database option enabled. DBAs should be aware of this fact, in the event that any applications make use of temporary tables.

  Default frequency 00:05:00

- **XA Distributed Transaction Support Enabled For InnoDB**

  XA Distributed Transaction support is turned on by default. If you are not using this feature, note that it adds an extra fsync for each transaction and may adversely affect performance.

  Default frequency 06:00:00

CPU Utilization

Name	CPU Utilization
Range Label	%
Series	**Expression**
Kernel	sys/(sys+user+wait+idle)*100
Total	(sys+user+wait)/(sys+user+wait+idle)*100

Name	Opened Tables
Range Label	total/min
Series	**Expression**
Opened Tables	openedTables
Variables	**Data Item**
openedTables	mysql:status:Opened_tables

Query Cache Blocks

Name	Query Cache Blocks
Range Label	num blocks
Series	**Expression**
Free	free_blocks
Size	size_blocks

Variables	**Data Item**
size_blocks	mysql:status:Qcache_total_blocks
free_blocks	mysql:status:Qcache_free_blocks

Query Cache Efficiency

Name	Query Cache Efficiency
Range Label	avg cache ops/sec
Series	**Expression**
Hits	(hits/60)
Inserts	(inserts/60)
Not Cached	(not_cached/60)
Variables	**Data Item**
hits	mysql:status:Qcache_hits
inserts	mysql:status:Qcache_inserts
not_cached	mysql:status:Qcache_not_cached

Query Cache Lowmem Prunes

Name	Query Cache Lowmem Prunes
Range Label	avg cache ops/sec
Series	**Expression**
Lowmem Prunes	(deletes/60)
Variables	**Data Item**
deletes	mysql:status:Qcache_lowmem_prunes

Query Cache Memory

Name	Query Cache Memory
Range Label	MB
Series	**Expression**
Free MB	free/(1024*1024)
Size MB	size/(1024*1024)
Variables	**Data Item**
size	mysql:variables:query_cache_size
free	mysql:status:Qcache_free_memory

Query Cache Queries

Name	Query Cache Queries
Range Label	num queries
Series	**Expression**
Queries in Cache	queries
Variables	**Data Item**
queries	mysql:status:Qcache_queries_in_cache

Replication Delay

Name	Replication Delay
Range Label	total seconds
Series	**Expression**
Seconds Behind Master	sbehind
Variables	**Data Item**
sbehind	mysql:slavestatus:Seconds_Behind_Master

Row Accesses

Name	Row Accesses
Range Label	avg rows/sec
Series	**Expression**
Average Rows Per Query	((first+key+next+prev+hread_rnd+hread_rnd_next+sort_rows) / questions)
Rows Read via Full Scan	((hread_rnd+hread_rnd_next)/60)
Rows Read via Indexes	((first+key+next+prev)/60)
Variables	**Data Item**
first	mysql:status:Handler_read_first
key	mysql:status:Handler_read_key
next	mysql:status:Handler_read_next
prev	mysql:status:Handler_read_prev
hread_rnd	mysql:status:Handler_read_rnd
hread_rnd_next	mysql:status:Handler_read_rnd_next
sort_rows	mysql:status:Sort_rows
questions	mysql:status:Questions

Row Writes

Name	Row Writes
Range Label	avg rows/sec
Series	**Expression**
Rows Deleted	(delete/60)
Rows Inserted	(write/60)
Rows Updated	(update/60)
Variables	**Data Item**
delete	mysql:status:Handler_delete
update	mysql:status:Handler_update
write	mysql:status:Handler_write

Sort Activity

Name	Sort Activity
Range Label	total/min
Series	**Expression**
Merge Passes	Sort_merge_passes
Range	Sort_range

Scan	Sort_scan
Variables	**Data Item**
Sort_merge_passes	mysql:status:Sort_merge_passes
Sort_range	mysql:status:Sort_range
Sort_scan	mysql:status:Sort_scan

Table Lock Wait Ratio

Name	Table Lock Wait Ratio
Range Label	lock wait %
Series	**Expression**
Wait Ratio	((lock_waits/lock_immediate)*100)
Variables	**Data Item**
lock_waits	mysql:status:Table_locks_waited
lock_immediate	mysql:status:Table_locks_immediate

Table Locks

Name	Table Locks
Range Label	avg locks/sec
Series	**Expression**
Immediate	(locks_immediate/60)
Waited	(locks_waited/60)
Variables	**Data Item**
locks_waited	mysql:status:Table_locks_waited
locks_immediate	mysql:status:Table_locks_immediate

Temporary Tables

Name	Temporary Tables
Range Label	total/min
Series	**Expression**
Disk Temp Tables	diskTempTables
Memory Temp Tables	memoryTempTables
Variables	**Data Item**
memoryTempTables	mysql:status:Created_tmp_tables
diskTempTables	mysql:status:Created_tmp_disk_tables

15.13. MySQL Enterprise Monitor Frequently Asked Questions

> **Note**
>
> MySQL Enterprise subscription, MySQL Enterprise Monitor, MySQL Replication Monitor, and MySQL Query Analyzer are only available to commercial customers. To learn more, see: http://www.mysql.com/products/enterprise/features.html.

FAQ Categories

- **General Usage**
- **MySQL Enterprise**
- **MySQL Monitor**
- **MySQL Query Analyzer**

General Usage

Questions

- 16.13.1: Can I run MySQL Enterprise Service Manager on machine with other applications running?
- 16.13.2: What is the relationship between the advisor JAR file and the key?
- 16.13.3: During query analysis, I am unable to obtain an `EXAMPLE` or `EXPLAIN` information when examining the detail of the analyzed query within the **QUERY ANALYZER** panel.
- 16.13.4: I have started a Data Migration of my old data for a server to MySQL Enterprise Service Manager 2.0, but I have noticed that the performance of the monitor server has degraded significantly. Can I stop the migration?
- 16.13.5: Can the Trial-level key work with the Gold-level advisors JAR file?
- 16.13.6: Does the Gold-level key support Silver-level advisors?
- 16.13.7: Does Query Analyzer work with all versions of MySQL and the MySQL Client Libraries?
- 16.13.8: I have enabled `EXPLAIN` queries for Query Analyzer, but no queries with the `EXPLAIN` data are showing up in the display.
- 16.13.9: While monitoring my network traffic I have noticed that the agents communicate information at irregular intervals to the MySQL Enterprise Service Manager. I cannot see anything in my configuration that would explain this behavior. What is going on?
- 16.13.10: How do I change the name of a server?
- 16.13.11: My MySQL Enterprise Service Manager is behind a firewall but it cannot communicate with the MySQL Enterprise website to register and download my license key and advisor bundle. I normally use a proxy service to access external websites. How do I configure the proxy settings for MySQL Enterprise Dashboard?
- 16.13.12: I have set the graphs to update every 5 minutes, and the page refresh to occur every minute. The page is refreshing correctly, but the graphs do not seem to update.
- 16.13.13: Why do some rules appear to have a **SEVERITY** of **UNKNOWN**?
- 16.13.14: How frequently is the data purge process executed?

Questions and Answers

16.13.1: Can I run MySQL Enterprise Service Manager on machine with other applications running?

You can, but ideally you should be running your MySQL Enterprise Service Manager on a dedicated machine, especially if you are monitoring a number of different agents. For more information, see Section 15.12.5, “Choosing Suitable MySQL Enterprise Service Manager Hardware Configurations”.

16.13.2: What is the relationship between the advisor JAR file and the key?

The JAR file contains graph and advisor definitions. The key file contains typical customer validation data such as contract information, number of servers covered, subscription level and dates.

16.13.3: During query analysis, I am unable to obtain an `EXAMPLE` or `EXPLAIN` information when examining the detail of the analyzed query within the QUERY ANALYZER panel.

You must explicitly enable the `EXAMPLE` and `EXPLAIN` query functionality. Make sure that you have enabled both panels. See Sec-

tion 15.10.7, “Query Analyzer Settings”.

16.13.4: I have started a Data Migration of my old data for a server to MySQL Enterprise Service Manager 2.0, but I have noticed that the performance of the monitor server has degraded significantly. Can I stop the migration?

You can stop the migration of your historical data at any time. Go to the **MANAGE SERVERS** display of the **SETTINGS** panel and click STOP next to each server that is being migrated. You can restart the migration at any point.

16.13.5: Can the Trial-level key work with the Gold-level advisors JAR file?

The Trial-level key can only be used with the Trial-level advisors JAR file.

16.13.6: Does the Gold-level key support Silver-level advisors?

The Gold-level advisor JAR file will contain Silver-level advisors plus Gold-level advisors. However, you cannot use the Gold-level key with the Silver-level advisors JAR file. The Gold-level key can only be used with the Gold-level advisors JAR file.

16.13.7: Does Query Analyzer work with all versions of MySQL and the MySQL Client Libraries?

The MySQL Proxy component, and Query Analyzer, require that clients connecting through MySQL Enterprise Monitor Agent are using MySQL 5.0 or later. Clients that use the library provided with MySQL 4.1 or earlier will not work with MySQL Enterprise Monitor Agent.

16.13.8: I have enabled `EXPLAIN` queries for Query Analyzer, but no queries with the `EXPLAIN` data are showing up in the display.

Query Analyzer only obtains `EXPLAIN` information when the MySQL Enterprise Monitor Agent identifies a long running query. If none of your queries exceed the defined threshold, then the `EXPLAIN` information is not obtain and provided to the Query Analyze for display.

To change the query duration at which an `EXPLAIN` is triggered, you must edit the `share/mysql-proxy/quan.lua` file within the MySQL Enterprise Monitor Agent directory on each server. You need to change the value configured in the `auto_explain_min_exec_time_us`. The default is 500ms:

```
---
-- configuration
--
-- SET GLOBAL analyze_query.auto_filter = 0
if not proxy.global.config.quan then
        proxy.global.config.quan = {
                analyze_queries  = true,   -- track all queries
                query_cutoff     = 160,    -- only show the first 160 chars of the query
                num_worst_queries = 5,
                auto_explain     = true,
                auto_explain_min_exec_time_us = 500 * 1000
        }
end
```

The value is expressed in microseconds, which is why the value must be multiplied by 1000. To reduce this value to 100ms you would modify the line:

```
auto_explain_min_exec_time_us = 100 * 1000
```

You do not need to restart MySQL Enterprise Monitor Agent for the changes to take effect.

16.13.9: While monitoring my network traffic I have noticed that the agents communicate information at irregular intervals to the MySQL Enterprise Service Manager. I cannot see anything in my configuration that would explain this behavior. What is going on?

Each MySQL Enterprise Monitor Agent periodically sends information to the server about a range of different information, including the core rule and statistical data, Query Analyzer information and other data used to monitor the status of your MySQL server.

One element of this is called the MySQL Enterprise Monitor Agent Heartbeat, which is core information exchange that indicates that the monitored server is still up and running. The heartbeat information is vital because it tells the MySQL Enterprise Service Manager that the agent and server are still communicating. This information is sent regularly to the MySQL Enterprise Service Manager, but to prevent multiple agents from sending the information at the same time, and creating a large network load (or storm), the interval is randomized with each heartbeat. The randomization ensures that the information is still uploaded periodically, but without the potential to overload the network with this data.

16.13.10: How do I change the name of a server?

Go to the **MANAGE SERVERS** panel within **SETTINGS** and click RENAME SERVER.

Renaming the server in this way will override all other server naming, including changes to the agent configuration.

16.13.11: My MySQL Enterprise Service Manager is behind a firewall but it cannot communicate with the MySQL Enterprise website to register and download my license key and advisor bundle. I normally use a proxy service to access external websites. How do I configure the proxy settings for MySQL Enterprise Dashboard?

To configure a proxy service, you need to edit the `apache-tomcat/conf/catalina.properties` file within the MySQL Enterprise Service Manager installation directory. To make the changes, the proxy configuration information to the end of the file by setting the `http.proxyHost` and `http.proxyPort` properties:

```
http.proxyHost=proxy.example.com
http.proxyPort=8080
```

You will need to restart the MySQL Enterprise Service Manager for the change to take effect:

```
shell> mysqlmonitorctl.sh restart
```

16.13.12: I have set the graphs to update every 5 minutes, and the page refresh to occur every minute. The page is refreshing correctly, but the graphs do not seem to update.

The graph refresh and page refresh are two different parameters. The graphs will update according to their refresh period, regardless of the refresh period set for the main display page.

16.13.13: Why do some rules appear to have a SEVERITY of UNKNOWN?

Due to timing issues, certain rules such as “32-Bit Binary Running on 64-Bit AMD Or Intel System” and “Key Buffer Size Greater Than 4 GB” do not evaluate correctly due to timing issues. This is a known issue and will be resolved in future versions of MySQL Enterprise Monitor.

16.13.14: How frequently is the data purge process executed?

A data purge process is started approximately once a minute. If you have changed the purge period then the data will start to be purged within the next minute.

MySQL Enterprise

Questions

- 16.13.1: Do all my MySQL Enterprise subscriptions need to be at the same tier?
- 16.13.2: Are there any MySQL Enterprise White Papers available?
- 16.13.3: Does MySQL Enterprise include Maintenance, Updates, and Upgrades?
- 16.13.4: What if I plan to add more MySQL servers to my MySQL Enterprise subscription?
- 16.13.5: What is the list of Supported Platforms?
- 16.13.6: How do I buy MySQL Enterprise?
- 16.13.7: How should I decide between MySQL Enterprise Basic, Silver, Gold and Platinum?
- 16.13.8: How do I get a 30-day trial on MySQL Enterprise?
- 16.13.9: Are there any Demo/Tutorials available for MySQL Enterprise?
- 16.13.10: What is MySQL Production Support?
- 16.13.11: Does MySQL Enterprise include 24x7 Technical Support?
- 16.13.12: What is MySQL Enterprise Server?

- 16.13.13: What is the pricing of MySQL Enterprise?
- 16.13.14: What is MySQL Enterprise Unlimited?
- 16.13.15: What is a Technical Account Manager?
- 16.13.16: Are there any Webinars available?
- 16.13.17: Can I buy MySQL Enterprise subscriptions for multiple years?
- 16.13.18: Does MySQL Enterprise include Emergency Hot Fix Builds?
- 16.13.19: Does MySQL provide IP (Intellectual Property) Indemnification?
- 16.13.20: What is MySQL Enterprise?
- 16.13.21: What is MySQL Consultative Support?
- 16.13.22: Can I buy MySQL Enterprise subscriptions for only some of my production MySQL database servers?

Questions and Answers

16.13.1: Do all my MySQL Enterprise subscriptions need to be at the same tier?

MySQL Enterprise subscriptions must be at the same tier (Basic, Silver, Gold, Platinum) for all database servers that power that specific application.

16.13.2: Are there any MySQL Enterprise White Papers available?

Yes. Detailed architecture, technology, and business white papers are available. http://www.mysql.com/products/enterprise/whitepapers.html

16.13.3: Does MySQL Enterprise include Maintenance, Updates, and Upgrades?

Yes. As long as you have a valid contract for MySQL Enterprise, you will receive all new MySQL Enterprise Server software releases including Software Maintenance, Updates, and Upgrades. The Software Update Service will automatically notify you of the new releases.

16.13.4: What if I plan to add more MySQL servers to my MySQL Enterprise subscription?

A great option is the MySQL Enterprise Unlimited offering that allows you cover an unlimited number of MySQL servers for a fixed, low price. http://www.mysql.com/products/enterprise/unlimited.html

16.13.5: What is the list of Supported Platforms?

MySQL Enterprise provides broad coverage in its list of Supported Platforms. http://www.mysql.com/support/supportedplatforms/

16.13.6: How do I buy MySQL Enterprise?

For pricing and to buy MySQL Enterprise, visit the Online Shop For volume discounts or for more information, please http://www.mysql.com/about/contact/sales.html?s=corporate

16.13.7: How should I decide between MySQL Enterprise Basic, Silver, Gold and Platinum?

MySQL Enterprise subscriptions are available in 4 tiers, providing you the flexibility of choosing the capabilities and SLA that best meet your requirements. http://www.mysql.com/products/enterprise/features.html If you have questions and what to discuss your specific requirements, please http://www.mysql.com/about/contact/sales.html?s=corporate

16.13.8: How do I get a 30-day trial on MySQL Enterprise?

You can experience the MySQL Enterprise Monitor for 30 days by registering to receive an email with login instructions. http://www.mysql.com/trials/enterprise

16.13.9: Are there any Demo/Tutorials available for MySQL Enterprise?

Yes. Multiple self-running demos are available. http://www.mysql.com/products/enterprise/demo.html

16.13.10: What is MySQL Production Support?

Production Support consists of 4 components:

- Problem Resolution Support
- Consultative Support
- Knowledge Base
- Technical Account Manager (option)

MySQL Production Support gives you priority access with guaranteed response times to assist you with the development, deployment and management of your MySQL applications. http://www.mysql.com/products/enterprise/support.html

16.13.11: Does MySQL Enterprise include 24x7 Technical Support?

MySQL Enterprise, at the Gold and Platinum tiers, includes 24x7 phone and email access to the MySQL Support Team. http://www.mysql.com/products/enterprise/problemresolution.html

16.13.12: What is MySQL Enterprise Server?

MySQL Enterprise Server software is the most reliable, secure and up-to-date version of MySQL for cost-effectively delivering E-commerce, Online Transaction Processing (OLTP), and multi-terabyte Data Warehousing applications. It is a fully integrated transaction-safe, ACID compliant database with full commit, rollback, crash recovery and row level locking capabilities. MySQL delivers the ease of use, scalability, and performance that has made it MySQL the world's most popular open source database. http://www.mysql.com/products/enterprise/server.html

16.13.13: What is the pricing of MySQL Enterprise?

The pricing model for MySQL Enterprise is based on two key components: per server and per year. MySQL Enterprise does not have artificial restrictions based on CPUs, Memory, Machine Size, or Named Users. MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold and Platinum). Choose the tier that best meets your requirements and budget. http://www.mysql.com/products/enterprise/features.html

16.13.14: What is MySQL Enterprise Unlimited?

MySQL Enterprise Unlimited is a unique offering that allows you to deploy an unlimited number of MySQL Enterprise Servers for the price of a single CPU of Oracle Enterprise Edition. http://www.mysql.com/products/enterprise/unlimited.html

16.13.15: What is a Technical Account Manager?

MySQL Enterprise, at the Platinum tier, provides the option for a Technical Account Manager (TAM). The TAM is your advocate within MySQL, who proactively works to maximize your benefits from MySQL Support Services. http://www.mysql.com/products/enterprise/tam.html

16.13.16: Are there any Webinars available?

Yes. MySQL provides regularly scheduled Live Webinars. http://www.mysql.com/news-and-events/web-seminars/index.html MySQL also provides On-Demand Webinars to fit your schedule. These are recordings of previously held Live Webinars that you can replay at any time. http://www.mysql.com/news-and-events/web-seminars/index.html

16.13.17: Can I buy MySQL Enterprise subscriptions for multiple years?

MySQL Enterprise subscriptions have duration of at least 1 year. Customers have the flexibility of choosing terms with multi-year durations. To purchase multi-year contracts, please http://www.mysql.com/about/contact/sales.html?s=corporate

16.13.18: Does MySQL Enterprise include Emergency Hot Fix Builds?

MySQL Enterprise, at the Gold and Platinum tiers, gives you the ability to request an Emergency Hot Fix Build to fix issues not already fixed in a MySQL Rapid Update or MySQL Quarterly Service Pack.

16.13.19: Does MySQL provide IP (Intellectual Property) Indemnification?

MySQL Enterprise, at the Gold and Platinum tiers, has the option of IP Indemnification, for qualifying customers at no extra cost. This

provides you with legal protection that you expect from enterprise software providers. http://www.mysql.com/products/enterprise/indemnification.html

16.13.20: What is MySQL Enterprise?

The MySQL Enterprise subscription is the most comprehensive offering of MySQL database software, services and production support to ensure your business achieves the highest levels of reliability, security and uptime.

MySQL Enterprise includes:

- MySQL Enterprise Server software, the most reliable, secure and up-to date version of the world's most popular open source database
- MySQL Enterprise Monitor that continuously monitors your database and proactively advises you on how to implement MySQL best practices
- MySQL 24x7 Production Support with fast response times to assist you in the development, deployment and management of MySQL applications

MySQL Enterprise is available in 4 tiers (Basic, Silver, Gold, Platinum). http://www.mysql.com/products/enterprise/features.html

16.13.21: What is MySQL Consultative Support?

MySQL Enterprise, at the Gold and Platinum tiers, includes Consultative Support. This is a proactive approach to support that is designed to help you avoid critical outages. MySQL Support Engineers advise you on how to properly design and tune your MySQL servers, schema, queries, and replication set-up to maximize performance and availability. Also, by taking the initiative to properly design and tune your MySQL database applications you can avoid having to purchase expensive hardware for your IT infrastructure. http://www.mysql.com/products/enterprise/consultativesupport.html

16.13.22: Can I buy MySQL Enterprise subscriptions for only some of my production MySQL database servers?

When you choose MySQL Enterprise subscriptions, they must cover all database servers that power that specific application. To negotiate volume discounts, please http://www.mysql.com/about/contact/sales.html?s=corporate

MySQL Monitor

Questions

- 16.13.1: What MySQL Enterprise subscription levels include the MySQL Enterprise Monitor?
- 16.13.2: What makes MySQL Enterprise unique?
- 16.13.3: How do I get the MySQL Enterprise Monitor?
- 16.13.4: How is the MySQL Enterprise Monitor installed and deployed?
- 16.13.5: How are subscribers notified about the availability of new or updated MySQL Enterprise Monitor, MySQL Enterprise Advisors and Advisor Rules?
- 16.13.6: What versions of MySQL are supported by the MySQL Enterprise Monitor?
- 16.13.7: What operating system platforms are supported by the MySQL Enterprise Monitor?
- 16.13.8: What are the long-term benefits of the MySQL Enterprise Monitor?
- 16.13.9: What is MySQL Enterprise Monitor?
- 16.13.10: What are the immediate benefits of implementing the MySQL Enterprise Monitor?
- 16.13.11: How is the Enterprise Monitor web application architected?
- 16.13.12: Which set of Enterprise Advisors, Advisor Rules and features are best for my use of MySQL?
- 16.13.13: What are the features and related benefits of the MySQL Enterprise Monitor?

- 16.13.14: Which Advisors and features are included under different MySQL Enterprise subscription levels?
- 16.13.15: What are the MySQL Enterprise Advisors and Advisor Rules?

Questions and Answers

16.13.1: What MySQL Enterprise subscription levels include the MySQL Enterprise Monitor?

The Enterprise Monitor is available under MySQL Enterprise subscription levels Silver, Gold and Platinum. http://www.mysql.com/products/enterprise/features.html

16.13.2: What makes MySQL Enterprise unique?

Of the products on the market that monitor MySQL, SQL code and OS specific metrics, the MySQL Enterprise Monitor is the only solution that is built and supported by the engineers at MySQL. Unlike other solutions that report on raw MySQL and OS level metrics, the MySQL Enterprise Monitor is designed to optimize the use of MySQL by proactively monitoring MySQL instances and providing notifications and "MySQL DBA expertise in a box" advice on corrective measures DBAs can take before problems occur.

16.13.3: How do I get the MySQL Enterprise Monitor?

The MySQL Enterprise Monitor is available for download to MySQL Enterprise customers at the Silver, Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the http://www.mysql.com/trials/enterprise
- To buy MySQL Enterprise, visit the Online Shop

16.13.4: How is the MySQL Enterprise Monitor installed and deployed?

The Enterprise Monitor is powered by a distributed web application that is installed and deployed within the confines of the corporate firewall.

16.13.5: How are subscribers notified about the availability of new or updated MySQL Enterprise Monitor, MySQL Enterprise Advisors and Advisor Rules?

Customers will receive notifications of new and updated MySQL Enterprise Monitor and Advisors as they become available via the MySQL Enterprise Software Update Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

16.13.6: What versions of MySQL are supported by the MySQL Enterprise Monitor?

The MySQL Enterprise Monitor can be used to monitor MySQL versions 4.0 – 5.x.

16.13.7: What operating system platforms are supported by the MySQL Enterprise Monitor?

The Enterprise Monitor Service Manager is fully supported on most current versions of Linux, Windows XP and Server Editions, Solaris and Mac OSX. The Monitor Agent supports any platform supported by the MySQL Enterprise server. For the complete list of MySQL Enterprise supported operating systems and CPUs, visit the http://www.mysql.com/support/supportedplatforms/enterprise.html.

16.13.8: What are the long-term benefits of the MySQL Enterprise Monitor?

Over time, the task of managing even medium-scale MySQL server farms becomes exponentially more complicated, especially as the load of users, connections, application queries, and objects on each MySQL server increases. The Enterprise Monitor continually monitors the dynamic security, performance, replication and schema relevant metrics of all MySQL servers, so as the number of MySQL continues to grow, DBAs are kept up to date on potential problems and proactive measures that can be implemented to ensure each server continues to operate at the highest levels of security, performance and reliability.

16.13.9: What is MySQL Enterprise Monitor?

Included as part of a MySQL Enterprise subscription, the MySQL Enterprise Monitor is a distributed, web-based application that helps customers reduce downtime, tighten security and increase throughput of their MySQL servers by telling them about problems in their database applications before they occur. It is downloadable from the Enterprise Customer web site and is deployed within the safety of the customer datacenter.http://www.mysql.com/products/enterprise/monitor.html

16.13.10: What are the immediate benefits of implementing the MySQL Enterprise Monitor?

Often MySQL installations are implemented with default settings that may not be best suited for specific applications or usage patterns. The MySQL Advisors go to work immediately in these environments to identify potential problems and proactively notify and advise DBAs on key MySQL settings that can be tuned to improve availability, tighten security, and increase the throughput of their existing MySQL servers

16.13.11: How is the Enterprise Monitor web application architected?

The Enterprise Monitor web application is comprised of 3 components:

- Monitor Agent: A lightweight C program that is installed on each of the monitored MySQL servers. Its purpose is to collect MySQL SQL and operating system metrics that allow the DBA to monitor the overall health, availability and performance of the MySQL server. The Monitor Agent is the only component within the application that touches or connects to the MySQL Server. It reports the data it collects via XML over HTTP to the centralized Service Manager.
- Service Manager: The main server of the application. The Service Manager manages and stores the data collections that come in from each monitor agent. It analyzes these collections using MySQL provided best practice Advisor rules to determine the health, security, availability and performance of each of the monitored MySQL Servers. The Service Manager also provides the content for the Enterprise Dashboard which serves as the client user interface for the distributed web application.
- Repository: A MySQL database that is used to stored data collections and application-level configuration data.

16.13.12: Which set of Enterprise Advisors, Advisor Rules and features are best for my use of MySQL?

The Enterprise Monitor Advisors and Advisor Rules are available at 3 MySQL Enterprise subscription tiers: Choose MySQL Enterprise Silver if you need:

- Assurance you are running the most current, bug-free version of MySQL across all of your servers.
- Recoverability of your MySQL servers.
- The highest level of security for your MySQL servers.
- Monitoring of maximum or disallowed MySQL connections.
- Optimized startup configuration settings.

Choose MySQL Enterprise Gold, when you need everything in Silver, PLUS:

- Easy collection and detection of problematic SQL code running on your production or development systems.
- Insight and corrective advice on MySQL replication status, sync, and performance related issues.
- Auto detection and documenting of your Replication topologies.
- Advanced monitoring of your Replication and Scale-out environment.

Choose MySQL Enterprise Platinum, when you need everything in Gold, PLUS:

- Identification and advice on unplanned database and object level schema changes (Create, Alter, and Drop) across your MySQL servers.
- Proactive monitoring and advice on tuning the performance of your MySQL servers.

16.13.13: What are the features and related benefits of the MySQL Enterprise Monitor?

The MySQL Enterprise Monitor is like having a "Virtual DBA Assistant" at your side to recommend best practices to eliminate security vulnerabilities, improve replication, and optimize performance. For the complete features and benefits, visit the ht-

tp://www.mysql.com/products/enterprise/monitor-features.html.

16.13.14: Which Advisors and features are included under different MySQL Enterprise subscription levels?

For the complete list of the MySQL Enterprise Advisors that are available under each MySQL Enterprise subscription level, visit the http://www.mysql.com/products/enterprise/features.html.

16.13.15: What are the MySQL Enterprise Advisors and Advisor Rules?

The MySQL Enterprise Advisors are a set of best practice guidelines for the optimal use of MySQL. Advisors are spread across database specific disciplines and are comprised of a set of MySQL Advisor Rules that proactively monitor all MySQL servers and report on database application problems before they occur. Each Advisor Rule provides a detailed overview of the problem it is designed to identify, advices on how to correct the problem, specifies commands to implement the recommended fix and links to resources for additional research into the issue at hand. http://www.mysql.com/products/enterprise/advisors.html

MySQL Query Analyzer

Questions

- 16.13.1: Can I leave the MySQL Query Analyzer enabled at all times?
- 16.13.2: What are the typical use cases of the MySQL Query Analyzer?
- 16.13.3: What is the MySQL Query Analyzer?
- 16.13.4: Does the query analyzer look at all queries? or only queries which would show up in the in the slow-queries log?
- 16.13.5: Do the MySQL clients have to connect to the port of the mysql proxy to enable the QA?
- 16.13.6: How is the MySQL Query Analyzer installed and enabled?
- 16.13.7: How are subscribers notified about updates to the MySQL Query Analyzer application components?
- 16.13.8: Does Query Analyzer capture queries by the root user?
- 16.13.9: What makes the MySQL Query Analyzer unique?
- 16.13.10: Does the "Rows" area show the rows returned/updated or the rows visited by the query?
- 16.13.11: Does Query Analyzer enable me to monitor the disk reads and writes during a query?
- 16.13.12: Does Query Analyzer work with MySQL Cluster?
- 16.13.13: Does Query Analyzer handler prepared statements?
- 16.13.14: How can I get the MySQL Query Analyzer?
- 16.13.15: How much degration in performance does mysql-proxy introduce?
- 16.13.16: What are the main features and benefits of the MySQL Query Analyzer?
- 16.13.17: What overhead can I expect when the MySQL Query Analyzer is installed and enabled?

Questions and Answers

16.13.1: Can I leave the MySQL Query Analyzer enabled at all times?

We have customers who have the Query Analyzer enabled and collecting queries on their development and QA servers so they can tune their code and monitor the fixes as part of the development process. For production systems, Query collection and analysis can easily be toggled on when a slowdown occurs. To avoid collection mode overhead many users are using simple scripts to enable the Query Analyzer to sample queries during nonpeak hours, typically during 30 minute windows. They can then view the collected queries using the date/time or interval filter options.

16.13.2: What are the typical use cases of the MySQL Query Analyzer?

The typical use cases for developers, DBAs and system administrators are:

- Developers – Monitor and tune application queries during development before they are promoted to production.
- DBAs and System Administrators – Identify problem SQL code as it runs in production and advise development teams on how to tune. This use case benefits the most from regular sampling of queries as they are running, most often during nonpeak hours.

16.13.3: What is the MySQL Query Analyzer?

The MySQL Query Analyzer allows DBAs, developers and system administrators to improve application performance by collecting, monitoring, and analyzing queries as they run on their MySQL servers. http://www.mysql.com/products/enterprise/query.html

16.13.4: Does the query analyzer look at all queries? or only queries which would show up in the in the slow-queries log?

The Query Analyzer sees all queries that you route through the agent/proxy that performs the query analysis and aggregate them directly.

16.13.5: Do the MySQL clients have to connect to the port of the mysql proxy to enable the QA?

Yes, or you can re-direct them in various ways, by reconfiguring mysqld to listen to some other port, and the proxy to 3306, use iptables redirection, etc. We have some examples in the manual for the product on how to do it (semi)-transparently.

16.13.6: How is the MySQL Query Analyzer installed and enabled?

The Query Analyzer feature is installed with the Monitor Agent. It is enabled during agent installation and can be toggled between collection and pass-thru modes from the Query Analysis page of the Enterprise Monitor.

16.13.7: How are subscribers notified about updates to the MySQL Query Analyzer application components?

Customers will receive notifications of the MySQL Query Analyzer updates as they become available via the MySQL Enterprise Software Update and Alert Service. Notifications will be generated and sent based on the customer profile and the MySQL Enterprise subscription level.

16.13.8: Does Query Analyzer capture queries by the root user?

Yes, Query Analyzer captures all queries by all users providing that the queries are sent through the proxy port configured by the MySQL Enterprise Monitor Agent.

16.13.9: What makes the MySQL Query Analyzer unique?

Other products (free, open source and commercial) that provide MySQL query monitoring are dependent on the MySQL Slow Query Log being enabled and available for sampling. While this provides some time savings over the DBA collecting and parsing the Log, the Slow Query Log comes with overhead and does not capture sub millisecond executions. The log data also grows very large very quickly.

The MySQL Query Analyzer collects queries and execution statistics with no dependence on the SQL Query Log, it captures all SQL statements sent to the MySQL server and provides an aggregated view into the most expensive queries in number of executions and total execution time. It is also fully supported as part of the MySQL Enterprise subscription.

16.13.10: Does the "Rows" area show the rows returned/updated or the rows visited by the query?

Returned/updated. We don't have visibility into how many rows were touched. at an instance level. Some of the graphs we provide will show you when you're queries are touching a lot of rows.

16.13.11: Does Query Analyzer enable me to monitor the disk reads and writes during a query?

No, that information is not available to be shown at this time.

16.13.12: Does Query Analyzer work with MySQL Cluster?

Yes, providing that eact node is monitored with an agent and query analyzer has been unabled for that node. Note that you must be accessing your cluster data through a standard MySQL node for this to work.

16.13.13: Does Query Analyzer handler prepared statements?

At this time, the query analyzer does not track server-side prepared statements. However the default configurations for most client-side libraries for MySQL don't use them, they emulate them client-side, and those will be tracked by the query analyzer.

16.13.14: How can I get the MySQL Query Analyzer?

The MySQL Query Analyzer is available for download to MySQL Enterprise customers at the Gold and Platinum subscription levels.

- To experience the MySQL Enterprise Monitor for 30 days, visit the http://www.mysql.com/trials/enterprise
- To buy MySQL Enterprise, visit the Online Shop

16.13.15: How much degration in performance does mysql-proxy introduce?

At the very least it's equivalent to a network hop in latency. The degredation is directly related to your average query execution time. If your queries execute in microseconds (which can happen if served from query cache) then the degradation will be higher, and noticable. We've seen some applications that actually do work when they execute queries, the degradation is much less, and in some limited cases because of scheduling, the application actually has better throughput.

16.13.16: What are the main features and benefits of the MySQL Query Analyzer?

For the complete features and benefits, visit the http://www.mysql.com/products/enterprise/monitor-features.html

16.13.17: What overhead can I expect when the MySQL Query Analyzer is installed and enabled?

The average overhead when in active collection mode is in the 15-20% range. In pass-thru mode the overhead is minimal, weighing in at 1-5% on most MySQL systems of average load.

Chapter 16. Replication

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous - slaves need not to connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see MySQL Cluster NDB 6.X/7.X).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 16.1.1, “How to Set Up Replication”.

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Section 16.1.2, “Replication Formats”. In MySQL 5.4, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Section 16.1.3, “Replication and Binary Logging Options and Variables”.

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 16.3, “Replication Solutions”.

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Section 16.4, “Replication Notes and Tips”.

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Section 16.2, “Replication Implementation”.

> **MySQL Enterprise**
> The MySQL Enterprise Monitor provides numerous advisors that provide immediate feedback about replication-related problems. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

16.1. Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's `master.info` file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, Section 16.1.1, “How to Set Up Replication”, deals with the configuration of the systems and provides methods for copying data between the master and slaves.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Section 16.1.2, “Replication Formats”.
- Detailed information on the different configuration options and variables that apply to replication is provided in Section 16.1.3, “Replication and Binary Logging Options and Variables”.
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Section 16.1.4, “Common Replication Administration Tasks”.

16.1.1. How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See Section 16.1.1.1, “Setting the Replication Master Configuration”.
- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.
- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See Section 16.1.1.3, “Creating a User for Replication”.
- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”) or by copying the data files directly (see Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”).
- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see Section 16.1.1.7, "Setting Up Replication with New Master and Slaves".
- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see Section 16.1.1.8, "Setting Up Replication with Existing Data".
- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See Section 16.1.1.9, "Introducing Additional Slaves to an Existing Replication Environment".

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in Section 12.5.1, "SQL Statements for Controlling Master Servers", and Section 12.5.2, "SQL Statements for Controlling Slave Servers". You should also familiarize yourself with the replication startup options described in Section 16.1.3, "Replication and Binary Logging Options and Variables".

> **Note**
>
> Note that certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

16.1.1.1. Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging *must* be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and (2^{32})–1. How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

> **Note**
>
> If you omit `server-id` (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

> **Note**
>
> For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

> **Note**
>
> Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, your slave will not able to communicate with the master and replication will fail.

16.1.1.2. Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server

restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

> **Note**
>
> If you omit `server-id` (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

16.1.1.3. Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file (see Section 16.2.2.2, “The Slave Status Files”). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new acccount, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See Section 12.4.1, “Account Management Statements”, for more information on statements for manipulation of user accounts.

16.1.1.4. Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before allowing the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   For `InnoDB` tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

   > **Warning**

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+------------------+----------+--------------+------------------+
| File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+------------------+----------+--------------+------------------+
| mysql-bin.000003 | 73       | test         | manual,mysql     |
+------------------+----------+--------------+------------------+
```

   The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

   If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`''`) and `4`.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be to synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”, or Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”. The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

16.1.1.5. Creating a Data Snapshot Using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

To obtain a snapshot of the data using `mysqldump`:

1. If you have not already locked the tables on the server to prevent statements that update data from executing:

   Start a session on the server by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

   Remember to use `SHOW MASTER STATUS` and record the binary log details for use when starting up the slave. The point in time of your snapshot and the binary log position must match. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

2. In another session, use `mysqldump` to create a dump either of all the databases you want to replicate, or of selected individual databases. For example:

```
shell> mysqldump --all-databases --lock-all-tables >dbdump.db
```

   An alternative to using a bare dump, is to use the `--master-data` option, which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process.

```
shell> mysqldump --all-databases --master-data >dbdump.db
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Alternatively, exit the first session to release the read lock.

When choosing databases to include in the dump, remember that you will need to filter out databases on each slave that you do not want to include in the replication process.

You will need either to copy the dump file to the slave, or to use the file from the master when connecting remotely to the slave to import the data.

16.1.1.6. Creating a Data Snapshot Using Raw Data Files

If your database is particularly large, copying the raw data files may be more efficient than using `mysqldump` and importing the file on each slave.

However, using this method with tables in storage engines with complex caching or logging algorithms may not give you a perfect "in time" snapshot as cache information and logging updates may not have been applied, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

In addition, this method does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you are using `InnoDB` tables, you can use the `InnoDB Hot Backup` tool to obtain a consistent snapshot. This tool records the log name and offset corresponding to the snapshot to be later used on the slave. `Hot Backup` is a nonfree (commercial) tool that is not included in the standard MySQL distribution. See the `InnoDB Hot Backup` home page at http://www.innodb.com/wp/products/hot-backup/ for detailed information.

Otherwise, you can obtain a reliable binary snapshot of `InnoDB` tables only after shutting down the MySQL Server.

To create a raw data snapshot of `MyISAM` tables you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases then make sure you copy only those files that related to those tables. (For `InnoDB`, all tables in all databases are stored in the shared tablespace files, unless you have the `innodb_file_per_table` option enabled.)

You may want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The `master.info` file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot you should shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates".
2. In a separate session, shut down the master server:

   ```
   shell> mysqladmin shutdown
   ```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

   ```
   shell> tar cf /tmp/db.tar ./data
   shell> zip -r /tmp/db.zip ./data
   shell> rsync --recursive ./data /tmp/dbdata
   ```

4. Restart the master server.

If you are not using InnoDB tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, you will need to copy the files to each slave before starting the slave replication process.

16.1.1.7. Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See Section 16.1.1.1, “Setting the Replication Master Configuration”.
2. Start up the MySQL master.
3. Set up a user. See Section 16.1.1.3, “Creating a User for Replication”.
4. Obtain the master status information. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.
7. Start up the MySQL slave.
8. Execute a CHANGE MASTER TO statement to set the master replication server configuration. See Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

16.1.1.8. Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before start-

ing the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See Section 16.1.1.3, “Creating a User for Replication”.

2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See Section 16.1.1.1, “Setting the Replication Master Configuration”.

   If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

3. If your master server is already correctly configured, obtain its status (see Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) and then use `mysqldump` to take a snapshot (see Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”) or take a raw snapshot of the live server using the guide in Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

4. Update the configuration of the slave. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.

5. The next step depends on how you created the snapshot of data on the master.

   If you used `mysqldump`:

   a. Start the slave, using the `--skip-slave-start` option so that replication does not start.

   b. Import the dump file:

   ```
   shell> mysql < fulldb.dump
   ```

   If you created a snapshot using the raw data files:

   a. Extract the data files into your slave data directory. For example:

   ```
   shell> tar xvf dbdump.tar
   ```

   You may need to set permissions and ownership on the files so that the slave server can access and modify them.

   b. Start the slave, using the `--skip-slave-start` option so that replication does not start.

6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

7. Start the slave threads:

   ```
   mysql> START SLAVE;
   ```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do *not* remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

> **Note**
>
> The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Section 16.1.3, "Replication and Binary Logging Options and Variables", for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

16.1.1.9. Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

   ```
   shell> mysqladmin shutdown
   ```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

   > **Note**
   >
   > A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:
   >
   > ```
   > 071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
   > replication may break when this MySQL server acts as a slave and has his hostname
   > changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
   > 071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
   > (relay_log_pos 22940879)
   > 071118 16:44:10 [ERROR] Could not find target log during relay log initialization
   > 071118 16:44:10 [ERROR] Failed to initialize the master info structure
   > ```
   >
   > This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See Section 16.1.3, "Replication and Binary Logging Options and Variables", for more information about these options.)
   >
   > To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use *`existing_slave_hostname`*`-relay-bin`.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use *`existing_slave_hostname`*`-relay-bin.index`.) Alternatively—if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:
   >
   > a. If you have not already done so, issue a `STOP SLAVE` on the new slave.
   >
   >   If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
   >
   > b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
   >
   > c. Proceed with the remaining steps in this section.

3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.

4. Start the existing slave.

5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.

6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

16.1.1.10. Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
    ->     MASTER_HOST='master_host_name',
    ->     MASTER_USER='replication_user_name',
    ->     MASTER_PASSWORD='replication_password',
    ->     MASTER_LOG_FILE='recorded_log_file_name',
    ->     MASTER_LOG_POS=recorded_log_position;
```

> **Note**
>
> Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum allowable length for the string-valued options, see Section 12.5.2.1, "`CHANGE MASTER TO` Syntax".

16.1.2. Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard statement-based binary logging format. In older versions of MySQL (5.1.4 and earlier), binary logging and replication used this format exclusively.

- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as *row-based replication* (often abbreviated as *RBR*). In row-based replication, the master writes *events* to the binary log that indicate how individual table rows are changed.

- The server can change the binary logging format in real time according to the type of event using *mixed-format logging*.

  When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see Section 5.2.4.3, "Mixed Binary Logging Format".

In MySQL 5.4, statement-based format is the default.

> **Note**
>
> **MySQL Cluster.** The default binary logging format in all MySQL Cluster NDB 6.1, 6.2, 6.3, and later 6.x releases is `ROW`. MySQL Cluster Replication always uses row-based replication, and the `NDBCLUSTER` storage engine is incompatible with statement-based replication. Using `NDBCLUSTER` sets row-based logging format automatically.
>
> See MySQL Cluster Replication: Assumptions and General Requirements, for more information.

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.2.4.3, "Mixed Binary Logging Format".

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible

to other sessions; setting the variable globally requires a restart of the server in order to take effect. For more information, see Section 12.4.4, “SET Syntax”.

You must have the SUPER privilege to set either the global or session binlog_format value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 16.1.2.1, “Comparison of Statement-Based and Row-Based Replication”.

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Section 18.7, “Binary Logging of Stored Programs”.

16.1.2.1. Comparison of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

Advantages of statement-based replication:

- Proven technology that has existed in MySQL since 3.23.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication:

- **Statements that are unsafe for SBR.** Not all statements which modify data (such as INSERT DELETE, UPDATE, and REPLACE statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See Section 16.4.1.8, “Replication of Invoked Features”, for more information.
  - DELETE and UPDATE statements that use a LIMIT clause without an ORDER BY are nondeterministic. See Section 16.4.1.12, “Replication and LIMIT”.
  - Statements using any of the following functions cannot be replicated properly using statement-based replication:
    - LOAD_FILE()
    - UUID(), UUID_SHORT()
    - USER()
    - FOUND_ROWS()
    - SYSDATE() (unless the server is started with the --sysdate-is-now option)

    However, all other functions are replicated correctly using statement-based replication, including RAND(), NOW(), and so forth.

    For more information, see Section 16.4.1.11, “Replication and System Functions”.

  Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
090213 16:58:54 [Warning] Statement is not safe to log in statement format.
```

  A similar warning is also issued to the client in such cases. The client can display it using SHOW WARNINGS.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 16.4.1.23, "Slave Errors During Replication".
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See Section 16.4.1.6, "Replication with Differing Table Definitions on Master and Slave", for more information.

Advantages of row-based replication:

- All changes can be replicated. This is the safest form of replication.

  The `mysql` database is not replicated. The `mysql` database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

  For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.
- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
- Fewer locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`
  - `INSERT` statements with `AUTO_INCREMENT`
  - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

Disadvantages of row-based replication:

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

  However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

16.1.2.2. Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see Section 16.1.2, "Replication Formats", and Section 16.1.2.1, "Comparison of Statement-Based and Row-Based Replication".

- **RBL, RBR, and temporary tables.** As noted in Section 16.4.1.19, "Replication and Temporary Tables", temporary tables are not replicated when using row-based format. When mixed format is in effect, "safe" statements involving temporary tables are logged using statement-based format. For more information, see Section 16.1.2.1, "Comparison of Statement-Based and Row-Based Replication".

  > **Note**
  >
  > Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log if the statement is an initial nontransactional statement (occuring in the transaction before any transactional statements). When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave's copy of the table.)

- **Latency and binary log size.** Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.

- **Reading the binary log.** When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see Section 4.6.7.2, "`mysqlbinlog` Row Event Display".

- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see Section 5.1.4, "Server System Variables".

  > **Note**
  >
  > `slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value.
  >
  > For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.
  >
  > The `NDBCLUSTER` storage engine is currently not supported in MySQL 5.4. MySQL Cluster users wishing to upgrade from MySQL 5.0 should instead migrate to MySQL Cluster NDB 7.0 or later; these are based on MySQL 5.1 but contain the latest improvements and fixes for `NDBCLUSTER`. For more information, see MySQL Cluster NDB 6.X/7.X.

- **Lack of binary log checksums.** RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also Section 12.5.2.1, "`CHANGE MASTER TO` Syntax", for general information about setting up MySQL with SSL.

- **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements, a simple example of such a clause being `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` system variable for statement filtering, you must also use `--binlog_format=STATEMENT`.

- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact that your choice of replication format has on how they operate, see Section 16.1.3, "Replication and Binary Logging Options and Variables".

16.1.3. Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

Command-Line Format	`--server-id=#`	
Config-File Format	`server-id`	
Option Sets Variable	Yes, `server_id`	
Variable Name	`server_id`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`0`
	Range	`0-4294967295`

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see Section 16.1.3.2, "Replication Master Options and Variables", and Section 16.1.3.3, "Replication Slave Options and Variables".

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. "Unique", means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id`, the default ID is 0, in which case a master refuses connections from all slaves, and a slave refuses to connect to a master. For more information, see Section 16.1.1.2, "Setting the Replication Slave Configuration".

16.1.3.1. Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

Table 16.1. Replication Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
abort-slave-event-count	Yes	Yes				
Com_change_master				Yes	Both	No
Com_show_master_status				Yes	Both	No
Com_show_new_master				Yes	Both	No
Com_show_slave_hosts				Yes	Both	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
Com_show_slave_status				Yes	Both	No
Com_slave_start				Yes	Both	No
Com_slave_stop				Yes	Both	No
disconnect-slave-event-count	Yes	Yes				
init_slave	Yes	Yes	Yes		Global	Yes
log-slave-updates	Yes	Yes			Global	No
- *Variable*: log_slave_updates			Yes		Global	No
master-bind	Yes	Yes	Yes			No
master-connect-retry	Yes	Yes				
master-host	Yes	Yes				
master-info-file	Yes	Yes				
master-password	Yes	Yes				
master-port	Yes	Yes				
master-retry-count	Yes	Yes				
master-ssl	Yes	Yes				
master-ssl-ca	Yes	Yes				
master-ssl-capath	Yes	Yes				
master-ssl-cert	Yes	Yes				
master-ssl-cipher	Yes	Yes				
master-ssl-key	Yes	Yes				
master-user	Yes	Yes				
relay-log	Yes	Yes				
relay-log-index	Yes	Yes			Both	No
- *Variable*: relay_log_index			Yes		Both	No
relay-log-info-file	Yes	Yes				
- *Variable*: relay_log_info_file						
relay_log_purge	Yes	Yes	Yes		Global	Yes
relay_log_space_limit	Yes	Yes	Yes		Global	No
replicate-do-db	Yes	Yes				
replicate-do-table	Yes	Yes				
replicate-ignore-db	Yes	Yes				
replicate-ignore-table	Yes	Yes				
replicate-rewrite-db	Yes	Yes				
replicate-same-server-id	Yes	Yes				
replicate-wild-do-table	Yes	Yes				
replicate-wild-ignore-table	Yes	Yes				
report-host	Yes	Yes			Global	No
- *Variable*: report_host			Yes		Global	No
report-password	Yes	Yes			Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
ents						
Com_show_binlogs				Yes	Both	No
max_binlog_cache_size	Yes	Yes	Yes		Global	Yes
max-binlog-dump-events	Yes	Yes				
max_binlog_size	Yes	Yes	Yes		Global	Yes
sporadic-binlog-dump-fail	Yes	Yes				

Section 16.1.3.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.2.4, “The Binary Log”.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

16.1.3.2. Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 16.1.3.4, “Binary Log Options and Variables”.

- `auto_increment_increment`

Command-Line Format	`--auto_increment_increment[=#]`	
Config-File Format	`auto_increment_increment`	
Option Sets Variable	Yes, `auto_increment_increment`	
Variable Name	`auto_increment_increment`	
Variable Scope	Both	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`1`
	Range	`1-65535`

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 1     |
```

```
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
  Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
|   5 |
|  15 |
|  25 |
|  35 |
+-----+
4 rows in set (0.02 sec)
```

  If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

`auto_increment_offset` + *N* × `auto_increment_increment`

where *N* is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
|  35 |
|  45 |
|  55 |
|  65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series 5 + *N* × 10, that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

- `auto_increment_offset`

Command-Line Format	`--auto_increment_offset[=#]`	
Config-File Format	`auto_increment_offset`	
Option Sets Variable	Yes, `auto_increment_offset`	
Variable Name	`auto_increment_offset`	
Variable Scope	Both	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`1`
	Range	`1-65535`

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment`.

16.1.3.3. Replication Slave Options and Variables

This section describes the server options and system variables that you can use on slave replication servers. You can specify the options either on the command line or in an option file. Many of the options can be reset while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

Server ID. On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. "Unique", means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

> **Important**
>
> Certain options are handled in a special way in order to ensure that the active replication configuration is not inadvertently altered or affected:
>
> - In MySQL 5.1.16 and earlier, these options are ignored if the `master.info` file exists (that is, when the MySQL server has already previously been configured for replication). If the file exists and these options are present in the `my.cnf` or as options on the command line to `mysqld`, they are silently ignored and the information in `master.info` used instead.
> - **Options deprecated.** *Beginning with MySQL 5.1.17, these options are deprecated. They will be removed in a future version of MySQL.* In MySQL 5.1.17 and later, these options have no effect when `mysqld` is started and an appropriate warning is written to the error log. To set the replication parameters associated with these you must use the `CHANGE MASTER TO ...` statement (see Section 12.5.2.1, "`CHANGE MASTER TO` Syntax").
>
> The options affected are shown in this list:
>
> - `--master-host`
> - `--master-user`
> - `--master-password`
> - `--master-port`
> - `--master-connect-retry`
> - `--master-ssl`
> - `--master-ssl-ca`
> - `--master-ssl-capath`
> - `--master-ssl-cert`
> - `--master-ssl-cipher`
> - `--master-ssl-key`

The `master.info` file format in MySQL 5.4 includes values corresponding to the SSL options. In addition, the file format includes as its first line the number of lines in the file. (See Section 16.2.2, "Replication Relay and Status Files".) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

If the `master.info` file exists when the slave server starts, the server uses its contents and ignores any options that correspond to the values listed in the file. Thus, if you start the slave server with different values of the startup options that correspond to values in the `master.info` file, the different values have no effect because the server continues to use the `master.info` file. To use different values, the preferred method is to use the `CHANGE MASTER TO` statement to reset the values while the slave is running. Alternatively, you can stop the server, remove the `master.info` file, and restart the server with different option values.

Suppose that you specify this option in your `my.cnf` file:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host of *`some_other_host`*, the change still has no effect. You should use `CHANGE MASTER TO` instead.

Startup options for replication slaves. The following list describes startup options for controlling replication slave servers. Many of these options can be reset while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--abort-slave-event-count`

Command-Line Format	`--abort-slave-event-count=#`	
Config-File Format	`abort-slave-event-count`	
	Permitted Values	
	Type	`numeric`
	Default	`0`
	Min Value	`0`

When this option is set to some positive integer *`value`* other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, *`value`* log events are allowed to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- `--disconnect-slave-event-count`

Command-Line Format	`--disconnect-slave-event-count=#`	
Config-File Format	`disconnect-slave-event-count`	
	Permitted Values	
	Type	`numeric`
	Default	`0`

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--log-slave-updates`

Command-Line Format	`--log-slave-updates`
Config-File Format	`log-slave-updates`
Option Sets Variable	Yes, `log_slave_updates`
Variable Name	`log_slave_updates`

Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	boolean
	Default	FALSE

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the master for the slave `B`, and `B` serves as the master for the slave `C`. For this to work, `B` must be both a master *and* a slave. You must start both `A` and `B` with `--log-bin` to enable binary logging, and `B` with the `--log-slave-updates` option so that updates received from `A` are logged by `B` to its binary log.

- `--log-slow-slave-statements`

Command-Line Format	--log-slow-slave-statements	
Config-File Format	log-slow-slave-statements	
	Permitted Values	
	Type	boolean
	Default	off

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

- `--log-warnings[=level]`

Command-Line Format	--log-warnings[=#]	
Config-File Format	log-warnings	
Option Sets Variable	Yes, log_warnings	
Variable Name	log_warnings	
Variable Scope	Both	
Dynamic Variable	Yes	
Disabled by	skip-log-warnings	
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	1
	Range	0-18446744073709547520

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled by default; to disable it, use `--skip-log-warnings`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds`

  The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

  This option is deprecated in MySQL 5.4 and is removed in MySQL 5.5.

- `--master-host=host_name`

  The host name or IP number of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

  This option is deprecated in MySQL 5.4 and is removed in MySQL 5.5.

- `--master-info-file=file_name`

Command-Line Format	`--master-info-file=name`	
Config-File Format	`master-info-file`	
	Permitted Values	
	Type	`filename`
	Default	`master.info`

  The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory.

- `--master-password=password`

  The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

  This option is deprecated in MySQL 5.4 and is removed in MySQL 5.5.

- `--master-port=port_number`

  The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

  This option is deprecated in MySQL 5.4 and is removed in MySQL 5.5.

- `--master-retry-count=count`

Command-Line Format	`--master-retry-count=#`	
Config-File Format	`master-retry-count`	
	Permitted Values	
	Type	`numeric`
	Default	`86400`

  The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400.

- `--master-ssl`, `--master-ssl-ca=file_name`, `--master-ssl-capath=directory_name`, `--master-ssl-cert=file_name`, `--master-ssl-cipher=cipher_list`, `--master-ssl-key=file_name`

  These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl`, `--ssl-ca`, `--ssl-capath`, `--ssl-cert`, `--ssl-cipher`, `--ssl-key` options that are described in Section 5.5.6.3, “SSL Command Options”. The values in the `master.info` file take precedence if they can be read.

These options are deprecated in MySQL 5.4 and are removed in MySQL 5.5.

- `--master-user=user_name`

  The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

  This option is deprecated in MySQL 5.4 and is removed in MySQL 5.5.

- `--max-relay-log-size=size`

  The size at which the server rotates relay log files automatically. For more information, see Section 16.2.2, "Replication Relay and Status Files". The default size is 1GB.

- `--read-only`

  Cause the slave to allow no updates except from slave threads or from users having the `SUPER` privilege. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

  The basename for the relay log. The default basename is *`host_name`*`-relay-bin`. The server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the basename.

  Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, "Specifying Program Options".

  If you specify this option, the value specified is also used as the basename for the relay log index file. You can override this behavior by specifying a different relay log index file basename using the `--relay-log-index` option.

  You may find the `--relay-log` option useful in performing the following tasks:

  - Creating relay logs whose names are independent of host names.
  - If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
  - To increase speed by using load-balancing between disks.

- `--relay-log-index=file_name`

  The name to use for the relay log index file. The default name is *`host_name`*`-relay-bin.index` in the data directory, where *`host_name`* is the name of the slave server.

  Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, "Specifying Program Options".

  If you specify this option, the value specified is also used as the basename for the relay logs. You can override this behavior by specifying a different relay log file basename using the `--relay-log` option.

- `--relay-log-info-file=file_name`

  The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `--relay-log-purge={0|1}`

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

  This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means "no limit." This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

  The effects of this option depend on whether statement-based or row-based replication is in use.

  Statement-based replication. Tell the slave to restrict replication to statements where the default database (that is, the one selected by `USE`) is *`db_name`*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

  > **Warning**
  >
  > To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

  An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

  ```
  USE prices;
  UPDATE sales.january SET amount=amount+1000;
  ```

  The main reason for this "check just the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

  Row-based replication. Tells the slave to restrict replication to database *`db_name`*. Only tables belonging to *`db_name`* are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

  ```
  USE prices;
  UPDATE sales.february SET amount=amount+100;
  ```

  The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

  ```
  USE prices;
  UPDATE prices.march SET amount=amount-25;
  ```

  Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

  Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

  ```
  USE db1;
  UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
  ```

  If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

  ```
  USE db4;
  UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
  ```

In this case, the UPDATE statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the UPDATE would change table1 on the slave, but not table2—in other words, only tables in the database named by --replicate-do-db are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use --replicate-wild-do-table=*db_name*.% instead. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

> **Note**
>
> This option affects replication in the same manner that --binlog-do-db affects binary logging, and the effects of the replication format on how --replicate-do-db affects replication behavior are the same as those of the logging format on the behavior of --binlog-do-db.
>
> Beginning with MySQL 5.4.2, this option has no effect on BEGIN, COMMIT, or ROLLBACK statements. (Bug#43263)

- --replicate-ignore-db=*db_name*

  As with --replicate-do-db, the effects of this option depend on whether statement-based or row-based replication is in use.

  Statement-based replication. Tells the slave to not replicate any statement where the default database (that is, the one selected by USE) is *db_name*.

  Row-based replication. Tells the slave not to update any tables in the database *db_name*. The default database has no effect.

  When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with --replicate-ignore-db=sales and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

  The UPDATE statement *is* replicated in such a case because --replicate-ignore-db applies only to the default database (determined by the USE statement). Because the sales database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the UPDATE statement's effects are *not* propagated to the slave, and the slave's copy of the sales.january table is unchanged; in this instance, --replicate-ignore-db=sales causes *all* changes made to tables in the master's copy of the sales database to be ignored by the slave.

  To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

  You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

  If you need cross-database updates to work, use --replicate-wild-ignore-table=*db_name*.% instead. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

  > **Note**
  >
  > This option affects replication in the same manner that --binlog-ignore-db affects binary logging, and the effects of the replication format on how --replicate-ignore-db affects replication behavior are the same as those of the logging format on the behavior of --binlog-ignore-db.
  >
  > Beginning with MySQL 5.4.2, this option has no effect on BEGIN, COMMIT, or ROLLBACK statements. (Bug#43263)

- --replicate-do-table=*db_name.tbl_name*

  Tells the slave thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to --replicate-do-db. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

  This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the --replicate-*-db options.

- --replicate-ignore-table=*db_name.tbl_name*

  Tells the slave thread to not replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-

database updates, in contrast to `--replicate-ignore-db`. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

  Tells the slave to translate the default database (that is, the one selected by `USE`) to *`to_name`* if it was *`from_name`* on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if *`from_name`* is the default database on the master. This does not work for cross-database updates. To specify multiple rewrites, use this option multiple times. The server uses the first one with a *`from_name`* value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

  If you use this option on the command line and the "`>`" character is special to your command interpreter, quote the option value. For example:

  ```
  shell> mysqld --replicate-rewrite-db="olddb->newdb"
  ```

- `--replicate-same-server-id`

  To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

  Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the "`%`" and "`_`" wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

  This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

  Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

  If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

  To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the "`_`" and "`%`" characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

  Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

  Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

  For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

The host name or IP number of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP number of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

  The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--report-port=slave_port_num`

  The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

- `--report-user=user_name`

  The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

- `--show-slave-auth-info`

  Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

  Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

  If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=file_name`

  The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

  The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

  The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...|all]`

  Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

  Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Errors, Error Codes, and Common Problems*, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned*.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

Obsolete options. *The following options are removed in MySQL 5.4. If you attempt to start `mysqld` with any of these options in MySQL 5.4, the server aborts with an `UNKNOWN VARIABLE` error*. To set the replication parameters formerly associated with these options, you must use the `CHANGE MASTER TO ...` statement (see Section 12.5.2.1, "`CHANGE MASTER TO` Syntax").

The options affected are shown in this list:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

System variables used on replication slaves. The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

Command-Line Format	`--init-slave=name`	
Config-File Format	`init_slave`	
Option Sets Variable	Yes, `init_slave`	
Variable Name	`init_slave`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`string`

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The

format of the string is the same as for the `init_connect` variable.

> **Note**
>
> The SQL thread sends an acknowledgement to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 12.5.2.7, "`START SLAVE` Syntax", for more information.

- `rpl_recovery_rank`

  This variable is unused.

- `slave_compressed_protocol`

Command-Line Format	`--slave_compressed_protocol`	
Config-File Format	`slave_compressed_protocol`	
Option Sets Variable	Yes, `slave_compressed_protocol`	
Variable Name	`slave_compressed_protocol`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`boolean`
	Default	`OFF`

  Whether to use compression of the slave/master protocol if both the slave and the master support it.

- `slave_exec_mode`

Variable Name	`slave_exec_mode`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`enumeration`
	Default	`STRICT` (ALL)
	Default	`IDEMPOTENT` (NDB)
	Valid Values	`IDEMPOTENT`, `STRICT`

  Controls whether `IDEMPOTENT` or `STRICT` mode is used in replication conflict resolution and error checking. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors. This mode should be employed in multi-master replication, circular replication, and some other special replication scenarios. `STRICT` mode is the default, and is suitable for most other cases.

- `slave_load_tmpdir`

Command-Line Format	`--slave-load-tmpdir=name`
Config-File Format	`slave-load-tmpdir`
Option Sets Variable	Yes, `slave_load_tmpdir`
Variable Name	`slave_load_tmpdir`
Variable Scope	Global
Dynamic Variable	No

	Permitted Values	
	Type	`filename`
	Default	`/tmp`

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- `slave_net_timeout`

Command-Line Format	`--slave-net-timeout=#`	
Config-File Format	`slave-net-timeout`	
Option Sets Variable	Yes, `slave_net_timeout`	
Variable Name	`slave_net_timeout`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`3600`
	Min Value	`1`

The number of seconds to wait for more data from a master/slave connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made via Unix socket files, named pipes, or shared memory.

- `slave_skip_errors`

Command-Line Format	`--slave-skip-errors=name`
Config-File Format	`slave-skip-errors`
Option Sets Variable	Yes, `slave_skip_errors`
Variable Name	`slave_skip_errors`
Variable Scope	Global
Dynamic Variable	No

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_transaction_retries`

Command-Line Format	`--slave_transaction_retries=#`
Config-File Format	`slave_transaction_retries`
Option Sets Variable	Yes, `slave_transaction_retries`
Variable Name	`slave_transaction_retries`
Variable Scope	Global
Dynamic Variable	Yes

	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	10
	Range	0-4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	10
	Range	0-18446744073709547520

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's innodb_lock_wait_timeout, it automatically retries slave_transaction_retries times before stopping with an error. The default value is 10.

- sql_slave_skip_counter

Variable Name	sql_slave_skip_counter	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric

The number of events from the master that a slave server should skip.

> **Important**
>
> If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 12.5.2.6, "SET GLOBAL sql_slave_skip_counter Syntax".

16.1.3.4. Binary Log Options and Variables

You can use the mysqld options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.2.4, "The Binary Log". For additional information about using MySQL server options and system variables, see Section 5.1.2, "Server Command Options", and Section 5.1.4, "Server System Variables".

Startup options used with binary logging. The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- --binlog-row-event-max-size=*N*

Command-Line Format	--binlog-row-event-max-size=#
Config-File Format	binlog-row-event-max-size

	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	1024
	Range	256-4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	1024
	Range	256-18446744073709547520

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See Section 16.1.2, "Replication Formats".

- `--log-bin[=base_name]`

Command-Line Format	`--log-bin`	
Config-File Format	`log-bin`	
Variable Name	`log_bin`	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	`filename`
	Default	`OFF`

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See Section 5.2.4, "The Binary Log".

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see Additional Known Issues, for the reason). Otherwise, MySQL uses *`host_name`*`-bin` as the basename.

- `--log-bin-index[=file_name]`

Command-Line Format	`--log-bin-index=name`	
Config-File Format	`log-bin-index`	
	Permitted Values	
	Type	`filename`
	Default	`OFF`

The index file for binary log file names. See Section 5.2.4, "The Binary Log". If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses *`host_name`*`-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

Command-Line Format	`--log-bin-trust-function-creators`
Config-File Format	`log-bin-trust-function-creators`
Option Sets Variable	Yes, `log_bin_trust_function_creators`

Variable Name	log_bin_trust_function_creators	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	FALSE

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See Section 18.7, “Binary Logging of Stored Programs”.

Statement selection options. The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Section 16.1.3.3, “Replication Slave Options and Variables”.

- `--binlog-do-db=`*`db_name`*

  This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

  The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use.

  Statement-based logging. Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is *`db_name`*. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

  > **Warning**
  >
  > To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

  An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

  The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

  Row-based logging. Logging is restricted to database *`db_name`*. Only changes to tables belonging to *`db_name`* are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

  The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

  Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

  Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose the server is started with `--binlog-do-db=db1`, and the

following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=`*`db_name`*

  This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

  The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use.

  Statement-based logging. Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is *`db_name`*.

  Row-based format. Tells the server not to log updates to any tables in the database *`db_name`*. The current database has no effect.

  When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

  ```
  USE prices;
  UPDATE sales.january SET amount=amount+1000;
  ```

  The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

  To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

  You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

Testing and debugging options. The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=`*`N`*

Command-Line Format	`--max-binlog-dump-events=#`	
Config-File Format	`max-binlog-dump-events`	
	Permitted Values	
	Type	`numeric`
	Default	`0`

  This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

Command-Line Format	`--sporadic-binlog-dump-fail`
Config-File Format	`sporadic-binlog-dump-fail`

	Permitted Values	
	Type	`boolean`
	Default	`FALSE`

This option is used internally by the MySQL test suite for replication testing and debugging.

System variables used with the binary log. The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- `binlog_cache_size`

Command-Line Format	`--binlog_cache_size=#`	
Config-File Format	`binlog_cache_size`	
Option Sets Variable	Yes, `binlog_cache_size`	
Variable Name	`binlog_cache_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	`32`
	Type	`numeric`
	Default	`32768`
	Range	`4096-4294967295`
	Permitted Values	
	Platform Bit Size	`64`
	Type	`numeric`
	Default	`32768`
	Range	`4096-18446744073709547520`

The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large, multiple-statement transactions, you can increase this cache size to get more performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.2.4, “The Binary Log”.

> **MySQL Enterprise**
> For recommendations on the optimum setting for `binlog_cache_size`, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- `binlog_format`

Command-Line Format	`--binlog-format`
Config-File Format	`binlog-format`
Option Sets Variable	Yes, `binlog_format`
Variable Name	`binlog_format`
Variable Scope	Both
Dynamic Variable	Yes

	Permitted Values	
	Type	`enumeration`
	Default	`STATEMENT`
	Valid Values	`ROW`, `STATEMENT`, `MIXED`

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See Section 16.1.2, "Replication Formats". `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

In MySQL 5.4, the default format is `STATEMENT`.

You must have the `SUPER` privilege to set either the global or session `binlog_format` value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. See Section 12.4.4, "`SET` Syntax", for more information.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.

Trying to switch the format in those cases results in an error.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `max_binlog_cache_size`

Command-Line Format	`--max_binlog_cache_size=#`	
Config-File Format	`max_binlog_cache_size`	
Option Sets Variable	Yes, `max_binlog_cache_size`	
Variable Name	`max_binlog_cache_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values (>= 5.4.0, <= 5.4.1)	
	Type	`numeric`
	Default	`4294967295`
	Range	`4096-4294967295`

	Permitted Values (>= 5.4.2)	
	Type	`numeric`
	Default	`18446744073709547520`
	Range	`4096-18446744073709547520`

If a multiple-statement transaction requires more than this many bytes of memory, the server generates a `MULTI-STATEMENT TRANSACTION REQUIRED MORE THAN 'MAX_BINLOG_CACHE_SIZE' BYTES OF STORAGE` error. The minimum value is 4096; the maximum and default values are 4GB on 32-bit platforms and 16 PB (petabytes) on 64-bit platforms. As of MySQL 5.4.2, the maximum value is 4GB on all platforms.

- `max_binlog_size`

Command-Line Format	`--max_binlog_size=#`	
Config-File Format	`max_binlog_size`	
Option Sets Variable	Yes, `max_binlog_size`	
Variable Name	`max_binlog_size`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	`numeric`
	Default	`1073741824`
	Range	`4096-1073741824`

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `sync_binlog`

Command-Line Format	`--sync-binlog=#`	
Config-File Format	`sync_binlog`	
Option Sets Variable	Yes, `sync_binlog`	
Variable Name	`sync_binlog`	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	`32`
	Type	`numeric`
	Default	`0`
	Range	`0-4294967295`

	Permitted Values	
	Platform Bit Size	`64`
	Type	`numeric`
	Default	`0`
	Range	`0-18446744073709547520`

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

16.1.4. Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

> **MySQL Enterprise**
> For regular reports regarding the status of your slaves, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

16.1.4.1. Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: master1
                  Master_User: root
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mysql-bin.000004
          Read_Master_Log_Pos: 931
               Relay_Log_File: slave1-relay-bin.000056
                Relay_Log_Pos: 950
        Relay_Master_Log_File: mysql-bin.000004
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
              Replicate_Do_DB:
          Replicate_Ignore_DB:
           Replicate_Do_Table:
       Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
  Replicate_Wild_Ignore_Table:
                   Last_Errno: 0
                   Last_Error:
                 Skip_Counter: 0
          Exec_Master_Log_Pos: 931
              Relay_Log_Space: 1365
              Until_Condition: None
               Until_Log_File:
                Until_Log_Pos: 0
           Master_SSL_Allowed: No
           Master_SSL_CA_File:
           Master_SSL_CA_Path:
              Master_SSL_Cert:
            Master_SSL_Cipher:
               Master_SSL_Key:
        Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
                Last_IO_Errno: 0
                Last_IO_Error:
               Last_SQL_Errno: 0
               Last_SQL_Error:
```

The key fields from the status report to examine are:

- `Slave_IO_State`: The current status of the slave. See Section 7.5.6.6, “Replication Slave I/O Thread States”, and Section 7.5.6.7, “Replication Slave SQL Thread States”, for more information.
- `Slave_IO_Running`: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be `Yes` unless you have not yet started replication or have explicitly stopped it with `STOP SLAVE`.
- `Slave_SQL_Running`: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be `Yes`.
- `Last_IO_Error`, `Last_SQL_Error`: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- `Seconds_Behind_Master`: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

  A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, `slave_net_timeout` has not yet elapsed.

  It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (`Master_Log_file`, `Read_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
     Id: 10
   User: root
   Host: slave1:58371
     db: NULL
Command: Binlog Dump
   Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
   Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----------+--------+------+------------------+-----------+
|        10 | slave1 | 3306 |                0 |         1 |
+-----------+--------+------+------------------+-----------+
```

```
1 row in set (0.00 sec)
```

16.1.4.2. Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread allows the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but allowing the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

16.2. Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see Section 16.2.1, “Replication Implementation Details”.

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Section 7.5.6, “Examining Thread Information”, for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Section 16.2.2, “Replication Relay and Status Files”.

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

16.2.1. Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

  The binlog dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

  The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

  The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

> **MySQL Enterprise**
> For constant monitoring of the status of slaves, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binlog dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Section 7.5.6.5, “Replication Master Thread States”. For slave states, see Section 7.5.6.6, “Replication Slave I/O Thread States”, and Section 7.5.6.7, “Replication Slave SQL Thread States”.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 2
   User: root
   Host: localhost:32931
     db: NULL
Command: Binlog Dump
   Time: 94
  State: Has sent all binlog to slave; waiting for binlog to
         be updated
   Info: NULL
```

Here, thread 2 is a `Binlog Dump` replication thread that services a connected slave. The `State` information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no `Binlog Dump` threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 10
   User: system user
   Host:
     db: NULL
```

```
Command: Connect
   Time: 11
  State: Waiting for master to send event
   Info: NULL
*************************** 2. row ***************************
     Id: 11
   User: system user
   Host:
     db: NULL
Command: Connect
   Time: 11
  State: Has read all relay log; waiting for the slave I/O
         thread to update it
   Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See Section 16.4.4, “Replication FAQ”. If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see Section 5.1.4, “Server System Variables”.

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See Section 16.1.4.1, “Checking Replication Status”.

16.2.2. Replication Relay and Status Files

During replication, a slave server creates several files that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three file types used in the process:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master.info* file contains the status and current configuration information for the slave's connectivity to the master. The file holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.
- The *relay-log.info* file holds the status information about the execution point within the slave's relay log.

16.2.2.1. The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see Section 4.6.7, “`mysqlbinlog` — Utility for Processing Binary Log Files”).

By default, relay log file names have the form *`host_name`*`-relay-bin.`*`nnnnnn`* in the data directory, where *`host_name`* is the name of the slave server host and *`nnnnnn`* is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is *`host_name`*`-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see Section 16.1.3, “Replication and Binary Logging Options and Variables”).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug#2122). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified via DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes "too large," determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

16.2.2.2. The Slave Status Files

A slave replication server creates two small status files. By default, these files are named `master.info` and `relay-log.info` and created in the data directory. Their names and locations can be changed by using the `--master-info-file` and `--relay-log-info-file` options (see Section 16.1.3, "Replication and Binary Logging Options and Variables").

The two status files contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 12.5.2, "SQL Statements for Controlling Slave Servers". Because the status files are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two files to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The `master.info` file should be protected because it contains the password for connecting to the master. See Section 5.3.2.1, "Administrator Guidelines for Password Security".

The I/O thread updates the `master.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1		Number of lines in the file
2	`Master_Log_File`	The name of the master binary log currently being read from the master
3	`Read_Master_Log_Pos`	The current position within the master binary log that have been read from the master
4	`Master_Host`	The host name of the master
5	`Master_User`	The user name used to connect to the master
6	Password (not shown by `SHOW SLAVE STATUS`)	The password used to connect to the master
7	`Master_Port`	The network port used to connect to the master
8	`Connect_Retry`	The period (in seconds) that the slave will wait before trying to re-connect to the master
9	`Master_SSL_Allowed`	Indicates whether the server supports SSL connections
10	`Master_SSL_CA_File`	The file used for the Certificate Authority (CA) certificate
11	`Master_SSL_CA_Path`	The path to the Certificate Authority (CA) certificates
12	`Master_SSL_Cert`	The name of the SSL certificate file
13	`Master_SSL_Cipher`	The name of the cipher in use for the SSL connection

14	`Master_SSL_Key`	The name of the SSL key file
15	`Master_SSL_Verify_Server_Cert`	Whether to verify the server certificate

The SQL thread updates the `relay-log.info` file. The following table shows the correspondence between the lines in the file and the columns displayed by `SHOW SLAVE STATUS`.

Line	Status Column	Description
1	`Relay_Log_File`	The name of the current relay log file
2	`Relay_Log_Pos`	The current position within the relay log file; events up to this position have been executed on the slave database
3	`Relay_Master_Log_File`	The name of the master binary log file from which the events in the relay log file were read
4	`Exec_Master_Log_Pos`	The equivalent position within the master's binary log file of events that have already been executed

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

16.2.3. How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See Section 16.1.3, “Replication and Binary Logging Options and Variables”.) The slave evaluates these options using the procedure described later in this section, which first checks the database-level options and then the table-level options.

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given. In general, to make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

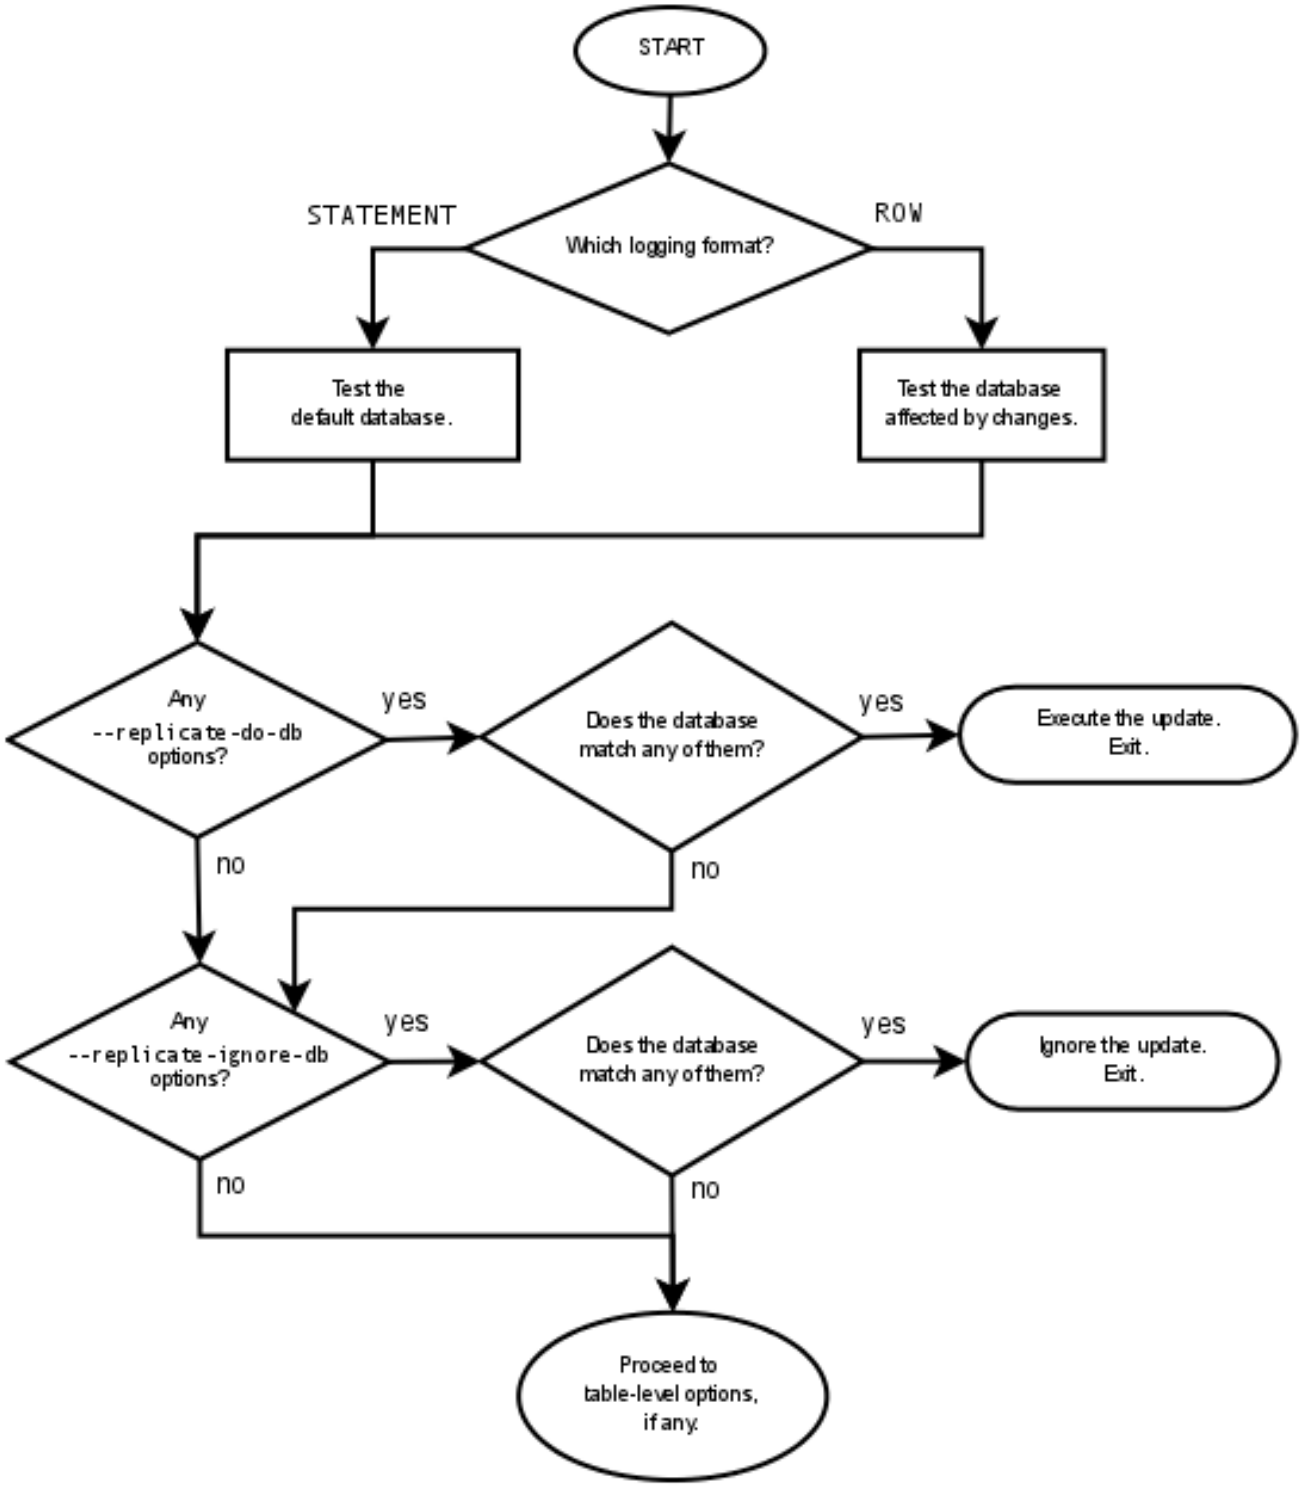
Evaluation of `--replicate-*` options is affected by whether row-based or statement-based logging is in use, but regardless of the logging format, database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”, for a description of this process. If no matching database-level options are found, option checking proceeds to any table-level options that may be in use, as discussed in Section 16.2.3.2, “Evaluation of Table-Level Replication Options”.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

16.2.3.1. Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.



The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
   - **Yes.** Do any of them match the database?
     - **Yes.** Execute the statement and exit.

    - **No.** Continue to step 2.
  - **No.** Continue to step 2.
2. Are there any `--replicate-ignore-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Ignore the statement and exit.
    - **No.** Continue to step 3.
  - **No.** Continue to step 3.
3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 16.2.3.2, "Evaluation of Table-Level Replication Options".

> **Important**
>
> A statement that is not yet disallowed at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
  - **Yes.** Continue to step 2.
  - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
  - **Yes.** Continue to step 3.
  - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
  - **Yes.** Do any of them match the database?
    - **Yes.** Log the statement and exit.
    - **No.** Ignore the statement and exit.
  - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
  - **Yes.** Ignore the statement and exit.
  - **No.** Log the statement and exit.

> **Important**
>
> For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, *or dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean "ignore other databases". For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

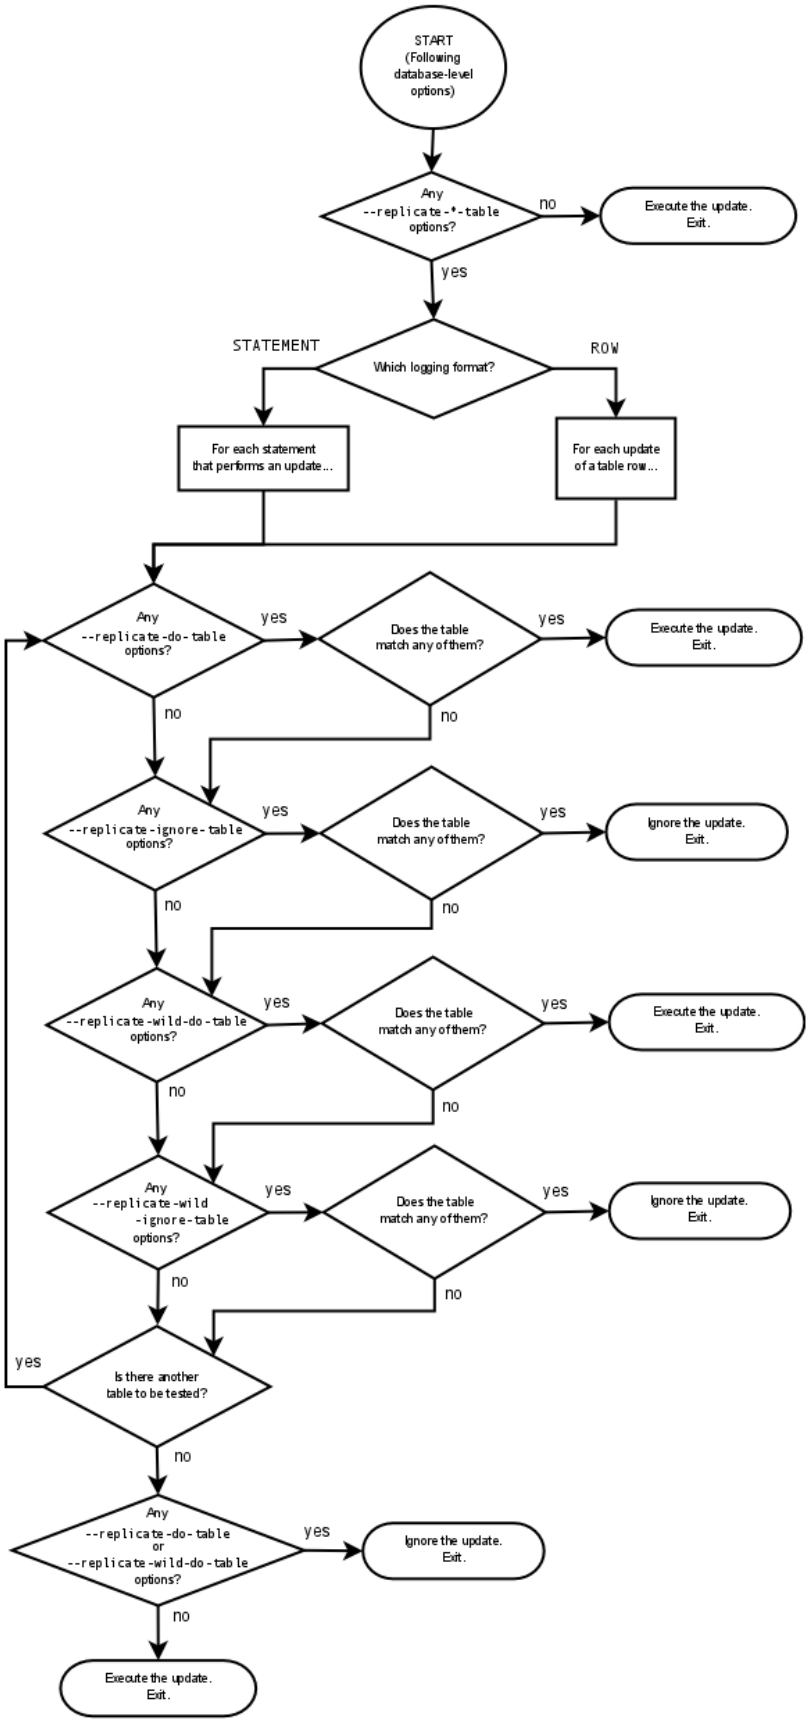
16.2.3.2. Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if no matching database options were found (see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

> **Note**
>
> For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.



START
(Following
database-level
options)
Any
--replicate-*-table
options?
no
Execute the update.
Exit.
yes
STATEMENT
Which logging format?
ROW
For each statement
that performs an update...
For each update
of a table row...
Any
--replicate-do-table
options?
yes
Does the table
match any of them?
yes
Execute the update.
Exit.
no
no
Any
--replicate-ignore-table
options?
yes
Does the table
match any of them?
yes
Ignore the update.
Exit.
no
no
Any
--replicate-wild-do-table
options?
yes
Does the table
match any of them?
yes
Execute the update.
Exit.
no
no
Any
--replicate-wild
-ignore-table
options?
yes
Does the table
match any of them?
yes
Ignore the update.
Exit.
no
no
yes
Is there another
table to be tested?
no
Any
--replicate-do-table
or
--replicate-wild-do-table
options?
yes
Ignore the update.
Exit.
no
Execute the update.
Exit.

The following steps describe this evaluation in more detail:

1. Are there any table options?
   - **Yes.** Continue to step 2.
   - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Execute the event and exit.
     - **No.** Continue to step 3.
   - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Ignore the event and exit.
     - **No.** Continue to step 4.
   - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Execute the event and exit.
     - **No.** Continue to step 5.
   - **No.** Continue to step 5.
5. Are there any `--replicate-ignore-table` options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Ignore the event and exit.
     - **No.** Continue to step 6.
   - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
   - **Yes.** Ignore the event and exit.
   - **No.** Execute the event and exit.

16.2.3.3. Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No `--replicate-*` options at all:	The slave executes all events that it receives from the master.
`--replicate-*-db` options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.

Condition (Types of Options)	Outcome
`--replicate-*-table` options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

Statement-based replication. The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, *and the `INSERT` statement is ignored*. The table options are not checked.

Row-based replication. The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, *and the row is inserted*.

16.3. Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 16.3.1, “Using Replication for Backups”.

For advice and tips on using different storage engines on the master and slaves, see Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”.

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 16.3.3, “Using Replication for Scale-Out”.

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See Section 16.3.4, “Replicating Different Databases to Different Slaves”

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as an replication master, see Section 16.3.5, “Improving Replication Performance”.

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Section 16.3.6, “Switching Masters During Failover”.

To secure your replication communication, you can use SSL to encrypt the communication channel. For step-by-step instructions, see Section 16.3.7, “Setting Up Replication Using SSL”.

16.3.1. Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of "live" data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See Section 16.3.1.1, "Backing Up a Slave Using `mysqldump`".
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see Section 16.3.1.2, "Backing Up Raw Data from a Slave".

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Section 16.3.1.3, "Backing Up a Master or Slave by Making It Read Only".

16.3.1.1. Backing Up a Slave Using `mysqldump`

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that allows the information to be imported into another instance of MySQL Server (see Section 4.5.4, "`mysqldump` — A Database Backup Program"). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

   ```
   shell> mysqladmin stop-slave
   ```

   Alternatively, you can stop only the slave SQL thread to pause event execution:

   ```
   shell> mysql -e 'STOP SLAVE SQL_THREAD;'
   ```

   This allows the slave to continue to receive data change events from the master's binary log and store them in the relay logs via the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, allowing the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

   ```
   shell> mysqldump --all-databases > fulldb.dump
   ```

3. Once the dump has completed, start slave operations again:

   ```
   shell> mysqladmin start-slave
   ```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See Section 16.1.4.1, "Checking Replication Status". If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Section 16.3.4, "Replicating Different Databases to Different Slaves".

16.3.1.2. Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place

while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as `InnoDB`. With `InnoDB`, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

   ```
   shell> mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

   ```
   shell> tar cf /tmp/dbbackup.tar ./data
   ```

3. Start the MySQL server again. Under Unix:

   ```
   shell> mysqld_safe &
   ```

   Under Windows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.4\bin\mysqld"
   ```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

16.3.1.3. Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

> **Note**
>
> The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see Section 4.5.4, “`mysqldump` — A Database Backup Program”). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

16.3.2. Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 16.3.3, “Using Replication for Scale-Out”), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

  Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the `InnoDB` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.

- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

   ```
   mysql> STOP SLAVE;
   ```

   This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the slave replication process again:

   ```
   mysql> START SLAVE;
   ```

Although the `storage_engine` and `table_type` variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

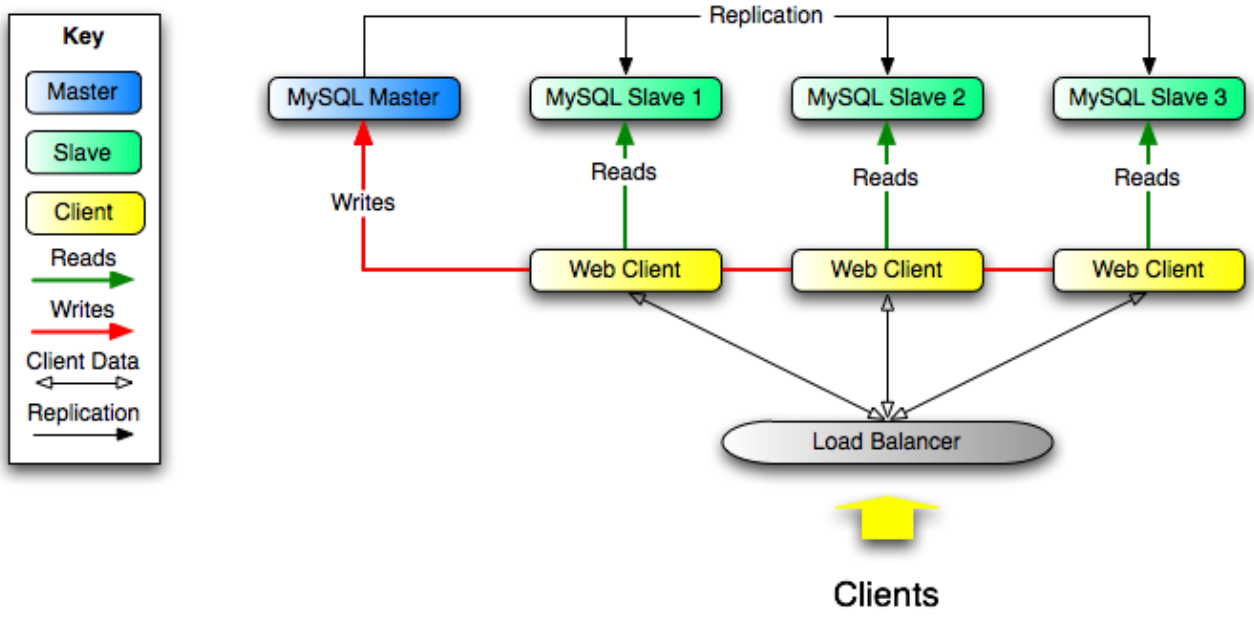
16.3.3. Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still allowing your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 16.1, “Using Replication to Improve Performance During Scale-Out”.

Figure 16.1. Using Replication to Improve Performance During Scale-Out



If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`

- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

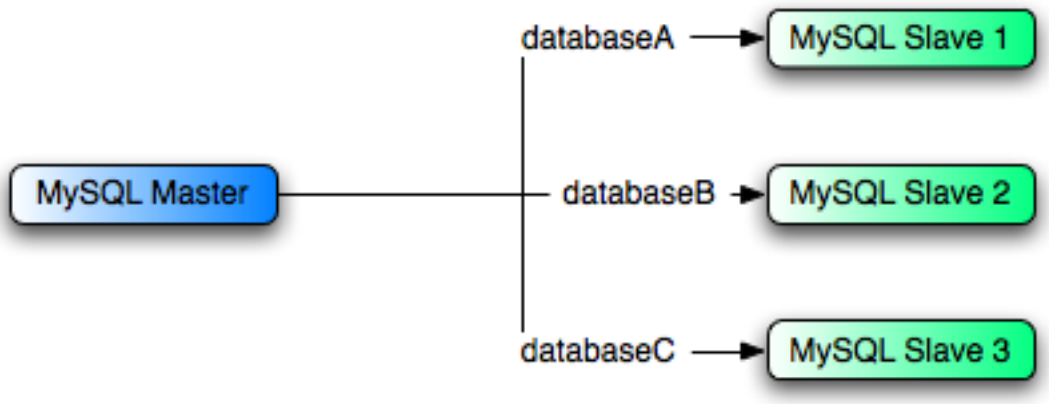
Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

16.3.4. Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.

Figure 16.2. Using Replication to Replicate Databases to Separate Replication Slaves



You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

> **Important**
>
> You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this allows some updates to be replicated using the statement-based format.
>
> However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.

- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

> **Note**
>
> This does not work with `InnoDB` databases unless you use `innodb_file_per_table`.

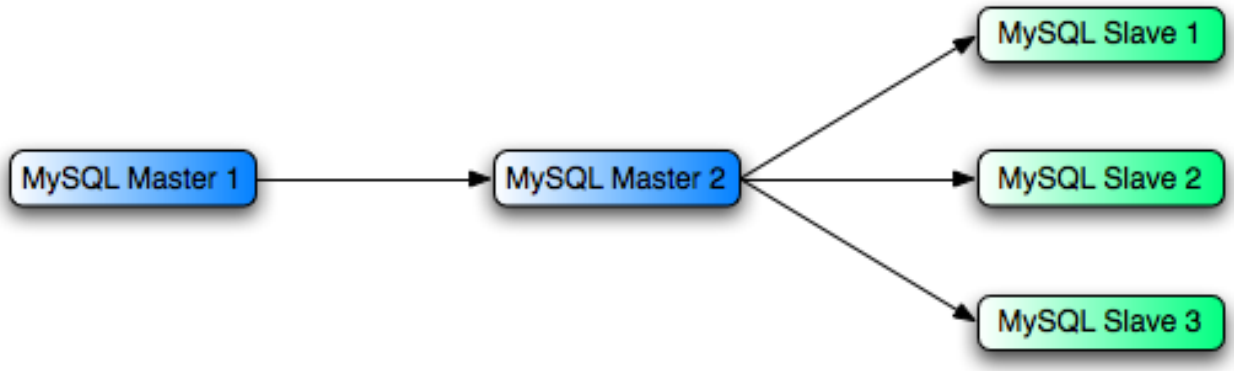
16.3.5. Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 16.3, “Using an Additional Replication Host to Improve Performance”.

Figure 16.3. Using an Additional Replication Host to Improve Performance



For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine allowed to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 16.3.4, “Replicating Different Databases to Different Slaves”.
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”.
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

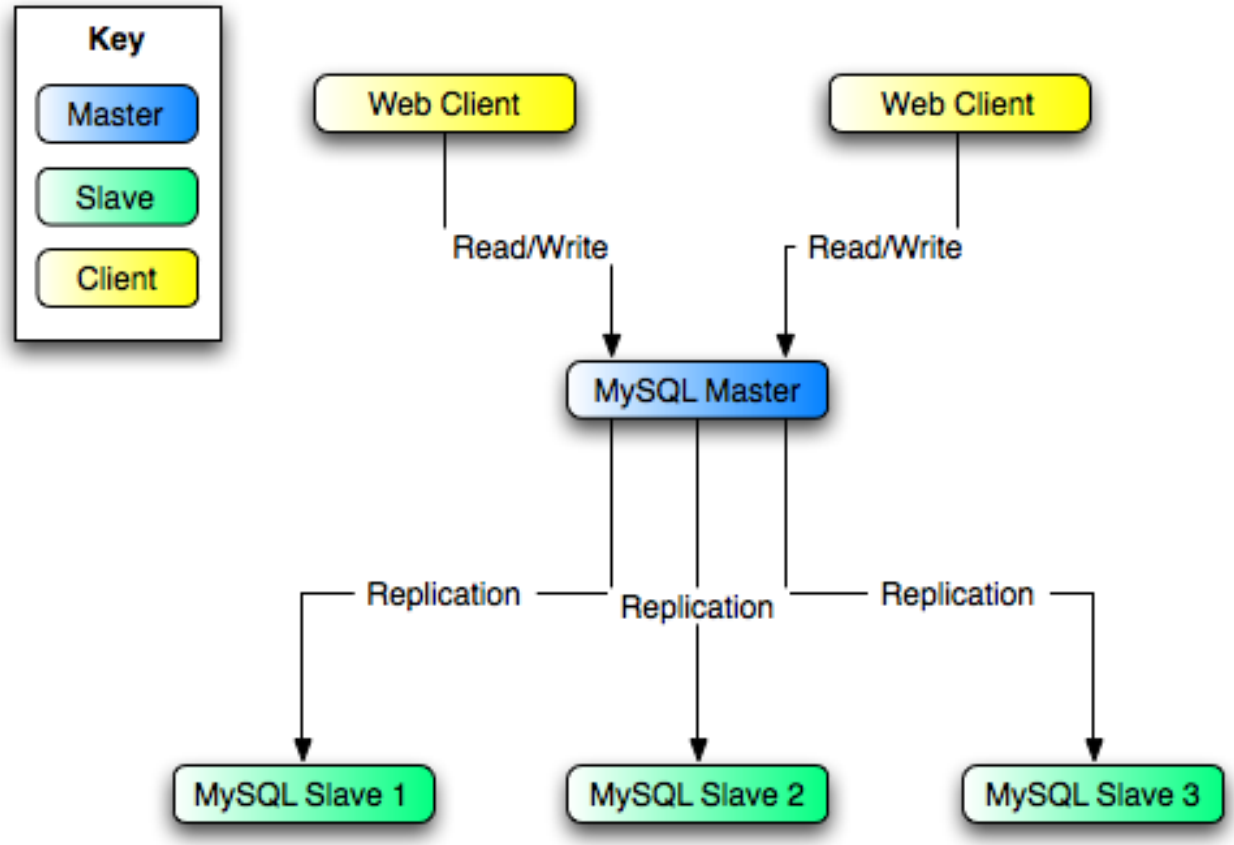
16.3.6. Switching Masters During Failover

There is currently no official solution for providing failover between master and slaves in the event of a failure. With the currently available features, you would have to set up a master and a slave (or several slaves), and to write a script that monitors the master to check whether it is up. Then instruct your applications and the slaves to change master in case of failure.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start reading and executing events from the specified binary log coordinates on the new master. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE`; `RESET MASTER`, and `CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in Figure 16.4, “Redundancy Using Replication, Initial Structure”.

Figure 16.4. Redundancy Using Replication, Initial Structure



In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 16.3.3, "Using Replication for Scale-Out".

Each MySQL Slave (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which will log updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. Suppose that `Slave 1` has `--log-slave-updates` enabled. Then it will write updates that it receives from `Master` to its own binary log. When `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

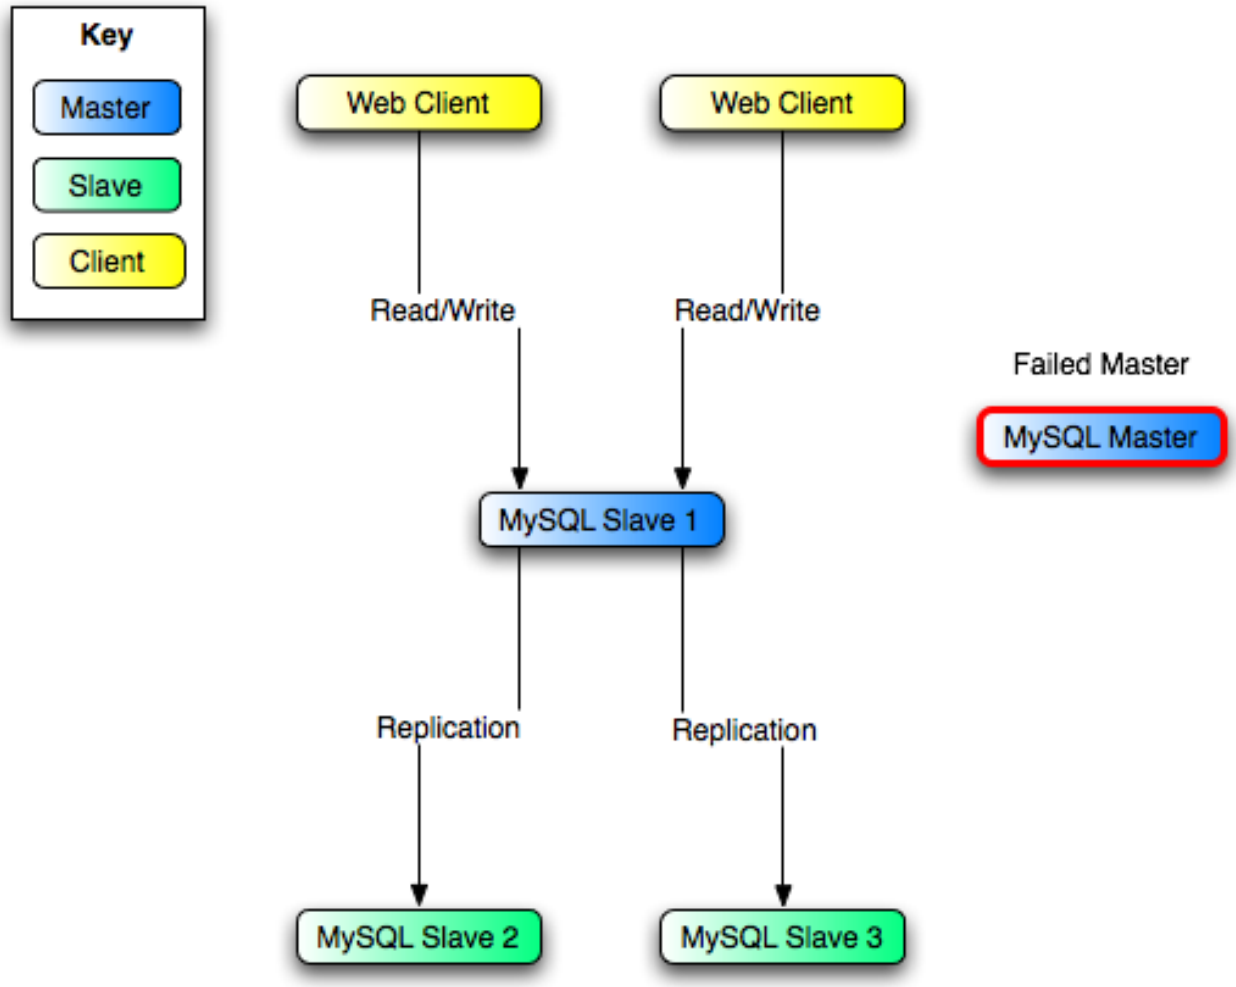
On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (*`user`*, *`password`*, *`port`*). In `CHANGE MASTER TO`, there is no need to specify the name of the `Slave 1` binary log file or log position to read from: We know it is the first binary log file and position 4, which are the defaults for `CHANGE MASTER TO`. Finally, use `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication is in place, you will then need to instruct each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains

every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 16.5, “Redundancy Using Replication, After Master Failure”.

Figure 16.5. Redundancy Using Replication, After Master Failure



When `Master` is up again, you must issue on it the same `CHANGE MASTER TO` as that issued on `Slave 2` and `Slave 3`, so that `Master` becomes a slave of `S1` and picks up each `Web Client` writes that it missed while it was down.

To make `Master` a master again (for example, because it is the most powerful machine), use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. Otherwise, they may pick up old `Web Client` writes from before the point at which `Master` became unavailable.

Note that there is no synchronization between the different slaves to a master. Some slaves might be ahead of others. This means that the concept outlined in the previous example might not work. In practice, however, the relay logs of different slaves will most likely not be far behind the master, so it would work, anyway (but there is no guarantee).

A good way to keep your applications informed as to the location of the master is by having a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to dynamically update your DNS.

16.3.7. Setting Up Replication Using SSL

To use SSL for encrypting the transfer of the binary log required during replication, both the master and the slave must support SSL network connections. If either host does not support SSL connections (because it has not been compiled or configured for SSL), replication through an SSL connection is not possible.

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

For more information on setting up a server and client for SSL connectivity, see Section 5.5.6.2, “Using SSL Connections”.

To enable SSL on the master you must create or obtain suitable certificates, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the certificates may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slave certificates to the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement:

- To add the slave certificates using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file:

  ```
  [client]
  ssl-ca=cacert.pem
  ssl-cert=client-cert.pem
  ssl-key=client-key.pem
  ```

  Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to enable SSL connectivity:

  ```
  mysql> CHANGE MASTER TO
      -> MASTER_HOST='master_hostname',
      -> MASTER_USER='replicate',
      -> MASTER_PASSWORD='password',
      -> MASTER_SSL=1;
  ```

- To specify the SSL certificate options using the `CHANGE MASTER TO` statement, append the SSL options:

  ```
  mysql> CHANGE MASTER TO
      -> MASTER_HOST='master_hostname',
      -> MASTER_USER='replicate',
      -> MASTER_PASSWORD='password',
      -> MASTER_SSL=1,
      -> MASTER_SSL_CA = 'ca_file_name',
      -> MASTER_SSL_CAPATH = 'ca_directory_name',
      -> MASTER_SSL_CERT = 'cert_file_name',
      -> MASTER_SSL_KEY = 'key_file_name';
  ```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that the SSL connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see Section 12.5.2.1, “CHANGE MASTER TO Syntax”.

If you want to enforce the use of SSL connections during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> GRANT USAGE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

16.4. Replication Notes and Tips

16.4.1. Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.4 (or later), you cannot replicate to a slave that uses MySQL 5.1 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.4 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Section 18.7, “Binary Logging of Stored Programs”. For more information about row-based logging and row-based replication, see Section 5.2.4.1, “Binary Logging Formats”, and Section 16.1.2, “Replication Formats”.

For additional information specific to replication and `InnoDB`, see Section 13.6.4.5, “`InnoDB` and MySQL Replication”. For information relating to replication with MySQL Cluster, see MySQL Cluster Replication.

16.4.1.1. Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- An insert into an `AUTO_INCREMENT` column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive). (Bug#33029)
- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

  ```
  CREATE TABLE t2 LIKE t1;
  ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
  INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
  ```

Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section B.5.7.1, "Problems with `ALTER TABLE`".

16.4.1.2. Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master uses MySQL 4.1, you must *always* use the same *global* character set and collation on the master and the slave, regardless of the slave MySQL version. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.
- If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the *global* value of these variables; as stated previously, the master and slave must always have identical global character set values. This is true whether you are using statement-based or row-based replication.
- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

16.4.1.3. Replication of `CREATE ... IF NOT EXISTS` Statements

This section discusses the rules that are applied when various `CREATE ... IF NOT EXISTS` statements are replicated.

Previous to MySQL 5.4.3. `CREATE DATABASE IF NOT EXISTS` was replicated only if the database named in the statement did not exist on the master. `CREATE TABLE IF NOT EXISTS` was replicated only if the table named in the statement did not exist on the master.

MySQL 5.4.3 and later. Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master. Similarly, every `CREATE TABLE IF NOT EXISTS` statement is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. However, replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see Section 16.4.1.4, "Replication of `CREATE TABLE ... SELECT` Statements", for more information.

Replication of `CREATE EVENT IF NOT EXISTS`. `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.4, whether or not the event named in the statement already exists on the master.

See also Bug#45574.

16.4.1.4. Replication of `CREATE TABLE ... SELECT` Statements

This section discusses the rules that are applied when a `CREATE TABLE ... SELECT` statement is replicated.

> **Note**
>
> `CREATE TABLE ... SELECT` always performs an implicit commit (Section 12.3.3, "Statements That Cause an Implicit Commit").

Statement succeeds. A successful `CREATE TABLE ... SELECT` replicates as follows:

- **`STATEMENT` or `MIXED` format.** The `CREATE TABLE ... SELECT` statement is itself replicated.
- **`ROW` format.** The statement is replicated as a `CREATE TABLE` statement followed by a series of `binwrite` events (that is, binary inserts).

Statement fails. A failed `CREATE TABLE ... SELECT` replicates as follows:

- **Statement does not use `IF NOT EXISTS`.** The statement has no effect. However, the implicit commit caused by the statement is logged. This is true regardless of the replication format, storage engine used, and the reason for which the statement failed.
- **Statement uses `IF NOT EXISTS`.** The failure is handled according to the replication format. If the row-based format is in use, the action taken depends additionally on whether the table to be created uses a transactional or nontransactional storage engine, and on the reason for the failure:
  - **`STATEMENT` or `MIXED` format.** The `CREATE TABLE IF NOT EXISTS ... SELECT` is logged with an error.
  - **`ROW` format.** Failure of a `CREATE TABLE ... SELECT` that includes `IF NOT EXISTS` is handled differently depending on the reason for the failure, as shown in the following table.

Transactional Table?	Reason for Failure		
	CREATE Succeeded; SELECT or Inserts Failed	CREATE Failed (Table Already Exists)	CREATE Failed (Other Reason)
YES	1. Table is dropped 2. Implicit commit is logged	1. CREATE TABLE statement is not logged 2. Applied rows are logged 3. Implicit commit is logged	Only implicit commit is logged
NO	1. CREATE TABLE statement is logged 2. Applied rows are logged 3. Implicit commit is logged		

16.4.1.5. Replication of `DROP ... IF EXISTS` Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master. (Bug#13684)

16.4.1.6. Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to

certain conditions.

In all cases where the source and target tables do not have identical definitions, the following must be true in order for replication to work:

- You must be using row-based replication. (Using `MIXED` for the binary logging format does not work.)
- The database and table names must be the same on both the master and the slave.

Additional conditions are discussed, with examples, in the following two sections.

16.4.1.6.1. Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave. (This is true even if the tables have the same number of columns.)
- Columns common to both versions of the table must be defined before any additional columns.
- Each “extra” column in the version of the table having more columns must have a default value.

> **Note**
>
> A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 10.1.4, “Data Type Default Values”).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

Examples. The following examples illustrate some valid and invalid table definitions:

- **More columns on the master.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise Error 1532 (`ER_BINLOG_ROW_RBR_TO_SBR`) because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise Error 1532 because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT);
```

- **More columns on the slave.** The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise Error 1532 because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave>  CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise Error 1532 because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
```

```
slave>  CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave>  CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

16.4.1.6.2. Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); this is sometimes known as *attribute promotion* because the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are allowed; the particulars are discussed later in this section.

> **Important**
>
> Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

Statement-based replication. When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Row-based replication. For row-based replication, the case is not so simple, due to the fact that changes rather than statements are replicated, and these changes are transmitted from master to slave using formats that do not always map directly to MySQL server column datatypes. For example, with row-based binary logging, you cannot replicate between different `INT` subtypes, such as from `TINYINT` to `BIGINT` because changes to columns of these types are represented differently from one another in the binary log. However, you can replicate from `BLOB` to `TEXT` because changes to `BLOB` and `TEXT` columns are represented using the same format in the binary log.

Supported conversions for attribute promotion when using row-based replication are shown in the following table.

From (Master)	To (Slave)
`BINARY`	`CHAR`
`BLOB`	`TEXT`
`CHAR`	`BINARY`
`DECIMAL`	`NUMERIC`
`NUMERIC`	`DECIMAL`
`TEXT`	`BLOB`
`VARBINARY`	`VARCHAR`
`VARCHAR`	`VARBINARY`

> **Note**
>
> In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you can replicate from a `CHAR(10)` column on the master to a column that uses `BINARY(10)` or `BINARY(25)` on the slave, but you cannot replicate from a `CHAR(10)` column on the master to `BINARY(5)` column on the

slave.

For `DECIMAL` and `NUMERIC` columns, both the mantissa (*M*) and the number of decimals (*D*) must be the same size or larger on the slave as compared with the master. For example, replication from a `NUMERIC(5,4)` to a `DECIMAL(6,4)` works, but not from a `NUMERIC(5,4)` to a `DECIMAL(5,3)`.

MySQL does *not* support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

- `INT` (including `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`).

  Promotion between `INT` subtypes—for example, from `SMALLINT` to `BIGINT`—is also not supported.

- `SET` or `ENUM`.
- `FLOAT` or `DOUBLE`.
- The temporal data types: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, `YEAR`.

16.4.1.7. Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table's database directory.

For more information, see Section 5.1.7, “Server SQL Modes”.

16.4.1.8. Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CREATE FUNCTION`
  - `DROP FUNCTION`
  - `CREATE TRIGGER`
  - `DROP TRIGGER`

  However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

  Note

  Attempting to replicate invoked features using statement-based replication produces the warning `STATEMENT IS NOT SAFE TO LOG IN STATEMENT FORMAT`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
  - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. (See Section 19.20, "The INFORMATION_SCHEMA EVENTS Table", and Section 12.4.5.19, "SHOW EVENTS Syntax".)
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), use `SHOW EVENTS`, like this:

```
SHOW EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you might wish to query the `INFORMATION_SCHEMA.EVENTS` table as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
    FROM INFORMATION_SCHEMA.EVENTS
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, use the following query to enable the events:

```
UPDATE mysql.event
    SET STATUS = 'ENABLED'
    WHERE STATUS = 'SLAVESIDE_DISABLED';
```

If more than one master was involved in creating events on this slave, and you wish to enable events that were created only on a given master having the server ID *`master_id`*, use the following query instead:

```
UPDATE mysql.event
    SET STATUS = 'ENABLED'
    WHERE ORIGINATOR = master_id
    AND STATUS = 'SLAVESIDE_DISABLED';
```

> **Important**
>
> Before executing either of the previous two `UPDATE` statements, you should disable the Event Scheduler on the slave (using `SET GLOBAL event_scheduler = OFF;`), run the `UPDATE`, restart the server, then re-enable the Event Scheduler afterwards (using `SET GLOBAL event_scheduler = ON;`).
>
> If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `UPDATE` statement. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using an `UPDATE` statement to rename the events with a common prefix to identify them, as shown in this example:
>
> ```
> UPDATE mysql.event
>     SET name = CONCAT('replicated_', name)
>     WHERE status = 'SLAVESIDE_DISABLED';
> ```
>
> When demoting this server back to being a replication slave, you can then rename and disable the events like this:
>
> ```
> UPDATE mysql.event
>     SET name = REPLACE(name, 'replicated_', ''),
>         status = 'SLAVESIDE_DISABLED'
>     WHERE INSTR(name, 'replicated_') = 1;
> ```

16.4.1.9. Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 11.2, "Type Conversion in Expression Evaluation", and Section B.5.5.8, "Problems with Floating-Point Values".

16.4.1.10. Replication and FLUSH

Some forms of the FLUSH statement are not logged because they could cause problems if replicated to a slave: FLUSH LOGS, FLUSH MASTER, FLUSH SLAVE, and FLUSH TABLES WITH READ LOCK. For a syntax example, see Section 12.4.6.3, "FLUSH Syntax". The FLUSH TABLES, ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the mysql database and update those tables directly without using GRANT, you must issue a FLUSH PRIVILEGES on the slaves to put the new privileges into effect. In addition, if you use FLUSH TABLES when renaming a MyISAM table that is part of a MERGE table, you must issue FLUSH TABLES manually on the slaves. These statements are written to the binary log unless you specify NO_WRITE_TO_BINLOG or its alias LOCAL.

16.4.1.11. Replication and System Functions

Certain functions do not replicate well under some conditions:

- The USER(), CURRENT_USER() (or CURRENT_USER), UUID(), VERSION(), and LOAD_FILE() functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See Section 16.1.2, "Replication Formats".)

  USER() and CURRENT_USER() are automatically replicated using row-based replication when using MIXED mode, and generate a warning in STATEMENT mode. (Bug#28086)

- For NOW(), the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table mytable, perform an INSERT statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

  Local time in Stockholm is 6 hours later than in New York; so, if you issue SELECT NOW() on the slave at that exact same instant, the value 2009-09-01 18:00:00 is returned. For this reason, if you select from the slave's copy of mytable after the CREATE TABLE and INSERT statements just shown have been replicated, you might expect mycol to contain the value 2009-09-01 18:00:00. However, this is not the case; when you select from the slave's copy of mytable, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

  Unlike NOW(), the SYSDATE() function is not replication-safe because it is not affected by SET TIMESTAMP statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used. Another option is to start the server with the --sysdate-is-now option to cause SYSDATE() to be an alias for NOW().

  See also Section 16.4.1.26, "Replication and Time Zones".

- *The following restriction applies to statement-based replication only, not to row-based replication.* The GET_LOCK(), RELEASE_LOCK(), IS_FREE_LOCK(), and IS_USED_LOCK() functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as INSERT INTO mytable VAL-

UES(GET_LOCK(...)).

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row INSERT is problematic due to the reference to the UUID() function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of @my_uuid is stored in the binary log as a user-variable event prior to the INSERT statement and is available for use in the INSERT.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, RAND() replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The FOUND_ROWS() and ROW_COUNT() functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the INSERT statement. For example, if you wish to store the result in a table named mytable, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating mytable, you should use SELECT INTO, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using MIXED mode, and generate a warning in STATEMENT mode. (Bug#12092, Bug#30244)

16.4.1.12. Replication and LIMIT

Statement-based replication of LIMIT clauses in DELETE, UPDATE, and INSERT ... SELECT statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an ORDER BY clause.) When such a statement is encountered:

- When using STATEMENT mode, a warning that the statement is not safe for statement-based replication is now issued.

  Currently, when using STATEMENT mode, warnings are issued for DML statements containing LIMIT even when they also have an ORDER BY clause (and so are made deterministic). This is a known issue. (Bug#42851)

- When using MIXED mode, the statement is now automatically replicated using row-based mode.

16.4.1.13. Replication and LOAD DATA INFILE

The LOAD DATA INFILE statement is not replicated correctly to a slave running MySQL 5.1 or later from a master running MySQL 4.0 or earlier.

When using statement-based replication, the `LOAD DATA INFILE` statement `CONCURRENT` option is not replicated; that is, `LOAD DATA CONCURRENT INFILE` is replicated as `LOAD DATA INFILE`, and `LOAD DATA CONCURRENT LOCAL INFILE` is replicated as `LOAD DATA LOCAL INFILE`. The `CONCURRENT` option *is* replicated when using row-based replication. (Bug#34628)

16.4.1.14. Replication and the Slow Query Log

Replication slaves do not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. This is a known issue. (Bug#23300)

16.4.1.15. Replication and `REPAIR TABLE`

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterwards compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

16.4.1.16. Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement or `--master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.1.4, “Server System Variables”.

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 16.4.1.19, “Replication and Temporary Tables”. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. Writes are not forced to disk because the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

16.4.1.17. Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

16.4.1.18. Replication and `MEMORY` Tables

When a server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log. See Section 13.9, “The `MEMORY` (`HEAP`) Storage Engine”, for more information about `MEMORY` tables.

16.4.1.19. Replication and Temporary Tables

This section does not apply when row-based replication is in use because in that case temporary tables are not replicated. It does apply with mixed-format replication for statements involving temporary tables that can be logged safely using statement-based format. See Section 16.1.2.2, "Usage of Row-Based Logging and Replication".

Safe slave shutdown when using temporary tables. Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

Temporary tables and replication options. By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

16.4.1.20. Replication of the `mysql` System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

16.4.1.21. Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Section 16.4.1.12, "Replication and `LIMIT`", for a detailed discussion of these.

16.4.1.22. Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `current_user` on a 4.0 master that is replicating to a 4.1 or higher slave because `CURRENT_USER` is a reserved word beginning in MySQL 4.1. Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax...`, *even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`` ` ``).

For listings of reserved words by MySQL version, see Reserved Words, in the *MySQL Server Version Reference*. For identifier quoting rules, see Section 8.2, “Schema Object Names”.

16.4.1.23. Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

> **MySQL Enterprise**
> For instant notification when a slave thread terminates, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

16.4.1.24. Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Section 5.1.7, “Server SQL Modes”.

16.4.1.25. Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB` `innodb_lock_wait_timeout` value, or the `NDBCLUSTER` `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see Section 5.1.6, “Server Status Variables”.

16.4.1.26. Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezone=`*`timezone_name`* option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also Section 16.4.1.11, “Replication and System Functions”.

If the master is MySQL 4.1 or earlier, both master and slave should also use the same default connection time zone. That is, the `--default-time-zone` parameter should have the same value for both master and slave.

`CONVERT_TZ(...,...,@@session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

16.4.1.27. Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

In MySQL 5.4 the server uses this rule for binary logging: If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is commited. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

To apply this rule, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that changes both nontransactional and transactional tables is mixed. Mixed statements, like transactional statements, are cached and logged when the transaction commits. (A mixed statement is unrelated to mixed binary logging format.)

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Using different storage engines on master and slave. It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN` ... `COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

16.4.1.28. Replication and Triggers

Triggers are executed on the slave under statement-based replication, but not under row-based replication. Instead, when using row-based replication, the changes caused by executing the trigger on the master are applied on the slave.

This behavior is by design. If the slave applied row-based changes from the master as well as changes caused by triggers, the trigger changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—then you must use statement-based replication. However, it is not necessary to use statement-based replication exclusively if you want to enable slave-side triggers; it is sufficient in such cases to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

16.4.1.29. Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

16.4.1.30. Replication and `TRUNCATE TABLE`

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in Section 12.2.10, "`TRUNCATE TABLE` Syntax" governing such tables. (Bug#36763)

16.4.1.31. Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.2.4.3, “Mixed Binary Logging Format”.

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full *`mode`* value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always

replicated safely. See Section 16.1.2, “Replication Formats”.

In MySQL 5.4 (and in MySQL 5.1.20 and later in MySQL 5.1, as well as in MySQL 5.0.46 and later in MySQL 5.0, for backward compatibility), the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

> **Important**
>
> Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

16.4.2. Replication Compatibility Between MySQL Versions

MySQL supports replication from one major version to the next higher major version. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so on.

The use of more than 2 MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to major versions, but to minor versions within the same major version as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.4.1, MySQL 5.4.2, and MySQL 5.4.3 concurrently, although you could use any 2 of these releases together.

In some cases, it is also possible to replicate between a master and a slave that is more than one major version newer than the master. However, there are known issues with trying to replicate from a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

> **Important**
>
> It is strongly recommended to use the most recent release available within a given MySQL major version because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a major version of MySQL to GA (production) releases when the latter become available for that major version.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

  This also has significant implications for upgrading replication servers; see Section 16.4.3, “Upgrading a Replication Setup”, for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.4 or later master to a slave older than MySQL 5.1.5.

For more information about row-based replication, see Section 16.1.2, “Replication Formats”.

- **SQL incompatiblities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

  However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see Section 16.4.1, “Replication Features and Issues”.

16.4.3. Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.4. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.4 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.4.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.4.x version, restart it, and restart replication. The 5.4 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.4 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.4.x release as the slaves, and restart it. The 5.4 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.4 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.4 format. These too are recognized by the 5.4 slaves.

In other words, when upgrading to MySQL 5.4, the slaves must be MySQL 5.4 before you can upgrade the master to 5.4. Note that downgrading from 5.4 to older versions does not work so simply: You must ensure that any 5.4 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See Section 16.1.2, “Replication Formats”.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, will be detailed at Section 2.12.1.1, “Upgrading from MySQL 5.1 to 5.4”. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect via TCP/IP, use the `--skip-networking` option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.

5. Restart the slaves, this time without the `--skip-slave-start` option.

16.4.4. Replication FAQ

MySQL Enterprise

For expert advice on replication, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

Questions

- 17.4.4.1: Must the slave be connected to the master all the time?
- 17.4.4.2: Must I enable networking on my master and slave to enable replication?
- 17.4.4.3: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?
- 17.4.4.4: How do I force the master to block updates until the slave catches up?
- 17.4.4.5: What issues should I be aware of when setting up two-way replication?
- 17.4.4.6: How can I use replication to improve performance of my system?
- 17.4.4.7: What should I do to prepare client code in my own applications to use performance-enhancing replication?
- 17.4.4.8: When and how much can MySQL replication improve the performance of my system?
- 17.4.4.9: How can I use replication to provide redundancy or high availability?
- 17.4.4.10: How do I tell whether a master server is using statement-based or row-based binary logging format?
- 17.4.4.11: How do I tell a slave to use row-based replication?
- 17.4.4.12: How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?
- 17.4.4.13: Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?
- 17.4.4.14: Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Questions and Answers

17.4.4.1: Must the slave be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

To ensure that catchup can occur for a slave that has been disconnected, you must not remove binary log files from the master that contain information that has not yet been replicated to the slaves. Asynchronous replication can work only if the slave is able to continue reading the binary log from the point where it last read events.

17.4.4.2: Must I enable networking on my master and slave to enable replication?

Yes, networking must be enabled on the master and slave. If networking is not enabled, the slave cannot connect to the master and transfer the binary log. Check that the `skip-networking` option has not been enabled in the configuration file for either server.

17.4.4.3: How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

Check the `Seconds_Behind_Master` column in the output from `SHOW SLAVE STATUS`. See Section 16.1.4.1, “Checking Replication Status”.

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see large `Time` values such as 3600 for the slave SQL thread in `SHOW PROCESS-`

LIST. This is because the slave is executing statements that are one hour old. See Section 16.2.1, “Replication Implementation Details”.

17.4.4.4: How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SHOW MASTER STATUS;
   ```

   Record the replication coordinates (the current binary log file name and position) from the output of the SHOW statement.

2. On the slave, issue the following statement, where the arguments to the MASTER_POS_WAIT() function are the replication coordinate values obtained in the previous step:

   ```
   mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
   ```

   The SELECT statement blocks until the slave reaches the specified log file and position. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to allow the master to begin processing updates again:

   ```
   mysql> UNLOCK TABLES;
   ```

17.4.4.5: What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of misordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

17.4.4.6: How can I use replication to improve performance of my system?

Set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the --skip-innodb, --low-priority-updates, and --delay-key-write=ALL options to get speed improvements on the slave end. In this case, the slave uses nontransactional MyISAM tables instead of InnoDB tables to get more speed by eliminating transactional overhead.

17.4.4.7: What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, Section 16.3.3, “Using Replication for Scale-Out”.

17.4.4.8: When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let reads and writes denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that reads is 1200 – 2 ×

`writes`. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the master and each slave have the same capacity, and that we have one master and *N* slaves. Then we have for each server (master or slave):

`reads` = 1200 – 2 × `writes`

`reads` = 9 × `writes` / (*N* + 1) (reads are split, but writes replicated to all slaves)

9 × `writes` / (*N* + 1) + 2 × `writes` = 1200

`writes` = 1200 / (2 + 9/(*N* + 1))

The last equation indicates the maximum number of writes for *N* slaves, given a maximum possible read rate of 1,200 per minute and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If *N* = 0 (which means we have no replication), our system can handle about 1200/11 = 109 writes per second.
- If *N* = 1, we get up to 184 writes per second.
- If *N* = 8, we get up to 400 writes per second.
- If *N* = 17, we get up to 480 writes per second.
- Eventually, as *N* approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

Note that these computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add *N* replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

17.4.4.9: How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see Section 16.3.6, “Switching Masters During Failover”.

17.4.4.10: How do I tell whether a master server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown will be one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, row-based logging is preferred but replication switches automatically to statement-based logging under certain conditions; for information about when this may occur, see Section 5.2.4.3, “Mixed Binary Logging Format”.

17.4.4.11: How do I tell a slave to use row-based replication?

Slaves automatically know which format to use.

17.4.4.12: How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.

17.4.4.13: Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on Mac OS X and Windows)?

Yes.

17.4.4.14: Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Yes.

16.4.5. Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See Section 16.2.1, “Replication Implementation Details”. If the I/O thread state says `Connecting to master`, check the following:
  - Verify the privileges for the user being used for replication on the master.
  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
  - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  - Check that you can reach the master by using `ping` or `traceroute`/`tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 16.4.1, “Replication Features and Issues”. If it is a bug, see Section 16.4.6, “How to Report Replication Bugs or Problems”, for instructions on how to report it.

  MySQL Enterprise
  For immediate notification whenever a slave stops, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:

  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.

2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.

3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;
mysql> START SLAVE;
```

   The value of *N* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

   See also Section 12.5.2.6, “`SET GLOBAL sql_slave_skip_counter` Syntax”.

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

16.4.6. How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*

2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:

   - All binary log files from the master
   - All binary log files from the slave
   - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
   - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
   - Error logs from the master and the slave

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. *`log_file`* and *`log_pos`* are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.7, “How to Report Bugs or Problems”.

Chapter 17. Partitioning

This chapter discusses MySQL's implementation of *user-defined partitioning*. You can determine whether your MySQL Server supports partitioning by means of a `SHOW VARIABLES` statement such as this one:

```
mysql> SHOW VARIABLES LIKE '%partition%';

+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| have_partitioning | YES   |
+-------------------+-------+
1 row in set (0.00 sec)
```

You can also check the output of the `SHOW PLUGINS` statement, as shown here:

```
mysql> SHOW PLUGINS;
+------------+----------+----------------+---------+---------+
| Name       | Status   | Type           | Library | License |
+------------+----------+----------------+---------+---------+
| binlog     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| partition  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| CSV        | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED  | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| InnoDB     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MyISAM     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster | DISABLED | STORAGE ENGINE | NULL    | GPL     |
+------------+----------+----------------+---------+---------+
11 rows in set (0.00 sec)
```

If you do not see the `have_partitioning` variable with the value `YES` listed in the output of an appropriate `SHOW VARIABLES` statement, or if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output of `SHOW PLUGINS` (show in bold text in the example just given), then your version of MySQL was not built with partitioning support.

MySQL Community binaries provided by Oracle Corporation include partitioning support. For information about partitioning support offered in commercial MySQL Server binaries, see *MySQL Enterprise Server 5.1*, on the MySQL Web site.

If you are compiling MySQL 5.4 from source, the build must be configured using `--with-partition` to enable partitioning.

If your MySQL binary is built with partitioning support, nothing further needs to be done in order to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option, in which case the value of `have_partitioning` is `DISABLED`. However, if you do this, you cannot access any partitioned tables until the server is once again restarted without the `--skip-partition` option.

An introduction to partitioning and partitioning concepts may be found in Section 17.1, “Overview of Partitioning in MySQL”.

MySQL supports several types of partitioning, which are discussed in Section 17.2, “Partition Types”, as well as subpartitioning, which is described in Section 17.2.5, “Subpartitioning”.

Methods of adding, removing, and altering partitions in existing partitioned tables are covered in Section 17.3, “Partition Management”.

Table maintenance commands for use with partitioned tables are discussed in Section 17.3.3, “Maintenance of Partitions”.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See Section 19.19, “The `INFORMATION_SCHEMA PARTITIONS` Table”, for more information; for some examples of queries against this table, see Section 17.2.6, “How MySQL Partitioning Handles `NULL`”.

The partitioning implementation in MySQL 5.4 is still undergoing development. For known issues with MySQL partitioning, see Section 17.5, “Restrictions and Limitations on Partitioning”, where we have noted these.

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

- MySQL Partitioning Forum

  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- Mikael Ronström's Blog

  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- PlanetMySQL

  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.4 binaries are available from http://dev.mysql.com/downloads/mysql/5.4.html. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see Section 2.10, "MySQL Installation Using a Source Distribution". If you have problems compiling a partitioning-enabled MySQL 5.4 build, check the MySQL Partitioning Forum and ask for assistance there if you do not find a solution to your problem already posted.

17.1. Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.4.

For information on partitioning restrictions and feature limitations, see Section 17.5, "Restrictions and Limitations on Partitioning".

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 7.6.1, "Using Symbolic Links", for an explanation of how this is done).

Partitioning takes this notion a step further, by allowing you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be either an integer column value, or a function acting on one or more column values and returning an integer. The value of this expression is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer *`intval`* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.)

There are some additional restrictions on partitioning functions; see Section 17.5, "Restrictions and Limitations on Partitioning", for more information about these.

Examples of partitioning functions can be found in the discussions of partitioning types later in this chapter (see Section 17.2, "Partition Types"), as well as in the partitioning syntax descriptions given in Section 12.1.14, "`CREATE TABLE` Syntax".

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.4 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are not at this time any plans to introduce vertical partitioning into MySQL 5.4.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see Chapter 17, *Partitioning*.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.4, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use `MyISAM` for one partition and `InnoDB` for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

> **Note**
>
> MySQL partitioning cannot be used with the `MERGE`, `CSV`, or `FEDERATED` storage engines.

To employ a particular storage engine for a partitioned table, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a nonpartitioned table. However, you should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
    ENGINE=INNODB
    PARTITION BY HASH( MONTH(tr_date) )
    PARTITIONS 6;
```

> **Note**
>
> Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.4 this has no effect.

> **Important**
>
> Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or *vice versa*, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

> **Note**
>
> The `DATA DIRECTORY` and `INDEX DIRECTORY` options have no effect when defining partitions for tables using the `InnoDB` storage engine.
>
> `DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions on Windows. These options are ignored on Windows, except that a warning is generated.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See Section 17.3, “Partition Management”, for more information on these options.

Some of the advantages of partitioning include:

- Being able to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily be removed from the table by dropping the partition containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding a new partition specifically for that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, thereby excluding any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been so when the partitioning scheme was first set up. This capability is sometimes referred to as *partition pruning*. For more information, see Section 17.4, “Partition Pruning”.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;`. By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.

- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as Partitioning development continues.

17.2. Partition Types

This section discusses the types of partitioning which are available in MySQL 5.4. These include:

- **`RANGE` partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 17.2.1, “`RANGE` Partitioning”.
- **`LIST` partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See Section 17.2.2, “`LIST` Partitioning”.
- **`HASH` partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See Section 17.2.3, “`HASH` Partitioning”.
- **`KEY` partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See Section 17.2.4, “`KEY` Partitioning”.

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.4. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found here:

- Section 17.2.1, “`RANGE` Partitioning”
- Section 17.2.3, “`HASH` Partitioning”

- Section 17.2.3.1, “LINEAR HASH Partitioning”

For more complex examples of date-based partitioning, see:

- Section 17.4, “Partition Pruning”
- Section 17.2.5, “Subpartitioning”

MySQL partitioning is optimized for use with the TO_DAYS() and YEAR() functions. However, you can use other date and time functions that return an integer or NULL, such as WEEKDAY(), DAYOFYEAR(), or MONTH(). See Section 11.7, “Date and Time Functions”, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the RANGE and LIST partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For HASH partitioning, the user function employed must return an integer value greater than 0. For KEY partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following CREATE TABLE statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
    -> PARTITION BY LIST(val)(
    ->     PARTITION mypart VALUES IN (1,3,5),
    ->     PARTITION MyPart VALUES IN (2,4,6)
    -> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names mypart and MyPart.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as 0.8E+01 or 6-2, even if it evaluates to an integer value. Decimal fractions are not allowed.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in Section 12.1.14, “CREATE TABLE Syntax”.

17.2.1. RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the VALUES LESS THAN operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the store_id column. For instance, you might decide to partition the table 4 ways by adding a PARTITION BY RANGE clause as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
```

```
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Michael', 'Widenius', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a "catchall" `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

> **Note**
>
> Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see Section 17.2.2, "`LIST` Partitioning". Also see Section 12.2.5, "`INSERT` Syntax", for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see Section 17.3, "Partition Management", for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create this partitioned table using the following statement:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN` (`<`) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of

`YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

Range partitioning is particularly useful when:

- You want or need to delete "old" data. If you are using the partitioning scheme shown immediately above, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 12.1.6, "`ALTER TABLE` Syntax", and Section 17.3, "Partition Management", for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See Section 17.4, "Partition Pruning", for more information about how this is accomplished.

17.2.2. `LIST` Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(`*`expr`*`)` where *`expr`* is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (`*`value_list`*`)`, where *`value_list`* is a comma-separated list of integers.

> **Note**
>
> In MySQL 5.4, it is possible to match against only a list of integers (and possibly `NULL`—see Section 17.2.6, "How MySQL Partitioning Handles `NULL`") when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 12.1.14, "`CREATE TABLE` Syntax".

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
);
```

(This is the same table used as a basis for the examples in Section 17.2.1, "`RANGE` Partitioning".)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LIST(store_id) (
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees DROP PARTITION pWest;`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`. However, the `ALTER TABLE ... DROP PARTITION` statement also removes the partition itself from the definition for the table, and you must execute an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme. (This problem is resolved in MySQL 5.5, which adds the `ALTER TABLE ... TRUNCATE PARTITION` statement for removing all rows from a given partition without affecting the table definition.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 17.2.5, “Subpartitioning”.

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
    ->   c1 INT,
    ->   c2 INT
    -> )
    -> PARTITION BY LIST(c1) (
    ->   PARTITION p0 VALUES IN (1, 4, 7),
    ->   PARTITION p1 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not:

```
mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT INTO h2 VALUES (4, 7), (3, 5), (6, 0);
ERROR 1525 (HY000): Table has no partition for value 3
mysql> SELECT * FROM h2;
+------+------+
| c1   | c2   |
+------+------+
|    4 |    7 |
+------+------+
1 row in set (0.00 sec)
```

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
+------+------+
| c1   | c2   |
+------+------+
|    7 |    5 |
|    1 |    9 |
|    2 |    5 |
+------+------+
3 rows in set (0.00 sec)
```

17.2.3. `HASH` Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where *`expr`* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you will most likely want to follow this with a `PARTITIONS num` clause, where *`num`* is a positive integer representing the number of partitions into which the table is to be divided.

For example, the following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to `1`.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *`expr`*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

`expr` must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 17.5, “Restrictions and Limitations on Partitioning”. You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for "pruning" on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce by widely different changes in the value of the expression. For example, changing `int_col` from `5` to `6` produces a change of `-1` in the value of the expression, but changing the value of `int_col` from `6` to `7` produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value *versus* the value of the expression follows a straight line as traced by the equation `y=nx` where *`n`* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of *`num`* partitions to use based on the modulus of the result of the user function. In other words, for an expression *`expr`*, the partition in which the record is stored is partition number *`N`*, where *`N = MOD(expr, num)`*. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY HASH( YEAR(col3) )
    PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
=  MOD(2005,4)
=  1
```

MySQL 5.4 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 17.2.3.1, "`LINEAR HASH` Partitioning", for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

> **Note**
>
> If a table to be partitioned has a `UNIQUE` key, then any columns supplied as arguments to the `HASH` user function or to the `KEY`'s *`column_list`* must be part of that key.

17.2.3.1. `LINEAR HASH` Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
```

```
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

   ```
   V = POWER(2, CEILING(LOG(2, num)))
   ```

   (Suppose that *num* is 13. Then `LOG(2,13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and *V* = `POWER(2,4)`, which is 16.)

2. Set *N* = *F*(*column_list*) & (*V* - 1).

3. While *N* >= *num*:

   - Set *V* = CEIL(*V* / 2)
   - Set *N* = *N* & (*V* - 1)

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR HASH( YEAR(col3) )
    PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values `'2003-04-14'` and `'1998-10-19'`. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
   = 2003 & 7
   = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8-1)
  = 1998 & 7
  = 6

(6 >= 6 is TRUE: additional step required)

N = 6 & CEILING(8 / 2)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

17.2.4. `KEY` Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. This internal hashing function is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are that:

- `KEY` is used rather than `HASH`.

- KEY takes only a list of one or more column names. The column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

  KEY takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following CREATE TABLE statement is valid in MySQL 5.4:

```
CREATE TABLE k1 (
    id INT NOT NULL PRIMARY KEY,
    name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

  If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
    id INT NOT NULL,
    name VARCHAR(20),
    UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

  However, if the unique key column were not defined as NOT NULL, then the previous statement would fail.

  In both of these cases, the partitioning key is the id column, even though it is not shown in the output of SHOW CREATE TABLE or in the PARTITION_EXPRESSION column of the INFORMATION_SCHEMA.PARTITIONS table.

  Unlike the case with other partitioning types, columns used for partitioning by KEY are not restricted to integer or NULL values. For example, the following CREATE TABLE statement is valid:

```
CREATE TABLE tm1 (
    s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

  The preceding statement would *not* be valid, were a different partitioning type to be specified.

  > **Note**
  >
  > In this case, simply using PARTITION BY KEY() would also be valid and have the same effect as PARTITION BY KEY(s1), since s1 is the table's primary key.

  For additional information about this issue, see Section 17.5, "Restrictions and Limitations on Partitioning".

  > **Important**
  >
  > For a key-partitioned table, you cannot execute an ALTER TABLE DROP PRIMARY KEY, as doing so generates the error ERROR 1466 (HY000): FIELD IN LIST OF FIELDS FOR PARTITION FUNCTION NOT FOUND IN TABLE.

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
    col1 INT NOT NULL,
    col2 CHAR(5),
    col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using LINEAR has the same effect on KEY partitioning as it does on HASH partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 17.2.3.1, "LINEAR HASH Partitioning", for a description of this algorithm and its implications.

17.2.5. Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. For example,

consider the following CREATE TABLE statement:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE
    );
```

Table ts has 3 RANGE partitions. Each of these partitions—p0, p1, and p2—is further divided into 2 subpartitions. In effect, the entire table is divided into 3 * 2 = 6 partitions. However, due to the action of the PARTITION BY RANGE clause, the first 2 of these store only those records with a value less than 1990 in the purchased column.

In MySQL 5.4, it is possible to subpartition tables that are partitioned by RANGE or LIST. Subpartitions may use either HASH or KEY partitioning. This is also known as *composite partitioning*.

> **Note**
>
> SUBPARTITION BY HASH and SUBPARTITION BY KEY generally follow the same syntax rules as PARTITION BY HASH and PARTITION BY KEY, respectively. An exception to this is that SUBPARTITION BY KEY (unlike PARTITION BY KEY) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.

It is also possible to define subpartitions explicitly using SUBPARTITION clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table ts as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

Some syntactical items of note:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using SUBPARTITION on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

  ```
  CREATE TABLE ts (id INT, purchased DATE)
      PARTITION BY RANGE( YEAR(purchased) )
      SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
          PARTITION p0 VALUES LESS THAN (1990) (
              SUBPARTITION s0,
              SUBPARTITION s1
          ),
          PARTITION p1 VALUES LESS THAN (2000),
          PARTITION p2 VALUES LESS THAN MAXVALUE (
              SUBPARTITION s2,
              SUBPARTITION s3
          )
      );
  ```

  This statement would still fail even if it included a SUBPARTITIONS 2 clause.
- Each SUBPARTITION clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- Subpartition names must be unique across the entire table. For example, the following CREATE TABLE statement is valid in

MySQL 5.4:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0,
            SUBPARTITION s1
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2,
            SUBPARTITION s3
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4,
            SUBPARTITION s5
        )
    );
```

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0
                DATA DIRECTORY = '/disk0/data'
                INDEX DIRECTORY = '/disk0/idx',
            SUBPARTITION s1
                DATA DIRECTORY = '/disk1/data'
                INDEX DIRECTORY = '/disk1/idx'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s2
                DATA DIRECTORY = '/disk2/data'
                INDEX DIRECTORY = '/disk2/idx',
            SUBPARTITION s3
                DATA DIRECTORY = '/disk3/data'
                INDEX DIRECTORY = '/disk3/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s4
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s5
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        )
    );
```

In this case, a separate disk is used for the data and for the indexes of each `RANGE`. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (
            SUBPARTITION s0a
                DATA DIRECTORY = '/disk0'
                INDEX DIRECTORY = '/disk1',
            SUBPARTITION s0b
                DATA DIRECTORY = '/disk2'
                INDEX DIRECTORY = '/disk3'
        ),
        PARTITION p1 VALUES LESS THAN (2000) (
            SUBPARTITION s1a
                DATA DIRECTORY = '/disk4/data'
                INDEX DIRECTORY = '/disk4/idx',
            SUBPARTITION s1b
                DATA DIRECTORY = '/disk5/data'
                INDEX DIRECTORY = '/disk5/idx'
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (
            SUBPARTITION s2a,
            SUBPARTITION s2b
        )
    );
```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.
- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`.
  - Data and indexes belonging to `p1`'s second subpartition (`s1b`) are stored on `/disk5`—the data in `/disk5/data`, and the indexes in `/disk5/idx`.
- Rows reflecting dates from the year 2000 to the present (partition `p2`) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

  In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See Section 17.3, “Partition Management”, for an explanation of how this can be done.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are disallowed when the `NO_DIR_IN_CREATE` server SQL mode is in effect. This is true for partitions and subpartitions.

17.2.6. How MySQL Partitioning Handles `NULL`

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

Handling of `NULL` with `RANGE` partitioning. If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. For example, consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->     PARTITION p0 VALUES LESS THAN (0),
    ->     PARTITION p1 VALUES LESS THAN (10),
    ->     PARTITION p2 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY RANGE(c1) (
    ->     PARTITION p0 VALUES LESS THAN (-5),
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (10),
    ->     PARTITION p3 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          0 |              0 |           0 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          0 |              0 |           0 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.00 sec)
```

(For more information about this table, see Section 19.19, “The INFORMATION_SCHEMA PARTITIONS Table”.) Now let us populate each of these tables with a single row containing a NULL in the column used as the partitioning key, and verify that the rows were inserted using a pair of SELECT statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against INFORMATION_SCHEMA.PARTITIONS and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          1 |             20 |          20 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          1 |             20 |          20 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then rerunning the SELECT statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on ALTER TABLE ... DROP PARTITION, see Section 12.1.6, “ALTER TABLE Syntax”.)

NULL is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a CREATE TABLE statement such as this one:

```
CREATE TABLE tndate (
    id INT,
    dt DATE
```

```
)
PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

Handling of `NULL` with `LIST` partitioning. A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between `0` and `8` inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number `9`. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8),
    ->     PARTITION p3 VALUES IN (NULL)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7, NULL),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| ts2        | p0             |          0 |              0 |           0 |
| ts2        | p1             |          0 |              0 |           0 |
| ts2        | p2             |          0 |              0 |           0 |
| ts2        | p3             |          1 |             20 |          20 |
| ts3        | p0             |          0 |              0 |           0 |
| ts3        | p1             |          1 |             20 |          20 |
| ts3        | p2             |          0 |              0 |           0 |
```

```
+-----------+---------------+-----------+---------------+-------------+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a SELECT.

Handling of NULL with HASH and KEY partitioning. NULL is handled somewhat differently for tables partitioned by HASH or KEY. In these cases, any partition expression that yields a NULL value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by HASH and populating it with a record containing appropriate values. Suppose that you have a table th (also in the p database) created using the following statement:

```
mysql> CREATE TABLE th (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY HASH(c1)
    -> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed like this:

```
mysql> SELECT TABLE_NAME,PARTITION_NAME,TABLE_ROWS,AVG_ROW_LENGTH,DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          0 |              0 |           0 |
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

Note that TABLE_ROWS for each partition is 0. Now insert two rows into th whose c1 column values are NULL and 0, and verify that these rows were inserted:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
+------+---------+
| c1   | c2      |
+------+---------+
| NULL | mothra  |
+------+---------+
|    0 | gigan   |
+------+---------+
2 rows in set (0.01 sec)
```

Recall that for any integer *N*, the value of NULL MOD *N* is always NULL. For tables that are partitioned by HASH or KEY, this result is treated for determining the correct partition as 0. Checking the INFORMATION_SCHEMA.PARTITIONS table once again, we can see that both rows were inserted into partition p0:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
     >   FROM INFORMATION_SCHEMA.PARTITIONS
     >   WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME ='th';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          2 |             20 |          20 |
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
2 rows in set (0.00 sec)
```

If you repeat this example using PARTITION BY KEY in place of PARTITION BY HASH in the definition of the table, you can verify easily that NULL is also treated like 0 for this type of partitioning as well.

17.3. Partition Management

MySQL 5.4 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the ALTER TABLE statement (see Section 12.1.6, “ALTER TABLE Syntax”, for syntax definitions). There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by RANGE or LIST, see Section 17.3.1, “Management of RANGE and LIST Partitions”.
- For a discussion of managing HASH and KEY partitions, see Section 17.3.2, “Management of HASH and KEY Partitions”.

- See Section 17.3.4, “Obtaining Information About Partitions”, for a discussion of mechanisms provided in MySQL 5.4 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see Section 17.3.3, “Maintenance of Partitions”.

> **Note**
>
> In MySQL 5.4, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a *`partition_options`* clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (2000),
        PARTITION p3 VALUES LESS THAN (2005)
    );
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See Section 12.1.6, “`ALTER TABLE` Syntax”.

> **Important**
>
> Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARITITIONS`).

17.3.1. Management of `RANGE` and `LIST` Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 17.3.2, “Management of `HASH` and `KEY` Partitions”. Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
    ->     PARTITION BY RANGE( YEAR(purchased) ) (
    ->         PARTITION p0 VALUES LESS THAN (1990),
    ->         PARTITION p1 VALUES LESS THAN (1995),
    ->         PARTITION p2 VALUES LESS THAN (2000),
    ->         PARTITION p3 VALUES LESS THAN (2005)
    ->     );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
    ->     (1, 'desk organiser', '2003-10-15'),
    ->     (2, 'CD player', '1993-11-05'),
    ->     (3, 'TV set', '1996-03-10'),
    ->     (4, 'bookcase', '1982-01-10'),
    ->     (5, 'exercise bike', '2004-05-09'),
    ->     (6, 'sofa', '1987-06-05'),
    ->     (7, 'popcorn maker', '2001-11-22'),
    ->     (8, 'aquarium', '1992-08-04'),
```

```
    ->     (9, 'study desk', '1984-09-16'),
    ->     (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
    -> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-----------+------------+
| id   | name      | purchased  |
+------+-----------+------------+
|    3 | TV set    | 1996-03-10 |
|   10 | lava lamp | 1998-12-25 |
+------+-----------+------------+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, you must have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See Section 12.2.10, “`TRUNCATE TABLE` Syntax”.)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in Section 12.1.6, “`ALTER TABLE` Syntax”, for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
*************************** 1. row ***************************
       Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
+------+---------------+------------+
| id   | name          | purchased  |
+------+---------------+------------+
|   11 | pencil holder | 1995-07-12 |
|    1 | desk organiser | 2003-10-15 |
|    5 | exercise bike | 2004-05-09 |
|    7 | popcorn maker | 2001-11-22 |
+------+---------------+------------+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '2004-12-31';
```

```
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See Section 17.2.2, "`LIST` Partitioning", for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organisation, which is defined as follows:

```
CREATE TABLE members (
    id INT,
    fname VARCHAR(25),
    lname VARCHAR(25),
    dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION p0 VALUES LESS THAN (1970),
    PARTITION p1 VALUES LESS THAN (1980),
    PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990 to 1999 as shown here:

```
ALTER TABLE ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

> **Important**
>
> With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions will result in an error as shown here:
>
> ```
> mysql> ALTER TABLE members
>      >     ADD PARTITION (
>      >     PARTITION p3 VALUES LESS THAN (1960));
> ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
>    increasing for each partition
> ```

In a similar fashion, you can add new partitions to a table that is partitioned by `LIST`. For example, given a table defined like so:

```
CREATE TABLE tt (
    id INT,
    data INT
)
PARTITION BY LIST(data) (
    PARTITION p0 VALUES IN (5, 10, 15),
    PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values `7`, `14`, and `21` as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
     >     (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
                    in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you

really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
    PARTITION p5 VALUES LESS THAN (2010),
    PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
       Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM.
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` in order to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
    PARTITION s0 VALUES LESS THAN (1960),
    PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, *`tbl_name`* is the name of the partitioned table, and *`partition_list`* is a comma-separated list of names of one or more ex-

isting partitions to be changed. *`partition_definitions`* is a comma-separated list of new partition definitions, which follow the same rules as for the *`partition_definitions`* list used in `CREATE TABLE` (see Section 12.1.14, “CREATE TABLE Syntax”). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

  Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

- The combination of partitions in the *`partition_definitions`* list should account for the same range or set of values overall as the combined partitions named in the *`partition_list`*.

  For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

  For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or *vice versa*. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

  ```
  ALTER TABLE members
      PARTITION BY HASH( YEAR(dob) )
      PARTITIONS 8;
  ```

17.3.2. Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 17.3.1, “Management of RANGE and LIST Partitions”.

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
    id INT,
    fname VARCHAR(30),
```

```
    lname VARCHAR(30),
    signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
    ->     id INT,
    ->     fname VARCHAR(30),
    ->     lname VARCHAR(30),
    ->     signed DATE
    -> )
    -> PARTITION BY LINEAR KEY(signed)
    -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18. use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

17.3.3. Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.4.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

  Example:

  ```
  ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
  ```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

  Example:

  ```
  ALTER TABLE t1 ANALYZE PARTITION p3;
  ```

- **Repairing partitions.** This repairs corrupted partitions.

  Example:

  ```
  ALTER TABLE t1 REPAIR PARTITION p0,p1;
  ```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

  Example:

  ```
  ALTER TABLE trb3 CHECK PARTITION p1;
  ```

  This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

17.3.4. Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. These include:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
*************************** 1. row ***************************
       Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See Section 12.4.5.37, “SHOW TABLE STATUS Syntax”, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See Sec-

tion 19.19, “The INFORMATION_SCHEMA PARTITIONS Table”.

It is possible to determine which partitions of a partitioned table are involved in a given SELECT query using EXPLAIN PARTITIONS. The PARTITIONS keyword adds a partitions column to the output of EXPLAIN listing the partitions from which records would be matched by the query.

Suppose that you have a table trb1 defined and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE(id)
    (
        PARTITION p0 VALUES LESS THAN (3),
        PARTITION p1 VALUES LESS THAN (7),
        PARTITION p2 VALUES LESS THAN (9),
        PARTITION p3 VALUES LESS THAN (11)
    );

INSERT INTO trb1 VALUES
    (1, 'desk organiser', '2003-10-15'),
    (2, 'CD player', '1993-11-05'),
    (3, 'TV set', '1996-03-10'),
    (4, 'bookcase', '1982-01-10'),
    (5, 'exercise bike', '2004-05-09'),
    (6, 'sofa', '1987-06-05'),
    (7, 'popcorn maker', '2001-11-22'),
    (8, 'aquarium', '1992-08-04'),
    (9, 'study desk', '1984-09-16'),
    (10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as SELECT * FROM trb1;, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 10
        Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 10
        Extra: Using where
```

EXPLAIN PARTITIONS provides information about keys used and possible keys, just as with the standard EXPLAIN SELECT statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: range
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 4
          ref: NULL
         rows: 7
```

```
        Extra: Using where
```

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN PARTITIONS` output displays the total number of records in the table.

See also Section 12.8.2, "`EXPLAIN` Syntax".

17.4. Partition Pruning

This section discusses an optimization known as *partition pruning*. The core concept behind partition pruning is relatively simple, and can be described as "Do not scan partitions where there can be no matching values". Suppose that you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
    PARTITION p0 VALUES LESS THAN (64),
    PARTITION p1 VALUES LESS THAN (128),
    PARTITION p2 VALUES LESS THAN (192),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a query such as this one:

```
SELECT fname, lname, region_code, dob
    FROM t1
    WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much more time and effort in finding matching rows than it is to scan all partitions in the table. This "cutting away" of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following:

- *`partition_column = constant`*
- *`partition_column IN (constant1, constant2, ..., constantN)`*

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (125, 126, 127, 128, 129, 130)`. Then the optimizer can determine that the first three values in the list are found in partition `p1`, the remaining three values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function.

Suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
    PARTITION d0 VALUES LESS THAN (1970),
    PARTITION d1 VALUES LESS THAN (1975),
    PARTITION d2 VALUES LESS THAN (1980),
    PARTITION d3 VALUES LESS THAN (1985),
    PARTITION d4 VALUES LESS THAN (1990),
    PARTITION d5 VALUES LESS THAN (2000),
    PARTITION d6 VALUES LESS THAN (2005),
    PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following queries on `t2` can make of use partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. *Find the partition containing the low end of the range*.

   `YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.

2. *Find the partition containing the high end of the range*.

   `YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.

3. *Scan only these two partitions and any partitions that may lie between them*.

   In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

> **Important**
>
> Invalid `DATE` and `DATETIME` values referenced in the `WHERE` clause of a query on a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug#40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
    PARTITION r0 VALUES IN (1, 3),
    PARTITION r1 VALUES IN (2, 5, 8),
    PARTITION r2 VALUES IN (4, 9),
    PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

Any query such as this one can be pruned:

```
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;

SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

> **Important**
>
> This optimization is used only if the range size is smaller than the number of partitions. Consider this query:
>
> ```
> SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 12;
> ```
>
> The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the previous query cannot be pruned.

Pruning can be used only on integer columns of tables partitioned by `HASH` or `KEY`. For example, this query on table `t4` cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

17.5. Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support, as listed here:

- **Prohibited constructs.** The following constructs are not permitted in partitioning expressions:
  - Stored procedures, stored functions, UDFs, or plugins.
  - Declared variables or user variables.

  For a list of SQL functions which are permitted in partitioning expressions, see Section 17.5.3, “Partitioning Limitations Relating to Functions”.
- **Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elswhere in this chapter; see Section 17.2, “Partition Types”, for more information).

  The `DIV` operator is also supported, and the `/` operator is disallowed. (Bug#30188, Bug#33182)

  The bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

- **Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in Section 5.1.7, “Server SQL Modes”, the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables*.

  Examples. The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

  1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as `column DIV 0` or `column MOD 0`, as shown here:

     ```
     mysql> CREATE TABLE tn (c1 INT)
         ->     PARTITION BY LIST(1 DIV c1) (
         ->       PARTITION p0 VALUES IN (NULL),
         ->       PARTITION p1 VALUES IN (1)
         -> );
     Query OK, 0 rows affected (0.05 sec)
     ```

     The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

     ```
     mysql> SELECT @@SQL_MODE;
     +------------+
     | @@SQL_MODE |
     +------------+
     |            |
     +------------+
     1 row in set (0.00 sec)

     mysql> INSERT INTO tn VALUES (NULL), (0), (1);
     Query OK, 3 rows affected (0.00 sec)
     Records: 3  Duplicates: 0  Warnings: 0
     ```

     However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

     ```
     mysql> SET SQL_MODE='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
     Query OK, 0 rows affected (0.00 sec)

     mysql> INSERT INTO tn VALUES (NULL), (0), (1);
     ERROR 1365 (22012): Division by 0
     ```

  2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

     ```
     mysql> SELECT @@SQL_MODE;
     +------------+
     | @@SQL_MODE |
     +------------+
     |            |
     +------------+
     1 row in set (0.00 sec)

     mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
         ->   PARTITION BY RANGE(c1 - 10) (
         ->     PARTITION p0 VALUES LESS THAN (-5),
         ->     PARTITION p1 VALUES LESS THAN (0),
         ->     PARTITION p2 VALUES LESS THAN (5),
         ->     PARTITION p3 VALUES LESS THAN (10),
         ->     PARTITION p4 VALUES LESS THAN (MAXVALUE)
         -> );
     ERROR 1563 (HY000): Partition constant is out of partition function domain

     mysql> SET SQL_MODE='NO_UNSIGNED_SUBTRACTION';
     Query OK, 0 rows affected (0.00 sec)

     mysql> SELECT @@SQL_MODE;
     +-------------------------+
     | @@SQL_MODE              |
     +-------------------------+
     | NO_UNSIGNED_SUBTRACTION |
     +-------------------------+
     1 row in set (0.00 sec)

     mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
         ->   PARTITION BY RANGE(c1 - 10) (
         ->     PARTITION p0 VALUES LESS THAN (-5),
     ```

```
    ->     PARTITION p1 VALUES LESS THAN (0),
    ->     PARTITION p2 VALUES LESS THAN (5),
    ->     PARTITION p3 VALUES LESS THAN (10),
    ->     PARTITION p4 VALUES LESS THAN (MAXVALUE)
    -> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET SQL_MODE='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

- **Performance considerations.** Some affects of partitioning operations on performance are given in the following list:

  - **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.

    See also Maximum number of partitions.

  - **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.

  - **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.

  - **Use of indexes and partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See Section 17.4, “Partition Pruning”, for more information.

  - **Performance with `LOAD DATA`.** In MySQL 5.4, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

- **Maximum number of partitions.** The maximum possible number of partitions for a given table is 1024. This includes subpartitions.

  If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.5.2.18, “`'File' Not Found` and Similar Errors”, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

  See also File system operations.

- **Foreign keys not supported.** Partitioned tables do not support foreign keys. This means that:

  1. Definitions of tables employing user-defined partitioning may not contain foreign key references to other tables.

  2. No table definition may contain a foreign key reference to a partitioned table.

The scope of these restrictions includes tables that use the `InnoDB` storage engine.

- **`ALTER TABLE ... ORDER BY`.** An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.
- **FULLTEXT indexes.** Partitioned tables do not support `FULLTEXT` indexes. This includes partitioned tables employing the `MyISAM` storage engine.
- **Spatial columns.** Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.
- **Temporary tables.** Temporary tables cannot be partitioned. (Bug#17497)
- **Log tables.** It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error. (Bug#27816)
- **Data type of partitioning key.** A partitioning key must be either an integer column or an expression that resolves to an integer. The column or expression value may also be `NULL`. (See Section 17.2.6, "How MySQL Partitioning Handles `NULL`".)

  The lone exception to this restriction occurs when partitioning by [`LINEAR`] `KEY`, where it is possible to use columns of other types as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;
```

  This exception does *not* apply to `BLOB` or `TEXT` column types.

- **Subqueries.** A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.
- **Issues with subpartitions.** Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

  Currently, `SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table's primary key column is used by default). Consider table created by this statement:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
);
```

  You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

  The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

  However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified in order for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
    ->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     name VARCHAR(30)
    -> )
```

```
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY()
    -> SUBPARTITIONS 4
    -> (
    ->     PARTITION p0 VALUES LESS THAN (100),
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ')

mysql> CREATE TABLE ts (
    ->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    ->     name VARCHAR(30)
    -> )
    -> PARTITION BY RANGE(id)
    -> SUBPARTITION BY KEY(id)
    -> SUBPARTITIONS 4
    -> (
    ->     PARTITION p0 VALUES LESS THAN (100),
    ->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
    -> );
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue, which we are currently working to address (Bug#51470).

- **Key caches not supported.** Key caches are not supported for partitioned tables. The `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements, when you attempt to use them on tables having user-defined partitioning, fail with the errors `The storage engine for the table doesn't support assign_to_keycache` and `The storage engine for the table doesn't support preload_keys`, respectively.

- **`DELAYED` option not supported.** Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Attempting to do so fails with an error. (Bug#31210)

- **`DATA DIRECTORY` and `INDEX DIRECTORY` options.** `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:

  - Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored. (Bug#32091)

  - On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions (Bug#30459).

- **Repairing and rebuilding partitioned tables.** The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables. (See Bug#20129.) `mysqlcheck` and `myisamchk` are not supported with partitioned tables.

  In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See Section 12.1.6, “`ALTER TABLE` Syntax”, for more information about these two statements.

17.5.1. Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
```

```
    col4 INT NOT NULL,
    UNIQUE KEY (col1),
    UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
    ->     col1 INT NOT NULL,
    ->     col2 DATE NOT NULL,
    ->     col3 INT NOT NULL,
    ->     col4 INT NOT NULL,
    ->     UNIQUE KEY (col1, col2),
    ->     UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col1 + col3)
    -> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
    ->     col1 INT NOT NULL,
    ->     col2 DATE NOT NULL,
    ->     col3 INT NOT NULL,
    ->     col4 INT NOT NULL,
    ->     UNIQUE KEY (col1, col2, col3),
    ->     UNIQUE KEY (col3)
    -> )
    -> PARTITION BY HASH(col3)
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNQIUE KEY (col1, col3),
    UNQIUE KEY (col2, col4)
);
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example,

the next two statements are invalid:

```
CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),
    UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider given the partitioned table defined as shown here:

```
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
    ->     PARTITION BY RANGE(c1) (
    ->         PARTITION p0 VALUES LESS THAN (10),
    ->         PARTITION p1 VALUES LESS THAN (20),
    ->         PARTITION p2 VALUES LESS THAN (30),
    ->         PARTITION p3 VALUES LESS THAN (40)
    ->     );
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
#  possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

#  use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
```

```
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
#  fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` defined as shown here:

```
mysql> CREATE TABLE np_pk (
    ->     id INT NOT NULL AUTO_INCREMENT,
    ->     name VARCHAR(50),
    ->     added DATE,
    ->     PRIMARY KEY (id)
    -> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statements fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
    ->     PARTITION BY HASH( TO_DAYS(added) )
    ->     PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY MUST INCLUDE ALL COLUMNS IN THE TABLE'S PARTITIONING FUNCTION
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
    ->     PARTITION BY HASH(id)
    ->     PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

We are working to remove this limitation in a future MySQL release series.

17.5.2. Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

`MERGE` storage engine. User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

`FEDERATED` storage engine. Partitioning of `FEDERATED` tables is not supported; it is not possible to create partitioned `FEDERATED` tables. We are working to remove this limitation in a future MySQL release.

`CSV` storage engine. Partitioned tables using the `CSV` storage engine are not supported; it is not possible to create partitioned `CSV` tables.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by `KEY` must be dumped and reloaded.

Same storage engine for all partitions. All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

We are working to remove this limitation in a future MySQL release.

17.5.3. Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following table are supported in partitioning expressions:

ABS()	CEILING() (see CEILING() and FLOOR())	DAY()
DAYOFMONTH()	DAYOFWEEK()	DAYOFYEAR()
DATEDIFF()	EXTRACT()	FLOOR() (see CEILING() and FLOOR())
HOUR()	MICROSECOND()	MINUTE()
MOD()	MONTH()	QUARTER()
SECOND()	TIME_TO_SEC()	TO_DAYS()
WEEKDAY()	YEAR()	YEARWEEK()

> **Note**
>
> In MySQL 5.4, partition pruning is supported only for the TO_DAYS() and YEAR() functions. See Section 17.4, "Partition Pruning", for more information.

CEILING() and FLOOR(). Each of these functions returns an integer only if it is passed an integer argument. This means, for example, that the following CREATE TABLE statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
    ->     PARTITION p0 VALUES IN (1,3,5),
    ->     PARTITION p1 VALUES IN (2,4,6)
    -> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

See Section 11.6.2, "Mathematical Functions", for more information about the return types of these functions.

Chapter 18. Stored Programs and Views

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See Section 12.1, “Data Definition Statements”.
- The `CALL` statement is used to invoke stored procedures. See Section 12.2.1, “`CALL` Syntax”.
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 12.7, “MySQL Compound-Statement Syntax”.

18.1. Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END
```

If you use the `mysql` client program to define a stored program that contains the semicolon characters within its definition, a problem arises. By default, `mysql` itself recognizes semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This allows the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    ->   SET @x = 0;
    ->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT @x;
+------+
| @x   |
+------+
| 1001 |
+------+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (“`\`”) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

18.2. Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.4. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.4 installation procedure. If you are upgrading to MySQL 5.4 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 4.4.7, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

> **MySQL Enterprise**
> For expert advice on using stored procedures and functions, subscribe to the MySQL Enterprise Monitor. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2.

The MySQL implementation of stored routines is still in progress. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, “MySQL 5.4 FAQ: Stored Procedures and Functions”.
- There are some restrictions on the use of stored routines. See Section D.1, “Restrictions on Stored Routines, Triggers, and Events”.
- Binary logging for stored routines takes place as described in Section 18.7, “Binary Logging of Stored Programs”.

18.2.1. Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 12.1.12, “`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax”). A procedure is invoked using a `CALL` statement (see Section 12.2.1, “`CALL` Syntax”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 12.7, “MySQL Compound-Statement Syntax”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 12.1.21, “`DROP PROCEDURE` and `DROP FUNCTION` Syntax”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 12.1.4, “`ALTER PROCEDURE` Syntax”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE` *`db_name`* is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is allowed but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.4, “Server System Variables”, for more information.

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See Section 20.9.3.52, “`mysql_real_connect()`”, and Section 20.9.12, “C API Support for Multiple Statement Execution”.

Access to this collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

18.2.2. Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a

routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

18.2.3. Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See Section 19.14, "The `INFORMATION_SCHEMA ROUTINES` Table".
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See Section 12.4.5.11, "`SHOW CREATE PROCEDURE` Syntax".
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See Section 12.4.5.30, "`SHOW PROCEDURE STATUS` Syntax".
- `INFORMATION_SCHEMA` does not have a `PARAMETERS` table until MySQL 5.5, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of `SHOW CREATE` statements or the `param_list` column of the `mysql.proc` table. `param_list` contents can be processed from within a stored routine, unlike the output from `SHOW`.

18.2.4. Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see Section 11.14, "Information Functions"). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

18.3. Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement executes for the associated table. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

> **Important**
>
> MySQL triggers are activated by SQL statements *only*. They are not activated by changes in views, nor by changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by changes in `INFORMATION_SCHEMA` tables, because these tables are actually views.

To use triggers if you have upgraded to MySQL 5.4 from an older release that did not support triggers, you should upgrade your grant

tables so that they contain the trigger-related privileges. See Section 4.4.7, “`mysql_upgrade` — Check Tables for MySQL Upgrade”.

The following discussion describes the syntax for creating and dropping triggers, and shows some examples of how to use them.

Additional Resources

- You may find the Triggers User Forum of use when working with views.
- For answers to some commonly asked questions regarding triggers in MySQL, see Section A.5, “MySQL 5.4 FAQ: Triggers”.
- There are some restrictions on the use of triggers; see Section D.1, “Restrictions on Stored Routines, Triggers, and Events”.
- Binary logging for triggers takes place as described in Section 18.7, “Binary Logging of Stored Programs”.

18.3.1. Trigger Syntax

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in Section 12.1.15, “`CREATE TRIGGER` Syntax”, and Section 12.1.24, “`DROP TRIGGER` Syntax”.

Here is a simple example that associates a trigger with a table for `INSERT` statements. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    -> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
| Total amount inserted |
+-----------------------+
| 1852.48               |
+-----------------------+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

Triggers for a table are also dropped if you drop the table.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different

schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activation time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
    -> FOR EACH ROW
    -> BEGIN
    ->     IF NEW.amount < 0 THEN
    ->         SET NEW.amount = 0;
    ->     ELSEIF NEW.amount > 100 THEN
    ->         SET NEW.amount = 100;
    ->     END IF;
    -> END;//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to invoke the same routine from within several triggers.

There are some limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are allowed to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if the `BEFORE` trigger (if any) and the row operation both execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so al-

though the statement fails, any changes performed prior to the point of the error remain in effect.

18.3.2. Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See Section 19.16, "The `INFORMATION_SCHEMA TRIGGERS` Table".
- Use the `SHOW TRIGGERS` statement. See Section 12.4.5.39, "`SHOW TRIGGERS` Syntax".

18.4. Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events: Tasks that run according to schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- Section 18.4.1, "Event Scheduler Overview", provides an introduction to and conceptual overview of MySQL Events.
- Section 18.4.3, "Event Syntax", discusses the SQL statements for creating, altering, and dropping MySQL Events.
- Section 18.4.4, "Event Metadata", shows how to obtain information about events and how this information is stored by the MySQL Server.
- Section 18.4.6, "The Event Scheduler and MySQL Privileges", discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.4 installation procedure. If you are upgrading to MySQL 5.4 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See Section 4.4.7, "`mysql_upgrade` — Check Tables for MySQL Upgrade".

Additional Resources

- You may find the MySQL Event Scheduler User Forum of use when working with scheduled events.
- There are some restrictions on the use of events; see Section D.1, "Restrictions on Stored Routines, Triggers, and Events".
- Binary logging for events takes place as described in Section 18.7, "Binary Logging of Stored Programs".

18.4.1. Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a "cron job") or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as "temporal triggers", implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* in order to avoid confusion with triggers of the type discussed in Section 18.3, "Using Triggers". Events should more specifically not be confused with "temporary triggers". Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.4, an event is uniquely identified by its name and the schema to which it is assigned.

- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN ... END` block if desired (see Section 12.7, “MySQL Compound-Statement Syntax”). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

  If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have*. The event creation or modification statement succeeds but the event's action fails. See Section 18.4.6, “The Event Scheduler and MySQL Privileges” for details.

- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See Section 12.1.2, “`ALTER EVENT` Syntax”.

  The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See Section 18.4.6, “The Event Scheduler and MySQL Privileges”.

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see Section D.1, “Restrictions on Stored Routines, Triggers, and Events”.

18.4.2. Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- `OFF`: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. `OFF` is the default value for `event_scheduler`.

  When the Event Scheduler is stopped (`event_scheduler` is `OFF`), it can be started by setting the value of `event_scheduler` to `ON`. (See next item.)

- `ON`: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

  When the Event Scheduler is `ON`, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
     Id: 1
   User: root
   Host: localhost
     db: NULL
Command: Query
   Time: 0
  State: NULL
   Info: show processlist
*************************** 2. row ***************************
     Id: 2
   User: event_scheduler
   Host: localhost
     db: NULL
Command: Daemon
   Time: 3
  State: Waiting for next activation
   Info: NULL
2 rows in set (0.00 sec)
```

  Event scheduling can be stopped by setting the value of `event_scheduler` to `OFF`.

- `DISABLED`: This value renders the Event Scheduler nonoperational. When the Event Scheduler is `DISABLED`, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to `DISABLED`, `event_scheduler` can be toggled between `ON` and `OFF` (using `SET`). It is also possible to use `0` for `OFF`, and `1` for `ON` when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although `ON` and `OFF` have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of `OFF`, `ON`, or `DISABLED`. *`DISABLED` has no numeric equivalent*. For this reason, `ON` and `OFF` are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql> SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL
```

> **Important**
>
> It is possible to set the Event Scheduler to `DISABLED` only at server startup. If `event_scheduler` is `ON` or `OFF`, you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

  ```
  --event-scheduler=DISABLED
  ```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

  ```
  event_scheduler=DISABLED
  ```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event-scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

> **Note**
>
> You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug#26807).

For SQL statements used to create, alter, and drop events, see Section 18.4.3, “Event Syntax”.

MySQL 5.4 provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Section 18.4.4, “Event Metadata”, and Section 19.20, “The `INFORMATION_SCHEMA EVENTS` Table”, for more information.

For information regarding event scheduling and the MySQL privilege system, see Section 18.4.6, “The Event Scheduler and MySQL Privileges”.

18.4.3. Event Syntax

MySQL 5.4 provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See Section 12.1.9, “`CREATE EVENT` Syntax”.
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See Section 12.1.2, “`ALTER EVENT` Syntax”.
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See Section 12.1.18, “`DROP EVENT` Syntax”. Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See Section 12.1.9, “`CREATE EVENT` Syntax”.

  An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See Section 18.4.6, “The Event Scheduler and MySQL Privileges”.

18.4.4. Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See Section 19.20, “The `INFORMATION_SCHEMA EVENTS` Table”.
- Use the `SHOW CREATE EVENT` statement. See Section 12.4.5.9, “`SHOW CREATE EVENT` Syntax”.
- Use the `SHOW EVENTS` statement. See Section 12.4.5.19, “`SHOW EVENTS` Syntax”.

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

Value	`mysql.event`	`INFORMATION_SCHEMA.EVENTS`	`SHOW EVENTS`
Execute at	UTC	ETZ	ETZ
Starts	UTC	ETZ	ETZ
Ends	UTC	ETZ	ETZ

Last executed	UTC	ETZ	n/a
Created	STZ	STZ	n/a
Last altered	STZ	STZ	n/a

18.4.5. Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See Section 18.4.6, “The Event Scheduler and MySQL Privileges” for an example.

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained by running `mysqladmin debug` (see Section 4.5.2, “`mysqladmin` — Client for Administering a MySQL Server”); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA        : init_scheduler:313
LUA        : init_scheduler:318
WOC        : NO
Workers    : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count   : 1
Data locked     : NO
Attempting lock : NO
LLA             : init_queue:148
LUA             : init_queue:168
WOC             : NO
Next activation : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see Section 12.7.4.2, “`DECLARE` for Handlers”. For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

18.4.6. The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires the `SUPER` privilege.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which

its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
    ON SCHEDULE
      EVERY 10 SECOND
    DO
      INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (*`hostname`*`.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:44 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:39:54 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:40:04 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT COMMAND DENIED TO USER
'JON'@'GHIDORA' FOR TABLE 'MYTABLE'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
    >     WHERE EVENT_NAME='e_store_ts'
    >     AND EVENT_SCHEMA='myschema'\G
*************************** 1. row ***************************
   EVENT_CATALOG: NULL
    EVENT_SCHEMA: myschema
      EVENT_NAME: e_store_ts
         DEFINER: jon@ghidora
      EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
      EVENT_TYPE: RECURRING
      EXECUTE_AT: NULL
  INTERVAL_VALUE: 5
  INTERVAL_FIELD: SECOND
        SQL_MODE: NULL
          STARTS: 0000-00-00 00:00:00
            ENDS: 0000-00-00 00:00:00
          STATUS: ENABLED
   ON_COMPLETION: NOT PRESERVE
         CREATED: 2006-02-09 22:36:06
    LAST_ALTERED: 2006-02-09 22:36:06
   LAST_EXECUTED: NULL
   EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

> **Important**
>
> Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.
>
> An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
```

```
    ON SCHEDULE
      EVERY 7 SECOND
    DO
      INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see Section 19.20, "The `INFORMATION_SCHEMA EVENTS` Table") before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
    WHERE db = 'myschema'
      AND definer = 'jon@ghidora'
      AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see Section D.1, "Restrictions on Stored Routines, Triggers, and Events"). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

18.5. Using Views

Views (including updatable views) are available in MySQL Server 5.4. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.4 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See Section 4.4.7, "`mysql_upgrade` — Check Tables for MySQL Upgrade".

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

- You may find the Views User Forum of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see Section A.6, “MySQL 5.4 FAQ: Views”.
- There are some restrictions on the use of views; see Section D.4, “Restrictions on Views”.

18.5.1. View Syntax

The `CREATE VIEW` statement creates a new view (see Section 12.1.16, “`CREATE VIEW` Syntax”). To alter the definition of a view or drop a view, use `ALTER VIEW` (see Section 12.1.7, “`ALTER VIEW` Syntax”), or `DROP VIEW` (see Section 12.1.25, “`DROP VIEW` Syntax”).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    3 |    50 |   150 |
|    5 |    60 |   300 |
+------+-------+-------+
mysql> SELECT * FROM v WHERE qty = 5;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    5 |    60 |   300 |
+------+-------+-------+
```

18.5.2. View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Refers only to literal values (in this case, there is no underlying table)

18.5.3. Updatable and Insertable Views

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)

- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Nonupdatable view in the `FROM` clause
- A subquery in the `WHERE` clause that refers to a table in the `FROM` clause
- Refers only to literal values (in this case, there is no underlying table to update)
- Uses `ALGORITHM = TEMPTABLE` (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table.

With respect to insertability (being updatable with `INSERT` statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is derived from an expression. But it is updatable if the update does not try to update `col2`. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the `MERGE` algorithm. For this to work, the view must use an inner join (not an outer join or a `UNION`). Also, only a single table in the view definition can be updated, so the `SET` clause must name only columns from one of the tables in the view. Views that use `UNION ALL` are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values

into columns not part of the view should not be visible.

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the *select_statement* is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
    -> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
    -> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
    -> WITH CASCADED CHECK OPTION;
```

Here the v2 and v3 views are defined in terms of another view, v1. v2 has a LOCAL check option, so inserts are tested only against the v2 check. v3 has a CASCADED check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the INFORMATION_SCHEMA.VIEWS table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such UPDATE, DELETE, and INSERT are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the updatable_views_with_limit system variable. See Section 5.1.4, “Server System Variables”.

18.5.4. View Metadata

Metadata about views can be obtained as follows:

- Query the VIEWS table of the INFORMATION_SCHEMA database. See Section 19.15, “The INFORMATION_SCHEMA VIEWS Table”.
- Use the SHOW CREATE VIEW statement. See Section 12.4.5.14, “SHOW CREATE VIEW Syntax”.

18.6. Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their DEFINER attribute, and, if there is one, their SQL SECURITY characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a DEFINER attribute that names a MySQL account. If the DEFINER attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a SQL SECURITY characteristic with a value of DEFINER or INVOKER to specify whether the object executes in definer or invoker context. If the SQL SECURITY characteristic is omitted, the default is definer context.

Triggers and events have no SQL SECURITY characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its

DEFINER attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, EXECUTE to call a stored procedure or SELECT to select from a view), but when the object executes, the invoker's privileges are ignored and only the DEFINER account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the DEFINER account is highly privileged (such as a root account), the object can perform powerful operations *no matter who invokes it.*

- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The DEFINER attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the EXECUTE privilege for p1 can invoke it with a CALL statement. However, when p1 executes, it does so in DEFINER security context and thus executes with the privileges of 'admin'@'localhost', the account named in the DEFINER attribute. This account must have the EXECUTE privilege for p1 as well as the UPDATE privilege for the table t1. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to p1 except that its SQL SECURITY characteristic is INVOKER:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

p2, unlike p1, executes in INVOKER security context. The DEFINER attribute is irrelevant and p2 executes with the privileges of the invoking user. p2 fails if the invoker lacks the EXECUTE privilege for p2 or the UPDATE privilege for the table t1.

MySQL uses the following rules to control which accounts a user can specify in an object DEFINER attribute:

- You can specify a DEFINER value other than your own account only if you have the SUPER privilege.
- If you do not have the SUPER privilege, the only legal user value is your own account, either specified literally or by using CURRENT_USER. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use SQL SECURITY INVOKER in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the SUPER privilege, specify an explicit DEFINER attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged DEFINER account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged DEFINER accounts by not granting them the SUPER privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
  - A stored procedure or function cannot be referenced by a user who does not have the EXECUTE privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (SELECT to select from it, INSERT to insert into it, and so forth).

  However, no such control exists for triggers because users do not reference them directly. A trigger always executes in DEFINER context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the DEFINER account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the SUPER and TRIGGER privileges needed to create the trigger are revoked from the account of the user who created it. Adminis-

trators should be especially careful about granting users that combination of privileges.

18.7. Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of "events" that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 16.2, "Replication Implementation".
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 6.3.2, "Using Backups for Recovery".

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.4 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see Section 16.1.2, "Replication Formats".

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See Section 5.2.4, "The Binary Log".) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.4 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See Section 12.1.12, "`CREATE PROCEDURE` and `CREATE FUNCTION` Syntax".)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

  By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
  RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
  RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the "honesty" of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

  ```
  mysql> SET GLOBAL log_bin_trust_function_creators = 1;
  ```

  You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

  If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 16.4.1, "Replication Features and Issues".

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.

- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

  When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

  The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:

  - It is possible for a function to follow different execution paths on master and slave servers.

  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

  The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
    -> BEGIN
    ->   IF @@server_id=2 THEN dangerous_statement; END IF;
    ->   RETURN 1;
    -> END;
    -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

  The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

  To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

  If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:

- It will make a slave different from the master.
- Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

  In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

  - A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

    ```
    NAME_CONST(var_name, var_value)
    ```

    `var_name` is the local variable name, and *`var_value`* is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of *`var_value`*, and a “name” of *`var_name`*. Thus, if you invoke this function directly, you get a result like this:

    ```
    mysql> SELECT NAME_CONST('myname', 14);
    +--------+
    | myname |
    +--------+
    |     14 |
    +--------+
    ```

    `NAME_CONST()` allows a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

    The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

    ```
    CREATE TABLE t1 SELECT myvar;
    ```

    That will be rewritten as follows:

    ```
    CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
    ```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where *`value`* is the value of `@my_var` on the master:

  ```
  SET @my_var = value;
  ```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.

- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 19. INFORMATION_SCHEMA Tables

INFORMATION_SCHEMA provides access to database metadata.

Metadata is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are *data dictionary* and *system catalog*.

INFORMATION_SCHEMA is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside INFORMATION_SCHEMA there are several read-only tables. They are actually views, not base tables, so there are no files associated with them.

In effect, we have a database named INFORMATION_SCHEMA, although the server does not create a database directory with that name. It is possible to select INFORMATION_SCHEMA as the default database with a USE statement, but it is possible only to read the contents of tables. You cannot insert into them, update them, or delete from them.

Here is an example of a statement that retrieves information from INFORMATION_SCHEMA:

```
mysql> SELECT table_name, table_type, engine
    -> FROM information_schema.tables
    -> WHERE table_schema = 'db5'
    -> ORDER BY table_name DESC;
+------------+------------+--------+
| table_name | table_type | engine |
+------------+------------+--------+
| v56        | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v          | VIEW       | NULL   |
| tables     | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t          | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| loop       | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| goto       | BASE TABLE | MyISAM |
| fk2        | BASE TABLE | InnoDB |
| fk         | BASE TABLE | InnoDB |
+------------+------------+--------+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database db5, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its storage engine.

The definition for character columns (for example, TABLES.TABLE_NAME) is generally VARCHAR(*N*) CHARACTER SET utf8 where *N* is at least 64. MySQL uses the default collation for this character set (utf8_general_ci) for all searches, sorts, comparisons, and other string operations on such columns. However, searches in INFORMATION_SCHEMA string columns are also affected by file system case sensitivity. For more information, see Section 9.1.7.8, “Collation and INFORMATION_SCHEMA Searches”.

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the ROUTINE_DEFINITION column in the INFORMATION_SCHEMA.ROUTINES table), users who have insufficient privileges will see NULL.

The SELECT ... FROM INFORMATION_SCHEMA statement is intended as a more consistent way to provide access to the information provided by the various SHOW statements that MySQL supports (SHOW DATABASES, SHOW TABLES, and so forth). Using SELECT has these advantages, compared to SHOW:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how SELECT works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.

- Migration is easier because every other DBMS does it this way.

However, because SHOW is popular and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate SHOW. In fact, along with the implementation of INFORMATION_SCHEMA, there are enhancements to SHOW as well. These are described in Section 19.28, "Extensions to SHOW Statements".

There is no difference between the privileges required for SHOW statements and those required to select information from INFORMATION_SCHEMA. In either case, you have to have some privilege on an object in order to see information about it.

INFORMATION_SCHEMA queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use EXPLAIN. For information about EXPLAIN output that is specific to interpreting the cost of INFORMATION_SCHEMA queries, see Section 7.2.20, "INFORMATION_SCHEMA Optimization".

The implementation for the INFORMATION_SCHEMA table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the ENGINE column in the INFORMATION_SCHEMA.TABLES table.

Although other DBMSs use a variety of names, like syscat or system, the standard name is INFORMATION_SCHEMA.

The following sections describe each of the tables and columns that are in INFORMATION_SCHEMA. For each column, there are three pieces of information:

- "INFORMATION_SCHEMA Name" indicates the name for the column in the INFORMATION_SCHEMA table. This corresponds to the standard SQL name unless the "Remarks" field says "MySQL extension."
- "SHOW Name" indicates the equivalent field name in the closest SHOW statement, if there is one.
- "Remarks" provides additional information where applicable. If this field is NULL, it means that the value of the column is always NULL. If this field says "MySQL extension," the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked "MySQL extension". (For example, we changed COLLATION to TABLE_COLLATION in the TABLES table.) See the list of reserved words near the end of this article: http://web.archive.org/web/20070409075643rn_1/www.dbazine.com/db2/db2-disarticles/gulutzan5.

Each section indicates what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA, if there is such a statement. For SHOW statements that display information for the default database if you omit a FROM *db_name* clause, you can often select information for the default database by adding an AND TABLE_SCHEMA = SCHEMA() condition to the WHERE clause of a query that retrieves information from an INFORMATION_SCHEMA table.

> **Note**
>
> At present, there are some missing columns and some columns out of order. We are working on this and updating the documentation as changes are made.

For answers to questions that are often asked concerning the INFORMATION_SCHEMA database, see Section A.7, "MySQL 5.4 FAQ: INFORMATION_SCHEMA".

19.1. The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the SCHEMATA table provides information about databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CATALOG_NAME		NULL
SCHEMA_NAME		Database
DEFAULT_CHARACTER_SET_NAME		
DEFAULT_COLLATION_NAME		

SQL_PATH		NULL

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
  FROM INFORMATION_SCHEMA.SCHEMATA
  [WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
  [LIKE 'wild']
```

19.2. The INFORMATION_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	The version number of the table's .frm file, MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension
TABLE_COMMENT	Comment	MySQL extension

Notes:

- TABLE_SCHEMA and TABLE_NAME are a single field in a SHOW display, for example Table_in_db1.
- TABLE_TYPE should be BASE TABLE or VIEW. Currently, the TABLES table does not list TEMPORARY tables.
- For partitioned tables, the ENGINE column shows the name of the storage engine used by all partitions. (Previously, this column showed PARTITION for such tables.)
- The TABLE_ROWS column is NULL if the table is in the INFORMATION_SCHEMA database.

  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- The DATA_FREE column shows the free space in bytes for InnoDB tables.
- We have nothing for the table's default character set. TABLE_COLLATION is close, because collation names begin with a character set name.
- The CREATE_OPTIONS column shows partitioned if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  WHERE table_schema = 'db_name'
  [AND table_name LIKE 'wild']

SHOW TABLES
  FROM db_name
  [LIKE 'wild']
```

19.3. The INFORMATION_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
PRIVILEGES	Privileges	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

Notes:

- In SHOW, the Type display includes values from several different COLUMNS columns.
- ORDINAL_POSITION is necessary because you might want to say ORDER BY ORDINAL_POSITION. Unlike SHOW, SELECT does not have automatic ordering.
- CHARACTER_OCTET_LENGTH should be the same as CHARACTER_MAXIMUM_LENGTH, except for multi-byte character sets.
- CHARACTER_SET_NAME can be derived from Collation. For example, if you say SHOW FULL COLUMNS FROM t, and you see in the Collation column a value of latin1_swedish_ci, the character set is what is before the first underscore: latin1.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
  FROM INFORMATION_SCHEMA.COLUMNS
  WHERE table_name = 'tbl_name'
  [AND table_schema = 'db_name']
  [AND column_name LIKE 'wild']

SHOW COLUMNS
  FROM tbl_name
  [FROM db_name]
  [LIKE 'wild']
```

19.4. The INFORMATION_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for sp_statistics, except that we replaced the name QUALIFIER with CATALOG and we replaced the name OWNER with SCHEMA.

  Clearly, the preceding table and the output from SHOW INDEX are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
  AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

19.5. The INFORMATION_SCHEMA USER_PRIVILEGES Table

The USER_PRIVILEGES table provides information about global privileges. This information comes from the mysql.user grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		*'user_name'@'host_name'* value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a nonstandard table. It takes its values from the `mysql.user` table.

19.6. The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		*'user_name'@'host_name'* value, MySQL extension
TABLE_CATALOG		NULL, MySQL extension
TABLE_SCHEMA		MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a nonstandard table. It takes its values from the `mysql.db` table.

19.7. The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		*'user_name'@'host_name'* value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES

SHOW GRANTS ...
```

19.8. The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The COLUMN_PRIVILEGES table provides information about column privileges. This information comes from the mysql.columns_priv grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		*'user_name'@'host_name'* value
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- In the output from SHOW FULL COLUMNS, the privileges are all in one field and in lowercase, for example, select,insert,update,references. In COLUMN_PRIVILEGES, there is one privilege per row, in uppercase.
- PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES.
- If the user has GRANT OPTION privilege, IS_GRANTABLE should be YES. Otherwise, IS_GRANTABLE should be NO. The output does not list GRANT OPTION as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES

SHOW GRANTS ...
```

19.9. The INFORMATION_SCHEMA CHARACTER_SETS Table

The CHARACTER_SETS table provides information about available character sets.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CHARACTER_SET_NAME	Charset	
DEFAULT_COLLATE_NAME	Default collation	
DESCRIPION	Description	MySQL extension
MAXLEN	Maxlen	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

19.10. The INFORMATION_SCHEMA COLLATIONS Table

The COLLATIONS table provides information about collations for each character set.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	MySQL extension
ID	Id	MySQL extension
IS_DEFAULT	Default	MySQL extension
IS_COMPILED	Compiled	MySQL extension
SORTLEN	Sortlen	MySQL extension

- COLLATION_NAME is the collation name.
- CHARACTER_SET_NAME is the name of the character set with which the collation is associated.
- ID is the collation ID.
- IS_DEFAULT indicates whether the collation is the default for its character set.
- IS_COMPILED indicates whether the character set is compiled into the server.
- SORTLEN is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the SHOW COLLATION statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

19.11. The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The COLLATION_CHARACTER_SET_APPLICABILITY table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from SHOW COLLATION.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
COLLATION_NAME	Collation	
CHARACTER_SET_NAME	Charset	

19.12. The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

Notes:

- The CONSTRAINT_TYPE value can be UNIQUE, PRIMARY KEY, or FOREIGN KEY.
- The UNIQUE and PRIMARY KEY information is about the same as what you get from the Key_name field in the output from SHOW INDEX when the Non_unique field is 0.
- The CONSTRAINT_TYPE column can contain one of these values: UNIQUE, PRIMARY KEY, FOREIGN KEY, CHECK. This is a CHAR (not ENUM) column. The CHECK value is not available until we support CHECK.

19.13. The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of ORDINAL_POSITION is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of POSITION_IN_UNIQUE_CONSTRAINT is NULL for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

  Suppose that there are two tables name t1 and t3 that have the following definitions:

```
CREATE TABLE t1
(
    s1 INT,
    s2 INT,
    s3 INT,
    PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
    s1 INT,
    s2 INT,
    s3 INT,
    KEY(s1),
    CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

  For those two tables, the KEY_COLUMN_USAGE table has two rows:

- One row with CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL.
- One row with CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1.

19.14. The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (both procedures and functions). The ROUTINES table does not include user-defined functions (UDFs) at this time.

The column named "mysql.proc name" indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA.ROUTINES table column, if any.

INFORMATION_SCHEMA Name	mysql.proc Name	Remarks
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL
ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
ROUTINE_TYPE	type	{PROCEDURE|FUNCTION}
DTD_IDENTIFIER		data type descriptor
ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
SQL_PATH		NULL
SECURITY_TYPE	security_type	
CREATED	created	
LAST_ALTERED	modified	
SQL_MODE	sql_mode	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- MySQL calculates EXTERNAL_LANGUAGE thus:
  - If mysql.proc.language='SQL', EXTERNAL_LANGUAGE is NULL
  - Otherwise, EXTERNAL_LANGUAGE is what is in mysql.proc.language. However, we do not have external languages yet, so it is always NULL.
- CHARACTER_SET_CLIENT is the session value of the character_set_client system variable when the routine was created. COLLATION_CONNECTION is the session value of the collation_connection system variable when the routine was

created. DATABASE_COLLATION is the collation of the database with which the routine is associated.

19.15. The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases. You must have the SHOW VIEW privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension

Notes:

- The VIEW_DEFINITION column has most of what you see in the Create Table field that SHOW CREATE VIEW produces. Skip the words before SELECT and skip the words WITH CHECK OPTION. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

  Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The CHECK_OPTION column has a value of NONE, CASCADE, or LOCAL.
- MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the VIEWS table displays the status of this flag. It means that the server always knows whether a view is updatable. If the view is not updatable, statements such UPDATE, DELETE, and INSERT are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to Section 12.1.16, “CREATE VIEW Syntax”.)
- The DEFINER column indicates who defined the view. SECURITY_TYPE has a value of DEFINER or INVOKER.
- CHARACTER_SET_CLIENT is the session value of the character_set_client system variable when the view was created. COLLATION_CONNECTION is the session value of the collation_connection system variable when the view was created.

MySQL lets you use different sql_mode settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
    -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+----------------------------------+
| VIEW_DEFINITION                  |
+----------------------------------+
| select concat('a','b') AS `col1` |
+----------------------------------+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

19.16. The INFORMATION_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. You must have the `TRIGGER` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		NULL
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	
EVENT_OBJECT_CATALOG		NULL
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		0
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED		NULL (0)
SQL_MODE		MySQL extension
DEFINER		MySQL extension
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension
DATABASE_COLLATION		MySQL extension

Notes:

- The `TRIGGER_SCHEMA` and `TRIGGER_NAME` columns contain the name of the database in which the trigger occurs and the trigger name, respectively.
- The `EVENT_MANIPULATION` column contains one of the values `'INSERT'`, `'DELETE'`, or `'UPDATE'`.
- As noted in Section 18.3, “Using Triggers”, every trigger is associated with exactly one table. The `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE` columns contain the database in which this table occurs, and the table's name.
- The `ACTION_ORDER` statement contains the ordinal position of the trigger's action within the list of all similar triggers on the same table. Currently, this value is always `0`, because it is not possible to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` on the same table.

- The ACTION_STATEMENT column contains the statement to be executed when the trigger is invoked. This is the same as the text displayed in the Statement column of the output from SHOW TRIGGERS. Note that this text uses UTF-8 encoding.
- The ACTION_ORIENTATION column always contains the value 'ROW'.
- The ACTION_TIMING column contains one of the two values 'BEFORE' or 'AFTER'.
- The columns ACTION_REFERENCE_OLD_ROW and ACTION_REFERENCE_NEW_ROW contain the old and new column identifiers, respectively. This means that ACTION_REFERENCE_OLD_ROW always contains the value 'OLD' and ACTION_REFERENCE_NEW_ROW always contains the value 'NEW'.
- The SQL_MODE column shows the server SQL mode that was in effect at the time when the trigger was created (and thus which remains in effect for this trigger whenever it is invoked, *regardless of the current server SQL mode*). The possible range of values for this column is the same as that of the sql_mode system variable. See Section 5.1.7, "Server SQL Modes".
- The DEFINER column indicates who defined the trigger.
- CHARACTER_SET_CLIENT is the session value of the character_set_client system variable when the trigger was created. COLLATION_CONNECTION is the session value of the collation_connection system variable when the trigger was created. DATABASE_COLLATION is the collation of the database with which the trigger is associated.
- The following columns currently always contain NULL: ACTION_CONDITION, ACTION_REFERENCE_OLD_TABLE, ACTION_REFERENCE_NEW_TABLE, and CREATED.

Example, using the ins_sum trigger defined in Section 18.3, "Using Triggers":

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS\G
*************************** 1. row ***************************
            TRIGGER_CATALOG: NULL
             TRIGGER_SCHEMA: test
               TRIGGER_NAME: ins_sum
         EVENT_MANIPULATION: INSERT
       EVENT_OBJECT_CATALOG: NULL
        EVENT_OBJECT_SCHEMA: test
         EVENT_OBJECT_TABLE: account
               ACTION_ORDER: 0
           ACTION_CONDITION: NULL
           ACTION_STATEMENT: SET @sum = @sum + NEW.amount
         ACTION_ORIENTATION: ROW
              ACTION_TIMING: BEFORE
ACTION_REFERENCE_OLD_TABLE: NULL
ACTION_REFERENCE_NEW_TABLE: NULL
  ACTION_REFERENCE_OLD_ROW: OLD
  ACTION_REFERENCE_NEW_ROW: NEW
                   CREATED: NULL
                 SQL_MODE:
                  DEFINER: me@localhost
```

See also Section 12.4.5.39, "SHOW TRIGGERS Syntax".

19.17. The INFORMATION_SCHEMA PLUGINS Table

The PLUGINS table provides information about server plugins.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
PLUGIN_NAME	Name	MySQL extension
PLUGIN_VERSION		MySQL extension
PLUGIN_STATUS	Status	MySQL extension
PLUGIN_TYPE	Type	MySQL extension
PLUGIN_TYPE_VERSION		MySQL extension
PLUGIN_LIBRARY	Library	MySQL extension
PLUGIN_LIBRARY_VERSION		MySQL extension
PLUGIN_AUTHOR		MySQL extension
PLUGIN_DESCRIPTION		MySQL extension

PLUGIN_LICENSE		MySQL extension

Notes:

- The PLUGINS table is a nonstandard table.
- PLUGIN_NAME is the name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.
- PLUGIN_VERSION is the version from the plugin's general type descriptor.
- PLUGIN_STATUS indicates the plugin status, one of ACTIVE, INACTIVE, DISABLED, or DELETED.
- PLUGIN_TYPE indicates the type of plugin, such as STORAGE ENGINE or INFORMATION_SCHEMA.
- PLUGIN_TYPE_VERSION is the version from the plugin's type-specific descriptor.
- PLUGIN_LIBRARY is the name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN. This file is located in the directory named by the plugin_dir system variable. If the library name is NULL, the plugin is compiled in and cannot be uninstalled with UNINSTALL PLUGIN.
- PLUGIN_LIBRARY_VERSION indicates the plugin API interface version.
- PLUGIN_AUTHOR names the plugin author.
- PLUGIN_DESCRIPTION provides a short description of the plugin.
- PLUGIN_LICENSE indicates how the plugin is licensed; for example, GPL.

For plugins installed with INSTALL PLUGIN, the PLUGIN_NAME and PLUGIN_LIBARY values are also registered in the mysql.plugin table.

These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the PLUGINS table, see Section 21.2, “The MySQL Plugin API”.

Plugin information is also available using the SHOW PLUGINS statement. See Section 12.4.5.27, “SHOW PLUGINS Syntax”.

19.18. The INFORMATION_SCHEMA ENGINES Table

The PLUGINS table provides information about storage engines.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ENGINE	Engine	MySQL extension
SUPPORT	Support	MySQL extension
COMMENT	Comment	MySQL extension
TRANSACTIONS	Transactions	MySQL extension
XA	XA	MySQL extension
SAVEPOINTS	Savepoints	MySQL extension

Notes:

- The ENGINES table is a nonstandard table.

See also Section 12.4.5.17, “SHOW ENGINES Syntax”.

19.19. The INFORMATION_SCHEMA PARTITIONS Table

The PARTITIONS table provides information about table partitions. See Chapter 17, *Partitioning*, for more information about partitioning tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
PARTITION_NAME		MySQL extension
SUBPARTITION_NAME		MySQL extension
PARTITION_ORDINAL_POSITION		MySQL extension
SUBPARTITION_ORDINAL_POSITION		MySQL extension
PARTITION_METHOD		MySQL extension
SUBPARTITION_METHOD		MySQL extension
PARTITION_EXPRESSION		MySQL extension
SUBPARTITION_EXPRESSION		MySQL extension
PARTITION_DESCRIPTION		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
PARTITION_COMMENT		MySQL extension
NODEGROUP		MySQL extension
TABLESPACE_NAME		MySQL extension

Notes:

- The PARTITIONS table is a nonstandard table.

  Each record in this table corresponds to an individual partition or subpartition of a partitioned table.

- TABLE_CATALOG: This column is always NULL.
- TABLE_SCHEMA: This column contains the name of the database to which the table belongs.
- TABLE_NAME: This column contains the name of the table containing the partition.
- PARTITION_NAME: The name of the partition.

- SUBPARTITION_NAME: If the PARTITIONS table record represents a subpartition, then this column contains the name of subpartition; otherwise it is NULL.

- PARTITION_ORDINAL_POSITION: All partitions are indexed in the same order as they are defined, with 1 being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown is this column reflects the current order, taking into account any indexing changes.

- SUBPARTITION_ORDINAL_POSITION: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- PARTITION_METHOD: One of the values RANGE, LIST, HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available partitioning types as discussed in Section 17.2, “Partition Types”.

- SUBPARTITION_METHOD: One of the values HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available subpartitioning types as discussed in Section 17.2.5, “Subpartitioning”.

- PARTITION_EXPRESSION: This is the expression for the partitioning function used in the CREATE TABLE or ALTER TABLE statement that created the table's current partitioning scheme.

  For example, consider a partitioned table created in the test database using this statement:

  ```
  CREATE TABLE tp (
      c1 INT,
      c2 INT,
      c3 VARCHAR(25)
  )
  PARTITION BY HASH(c1 + c2)
  PARTITIONS 4;
  ```

  The PARTITION_EXPRESSION column in a PARTITIONS table record for a partition from this table displays c1 + c2, as shown here:

  ```
  mysql> SELECT DISTINCT PARTITION_EXPRESSION
      >     FROM INFORMATION_SCHEMA.PARTITIONS
      >     WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
  +----------------------+
  | PARTITION_EXPRESSION |
  +----------------------+
  | c1 + c2              |
  +----------------------+
  1 row in set (0.09 sec)
  ```

- SUBPARTITION_EXPRESSION: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as PARTITION_EXPRESSION does for the partitioning expression used to define a table's partitioning.

  If the table has no subpartitions, then this column is NULL.

- PARTITION_DESCRIPTION: This column is used for RANGE and LIST partitions. For a RANGE partition, it contains the value set in the partition's VALUES LESS THAN clause, which can be either an integer or MAXVALUE. For a LIST partition, this column contains the values defined in the partition's VALUES IN clause, which is a comma-separated list of integer values.

  For partitions whose PARTITION_METHOD is other than RANGE or LIST, this column is always NULL.

- TABLE_ROWS: The number of table rows in the partition.

  For partitioned InnoDB tables, the row count given in the TABLE_ROWS column is only an estimated value used in SQL optimization, and may not always be exact.

- AVG_ROW_LENGTH: The average length of the rows stored in this partition or subpartition, in bytes.

  This is the same as DATA_LENGTH divided by TABLE_ROWS.

- DATA_LENGTH: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.

- MAX_DATA_LENGTH: The maximum number of bytes that can be stored in this partition or subpartition.

- INDEX_LENGTH: The length of the index file for this partition or subpartition, in bytes.

- DATA_FREE: The number of bytes allocated to the partition or subpartition but not used.
- CREATE_TIME: The time of the partition's or subpartition's creation.
- UPDATE_TIME: The time that the partition or subpartition was last modified.
- CHECK_TIME: The last time that the table to which this partition or subpartition belongs was checked.

  Note

  Some storage engines do not update this time; for tables using these storage engines, this value is always NULL.

- CHECKSUM: The checksum value, if any; otherwise, this column is NULL.
- PARTITION_COMMENT: This column contains the text of any comment made for the partition.

  The default value for this column is an empty string.
- NODEGROUP: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- TABLESPACE_NAME: This column contains the name of the tablespace to which the partition belongs. Currently, the value of this column is always DEFAULT.
- A nonpartitioned table has one record in INFORMATION_SCHEMA.PARTITIONS; however, the values of the PARTITION_NAME, SUBPARTITION_NAME, PARTITION_ORDINAL_POSITION, SUBPARTITION_ORDINAL_POSITION, PARTITION_METHOD, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, and PARTITION_DESCRIPTION columns are all NULL. (The PARTITION_COMMENT column in this case is blank.)

19.20. The INFORMATION_SCHEMA EVENTS Table

The EVENTS table provides information about scheduled events, which are discussed in Section 18.4, "Using the Event Scheduler". The SHOW Name values correspond to column names of the SHOW EVENTS statement.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
EVENT_CATALOG		NULL, MySQL extension
EVENT_SCHEMA	Db	MySQL extension
EVENT_NAME	Name	MySQL extension
DEFINER	Definer	MySQL extension
TIME_ZONE	Time zone	MySQL extension
EVENT_BODY		MySQL extension
EVENT_DEFINITION		MySQL extension
EVENT_TYPE	Type	MySQL extension
EXECUTE_AT	Execute at	MySQL extension
INTERVAL_VALUE	Interval value	MySQL extension
INTERVAL_FIELD	Interval field	MySQL extension
SQL_MODE		MySQL extension
STARTS	Starts	MySQL extension
ENDS	Ends	MySQL extension
STATUS	Status	MySQL extension
ON_COMPLETION		MySQL extension
CREATED		MySQL extension
LAST_ALTERED		MySQL extension
LAST_EXECUTED		MySQL extension
EVENT_COMMENT		MySQL extension

ORIGINATOR	Originator	MySQL extension
CHARACTER_SET_CLIENT	character_set_client	MySQL extension
COLLATION_CONNECTION	collation_connection	MySQL extension
DATABASE_COLLATION	Database Collation	MySQL extension

Notes:

- The EVENTS table is a nonstandard table.
- EVENT_CATALOG: The value of this column is always NULL.
- EVENT_SCHEMA: The name of the schema (database) to which this event belongs.
- EVENT_NAME: The name of the event.
- DEFINER: The account of the user who created the event, in *'user_name'@'host_name'* format.
- TIME_ZONE: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is SYSTEM.
- EVENT_BODY: The language used for the statements in the event's DO clause; in MySQL 5.4, this is always SQL.

  This column is not to be confused with the column of the same name (now named EVENT_DEFINITION) that existed in earlier MySQL versions.
- EVENT_DEFINITION: The text of the SQL statement making up the event's DO clause; in other words, the statement executed by this event.
- EVENT_TYPE: The event repetition type, either ONE TIME (transient) or RECURRING (repeating).
- EXECUTE_AT: For a one-time event, this is the DATETIME value specified in the AT clause of the CREATE EVENT statement used to create the event, or of the last ALTER EVENT statement that modified the event. The value shown in this column reflects the addition or subtraction of any INTERVAL value included in the event's AT clause. For example, if an event is created using ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '2006-02-10 20:05:30'.

  If the event's timing is determined by an EVERY clause instead of an AT clause (that is, if the event is recurring), the value of this column is NULL.
- INTERVAL_VALUE: For recurring events, this column contains the numeric portion of the event's EVERY clause.

  For a one-time event (that is, an event whose timing is determined by an AT clause), this column is NULL.
- INTERVAL_FIELD: For recurring events, this column contains the units portion of the EVERY clause governing the timing of the event. Thus, this column contains a value such as 'YEAR', 'QUARTER', 'DAY', and so on.

  For a one-time event (that is, an event whose timing is determined by an AT clause), this column is NULL.
- SQL_MODE: The SQL mode in effect at the time the event was created or altered.
- STARTS: For a recurring event whose definition includes a STARTS clause, this column contains the corresponding DATETIME value. As with the EXECUTE_AT column, this value resolves any expressions used.

  If there is no STARTS clause affecting the timing of the event, this column is NULL
- ENDS: For a recurring event whose definition includes a ENDS clause, this column contains the corresponding DATETIME value. As with the EXECUTE_AT column, this value resolves any expressions used.

  If there is no ENDS clause affecting the timing of the event, this column is NULL.
- STATUS: One of the three values ENABLED, DISABLED, or SLAVESIDE_DISABLED.

  SLAVESIDE_DISABLED indicates that the creation of the event occurred on another MySQL server acting as a replication master

and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See Section 16.4.1.8, “Replication of Invoked Features”, for more information.

- ON_COMPLETION: One of the two values PRESERVE or NOT PRESERVE.
- CREATED: The date and time when the event was created. This is a DATETIME value.
- LAST_ALTERED: The date and time when the event was last modified. This is a DATETIME value. If the event has not been modified since its creation, this column holds the same value as the CREATED column.
- LAST_EXECUTED: The date and time when the event last executed. A DATETIME value. If the event has never executed, this column is NULL.

  LAST_EXECUTED indicates when the event started. As a result, the ENDS column is never less than LAST_EXECUTED.
- EVENT_COMMENT: The text of a comment, if the event has one. If not, the value of this column is an empty string.
- ORIGINATOR: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0.
- CHARACTER_SET_CLIENT is the session value of the character_set_client system variable when the event was created. COLLATION_CONNECTION is the session value of the collation_connection system variable when the event was created. DATABASE_COLLATION is the collation of the database with which the event is associated.

Example: Suppose the user jon@ghidora creates an event named e_daily, and then modifies it a few minutes later using an ALTER EVENT statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
    ON SCHEDULE
      EVERY 1 DAY
    COMMENT 'Saves total number of sessions then clears the table each day'
    DO
      BEGIN
        INSERT INTO site_activity.totals (time, total)
          SELECT CURRENT_TIMESTAMP, COUNT(*)
            FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
      END |

DELIMITER ;

ALTER EVENT e_daily
    ENABLED;
```

(Note that comments can span multiple lines.)

This user can then run the following SELECT statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
     > WHERE EVENT_NAME = 'e_daily'
     > AND EVENT_SCHEMA = 'myschema'\G
*************************** 1. row ***************************
       EVENT_CATALOG: NULL
        EVENT_SCHEMA: test
          EVENT_NAME: e_daily
             DEFINER: paul@localhost
           TIME_ZONE: SYSTEM
          EVENT_BODY: SQL
    EVENT_DEFINITION: BEGIN
        INSERT INTO site_activity.totals (time, total)
          SELECT CURRENT_TIMESTAMP, COUNT(*)
            FROM site_activity.sessions;
        DELETE FROM site_activity.sessions;
      END
          EVENT_TYPE: RECURRING
          EXECUTE_AT: NULL
      INTERVAL_VALUE: 1
      INTERVAL_FIELD: DAY
            SQL_MODE:
              STARTS: 2008-09-03 12:13:39
                ENDS: NULL
              STATUS: ENABLED
       ON_COMPLETION: NOT PRESERVE
             CREATED: 2008-09-03 12:13:39
        LAST_ALTERED: 2008-09-03 12:13:39
       LAST_EXECUTED: NULL
```

```
       EVENT_COMMENT: Saves total number of sessions then clears the
                      table each day
          ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
  DATABASE_COLLATION: latin1_swedish_ci
```

Times in the EVENTS table are displayed using the event time zone or the current session time zone, as described in Section 18.4.4, “Event Metadata”.

See also Section 12.4.5.19, “SHOW EVENTS Syntax”.

19.21. The INFORMATION_SCHEMA FILES Table

The FILES table provides information about the files in which MySQL tablespace data is stored.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
FILE_ID		MySQL extension
FILE_NAME		MySQL extension
FILE_TYPE		MySQL extension
TABLESPACE_NAME		MySQL extension
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
LOGFILE_GROUP_NAME		MySQL extension
LOGFILE_GROUP_NUMBER		MySQL extension
ENGINE		MySQL extension
FULLTEXT_KEYS		MySQL extension
DELETED_ROWS		MySQL extension
UPDATE_COUNT		MySQL extension
FREE_EXTENTS		MySQL extension
TOTAL_EXTENTS		MySQL extension
EXTENT_SIZE		MySQL extension
INITIAL_SIZE		MySQL extension
MAXIMUM_SIZE		MySQL extension
AUTOEXTEND_SIZE		MySQL extension
CREATION_TIME		MySQL extension
LAST_UPDATE_TIME		MySQL extension
LAST_ACCESS_TIME		MySQL extension
RECOVER_TIME		MySQL extension
TRANSACTION_COUNTER		MySQL extension
VERSION		MySQL extension
ROW_FORMAT		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension

CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
STATUS		MySQL extension
EXTRA		MySQL extension

Notes:

- FILE_ID column values are auto-generated.
- FILE_NAME is the name of a data file created by CREATE TABLESPACE or ALTER TABLESPACE.
- FILE_TYPE is the tablespace file type.
- TABLESPACE_NAME is the name of the tablespace with which the file is associated.
- Currently, the value of the TABLESPACE_CATALOG column is always NULL.
- TABLE_NAME is the name of the table with which the file is associated, if any.
- The EXTENT_SIZE is always 0.
- There are no SHOW statements associated with the FILES table.

19.22. The INFORMATION_SCHEMA PROCESSLIST Table

The PROCESSLIST table provides information about which threads are running.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ID	Id	MySQL extension
USER	User	MySQL extension
HOST	Host	MySQL extension
DB	db	MySQL extension
COMMAND	Command	MySQL extension
TIME	Time	MySQL extension
STATE	State	MySQL extension
INFO	Info	MySQL extension

For an extensive description of the table columns, see Section 12.4.5.31, “SHOW PROCESSLIST Syntax”.

Notes:

- The PROCESSLIST table is a nonstandard table.
- Like the output from the corresponding SHOW statement, the PROCESSLIST table will only show information about your own threads, unless you have the PROCESS privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to INFORMATION_SCHEMA.PROCESSLIST, then MySQL will populate the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
```

```
SHOW FULL PROCESSLIST
```

19.23. The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The REFERENTIAL_CONSTRAINTS table provides information about foreign keys.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
UNIQUE_CONSTRAINT_CATALOG		NULL
UNIQUE_CONSTRAINT_SCHEMA		
UNIQUE_CONSTRAINT_NAME		
MATCH_OPTION		
UPDATE_RULE		
DELETE_RULE		
TABLE_NAME		
REFERENCED_TABLE_NAME		

Notes:

- TABLE_NAME has the same value as TABLE_NAME in INFORMATION_SCHEMA.TABLE_CONSTRAINTS.
- CONSTRAINT_SCHEMA and CONSTRAINT_NAME identify the foreign key.
- UNIQUE_CONSTRAINT_SCHEMA, UNIQUE_CONSTRAINT_NAME, and REFERENCED_TABLE_NAME identify the referenced key.
- The only valid value at this time for MATCH_OPTION is NONE.
- The possible values for UPDATE_RULE or DELETE_RULE are CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.

19.24. The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

The GLOBAL_STATUS and SESSION_STATUS tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL STATUS and SHOW SESSION STATUS statements (see Section 12.4.5.36, “SHOW STATUS Syntax”).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_NAME	Variable_name	
VARIABLE_VALUE	Value	

Notes:

- The VARIABLE_VALUE column for each of these tables is defined as VARCHAR(20480).

19.25. The INFORMATION_SCHEMA GLOBAL_VARIABLES and SES-

SION_VARIABLES Tables

The GLOBAL_VARIABLES and SESSION_VARIABLES tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL VARIABLES and SHOW SESSION VARIABLES statements (see Section 12.4.5.40, "SHOW VARIABLES Syntax").

INFORMATION_SCHEMA Name	SHOW Name	Remarks
VARIABLE_NAME	Variable_name	
VARIABLE_VALUE	Value	

Notes:

- The VARIABLE_VALUE column for each of these tables is defined as VARCHAR(20480).

19.26. The INFORMATION_SCHEMA PROFILING Table

The PROFILING table provides statement profiling information. Its contents correspond to the information produced by the SHOW PROFILES and SHOW PROFILE statements (see Section 12.4.5.33, "SHOW PROFILES Syntax"). The table is empty unless the profiling session variable is set to 1.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
QUERY_ID	Query_ID	
SEQ		
STATE	Status	
DURATION	Duration	
CPU_USER	CPU_user	
CPU_SYSTEM	CPU_system	
CONTEXT_VOLUNTARY	Context_voluntary	
CONTEXT_INVOLUNTARY	Context_involuntary	
BLOCK_OPS_IN	Block_ops_in	
BLOCK_OPS_OUT	Block_ops_out	
MESSAGES_SENT	Messages_sent	
MESSAGES_RECEIVED	Messages_received	
PAGE_FAULTS_MAJOR	Page_faults_major	
PAGE_FAULTS_MINOR	Page_faults_minor	
SWAPS	Swaps	
SOURCE_FUNCTION	Source_function	
SOURCE_FILE	Source_file	
SOURCE_LINE	Source_line	

Notes:

- QUERY_ID is a numeric statement identifier.
- SEQ is a sequence number indicating the display order for rows with the same QUERY_ID value.
- STATE is the profiling state to which the row measurements apply.
- DURATION indicates how long statement execution remained in the given state, in seconds.

- CPU_USER and CPU_SYSTEM indicate user and system CPU use, in seconds.
- CONTEXT_VOLUNTARY and CONTEXT_INVOLUNTARY indicate how many voluntary and involuntary context switches occurred.
- BLOCK_OPS_IN and BLOCK_OPS_OUT indicate the number of block input and output operations.
- MESSAGES_SENT and MESSAGES_RECEIVED indicate the number of communication messages sent and received.
- PAGE_FAULTS_MAJOR and PAGE_FAULTS_MINOR indicate the number of major and minor page faults.
- SWAPS indicates how many swaps occurred.
- SOURCE_FUNCTION, SOURCE_FILE, and SOURCE_LINE provide information indicating where in the source code the profiled state executes.

19.27. Other INFORMATION_SCHEMA Tables

We intend to implement additional INFORMATION_SCHEMA tables. In particular, we acknowledge the need for the PARAMETERS table. (PARAMETERS is implemented in MySQL 5.5.)

19.28. Extensions to SHOW Statements

Some extensions to SHOW statements accompany the implementation of INFORMATION_SCHEMA:

- SHOW can be used to get information about the structure of INFORMATION_SCHEMA itself.
- Several SHOW statements accept a WHERE clause that provides more flexibility in specifying which rows to display.

INFORMATION_SCHEMA is an information database, so its name is included in the output from SHOW DATABASES. Similarly, SHOW TABLES can be used with INFORMATION_SCHEMA to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+---------------------------------------+
| Tables_in_INFORMATION_SCHEMA          |
+---------------------------------------+
| CHARACTER_SETS                        |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                               |
| COLUMN_PRIVILEGES                     |
| ENGINES                               |
| EVENTS                                |
| FILES                                 |
| GLOBAL_STATUS                         |
| GLOBAL_VARIABLES                      |
| KEY_COLUMN_USAGE                      |
| PARTITIONS                            |
| PLUGINS                               |
| PROCESSLIST                           |
| REFERENTIAL_CONSTRAINTS               |
| ROUTINES                              |
| SCHEMATA                              |
| SCHEMA_PRIVILEGES                     |
| SESSION_STATUS                        |
| SESSION_VARIABLES                     |
| STATISTICS                            |
| TABLES                                |
| TABLE_CONSTRAINTS                     |
| TABLE_PRIVILEGES                      |
| TRIGGERS                              |
| USER_PRIVILEGES                       |
| VIEWS                                 |
+---------------------------------------+
27 rows in set (0.00 sec)
```

SHOW COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION_SCHEMA tables.

SHOW statements that accept a LIKE clause to limit the rows displayed also allow a WHERE clause that enables specification of more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |      2 |
| dec8     | DEC West European           | dec8_swedish_ci     |      1 |
| cp850    | DOS West European           | cp850_general_ci    |      1 |
| hp8      | HP West European            | hp8_english_ci      |      1 |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |      1 |
| latin1   | cp1252 West European        | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |      1 |
...
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    |      3 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   |      2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci |      3 |
+---------+---------------------------+---------------------+--------+
```

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| big5    | Big5 Traditional Chinese  | big5_chinese_ci     |      2 |
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    |      3 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    |      2 |
| euckr   | EUC-KR Korean             | euckr_korean_ci     |      2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci   |      2 |
| gbk     | GBK Simplified Chinese    | gbk_chinese_ci      |      2 |
| utf8    | UTF-8 Unicode             | utf8_general_ci     |      3 |
| ucs2    | UCS-2 Unicode             | ucs2_general_ci     |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   |      2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci |      3 |
+---------+---------------------------+---------------------+--------+
```

Chapter 20. Connectors and APIs

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including Java (JDBC), ODBC, Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

> **Note**
>
> Connector version numbers do not correlate with MySQL Server version numbers. See also Table 20.2, "MySQL Connector Versions and MySQL Server Versions".

A number of connectors are developed by MySQL:

- Connector/ODBC provides driver support for connecting to a MySQL server using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix and Mac OS X platforms.
- Connector/NET enables developers to create .NET applications that use data stored in a MySQL database. Connector/NET implement a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that want to use Connector/NET can be written in any of the supported .NET languages.

  The MySQL Visual Studio Plugin works with Connector/NET and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools within Visual Studio to create and edit objects within a MySQL database.
- Connector/J provides driver support for connecting to MySQL from a Java application using the standard Java Database Connectivity (JDBC) API.
- Connector/MXJ is a tool that enables easy deployment and management of MySQL server and database through your Java application.
- Connector/C++ is a tool that enables easy deployment and management of MySQL server and database through your C++ application.
- Connector/C is a stand-alone replacement for the MySQL Client Library (`libmysql`).
- Connector/OpenOffice.org is a tool that enables OpenOffice.org applications to connect to MySQL server.

There are two direct access methods for using MySQL natively within a C application:

- The C API provides low-level access to the MySQL protocol through the `libmysql` client library; this is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command line clients and many of the APIs also detailed in this section. MySQL Connector/C can now also be used for this purpose.
- `libmysqld` is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

If you need to access MySQL from a C application, or build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where you would start. A number of programmers utilities are available to help with the process, and also covered in this section.

The remaining APIs provide an interface to MySQL from specific application langauges. These solutions are not developed or supported by MySQL. Basic information on their usage and abilities is provided here for reference purposes only.

All the language APIs are developed using one of two methods, using `libmysql` or by building a *native driver*. The two solutions offer different benefits:

- Using *`libmysql`* offers complete compatibility with MySQL as it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysql` and the performance may be lower as data is copied between the native langiage, and the MySQL API components. MySQL Connector/C is a possible alternative to using `libmysql`.

- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier to build and deploy, as you do not need a copy of the MySQL client libraries to build the native driver components.

A list of many of the libraries and interfaces available for MySQL are shown in the table. See Table 20.1, "MySQL APIs and Interfaces".

Table 20.1. MySQL APIs and Interfaces

Environment	API	Type	Notes
Ada	MySQL Bindings for GNU Ada	`libmysql`	See MySQL Bindings for GNU Ada
C	Connector/C	Replacement for `libmysql`	See Section 20.6, "MySQL Connector/C".
C++	Connector/C++	`libmysql`	See Section 20.5, "MySQL Connector/C++".
	MySQL++	`libmysql`	See Section 20.12, "MySQL C++ API".
	MySQL wrapped	`libmysql`	See MySQL wrapped.
Cocoa	MySQL-Cocoa	`libmysql`	Compatible with the Objective-C Cocoa environment. See http://mysql-cocoa.sourceforge.net/
D	MySQL for D	`libmysql`	See MySQL for D.
Eiffel	Eiffel MySQL	`libmysql`	See Section 20.16, "MySQL Eiffel Wrapper".
Erlang	`erlang-mysql-driver`	`libmysql`	See `erlang-mysql-driver`.
Haskell	Haskell MySQL Bindings	Native Driver	See Brian O'Sullivan's pure Haskell MySQL bindings.
	`hsql-mysql`	`libmysql`	See MySQL driver for Haskell .
Java/JDBC	Connector/J	Native Driver	See Section 20.3, "MySQL Connector/J".
Kaya	MyDB	`libmysql`	See MyDB.
Lua	LuaSQL	`libmysql`	See LuaSQL.
.NET/Mono	Connector/NET	Native Driver	See Section 20.2, "MySQL Connector/NET".
Objective Caml	MySQL Bindings for OBjective Caml	`libmysql`	See MySQL Bindings for Objective Caml.
Octave	Database bindings for GNU Octave	`libmysql`	See Database bindings for GNU Octave.
ODBC	Connector/ODBC	`libmysql`	See Section 20.1, "MySQL Connector/ODBC".
OpenOffice	MySQL Connector/OpenOffice.org	`libmysql`	Direct connectivity, without using JDBC/ODBC. See Section 20.7, "MySQL Connector/OpenOffice.org".
Perl	`DBI/DBD::mysql`	`libmysql`	See Section 20.11, "MySQL Perl API".
	`Net::MySQL`	Native Driver	See `Net::MySQL` at CPAN
PHP	`mysql`, `ext/mysql` interface (deprecated)	`libmysql`	See Section 20.10.1, "MySQL".
	`mysqli`, `ext/mysqli` interface	`libmysql`	See Section 20.10.2, "MySQL Improved Extension (`Mysqli`)".
	`PDO_MYSQL`	`libmysql`	See Section 20.10.4, "MySQL Functions (PDO_MYSQL)".
	PDO mysqlnd	Native Driver	See PHP PDO `mysqlnd`.
Python	MySQLdb	`libmysql`	See Section 20.13, "MySQL Python API".
Ruby	MySQL/Ruby	`libmysql`	Uses `libmysql`. See Section 20.14.1, "The MySQL/Ruby API".
	Ruby/MySQL	Native Driver	See Section 20.14.2, "The Ruby/MySQL API".
Scheme	`Myscsh`	`libmysql`	See `Myscsh`.
SPL	`sql_mysql`	`libmysql`	See `sql_mysql` for SPL.

Environ-ment	API	Type	Notes
Tcl	MySQLtcl	`libmysql`	See Section 20.15, “MySQL Tcl API”.

Table 20.2. MySQL Connector Versions and MySQL Server Versions

Connector	Connector version	MySQL Server version
Connector/C++	1.0.5 GA	5.1, 5.4
Connector/OpenOffice.org	1.0 GA	5.0, 5.1, 5.4
Connector/J	5.1.8	4.1, 5.0, 5.1, 5.4
Connector/NET	1.0 (No longer supported)	4.0, 5.0
Connector/NET	5.2	5.0, 5.1, 5.4
Connector/NET	6.0	5.0, 5.1, 5.4
Connector/NET	6.1	5.0, 5.1, 5.4
Connector/ODBC	3.51 (Unicode not supported)	4.1, 5.0, 5.1, 5.4
Connector/ODBC	5.1	4.1.1+, 5.0, 5.1, 5.4

20.1. MySQL Connector/ODBC

The MySQL Connector/ODBC is the name for the family of MySQL ODBC drivers (previously called MyODBC drivers) that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. This reference covers Connector/ODBC 3.51 and Connector/ODBC 5.1. Both releases provide an ODBC compliant interface to MySQL Server.

MySQL Connector/ODBC provides both driver-manager based and native interfaces to the MySQL database, which full support for MySQL functionality, including stored procedures, transactions and, with Connector/ODBC 5.1, full Unicode compliance.

For more information on the ODBC API standard and how to use it, refer to http://support.microsoft.com/kb/110093.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to http://dev.mysql.com/doc/.

Typically, you need to install Connector/ODBC only on Windows machines. For Unix and Mac OS X you can use the native MySQL network or named pipe to communicate with your MySQL database. You may need Connector/ODBC for Unix or Mac OS X if you have an application that requires an ODBC interface to communicate with the database. Applications that require ODBC to communicate with MySQL include ColdFusion, Microsoft Office, and Filemaker Pro.

Key topics:

- For help installing Connector/ODBC see Section 20.1.3, “Connector/ODBC Installation”.
- For information on the configuration options, see Section 20.1.4.2, “Connector/ODBC Connection Parameters”.
- For more information on connecting to a MySQL database from a Windows host using Connector/ODBC see Section 20.1.5.2, “Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC”.
- If you want to use Microsoft Access as an interface to a MySQL database using Connector/ODBC see Section 20.1.5.4, “Using Connector/ODBC with Microsoft Access”.
- General tips on using Connector/ODBC, including obtaining the last auto-increment ID see Section 20.1.7.1, “Connector/ODBC General Functionality”.
- For tips and common questions on using Connector/ODBC with specific application see Section 20.1.7.2, “Connector/ODBC Application Specific Tips”.
- For a general list of Frequently Asked Questions see Section 20.1.7.3, “Connector/ODBC Errors and Resolutions (FAQ)”.

- Additional support when using Connector/ODBC is available, see Section 20.1.8, “Connector/ODBC Support”.

> **MySQL Enterprise**
> MySQL Enterprise subscribers will find more information about MySQL and ODBC in the Knowledge Base articles about ODBC. Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

20.1.1. Connector/ODBC Versions

There are currently two version of Connector/ODBC available:

- Connector/ODBC 5.1, currently in GA status, is a partial rewrite of the of the 3.51 code base and is designed to work with all versions of MySQL from 4.1.1. It does not work with versions of MySQL Server prior to 4.1.1.

  Connector/ODBC 5.1 also includes the following changes and improvements over the 3.51 release:

  - Improved support on Windows 64-bit platforms.
  - Full Unicode support at the driver level. This includes support for the `SQL_WCHAR` datatype, and support for Unicode login, password and DSN configurations. For more information,. see Microsoft Knowledgebase Article #716246.
  - Support for the `SQL_NUMERIC_STRUCT` datatype, which provides easier access to the precise definition of numeric values. For more information, see Microsoft Knowledgebase Article #714556
  - Native Windows setup library. This replaces the Qt library based interface for configuring DSN information within the ODBC Data Sources application.
  - Support for the ODBC descriptor, which improves the handling and metadata of columns and parameter data. For more information, see Microsoft Knowledgebase Article #716339.
- Connector/ODBC 3.51 is the current release of the 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. Connector/ODBC 3.51 has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.

The manual for versions of Connector/ODBC older than 3.51 can be located in the corresponding binary or source distribution. Please note that versions of Connector/ODBC earlier than the 3.51 revision were not fully compliant with the ODBC specification.

> **Note**
>
> From this section onward, the primary focus of this guide is the Connector/ODBC 3.51 and Connector/ODBC 5.1 drivers.

> **Note**
>
> Version numbers for MySQL products are formatted as X.X.X. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.XX.XX. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

20.1.2. Connector/ODBC Introduction

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to http://support.microsoft.com/kb/110093.

20.1.2.1. General Information About ODBC and Connector/ODBC

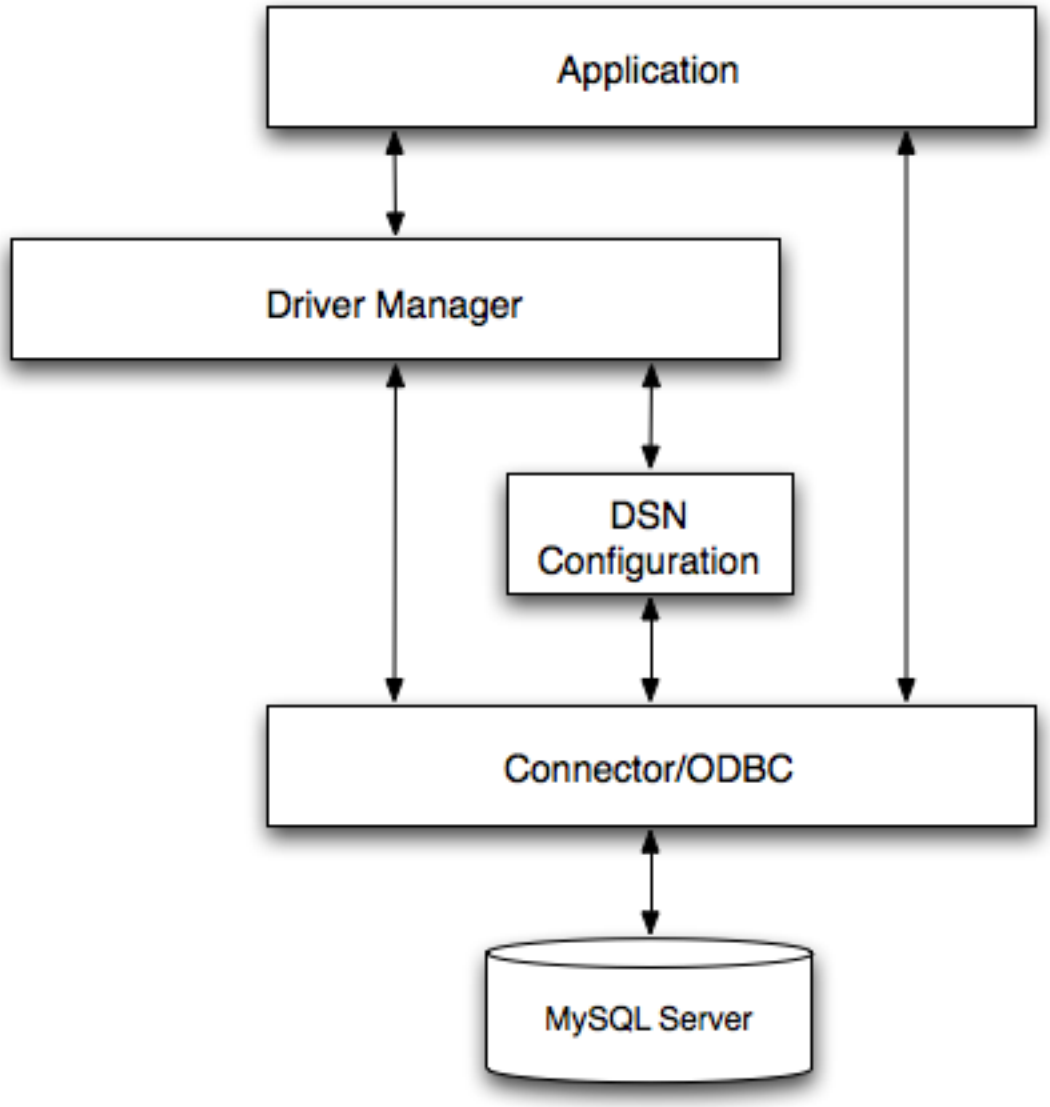
Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on

the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by Connector/ODBC is given at Section 20.1.6.1, “Connector/ODBC API Reference”. For general information about ODBC, see http://support.microsoft.com/kb/110093.

20.1.2.1.1. Connector/ODBC Architecture

The Connector/ODBC architecture is based on five components, as shown in the following diagram:



- **Application:**

  The Application uses the ODBC API to access the data from the MySQL server. The ODBC API in turn uses the communicates with the Driver Manager. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

  A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors
- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

  The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

  - Resolves Data Source Names (DSN). The DSN is a configuration string that identifies a given database driver, database, database host and optionally authentication information that enables an ODBC application to connect to a database using a standardized reference.

    Because the database connectivity information is identified by the DSN, any ODBC compliant application can connect to the data source using the same DSN reference. This eliminates the need to separately configure each application that needs access to a given database; instead you instruct the application to use a pre-configured DSN.

  - Loading and unloading of the driver required to access a specific database as defined within the DSN. For example, if you have configured a DSN that connects to a MySQL database then the driver manager will load the Connector/ODBC driver to enable the ODBC API to communicate with the MySQL host.

  - Processes ODBC function calls or passes them to the driver for processing.

- **Connector/ODBC Driver:**

  The Connector/ODBC driver is a library that implements the functions supported by the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by MySQL.

- **DSN Configuration:**

  The ODBC configuration file stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded according to the definition in the DSN. The driver uses this to read connection parameters based on the DSN specified. For more information, Section 20.1.4, “Connector/ODBC Configuration”.

- **MySQL Server:**

  The MySQL database where the information is stored. The database is used as the source of the data (during queries) and the destination for data (during inserts and updates).

20.1.2.1.2. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC-aware application and any drivers. Its main functionality includes:

- Resolving Data Source Names (DSN).
- Driver loading and unloading.
- Processing ODBC function calls or passing them to the driver.

Both Windows and Mac OS X include ODBC driver managers with the operating system. Most ODBC Driver Manager implementations also include an administration application that makes the configuration of DSN and drivers easier. Examples and information on these managers, including Unix ODBC driver managers are listed below:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), http://support.microsoft.com/kb/110093.
- Mac OS X includes `ODBC Administrator`, a GUI application that provides a simpler configuration mechanism for the Unix iODBC Driver Manager. You can configure DSN and driver information either through ODBC Administrator or through the iODBC configuration files. This also means that you can test ODBC Administrator configurations using the `iodbctest` command. http://www.apple.com.
- `unixODBC` Driver Manager for Unix (`libodbc.so`). See http://www.unixodbc.org, for more information. The `unixODBC` Driver Manager includes the Connector/ODBC driver 3.51 in the installation package, starting with version `unixODBC` 2.1.2.
- `iODBC` ODBC Driver Manager for Unix (`libiodbc.so`), see http://www.iodbc.org, for more information.

20.1.3. Connector/ODBC Installation

You can install the Connector/ODBC drivers using two different methods, a binary installation and a source installation. The binary installation is the easiest and most straightforward method of installation. Using the source installation methods should only be necessary on platforms where a binary installation package is not available, or in situations where you want to customize or modify the installation process or Connector/ODBC drivers before installation.

Where to Get Connector/ODBC

Sun Microsystems, Inc distributes its MySQL products under the General Public License (GPL). You can get a copy of the latest version of Connector/ODBC binaries and sources from our Web site at http://dev.mysql.com/downloads/connector/odbc/.

For more information about Connector/ODBC, visit http://www.mysql.com/products/myodbc/.

For more information about licensing, visit http://www.mysql.com/company/legal/licensing/.

Supported Platforms

Connector/ODBC can be used on all major platforms supported by MySQL. You can install it on:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix-like Operating Systems, including: AIX, Amiga, BSDI, DEC, FreeBSD, HP-UX 10/11, Linux, NetBSD, OpenBSD, OS/2, SGI Irix, Solaris, SunOS, SCO OpenServer, SCO UnixWare, Tru64 Unix
- Mac OS X and Mac OS X Server

Using a binary distribution offers the most straightforward method for installing Connector/ODBC. If you want more control over the driver, the installation location and or to customize elements of the driver you will need to build and install from the source.

If a binary distribution is not available for a particular platform build the driver from the original source code. You can contribute the binaries you create to MySQL by sending a mail message to `<myodbc@lists.mysql.com>`, so that it becomes available for other users.

> **Note**
>
> On all non-Windows platforms except Mac OS X, the driver is built against `unixODBC` and is expecting a 2-byte `SQLWCHAR`, not 4 bytes as `iODBC` is using. For this reason, the binaries are **only** compatible with `unixODBC` and you will need to recompile the driver against `iODBC` if you wish to use them together. For further information see Section 20.1.2.1.2, “ODBC Driver Managers”.

For further instructions:

Platform	Binary	Source
Windows	Installation Instructions	Build Instructions

Platform	Binary	Source
Unix/Linux	Installation Instructions	Build Instructions
Mac OS X	Installation Instructions	

20.1.3.1. Installing Connector/ODBC from a Binary Distribution on Windows

Before installing the Connector/ODBC drivers on Windows you should ensure that your Microsoft Data Access Components (MDAC) are up to date. You can obtain the latest version from the Microsoft Data Access and Storage Web site.

There are three available distribution types to use when installing for Windows. The contents in each case are identical, it is only the installation method which is different.

- Zipped installer consists of a Zipped package containing a standalone installation application. To install from this package, you must unzip the installer, and then run the installation application. See Section 20.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer” to complete the installation.
- MSI installer, an installation file that can be used with the installer included in Windows 2000, Windows XP and Windows Server 2003. See Section 20.1.3.1.1, “Installing the Windows Connector/ODBC Driver using an installer” to complete the installation.
- Zipped DLL package, containing the DLL files that need must be manually installed. See Section 20.1.3.1.2, “Installing the Windows Connector/ODBC Driver using the Zipped DLL package” to complete the installation.

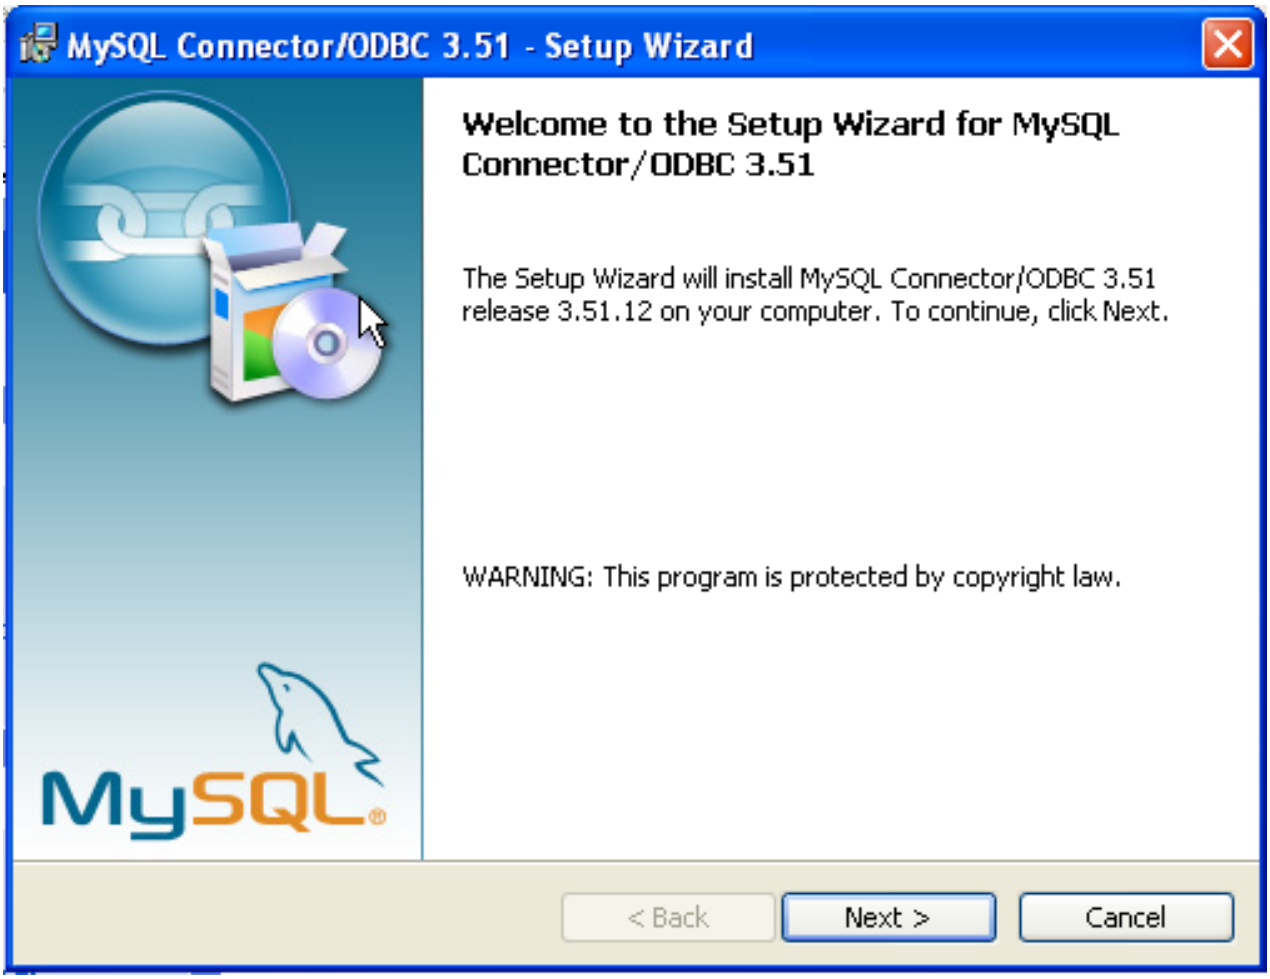
> **Note**
>
> An OLEDB/ODBC driver for Windows 64-bit is available from Microsoft Downloads.

20.1.3.1.1. Installing the Windows Connector/ODBC Driver using an installer

The installer packages offer a very simple method for installing the Connector/ODBC drivers. If you have downloaded the zipped installer then you must extract the installer application. The basic installation process is identical for both installers.

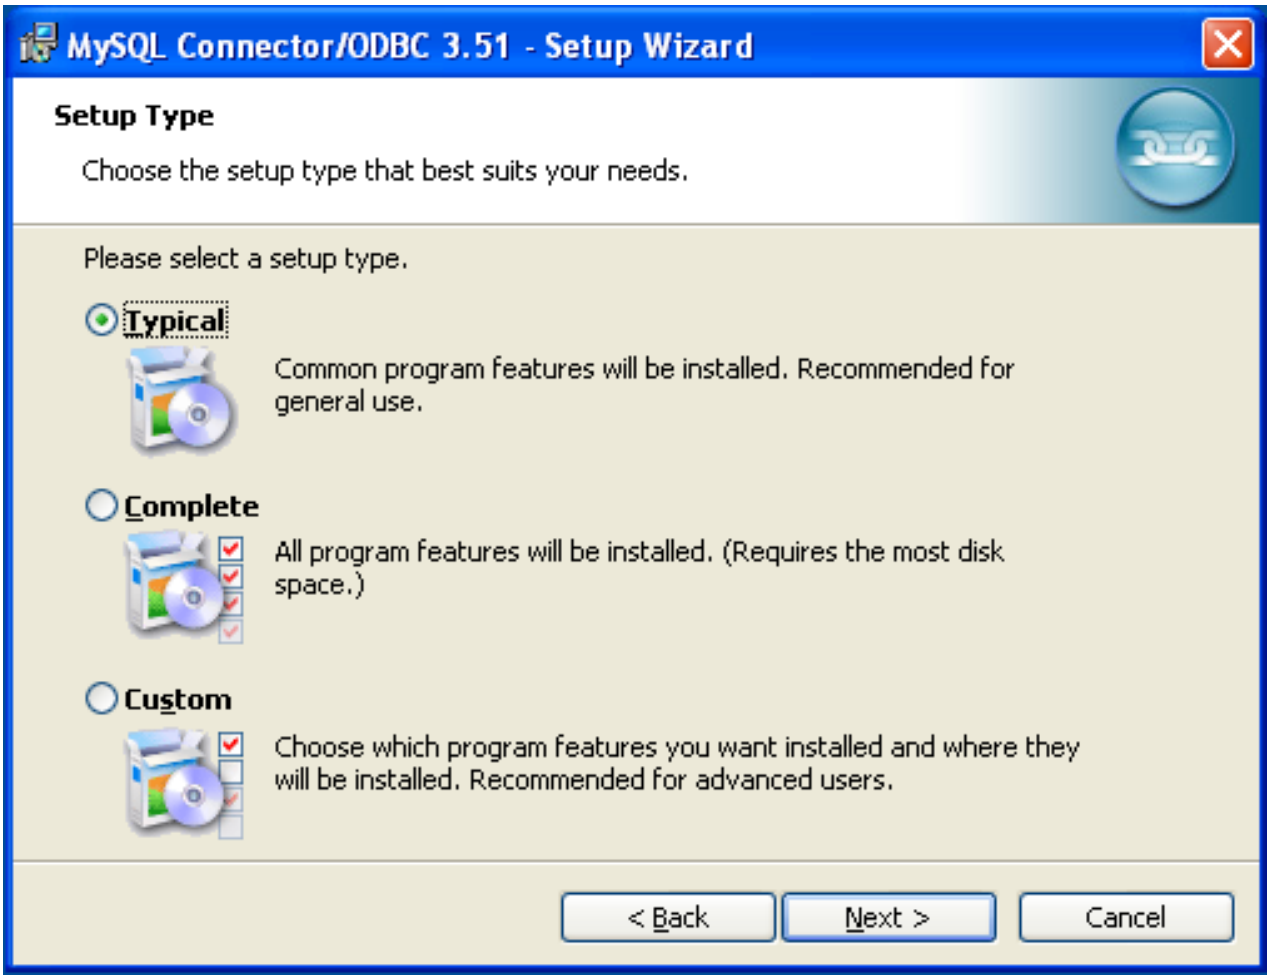
You should follow these steps to complete the installation:

1. Double-click the standalone installer that you extracted, or the MSI file you downloaded.
2. The MySQL Connector/ODBC 3.51 - Setup Wizard will start. Click the NEXT button to begin the installation process.

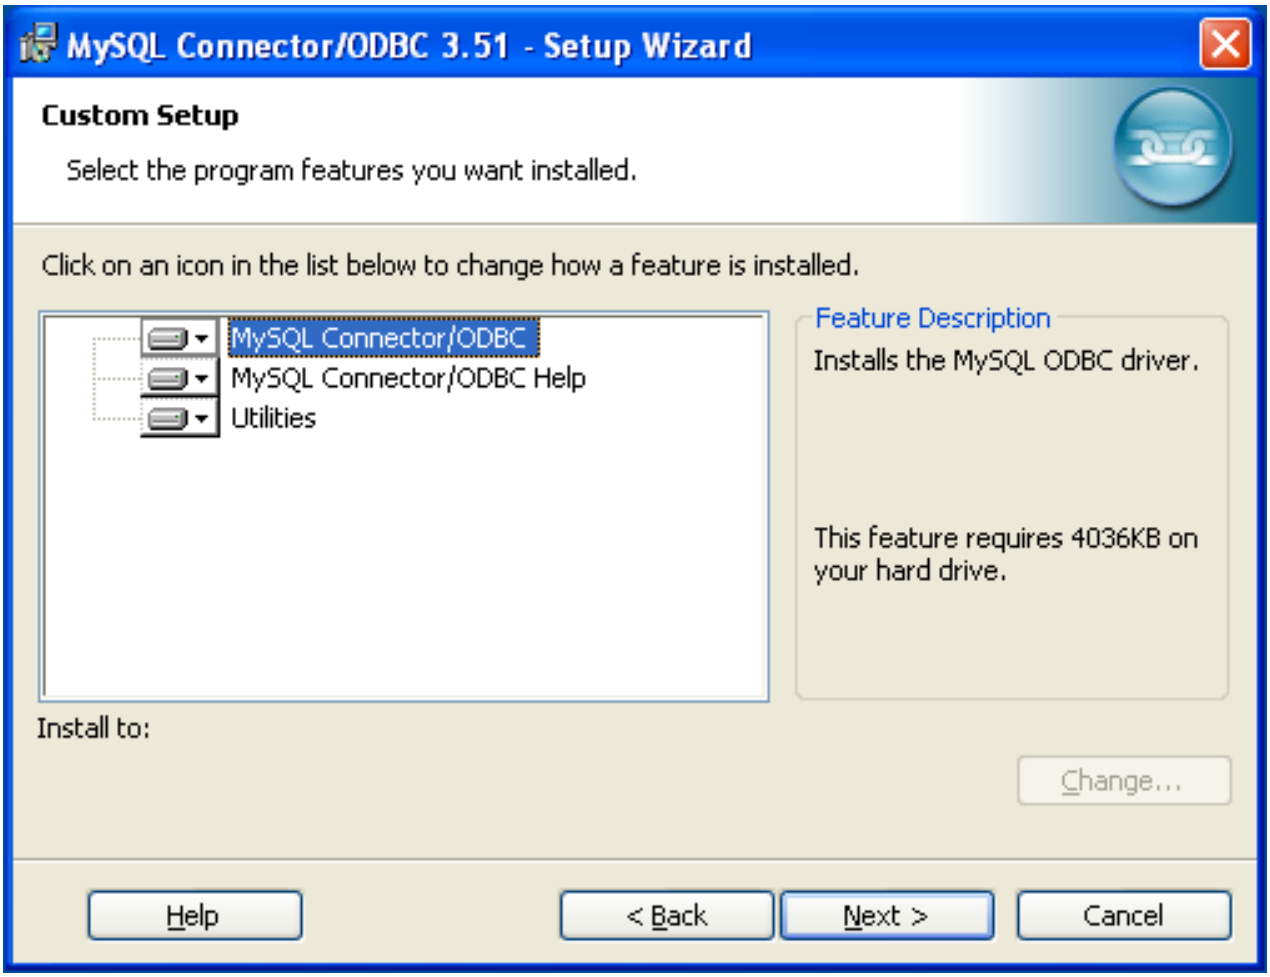


3. You will need to choose the installation type. The Typical installation provides the standard files you will need to connect to a MySQL database using ODBC. The Complete option installs all the available files, including debug and utility components. It is recommended you choose one of these two options to complete the installation. If choose one of these methods, click NEXT and then proceed to step 5.

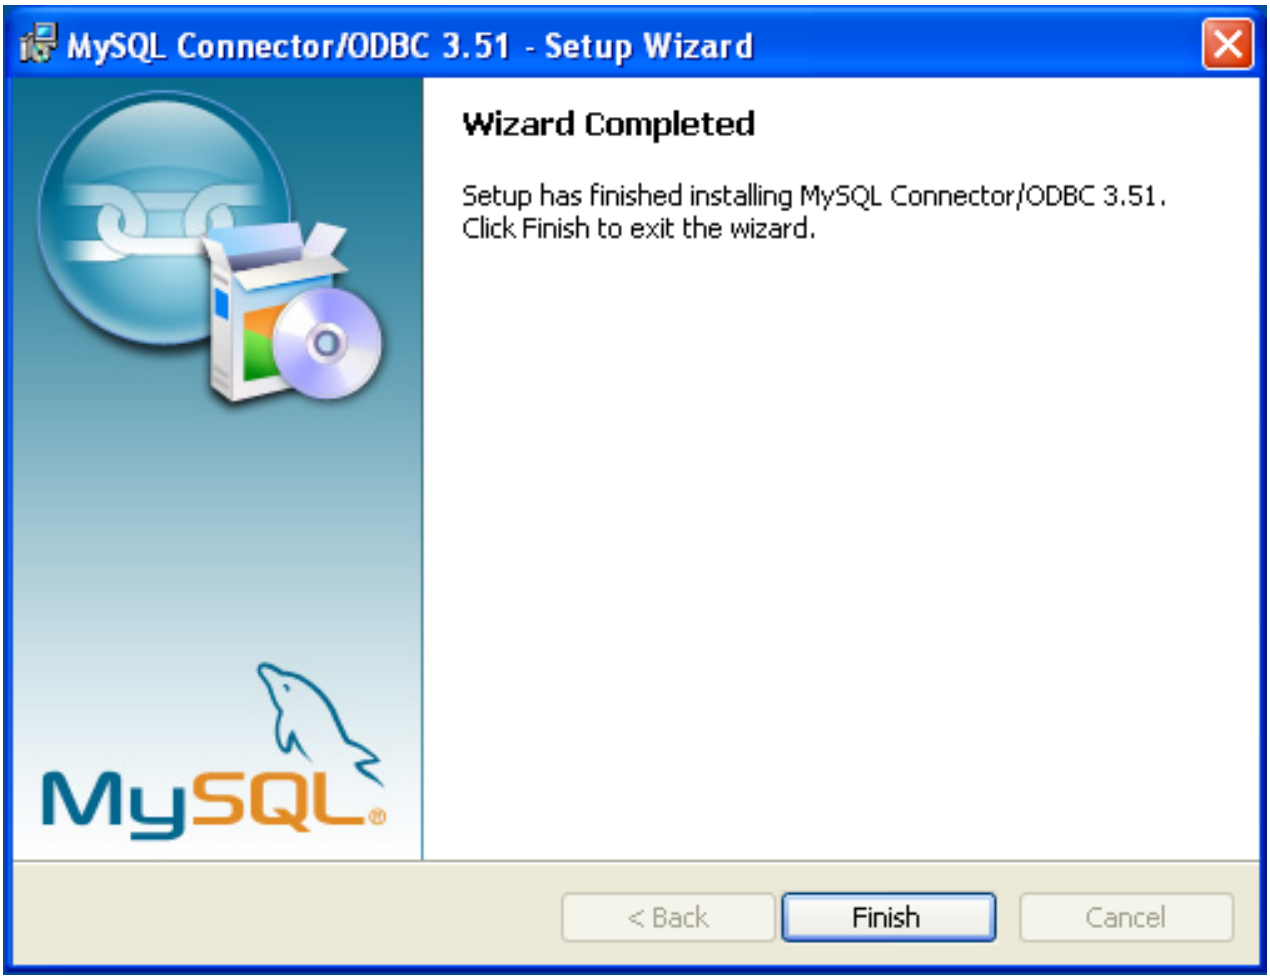
   You may also choose a Custom installation, which enables you to select the individual components that you want to install. You have chosen this method, click NEXT and then proceed to step 4.



4. If you have chosen a custom installation, use the pop-ups to select which components to install and then click NEXT to install the necessary files.



5. Once the files have copied to your machine, the installation is complete. Click FINISH to exit the installer.



Now the installation is complete, you can continue to configure your ODBC connections using Section 20.1.4, “Connector/ODBC Configuration”.

20.1.3.1.2. Installing the Windows Connector/ODBC Driver using the Zipped DLL package

If you have downloaded the Zipped DLL package then you must install the individual files required for Connector/ODBC operation manually. Once you have unzipped the installation files, you can either perform this operation by hand, executing each statement individually, or you can use the included Batch file to perform an installation to the default locations.

To install using the Batch file:

1. Unzip the Connector/ODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Run `Install.bat`:

```
C:\> Install.bat
```

This will copy the necessary files into the default location, and then register the Connector/ODBC driver with the Windows ODBC manager.

If you want to copy the files to an alternative location - for example, to run or test different versions of the Connector/ODBC driver on the same machine, then you must copy the files by hand. It is however not recommended to install these files in a nonstandard location. To copy the files by hand to the default installation location use the following steps:

1. Unzip the Connector/ODBC Zipped DLL package.
2. Open a Command Prompt.
3. Change to the directory created when you unzipped the Connector/ODBC Zipped DLL package.
4. Copy the library files to a suitable directory. The default is to copy them into the default Windows system directory `\Windows\System32`:

```
C:\> copy lib\myodbc3S.dll \Windows\System32
C:\> copy lib\myodbc3S.lib \Windows\System32
C:\> copy lib\myodbc3.dll \Windows\System32
C:\> copy lib\myodbc3.lib \Windows\System32
```

5. Copy the Connector/ODBC tools. These must be placed into a directory that is in the system `PATH`. The default is to install these into the Windows system directory `\Windows\System32`:

```
C:\> copy bin\myodbc3i.exe \Windows\System32
C:\> copy bin\myodbc3m.exe \Windows\System32
C:\> copy bin\myodbc3c.exe \Windows\System32
```

6. Optionally copy the help files. For these files to be accessible through the help system, they must be installed in the Windows system directory:

```
C:\> copy doc\*.hlp \Windows\System32
```

7. Finally, you must register the Connector/ODBC driver with the ODBC manager:

```
C:\> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;\
  DRIVER=myodbc3.dll;SETUP=myodbc3S.dll"
```

   You must change the references to the DLL files and command location in the above statement if you have not installed these files into the default location.

20.1.3.2. Installing Connector/ODBC from a Binary Distribution on Unix

There are two methods available for installing Connector/ODBC on Unix from a binary distribution. For most Unix environments you will need to use the tarball distribution. For Linux systems, there is also an RPM distribution available.

> **Note**
>
> To install Connector/ODBC 5.1 on Unix you require unixODBC 2.2.12 or later to be installed.

20.1.3.2.1. Installing Connector/ODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps that demonstrate the process using the Linux version of the tarball:

```
shell> su root
shell> gunzip mysql-connector-odbc-3.51.11-i686-pc-linux.tar.gz
shell> tar xvf mysql-connector-odbc-3.51.11-i686-pc-linux.tar
shell> cd mysql-connector-odbc-3.51.11-i686-pc-linux
```

Read the installation instructions in the `INSTALL` file and execute these commands.

Then proceed on to Section 20.1.4.5, “Configuring a Connector/ODBC DSN on Unix”, to configure the DSN for Connector/ODBC. For more information, refer to the `INSTALL` file that comes with your distribution.

20.1.3.2.2. Installing Connector/ODBC from an RPM Distribution

To install or upgrade Connector/ODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of Connector/ODBC and follow the instructions below. Use `su root` to become `root`, then install the RPM file.

If you are installing for the first time:

```
shell> su root
 shell> rpm -ivh mysql-connector-odbc-3.51.12.i386.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh mysql-connector-odbc-3.51.12.i386.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC`, respectively. Proceed onto Section 20.1.4.5, “Configuring a Connector/ODBC DSN on Unix”.

To **uninstall** the driver, become `root` and execute an `rpm` command:

```
shell> su root
shell> rpm -e mysql-connector-odbc
```

20.1.3.3. Installing Connector/ODBC from a Binary Distribution on Mac OS X

Mac OS X is based on the FreeBSD operating system, and you can normally use the MySQL network port for connecting to MySQL servers on other hosts. Installing the Connector/ODBC driver enables you to connect to MySQL databases on any platform through the ODBC interface. You should only need to install the Connector/ODBC driver when your application requires an ODBC interface. Applications that require or can use ODBC (and therefore the Connector/ODBC driver) include ColdFusion, Filemaker Pro, 4th Dimension and many other applications.

Mac OS X includes its own ODBC manager, based on the `iODBC` manager. Mac OS X includes an administration tool that provides easier administration of ODBC drivers and configuration, updating the underlying `iODBC` configuration files.

The method for installing Connector/ODBC on Mac OS X depends on the version on Connector/ODBC you are using. For Connector/ODBC 3.51.14 and later, the package is provided as a compressed tar archive that you must manually install. For Connector/ODBC 3.51.13 and earlier the software was provided on a compressed disk image (`.dmg`) file and included an installer.

In either case, the driver is designed to work with the iODBC driver manager included with Mac OS X.

To install Connector/ODBC 3.51.14 and later:

1. Download the installation file. Note that versions are available for both PowerPC and Intel platforms.
2. Extract the archive:

   ```
   shell> tar zxf mysql-connector-odbc-3.51.16-osx10.4-x86-32bit.tar.gz
   ```

3. The directory created will contain two subdirectories, `lib` and `bin`. You need to copy these to a suitable location such as `/usr/local`:

   ```
   shell> cp bin/* /usr/local/bin
   shell> cp lib/* /usr/local/lib
   ```

4. Finally, you must register the driver with iODBC using the `myodbc3i` tool you just installed:

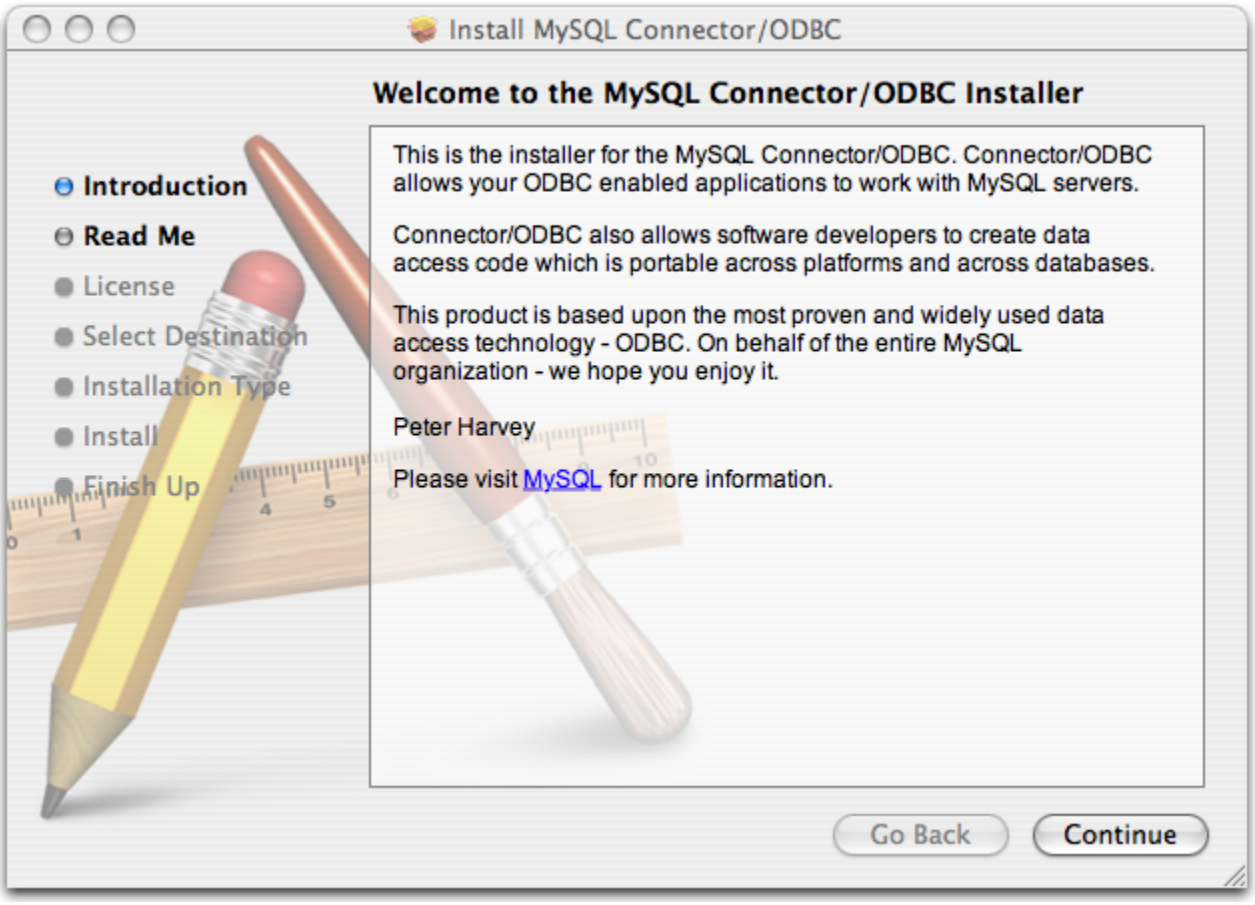
   ```
   shell> myodbc3i -a -d -t"MySQL ODBC 3.51 Driver;Driver=/usr/local/lib/libmyodbc3.so;Setup=/usr/local/lib/libmyodbc3S.s
   ```

You can verify the installed drivers either by using the ODBC Administrator application or the `myodbc3i` utility:

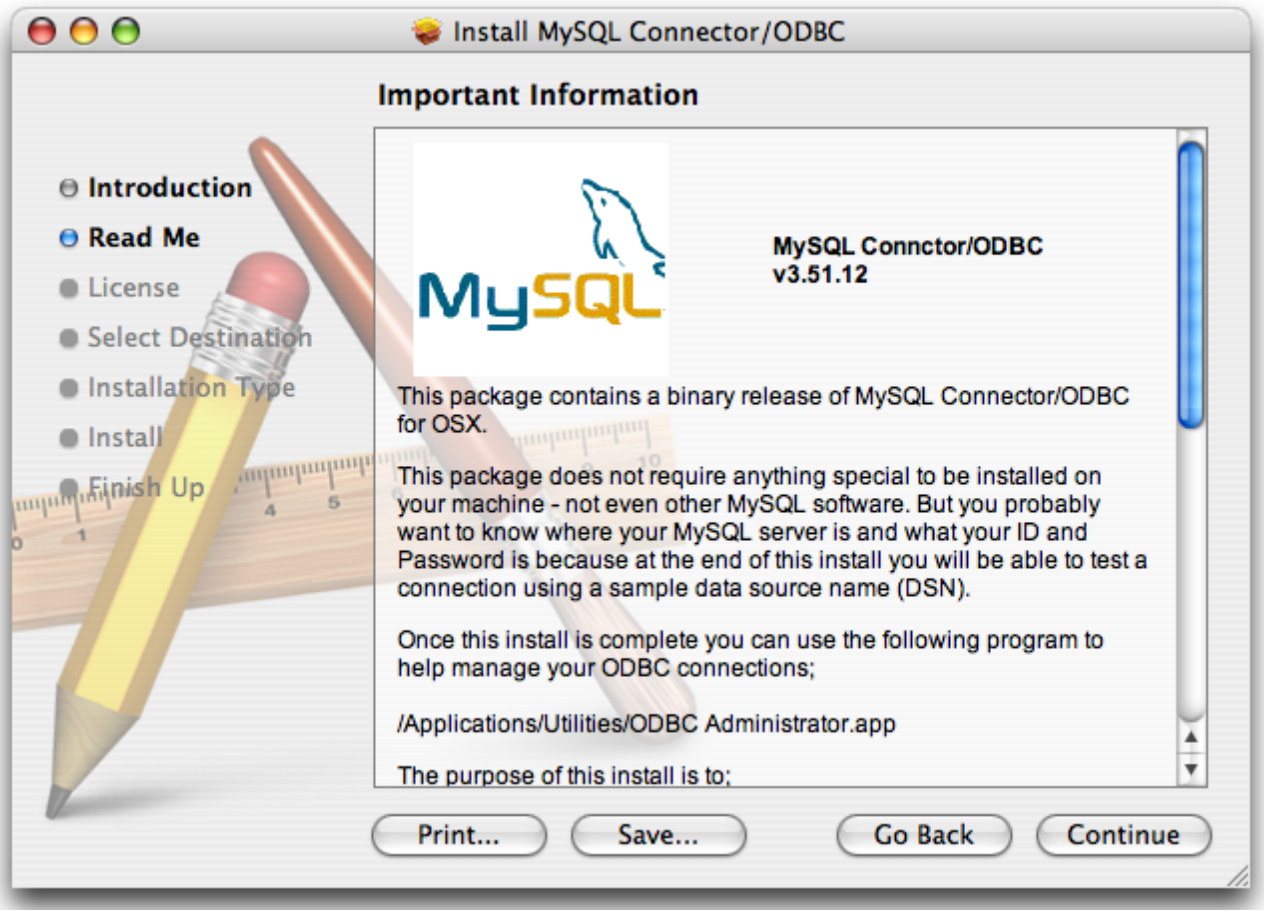
```
shell> myodbc3i -q -d
```

To install Connector/ODBC 3.51.13 and earlier, follow these steps:

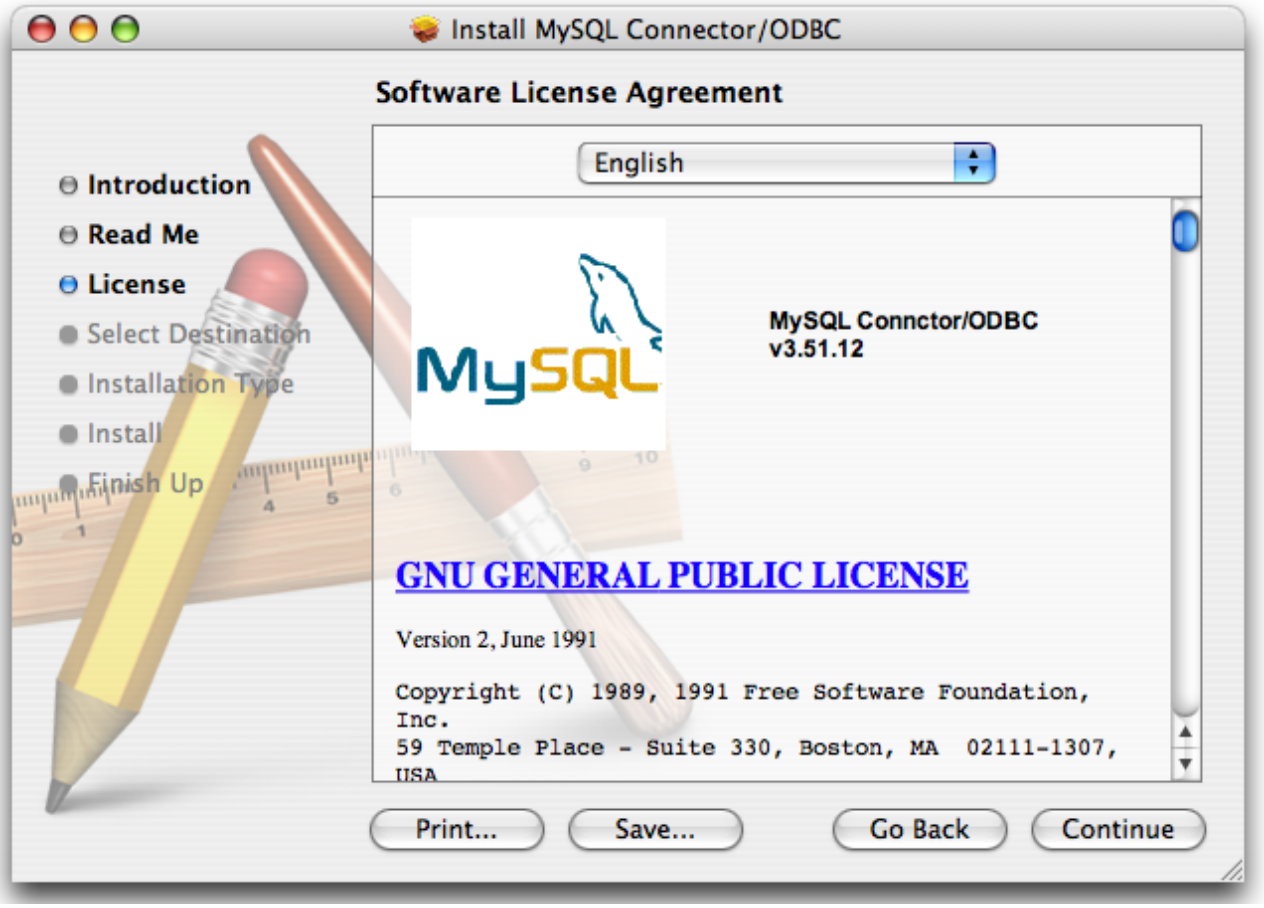
1. Download the file to your computer and double-click the downloaded image file.
2. Within the disk image you will find an installer package (with the `.pkg` extension). Double-click on this file to start the Mac OS X installer.
3. You will be presented with the installer welcome message. Click the CONTINUE button to begin the installation process.



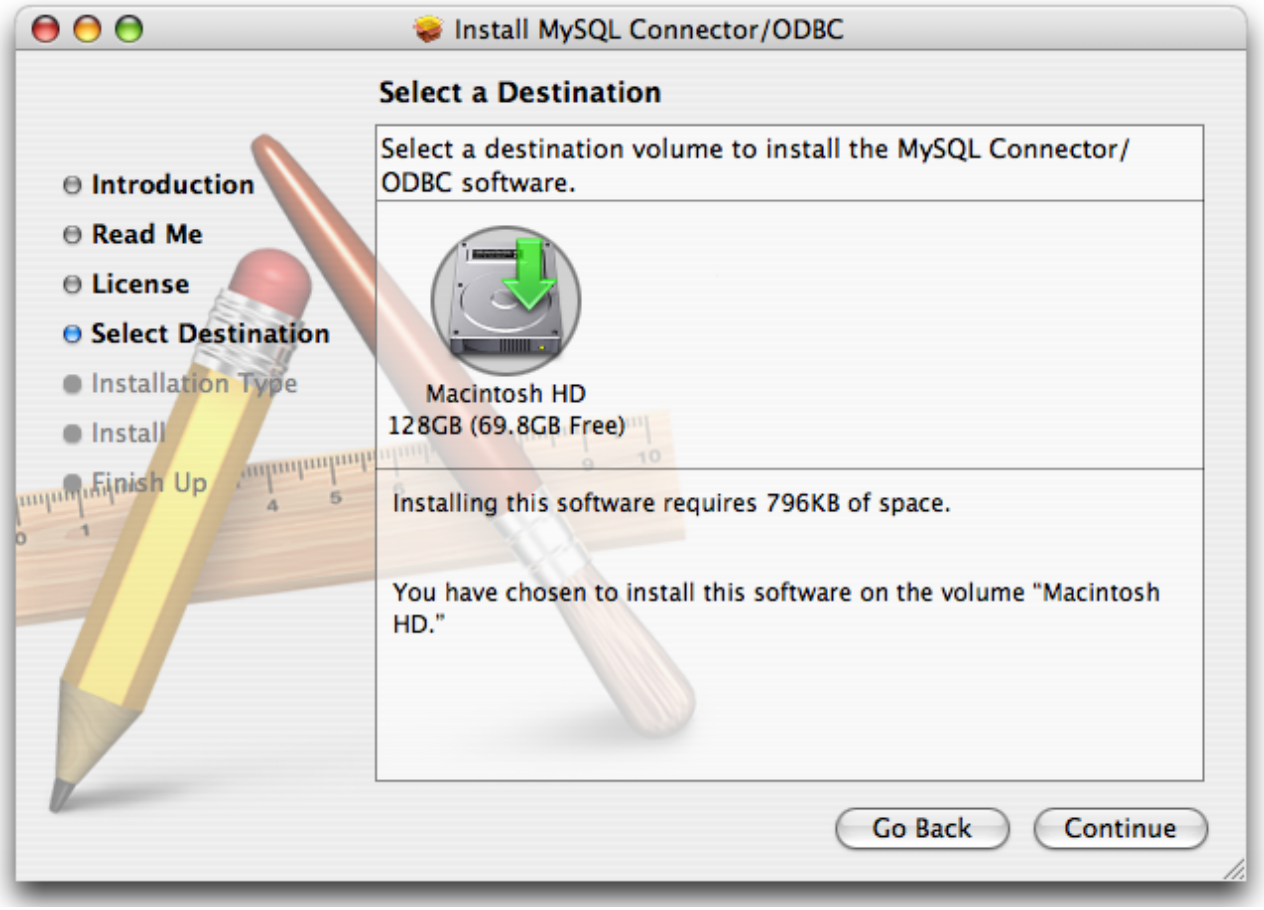
4. Please take the time to read the Important Information as it contains guidance on how to complete the installation process. Once you have read the notice and collected the necessary information, click CONTINUE.



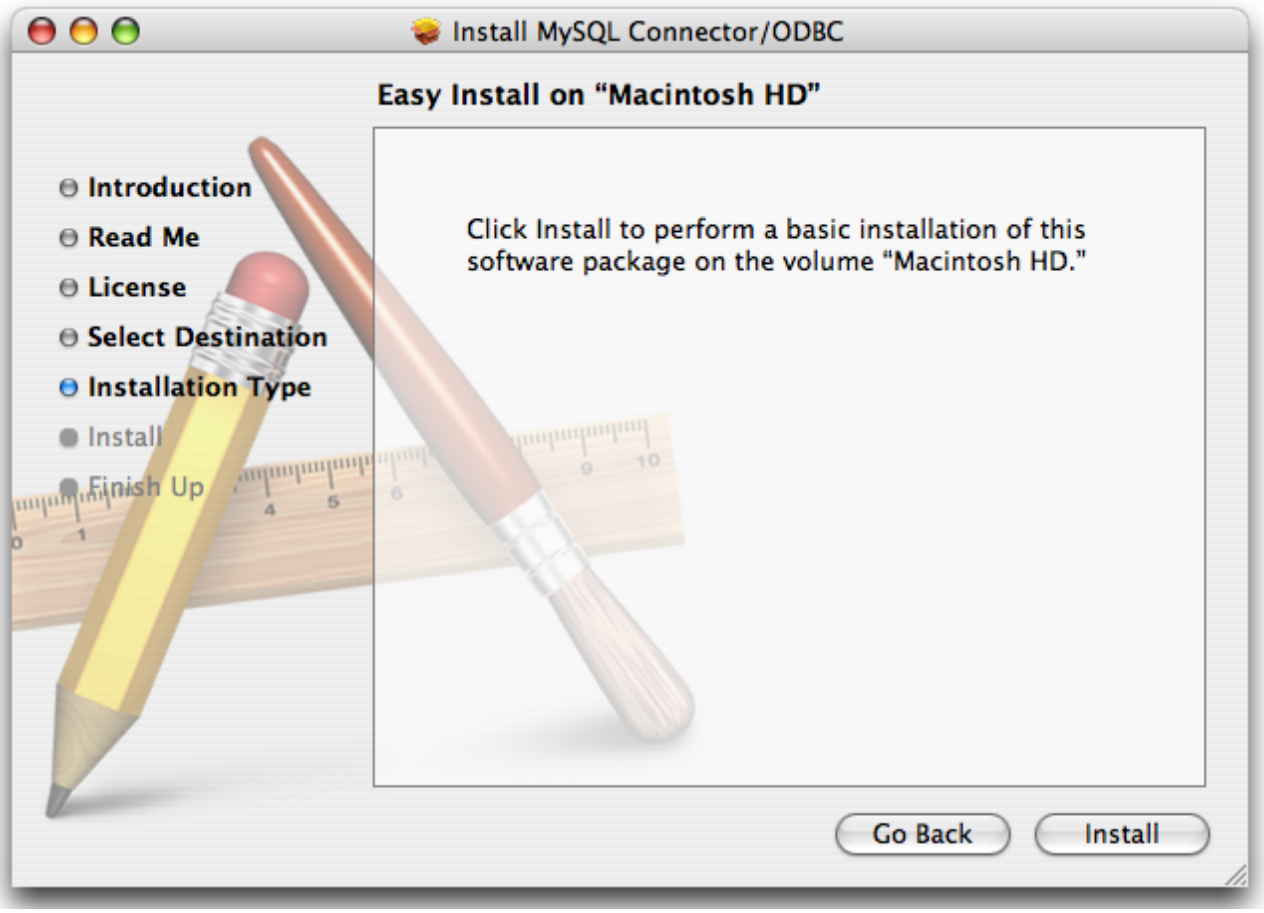
5. Connector/ODBC drivers are made available under the GNU General Public License. Please read the license if you are not familiar with it before continuing installation. Click CONTINUE to approve the license (you will be asked to confirm that decision) and continue the installation.



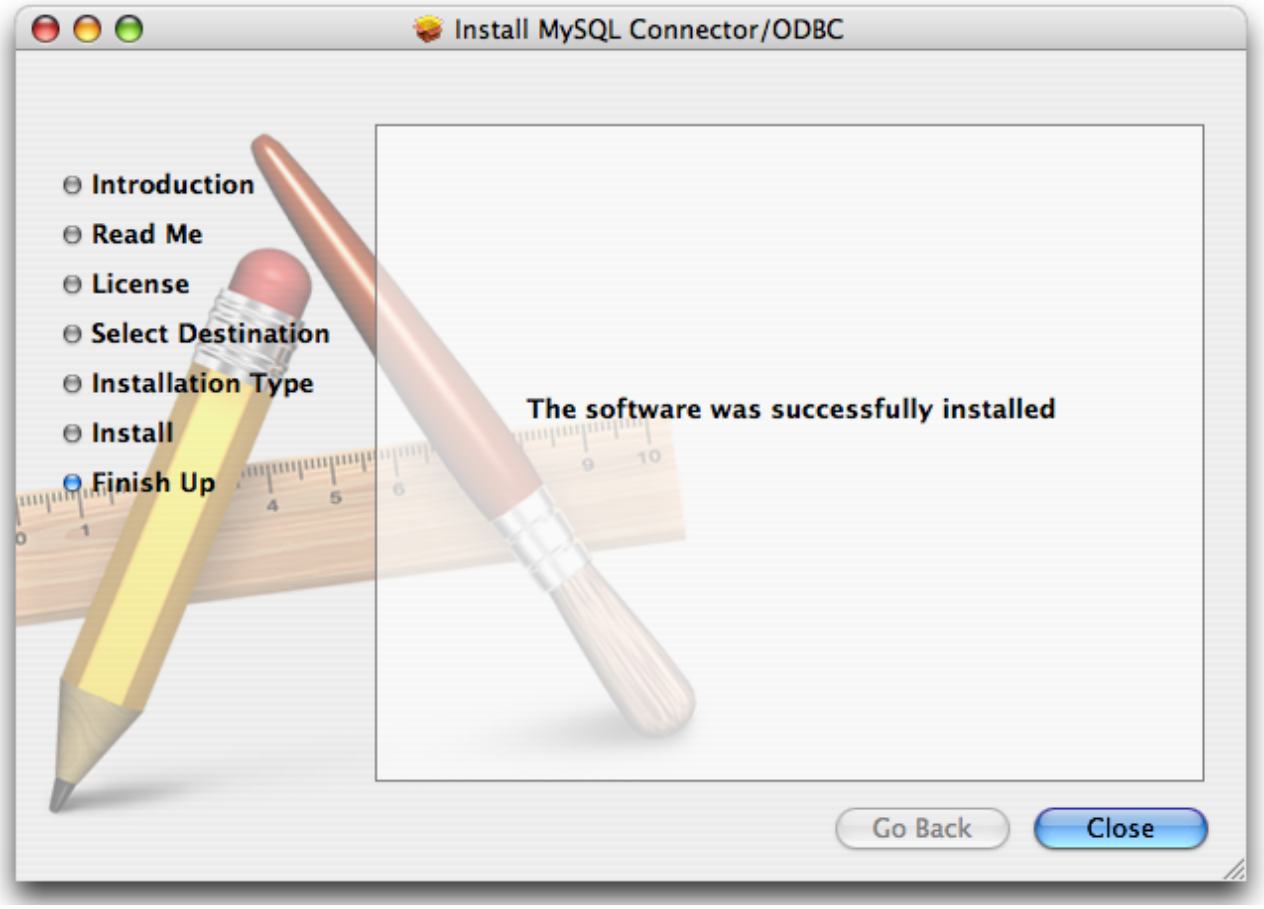
6. Choose a location to install the Connector/ODBC drivers and the ODBC Administrator application. You must install the files onto a drive with an operating system and you may be limited in the choices available. Select the drive you want to use, and then click CONTINUE.



7. The installer will automatically select the files that need to be installed on your machine. Click INSTALL to continue. The installer will copy the necessary files to your machine. A progress bar will be shown indicating the installation progress.



8. When installation has been completed you will get a window like the one shown below. Click CLOSE to close and quit the installer.



20.1.3.4. Installing Connector/ODBC from a Source Distribution on Windows

You should only need to install Connector/ODBC from source on Windows if you want to change or modify the source or installation. If you are unsure whether to install from source, please use the binary installation detailed in Section 20.1.3.1, “Installing Connector/ODBC from a Binary Distribution on Windows”.

Installing Connector/ODBC from source on Windows requires a number of different tools and packages:

- MDAC, Microsoft Data Access SDK from http://support.microsoft.com/kb/110093.
- Suitable C compiler, such as Microsoft Visual C++ or the C compiler included with Microsoft Visual Studio.
- Compatible `make` tool. Microsoft's `nmake` is used in the examples in this section.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit http://dev.mysql.com/downloads/.

20.1.3.4.1. Building Connector/ODBC 3.51

Connector/ODBC source distributions include `Makefiles` that require the `nmake` or other `make` utility. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

1. Download and extract the sources to a folder, then change directory into that folder. The following command assumes the folder is named `myodbc3-src`:

   ```
   C:\> cd myodbc3-src
   ```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

   ```
   C:\> nmake -f Makefile
   C:\> nmake -f Makefile install
   ```

   `nmake -f Makefile` builds the release version of the driver and places the binaries in subdirectory called `Release`.

   `nmake -f Makefile install` installs (copies) the driver DLLs and libraries (`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

   ```
   C:\> nmake -f Makefile_debug
   C:\> nmake -f Makefile_debug install
   ```

4. You can clean and rebuild the driver by using:

   ```
   C:\> nmake -f Makefile clean
   C:\> nmake -f Makefile install
   ```

Note

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of `nmake`, visit http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcce4/html/evgrfRunningNMAKE.asp.
- If you are using the Subversion tree for compiling, all Windows-specific `Makefiles` are named as `Win_Makefile*`.

20.1.3.4.2. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile all
```

20.1.3.5. Installing Connector/ODBC from a Source Distribution on Unix

You need the following tools to build MySQL from source on Unix:

- A working ANSI C++ compiler. `gcc` 2.95.2 or later, SGI C++, and SunPro C++ are some of the compilers that are known to work.
- A good `make` program. GNU `make` is always recommended and is sometimes required.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because Connector/ODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit http://dev.mysql.com/downloads/.

  If you have built your own MySQL server and/or client libraries from source then you must have used the `-`

`-enable-thread-safe-client` option to `configure` when the libraries were built.

You should also ensure that the `libmysqlclient` library were built and installed as a shared library.

- A compatible ODBC manager must be installed. Connector/ODBC is known to work with the `iODBC` and `unixODBC` managers. See Section 20.1.2.1.2, "ODBC Driver Managers", for more information.
- If you are using a character set that isn't compiled into the MySQL client library then you need to install the MySQL character definitions from the `charsets` directory into *`SHAREDIR`* (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine. See Section 9.1, "Character Set Support", for more information on character set support.

Once you have all the required files, unpack the source files to a separate directory, you then have to run `configure` and build the library using `make`.

20.1.3.5.1. Typical `configure` Options

The `configure` script gives you a great deal of control over how you configure your Connector/ODBC build. Typically you do this using options on the `configure` command line. You can also affect `configure` using certain environment variables. For a list of options and environment variables supported by `configure`, run this command:

```
shell> ./configure --help
```

Some of the more commonly used `configure` options are described here:

1. To compile Connector/ODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=`*`DIR`* option, where *`DIR`* is the directory where MySQL is installed.

   MySQL compile options can be determined by running *`DIR`*`/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager (`iODBC` or `unixODBC`).

   - If you are using `iODBC` and `iODBC` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=`*`DIR`* option, where *`DIR`* is the directory where `iODBC` is installed.

     If the `iODBC` headers do not reside in *`DIR`*`/include`, you can use the `--with-iodbc-includes=`*`INCDIR`* option to specify their location.

     The applies to libraries. If they are not in *`DIR`*`/lib`, you can use the `--with-iodbc-libs=`*`LIBDIR`* option.

   - If you are using `unixODBC`, use the `--with-unixODBC=`*`DIR`* option (case sensitive) to make `configure` look for `unixODBC` instead of `iODBC` by default, *`DIR`* is the directory where `unixODBC` is installed.

     If the `unixODBC` headers and libraries aren't located in *`DIR`*`/include` and *`DIR`*`/lib`, use the `--with-unixODBC-includes=`*`INCDIR`* and `--with-unixODBC-libs=`*`LIBDIR`* options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the Connector/ODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \
         --with-iodbc=/usr/local \
         --with-mysql-path=/usr/local/mysql
```

20.1.3.5.2. Additional configure Options

There are a number of other options that you need, or want, to set when configuring the Connector/ODBC driver before it is built.

- To link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following `configure` option:

```
--enable-thread-safe
```

and can be disabled (default) using

```
--disable-thread-safe
```

This option enables the building of the driver thread-safe library `libmyodbc3_r.so` from by linking with MySQL thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

If the compilation with the thread-safe option fails, it may be because the correct thread-libraries on the system could not be located. You should set the value of `LIBS` to point to the correct thread library for your system.

```
LIBS="-lpthread" ./configure ..
```

- You can enable or disable the shared and static versions of Connector/ODBC using these options:

```
--enable-shared[=yes/no]
--disable-shared
--enable-static[=yes/no]
--disable-static
```

- By default, all the binary distributions are built as nondebugging versions (configured with `--without-debug`).

  To enable debugging information, build the driver from source distribution and use the `--with-debug` option when you run `configure`.

- This option is available only for source trees that have been obtained from the Subversion repository. This option does not apply to the packaged source distributions.

  By default, the driver is built with the `--without-docs` option. If you would like the documentation to be built, then execute `configure` with:

```
--with-docs
```

20.1.3.5.3. Building and Compilation

To build the driver libraries, you have to just execute `make`.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a detailed email to `<myodbc@lists.mysql.com>` for further assistance.

20.1.3.5.4. Building Shared Libraries

On most platforms, MySQL does not build or support `.so` (shared) client libraries by default. This is based on our experience of problems when building shared libraries.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for `configure`. By default, `configure` does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd mysql-connector-odbc-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
          $CC -bundle -flat_namespace -undefined error \
```

```
          -o .libs/libmyodbc3-3.51.01.so \
          catalog.o connect.o cursor.o dll.o error.o execute.o \
          handle.o info.o misc.o myodbc3.o options.o prepare.o \
          results.o transact.o utility.o \
          -L/usr/local/mysql/lib/mysql/ \
          -L/usr/local/iodbc/lib/ \
          -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using `unixODBC` instead of `iODBC`, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to the Connector/ODBC library installation directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `--prefix`).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
          $CC -bundle -flat_namespace -undefined error
          -o .libs/libmyodbc3_r-3.51.01.so
          catalog.o connect.o cursor.o dll.o error.o execute.o
          handle.o info.o misc.o myodbc3.o options.o prepare.o
          results.o transact.o utility.o
          -L/usr/local/mysql/lib/mysql/
          -L/usr/local/iodbc/lib/
          -lz -lc -lmysqlclient_r -liodbcinst
```

20.1.3.5.5. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For Connector/ODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe Connector/ODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`
- `libmyodbc3_r.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

20.1.3.5.6. Testing Connector/ODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, use the following command:

```
shell> make test
```

Before running the tests, create the DSN 'myodbc3' in `odbc.ini` and set the environment variable `ODBCINI` to the correct

`odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command-line arguments to each sample.

20.1.3.5.7. Building Connector/ODBC from Source on Mac OS X

To build the driver on Mac OS X (Darwin), make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
          --with-unixODBC=/usr/local
          --with-mysql-path=/usr/local/mysql
          --disable-shared
          --enable-gui=no
          --host=powerpc-apple
```

The command assumes that the `unixODBC` and MySQL are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
          $CC -bundle -flat_namespace -undefined error
          -o .libs/libmyodbc3-3.51.01.so *.o
          -L/usr/local/mysql/lib/
          -L/usr/local/iodbc/lib
          -liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
          $CC -bundle -flat_namespace -undefined error
          -o .libs/libmyodbc3-3.51.01.so *.o
          -L/usr/local/mysql/lib/
          -L/usr/local/iodbc/lib
          -liodbcinst -lmysqlclienti_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using `unixODBC` instead of `iODBC` and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

20.1.3.5.8. Building Connector/ODBC from Source on HP-UX

To build the driver on HP-UX 10.x or 11.x, make use of the following `configure` example:

If using `cc`:

```
shell> CC="cc" \
          CFLAGS="+z" \
          LDFLAGS="-Wl,+b:-Wl,+s" \
          ./configure --prefix=/usr/local
          --with-unixodbc=/usr/local
          --with-mysql-path=/usr/local/mysql/lib/mysql
          --enable-shared
          --enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \
          LDFLAGS="-Wl,+b:-Wl,+s" \
          ./configure --prefix=/usr/local
          --with-unixodbc=/usr/local
          --with-mysql-path=/usr/local/mysql
          --enable-shared
          --enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.sl` to determine whether you need to have set the MySQL client library path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run `configure` with the `--disable-shared` option.

20.1.3.5.9. Building Connector/ODBC from Source on AIX

To build the driver on AIX, make use of the following `configure` example:

```
shell> ./configure --prefix=/usr/local
          --with-unixodbc=/usr/local
          --with-mysql-path=/usr/local/mysql
          --disable-shared
          --enable-thread-safe
```

> **Note**
>
> For more information about how to build and set up the static and shared libraries across the different platforms refer to ' Using static and shared libraries across platforms'.

20.1.3.6. Installing Connector/ODBC from the Development Source Tree

> **Caution**
>
> You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/ODBC up and running on your system, you should use a standard release distribution.

To obtain the most recent development source tree, you first need to download and install Bazaar. You can obtain Bazaar from the Bazaar VCS Web site. Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

To build from the source trees, you need the following tools:

- autoconf 2.52 (or newer)
- automake 1.4 (or newer)
- libtool 1.4 (or newer)
- m4

The most recent development source tree is available from our public Subversion trees at http://dev.mysql.com/tech-resources/sources.html.

To checkout out the Connector/ODBC sources, change to the directory where you want the copy of the Connector/ODBC tree to be stored, then use the following command:

```
shell> bzr branch lp:myodbc
```

You should now have a copy of the entire Connector/ODBC source tree in the directory `connector-odbc3`. To build from this source tree on Unix or Linux follow these steps:

```
shell> cd myodbc
shell> aclocal
shell> autoheader
shell> libtoolize -c -f
shell> autoconf
shell> automake;
shell> ./configure  # Add your favorite options here
shell> make
```

For more information on how to build, refer to the `INSTALL` file located in the same directory. For more information on options to `configure`, see Section 20.1.3.5.1, “Typical `configure` Options”

When the build is done, run `make install` to install the Connector/ODBC 3.51 driver on your system.

If you have gotten to the `make` stage and the distribution does not compile, please report it to `<myodbc@lists.mysql.com>`.

On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver. For more information, see Section 20.1.3.4, “Installing Connector/ODBC from a Source Distribution on Windows”.

After the initial checkout operation to get the source tree, you should run `bzr pull` periodically to update your source according to the latest version.

20.1.4. Connector/ODBC Configuration

Before you connect to a MySQL database using the Connector/ODBC driver you must configure an ODBC *Data Source Name*. The DSN associates the various configuration parameters required to communicate with a database to a specific name. You use the DSN in an application to communicate with the database, rather than specifying individual parameters within the application itself. DSN information can be user specific, system specific, or provided in a special file. ODBC data source names are configured in different ways, depending on your platform and ODBC driver.

20.1.4.1. Data Source Names

A Data Source Name associates the configuration parameters for communicating with a specific database. Generally a DSN consists of the following parameters:

- Name
- Host Name
- Database Name
- Login
- Password

In addition, different ODBC drivers, including Connector/ODBC, may accept additional driver-specific options and parameters.

There are three types of DSN:

- A *System DSN* is a global DSN definition that is available to any user and application on a particular system. A System DSN can normally only be configured by a systems administrator, or by a user who has specific permissions that let them create System DSNs.
- A *User DSN* is specific to an individual user, and can be used to store database connectivity information that the user regularly uses.
- A *File DSN* uses a simple file to define the DSN configuration. File DSNs can be shared between users and machines and are therefore more practical when installing or deploying DSN information as part of an application across many machines.

DSN information is stored in different locations depending on your platform and environment.

20.1.4.2. Connector/ODBC Connection Parameters

You can specify the parameters in the following tables for Connector/ODBC when configuring a DSN. Users on Windows can use the Options and Advanced panels when configuring a DSN to set these parameters; see the table for information on which options relate to which fields and checkboxes. On Unix and Mac OS X, use the parameter name and value as the keyword/value pair in the DSN configuration. Alternatively, you can set these parameters within the `InConnectionString` argument in the `SQLDriverConnect()` call.

Parameter	Default Value	Comment
`user`	ODBC	The user name used to connect to MySQL.
`uid`	ODBC	Synonymous with `user`. Added in 3.51.16.
`server`	`localhost`	The host name of the MySQL server.

Parameter	Default Value	Comment
database		The default database.
option	0	Options that specify how Connector/ODBC should work. See below.
port	3306	The TCP/IP port to use if server is not localhost.
initstmt		Initial statement. A statement to execute when connecting to MySQL. In version 3.51 the parameter is called stmt. Note, the driver supports the initial statement being executed only at the time of the initial connection.
password		The password for the user account on server.
pwd		Synonymous with password. Added in 3.51.16.
socket		The Unix socket file or Windows named pipe to connect to if server is localhost.
sslca		The path to a file with a list of trust SSL CAs. Added in 3.51.16.
sslcapath		The path to a directory that contains trusted SSL CA certificates in PEM format. Added in 3.51.16.
sslcert		The name of the SSL certificate file to use for establishing a secure connection. Added in 3.51.16.
sslcipher		A list of allowable ciphers to use for SSL encryption. The cipher list has the same format as the openssl ciphers command Added in 3.51.16.
sslkey		The name of the SSL key file to use for establishing a secure connection. Added in 3.51.16.
charset		The character set to use for the connection. Added in 3.51.17.
sslverify		If set to 1, the SSL certificate will be verified when used with the MySQL connection. If not set, then the default behavior is to ignore SSL certificate verification.
readtimeout		The timeout in seconds for attempts to read from the server. Each attempt uses this timeout value and there are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP Close_Wait_Timeout value of 10 minutes. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the MYSQL_OPT_READ_TIMEOUT option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.
writetimeout		The timeout in seconds for attempts to write to the server. Each attempt uses this timeout value and there are net_retry_count retries if necessary, so the total effective timeout value is net_retry_count times the option value. This option works only for TCP/IP connections, and only for Windows prior to MySQL 5.1.12. Corresponds to the MYSQL_OPT_WRITE_TIMEOUT option of the MySQL Client Library. This option was added in Connector/ODBC 3.51.27.

Note

The SSL configuration parameters can also be automatically loaded from a my.ini or my.cnf file.

The option argument is used to tell Connector/ODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the option argument. The following options are listed in the order in which they appear in the Connector/ODBC connect screen.

Value	Flagname	GUI Option	Description
1	FLAG_FIELD_LENGTH	Do not Optimize Column Width	The client cannot handle that Connector/ODBC returns the real width of a column. This option was removed in 3.51.18.
2	FLAG_FOUND_ROWS	Return Matching Rows	The client cannot handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns “found rows” instead. You must have MySQL 3.21.14 or newer to get this to work.
4	FLAG_DEBUG	Trace Driver Calls To myodbc.log	Make a debug log in C:\myodbc.log on Windows, or /tmp/myodbc.log on Unix variants. This option was removed in Connector/ODBC 3.51.18.

8	FLAG_BIG_PACKETS	Allow Big Results	Do not set any packet limit for results and bind parameters. Without this option, parameter binding will be truncated to 255 characters.
16	FLAG_NO_PROMPT	Do not Prompt Upon Connect	Do not prompt for questions even if driver would like to prompt.
32	FLAG_DYNAMIC_CURSOR	Enable Dynamic Cursor	Enable or disable the dynamic cursor support.
64	FLAG_NO_SCHEMA	Ignore # in Table Name	Ignore use of database name in *db_name.tbl_name.col_name*.
128	FLAG_NO_DEFAULT_CURSOR	User Manager Cursors	Force use of ODBC manager cursors (experimental).
256	FLAG_NO_LOCALE	Do not Use Set Locale	Disable the use of extended fetch (experimental).
512	FLAG_PAD_SPACE	Pad Char To Full Length	Pad CHAR columns to full column length.
1024	FLAG_FULL_COLUMN_NAMES	Return Table Names for SQLDescribeCol	SQLDescribeCol() returns fully qualified column names.
2048	FLAG_COMPRESSED_PROTO	Use Compressed Protocol	Use the compressed client/server protocol.
4096	FLAG_IGNORE_SPACE	Ignore Space After Function Names	Tell server to ignore space after function name and before "(" (needed by PowerBuilder). This makes all function names keywords.
8192	FLAG_NAMED_PIPE	Force Use of Named Pipes	Connect with named pipes to a mysqld server running on NT.
16384	FLAG_NO_BIGINT	Change BIGINT Columns to Int	Change BIGINT columns to INT columns (some applications cannot handle BIGINT).
32768	FLAG_NO_CATALOG	No Catalog	Forces results from the catalog functions, such as SQLTables, to always return NULL and the driver to report that catalogs are not supported.
65536	FLAG_USE_MYCNF	Read Options From my.cnf	Read parameters from the [client] and [odbc] groups from my.cnf.
131072	FLAG_SAFE	Safe	Add some extra safety checks.
262144	FLAG_NO_TRANSACTIONS	Disable transactions	Disable transactions.
524288	FLAG_LOG_QUERY	Save queries to myodbc.sql	Enable query logging to c:\myodbc.sql(/tmp/myodbc.sql) file. (Enabled only in debug mode.)
1048576	FLAG_NO_CACHE	Do not Cache Result (forward only cursors)	Do not cache the results locally in the driver, instead read from server (mysql_use_result()). This works only for forward-only cursors. This option is very important in dealing with large tables when you do not want the driver to cache the entire result set.
2097152	FLAG_FORWARD_CURSOR	Force Use Of Forward Only Cursors	Force the use of Forward-only cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use noncache result sets, then this option ensures the forward-only cursor behavior.
4194304	FLAG_AUTO_RECONNECT	Enable auto-reconnect.	Enables auto-reconnection functionality. You should not use this option with transactions, since a auto reconnection during a incomplete transaction may cause corruption. Note that an auto-reconnected connection will not inherit the same settings and environment as the original. This option was added in Connector/ODBC 3.51.13.
8388608	FLAG_AUTO_IS_NULL	Flag Auto Is Null	When FLAG_AUTO_IS_NULL is set, the driver does not change the default value of sql_auto_is_null, leaving it at 1, so you get the MySQL default, not the SQL standard behavior. When FLAG_AUTO_IS_NULL is not set, the driver changes the default value of SQL_AUTO_IS_NULL to 0 after connecting, so

			you get the SQL standard, not the MySQL default behavior. Thus, omitting the flag disables the compatibility option and forces SQL standard behavior. See `IS NULL`. This option was added in Connector/ODBC 3.51.13.
16777216	`FLAG_ZERO_DATE_TO_MIN`	Flag Zero Date to Min	Translates zero dates (`XXXX-00-00`) into the minimum date values supported by ODBC, `XXXX-01-01`. This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
33554432	`FLAG_MIN_DATE_TO_ZERO`	Flag Min Date to Zero	Translates the minimum ODBC date value (`XXXX-01-01`) to the zero date format supported by MySQL (`XXXX-00-00`). This resolves an issue where some statements will not work because the date returned and the minimum ODBC date value are incompatible. This option was added in Connector/ODBC 3.51.17.
67108864	`FLAG_MULTI_STATEMENTS`	Allow multiple statements	Enables support for batched statements. This option was added in Connector/ODBC 3.51.18.
134217728	`FLAG_COLUMN_SIZE_S32`	Limit column size to 32-bit value	Limits the column size to a signed 32-bit value to prevent problems with larger column sizes in applications that do not support them. This option is automatically enabled when working with ADO applications. This option was added in Connector/ODBC 3.51.22.
268435456	`FLAG_NO_BINARY_RESULT`	Always handle binary function results as character data	When set this option disables charset 63 for columns with an empty `org_table`. This option was added in Connector/ODBC 3.51.26.

To select multiple options, add together their values. For example, setting `option` to 12 (4+8) gives you debugging without packet limits.

> **Note**
>
> From version of MySQL Connector/ODBC 5.1.6 onwards, it is possible to use the flag name directly as a parameter in the connection string, by using the flag name without the FLAG_ prefix. So, in addition to using the `options` parameter with various flags set, it is now possible to use the flags directly as parameters. For example, `FIELD_LENGTH`, `FOUND_ROWS` and `DEBUG` could all be used as parameters.

The following table shows some recommended `option` values for various configurations.

Configuration	Option Value
Microsoft Access, Visual Basic	3
Driver trace generation (Debug mode)	4
Microsoft Access (with improved DELETE queries)	35
Large tables with too many rows	2049
Sybase PowerBuilder	135168
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

20.1.4.3. Configuring a Connector/ODBC DSN on Windows

The `ODBC Data Source Administrator` within Windows enables you to create DSNs, check driver installation and configure ODBC systems such as tracing (used for debugging) and connection pooling.

Different editions and versions of Windows store the `ODBC Data Source Administrator` in different locations depending on

the version of Windows that you are using.

To open the ODBC Data Source Administrator in Windows Server 2003:

> **Tip**
>
> Because it is possible to create DSN using either the 32-bit or 64-bit driver, but using the same DNS identifier, it is advisable to include the driver being used within the DSN identifier. This will help you to identify the DSN when using it from applications such as Excel that are only compatible with the 32-bit driver. For example, you might add Using32bitCODBC to the DSN identifier for the 32-bit interface and Using64bitCODBC for those using the 64-bit Connector/ODBC driver.

1. On the Start menu, choose Administrative Tools, and then click Data Sources (ODBC).

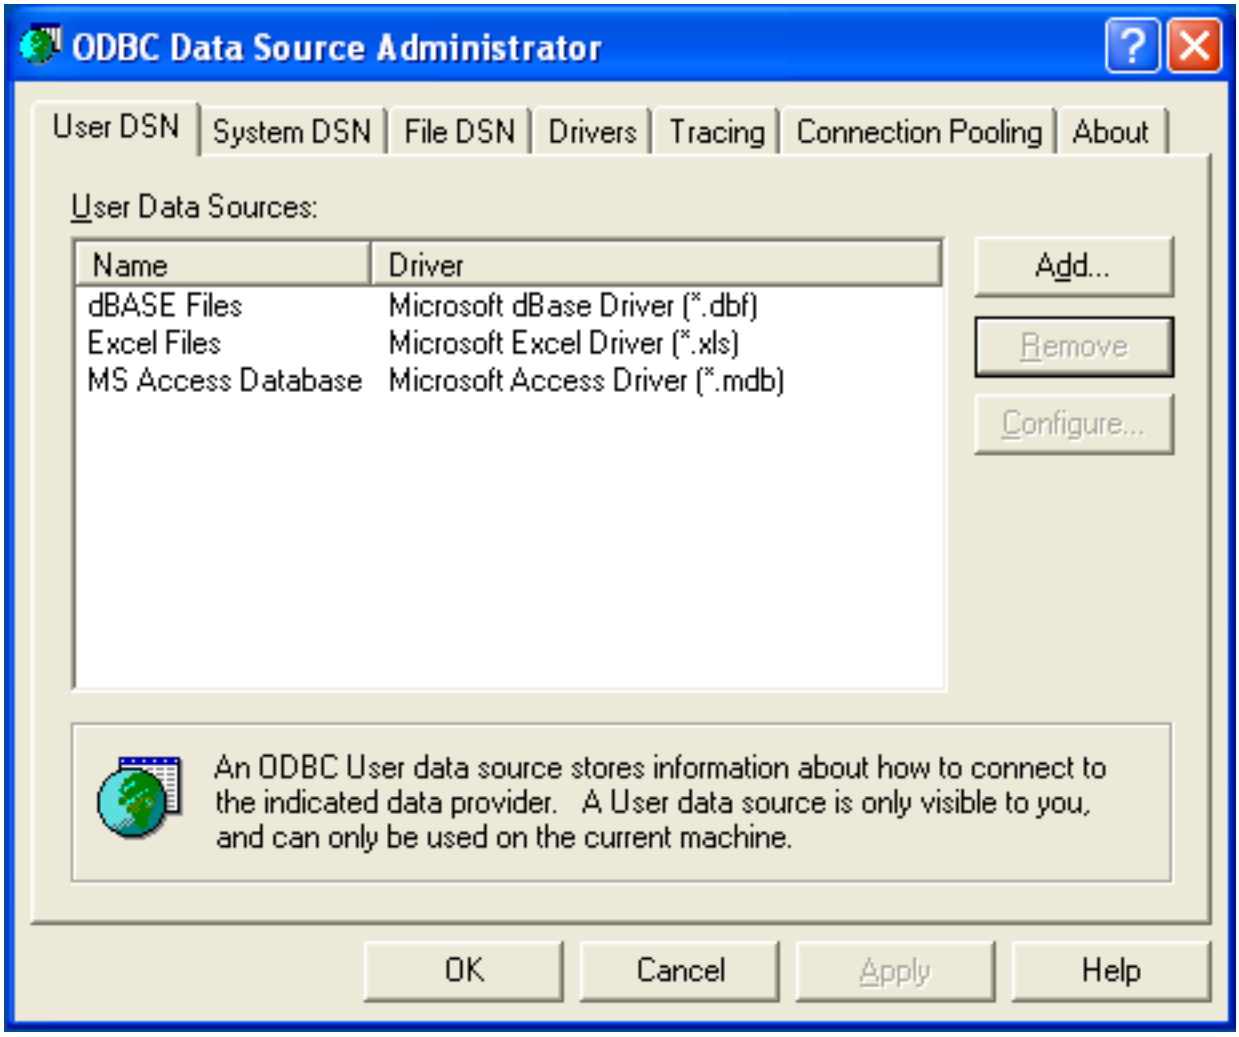
To open the ODBC Data Source Administrator in Windows 2000 Server or Windows 2000 Professional:

1. On the Start menu, choose Settings, and then click Control Panel.
2. In Control Panel, click Administrative Tools.
3. In Administrative Tools, click Data Sources (ODBC).

To open the ODBC Data Source Administrator on Windows XP:

1. On the Start menu, click Control Panel.
2. In the Control Panel when in Category View click Performance and Maintenance and then click Administrative Tools.. If you are viewing the Control Panel in Classic View, click Administrative Tools.
3. In Administrative Tools, click Data Sources (ODBC).

Irrespective of your Windows version, you should be presented the ODBC Data Source Administrator window:



Within Windows XP, you can add the `Administrative Tools` folder to your START menu to make it easier to locate the ODBC Data Source Administrator. To do this:

1. Right-click the START menu.
2. Select `Properties`.
3. Click CUSTOMIZE....
4. Select the ADVANCED tab.
5. Within `Start menu items`, within the `System Administrative Tools` section, select `Display on the All Programs menu`.

Within both Windows Server 2003 and Windows XP you may want to permanently add the `ODBC Data Source Administrator` to your START menu. To do this, locate the `Data Sources (ODBC)` icon using the methods shown, then right-click on the icon and then choose PIN TO START MENU.

The interfaces for the 3.51 and 5.1 versions of the Connector/ODBC driver are different, although the fields and information that you need to enter remain the same.

To configure a DSN using Connector/ODBC 3.51.x or Connector/ODBC 5.1.0, see Section 20.1.4.3.1, “Configuring a Connector/ODBC 3.51 DSN on Windows”.

To configure a DSN using Connector/ODBC 5.1.1 or later, see Section 20.1.4.3.2, “Configuring a Connector/ODBC 5.1 DSN on Windows”.

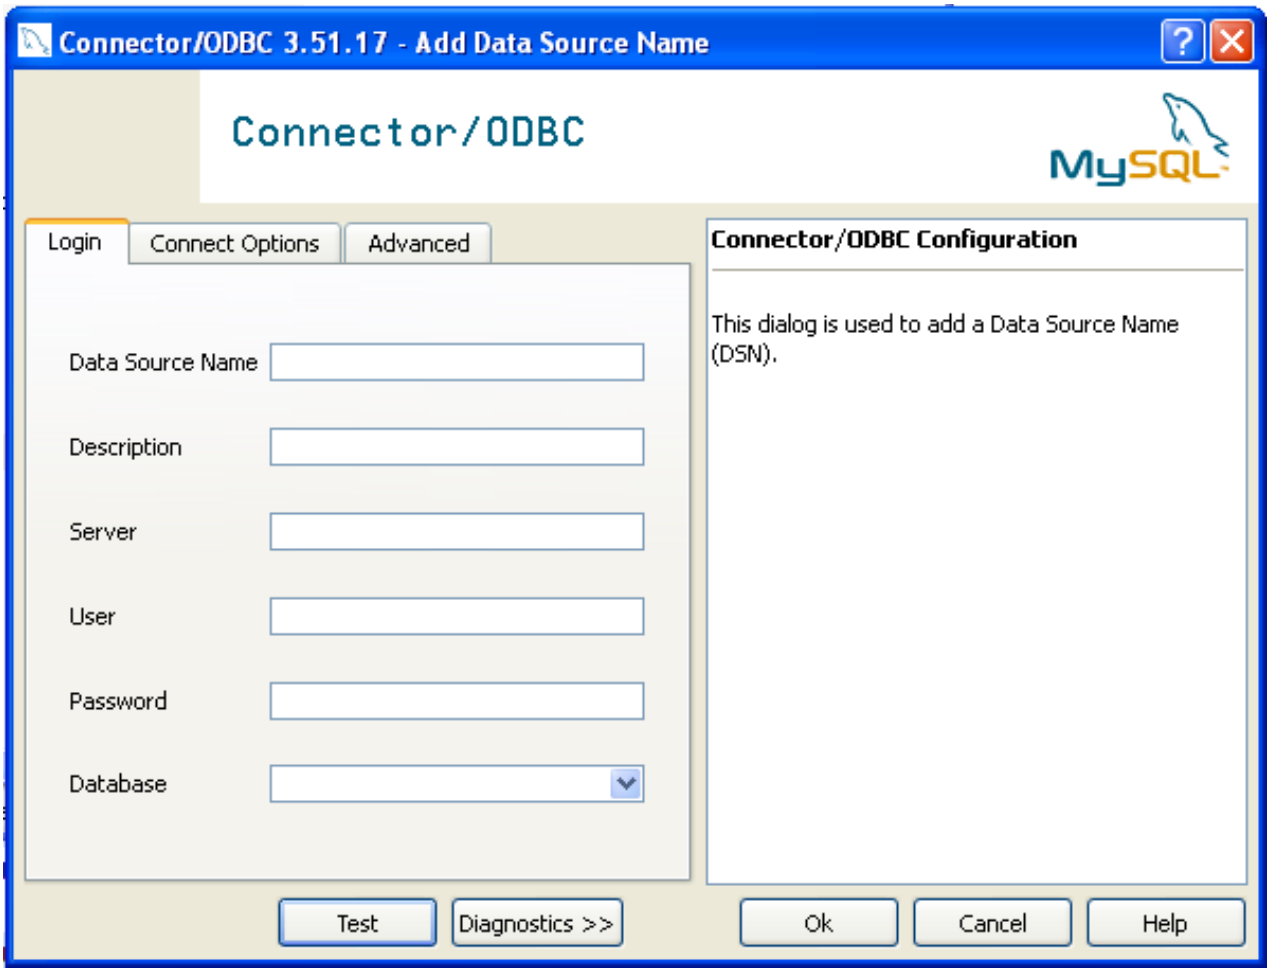
20.1.4.3.1. Configuring a Connector/ODBC 3.51 DSN on Windows

To add and configure a new Connector/ODBC data source on Windows, use the `ODBC Data Source Administrator`:

1. Open the `ODBC Data Source Administrator`.
2. To create a System DSN (which will be available to all users) , select the `System DSN` tab. To create a User DSN, which will be unique only to the current user, click the ADD... button.
3. You will need to select the ODBC driver for this DSN.

   Select `MySQL ODBC 3.51 Driver`, then click FINISH.

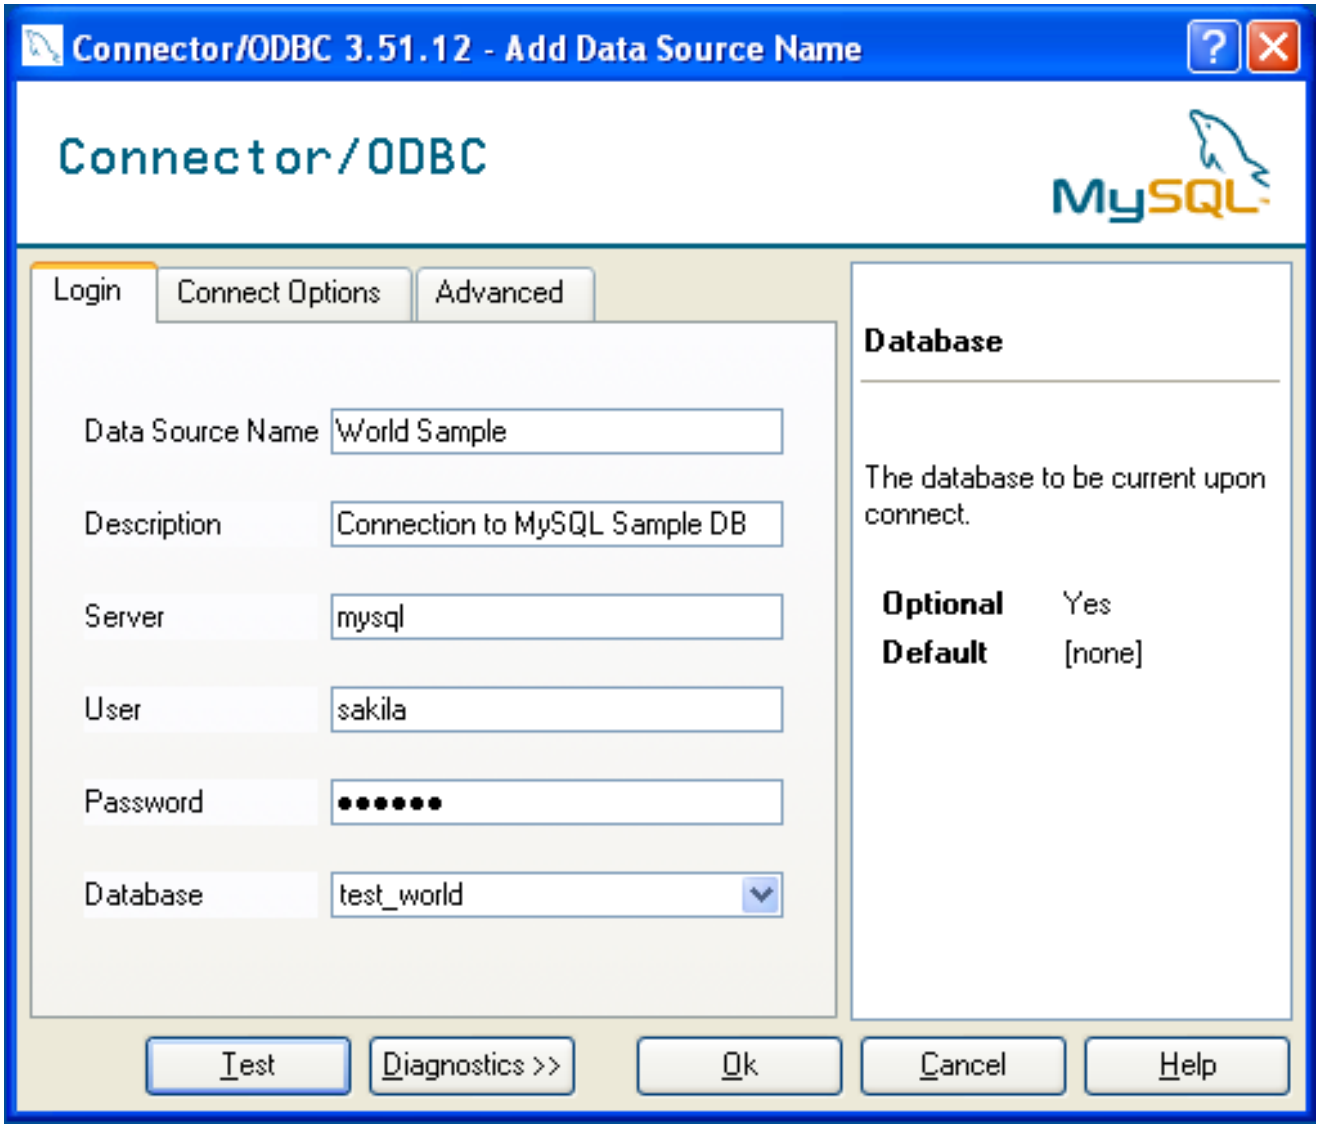
4. You now need to configure the specific fields for the DSN you are creating through the `Add Data Source Name` dialog.



In the **DATA SOURCE NAME** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **DESCRIPTION** box, enter some text to help identify the connection.
6. In the **SERVER** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **USER** field, enter the user name to use for this connection.
8. In the **PASSWORD** field, enter the corresponding password for this connection.
9. The **DATABASE** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. Click OK to save the DSN.

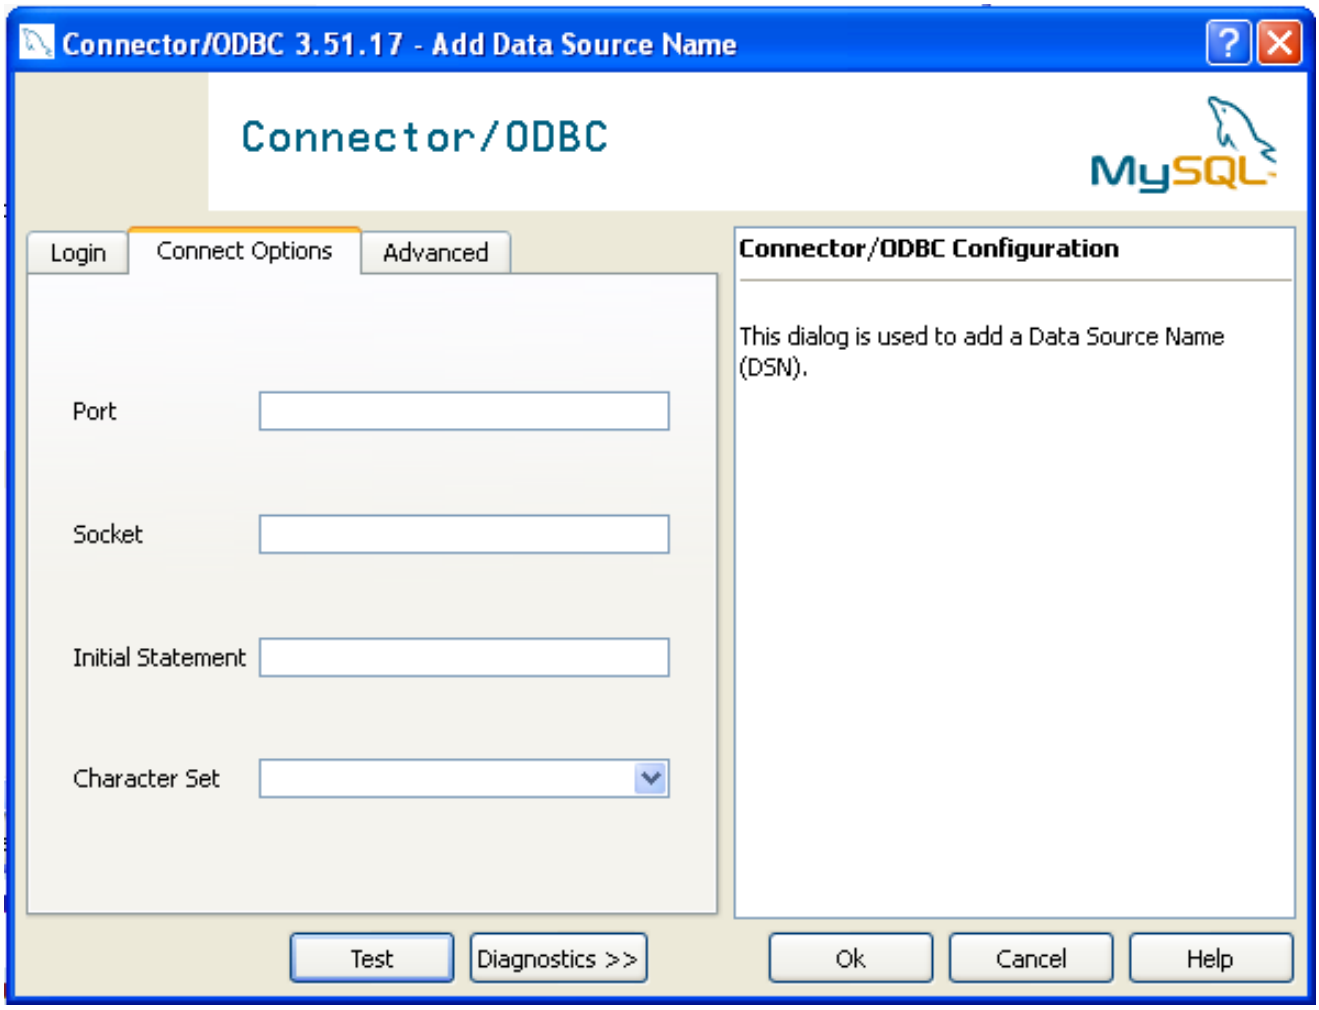
A completed DSN configuration may look like this:



You can verify the connection using the parameters you have entered by clicking the TEST button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

If the connection failed, you can obtain more information on the test and why it may have failed by clicking the DIAGNOSTICS... button to show additional error messages.

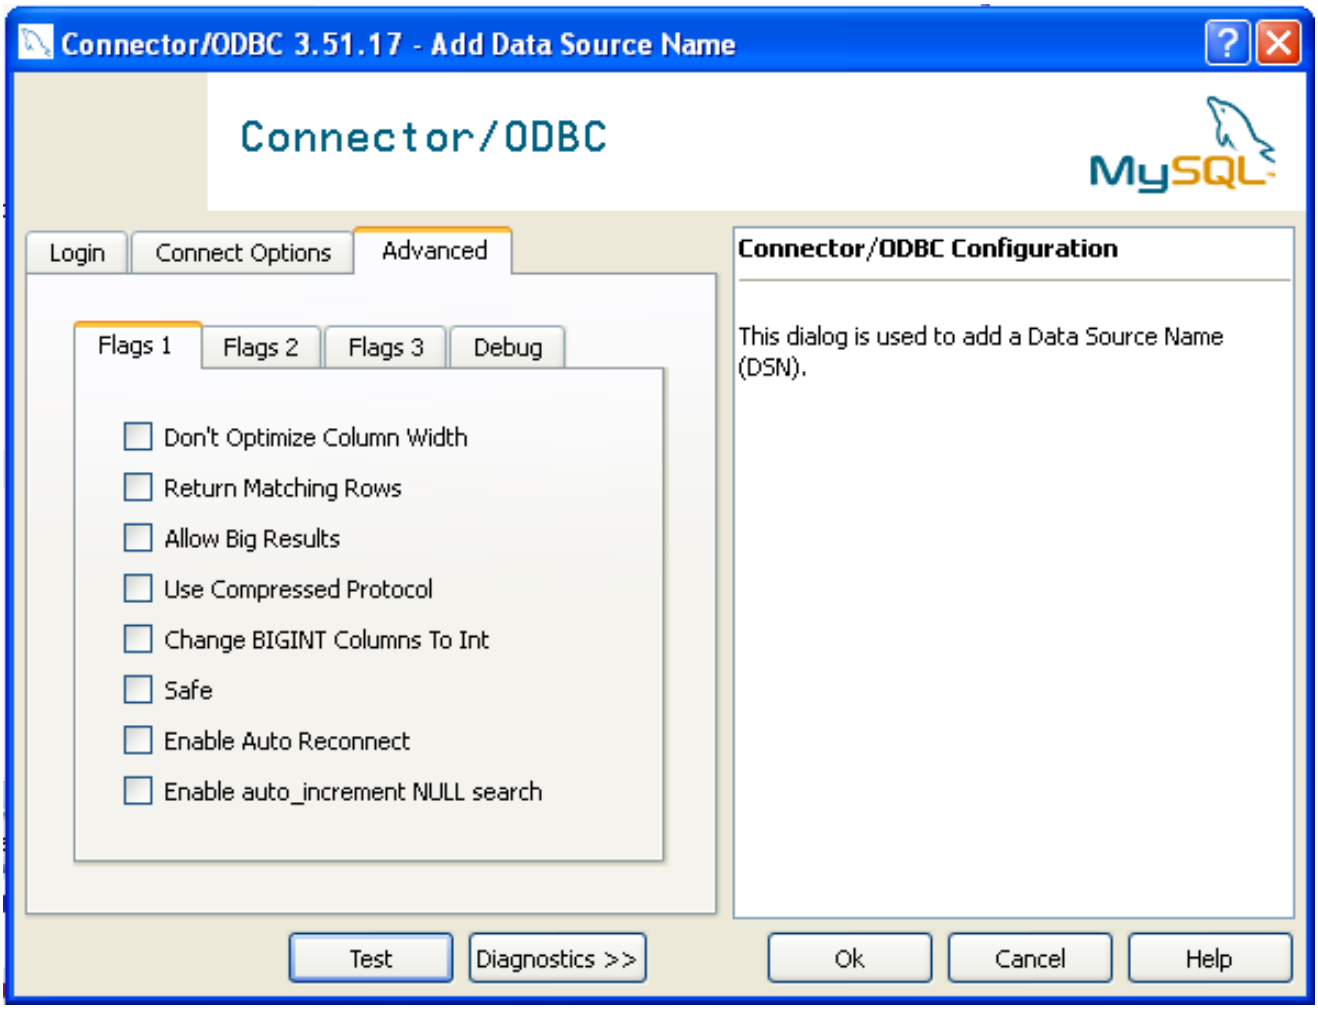
You can configure a number of options for a specific DSN by using either the CONNECT OPTIONS or ADVANCED tabs in the DSN configuration dialog.



The three options you can configure are:

- **PORT** sets the TCP/IP port number to use when communicating with MySQL. Communication with MySQL uses port 3306 by default. If your server is configured to use a different TCP/IP port, you must specify that port number here.
- **SOCKET** sets the name or location of a specific socket or Windows pipe to use when communicating with MySQL.
- **INITIAL STATEMENT** defines an SQL statement that will be executed when the connection to MySQL is opened. You can use this to set MySQL options for your connection, such as disabling autocommit.
- **CHARACTER SET** is a pop-up list from which you can select the default character set to be used with this connection. The Character Set option was added in 3.5.17.

The ADVANCED tab enables you to configure Connector/ODBC connection parameters. Refer to Section 20.1.4.2, "Connector/ODBC Connection Parameters", for information about the meaning of these options.

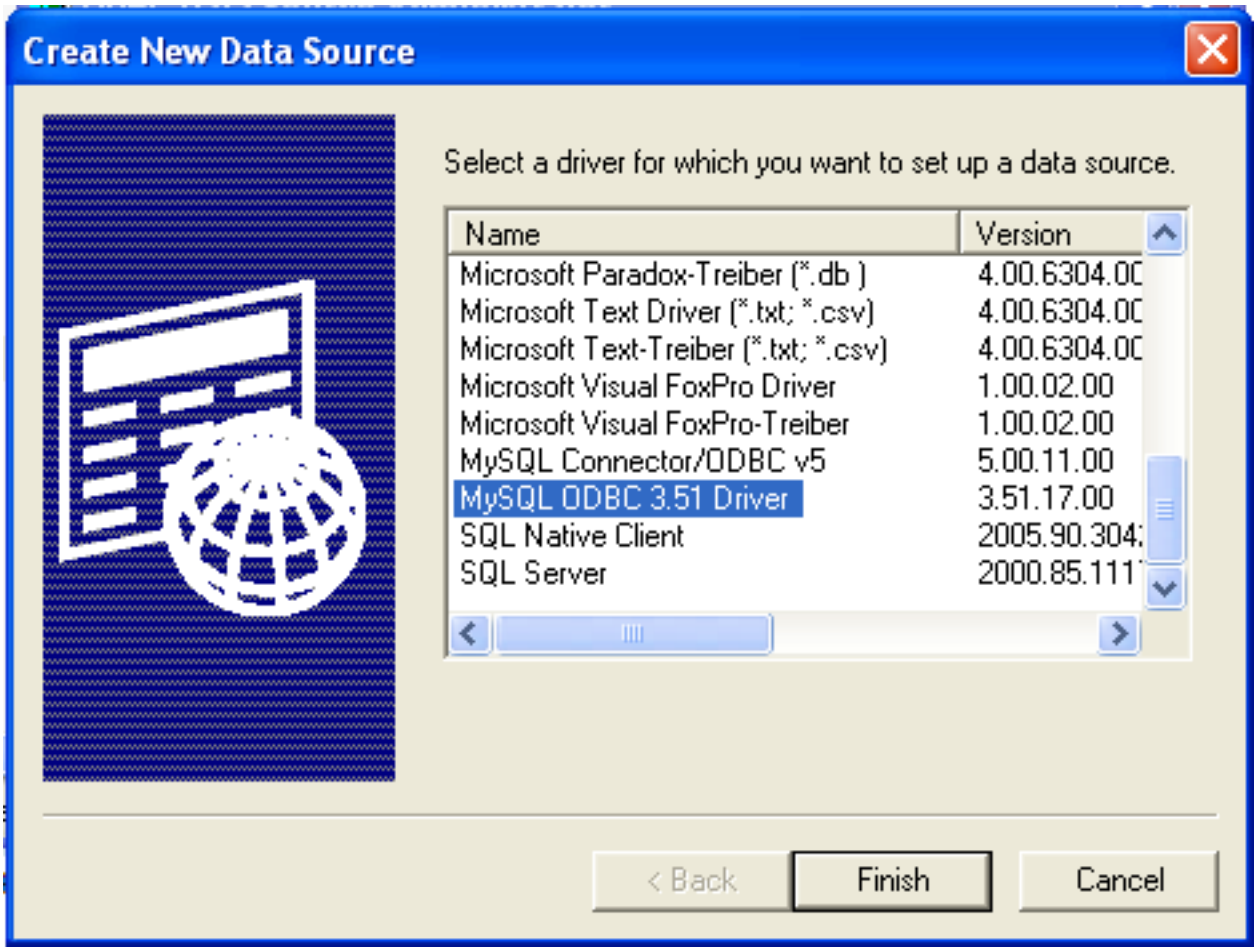


20.1.4.3.2. Configuring a Connector/ODBC 5.1 DSN on Windows

The DSN configuration when using Connector/ODBC 5.1.1 and later has a slightly different layout. Also, due to the native Unicode support within Connector/ODBC 5.1, you no longer need to specify the initial character set to be used with your connection.

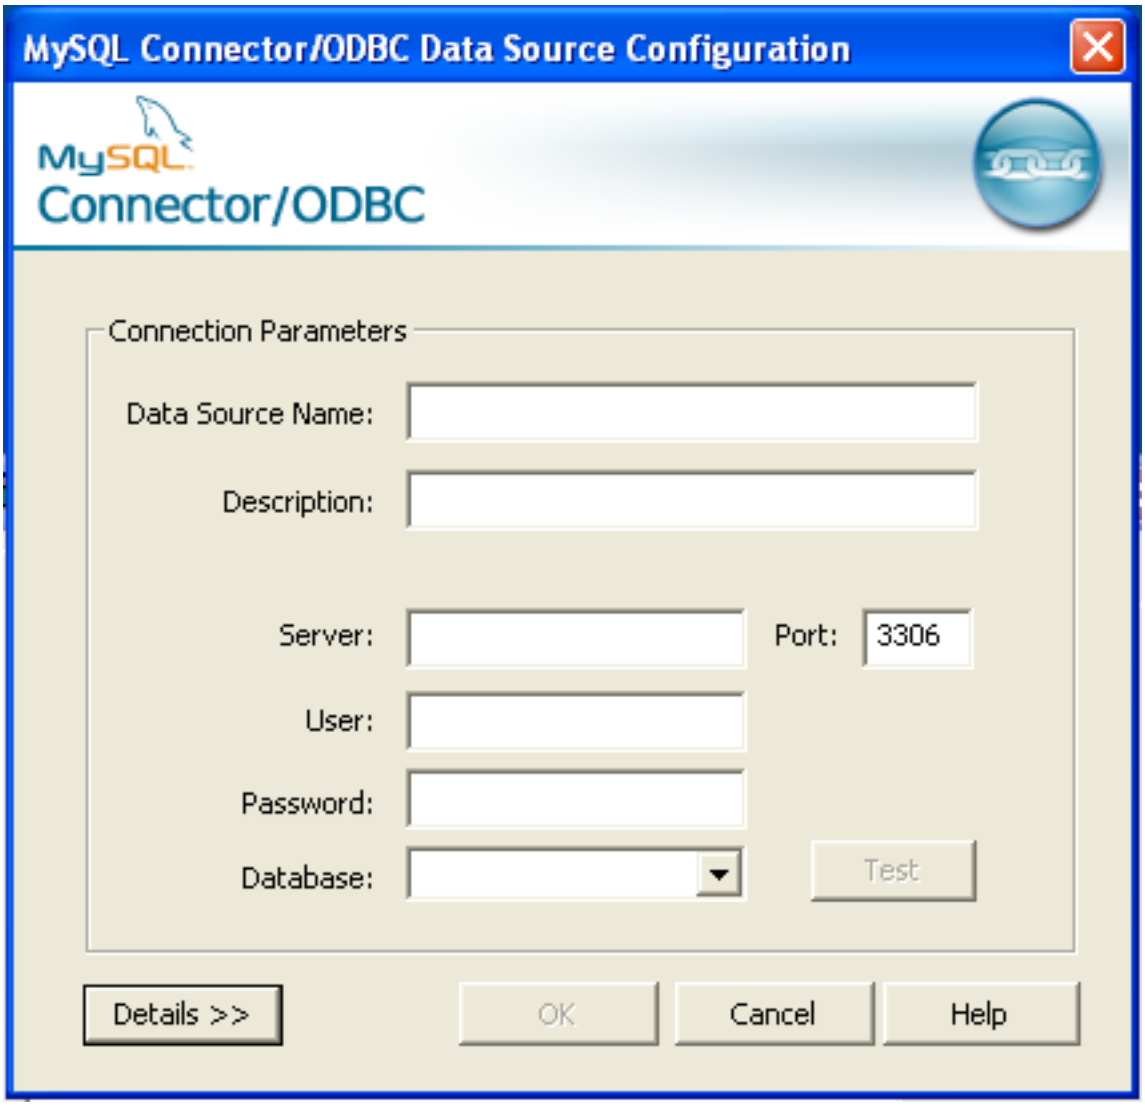
To configure a DSN using the Connector/ODBC 5.1.1 or later driver:

1. Open the `ODBC Data Source Administrator`.
2. To create a System DSN (which will be available to all users) , select the **System DSN** tab. To create a User DSN, which will be unique only to the current user, click the Add... button.
3. You will need to select the ODBC driver for this DSN.



Select `MySQL ODBC 5.1 Driver`, then click FINISH.

4. You now need to configure the specific fields for the DSN you are creating through the `Connection Parameters` dialog.

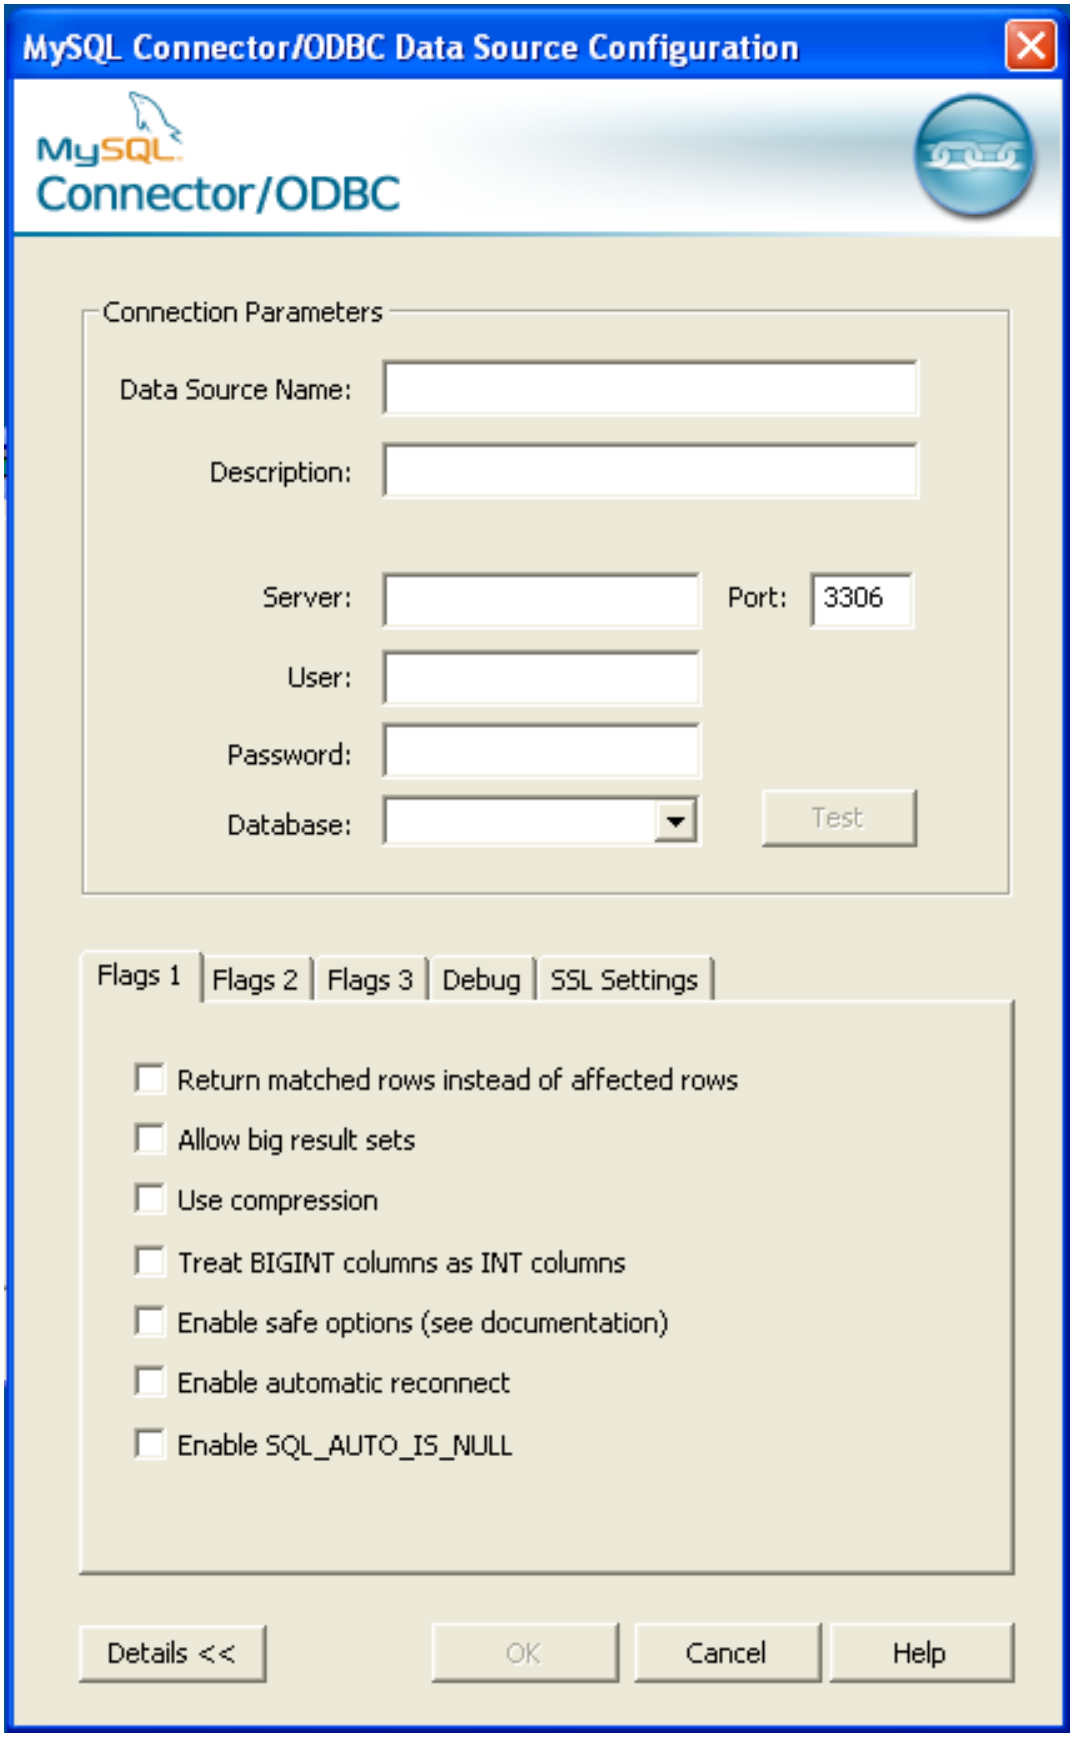


In the **Data Source Name** box, enter the name of the data source you want to access. It can be any valid name that you choose.

5. In the **Description** box, enter some text to help identify the connection.
6. In the **Server** field, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the **User** field, enter the user name to use for this connection.
8. In the **Password** field, enter the corresponding password for this connection.
9. The **Database** pop-up should automatically populate with the list of databases that the user has permissions to access.
10. To communicate over a different TCP/IP port than the default (3306), change the value of the **Port**.
11. Click OK to save the DSN.

You can verify the connection using the parameters you have entered by clicking the Test button. If the connection could be made successfully, you will be notified with a `Success; connection was made!` dialog.

You can configure a number of options for a specific DSN by using the Details button.



MySQL Connector/ODBC Data Source Configuration
MySQL
Connector/ODBC
Connection Parameters
Data Source Name:
Description:
Server:

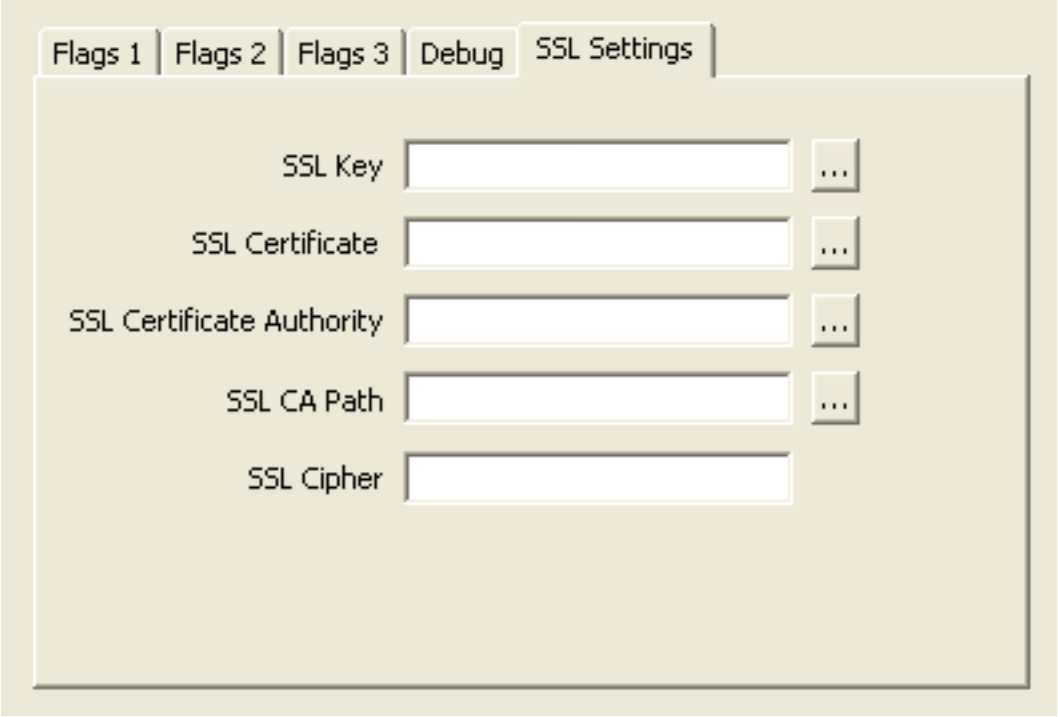
Enable automatic reconnect
Enable SQL_AUTO_IS_NULL
Details <<
OK
Cancel
Help

The **DETAILS** button opens a tabbed display which allows you to set additional options:

- **FLAGS 1**, **FLAGS 2**, and **FLAGS 3** enable you to select the additional flags for the DSN connection. For more information on these flags, see Section 20.1.4.2, "Connector/ODBC Connection Parameters".
- **DEBUG** allows you to enable ODBC debugging to record the queries you execute through the DSN to the `myodbc.sql` file. For more information, see Section 20.1.4.8, "Getting an ODBC Trace File".
- **SSL SETTINGS** configures the additional options required for using the Secure Sockets Layer (SSL) when communicating with MySQL server. Note that you must have enabled SSL and configured the MySQL server with suitable certificates to communicate over SSL.



The ADVANCED tab enables you to configure Connector/ODBC connection parameters. Refer to Section 20.1.4.2, "Connector/ODBC Connection Parameters", for information about the meaning of these options.

20.1.4.3.3. Errors and Debugging

This section answers Connector/ODBC connection-related questions.

- **While configuring a Connector/ODBC DSN, a `Could Not Load Translator or Setup Library` error occurs**

  For more information, refer to MS KnowledgeBase Article(Q260558). Also, make sure you have the latest valid `ctl3d32.dll` in your system directory.

- On Windows, the default `myodbc3.dll` is compiled for optimal performance. If you want to debug Connector/ODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues. Note that the `myodbc3d.dll` isn't included in Connector/ODBC 3.51.07 through 3.51.11. If you are using one of these versions, you should copy that DLL from a previous version (for example, 3.51.06).

20.1.4.4. Configuring a Connector/ODBC DSN on Mac OS X

To configure a DSN on Mac OS X you can either use the `myodbc3i` utility, edit the `odbc.ini` file within the `Library/ODBC` dir-

ectory of the user or the should use the ODBC Administrator. If you have Mac OS X 10.2 or earlier, refer to Section 20.1.4.5, "Configuring a Connector/ODBC DSN on Unix". Select whether you want to create a User DSN or a System DSN. If you want to add a System DSN, you may need to authenticate with the system. You must click the padlock and enter a user and password with administrator privileges.

For correct operation of ODBC Administrator, you should ensure that the `/Library/ODBC/odbc.ini` file used to set up ODBC connectivity and DSNs are writable by the `admin` group. If this file is not writable by this group then the ODBC Administrator may fail, or may appear to have worked but not generated the correct entry.

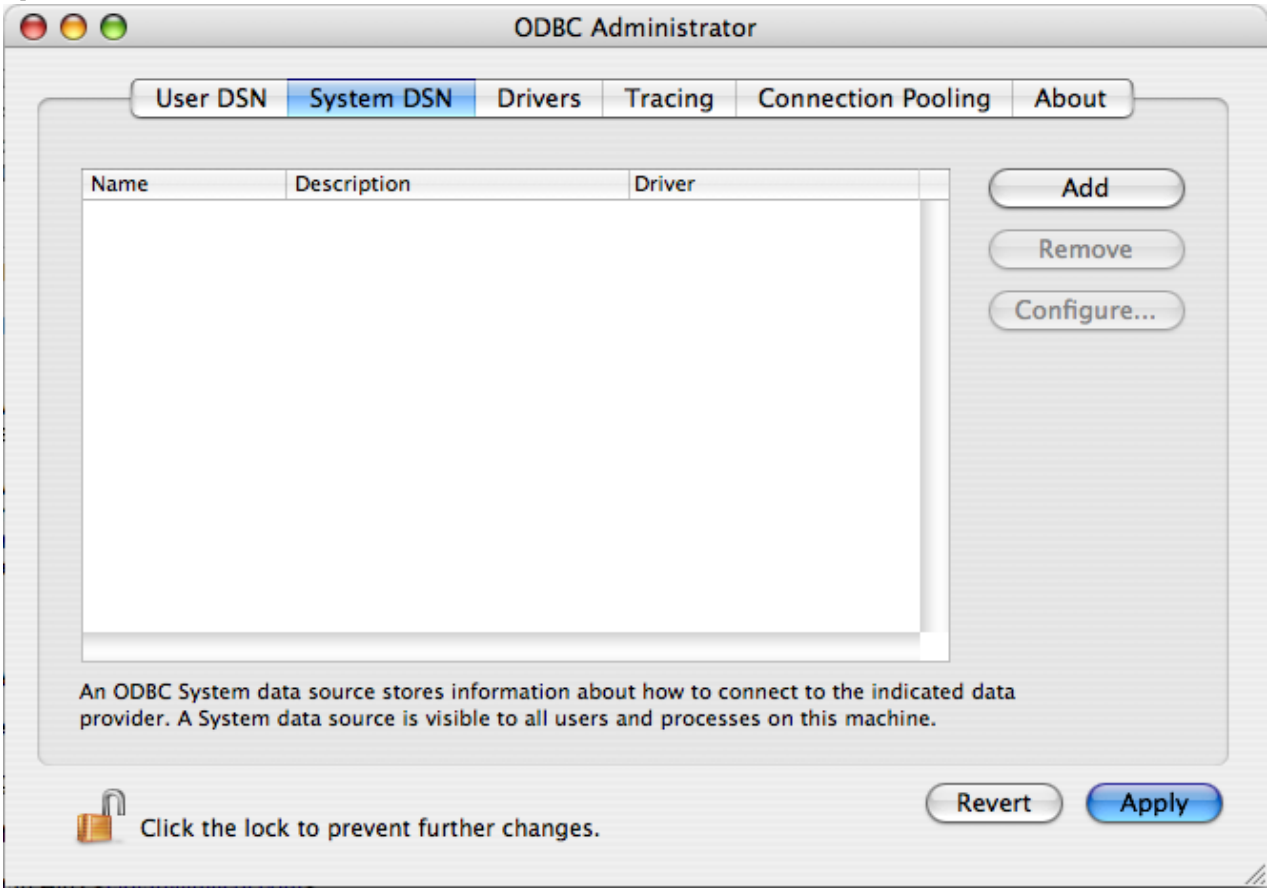
> **Warning**
>
> There are known issues with the OS X ODBC Administrator and Connector/ODBC that may prevent you from creating a DSN using this method. In this case you should use the command-line or edit the `odbc.ini` file directly. Note that existing DSNs or those that you create via the `myodbc3i` or `myodbc-installer`tool can still be checked and edited using ODBC Administrator.

To create a DSN using the `myodbc3i` utility, you need only specify the DSN type and the DSN connection string. For example:

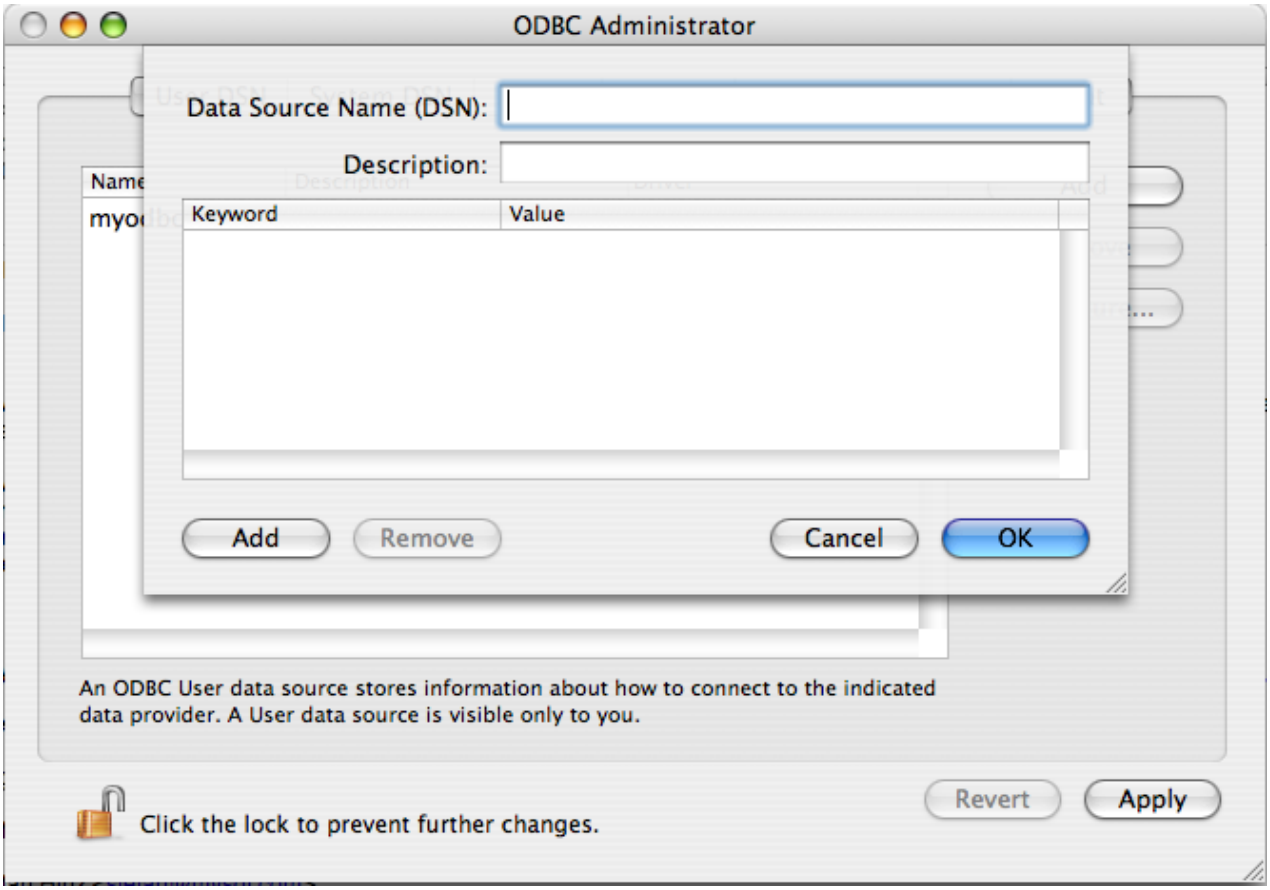
```
shell> myodbc3i -a -s -t"DSN=mydb;DRIVER=MySQL ODBC 3.51 Driver;SERVER=mysql;USER=username;PASSWORD=pass"
```

To use ODBC Administrator:

1. Open the ODBC Administrator from the `Utilities` folder in the `Applications` folder.



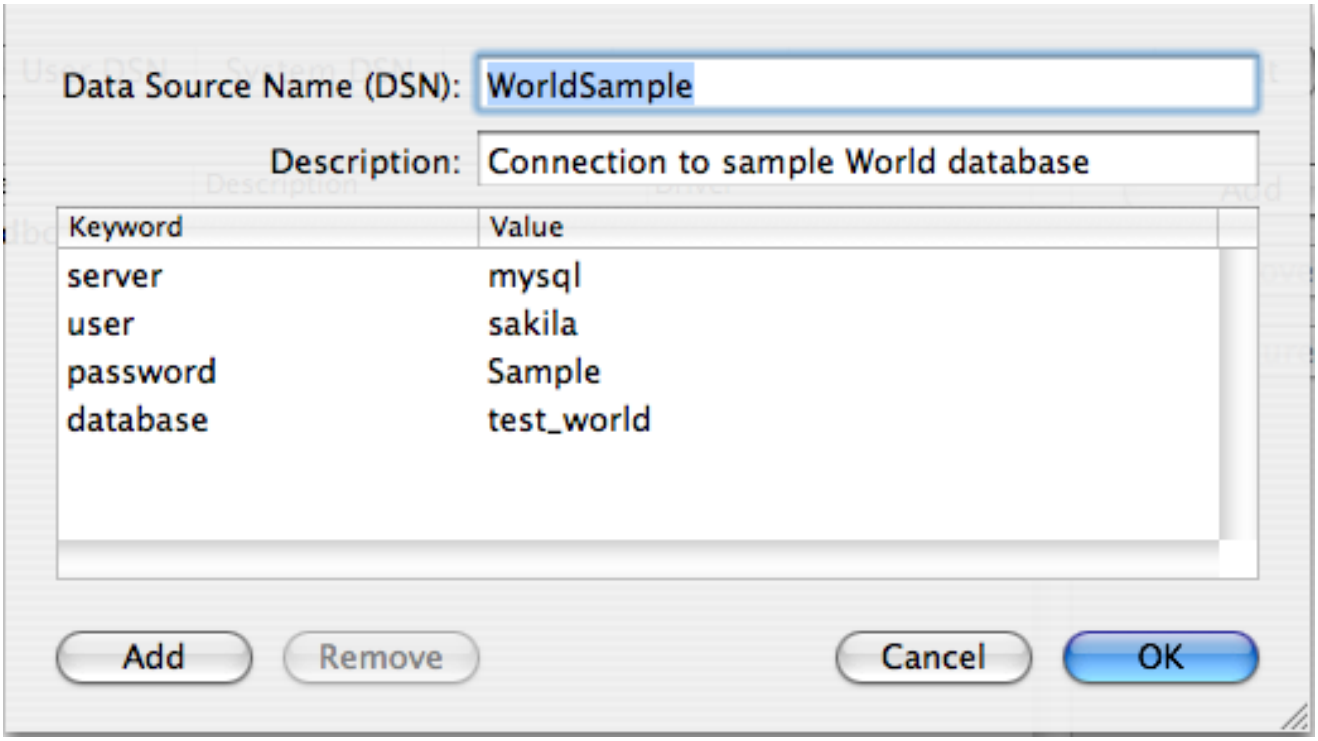
2. On the User DSN or System DSN panel, click ADD.
3. Select the Connector/ODBC driver and click OK.
4. You will be presented with the `Data Source Name` dialog. Enter The `Data Source Name` and an optional `Description` for the DSN.



5. Click ADD to add a new keyword/value pair to the panel. You should configure at least four pairs to specify the `server`, `username`, `password` and `database` connection parameters. See Section 20.1.4.2, "Connector/ODBC Connection Parameters".

6. Click OK to add the DSN to the list of configured data source names.

A completed DSN configuration may look like this:



You can configure other ODBC options in your DSN by adding further keyword/value pairs and setting the corresponding values. See Section 20.1.4.2, “Connector/ODBC Connection Parameters”.

20.1.4.5. Configuring a Connector/ODBC DSN on Unix

On `Unix`, you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc3` as the DSN name for Connector/ODBC 3.51:

```
;
;  odbc.ini configuration for Connector/ODBC and Connector/ODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc3     = MyODBC 3.51 Driver DSN

[myodbc3]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER       = localhost
PORT         =
USER         = root
Password     =
Database     = test
OPTION       = 3
SOCKET       =

[Default]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = Connector/ODBC 3.51 Driver DSN
SERVER       = localhost
PORT         =
USER         = root
Password     =
Database     = test
OPTION       = 3
SOCKET       =
```

Refer to the Section 20.1.4.2, “Connector/ODBC Connection Parameters”, for the list of connection parameters that can be supplied.

> **Note**
>
> If you are using `unixODBC`, you can use the following tools to set up the DSN:

- ODBCConfig GUI tool(HOWTO: ODBCConfig)
- odbcinst

In some cases when using `unixODBC`, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the `ODBCINI` and `ODBCSYSINI` environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

20.1.4.6. Connecting Without a Predefined DSN

You can connect to the MySQL server using SQLDriverConnect, by specifying the `DRIVER` name field. Here are the connection strings for Connector/ODBC using DSN-Less connections:

For Connector/ODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
                   SERVER=localhost;\
                   DATABASE=test;\
                   USER=venu;\
                   PASSWORD=venu;\
                   OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
                   "SERVER=localhost;"
                   "DATABASE=test;"
                   "USER=venu;"
                   "PASSWORD=venu;"
                   "OPTION=3;"
```

Note. Note that on Mac OS X you may need to specify the full path to the Connector/ODBC driver library.

Refer to the Section 20.1.4.2, “Connector/ODBC Connection Parameters”, for the list of connection parameters that can be supplied.

20.1.4.7. ODBC Connection Pooling

Connection pooling enables the ODBC driver to re-use existing connections to a given database from a pool of connections, instead of opening a new connection each time the database is accessed. By enabling connection pooling you can improve the overall performance of your application by lowering the time taken to open a connection to a database in the connection pool.

For more information about connection pooling: http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470.

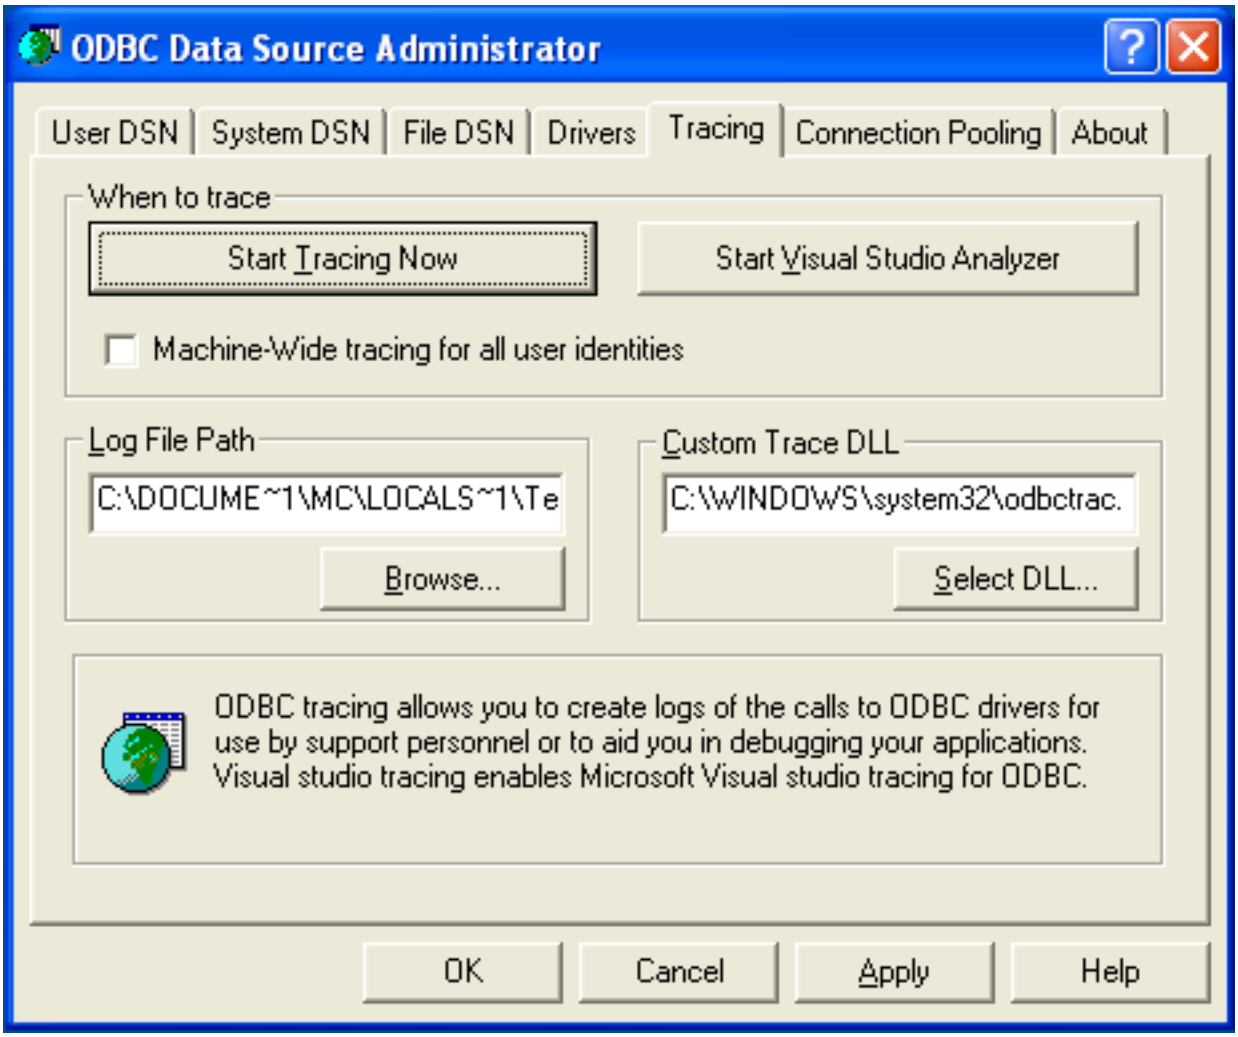
20.1.4.8. Getting an ODBC Trace File

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the `ODBC Manager` and Connector/ODBC. This is called *tracing*, and is enabled through the ODBC Manager. The procedure for this differs for Windows, Mac OS X and Unix.

20.1.4.8.1. Enabling ODBC Tracing on Windows

To enable the trace option on Windows:

1. The `Tracing` tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.



2. When you activate tracing from the `Tracing` tab, the `Driver Manager` logs all ODBC function calls for all subsequently run applications.

3. ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.

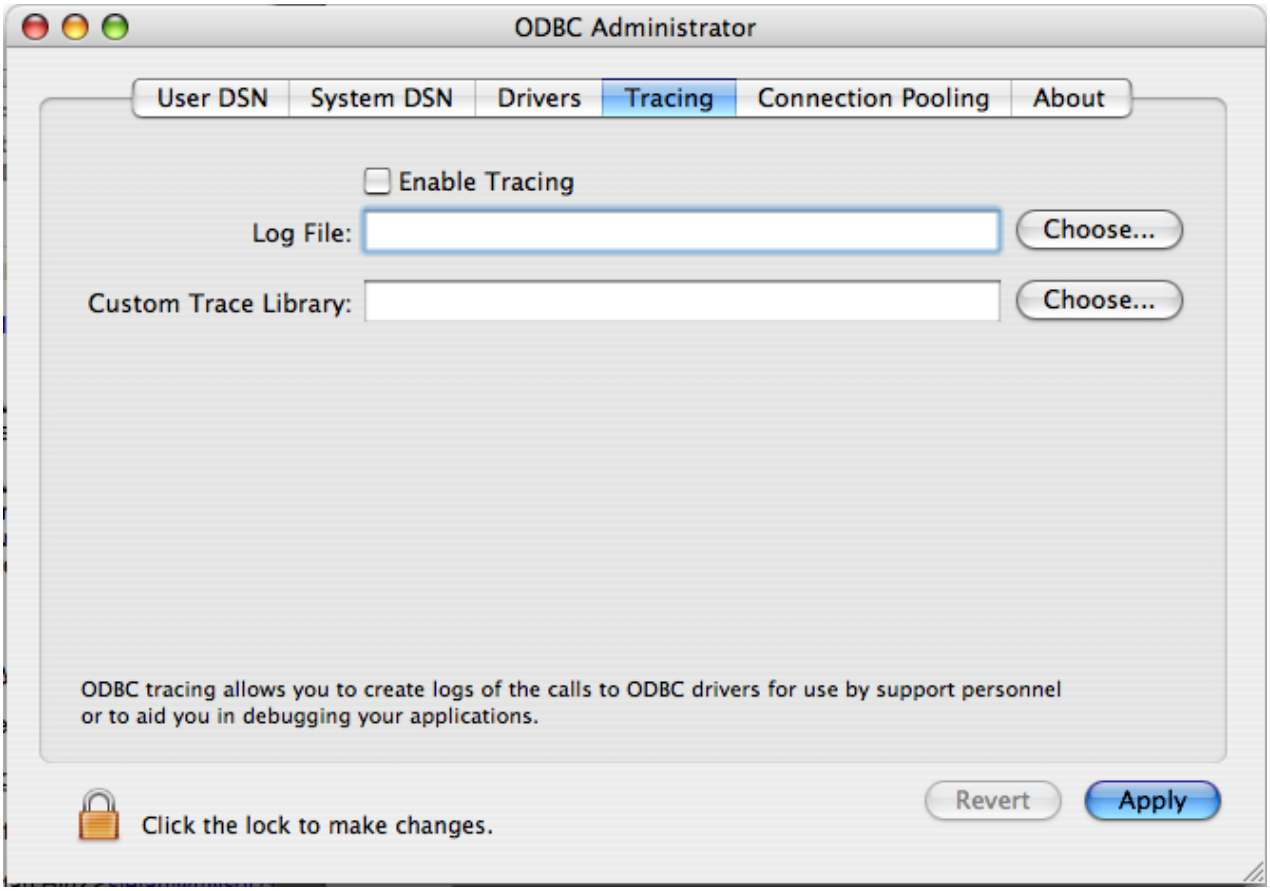
4. Tracing ceases only after you click `Stop Tracing Now`. Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

20.1.4.8.2. Enabling ODBC Tracing on Mac OS X

To enable the trace option on Mac OS X 10.3 or later you should use the `Tracing` tab within ODBC Administrator .

1. Open the ODBC Administrator.

2. Select the `Tracing` tab.



3. Select the `Enable Tracing` checkbox.

4. Enter the location where you want to save the Tracing log. If you want to append information to an existing log file, click the CHOOSE... button.

20.1.4.8.3. Enabling ODBC Tracing on Unix

To enable the trace option on Mac OS X 10.2 (or earlier) or Unix you must add the `trace` option to the ODBC configuration:

1. On Unix, you need to explicitly set the `Trace` option in the `ODBC.INI` file.

   Set the tracing `ON` or `OFF` by using `TraceFile` and `Trace` parameters in `odbc.ini` as shown below:

   ```
   TraceFile  = /tmp/odbc.trace
   Trace      = 1
   ```

   `TraceFile` specifies the name and full path of the trace file and `Trace` is set to `ON` or `OFF`. You can also use `1` or `YES` for `ON` and `0` or `NO` for `OFF`. If you are using `ODBCConfig` from `unixODBC`, then follow the instructions for tracing `unixODBC` calls at HOWTO-ODBCConfig.

20.1.4.8.4. Enabling a Connector/ODBC Log

To generate a Connector/ODBC log, do the following:

1. Within Windows, enable the `Trace Connector/ODBC` option flag in the Connector/ODBC connect/configure screen. The log is written to file `C:\myodbc.log`. If the trace option is not remembered when you are going back to the above screen, it means

that you are not using the `myodbcd.dll` driver, see Section 20.1.4.3.3, “Errors and Debugging”.

On Mac OS X, Unix, or if you are using DSN-Less connection, then you need to supply `OPTION=4` in the connection string or set the corresponding keyword/value pair in the DSN.

2. Start your application and try to get it to fail. Then check the Connector/ODBC trace file to find out what could be wrong.

If you need help determining what is wrong, see Section 20.1.8.1, “Connector/ODBC Community Support”.

20.1.5. Connector/ODBC Examples

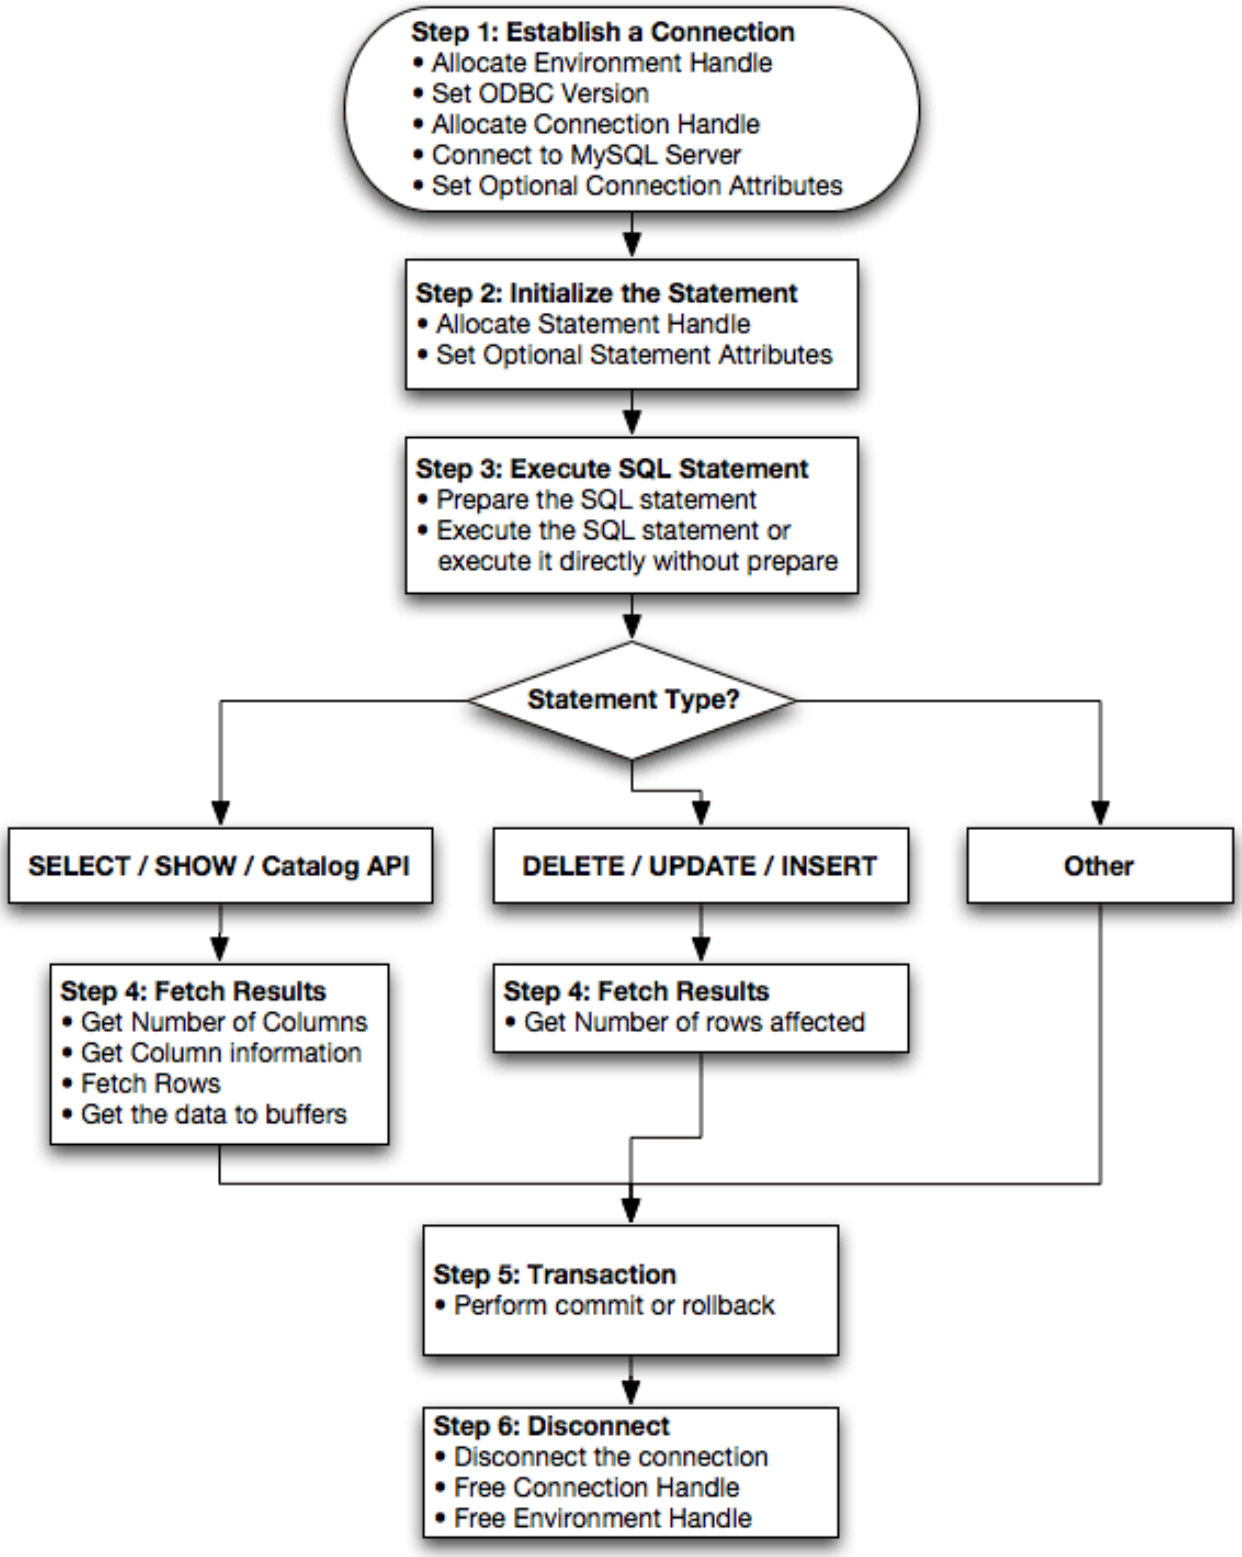
Once you have configured a DSN to provide access to a database, how you access and use that connection is dependent on the application or programming language. As ODBC is a standardized interface, any application or language that supports ODBC can use the DSN and connect to the configured database.

20.1.5.1. Basic Connector/ODBC Application Steps

Interacting with a MySQL server from an applications using the Connector/ODBC typically involves the following operations:

- Configure the Connector/ODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:



20.1.5.2. Step-by-step Guide to Connecting to a MySQL Database through Connector/ODBC

A typical installation situation where you would install Connector/ODBC is when you want to access a database on a Linux or Unix host from a Windows machine.

As an example of the process required to set up access between two machines, the steps below take you through the basic steps. These instructions assume that you want to connect to system ALPHA from system BETA with a user name and password of `myuser` and `mypassword`.

On system ALPHA (the MySQL server) follow these steps:

1. Start the MySQL server.

2. Use `GRANT` to set up an account with a user name of `myuser` that can connect from system BETA using a password of `myuser` to the database `test`:

   ```
   GRANT ALL ON test.* to 'myuser'@'BETA' IDENTIFIED BY 'mypassword';
   ```

   For more information about MySQL privileges, refer to Section 5.5, “MySQL User Account Management”.

On system BETA (the Connector/ODBC client), follow these steps:

1. Configure a Connector/ODBC DSN using parameters that match the server, database and authentication information that you have just configured on system ALPHA.

Parameter	Value	Comment
DSN	remote_test	A name to identify the connection.
SERVER	ALPHA	The address of the remote server.
DATABASE	test	The name of the default database.
USER	myuser	The user name configured for access to this database.
PASSWORD	mypassword	The password for `myuser`.

2. Using an ODBC-capable application, such as Microsoft Office, connect to the MySQL server using the DSN you have just created. If the connection fails, use tracing to examine the connection process. See Section 20.1.4.8, “Getting an ODBC Trace File”, for more information.

20.1.5.3. Connector/ODBC and Third-Party ODBC Tools

Once you have configured your Connector/ODBC DSN, you can access your MySQL database through any application that supports the ODBC interface, including programming languages and third-party applications. This section contains guides and help on using Connector/ODBC with various ODBC-compatible tools and applications, including Microsoft Word, Microsoft Excel and Adobe/Macromedia ColdFusion.

Connector/ODBC has been tested with the following applications.

Publisher	Application	Notes
Adobe	ColdFusion	Formerly Macromedia ColdFusion
Borland	C++ Builder	
	Builder 4	
	Delphi	
Business Objects	Crystal Reports	
Claris	Filemaker Pro	
Corel	Paradox	
Computer Associates	Visual Objects	Also known as CAVO
	AllFusion ERwin Data Modeler	

Gupta	Team Developer	Previously known as Centura Team Developer; Gupta SQL/ Windows
Gensym	G2-ODBC Bridge	
Inline	iHTML	
Lotus	Notes	Versions 4.5 and 4.6
Microsoft	Access	
	Excel	
	Visio Enterprise	
	Visual C++	
	Visual Basic	
	ODBC.NET	Using C#, Visual Basic, C++
	FoxPro	
	Visual Interdev	
OpenOffice.org	OpenOffice.org	
Perl	DBD::ODBC	
Pervasive Software	DataJunction	
Sambar Technologies	Sambar Server	
SPSS	SPSS	
SoftVelocity	Clarion	
SQLExpress	SQLExpress for Xbase++	
Sun	StarOffice	
SunSystems	Vision	
Sybase	PowerBuilder	
	PowerDesigner	
theKompany.com	Data Architect	

If you know of any other applications that work with Connector/ODBC, please send mail to <myodbc@lists.mysql.com> about them.

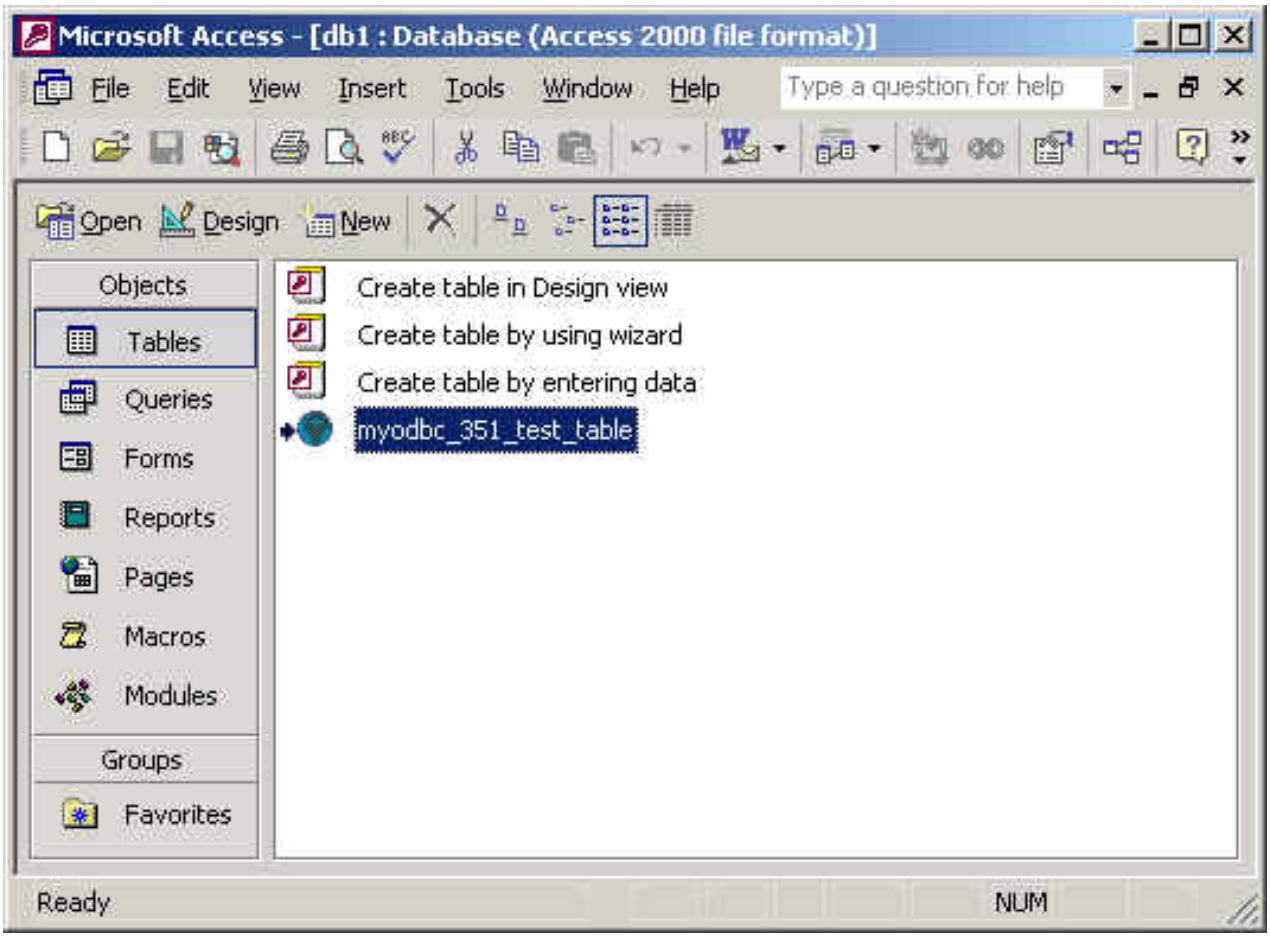
20.1.5.4. Using Connector/ODBC with Microsoft Access

You can use MySQL database with Microsoft Access using Connector/ODBC. The MySQL database can be used as an import source, an export source, or as a linked table for direct use within an Access application, so you can use Access as the front-end interface to a MySQL database.

20.1.5.4.1. Exporting Access Data to MySQL

To export a table of data from an Access database to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.



2. Click the name of the `table` or `query` you want to export, and then in the `File` menu, select `Export`.

3. In the `Export Object Type` *`Object name`* `To` dialog box, in the `Save As Type` box, select `ODBC Databases ()` as shown here:

4. In the `Export` dialog box, enter a name for the file (or use the suggested name), and then select `OK`.

5. The Select Data Source dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the File Data Source or Machine Data Source tab, and then double-click the Connector/ODBC or Connector/ODBC 3.51 data source that you want to export to. To define a new data source for Connector/ODBC, please Section 20.1.4.3, “Configuring a Connector/ODBC DSN on Windows”.

> **Note**
>
> Ensure that the information that you are exporting to the MySQL table is valid for the corresponding MySQL data types.

Values that are outside of the supported range of the MySQL data type but valid within Access may trigger an “overflow” error during the export.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

20.1.5.4.2. Importing MySQL Data to Access

To import a table or tables from MySQL to Access, follow these instructions:

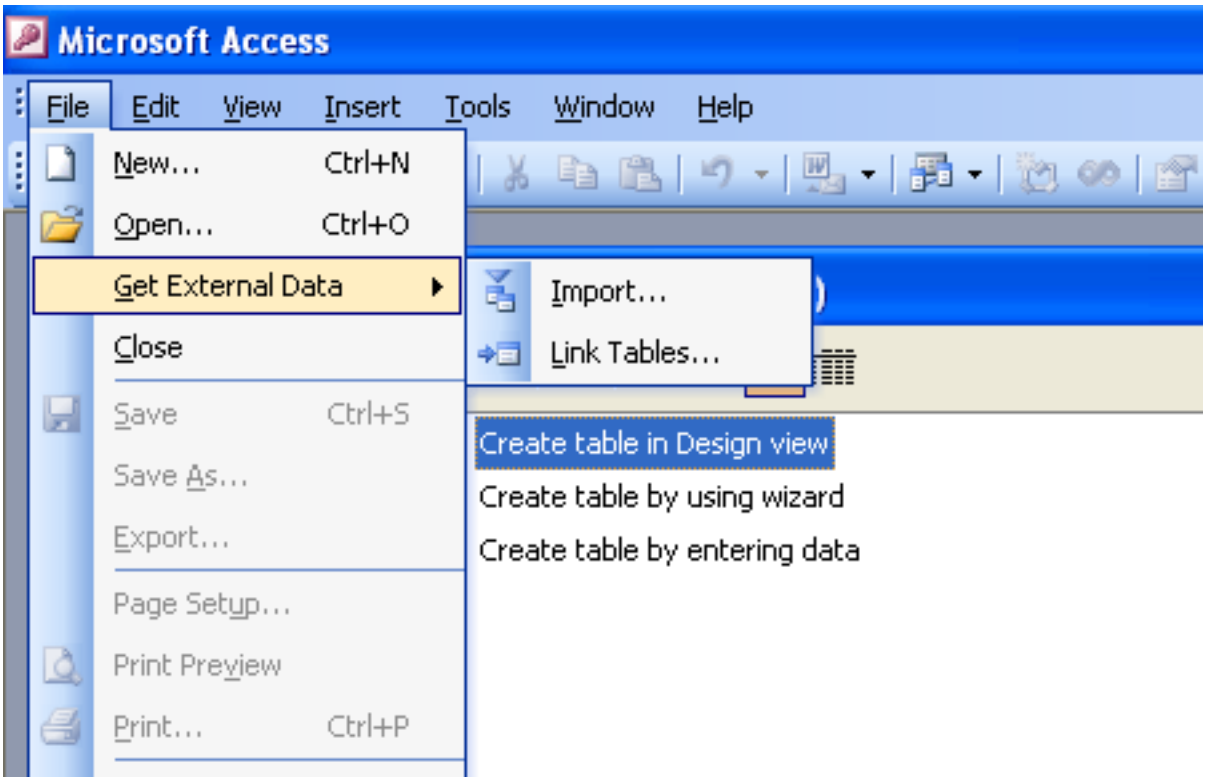
1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the `File` menu, point to `Get External Data`, and then click `Import`.
3. In the `Import` dialog box, in the Files Of Type box, select **ODBC DATABASES ()**. The Select Data Source dialog box lists the defined data sources **THE SELECT DATA SOURCE** dialog box is displayed; it lists the defined data source names.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click `OK`.
5. Microsoft Access connects to the MySQL server through `ODBC data source` and displays the list of tables that you can `import`.
6. Click each table that you want to `import`, and then click `OK`.

20.1.5.4.3. Using Microsoft Access as a Front-end to MySQL

You can use Microsoft Access as a front end to a MySQL database by linking tables within your Microsoft Access database to tables that exist within your MySQL database. When a query is requested on a table within Access, ODBC is used to execute the queries on the MySQL database instead.

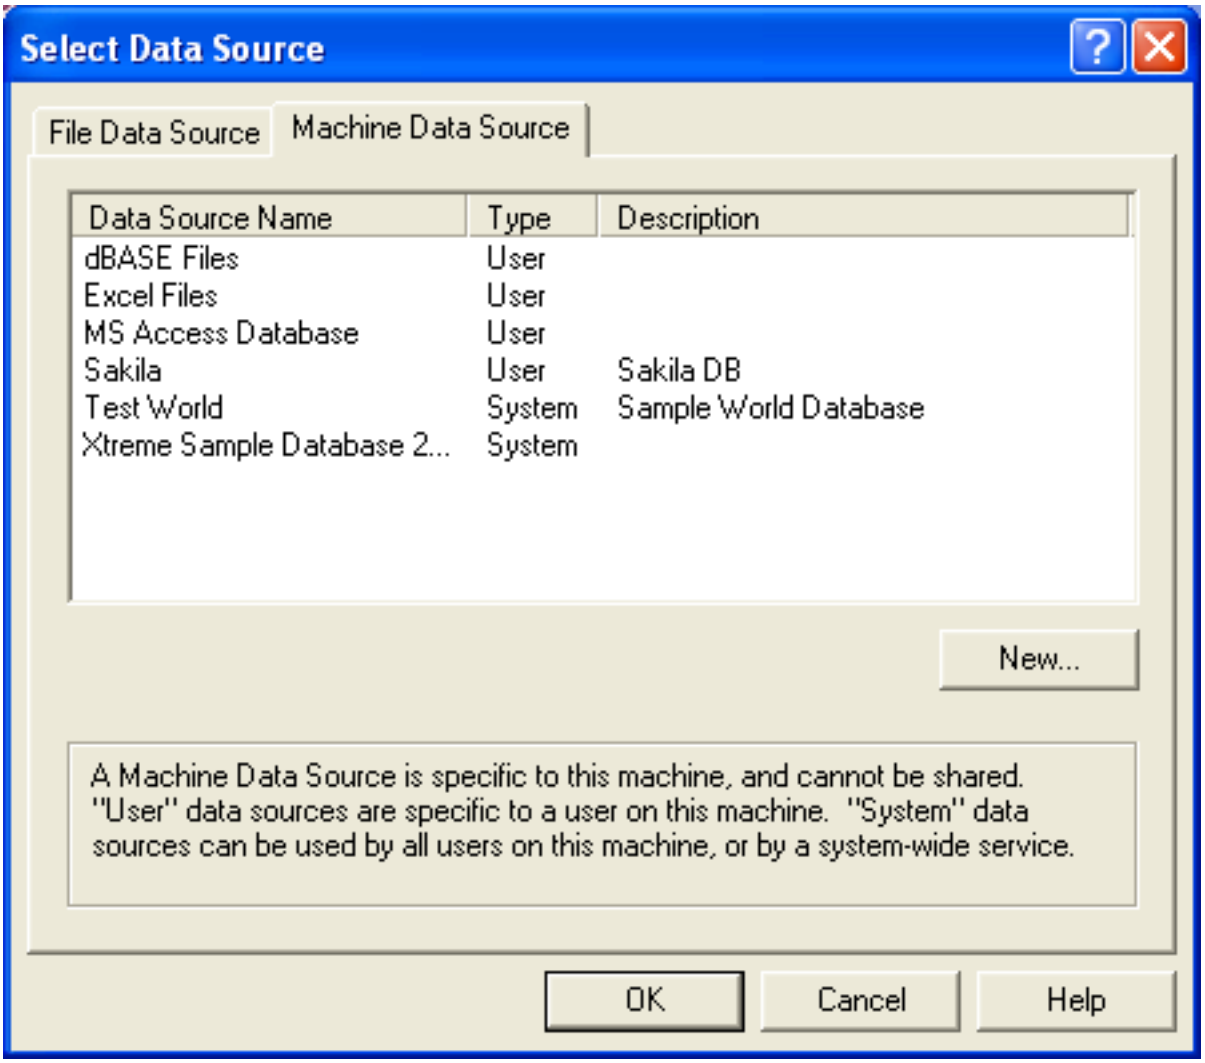
To create a linked table:

1. Open the Access database that you want to link to MySQL.
2. From the FILE, choose GET EXTERNAL DATA->LINK TABLES.

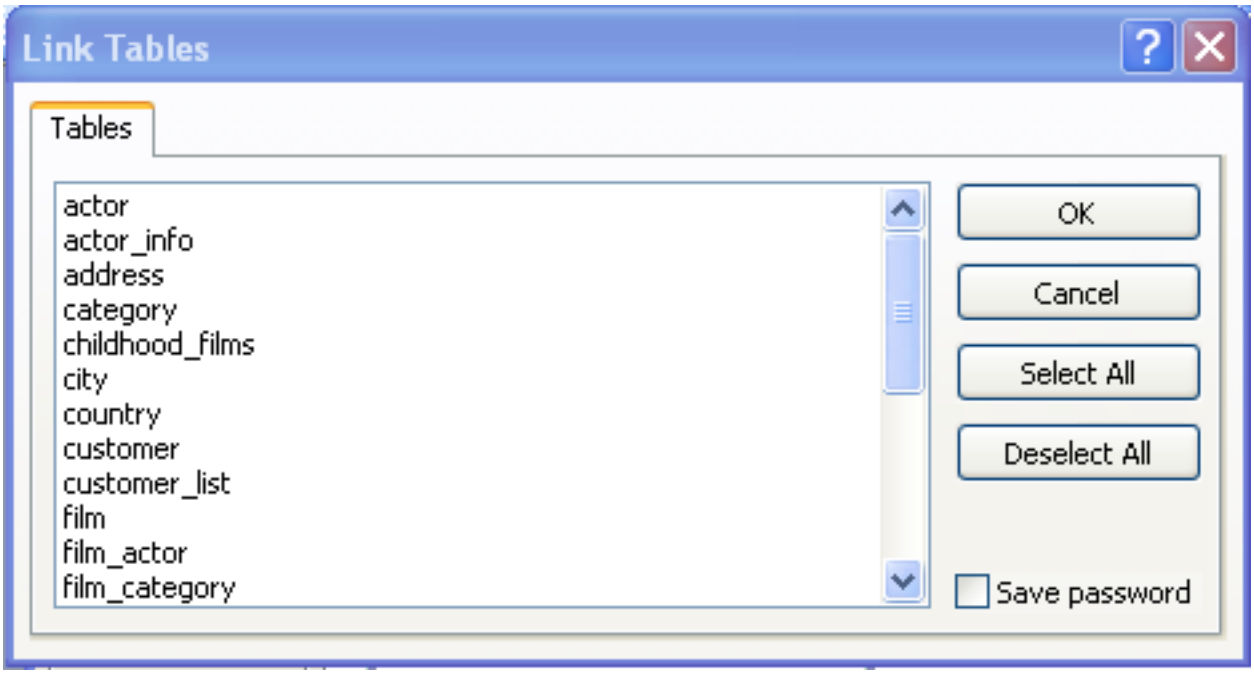


3. From the browser, choose **ODBC DATABASES ()** from the **FILES OF TYPE** pop-up.

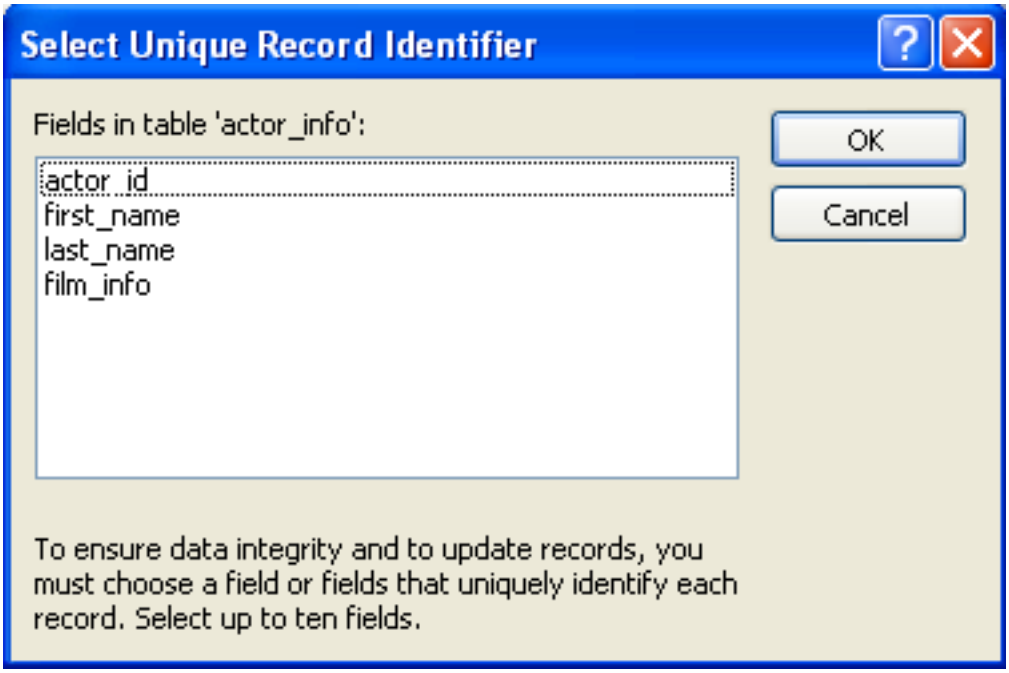
4. In the **SELECT DATA SOURCE** window, choose an existing DSN, either from a **FILE DATA SOURCE** or **MACHINE DATA SOURCE**.You can also create a new DSN using the NEW... button. For more information on creating a DSN see Section 20.1.4.3, “Configuring a Connector/ODBC DSN on Windows”.



5. In the **LINK TABLES** dialog, select one or more tables from the MySQL database. A link will be created to each table that you select from this list.



6. If Microsoft Access is unable to determine the unique record identifier for a table automatically then it may ask you to confirm the column, or combination of columns, to be used to uniquely identify each row from the source table. Select the columns you want to use and click OK.



Once the process has been completed, you can now build interfaces and queries to the linked tables just as you would for any Access database.

Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

To view or refresh links:

1. Open the database that contains links to MySQL tables.
2. On the Tools menu, point to Add-ins (Database Utilities in Access 2000 or newer), and then click Linked Table Manager.
3. Select the check box for the tables whose links you want to refresh.
4. Click OK to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the Select New Location of <table name> dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

To change the path for a set of linked tables:

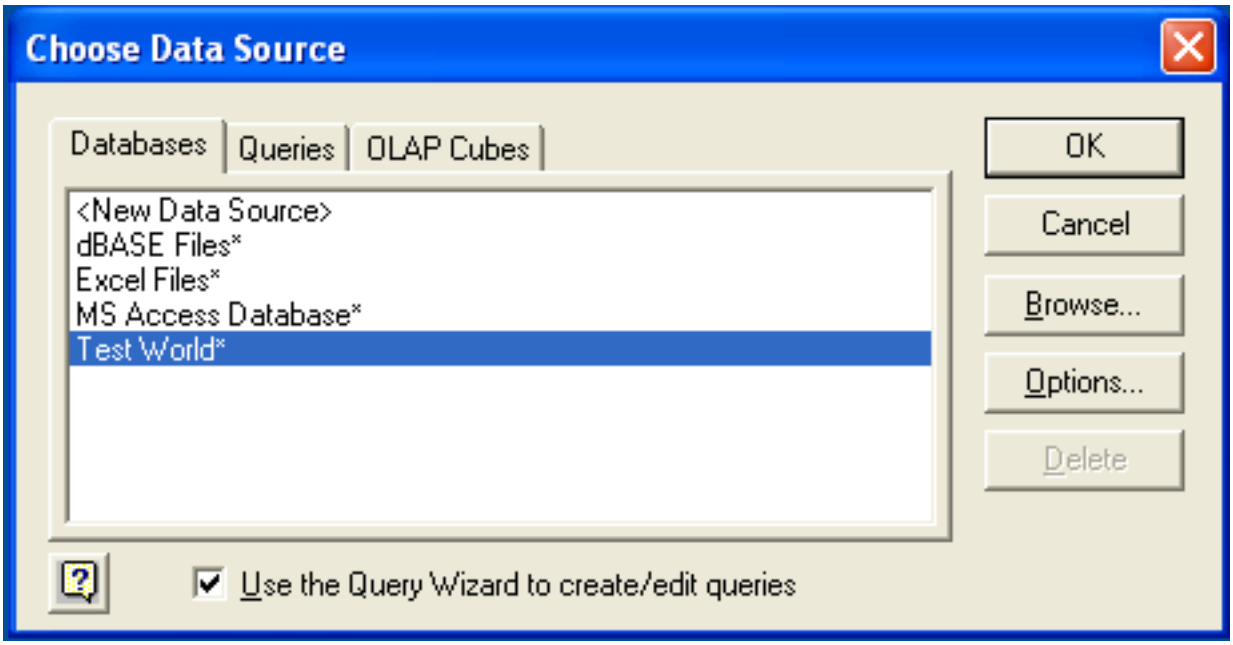
1. Open the database that contains links to tables.
2. On the Tools menu, point to Add-ins (Database Utilities in Access 2000 or newer), and then click Linked Table Manager.
3. Select the Always Prompt For A New Location check box.
4. Select the check box for the tables whose links you want to change, and then click OK.
5. In the Select New Location of <table name> dialog box, specify the new location, click Open, and then click OK.

20.1.5.5. Using Connector/ODBC with Microsoft Word or Excel

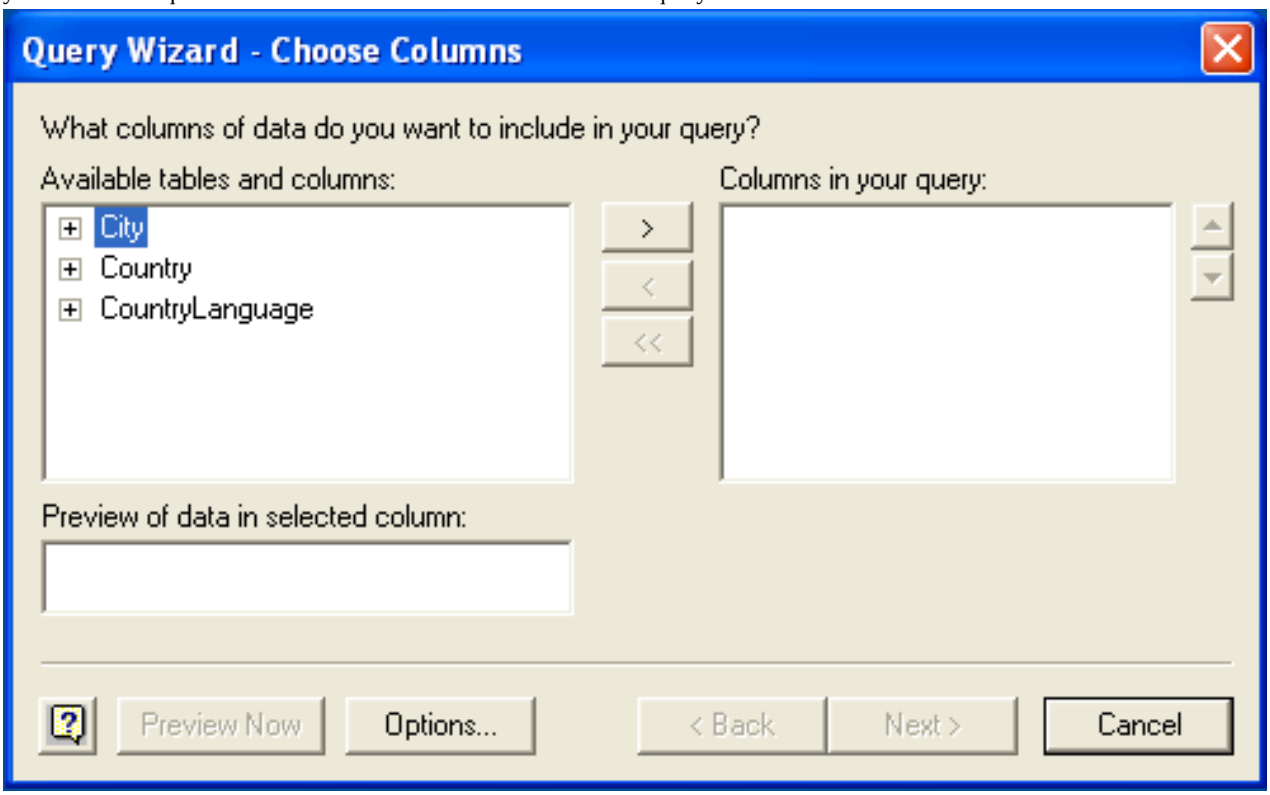
You can use Microsoft Word and Microsoft Excel to access information from a MySQL database using Connector/ODBC. Within Microsoft Word, this facility is most useful when importing data for mailmerge, or for tables and data to be included in reports. Within Microsoft Excel, you can execute queries on your MySQL server and import the data directly into an Excel Worksheet, presenting the data as a series of rows and columns.

With both applications, data is accessed and imported into the application using Microsoft Query , which enables you to execute a query though an ODBC source. You use Microsoft Query to build the SQL statement to be executed, selecting the tables, fields, selection criteria and sort order. For example, to insert information from a table in the World test database into an Excel spreadsheet, using the DSN samples shown in Section 20.1.4, “Connector/ODBC Configuration”:

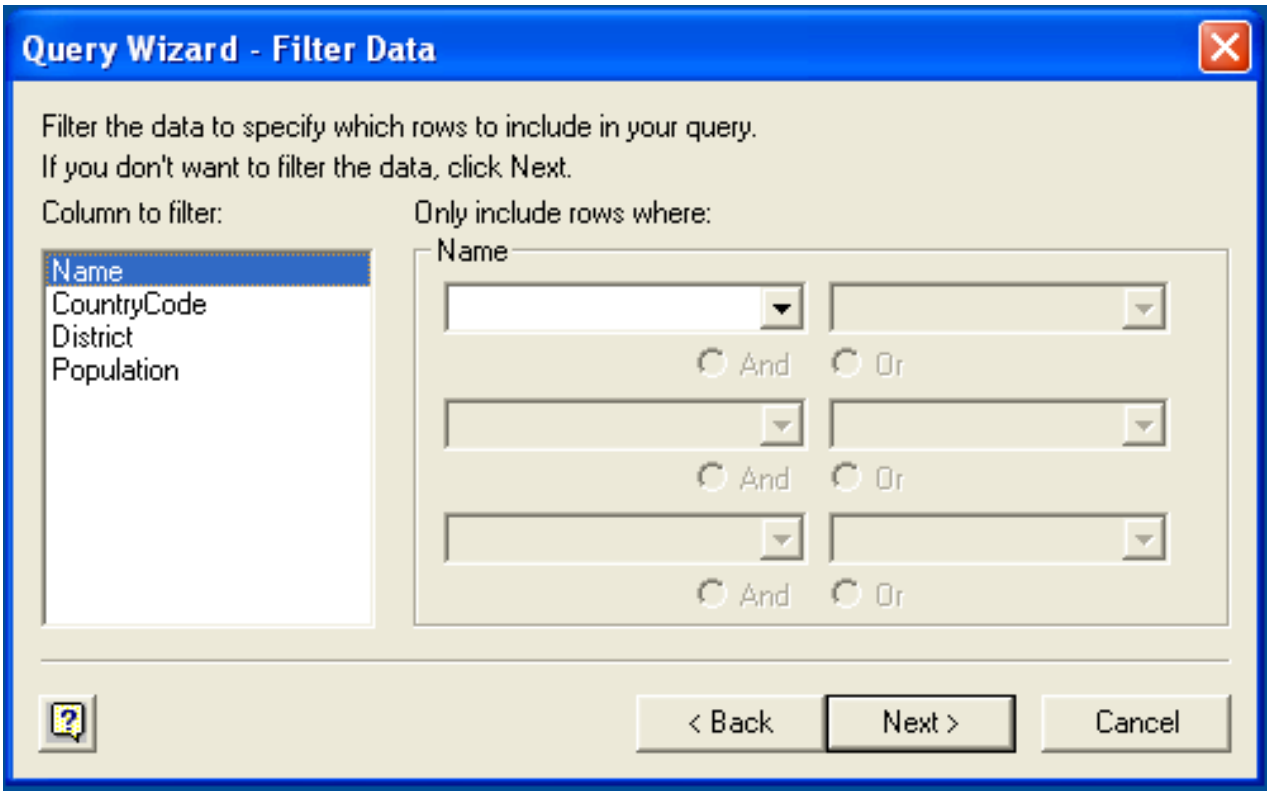
1. Create a new Worksheet.
2. From the Data menu, choose Import External Data, and then select New Database Query.
3. Microsoft Query will start. First, you need to choose the data source, by selecting an existing Data Source Name.



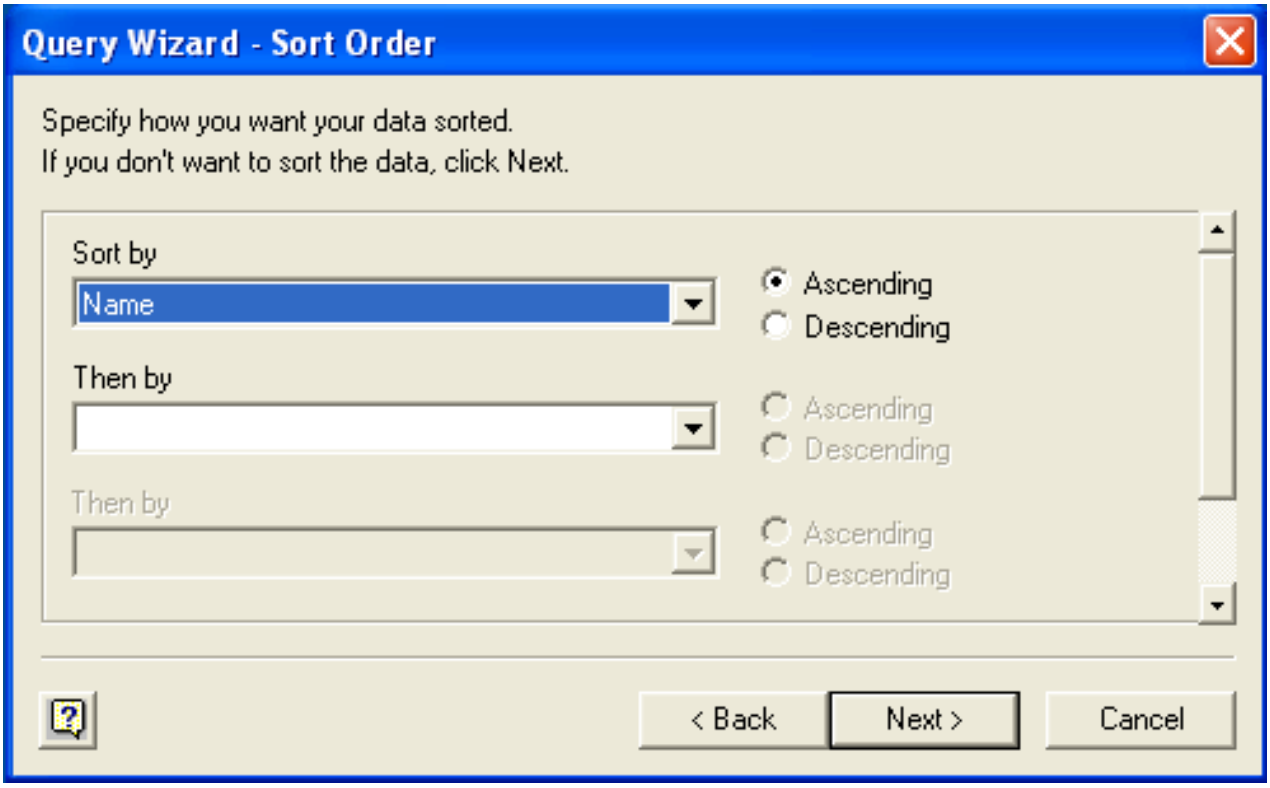
4. Within the `Query Wizard`, you must choose the columns that you want to import. The list of tables available to the user configured through the DSN is shown on the left, the columns that will be added to your query are shown on the right. The columns you choose are equivalent to those in the first section of a `SELECT` query. Click NEXT to continue.



5. You can filter rows from the query (the equivalent of a `WHERE` clause) using the `Filter Data` dialog. Click NEXT to continue.

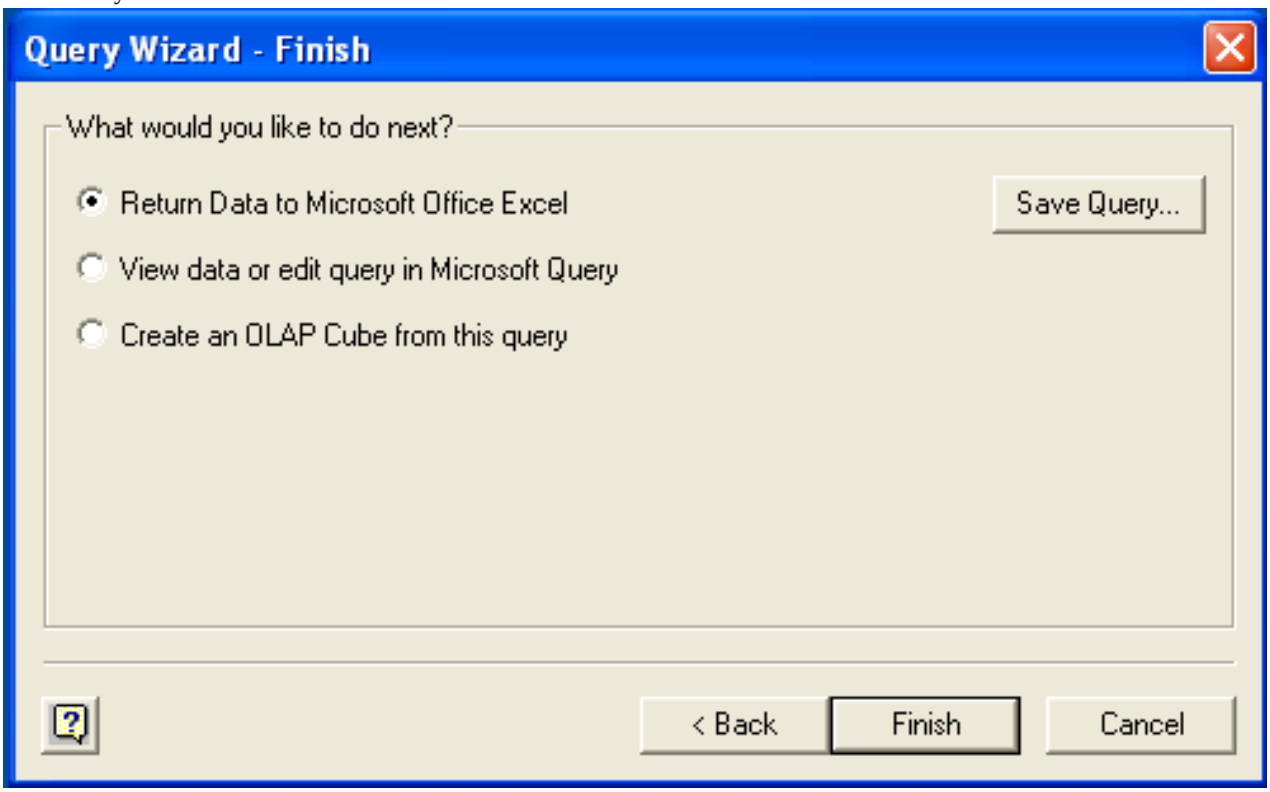


6. Select an (optional) sort order for the data. This is equivalent to using a `ORDER BY` clause in your SQL query. You can select up to three fields for sorting the information returned by the query. Click NEXT to continue.



7. Select the destination for your query. You can select to return the data Microsoft Excel, where you can choose a worksheet and cell

where the data will be inserted; you can continue to view the query and results within Microsoft Query, where you can edit the SQL query and further filter and sort the information returned; or you can create an OLAP Cube from the query, which can then be used directly within Microsoft Excel. Click FINISH.



The same process can be used to import data into a Word document, where the data will be inserted as a table. This can be used for mail merge purposes (where the field data is read from a Word table), or where you want to include data and reports within a report or other document.

20.1.5.6. Using Connector/ODBC with Crystal Reports

Crystal Reports can use an ODBC DSN to connect to a database from which you to extract data and information for reporting purposes.

> **Note**
>
> There is a known issue with certain versions of Crystal Reports where the application is unable to open and browse tables and fields through an ODBC connection. Before using Crystal Reports with MySQL, please ensure that you have update to the latest version, including any outstanding service packs and hotfixes. For more information on this issue, see the Business) Objects Knowledgebase for more information.

For example, to create a simple crosstab report within Crystal Reports XI, you should follow these steps:

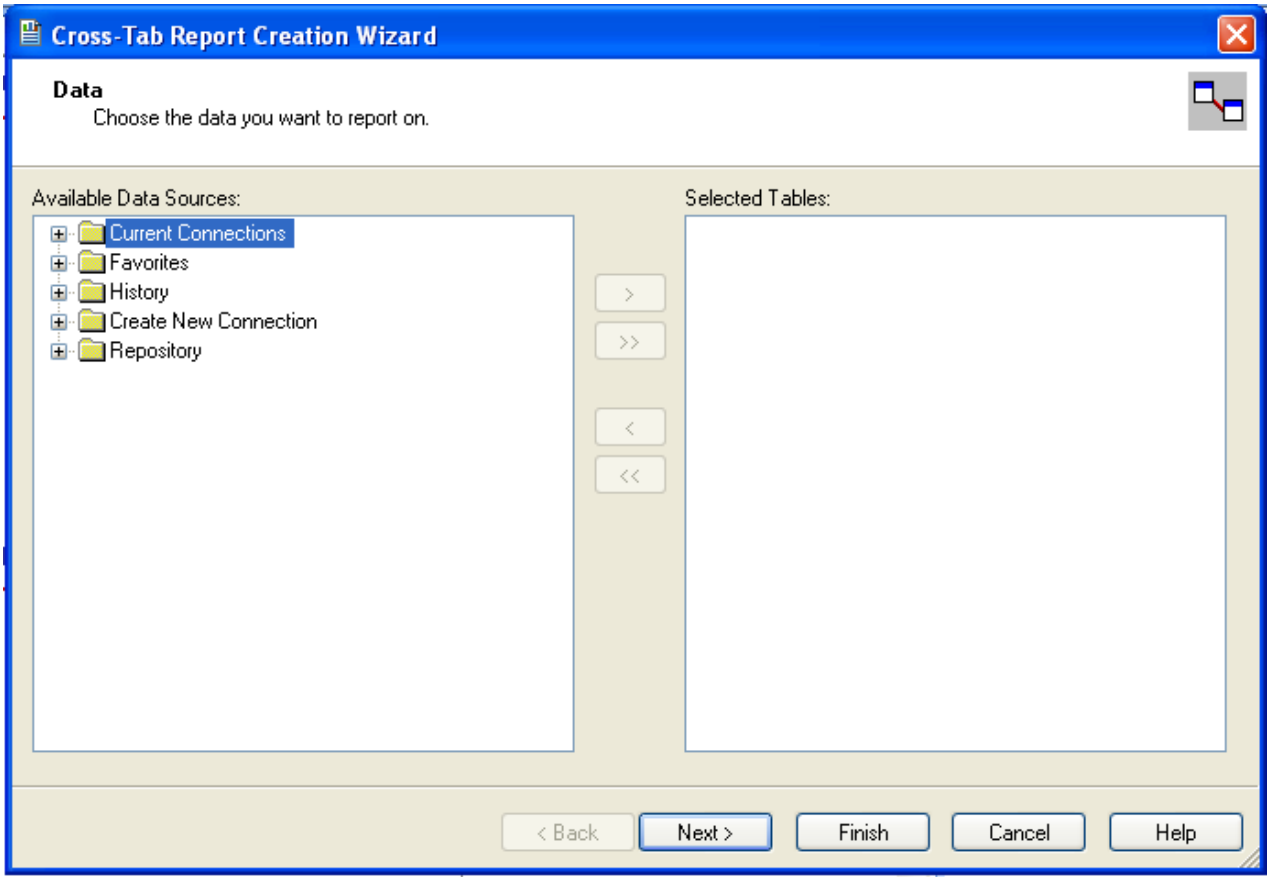
1. Create a DSN using the `Data Sources (ODBC)` tool. You can either specify a complete database, including user name and password, or you can build a basic DSN and use Crystal Reports to set the user name and password.

   For the purposes of this example, a DSN that provides a connection to an instance of the MySQL Sakila sample database has been created.

2. Open Crystal Reports and create a new project, or an open an existing reporting project into which you want to insert data from your MySQL data source.

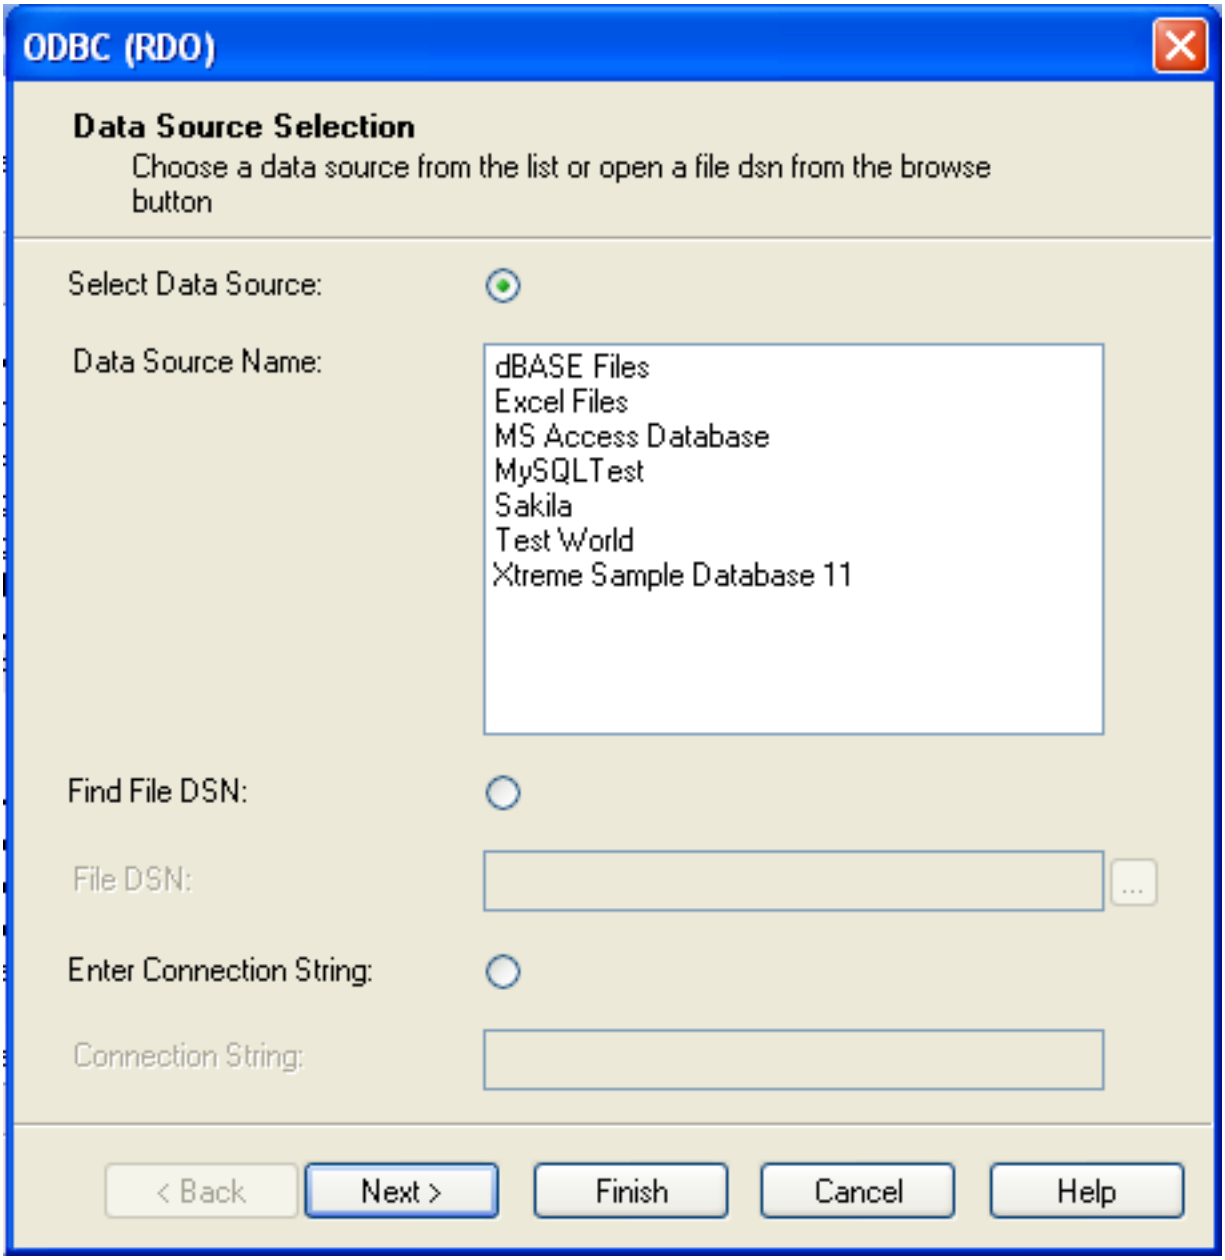
3. Start the Cross-Tab Report Wizard, either by clicking the option on the Start Page. Expand the **CREATE NEW CONNECTION** folder, then expand the **ODBC (RDO)** folder to obtain a list of ODBC data sources.

You will be asked to select a data source.



4. When you first expand the **ODBC (RDO)** folder you will be presented the Data Source Selection screen. From here you can select either a pre-configured DSN, open a file-based DSN or enter and manual connection string. For this example, the **SAKILA** DSN will be used.

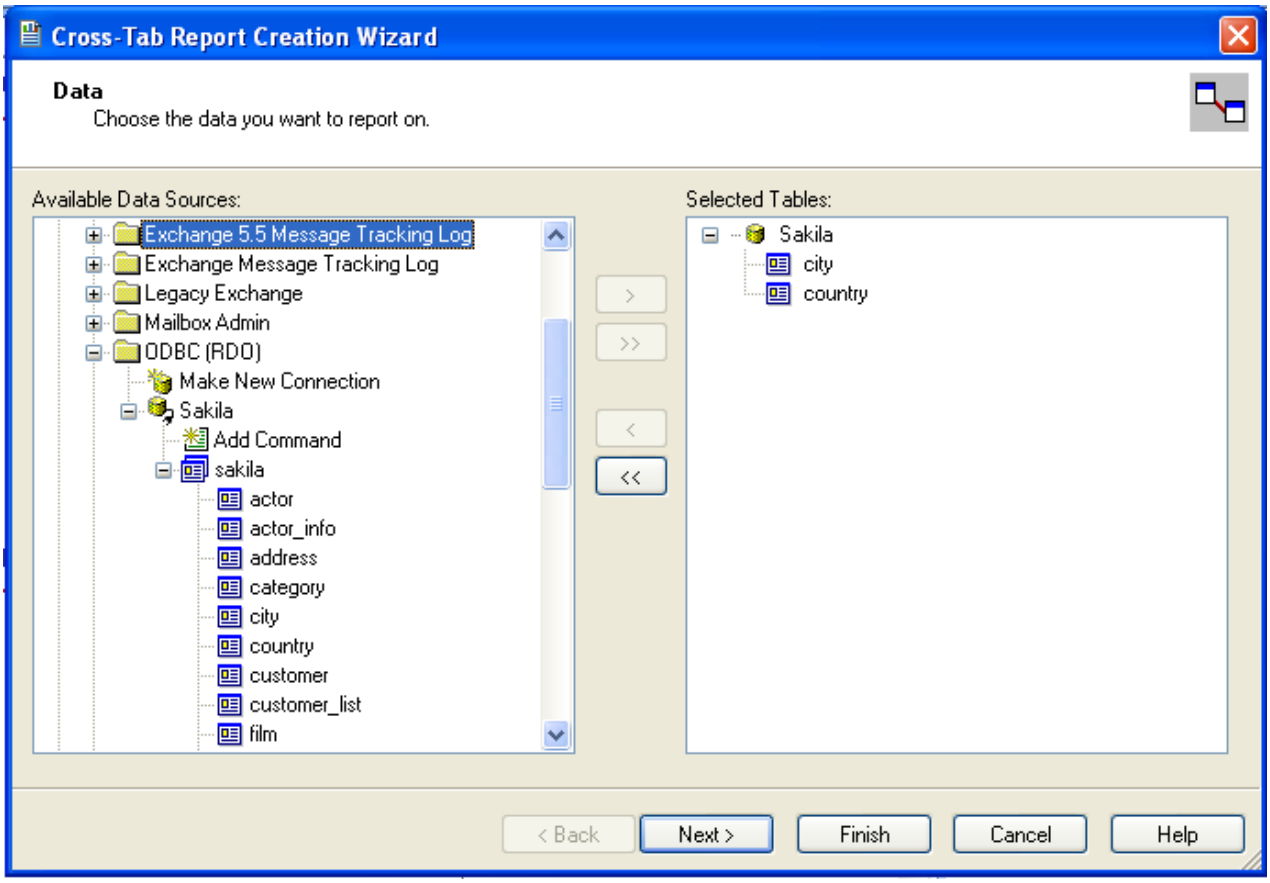
   If the DSN contains a user name/password combination, or you want to use different authentication credentials, click NEXT to enter the user name and password that you want to use. Otherwise, click FINISH to continue the data source selection wizard.



5. You will be returned the Cross-Tab Report Creation Wizard. You now need to select the database and tables that you want to include in your report. For our example, we will expand the selected Sakila database. Click the `city` table and use the > button to add the table to the report. Then repeat the action with the `country` table. Alternatively you can select multiple tables and add them to the report.

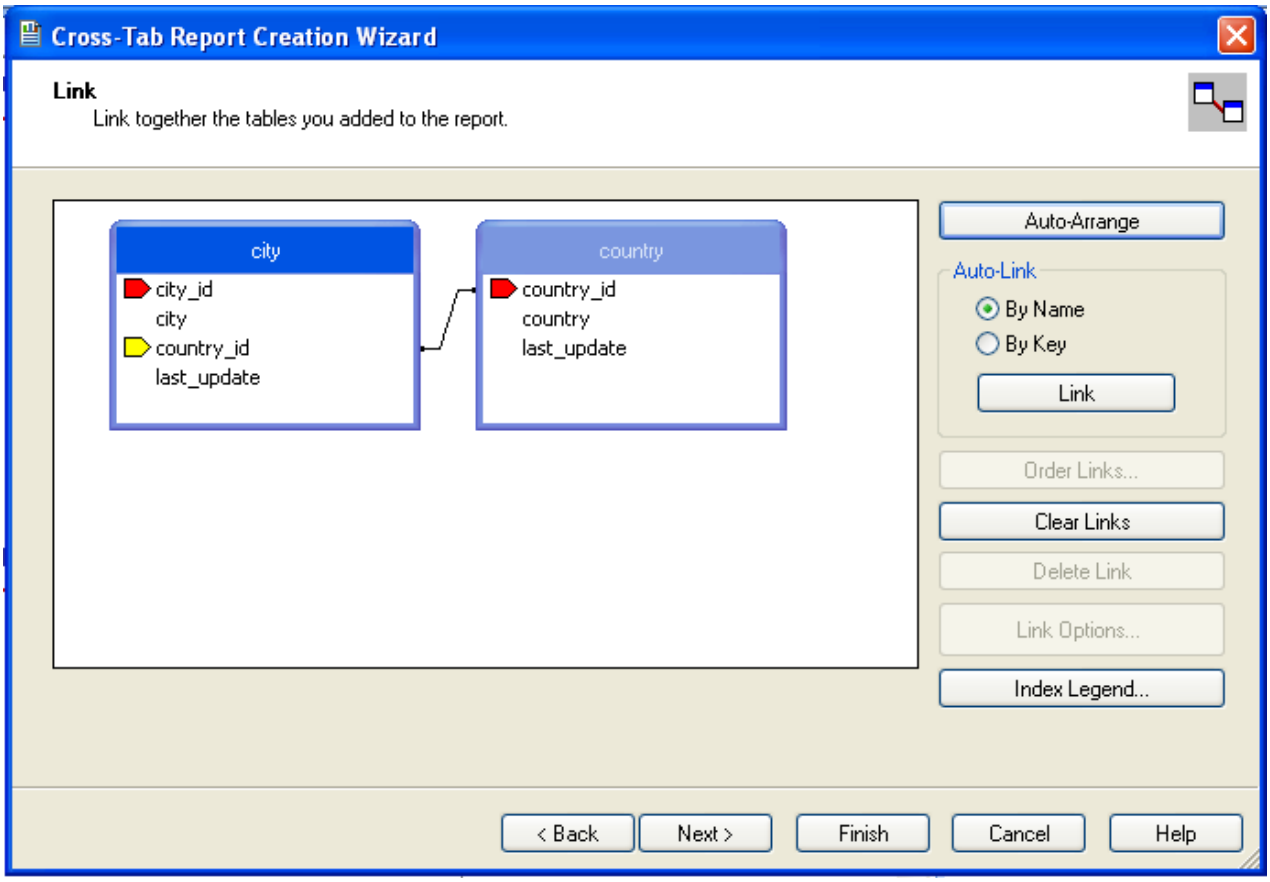
   Finally, you can select the parent **SAKILA** resource and add of the tables to the report.

   Once you have selected the tables you want to include, click NEXT to continue.



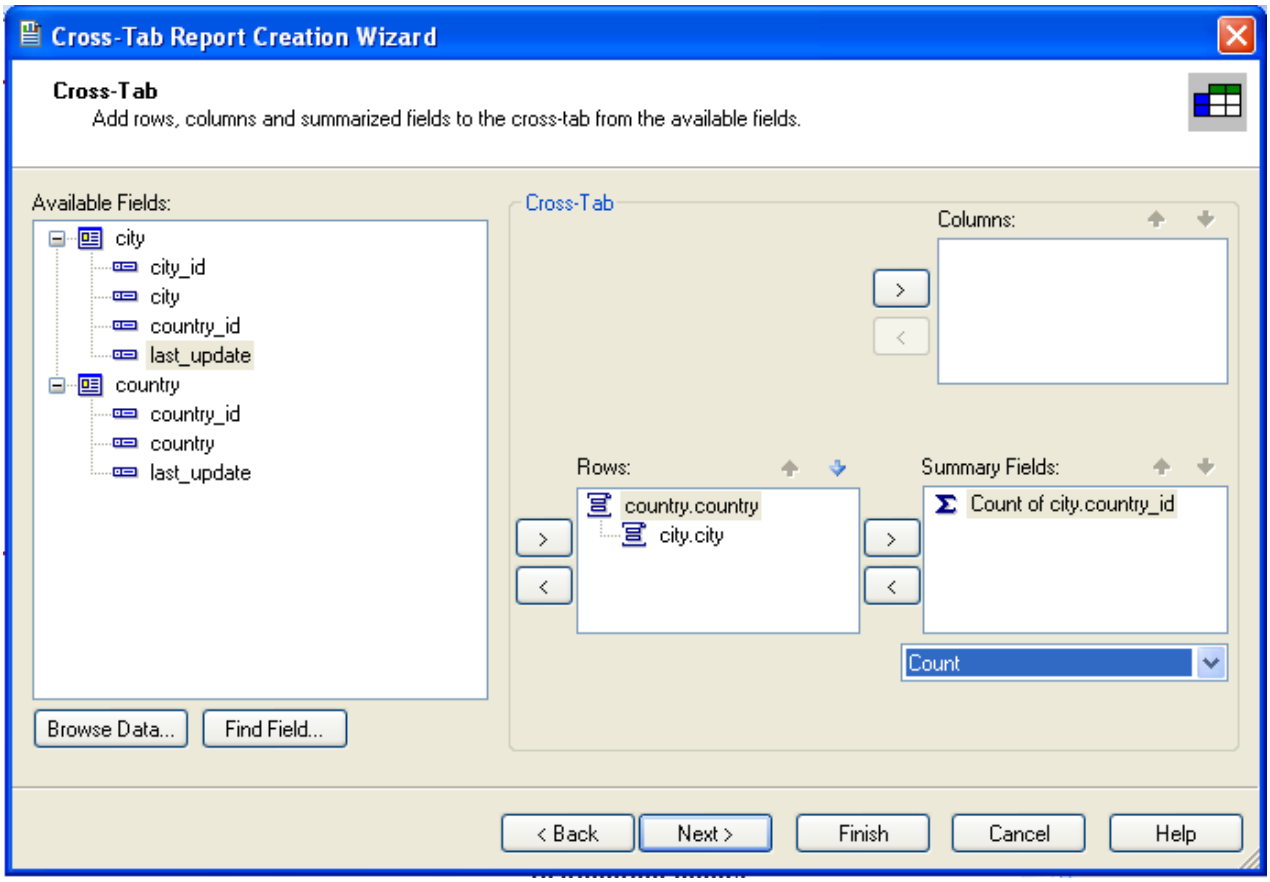
6. Crystal Reports will now read the table definitions and automatically identify the links between the tables. The identification of links between tables enables Crystal Reports to automatically lookup and summarize information based on all the tables in the database according to your query. If Crystal Reports is unable to perform the linking itself, you can manually create the links between fields in the tables you have selected.

   Click NEXT to continue the process.



7. You can now select the columns and rows that you wish to include within the Cross-Tab report. Drag and drop or use the > buttons to add fields to each area of the report. In the example shown, we will report on cities, organized by country, incorporating a count of the number of cities within each country. If you want to browse the data, select a field and click the BROWSE DATA... button.

   Click NEXT to create a graph of the results. Since we are not creating a graph from this data, click FINISH to generate the report.



8. The finished report will be shown, a sample of the output from the Sakila sample database is shown below.

		Total
Total		600
Afghanistan	Total	1
	Kabul	1
Algeria	Total	3
	Batna	1
	Bchar	1
	Skikda	1
American Samoa	Total	1
	Tafuna	1
Angola	Total	2
	Benguela	1
	Namibe	1
Anguilla	Total	1
	South Hill	1
Argentina	Total	13
	Almirante Brow	1

Once the ODBC connection has been opened within Crystal Reports, you can browse and add any fields within the available tables into your reports.

20.1.5.7. Connector/ODBC Programming

With a suitable ODBC Manager and the Connector/ODBC driver installed, any programming language or environment that can support ODBC should be able to connect to a MySQL database through Connector/ODBC.

This includes, but is certainly not limited to, Microsoft support languages (including Visual Basic, C# and interfaces such as ODBC.NET), Perl (through the DBI module, and the DBD::ODBC driver).

20.1.5.7.1. Using Connector/ODBC with Visual Basic Using ADO, DAO and RDO

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

20.1.5.7.1.1. ADO: `rs.addNew`, `rs.delete`, and `rs.update`

The following ADO (ActiveX Data Objects) example creates a table `my_ado` and demonstrates the use of `rs.addNew`, `rs.delete`, and `rs.update`.

```
Private Sub myodbc_ado_Click()

Dim conn As ADODB.Connection
Dim rs As ADODB.Recordset
Dim fld As ADODB.Field
Dim sql As String

'connect to MySQL server using MySQL ODBC 3.51 Driver
Set conn = New ADODB.Connection
conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

conn.Open

'create table
conn.Execute "DROP TABLE IF EXISTS my_ado"
conn.Execute "CREATE TABLE my_ado(id int not null primary key, name varchar(20)," _
& "txt text, dt date, tm time, ts timestamp)"

'direct insert
conn.Execute "INSERT INTO my_ado(id,name,txt) values(1,100,'venu')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(2,200,'MySQL')"
conn.Execute "INSERT INTO my_ado(id,name,txt) values(3,300,'Delete')"

Set rs = New ADODB.Recordset
rs.CursorLocation = adUseServer

'fetch the initial table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Initial my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close

'rs insert
rs.Open "select * from my_ado", conn, adOpenDynamic, adLockOptimistic
rs.AddNew
rs!Name = "Monty"
rs!txt = "Insert row"
rs.Update
rs.Close

'rs update
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-row"
rs.Update
rs.Close

'rs update second time..
rs.Open "SELECT * FROM my_ado"
rs!Name = "update"
rs!txt = "updated-second-time"
rs.Update
rs.Close

'rs delete
rs.Open "SELECT * FROM my_ado"
rs.MoveNext
rs.MoveNext
rs.Delete
rs.Close
```

```
'fetch the updated table ..
rs.Open "SELECT * FROM my_ado", conn
Debug.Print rs.RecordCount
rs.MoveFirst
Debug.Print String(50, "-") & "Updated my_ado Result Set " & String(50, "-")
For Each fld In rs.Fields
Debug.Print fld.Name,
Next
Debug.Print

Do Until rs.EOF
For Each fld In rs.Fields
Debug.Print fld.Value,
Next
rs.MoveNext
Debug.Print
Loop
rs.Close
conn.Close
End Sub
```

20.1.5.7.1.2. DAO: `rs.addNew`, `rs.update`, and Scrolling

The following DAO (Data Access Objects) example creates a table `my_dao` and demonstrates the use of `rs.addNew`, `rs.update`, and result set scrolling.

```
Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, " _
& "Ts TIMESTAMP(14) NOT NULL, Name varchar(20), Id2 INT)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

For i = 10 To 15
rs.AddNew
rs!Name = "insert record" & i
rs!Id2 = i
rs.Update
Next i
rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str
```

```
rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & ", " & rs!Ts & ", " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub
```

20.1.5.7.1.3. RDO: `rs.addNew` and `rs.update`

The following RDO (Remote Data Objects) example creates a table `my_rdo` and demonstrates the use of `rs.addNew` and `rs.update`.

```
Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"
cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
& "SERVER=localhost;"_
& " DATABASE=test;"_
& "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount
```

```
'close
rs.Close
cn.Close

End Sub
```

20.1.5.7.2. Using Connector/ODBC with .NET

This section contains simple examples that demonstrate the use of Connector/ODBC drivers with ODBC.NET.

20.1.5.7.2.1. Using Connector/ODBC with ODBC.NET and C# (C sharp)

The following sample creates a table `my_odbc_net` and demonstrates its use in C#.

```
/**
 * @sample    : mycon.cs
 * @purpose   : Demo sample for ODBC.NET using Connector/ODBC
 * @author    : Venu, <myodbc@lists.mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2006
 *
 **/

/* build command
 *
 *  csc /t:exe
 *      /out:mycon.exe mycon.cs
 *      /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
  class mycon
  {
    static void Main(string[] args)
    {
      try
        {
          //Connection string for Connector/ODBC 3.51
          string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
            "SERVER=localhost;" +
            "DATABASE=test;" +
            "UID=venu;" +
            "PASSWORD=venu;" +
            "OPTION=3";

          //Connect to MySQL using Connector/ODBC
          OdbcConnection MyConnection = new OdbcConnection(MyConString);
          MyConnection.Open();

          Console.WriteLine("\n !!! success, connected successfully !!!\n");

          //Display connection information
          Console.WriteLine("Connection Information:");
          Console.WriteLine("\tConnection String:" +
                            MyConnection.ConnectionString);
          Console.WriteLine("\tConnection Timeout:" +
                            MyConnection.ConnectionTimeout);
          Console.WriteLine("\tDatabase:" +
                            MyConnection.Database);
          Console.WriteLine("\tDataSource:" +
                            MyConnection.DataSource);
          Console.WriteLine("\tDriver:" +
                            MyConnection.Driver);
          Console.WriteLine("\tServerVersion:" +
                            MyConnection.ServerVersion);

          //Create a sample table
          OdbcCommand MyCommand =
            new OdbcCommand("DROP TABLE IF EXISTS my_odbc_net",
                            MyConnection);
          MyCommand.ExecuteNonQuery();
          MyCommand.CommandText =
            "CREATE TABLE my_odbc_net(id int, name varchar(20), idb bigint)";
          MyCommand.ExecuteNonQuery();

          //Insert
          MyCommand.CommandText =
            "INSERT INTO my_odbc_net VALUES(10,'venu', 300)";
          Console.WriteLine("INSERT, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());;
```

```
          //Insert
          MyCommand.CommandText =
            "INSERT INTO my_odbc_net VALUES(20,'mysql',400)";
          Console.WriteLine("INSERT, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());

          //Insert
          MyCommand.CommandText =
            "INSERT INTO my_odbc_net VALUES(20,'mysql',500)";
          Console.WriteLine("INSERT, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());

          //Update
          MyCommand.CommandText =
            "UPDATE my_odbc_net SET id=999 WHERE id=20";
          Console.WriteLine("Update, Total rows affected:" +
                            MyCommand.ExecuteNonQuery());

          //COUNT(*)
          MyCommand.CommandText =
            "SELECT COUNT(*) as TRows FROM my_odbc_net";
          Console.WriteLine("Total Rows:" +
                            MyCommand.ExecuteScalar());

          //Fetch
          MyCommand.CommandText = "SELECT * FROM my_odbc_net";
          OdbcDataReader MyDataReader;
          MyDataReader =  MyCommand.ExecuteReader();
          while (MyDataReader.Read())
            {
              if(string.Compare(MyConnection.Driver,"myodbc3.dll") == 0) {
                //Supported only by Connector/ODBC 3.51
                Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
                                  MyDataReader.GetString(1) + " " +
                                  MyDataReader.GetInt64(2));
              }
              else {
                //BIGINTs not supported by Connector/ODBC
                Console.WriteLine("Data:" + MyDataReader.GetInt32(0) + " " +
                                  MyDataReader.GetString(1) + " " +
                                  MyDataReader.GetInt32(2));
              }
            }

          //Close all resources
          MyDataReader.Close();
          MyConnection.Close();
        }
      catch (OdbcException MyOdbcException) //Catch any ODBC exception ..
        {
          for (int i=0; i < MyOdbcException.Errors.Count; i++)
            {
              Console.Write("ERROR #" + i + "\n" +
                            "Message: " +
                            MyOdbcException.Errors[i].Message + "\n" +
                            "Native: " +
                            MyOdbcException.Errors[i].NativeError.ToString() + "\n" +
                            "Source: " +
                            MyOdbcException.Errors[i].Source + "\n" +
                            "SQL: " +
                            MyOdbcException.Errors[i].SQLState + "\n");
            }
        }
    }
  }
}
```

20.1.5.7.2.2. Using Connector/ODBC with ODBC.NET and Visual Basic

The following sample creates a table `my_vb_net` and demonstrates the use in VB.

```
' @sample    : myvb.vb
' @purpose   : Demo sample for ODBC.NET using Connector/ODBC
' @author    : Venu, <myodbc@lists.mysql.com>
'
' (C) Copyright MySQL AB, 1995-2006
'
'

'
' build command
'
' vbc /target:exe
'     /out:myvb.exe
'     /r:Microsoft.Data.Odbc.dll
'     /r:System.dll
'     /r:System.Data.dll
```

```
'

Imports Microsoft.Data.Odbc
Imports System

Module myvb
  Sub Main()
    Try

      'Connector/ODBC 3.51 connection string
      Dim MyConString As String = "DRIVER={MySQL ODBC 3.51 Driver};" & _
      "SERVER=localhost;" & _
      "DATABASE=test;" & _
      "UID=venu;" & _
      "PASSWORD=venu;" & _
      "OPTION=3;"

      'Connection
      Dim MyConnection As New OdbcConnection(MyConString)
      MyConnection.Open()

      Console.WriteLine("Connection State::" & MyConnection.State.ToString)

      'Drop
      Console.WriteLine("Dropping table")
      Dim MyCommand As New OdbcCommand()
      MyCommand.Connection = MyConnection
      MyCommand.CommandText = "DROP TABLE IF EXISTS my_vb_net"
      MyCommand.ExecuteNonQuery()

      'Create
      Console.WriteLine("Creating....")
      MyCommand.CommandText = "CREATE TABLE my_vb_net(id int, name varchar(30))"
      MyCommand.ExecuteNonQuery()

      'Insert
      MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(10,'venu')"
      Console.WriteLine("INSERT, Total rows affected:" & _
      MyCommand.ExecuteNonQuery())

      'Insert
      MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(20,'mysql')"
      Console.WriteLine("INSERT, Total rows affected:" & _
      MyCommand.ExecuteNonQuery())

      'Insert
      MyCommand.CommandText = "INSERT INTO my_vb_net VALUES(20,'mysql')"
      Console.WriteLine("INSERT, Total rows affected:" & _
      MyCommand.ExecuteNonQuery())

      'Insert
      MyCommand.CommandText = "INSERT INTO my_vb_net(id) VALUES(30)"
      Console.WriteLine("INSERT, Total rows affected:" & _
                        MyCommand.ExecuteNonQuery())

      'Update
      MyCommand.CommandText = "UPDATE my_vb_net SET id=999 WHERE id=20"
      Console.WriteLine("Update, Total rows affected:" & _
      MyCommand.ExecuteNonQuery())

      'COUNT(*)
      MyCommand.CommandText = "SELECT COUNT(*) as TRows FROM my_vb_net"
      Console.WriteLine("Total Rows:" & MyCommand.ExecuteScalar())

      'Select
      Console.WriteLine("Select * FROM my_vb_net")
      MyCommand.CommandText = "SELECT * FROM my_vb_net"
      Dim MyDataReader As OdbcDataReader
      MyDataReader = MyCommand.ExecuteReader
      While MyDataReader.Read
        If MyDataReader("name") Is DBNull.Value Then
          Console.WriteLine("id = " & _
          CStr(MyDataReader("id")) & "  name = " & _
          "NULL")
        Else
          Console.WriteLine("id = " & _
          CStr(MyDataReader("id")) & "  name = " & _
          CStr(MyDataReader("name")))
        End If
      End While

      'Catch ODBC Exception
    Catch MyOdbcException As OdbcException
      Dim i As Integer
      Console.WriteLine(MyOdbcException.ToString)

      'Catch program exception
    Catch MyException As Exception
      Console.WriteLine(MyException.ToString)
    End Try
  End Sub
```

20.1.6. Connector/ODBC Reference

This section provides reference material for the Connector/ODBC API, showing supported functions and methods, supported MySQL column types and the corresponding native type in Connector/ODBC, and the error codes returned by Connector/ODBC when a fault occurs.

20.1.6.1. Connector/ODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at http://msdn.microsoft.com/en-us/library/ms714177.aspx.

An application can call `SQLGetInfo` function to obtain conformance information about Connector/ODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

> **Note**
>
> For backward compatibility, the Connector/ODBC 3.51 driver supports all deprecated functions.

The following tables list Connector/ODBC API calls grouped by task:

Connecting to a data source

Function name	C/ODBC 3.51	Standard	Purpose
`SQLAllocHandle`	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
`SQLConnect`	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
`SQLDriverConnect`	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.
`SQLAllocEnv`	Yes	Deprecated	Obtains an environment handle allocated from driver.
`SQLAllocConnect`	Yes	Deprecated	Obtains a connection handle

Obtaining information about a driver and data source

Function name	C/ODBC 3.51	Standard	Purpose
`SQLDataSources`	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
`SQLDrivers`	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
`SQLGetInfo`	Yes	ISO 92	Returns information about a specific driver and data source.
`SQLGetFunctions`	Yes	ISO 92	Returns supported driver functions.
`SQLGetTypeInfo`	Yes	ISO 92	Returns information about supported data types.

Setting and retrieving driver attributes

Function name	C/ODBC 3.51	Standard	Purpose
`SQLSetConnectAttr`	Yes	ISO 92	Sets a connection attribute.
`SQLGetConnectAttr`	Yes	ISO 92	Returns the value of a connection attribute.
`SQLSetConnectOption`	Yes	Deprecated	Sets a connection option
`SQLGetConnectOption`	Yes	Deprecated	Returns the value of a connection option
`SQLSetEnvAttr`	Yes	ISO 92	Sets an environment attribute.
`SQLGetEnvAttr`	Yes	ISO 92	Returns the value of an environment attribute.

SQLSetStmtAttr	Yes	ISO 92	Sets a statement attribute.
SQLGetStmtAttr	Yes	ISO 92	Returns the value of a statement attribute.
SQLSetStmtOption	Yes	Deprecated	Sets a statement option
SQLGetStmtOption	Yes	Deprecated	Returns the value of a statement option

Preparing SQL requests

Function name	C/ODBC 3.51	Standard	Purpose
SQLAllocStmt	Yes	Deprecated	Allocates a statement handle
SQLPrepare	Yes	ISO 92	Prepares an SQL statement for later execution.
SQLBindParameter	Yes	ODBC	Assigns storage for a parameter in an SQL statement.
SQLGetCursorName	Yes	ISO 92	Returns the cursor name associated with a statement handle.
SQLSetCursorName	Yes	ISO 92	Specifies a cursor name.
SQLSetScrollOptions	Yes	ODBC	Sets options that control cursor behavior.

Submitting requests

Function name	C/ODBC 3.51	Standard	Purpose
SQLExecute	Yes	ISO 92	Executes a prepared statement.
SQLExecDirect	Yes	ISO 92	Executes a statement
SQLNativeSql	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
SQLDescribeParam	Yes	ODBC	Returns the description for a specific parameter in a statement.
SQLNumParams	Yes	ISO 92	Returns the number of parameters in a statement.
SQLParamData	Yes	ISO 92	Used in conjunction with SQLPutData to supply parameter data at execution time. (Useful for long data values.)
SQLPutData	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)

Retrieving results and information about results

Function name	C/ODBC 3.51	Standard	Purpose
SQLRowCount	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
SQLNumResultCols	Yes	ISO 92	Returns the number of columns in the result set.
SQLDescribeCol	Yes	ISO 92	Describes a column in the result set.
SQLColAttribute	Yes	ISO 92	Describes attributes of a column in the result set.
SQLColAttributes	Yes	Deprecated	Describes attributes of a column in the result set.
SQLFetch	Yes	ISO 92	Returns multiple result rows.
SQLFetchScroll	Yes	ISO 92	Returns scrollable result rows.
SQLExtendedFetch	Yes	Deprecated	Returns scrollable result rows.
SQLSetPos	Yes	ODBC	Positions a cursor within a fetched block of data and allows an application to refresh data in the rowset or to update or delete data in the result set.
SQLBulkOperations	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

Retrieving error or diagnostic information

Function name	C/ODBC 3.51	Standard	Purpose
SQLError	Yes	Deprecated	Returns additional error or status information
SQLGetDiagField	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
SQLGetDiagRec	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

Obtaining information about the data source's system tables (catalog functions) item

Function name	C/ODBC 3.51	Standard	Purpose
SQLColumnPrivileges	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
SQLColumns	Yes	X/Open	Returns the list of column names in specified tables.
SQLForeignKeys	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
SQLPrimaryKeys	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
SQLSpecialColumns	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are automatically updated when any value in the row is updated by a transaction.
SQLStatistics	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
SQLTablePrivileges	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
SQLTables	Yes	X/Open	Returns the list of table names stored in a specific data source.

Performing transactions

Function name	C/ODBC 3.51	Standard	Purpose
SQLTransact	Yes	Deprecated	Commits or rolls back a transaction
SQLEndTran	Yes	ISO 92	Commits or rolls back a transaction.

Terminating a statement

Function name	C/ODBC 3.51	Standard	Purpose
SQLFreeStmt	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
SQLCloseCursor	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
SQLCancel	Yes	ISO 92	Cancels an SQL statement.

Terminating a connection

Function name	C/ODBC 3.51	Standard	Purpose
SQLDisconnect	Yes	ISO 92	Closes the connection.
SQLFreeHandle	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
SQLFreeConnect	Yes	Deprecated	Releases connection handle
SQLFreeEnv	Yes	Deprecated	Releases an environment handle

20.1.6.2. Connector/ODBC Data Types

The following table illustrates how driver maps the server data types to default SQL and C data types.

Native Value	SQL Type	C Type
bigint unsigned	SQL_BIGINT	SQL_C_UBIGINT
bigint	SQL_BIGINT	SQL_C_SBIGINT
bit	SQL_BIT	SQL_C_BIT
bit	SQL_CHAR	SQL_C_CHAR
blob	SQL_LONGVARBINARY	SQL_C_BINARY
bool	SQL_CHAR	SQL_C_CHAR
char	SQL_CHAR	SQL_C_CHAR
date	SQL_DATE	SQL_C_DATE
datetime	SQL_TIMESTAMP	SQL_C_TIMESTAMP
decimal	SQL_DECIMAL	SQL_C_CHAR
double precision	SQL_DOUBLE	SQL_C_DOUBLE
double	SQL_FLOAT	SQL_C_DOUBLE
enum	SQL_VARCHAR	SQL_C_CHAR
float	SQL_REAL	SQL_C_FLOAT
int unsigned	SQL_INTEGER	SQL_C_ULONG
int	SQL_INTEGER	SQL_C_SLONG
integer unsigned	SQL_INTEGER	SQL_C_ULONG
integer	SQL_INTEGER	SQL_C_SLONG
long varbinary	SQL_LONGVARBINARY	SQL_C_BINARY
long varchar	SQL_LONGVARCHAR	SQL_C_CHAR
longblob	SQL_LONGVARBINARY	SQL_C_BINARY
longtext	SQL_LONGVARCHAR	SQL_C_CHAR
mediumblob	SQL_LONGVARBINARY	SQL_C_BINARY
mediumint unsigned	SQL_INTEGER	SQL_C_ULONG
mediumint	SQL_INTEGER	SQL_C_SLONG
mediumtext	SQL_LONGVARCHAR	SQL_C_CHAR
numeric	SQL_NUMERIC	SQL_C_CHAR
real	SQL_FLOAT	SQL_C_DOUBLE
set	SQL_VARCHAR	SQL_C_CHAR
smallint unsigned	SQL_SMALLINT	SQL_C_USHORT
smallint	SQL_SMALLINT	SQL_C_SSHORT
text	SQL_LONGVARCHAR	SQL_C_CHAR
time	SQL_TIME	SQL_C_TIME
timestamp	SQL_TIMESTAMP	SQL_C_TIMESTAMP
tinyblob	SQL_LONGVARBINARY	SQL_C_BINARY
tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
tinyint	SQL_TINYINT	SQL_C_STINYINT
tinytext	SQL_LONGVARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
year	SQL_SMALLINT	SQL_C_SHORT

20.1.6.3. Connector/ODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	`SQLBindParameter` not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code
524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available
526	S1024	HY024	Invalid attribute value
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute/option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation
0	42S02	42S02	Base table or view not found

0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found
0	08S01	08S01	Communication link failure

20.1.7. Connector/ODBC Notes and Tips

Here are some common notes and tips for using Connector/ODBC within different environments, applications and tools. The notes provided here are based on the experiences of Connector/ODBC developers and users.

20.1.7.1. Connector/ODBC General Functionality

This section provides help with common queries and areas of functionality in MySQL and how to use them with Connector/ODBC.

20.1.7.1.1. Obtaining Auto-Increment Values

Obtaining the value of column that uses `AUTO_INCREMENT` after an `INSERT` statement can be achieved in a number of different ways. To obtain the value immediately after an `INSERT`, use a `SELECT` query with the `LAST_INSERT_ID()` function.

For example, using Connector/ODBC you would execute two separate statements, the `INSERT` statement and the `SELECT` query to obtain the auto-increment value.

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

If you do not require the value within your application, but do require the value as part of another `INSERT`, the entire process can be handled by executing the following statements:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

Certain ODBC applications (including Delphi and Access) may have trouble obtaining the auto-increment value using the previous examples. In this case, try the following statement as an alternative:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

This alternative method requires that `sql_auto_is_null` variable is not set to 0. See Section 5.1.4, “Server System Variables”.

See also Section 20.9.10.3, “How to Get the Unique ID for the Last Inserted Row”.

20.1.7.1.2. Dynamic Cursor Support

Support for the `dynamic cursor` is provided in Connector/ODBC 3.51, but dynamic cursors are not enabled by default. You can enable this function within Windows by selecting the `Enable Dynamic Cursor` checkbox within the ODBC Data Source Administrator.

On other platforms, you can enable the dynamic cursor by adding `32` to the `OPTION` value when creating the DSN.

20.1.7.1.3. Connector/ODBC Performance

The Connector/ODBC driver has been optimized to provide very fast performance. If you experience problems with the performance of Connector/ODBC, or notice a large amount of disk activity for simple queries, there are a number of aspects you should check:

- Ensure that `ODBC Tracing` is not enabled. With tracing enabled, a lot of information is recorded in the tracing file by the ODBC Manager. You can check, and disable, tracing within Windows using the TRACING panel of the ODBC Data Source Administrator. Within Mac OS X, check the TRACING panel of ODBC Administrator. See Section 20.1.4.8, “Getting an ODBC Trace File”.
- Make sure you are using the standard version of the driver, and not the debug version. The debug version includes additional checks and reporting measures.

- Disable the Connector/ODBC driver trace and query logs. These options are enabled for each DSN, so make sure to examine only the DSN that you are using in your application. Within Windows, you can disable the Connector/ODBC and query logs by modifying the DSN configuration. Within Mac OS X and Unix, ensure that the driver trace (option value 4) and query logging (option value 524288) are not enabled.

20.1.7.1.4. Setting ODBC Query Timeout in Windows

For more information on how to set the query timeout on Microsoft Windows when executing queries through an ODBC connection, read the Microsoft knowledgebase document at http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756.

20.1.7.2. Connector/ODBC Application Specific Tips

Most programs should work with Connector/ODBC, but for each of those listed here, there are specific notes and tips to improve or enhance the way you work with Connector/ODBC and these applications.

With all applications you should ensure that you are using the latest Connector/ODBC drivers, ODBC Manager and any supporting libraries and interfaces used by your application. For example, on Windows, using the latest version of Microsoft Data Access Components (MDAC) will improve the compatibility with ODBC in general, and with the Connector/ODBC driver.

20.1.7.2.1. Using Connector/ODBC with Microsoft Applications

The majority of Microsoft applications have been tested with Connector/ODBC, including Microsoft Office, Microsoft Access and the various programming languages supported within ASP and Microsoft Visual Studio.

20.1.7.2.1.1. Microsoft Access

To improve the integration between Microsoft Access and MySQL through Connector/ODBC:

- For all versions of Access, you should enable the Connector/ODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a `TIMESTAMP` column in all tables that you want to be able to update. For maximum portability, do not use a length specification in the column declaration (which is unsupported within MySQL in versions earlier than 4.1).
- You should have a primary key in each MySQL table you want to use with Access. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED#`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

  Old records may still display as `#DELETED#`, but newly added/updated records are displayed properly.
- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

  Do not use a `table` data sheet view. Instead, create a form with the fields you want, and use that `form` data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.
- In some cases, Access may generate SQL statements that MySQL cannot understand. You can fix this by selecting `"Query|SQLSpecific|Pass-Through"` from the Access menu.
- On Windows NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.

- Access cannot always handle the MySQL `DATE` column properly. If you have a problem with these, change the columns to `DATETIME`.
- If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an `ODBC Query Failed` error and the table cannot open. To deal with this, select the following options:
  - Return Matching Rows (2)
  - Allow BIG Results (8).

  These add up to a value of 10 (`OPTION=10`).

Some external articles and tips that may be useful when using Access, ODBC and Connector/ODBC:

- Read How to Trap ODBC Login Error Messages in Access
- Optimizing Access ODBC Applications
  - Optimizing for Client/Server Performance
  - Tips for Converting Applications to Using ODBCDirect
  - Tips for Optimizing Queries on Attached SQL Tables
- For a list of tools that can be used with Access and ODBC data sources, refer to http://www.mysql.com/portal/software/convertors/ section for list of available tools.

> **MySQL Enterprise**
> MySQL Enterprise subscribers will find more information about using ODBC with Access in Knowledge Base articles such as Use MySQL-Specific Syntax with Microsoft Access. To subscribe to MySQL Enterprise see http://www.mysql.com/products/enterprise/advisors.html.

20.1.7.2.1.2. Microsoft Excel and Column Types

If you have problems importing data into Microsoft Excel, particularly numerical, date, and time values, this is probably because of a bug in Excel, where the column type of the source data is used to determine the data type when that data is inserted into a cell within the worksheet. The result is that Excel incorrectly identifies the content and this affects both the display format and the data when it is used within calculations.

To address this issue, use the `CONCAT()` function in your queries. The use of `CONCAT()` forces Excel to treat the value as a string, which Excel will then parse and usually correctly identify the embedded information.

However, even with this option, some data may be incorrectly formatted, even though the source data remains unchanged. Use the `Format Cells` option within Excel to change the format of the displayed information.

20.1.7.2.1.3. Microsoft Visual Basic

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO cannot handle big integers. This means that some queries like `SHOW PROCESSLIST` do not work properly. The fix is to use `OPTION=16384` in the ODBC connect string or to select the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen. You may also want to select the `Return matching rows` option.

> **MySQL Enterprise**
> MySQL Enterprise subscribers can find a discussion about using VBA in the Knowledge Base article, MySQL-Specific Syntax with VBA. To subscribe to MySQL Enterprise see http://www.mysql.com/products/enterprise/advisors.html.

20.1.7.2.1.4. Microsoft Visual InterDev

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the Connector/ODBC connect screen.

20.1.7.2.1.5. Visual Objects

You should select the `Don't optimize column widths` option.

20.1.7.2.1.6. Microsoft ADO

When you are coding with the ADO API and Connector/ODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation Property` as `adUseServer` returns a result of –1 for the `RecordCount Property`. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

To find the number of rows affected by a specific SQL statement in ADO, use the `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/htm/mdmthcnnexecute.asp.

For information, see ActiveX Data Objects(ADO) Frequently Asked Questions.

20.1.7.2.1.7. Using Connector/ODBC with Active Server Pages (ASP)

You should select the `Return matching rows` option in the DSN.

For more information about how to access MySQL via ASP using Connector/ODBC, refer to the following articles:

- Using MyODBC To Access Your MySQL Database Via ASP
- ASP and MySQL at DWAM.NT

A Frequently Asked Questions list for ASP can be found at http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp.

20.1.7.2.1.8. Using Connector/ODBC with Visual Basic (ADO, DAO and RDO) and ASP

Some articles that may help with Visual Basic and ASP:

- MySQL BLOB columns and Visual Basic 6 by Mike Hillyer (`<mike@openwin.org>`).
- How to map Visual basic data type to MySQL types by Mike Hillyer (`<mike@openwin.org>`).

20.1.7.2.2. Using Connector/ODBC with Borland Applications

With all Borland applications where the Borland Database Engine (BDE) is used, follow these steps to improve compatibility:

- Update to BDE 3.2 or newer.

- Enable the `Don't optimize column widths` option in the DSN.
- Enabled the `Return matching rows` option in the DSN.

20.1.7.2.2.1. Using Connector/ODBC with Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

20.1.7.2.2.2. Using Connector/ODBC with Delphi

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for Connector/ODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton `<bryan@flesherfab.com>` for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', ' ');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', ' ');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memo1.Lines.Add('DATABASE NAME=');
Memo1.Lines.Add('USER NAME=');
Memo1.Lines.Add('ODBC DSN=DocumentsFab');
Memo1.Lines.Add('OPEN MODE=READ/WRITE');
Memo1.Lines.Add('BATCH COUNT=200');
Memo1.Lines.Add('LANGDRIVER=');
Memo1.Lines.Add('MAX ROWS=-1');
Memo1.Lines.Add('SCHEMA CACHE DIR=');
Memo1.Lines.Add('SCHEMA CACHE SIZE=8');
Memo1.Lines.Add('SCHEMA CACHE TIME=-1');
Memo1.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memo1.Lines.Add('SQLQRYMODE=');
Memo1.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memo1.Lines.Add('ENABLE BCD=FALSE');
Memo1.Lines.Add('ROWSET SIZE=20');
Memo1.Lines.Add('BLOBS TO CACHE=64');
Memo1.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab','MySQL',Memo1.Lines);
```

20.1.7.2.2.3. Using Connector/ODBC with C++ Builder

Tested with BDE 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named `PRIMARY`, although this has not been a problem.

20.1.7.2.3. Using Connector/ODBC with ColdFusion

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the `unixODBC` driver with Connector/ODBC for MySQL data sources. You can download Connector/ODBC at http://dev.mysql.com/downloads/connector/odbc/.

ColdFusion version 4.5.1 allows you to us the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion version 4.5.1. Before the MySQL driver appears in the ODBC data sources drop-down list, you must build and copy the Connector/ODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The Contrib directory contains the program `mydsn-xxx.zip` which allows you to build and remove the DSN registry file for the Connector/ODBC driver on ColdFusion applications.

For more information and guides on using ColdFusion and Connector/ODBC, see the following external sites:

- Troubleshooting Data Sources and Database Connectivity for Unix Platforms.

20.1.7.2.4. Using Connector/ODBC with OpenOffice.org

Open Office (http://www.openoffice.org) How-to: MySQL + OpenOffice. How-to: OpenOffice + MyODBC + unixODBC.

20.1.7.2.5. Using Connector/ODBC with Sambar Server

Sambar Server (http://www.sambarserver.info) How-to: MyODBC + SambarServer + MySQL.

20.1.7.2.6. Using Connector/ODBC with Pervasive Software DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

20.1.7.2.7. Using Connector/ODBC with SunSystems Vision

You should select the `Return matching rows` option.

20.1.7.3. Connector/ODBC Errors and Resolutions (FAQ)

The following section details some common errors and their suggested fix or alternative solution. If you are still experiencing problems, use the Connector/ODBC mailing list; see Section 20.1.8.1, "Connector/ODBC Community Support".

Many problems can be resolved by upgrading your Connector/ODBC drivers to the latest available release. On Windows, you should also make sure that you have the latest versions of the Microsoft Data Access Components (MDAC) installed.

Questions

- 21.1.7.3.1: I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in `ODBC Data Source Administrator`.
- 21.1.7.3.2: When connecting or using the TEST button in `ODBC Data Source Administrator` I get error 10061 (Cannot connect to server)
- 21.1.7.3.3: The following error is reported when using transactions: `Transactions are not enabled`
- 21.1.7.3.4: Access reports records as `#DELETED#` when inserting or updating records in linked tables.
- 21.1.7.3.5: How do I handle Write Conflicts or Row Location errors?
- 21.1.7.3.6: Exporting data from Access 97 to MySQL reports a `Syntax Error`.
- 21.1.7.3.7: Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.
- 21.1.7.3.8: Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the SQL_NO_DATA exception.
- 21.1.7.3.9: Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.
- 21.1.7.3.10: Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value` error is returned.
- 21.1.7.3.11: Access Returns `Another user had modified the record that you have modified` while editing records on a Linked Table.
- 21.1.7.3.12: When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.
- 21.1.7.3.13: Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.
- 21.1.7.3.14: When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.
- 21.1.7.3.15: When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.
- 21.1.7.3.16: When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table de-

signer interface, you may get errors about tables not existing.

- 21.1.7.3.17: When I try to use batched statements, the excution of the batched statements fails.
- 21.1.7.3.18: When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.
- 21.1.7.3.19: When using some applications to access a MySQL server using C/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.
- 21.1.7.3.20: I can correctly store extended characters in the database (Hebrew/CJK) using C/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.
- 21.1.7.3.21: I have a duplicate MySQL Connector/ODBC entry within my **INSTALLED PROGRAMS** list, but I cannot delete one of them.
- 21.1.7.3.22: When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.
- 21.1.7.3.23: Is it possible to disable data-at-execution using a flag?

Questions and Answers

21.1.7.3.1: I have installed Connector/ODBC on Windows XP x64 Edition or Windows Server 2003 R2 x64. The installation completed successfully, but the Connector/ODBC driver does not appear in `ODBC Data Source Administrator`.

This is not a bug, but is related to the way Windows x64 editions operate with the ODBC driver. On Windows x64 editions, the Connector/ODBC driver is installed in the `%SystemRoot%\SysWOW64` folder. However, the default `ODBC Data Source Administrator` that is available through the `Administrative Tools` or `Control Panel` in Windows x64 Editions is located in the `%SystemRoot%\system32` folder, and only searches this folder for ODBC drivers.

On Windows x64 editions, you should use the ODBC administration tool located at `%SystemRoot%\SysWOW64\odbcad32.exe`, this will correctly locate the installed Connector/ODBC drivers and enable you to create a Connector/ODBC DSN.

This issue was originally reported as Bug#20301.

21.1.7.3.2: When connecting or using the TEST button in `ODBC Data Source Administrator` I get error 10061 (Cannot connect to server)

This error can be raised by a number of different issues, including server problems, network problems, and firewall and port blocking problems. For more information, see Section B.5.2.2, “`Can't connect to [local] MySQL server`”.

21.1.7.3.3: The following error is reported when using transactions: `Transactions are not enabled`

This error indicates that you are trying to use transactions with a MySQL table that does not support transactions. Transactions are supported within MySQL when using the `InnoDB` database engine. In versions of MySQL before Mysql 5.1 you may also use the `BDB` engine.

You should check the following before continuing:

- Verify that your MySQL server supports a transactional database engine. Use `SHOW ENGINES` to obtain a list of the available engine types.
- Verify that the tables you are updating use a transaction database engine.
- Ensure that you have not enabled the `disable transactions` option in your DSN.

21.1.7.3.4: Access reports records as `#DELETED#` when inserting or updating records in linked tables.

If the inserted or updated records are shown as `#DELETED#` in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (`Microsoft Data Access Components`) from http://support.microsoft.com/kb/110093. This fixes a bug in Access that when you export data to

MySQL, the table and column names aren't specified.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114. This fixes some cases where columns are marked as `#DELETED#` in Access.

- For all versions of Access, you should enable the Connector/ODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update.
- You should have a primary key in the table. If not, new or updated rows may show up as `#DELETED#`.
- Use only `DOUBLE` float fields. Access fails when comparing with single-precision floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you cannot find or update rows.
- If you are using Connector/ODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:
  - Have one more dummy column with `TIMESTAMP` as the data type.
  - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
  - Delete the table link from Access and re-create it.

  Old records still display as `#DELETED#`, but newly added/updated records are displayed properly.

21.1.7.3.5: How do I handle Write Conflicts or Row Location errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

```
Write Conflict. Another user has changed your data.

Row cannot be located for updating. Some values may have been changed
since it was last read.
```

21.1.7.3.6: Exporting data from Access 97 to MySQL reports a `Syntax Error`.

This error is specific to Access 97 and versions of Connector/ODBC earlier than 3.51.02. Update to the latest version of the Connector/ODBC driver to resolve this problem.

21.1.7.3.7: Exporting data from Microsoft DTS to MySQL reports a `Syntax Error`.

This error occurs only with MySQL tables using the `TEXT` or `VARCHAR` data types. You can fix this error by upgrading your Connector/ODBC driver to version 3.51.02 or higher.

21.1.7.3.8: Using ODBC.NET with Connector/ODBC, while fetching empty string (0 length), it starts giving the SQL_NO_DATA exception.

You can get the patch that addresses this problem from http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243.

21.1.7.3.9: Using `SELECT COUNT(*) FROM tbl_name` within Visual Basic and ASP returns an error.

This error occurs because the `COUNT(*)` expression is returning a `BIGINT`, and ADO cannot make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

21.1.7.3.10: Using the `AppendChunk()` or `GetChunk()` ADO methods, the `Multiple-step operation generated errors. Check each status value` error is returned.

The `GetChunk()` and `AppendChunk()` methods from ADO doesn't work as expected when the cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm

21.1.7.3.11: Access Returns `Another user had modified the record that you have modified` while editing re-

cords on a Linked Table.

In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double-precision float fields. Some programs may fail when they compare single-precision floats.

If these strategies do not help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a Connector/ODBC log to help you figure out why things go wrong. For instructions, see Section 20.1.4.8, "Getting an ODBC Trace File".

21.1.7.3.12: When linking an application directly to the Connector/ODBC library under Unix/Linux, the application crashes.

Connector/ODBC 3.51 under Unix/Linux is not compatible with direct application linking. You must use a driver manager, such as iODBC or unixODBC to connect to an ODBC source.

21.1.7.3.13: Applications in the Microsoft Office suite are unable to update tables that have `DATE` or `TIMESTAMP` columns.

This is a known issue with Connector/ODBC. You must ensure that the field has a default value (rather than `NULL` and that the default value is nonzero (that is, the default value is not `0000-00-00 00:00:00`).

21.1.7.3.14: When connecting Connector/ODBC 5.x (Beta) to a MySQL 4.x server, the error `1044 Access denied for user 'xxx'@'%' to database 'information_schema'` is returned.

Connector/ODBC 5.x is designed to work with MySQL 5.0 or later, taking advantage of the `INFORMATION_SCHEMA` database to determine data definition information. Support for MySQL 4.1 is planned for the final release.

21.1.7.3.15: When calling `SQLTables`, the error `S1T00` is returned, but I cannot find this in the list of error numbers for Connector/ODBC.

The `S1T00` error indicates that a general timeout has occurred within the ODBC system and is not a MySQL error. Typically it indicates that the connection you are using is stale, the server is too busy to accept your request or that the server has gone away.

21.1.7.3.16: When linking to tables in Access 2000 and generating links to tables programmatically, rather than through the table designer interface, you may get errors about tables not existing.

There is a known issue with a specific version of the `msjet40.dll` that exhibits this issue. The version affected is 4.0.9025.0. Reverting to an older version will enable you to create the links. If you have recently updated your version, check your `WINDOWS` directory for the older version of the file and copy it to the drivers directory.

21.1.7.3.17: When I try to use batched statements, the excution of the batched statements fails.

Batched statement support was added in 3.51.18. Support for batched statements is not enabled by default. You must enable option `FLAG_MULTI_STATEMENTS`, value 67108864, or select the **ALLOW MULTIPLE STATEMENTS** flag within a GUI configuration.

21.1.7.3.18: When connecting to a MySQL server using ADODB and Excel, occasionally the application fails to communicate with the server and the error `Got an error reading communication packets` appears in the error log.

This error may be related to Keyboard Logger 1.1 from PanteraSoft.com, which is known to interfere with the network communication between MySQL Connector/ODBC and MySQL.

21.1.7.3.19: When using some applications to access a MySQL server using C/ODBC and outer joins, an error is reported regarding the Outer Join Escape Sequence.

This is a known issue with MySQL Connector/ODBC which is not correctly parsing the "Outer Join Escape Sequence", as per the specs at Microsoft ODBC Specs. Currently, Connector/ODBC will return value > 0 when asked for `SQL_OJ_CAPABILITIES` even though no parsing takes place in the driver to handle the outer join escape sequence.

21.1.7.3.20: I can correctly store extended characters in the database (Hebrew/CJK) using C/ODBC 5.1, but when I retrieve the data, the text is not formatted correctly and I get garbled characters.

When using ASP and UTF8 characters you should add the following to your ASP files to ensure that the data returned is correctly en-

coded:

```
Response.CodePage = 65001
Response.CharSet = "utf-8"
```

21.1.7.3.21: I have a duplicate MySQL Connector/ODBC entry within my INSTALLED PROGRAMS list, but I cannot delete one of them.

This problem can occur when you upgrade an existing Connector/ODBC installation, rather than removing and then installing the updated version.

> **Warning**
>
> To fix the problem you should use any working uninstallers to remove existing installations and then may have to edit the contents of the registry. Make sure you have a backup of your registry information before attempting any editing of the registry contents.

21.1.7.3.22: When submitting queries with parameter binding using `UPDATE`, my field values are being truncated to 255 characters.

You should ensure that the `FLAG_BIG_PACKETS` option is set for your connection. This removes the 255 character limitation on bound parameters.

21.1.7.3.23: Is it possible to disable data-at-execution using a flag?

If you do not wish to use data-at-execution, simply remove the corresponding calls. For example:

```
SQLLEN ylen = SQL_LEN_DATA_AT_EXEC(10);
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, &ylen);
```

Would become:

```
SQLBindCol(hstmt,2,SQL_C_BINARY, buf, 10, NULL);
```

Note that in the call to `SQLBindCol()`, &ylen has been replaced by NULL.

For further information please refer to the MSDN documentation for `SQLBindCol()`.

20.1.8. Connector/ODBC Support

There are many different places where you can get support for using Connector/ODBC. You should always try the Connector/ODBC Mailing List or Connector/ODBC Forum. See Section 20.1.8.1, “Connector/ODBC Community Support”, for help before reporting a specific bug or issue to MySQL.

20.1.8.1. Connector/ODBC Community Support

Sun Microsystems, Inc. provides assistance to the user community by means of its mailing lists. For Connector/ODBC-related issues, you can get help from experienced users by using the `<myodbc@lists.mysql.com>` mailing list. Archives are available online at http://lists.mysql.com/myodbc.

For information about subscribing to MySQL mailing lists or to browse list archives, visit http://lists.mysql.com/. See Section 1.6.1, “MySQL Mailing Lists”.

Community support from experienced users is also available through the ODBC Forum. You may also find help from other users in the other MySQL Forums, located at http://forums.mysql.com. See Section 1.6.2, “MySQL Community Support at the MySQL Forums”.

20.1.8.2. How to Report Connector/ODBC Problems or Bugs

If you encounter difficulties or problems with Connector/ODBC, you should start by making a log file from the `ODBC Manager` (the log you get when requesting logs from `ODBC ADMIN`) and Connector/ODBC. The procedure for doing this is described in Section 20.1.4.8, “Getting an ODBC Trace File”.

Check the Connector/ODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the `mysql` client program or from `admndemo`. This helps you determine whether the error is in Connector/ODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See Section 1.6.1, "MySQL Mailing Lists". Please never send the whole Connector/ODBC or ODBC log file!

You should ideally include the following information with the email:

- Operating system and version
- Connector/ODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- Connector/ODBC log file from Connector/ODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at http://lists.mysql.com/myodbc.

If you are unable to find out what is wrong, the last option is to create an archive in `tar` or Zip format that contains a Connector/ODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to ftp://ftp.mysql.com/pub/mysql/upload/. Only MySQL engineers have access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with another SQL server, you should include an ODBC log file where you perform exactly the same SQL statements so that we can compare the results between the two systems.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

20.1.8.3. How to Submit a Connector/ODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to `<myodbc@lists.mysql.com>`.

20.1.8.4. Connector/ODBC Change History

The Connector/ODBC Change History (Changelog) is located with the main Changelog for MySQL. See Section C.3, "MySQL Connector/ODBC (MyODBC) Change History".

20.1.8.5. Credits

These are the developers that have worked on the Connector/ODBC and Connector/ODBC 3.51 Drivers from MySQL AB.

- Michael (Monty) Widenius
- Venu Anuganti
- Peter Harvey

20.2. MySQL Connector/NET

Connector/NET enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and integrates into ADO.NET aware tools. Developers can build applications

using their choice of .NET languages. Connector/NET is a fully managed ADO.NET driver written in 100% pure C#.

Connector/NET includes full support for:

- Features provided by MySQL Server up to and including MySQL Server version 5.5.
- Large-packet support for sending and receiving rows and BLOBs up to 2 gigabytes in size.
- Protocol compression which allows for compressing the data stream between the client and server.
- Support for connecting using TCP/IP sockets, named pipes, or shared memory on Windows.
- Support for connecting using TCP/IP sockets or Unix sockets on Unix.
- Support for the Open Source Mono framework developed by Novell.
- Fully managed, does not utilize the MySQL client library.

This document is intended as a user's guide to Connector/NET and includes a full syntax reference. Syntax information is also included within the `Documentation.chm` file included with the Connector/NET distribution.

If you are using MySQL 5.0 or later, and Visual Studio as your development environment, you may want also want to use the MySQL Visual Studio Plugin. The plugin acts as a DDEX (Data Designer Extensibility) provider, enabling you to use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For more information, see Section 20.2.3, “Connector/NET Visual Studio Integration”.

> **Note**
>
> Connector/NET 5.1.2 and later include the Visual Studio Plugin by default.

MySQL Connector/NET supports full versions of Visual Studio 2005, 2008, and 2010, although certain features are only available in Visual Studio 2010 when using MySQL Connector/NET version 6.3.2 and later. Note that MySQL Connector/NET does not currently support Express versions of Microsoft products, including Microsoft Visual Web Developer.

Key topics:

- For connection string properties when using the `MySqlConnection` class, see Section 20.2.6, “Connector/NET Connection String Options Reference”.

20.2.1. Connector/NET Versions

There are several versions of Connector/NET available:

- Connector/NET 1.0 includes support for MySQL Server 4.0, 4.1, and 5.0 features, and full compatibility with the ADO.NET driver interface.

  This version of Connector/NET is no longer supported.

- Connector/NET 5.0 includes support for MySQL Server 4.0, 4.1, 5.0 and 5.1 features. Connector/NET 5.0 also includes full support for the ADO.Net 2.0 interfaces and subclasses, includes support for the usage advisor and performance monitor (PerfMon) hooks.

  This version of Connector/NET is no longer supported.

- Connector/NET 5.1 includes support for MySQL Server 4.0, 4.1, 5.0, 5.1, 5.4 and 5.5 features. Connector/NET 5.1 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetSchema`. Connector/NET 5.1 also includes the Visual Studio Plugin as a standard installable component.

  This version of Connector/NET is no longer supported.

- Connector/NET 5.2 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4, and 5.5 features. Connector/NET 5.2 also includes support for a new membership/role provider, Compact Framework 2.0, a new stored procedure parser and improvements to `GetS-`

chema. Connector/NET 5.2 also includes the Visual Studio Plugin as a standard installable component.

- Connector/NET 6.0 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4 and 5.5.
- Connector/NET 6.1 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4, and 5.5. Important new features include the MySQL Website Configuration Tool and a Session State Provider.
- Connector/NET 6.2 includes support for MySQL Server 4.1, 5.0, 5.1, 5.4, and 5.5. Important new features include a new logging system and client SSL certificates. Connector/NET 6.2 is currently available as a Beta release.
- Connector/NET 6.3 includes support for MySQL Server 5.0, 5.1, 5.4, and 5.5. Important new features include integration with Visual Studio 2010, such as availability of DDL T4 template for Entity Framework, and a custom MySQL SQL Editor. Other features include refactored transaction scope: Connector/NET now supports nested transactions in a scope where they use the same connection string. Connector/NET 6.3 is available as a Beta release.

The latest source code for Connector/NET can be downloaded from the MySQL public Subversion server. For further details see Section 20.2.2.3, “Installing Connector/NET from the source code”.

The following table shows the .NET Framework version required, and MySQL Server version supported by Connector/NET:

Connector/NET version	ADO.NET version supported	.NET Framework version required	MySQL Server version supported
1.0	1.x	1.x	4.0, 4.1, 5.0
5.0	2.x+	2.x+	4.0, 4.1, 5.0
5.1	2.x+	2.x+	4.0, 4.1, 5.0, 5.1, 5.4, 5.5
5.2	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5
6.0	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5
6.1	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5
6.2	2.x+	2.x+	4.1, 5.0, 5.1, 5.4, 5.5
6.3	2.x+	2.x+, 4.x+ for VS 2010 support	5.0, 5.1, 5.4, 5.5

Note

Version numbers for MySQL products are formatted as X.Y.Z, where Z=0 indicates alpha, Z=1 indicates beta, and Z>=2 indicates GA. However, Windows tools (Control Panel, properties display) may show the version numbers as XX.YY.ZZ. For example, the official MySQL formatted version number 5.0.9 may be displayed by Windows tools as 5.00.09. The two versions are the same; only the number display format is different.

20.2.2. Connector/NET Installation

Connector/NET runs on any platform that supports the .NET framework. The .NET framework is primarily supported on recent versions of Microsoft Windows, and is supported on Linux through the Open Source Mono framework (see http://www.mono-project.com).

Connector/NET is available for download from http://dev.mysql.com/downloads/connector/net/5.2.html.

20.2.2.1. Installing Connector/NET on Windows

On Windows, installation is supported either through a binary installation process or by downloading a Zip file with the Connector/NET components.

Before installing, you should ensure that your system is up to date, including installing the latest version of the .NET Framework.

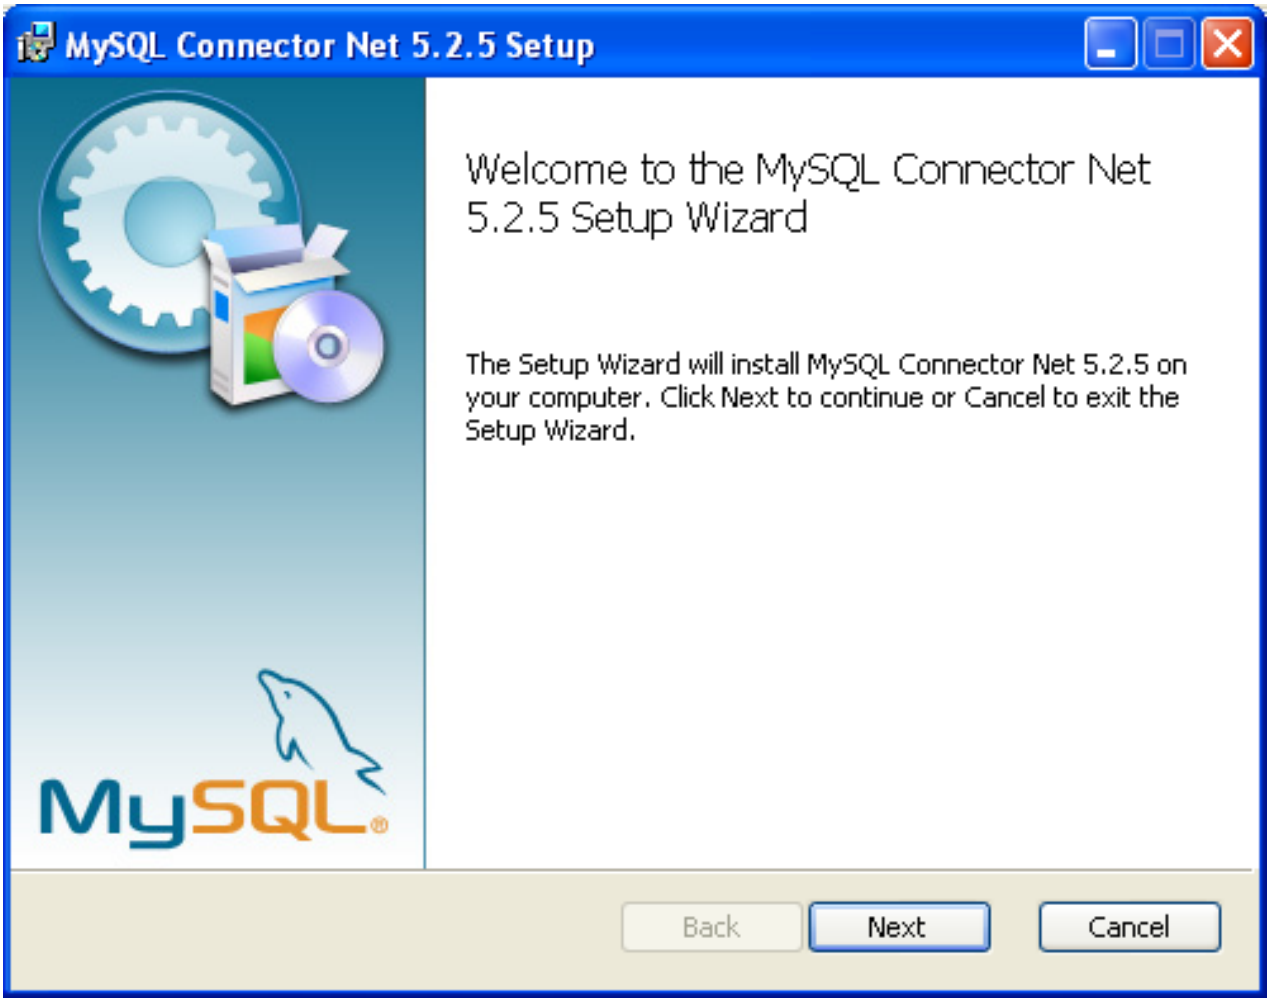
20.2.2.1.1. Installing Connector/NET using the Installer

Using the installer is the most straightforward method of installing Connector/NET on Windows and the installed components include the source code, test code and full reference documentation.

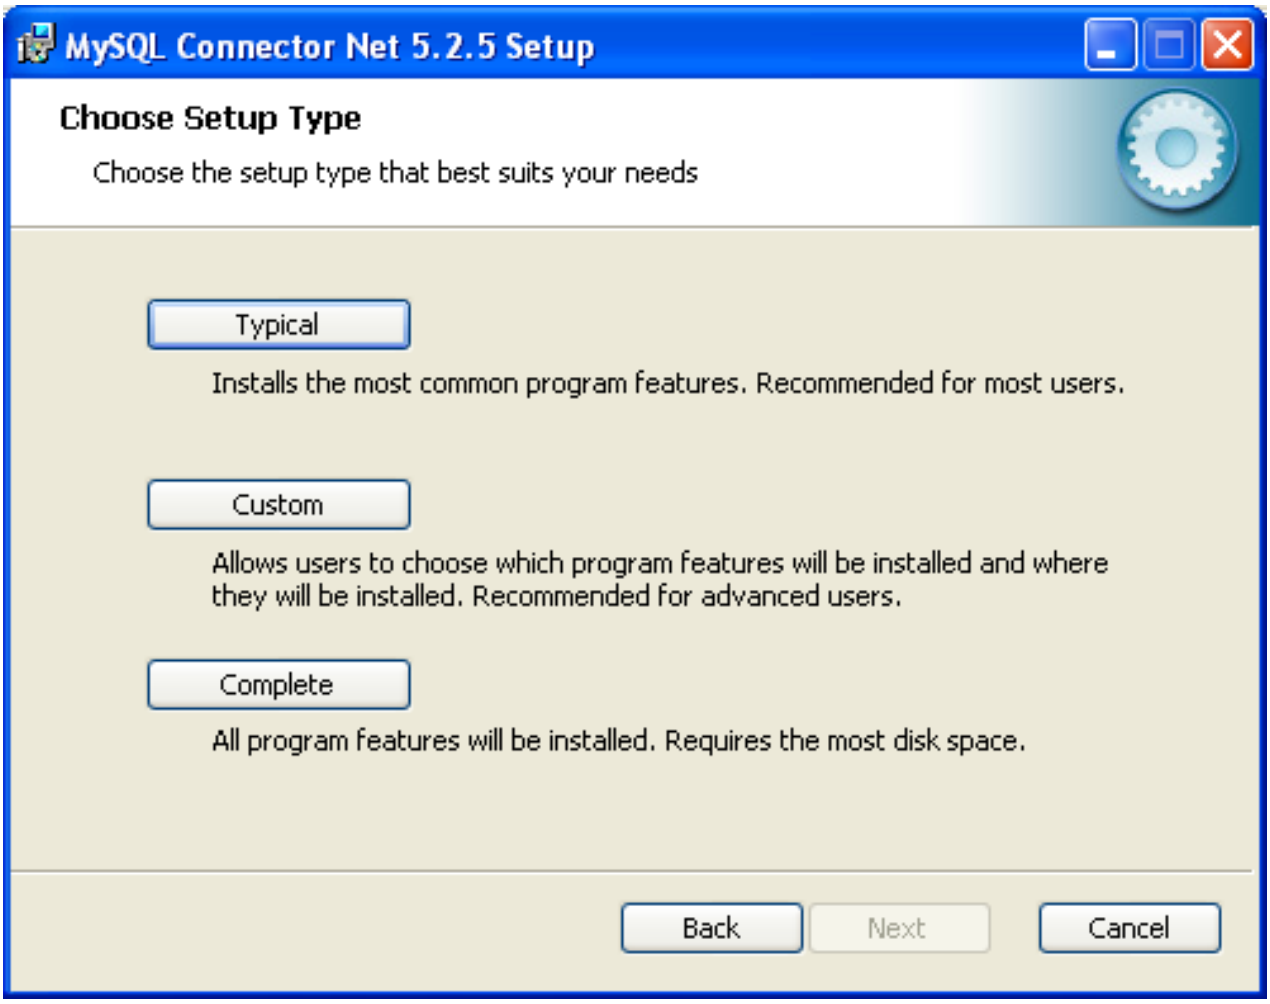
Connector/NET is installed through the use of a Windows Installer (`.msi`) installation package, which can be used to install Connector/NET on all Windows operating systems. The MSI package in contained within a ZIP archive named `mysql-connector-net-version.zip`, where *`version`* indicates the Connector/NET version.

To install Connector/NET:

1. Double-click the MSI installer file extracted from the Zip you downloaded. Click NEXT to start the installation.



2. You must choose the type of installation that you want to perform.

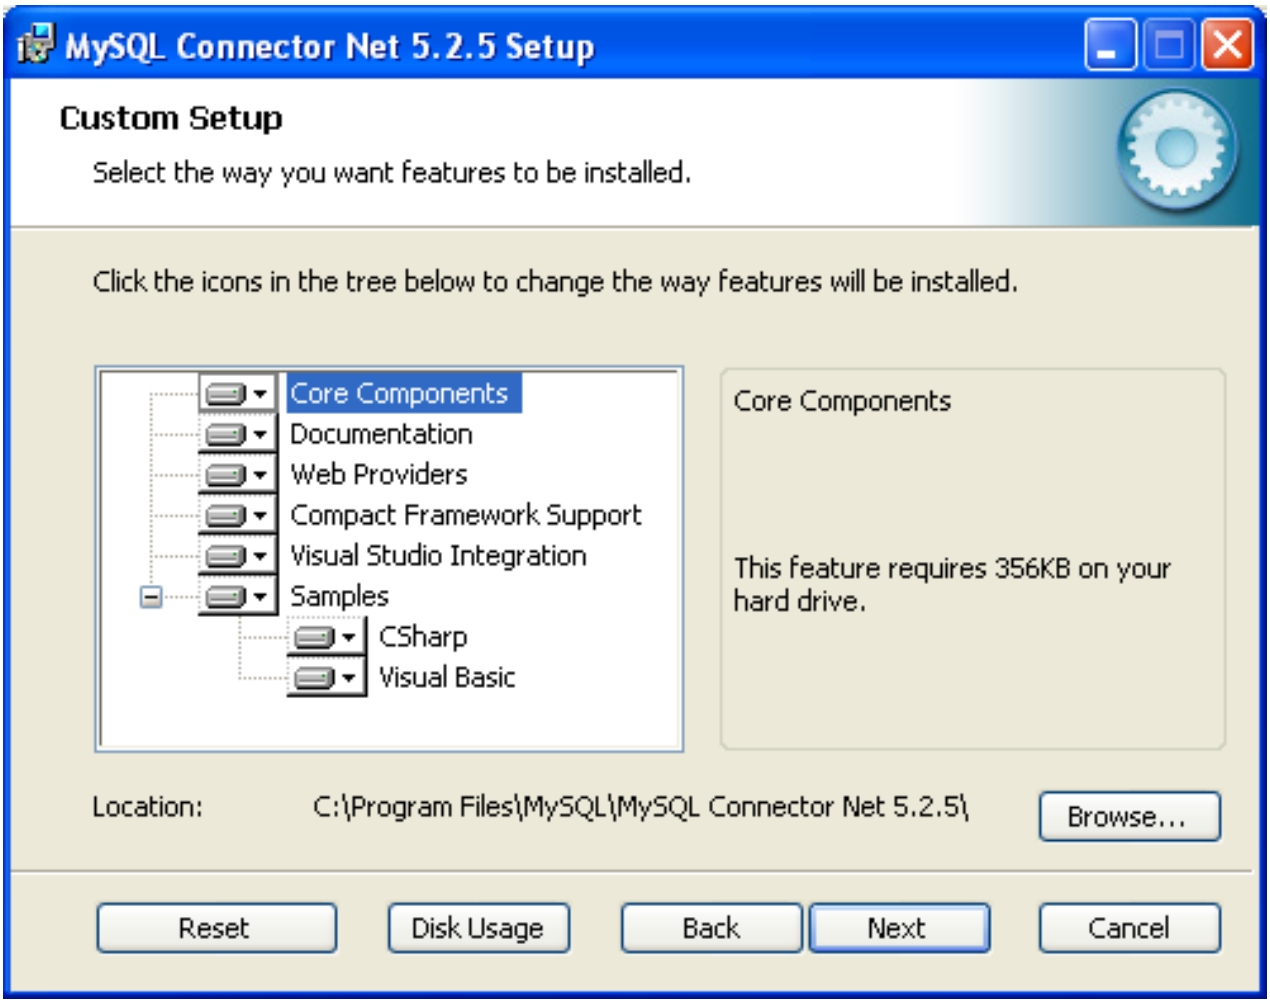


For most situations, the Typical installation will be suitable. Click the TYPICAL button and proceed to Step 5. A Complete installation installs all the available files. To conduct a Complete installation, click the COMPLETE button and proceed to step 5. If you want to customize your installation, including choosing the components to install and some installation options, click the CUSTOM button and proceed to Step 3.

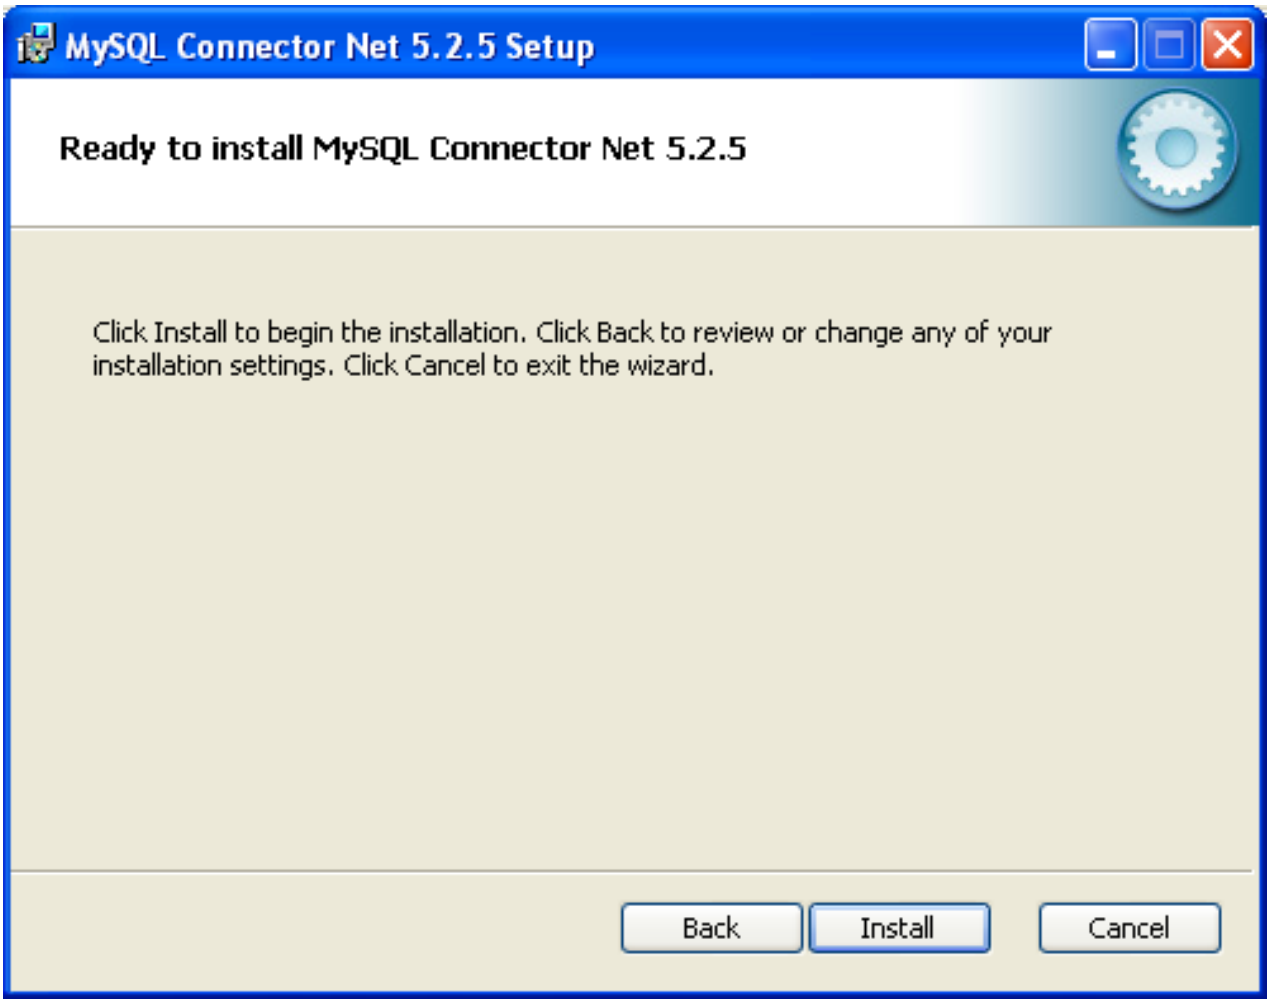
The Connector/NET installer will register the connector within the Global Assembly Cache (GAC) - this will make the Connector/NET component available to all applications, not just those where you explicitly reference the Connector/NET component. The installer will also create the necessary links in the Start menu to the documentation and release notes.

3. If you have chosen a custom installation, you can select the individual components that you want to install, including the core interface component, supporting documentation (a CHM file) samples and examples and the source code. Select the items, and their installation level, and then click NEXT to continue the installation.

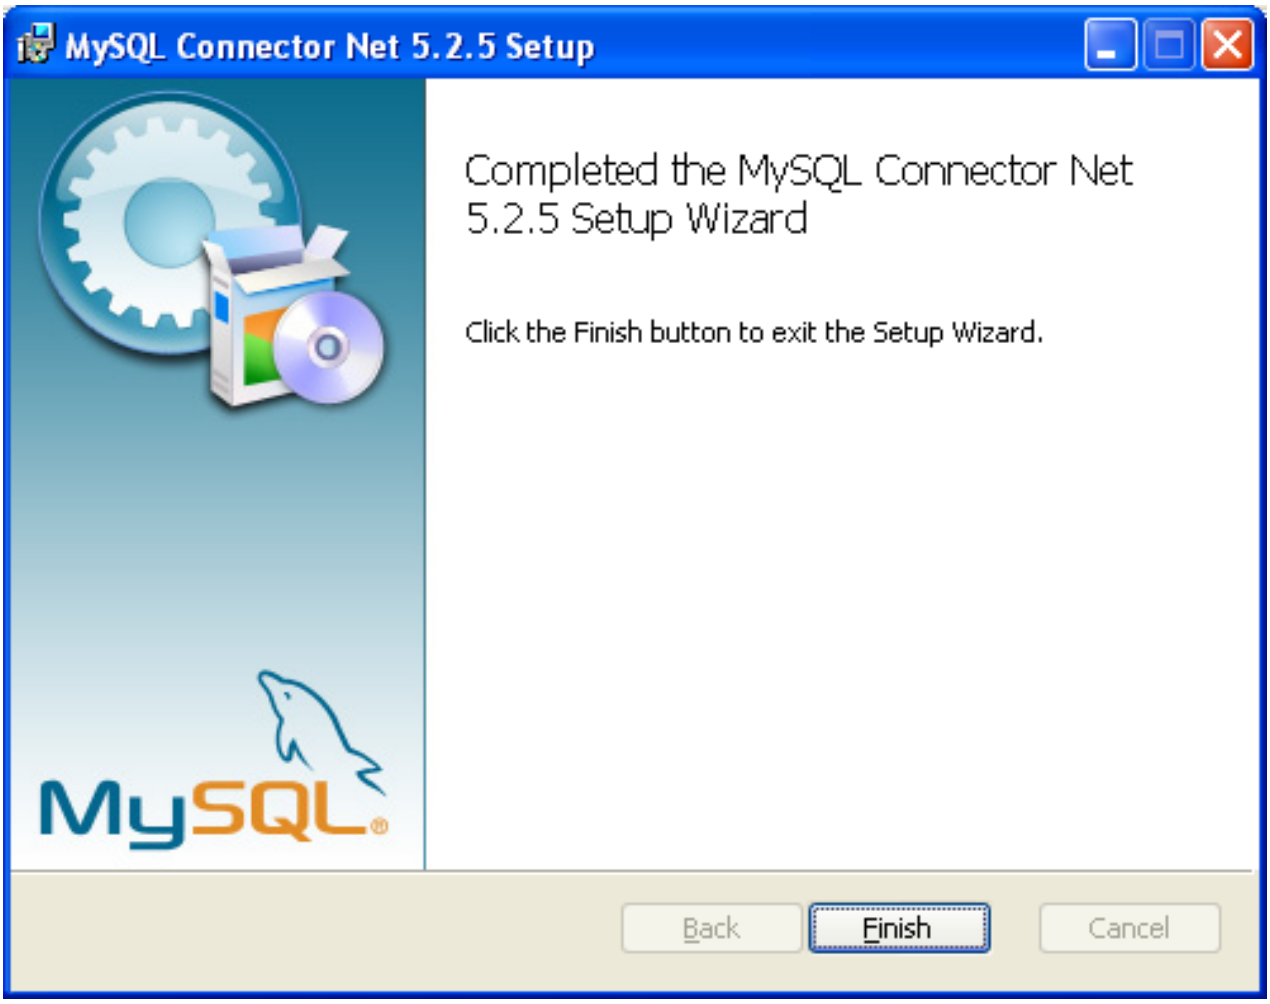
> **Note**
>
> For Connector/NET 1.0.8 or lower and Connector 5.0.4 and lower the installer will attempt to install binaries for both 1.x and 2.x of the .NET Framework. If you only have one version of the framework installed, the connector installation may fail. If this happens, you can choose the framework version to be installed through the custom installation step.



4. You will be given a final opportunity to confirm the installation. Click INSTALL to copy and install the files onto your machine.



5. Once the installation has been completed, click FINISH to exit the installer.



Unless you choose otherwise, Connector/NET is installed in `C:\Program Files\MySQL\MySQL Connector Net X.X.X`, where `X.X.X` is replaced with the version of Connector/NET you are installing. New installations do not overwrite existing versions of Connector/NET.

Depending on your installation type, the installed components will include some or all of the following components:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `docs` - contains a CHM of the Connector/NET documentation.
- `samples` - sample code and applications that use the Connector/NET component.
- `src` - the source code for the Connector/NET component.

You may also use the `/quiet` or `/q` command-line option with the `msiexec` tool to install the Connector/NET package automatically (using the default options) with no notification to the user. Using this method the user cannot select options. Additionally, no prompts, messages or dialog boxes will be displayed.

```
C:\> msiexec /package conector-net.msi /quiet
```

To provide a progress bar to the user during automatic installation, use the `/passive` option.

20.2.2.1.2. Installing Connector/NET using the Zip packages

If you are having problems running the installer, you can download a Zip file without an installer as an alternative. That file is called `mysql-connector-net-version-noinstall.zip`. Once downloaded, you can extract the files to a location of your choice.

The file contains the following directories:

- `bin` - Connector/NET MySQL libraries for different versions of the .NET environment.
- `Docs` - contains a CHM of the Connector/NET documentation.
- `Samples` - sample code and applications that use the Connector/NET component.

Connector/NET 6.0.x has a different directory structure:

- `Assemblies` - contains a collection of DLLs that make up the connector functionality.
- `Documentation` - contains the Connector/NET documentation as a CHM file.
- `Samples` - sample code and applications that use the Connector/NET component.

There is also another Zip file available for download called `mysql-connector-net-version-src.zip`. This file contains the source code distribution.

The file contains the following directories:

- `Documentation` - This folder contains the source files to build the documentation into the compiled HTML (CHM) format.
- `Installer` - This folder contains the source files to build the Connector/NET installer program.
- `MySql.Data` - This folder contains the source files for the core data provider.
- `MySql.VisualStudio` - This folder contains the source files for the Microsoft Visual Studio extensions.
- `MySql.Web` - This folder contains the source files for the web providers. This includes code for the membership provider, role provider and profile provider. These are used in ASP.NET web sites.
- `Samples` - This folder contains the source files for several example applications.
- `Tests` - Ths folder contains a spreadsheet listing test cases.
- `VisualStudio` - Contains resources used by the Visual Studio plug in.

Finally, you need to ensure that `MySql.Data.dll` is accessible to your program at build time (and run time). If using Microsoft Visual Studio you will need to add `MySql.Data` as a Reference to your project.

20.2.2.2. Installing Connector/NET on Unix with Mono

There is no installer available for installing the Connector/NET component on your Unix installation. Before installing, please ensure that you have a working Mono project installation. You can test whether your system has Mono installed by typing:

```
shell> mono --version
```

The version of the Mono JIT compiler will be displayed.

To compile C# source code you will also need to make sure a Mono C# compiler, is installed. Note that there are two Mono C# compilers available, `mcs`, which accesses the 1.0-profile libraries, and `gmcs`, which acesses the 2.0-profile libraries.

To install Connector/NET on Unix/Mono:

1. Download the `mysql-connector-net-version-noinstall.zip` and extract the contents to a directory of your choice,

for example: `~/connector-net/`.

2. In the directory where you unzipped the connector to, change into the `bin` directory. Ensure the file `MySql.Data.dll` is present.

3. You must register the Connector/NET component, `MySql.Data`, in the Global Assembly Cache (GAC). In the current directory enter the `gacutil` command:

   ```
   root-shell> gacutil /i MySql.Data.dll
   ```

   This will register `MySql.Data` into the GAC. You can check this by listing the contents of `/usr/lib/mono/gac`, where you will find `MySql.Data` if the registration has been successful.

You are now ready to compile your application. You must ensure that when you compile your application you include the Connector/NET component using the `-r:` command-line option. For example:

```
shell> gmcs -r:System.dll -r:System.Data.dll -r:MySql.Data.dll HelloWorld.cs
```

Note, the assemblies that need to be referenced will depend on the requirements of the application, but applications using Connector/NET will need to provide `-r:MySql.Data` as a minimum.

You can further check your installation by running the compiled program, for example:

```
shell> mono HelloWorld.exe
```

20.2.2.3. Installing Connector/NET from the source code

> **Caution**
>
> You should read this section only if you are interested in helping us test our new code. If you just want to get Connector/NET up and running on your system, you should use a standard release distribution.

Obtaining the source code

To obtain the most recent development source tree, you first need to download and install Bazaar. You can obtain Bazaar from the Bazaar VCS Website. Bazaar is supported by any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows or Mac OS X host. Instructions for downloading and installing Bazaar on the different platforms are available on the Bazaar Web site.

The most recent development source tree is available from our public Subversion trees at http://dev.mysql.com/tech-resources/sources.html.

To checkout out the Connector/NET sources, change to the directory where you want the copy of the Connector/NET tree to be stored, then use the following command:

```
shell> bzr branch lp:connectornet/trunk
```

To download a specific version of Connector/NET, specify the version number instead of `trunk`. For example, to obtain a copy of the 6.0 version of the source tree:

```
shell> bzr branch lp:connectornet/6.0
```

Source packages are also available on the downloads page.

Building the source code on Windows

The following procedure can be used to build the connector on Microsoft Windows.

- Obtain the source code, either from the Subversion server, or through one of the prepared source code packages.
- Navigate to the root of the source code tree.

- A Microsoft Visual Studio 2005 solution file is available to build the connector, this is called `MySQL-VS2005.sln`. Click this file to load the solution into Visual Studio.
- Select BUILD, BUILD SOLUTION from the main menu to build the solution.

Building the source code on Unix

Support for building Connector/NET on Mono/Unix is currently not available.

20.2.3. Connector/NET Visual Studio Integration

When MySQL Connector/NET is installed on Microsoft Windows, Visual Studio integration components are also installed and initialized. This allows the developer to work seamlessly with MySQL Connector/NET in the familiar Visual Studio environment, as described in the following sections of the manual.

MySQL Connector/NET supports Visual Studio versions 2005, 2008, and 2010. However, only MySQL Connector/NET version 6.3 fully integrates with Visual Studio 2010, although applications using earlier versions of the connector can be built with the Visual Studio 2010 environment using .NET 2.x frameworks.

Visual Studio 2010 support was introduced with MySQL Connector/NET 6.3.2. From version 6.3.2 the connector ships with both .NET 2.x and .NET 4.x versions of the entity framework support files, `mysql.data.ef.dll` and `mysql.visualstudio.dll`. The .NET 4.x versions need to be shipped to enable new integration features supported in Visual Studio 2010, including:

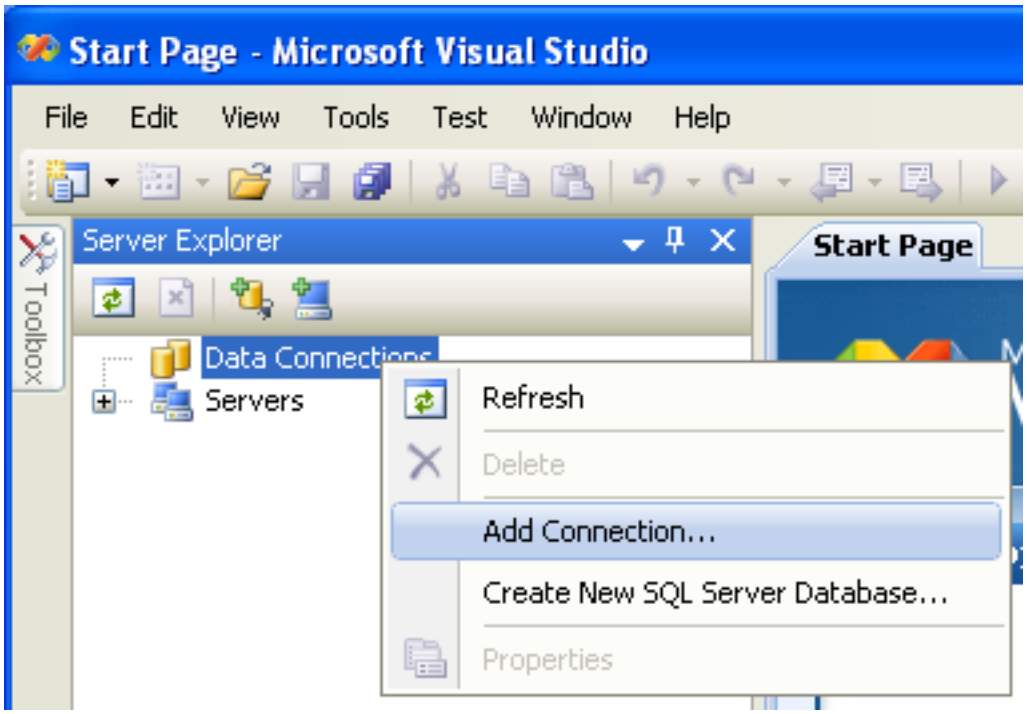
- New DDL T4 template for the Entity Framework (EF) - This allows developers to design an EF model from scratch and use the native Visual Studio 2010 facility to generate MySQL DDL from that model. This is done by creating the model, and with the model open, choosing the SSDLToMySQL template in the properties window. The correct DDL is then generated. The developer can then save this code as a `.mysql` file in their project and execute it against the MySQL server.
- New SQL Editor - A new SQL editor has been included that allows connection to servers to execute SQL. This is activated by creating a new file with a `.mysql` extension. A new template is also included to allow creation of this file type using the Visual Studio 2010 main menu item FILE, NEW. Note that the MySQL SQL Editor is also available in 2005 and 2008.

20.2.3.1. Making a connection

Once the connector is installed, you can use it to create, modify, and delete connections to MySQL databases. To create a connection with a MySQL database, perform the following steps:

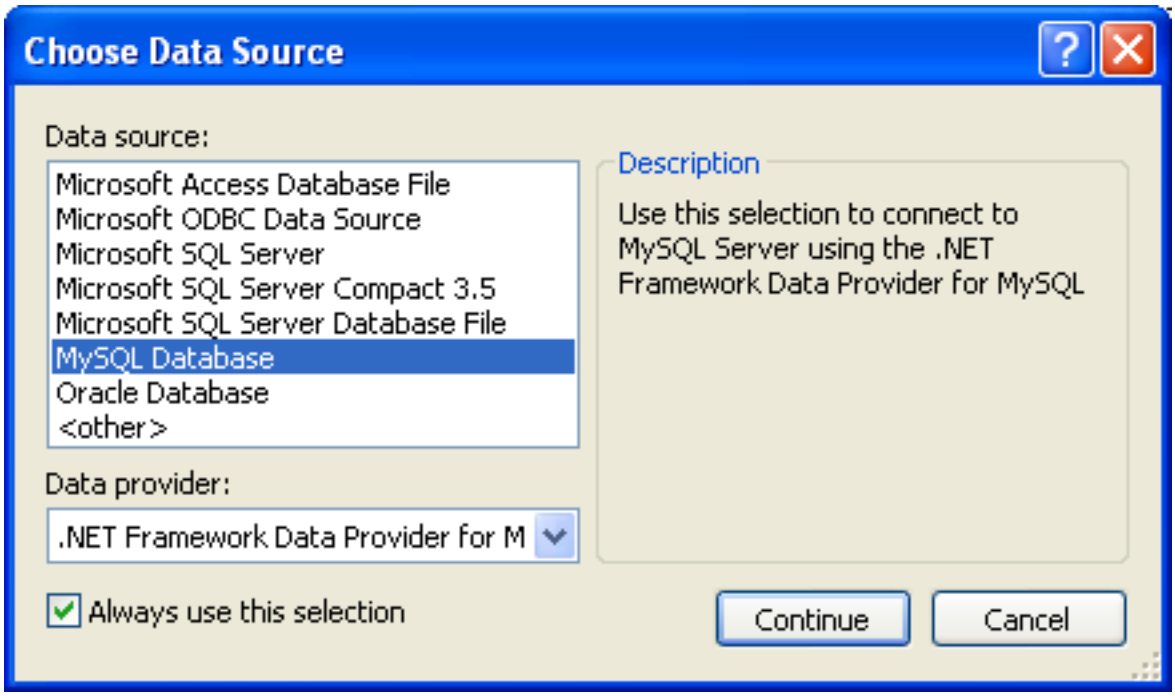
- Start Visual Studio, and open the Server Explorer window (VIEW, SERVER EXPLORER option in the main Visual Studio menu, or **Ctrl**+**W**, **L** hot keys).
- Right-click the Data Connections node, and choose the ADD CONNECTION... menu item.
- Add Connection dialog opens. Press the CHANGE button to choose MySQL Database as a data source.

Figure 20.1. Add Connection Context Menu



- Change Data Source dialog opens. Choose MySQL Database in the list of data sources (or the `<other>` option, if MySQL Database is absent), and then choose .NET Framework Data Provider for MySQL in the combo box of data providers.

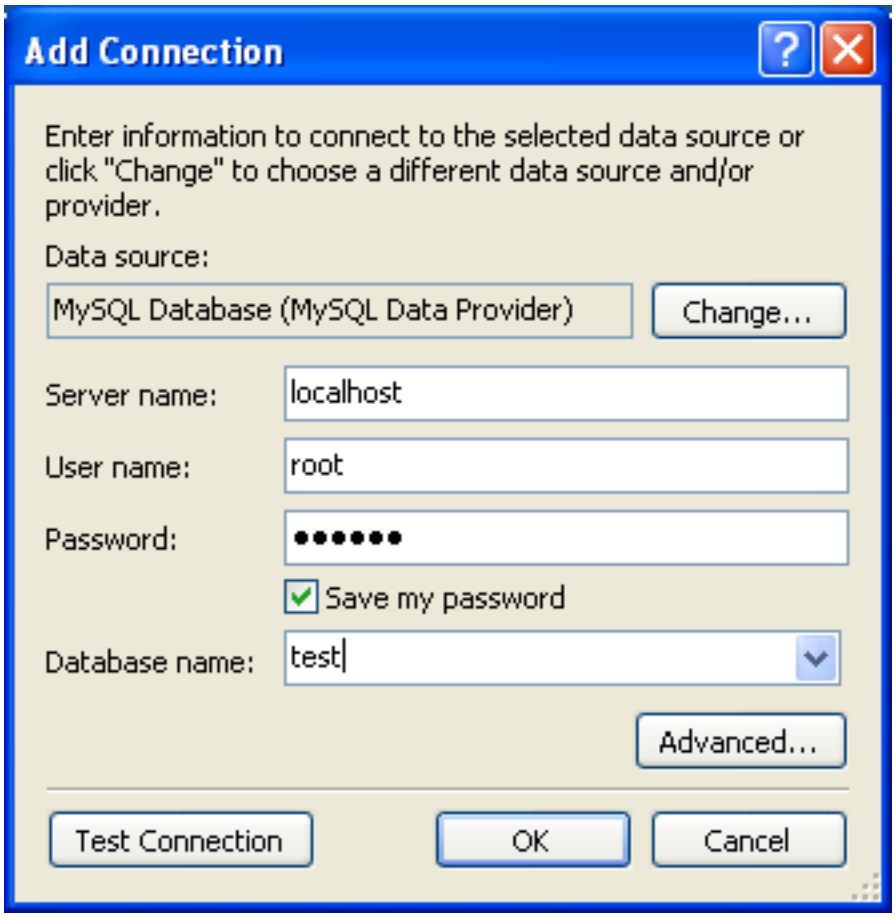
Figure 20.2. Choose Data Source



- Input the connection settings: the server host name (for example, localhost if the MySQL server is installed on the local machine), the user name, the password, and the default schema name. Note that you must specify the default schema name to open the connec-

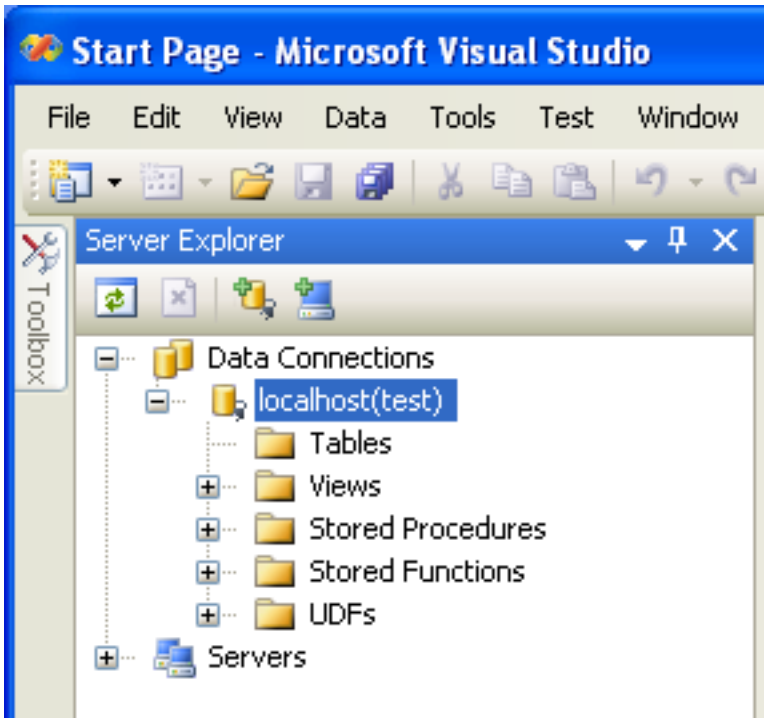
tion.

Figure 20.3. Add Connection Dialog



- You can also set the port to connect with the MySQL server by pressing the ADVANCED button. To test connection with the MySQL server, set the server host name, the user name, and the password, and press the TEST CONNECTION button. If the test succeeds, the success confirmation dialog opens.
- After you set all settings and test the connection, press OK. The newly created connection is displayed in Server Explorer. Now you can work with the MySQL server through standard Server Explorer GUI.

Figure 20.4. New Data Connection



After the connection is successfully established, all settings are saved for future use. When you start Visual Studio for the next time, just open the connection node in Server Explorer to establish a connection to the MySQL server again.

To modify and delete a connection, use the Server Explorer context menu for the corresponding node. You can modify any of the settings just by overwriting the existing values with new ones. Note that the connection may be modified or deleted only if no active editor for its objects is opened: otherwise you may loose your data.

20.2.3.2. Editing Tables

Connector/Net contains a table editor, which enables the visual creation and modification of tables.

The Table Designer can be accessed through a mouse action on table-type node of Server Explorer. To create a new table, right-click the **TABLES** node (under the connection node) and choose the CREATE TABLE command from the context menu.

To modify an existing table, double-click the node of the table you wish to modify, or right-click this node and choose the DESIGN item from the context menu. Either of the commands opens the Table Designer.

The table editor is implemented in the manner of the well-known Query Browser Table Editor, but with minor differences.

Figure 20.5. Editing New Table

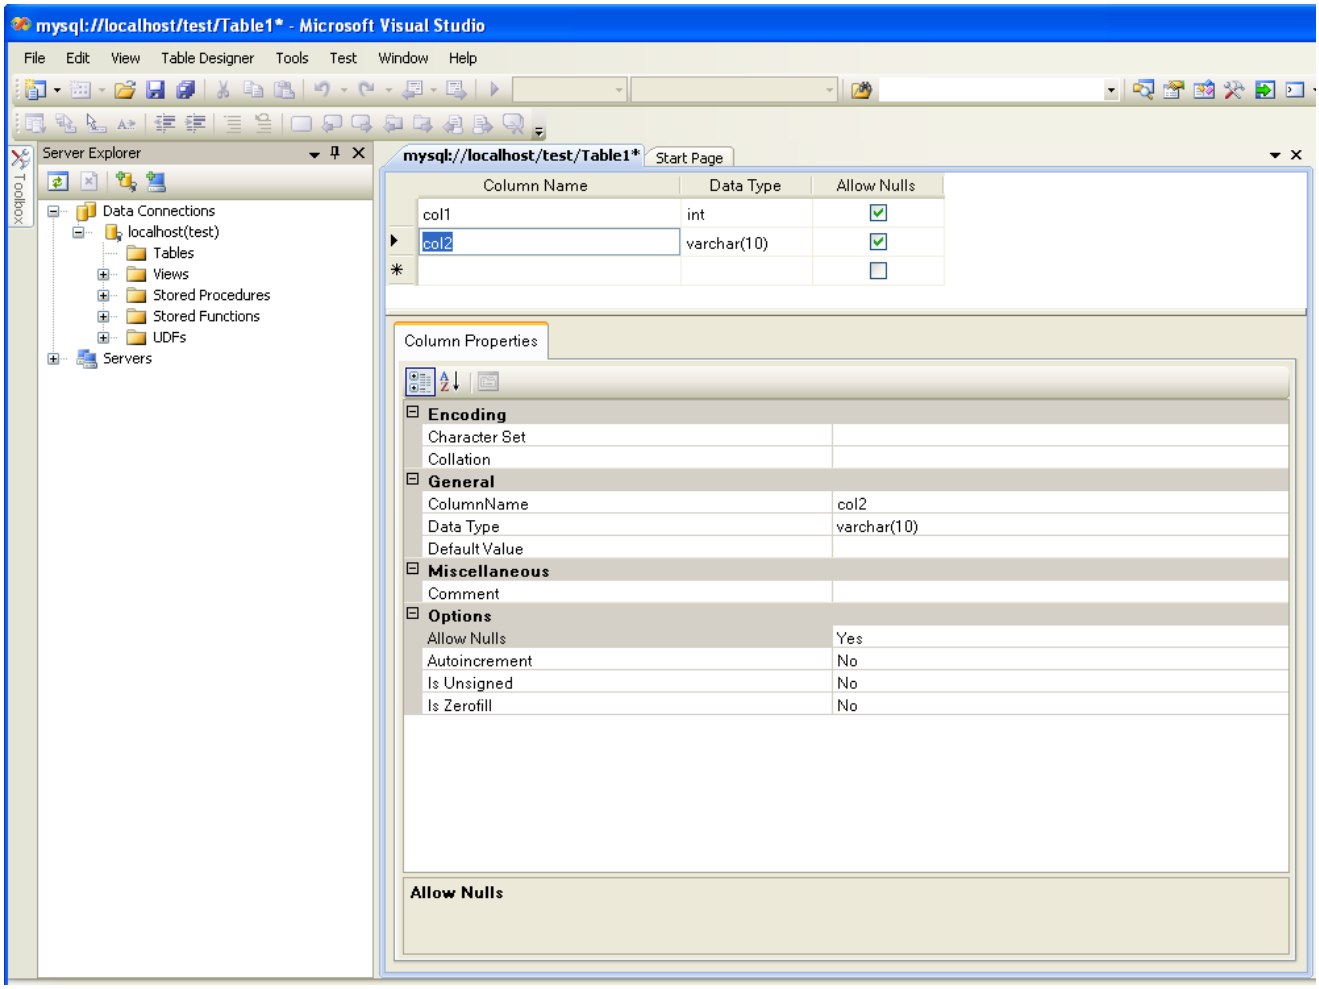


Table Designer consists of the following parts:

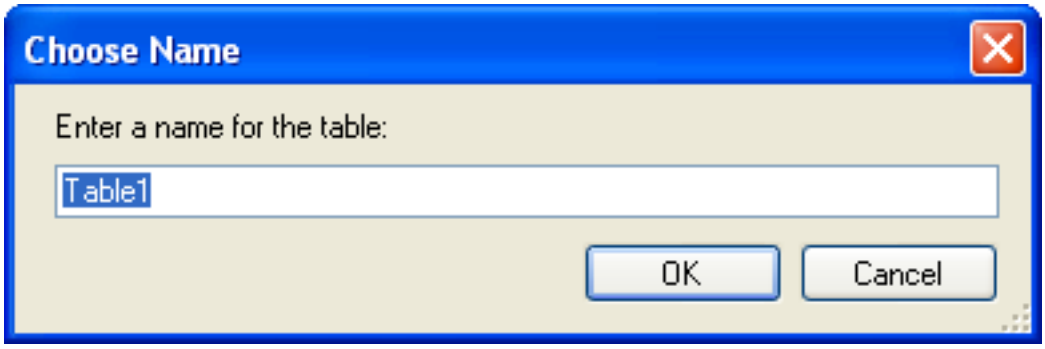
- Columns Editor - a data grid on top of the Table Designer. Use the Columns grid for column creation, modification, and deletion.
- Indexes tab - a tab on bottom of the Table Designer. Use the Indexes tab for indexes management.
- Foreign Keys tab - a tab on bottom of the Table Designer. Use the Foreign Keys tab for foreign keys management.
- Column Details tab - a tab on bottom of the Table Designer. Use the Column Details tab to set advanced column options.
- Properties window - a standard Visual Studio Properties window, where the properties of the edited table are displayed. Use the Properties window to set the table properties.

Each of these areas is discussed in more detail in subsequent sections.

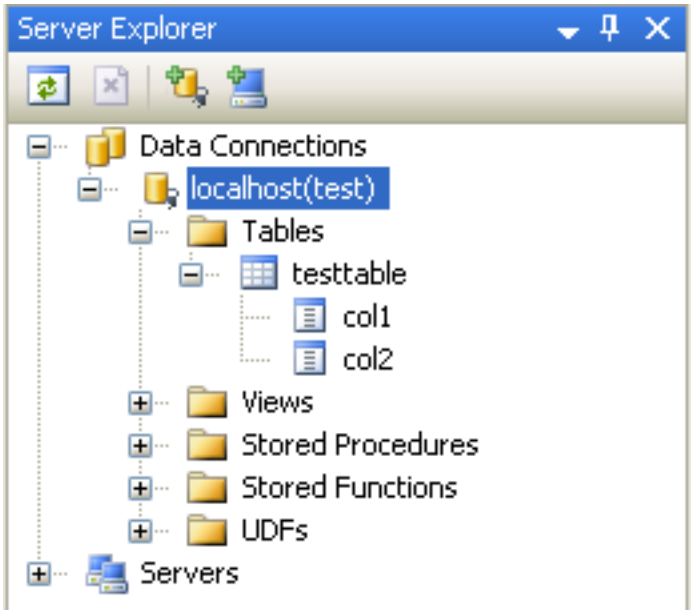
To save changes you have made in the Table Designer, use either SAVE or SAVE ALL button of the Visual Studio main toolbar, or just press **Ctrl**+**S**. If you have not already named the table you will be prompted to do so.

Figure 20.6. Choose Table Name



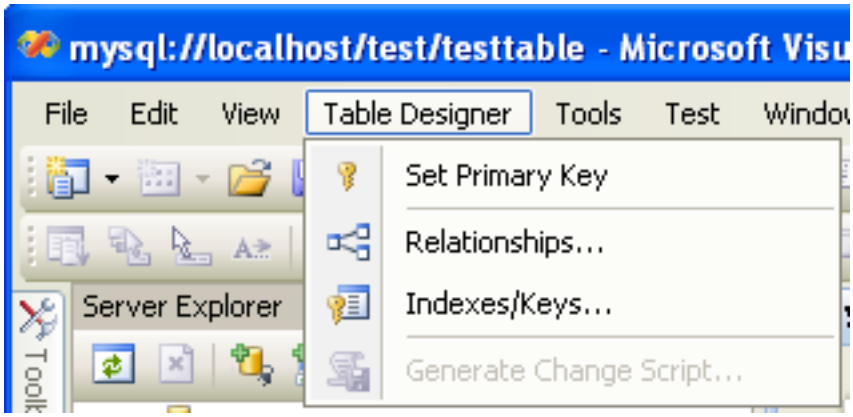
Once created you can view the table in the Server Explorer.

Figure 20.7. Newly Created Table



The Table Designer main menu allows you to set a Primary Key column, edit Relationships such as Foreign Keys, and create Indexes.

Figure 20.8. Table Designer Main Menu



20.2.3.2.1. Column Editor

You can use the Column Editor to set or change the name, data type, default value, and other properties of a table column. To set the focus to a needed cell of a grid, use the mouse click. Also you can move through the grid using **Tab** and **Shift**+**Tab** keys.

To set or change the name, data type, default value and comment of a column, activate the appropriate cell and type the desired value.

To set or unset flag-type column properties (`NOT NULL`, auto incremented, flags), check or uncheck the corresponding check boxes. Note that the set of column flags depends on its data type.

To reorder columns, index columns or foreign key columns in the Column Editor, select the whole column you wish to reorder by clicking the selector column on the left of the column grid. Then move the column by using **Ctrl**+**Up** (to move the column up) or **Ctrl**+**Down** (to move the column down) keys.

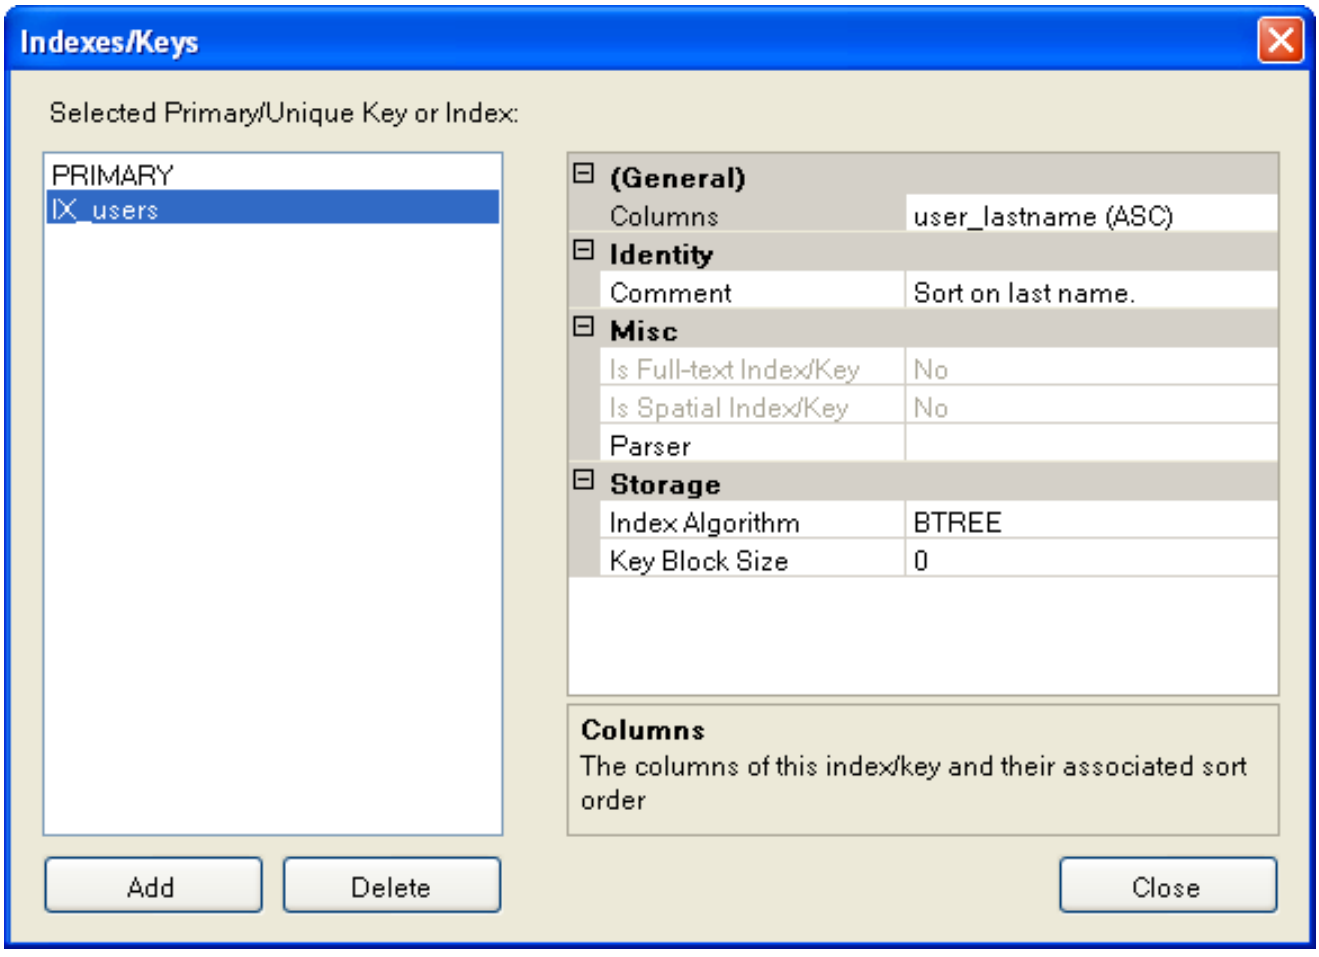
To delete a column, select it by clicking the selector column on the left of the column grid, then press the **Delete** button on a keyboard.

20.2.3.2.2. Editing Indexes

Indexes management is performed via the **INDEXES/KEYS** dialog.

To add an index, select TABLE DESIGNER, INDEXES/KEYS... from the main menu, and click ADD to add a new index. You can then set the index name, index kind, index type, and a set of index columns.

Figure 20.9. Indexes Dialog



To remove an index, select it in the list box on the left, and click the DELETE button.

To change index settings, select the needed index in the list box on the left. The detailed information about the index is displayed in the panel on the right hand side. Change the desired values.

20.2.3.2.3. Editing Foreign Keys

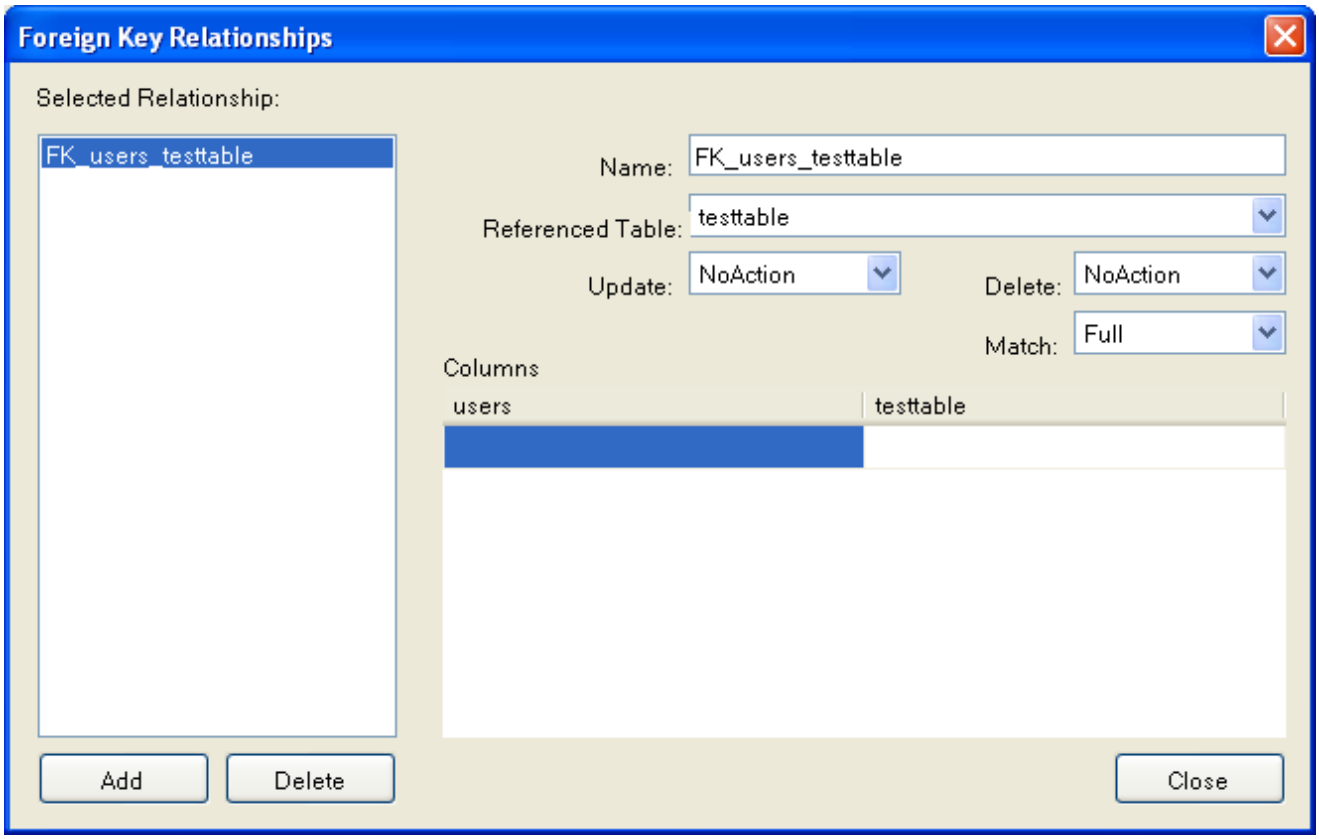
Foreign Keys management is performed via the **FOREIGN KEY RELATIONSHIPS** dialog.

To add a foreign key, select TABLE DESIGNER, RELATIONSHIPS... from the main menu. This displays the **FOREIGN KEY RELATIONSHIP** dialog. Click ADD. You can then set the foreign key name, referenced table name, foreign key columns, and actions upon update and delete.

To remove a foreign key, select it in the list box on the left, and click the DELETE button.

To change foreign key settings, select the required foreign key in the list box on the left. The detailed information about the foreign key is displayed in the right hand panel. Change the desired values.

Figure 20.10. Foreign Key Relationships Dialog



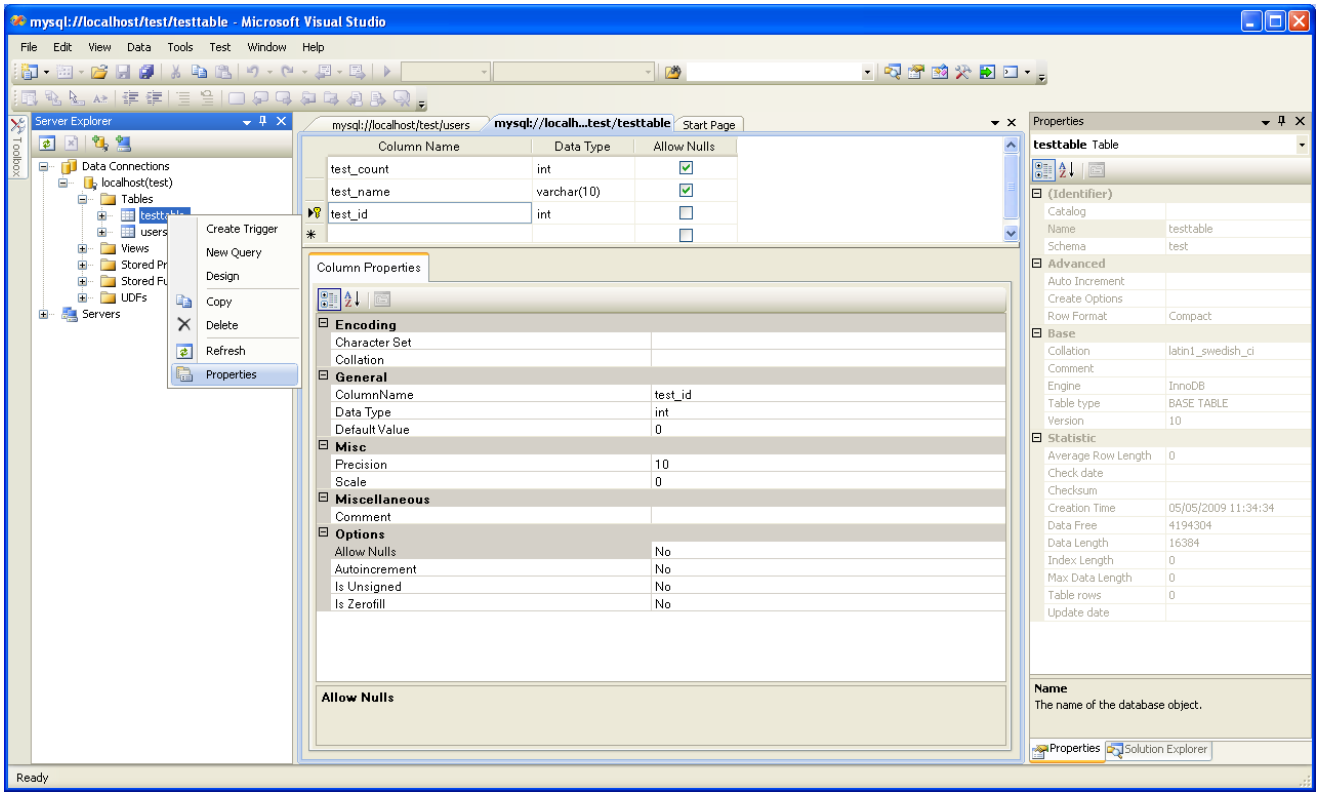
20.2.3.2.4. Column Properties

The **COLUMN PROPERTIES** tab can be used to set column options. In addition to the general column properties presented in the Column Editor, in the **COLUMN PROPERTIES** tab you can set additional properties such as Character Set, Collation and Precision.

20.2.3.2.5. Table Properties

To bring up Table Properties select the table and right-click to activate the context menu. Select PROPERTIES. The **TABLE PROPERTIES** dockable window will be displayed.

Figure 20.11. Table Properties Menu Item

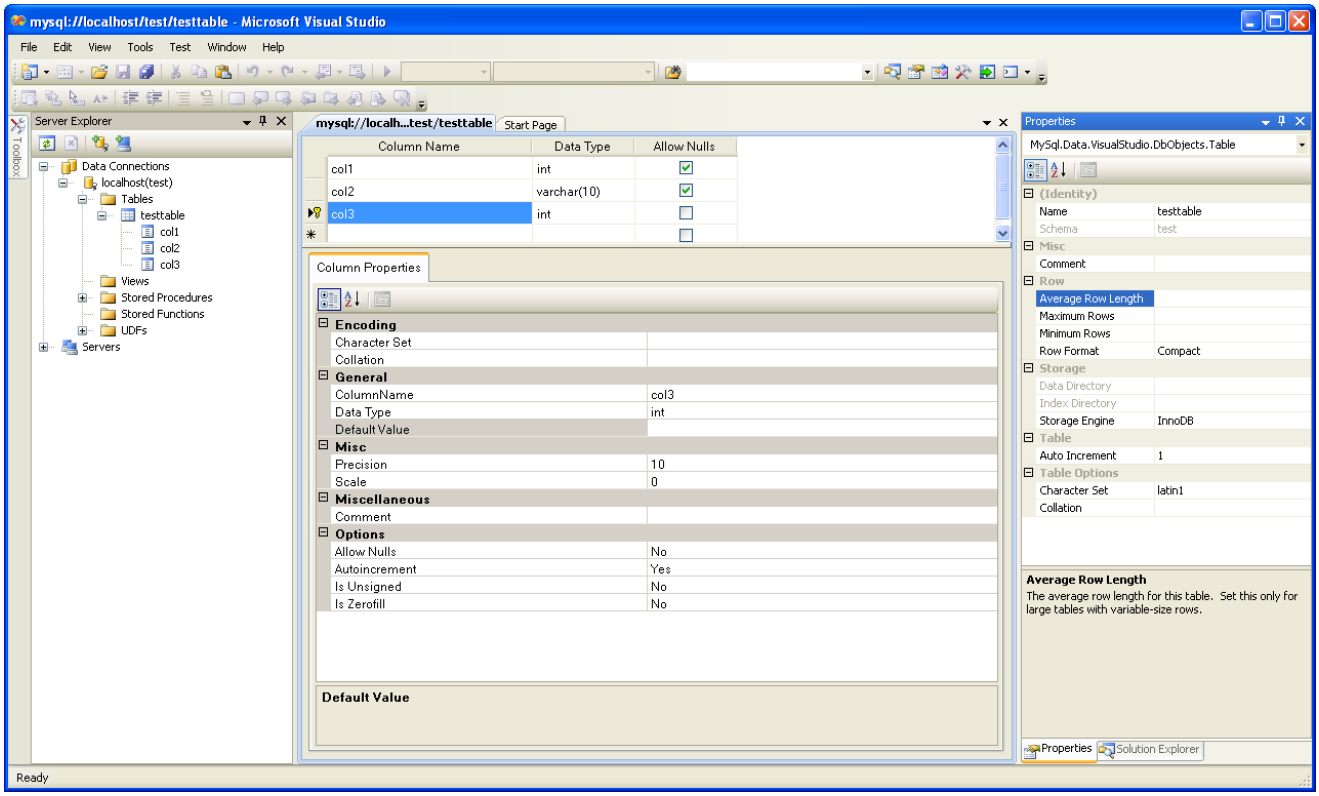


The following table properties can be set:

- Auto Increment
- Average Row Length
- Character Set
- Collation
- Comment
- Data Directory
- Index Directory
- Maximum Rows
- Minimum Rows
- Name
- Row Format
- Schema
- Storage Engine

The property `Schema` is read only.

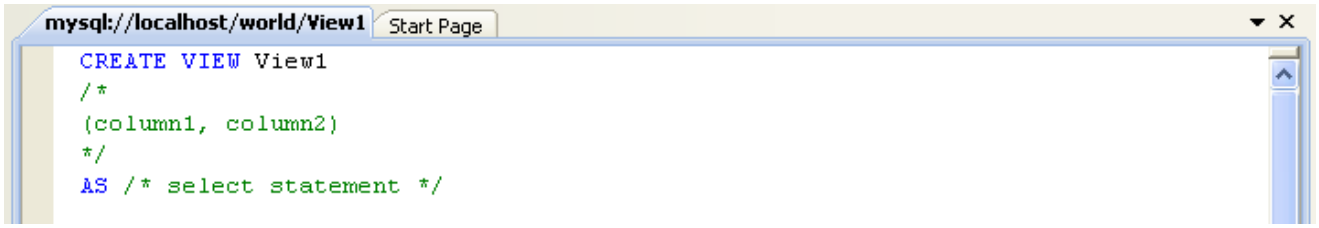
Figure 20.12. Table Properties



20.2.3.3. Editing Views

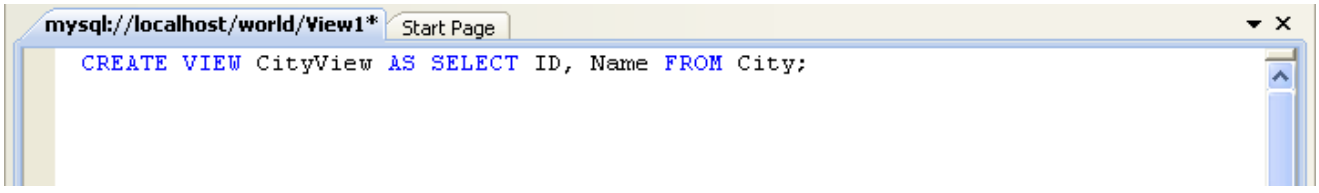
To create a new view, right-click the Views node under the connection node in Server Explorer. From the node's context menu, choose the CREATE VIEW command. This command opens the SQL Editor.

Figure 20.13. Editing View SQL



You can then enter the SQL for your view.

Figure 20.14. View SQL Added



To modify an existing view, double-click a node of the view you wish to modify, or right-click this node and choose the ALTER VIEW command from a context menu. Either of the commands opens the SQL Editor.

All other view properties can be set in the Properties window. These properties are:

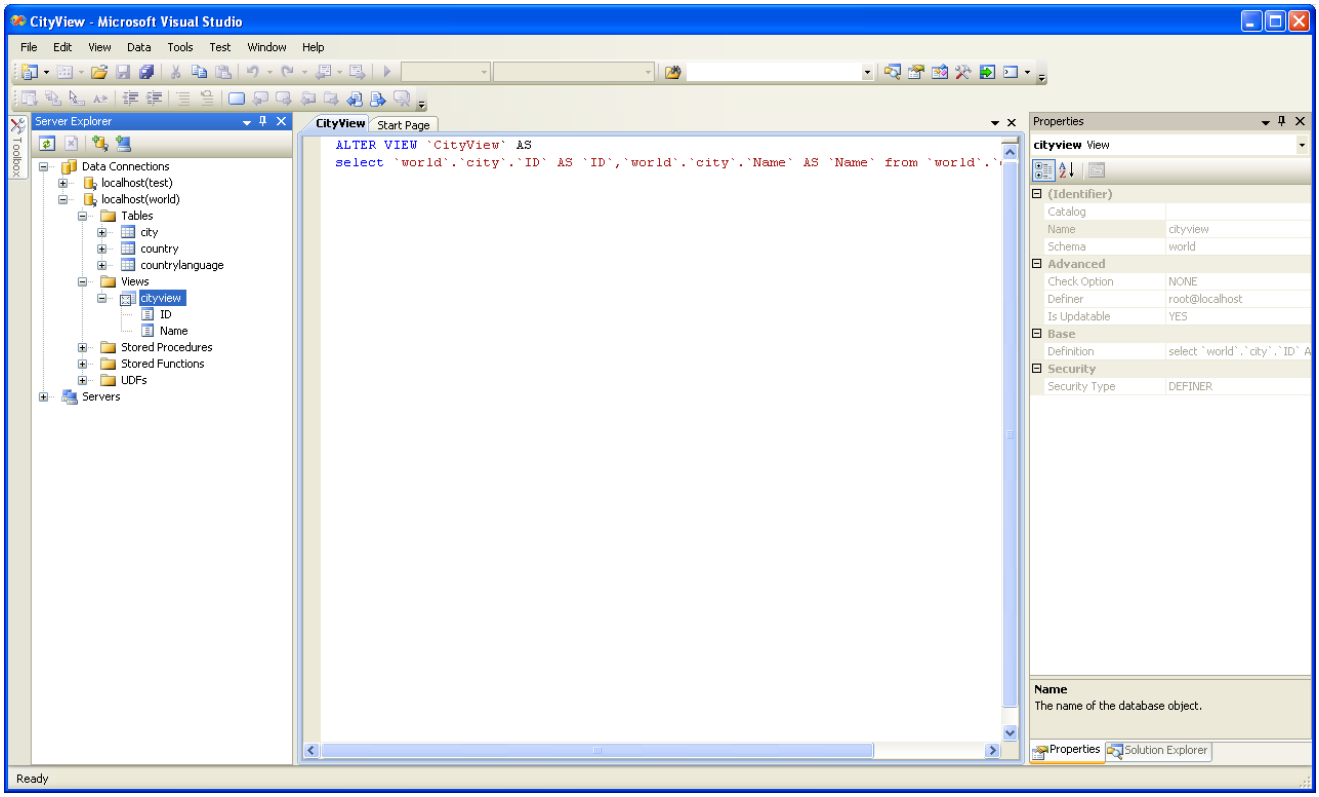
- Catalog
- Check Option
- Definer
- Definition
- Definer
- Is Updateable
- Name
- Schema
- Security Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case you set the desired value with an embedded combobox.

The properties `Is Updatable` and `Schema` are readonly.

To save changes you have made, use either SAVE or SAVE ALL buttons of the Visual Studio main toolbar, or just press **Ctrl**+**S**.

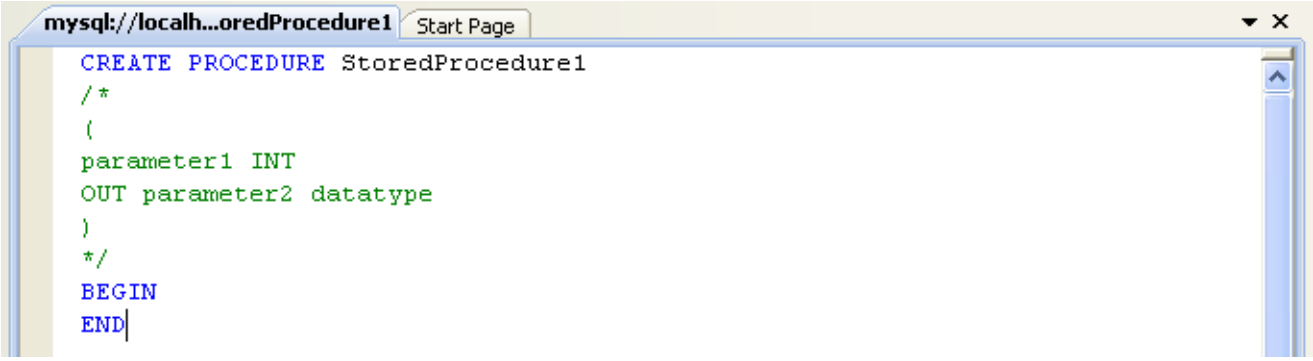
Figure 20.15. View SQL Saved



20.2.3.4. Editing Stored Procedures and Functions

To create a new stored procedure, right-click the **STORED PROCEDURES** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command. This command opens the SQL Editor.

Figure 20.16. Edit Stored Procedure SQL



To create a new stored function, right-click the **FUNCTIONS** node under the connection node in Server Explorer. From the node's context menu, choose the **CREATE ROUTINE** command.

To modify an existing stored routine (procedure or function), double-click the node of the routine you wish to modify, or right-click this node and choose the **ALTER ROUTINE** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the routine definition using SQL Editor, type this definition in the SQL Editor using standard SQL. All other routine properties can be set in the Properties window. These properties are:

- Body
- Catalog
- Comment
- Creation Time
- Data Access
- Definer
- Definition
- External Name
- External Language
- Is Deterministic
- Last Modified
- Name
- Parameter Style
- Returns
- Schema
- Security Type
- Specific Name
- SQL Mode

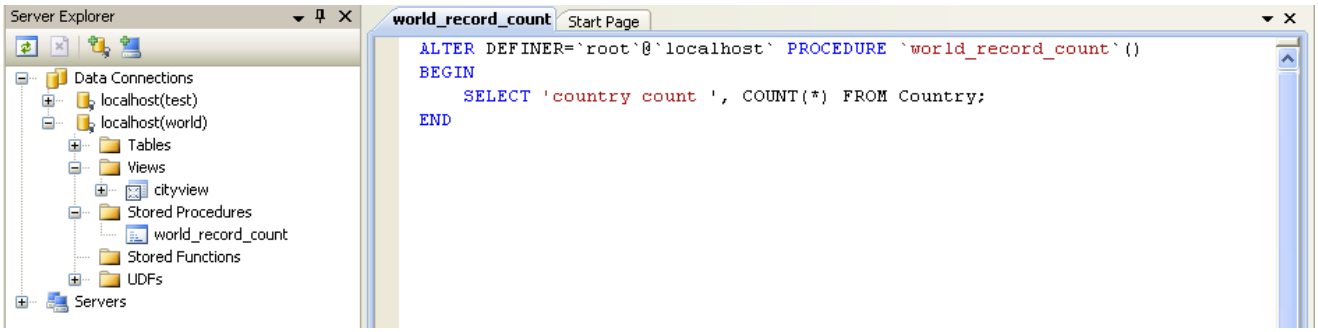
- SQL Path
- Type

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case set the desired value using the embedded combo box.

You can also set all the options directly in the SQL Editor, using the standard `CREATE PROCEDURE` or `CREATE FUNCTION` statement. However, it is recommended to use the Properties window instead.

To save changes you have made, use either **SAVE** or **SAVE ALL** buttons of the Visual Studio main toolbar, or just press **Ctrl**+**S**.

Figure 20.17. Stored Procedure SQL Saved



20.2.3.5. Editing Triggers

To create a new trigger, right-click the node of the table, for which you wish to add a trigger. From the node's context menu, choose the **CREATE TRIGGER** command. This command opens the SQL Editor.

To modify an existing trigger, double-click the node of the trigger you wish to modify, or right-click this node and choose the **ALTER TRIGGER** command from the context menu. Either of the commands opens the SQL Editor.

To create or alter the trigger definition using SQL Editor, type the trigger statement in the SQL Editor using standard SQL.

> **Note**
>
> You should enter only the trigger statement, that is, the part of the `CREATE TRIGGER` query that is placed after the `FOR EACH ROW` clause.

All other trigger properties are set in the Properties window. These properties are:

- Definer
- Event Manipulation
- Name
- Timing

Some of these properties can have arbitrary text values, others accept values from a predefined set. In the latter case set the desired value using the embedded combo box.

The properties `Event Table`, `Schema`, and `Server` in the Properties window are read only.

To save changes you have made, use either SAVE or SAVE ALL buttons of the Visual Studio main toolbar, or just press **Ctrl**+**S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

20.2.3.6. Editing User Defined Functions (UDF)

To create a new User Defined Function (UDF), right-click the **UDFs** node under the connection node in Server Explorer. From the node's context menu, choose the CREATE UDF command. This command opens the UDF Editor.

To modify an existing UDF, double-click the node of the UDF you wish to modify, or right-click this node and choose the ALTER UDF command from the context menu. Either of the commands opens the UDF Editor.

The UDF editor allows you to set the following properties:

- Name
- So-name (DLL name)
- Return type
- Is Aggregate

There are text fields for both names, a combo box for the return type, and a check box to indicate if the UDF is aggregate. All these options are also accessible via the Properties window.

The property `Server` in the Properties window is read only.

To save changes you have made, use either SAVE or SAVE ALL buttons of the Visual Studio main toolbar, or just press **Ctrl**+**S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

20.2.3.7. Cloning Database Objects

Tables, views, stored procedures, and functions can be cloned using the appropriate Clone command from the context menu: CLONE TABLE, CLONE VIEW, CLONE ROUTINE. The clone commands open the corresponding editor for a new object: the **TABLE EDITOR** for cloning a table, and the **SQL EDITOR** for cloning a view or a routine.

The editor is filled with values of the original object. You can modify these values in a usual manner.

To save the cloned object, use either Save or Save All buttons of the Visual Studio main toolbar, or just press **Ctrl**+**S**. Before changes are saved, you will be asked to confirm the execution of the corresponding SQL query in a confirmation dialog.

20.2.3.8. Dropping Database Objects

Tables, views, stored routines, triggers, and UDFs can be dropped with the appropriate Drop command selected from its context menu: DROP TABLE, DROP VIEW, DROP ROUTINE, DROP TRIGGER, DROP UDF.

You will be asked to confirm the execution of the corresponding drop query in a confirmation dialog.

Dropping of multiple objects is not supported.

20.2.3.9. Using the ADO.NET Entity Framework

Connector/NET 6.0 introduced support for the ADO.NET Entity Framework. ADO.NET Entity Framework was included with .NET Framework 3.5 Service Pack 1, and Visual Studio 2008 Service Pack 1. ADO.NET Entity Framework was released on 11th August 2008.

ADO.NET Entity Framework provides an Object Relational Mapping (ORM) service, mapping the relational database schema to objects. The ADO.NET Entity Framework defines several layers, these can be summarized as:

- **Logical** - this layer defines the relational data and is defined by the Store Schema Definition Language (SSDL).
- **Conceptual** - this layer defines the .NET classes and is defined by the Conceptual Schema Definition Language (CSDL)
- **Mapping** - this layer defines the mapping from .NET classes to relational tables and associations, and is defined by Mapping Specification Language (MSL).

Connector/NET integrates with Visual Studio 2008 to provide a range of helpful tools to assist the developer.

A full treatment of ADO.NET Entity Framework is beyond the scope of this manual. You are encouraged to review the Microsoft ADO.NET Entity Framework documentation.

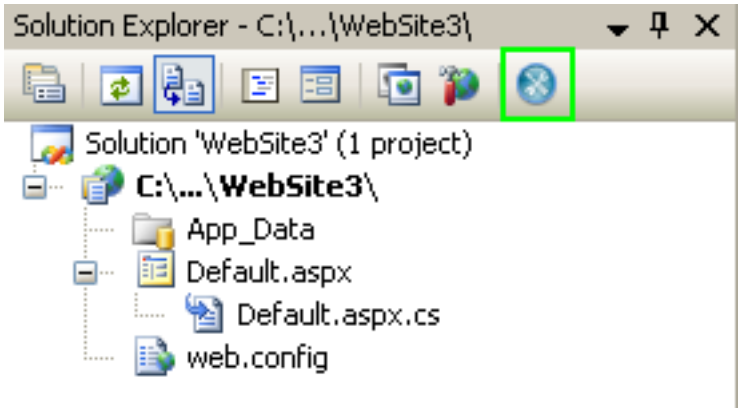
Tutorials on getting started with ADO.NET Entity Framework are available. See Section 20.2.4.5, “Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source” and Section 20.2.4.6, “Tutorial: Databinding in ASP.NET using LINQ on Entities”.

20.2.3.10. MySQL Website Configuration Tool

MySQL Connector/NET 6.1 introduced the MySQL Website Configuration Tool. This is a facility available in Visual Studio that allows you to configure the Membership, Role, Session State and Profile Provider, without having to resort to editing configuration files. You simply run the tool, set your configuration options, and the tool will modify your `web.config` file accordingly.

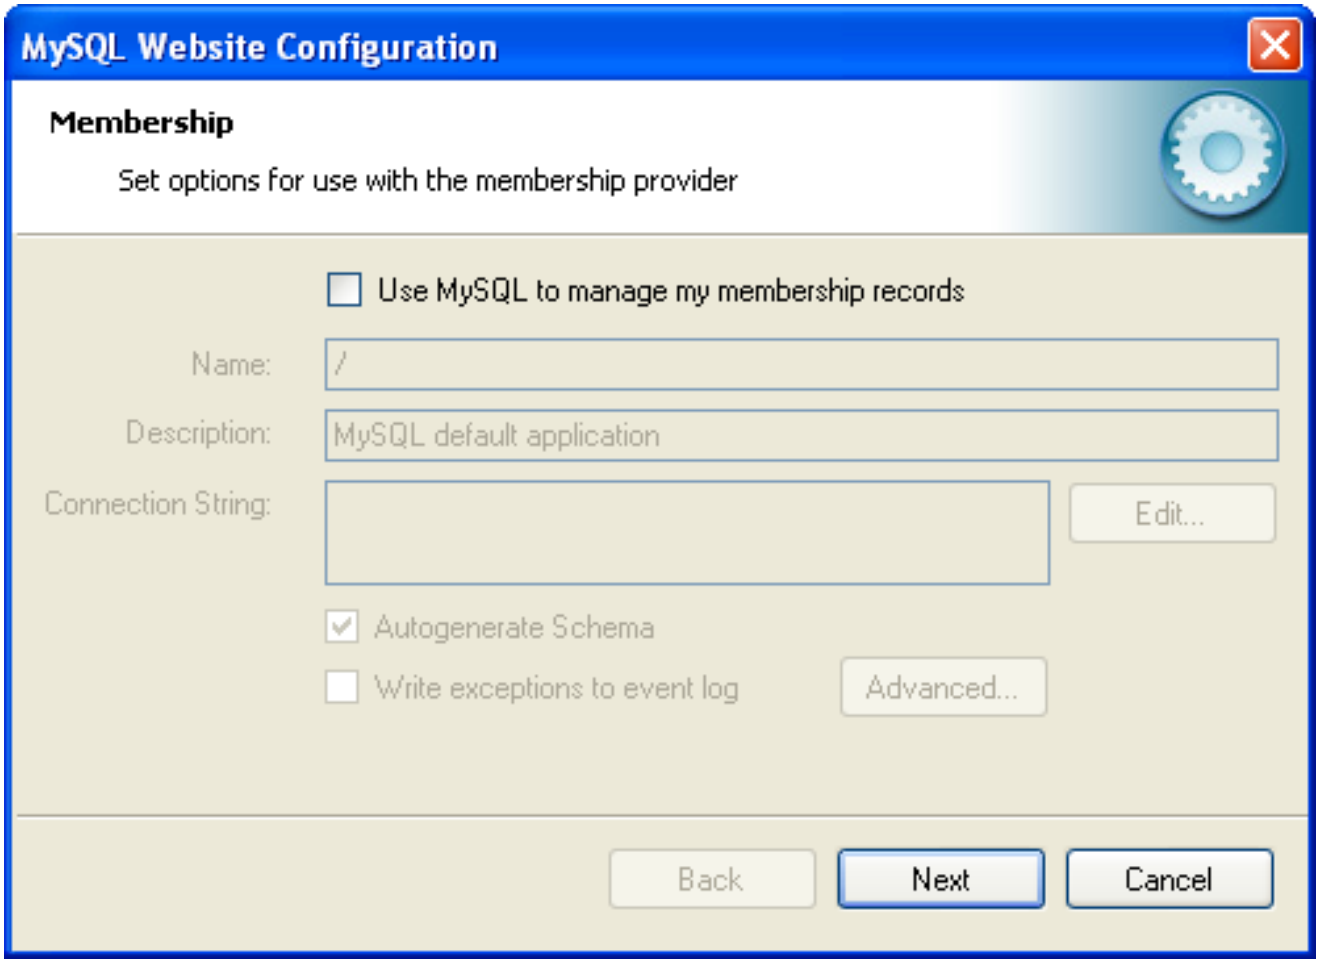
The MySQL Website Configuration Tool appears as a small icon on the Solution Explorer toolbar in Visual Studio, as show by the following screenshot:

Figure 20.18. MySQL Website Configuration Tool



Clicking the Website Configuration Tool icon launches the wizard and displays the first screen:

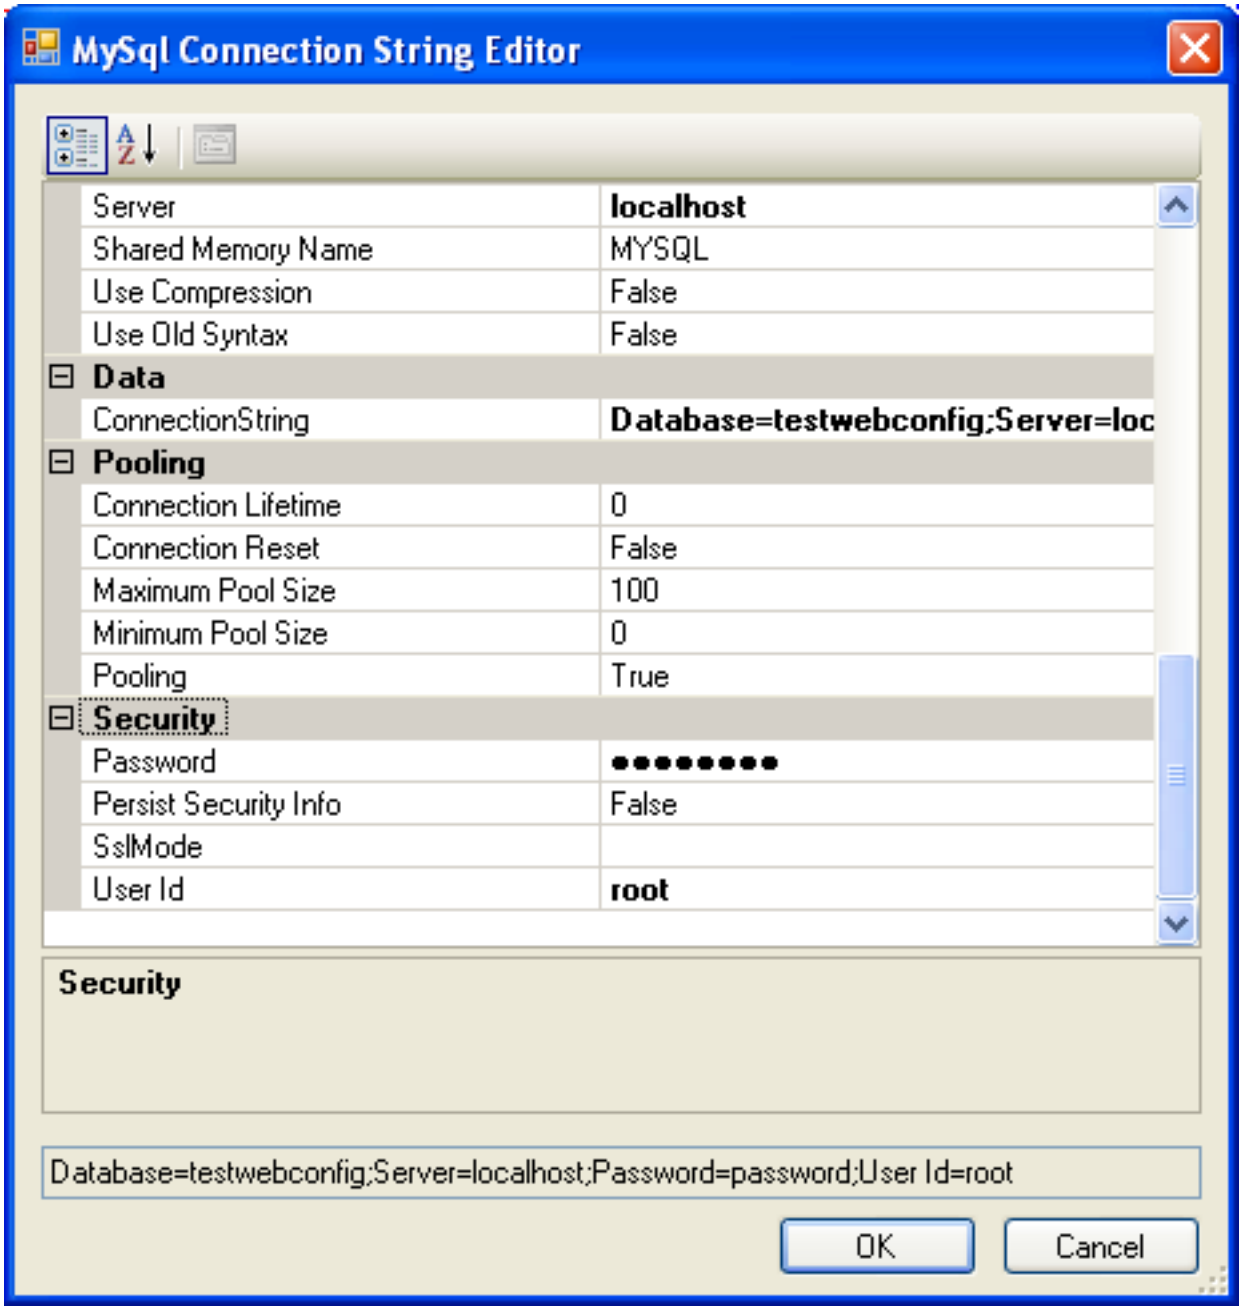
Figure 20.19. MySQL Website Configuration Tool - Membership



This allows you to enable use of the MySQL Membership Provider. Simply click the checkbox to enable this. You can now enter the name of the application that you are creating the configuration for. You can also enter a description for the application.

You can then click the EDIT... button to launch the Connection String Editor:

Figure 20.20. MySQL Website Configuration Tool - Connection String Editor



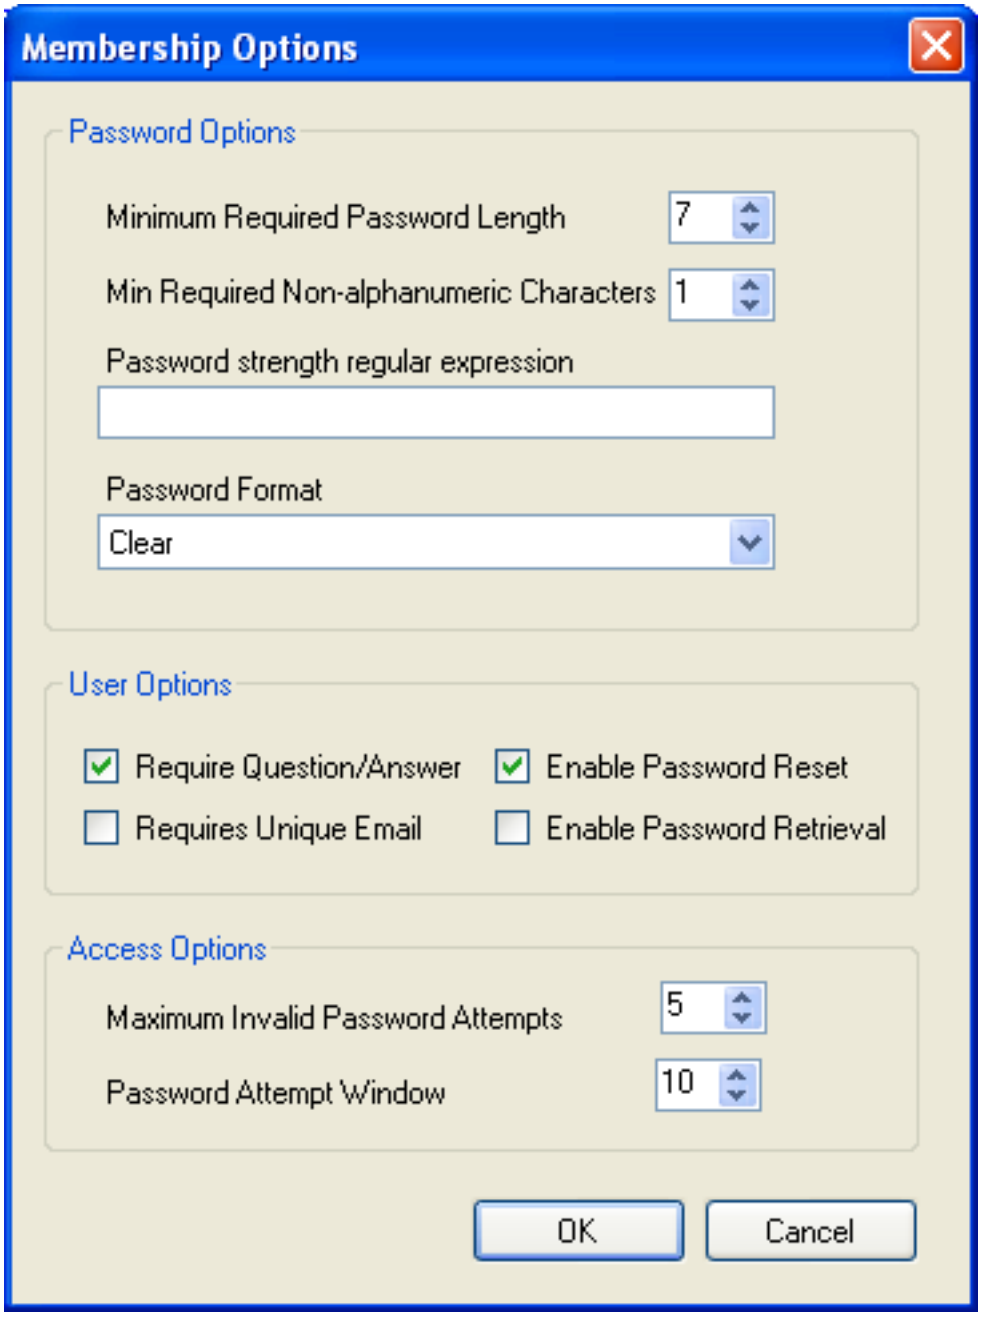
Note that if you have already defined a connection string for the providers manually in `web.config`, or previously using the tool, this will be automatically loaded and displayed, and can then be modified in this dialog.

You can also ensure that the necessary schema are created automatically for you by selecting the Autogenerate Schema checkbox. These schema are used to store membership information. The database used to storage is the one specified in the connection string.

You can also ensure that exceptions generated by the application will be written to the event log by selecting the **WRITE EXCPETIONS TO EVENT LOG** checkbox.

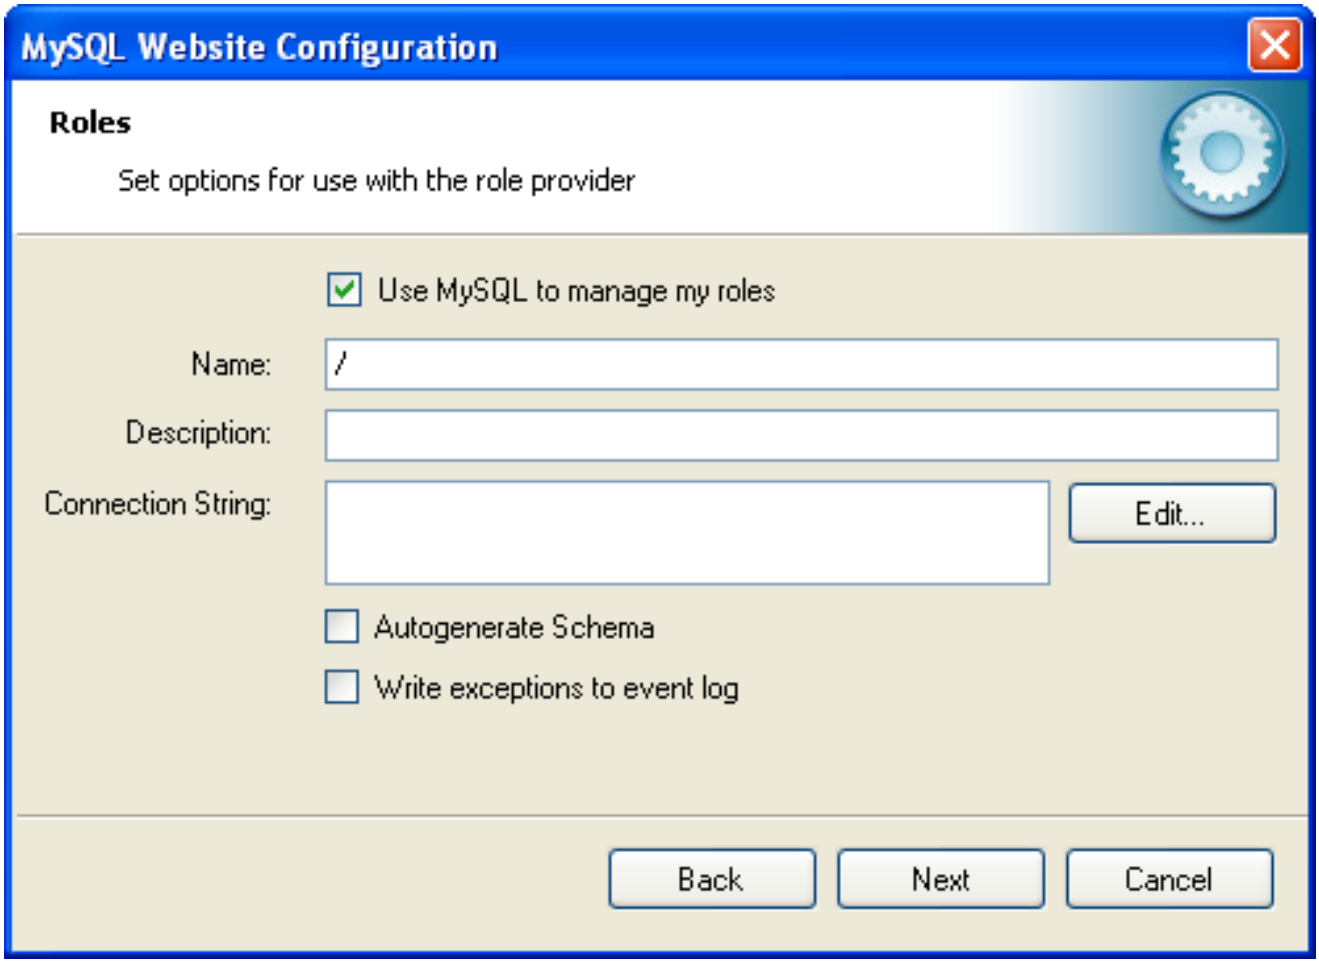
Clicking the ADVANCED... button launches a dialog that allows you to set Membership Options. These options dictate such variables as password length required when a user signs up, whether the password is encrypted and whether the user can reset their password or not.

Figure 20.21. MySQL Website Configuration Tool - Advanced Options



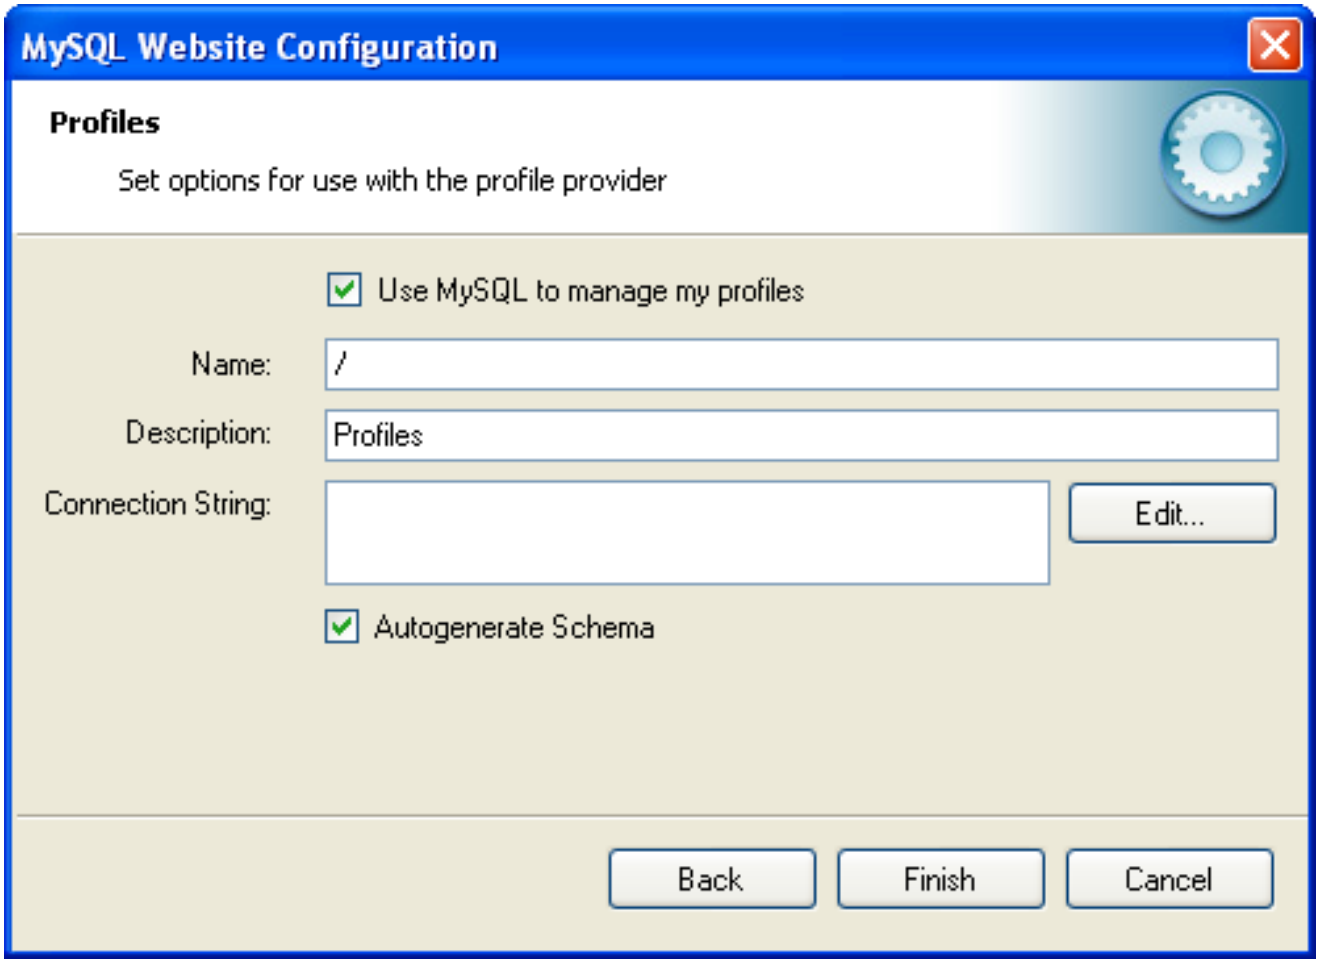
Once information has been set up as required for configuration of the Membership Provider the NEXT button can be clicked to display the Roles Provider screen:

Figure 20.22. MySQL Website Configuration Tool - Roles



Again the connection string can be edited, a description added and Autogenerate Schema can be enabled before clicking NEXT to go to the Profiles Provider screen:

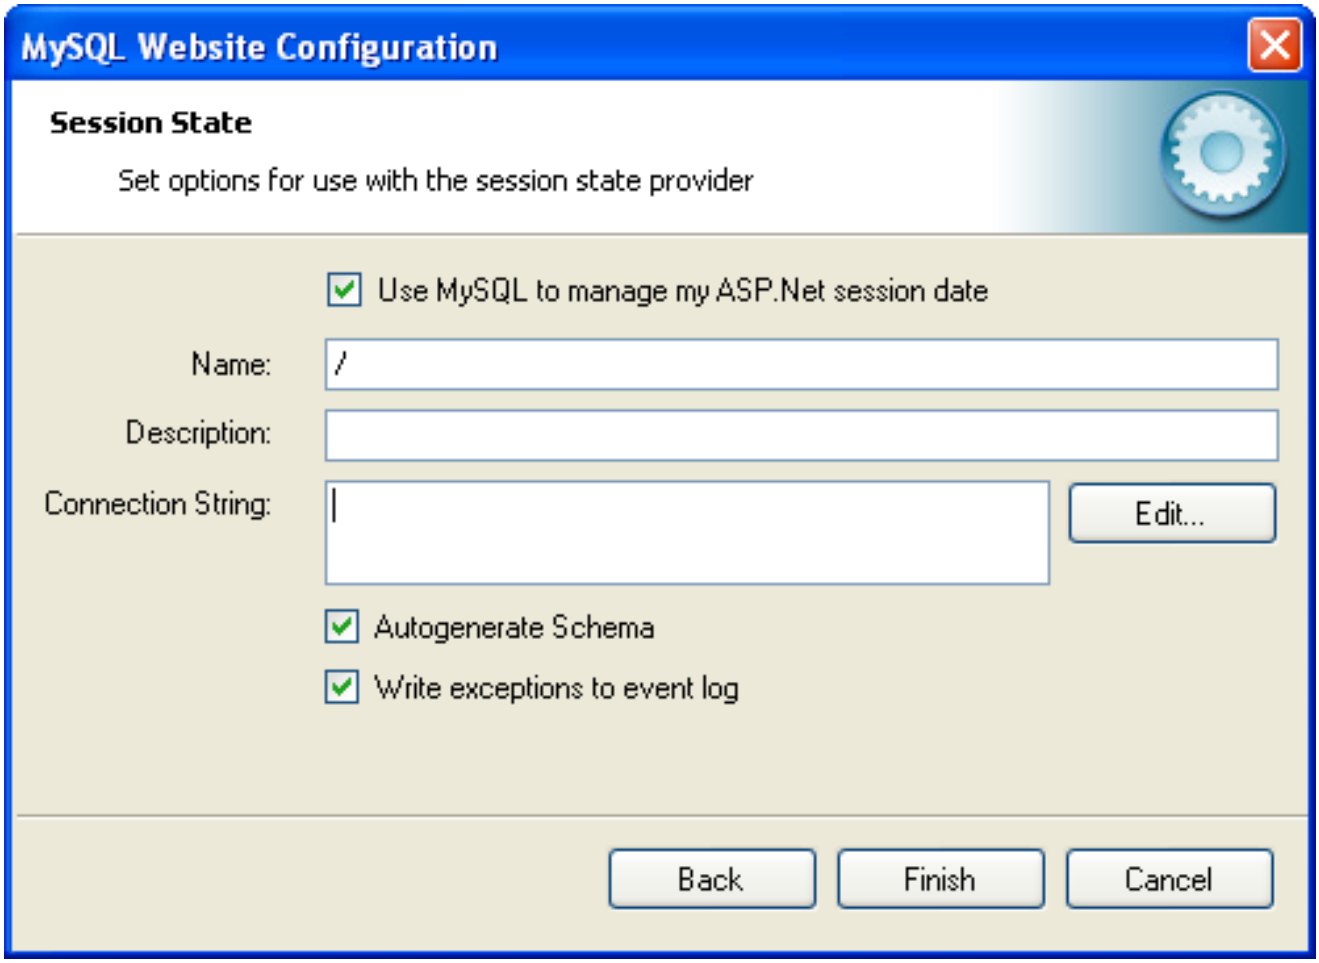
Figure 20.23. MySQL Website Configuration Tool - Profiles



This screen display similar options to the previous screens.

Click NEXT to proceed to the Session State configuration page:

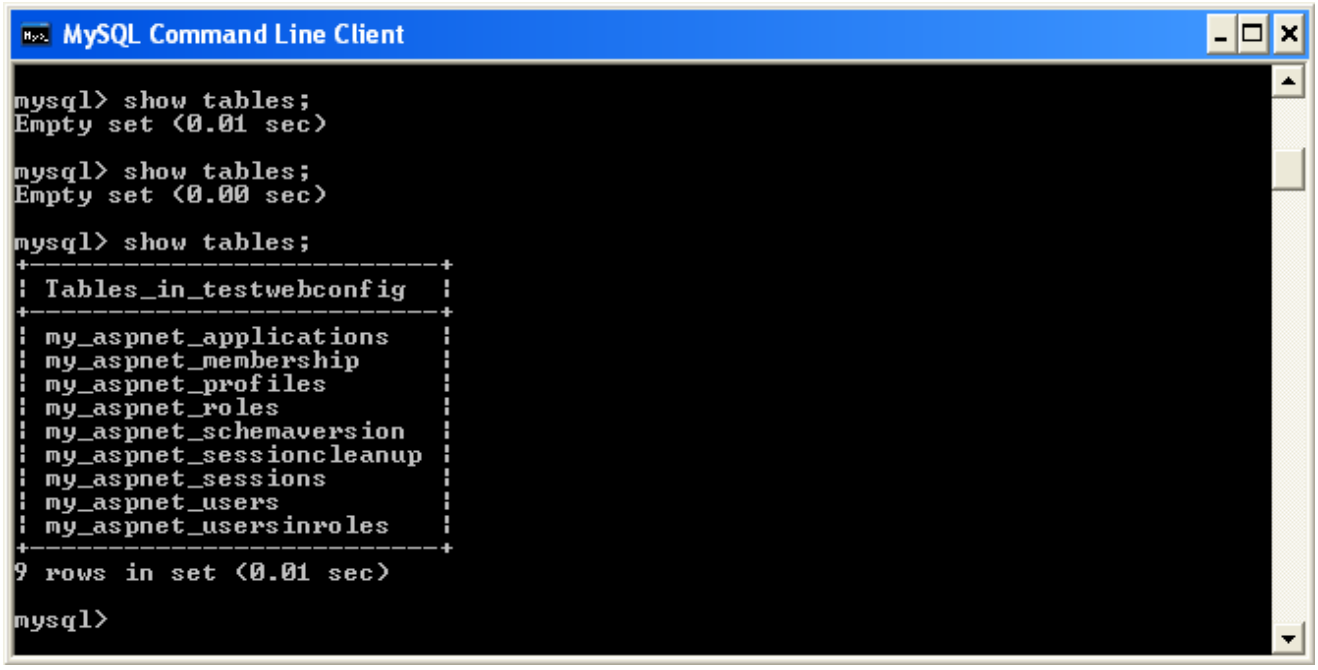
Figure 20.24. MySQL Website Configuration Tool - Session State



Once you have set up the Session State Provider as required, click FINISH to exit the wizard.

At this point it is necessary to select the Authentication Type to From Internet. This can be done by launching the ASP.NET Configuration Tool, and selecting the Security tab. Click the Select authentication type link and ensure that the From the internet radio button is selected. You can now examine the database you created to store membership information. All the necessary tables will have been created for you:

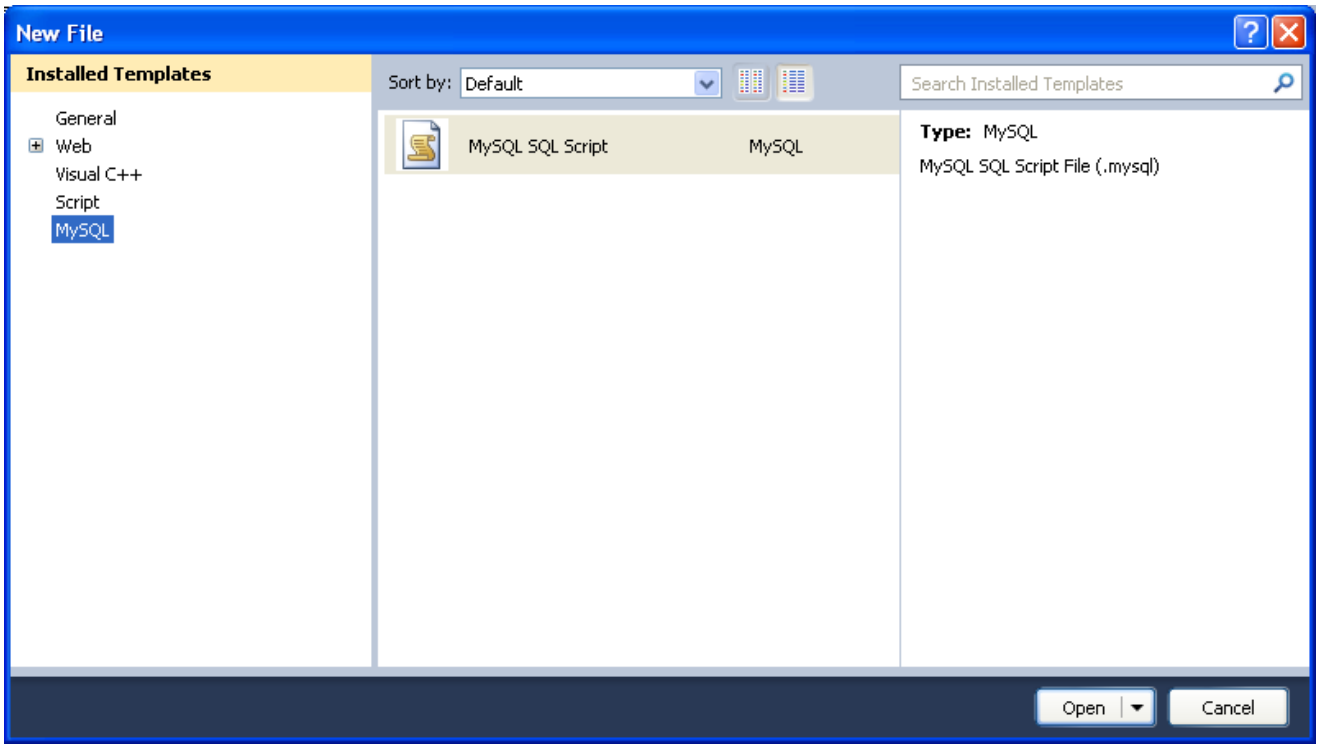
Figure 20.25. MySQL Website Configuration Tool - Tables



20.2.3.11. MySQL SQL Editor

MySQL Connector/NET 6.3.2 introduced a new MySQL SQL Editor. The easiest way to invoke the editor is by selecting the NEW, FILE menu item from the Visual Studio main menu. This displays the **NEW FILE** dialog:

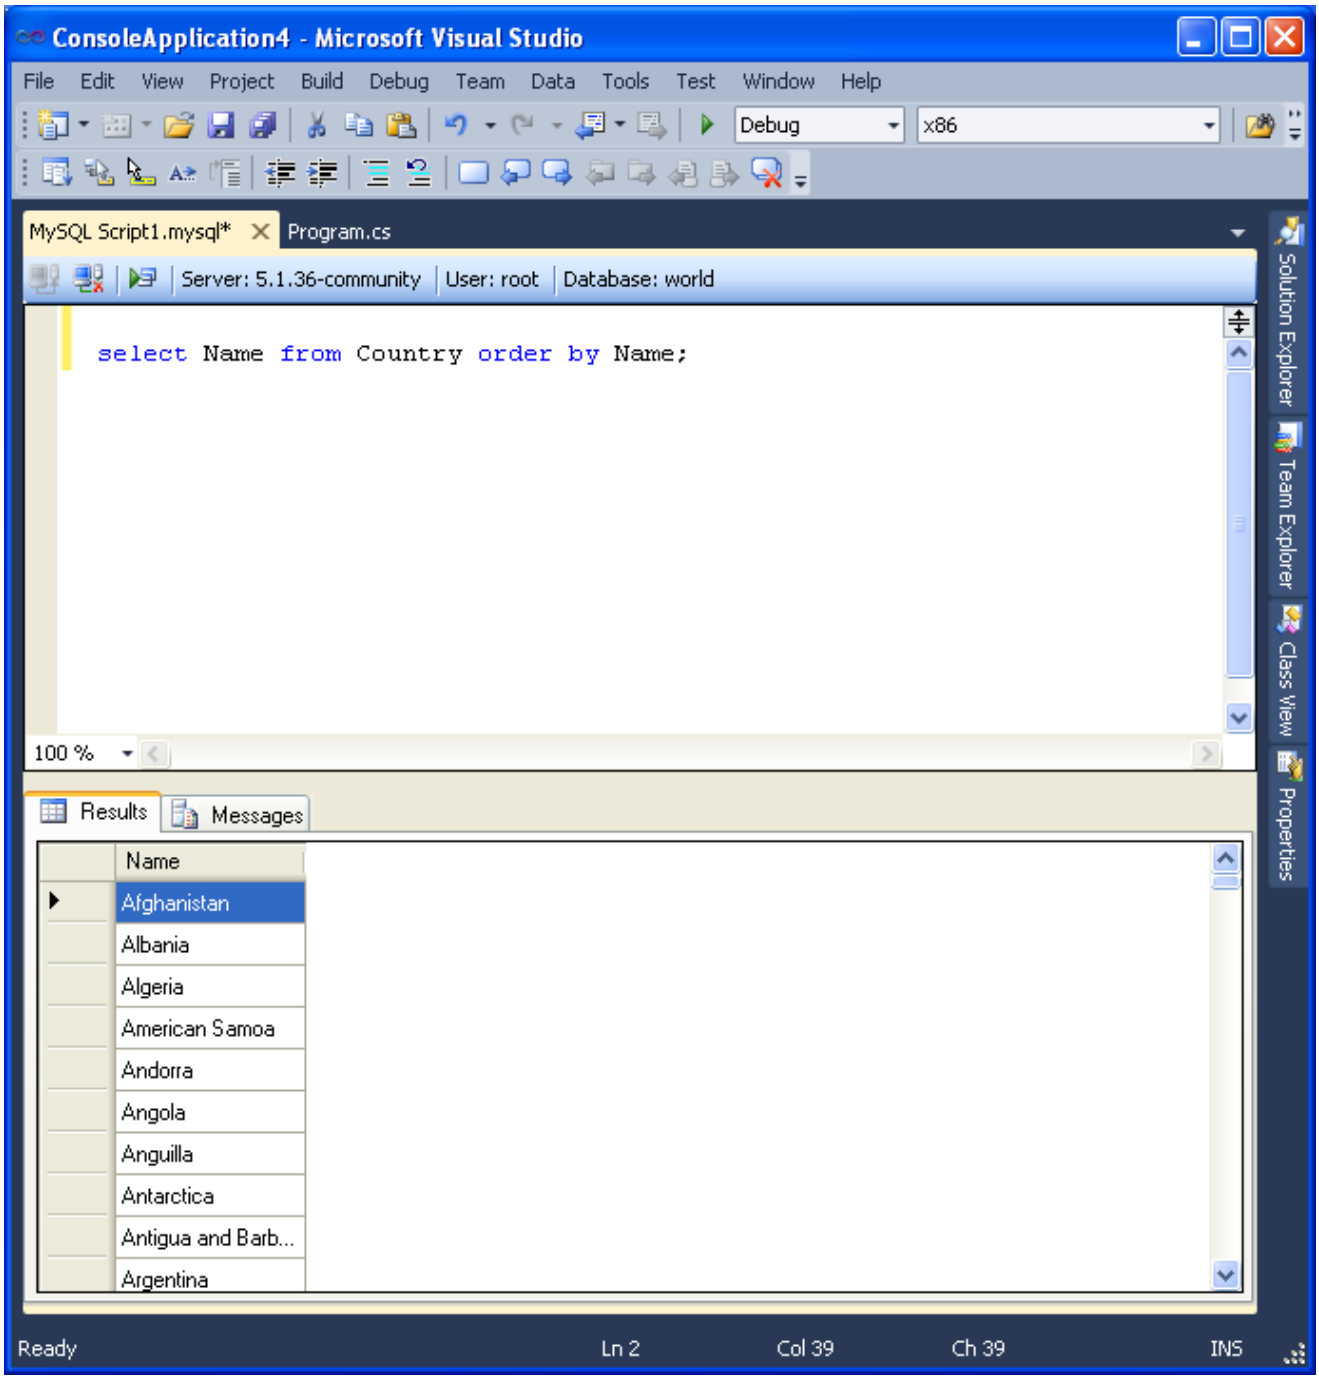
Figure 20.26. MySQL SQL Editor - New File



From the **NEW FILE** dialog select the MySQL template, and then double-click the **MYSQL SQL SCRIPT** document, or click the OPEN button.

The MySQL SQL Editor will be displayed. You can now enter SQL code as required, or connect to a MySQL server. Click the CONNECT TO MYSQL button in the MySQL SQL Editor toolbar. You can enter the connection details into the **CONNECT TO MYSQL** dialog that is displayed. You can enter the server name, user id, password and database to connect to, or click the ADVANCED button to select other connection string options. Click the CONNECT button to connect to the MySQL server. It is now possible to execute your SQL code against the server by clicking the RUN SQL button on the toolbar.

Figure 20.27. MySQL SQL Editor - Query



The results from any queries are displayed on the **RESULTS** tab. Any errors are displayed on the **MESSAGES** tab.

20.2.3.12. DDL T4 Template Macro

MySQL Connector/NET 6.3 introduced the ability to convert an Entity Framework model to MySQL DDL code. Starting with a blank model, an entity model can be developed in Visual Studio's designer. Once the model has been created, the model's properties can be selected, and in the Database Script Generation category of the model's properties, the property **DDL GENERATION** can be found. The value **SSDLTOMYSQL.TT(VS)** can then be selected from the drop-down listbox. Right-clicking the model design area will display a context-sensitive menu. Selecting **GENERATE DATABASE FROM MODEL** from the menu will display the **GENERATE DATABASE WIZARD**. The wizard can then be used to generate MySQL DDL code.

20.2.4. Connector/NET Tutorials

20.2.4.1. Tutorial: An Introduction to Connector/NET Programming

This section provides a gentle introduction to programming with Connector/NET. The example code is written in C#, and is designed to work on both Microsoft .NET Framework and Mono.

This tutorial is designed to get you up and running with Connector/NET as quickly as possible, it does not go into detail on any particular topic. However, the following sections of this manual describe each of the topics introduced in this tutorial in more detail. In this tutorial you are encouraged to type in and run the code, modifying it as required for your setup.

This tutorial assumes you have MySQL and Connector/NET already installed. It also assumes that you have installed the World example database, which can be downloaded from the MySQL Documentation page. You can also find details on how to install the database on the same page.

> **Note**
>
> Before compiling the example code make sure that you have added References to your project as required. The References required are `System`, `System.Data` and `MySql.Data`.

20.2.4.1.1. The MySqlConnection Object

For your Connector/NET application to connect to a MySQL database it needs to establish a connection. This is achieved through the use of a `MySqlConnection` object.

The MySqlConnection constructor takes a connection string as one of its parameters. The connection string provides necessary information to make the connection to the MySQL database. The connection string is discussed more fully in Section 20.2.5.1, “Connecting to MySQL Using Connector/NET”. A reference containing a list of supported connection string options can also be found in Section 20.2.6, “Connector/NET Connection String Options Reference”.

The following code shows how to create a connection object.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial1
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();
            // Perform databse operations
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }
        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When the `MySqlConnection` constructor is invoked it returns a connection object, which is used for subsequent database operations. The first operation in this example is to open the connection. This needs to be done before further operations take place. Before the application exits the connection to the database needs to be closed by calling `Close` on the connection object.

Sometimes an attempt to perform an `Open` on a connection object can fail, this will generate an exception that can be handled via standard exception handling code.

In this section you have learned how to create a connection to a MySQL database, and open and close the corresponding connection object.

20.2.4.1.2. The MySqlCommand Object

Once a connection has been established with the MySQL database, the next step is do carry out the desired database operations. This can be achieved through the use of the `MySqlCommand` object.

You will see how to create a `MySqlCommand` object. Once it has been created there are three main methods of interest that you can call:

- **ExecuteReader** - used to query the database. Results are usually returned in a `MySqlDataReader` object, created by `ExecuteReader`.
- **ExecuteNonQuery** - used to insert and delete data.
- **ExecuteScalar** - used to return a single value.

Once a `MySqlCommand` object has been created, you will call one of the above methods on it to carry out a database operation, such as perform a query. The results are usually returned into a `MySqlDataReader` object, and then processed, for example the results might be displayed. The following code demonstrates how this could be done.

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial2
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr[0]+" -- "+rdr[1]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

When a connection has been created and opened, the code then creates a `MySqlCommand` object. Note that the SQL query to be executed is passed to the `MySqlCommand` constructor. The `ExecuteReader` method is then used to generate a `MySqlReader` object. The `MySqlReader` object contains the results generated by the SQL executed on the command object. Once the results have been obtained in a `MySqlReader` object, the results can be processed. In this case the information is simply printed out as part of a `while` loop. Finally, the `MySqlReader` object is displosed of by running its `Close` method on it.

In the next example you will see how to use the `ExecuteNonQuery` method.

The procedure for performing an `ExecuteNonQuery` method call is simpler, as there is no need to create an object to store results. This is because `ExecuteNonQuery` is only used for inserting, updating and deleting data. The following example illustrates a simple update to the Country table:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial3
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "INSERT INTO Country (Name, HeadOfState, Continent) VALUES ('Disneyland','Mickey Mouse', 'North A
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            cmd.ExecuteNonQuery();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

The query is constructed, the command object created and the `ExecuteNonQuery` method called on the command object. You can access your MySQL database with the MySQL Client program and verify that the update was carried out correctly.

Finally, you will see how the `ExecuteScalar` method can be used to return a single value. Again, this is straightforward, as a `MySqlDataReader` object is not required to store results, a simple variable will do. The following code illustrates how to use `ExecuteScalar`:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial4
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT COUNT(*) FROM Country";
            MySqlCommand cmd = new MySqlCommand(sql, conn);
            object result = cmd.ExecuteScalar();
            if (result != null)
            {
                int r = Convert.ToInt32(result);
                Console.WriteLine("Number of countries in the World database is: " + r);
            }

        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

This example uses a simple query to count the rows in the Country table. The result is obtained by calling `ExecuteScaler` on the

command object.

20.2.4.1.3. Working with Decoupled Data

Previously, when using MySqlDataReader, the connection to the database was continually maintained, unless explicitly closed. It is also possible to work in a manner where a connection is only established when needed. For example, in this mode, a connection could be established in order to read a chunk of data, the data could then be modified by the application as required. A connection could then be reestablished only if and when the application needs to write data back to the database. This decouples the working data set from the database.

This decouple mode of working with data is supported by Connector/NET. There are several parts involved in allowing this method to work:

- **Data Set** - The Data Set is the area in which data is loaded in order to read or modify it. A `DataSet` object is instantiated, which can store multiple tables of data.
- **Data Adapter** - The Data Adapter is the interface between the Data Set and the database itself. The Data Adapter is responsible for efficiently managing connections to the database, opening and closing them as required. The Data Adapter is created by instantiating an object of the `MySqlDataAdapter` class. The `MySqlDataAdapter` object has two main methods: `Fill` which reads data into the Data Set, and `Update`, which writes data from the Data Set to the database.
- **Command Builder** - The Command Builder is a support object. The Command Builder works in conjunction with the Data Adapter. When a `MySqlDataAdapter` object is created it is typically given an initial SELECT statement. From this SELECT statement the Command Builder can work out the corresponding INSERT, UPDATE and DELETE statements that would be required should the database need to be updated. To create the Command Builder an object of the class `MySqlCommandBuilder` is created.

Each of these classes will now be discussed in more detail.

Instantiating a DataSet object

A `DataSet` object can be created simply, as shown in the following example code snippet:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
```

Although this creates the `DataSet` object it has not yet filled it with data. For that a Data Adapter is required.

Instantiating a MySqlDataAdapter object

The `MySqlDataAdapter` can be created as illustrated by the following example:

```
MySqlDataAdapter daCountry;
...
string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
daCountry = new MySqlDataAdapter (sql, conn);
```

Note, the `MySqlDataAdapter` is given the SQL specifying the data you wish to work with.

Instantiating a MySqlCommandBuilder object

Once the `MySqlDataAdapter` has been created, it is necessary to generate the additional statements required for inserting, updating and deleting data. There are several ways to do this, but in this tutorial you will see how this can most easily be done with `MySqlCommandBuilder`. The following code snippet ilustrates how this is done:

```
MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);
```

Note that the `MySqlDataAdapter` object is passed as a parameter to the command builder.

Filling the Data Set

In order to do anything useful with the data from your datbase, you need to load it into a Data Set. This is one of the jobs of the `MySqlDataAdapter` object, and is carried out with its `Fill` method. The following example code illustrates this:

```
DataSet dsCountry;
...
dsCountry = new DataSet();
...
daCountry.Fill(dsCountry, "Country");
```

Note the `Fill` method is a `MySqlDataAdapter` method, the Data Adapter knows how to establish a connec tion with the database and retrieve the required data, and then populates the Data Set when the `Fill` method is called. The second parameter “Country” is the table in the Data Set to update.

Updating the Data Set

The data in the Data Set can now be manipulated by the application as required. At some point, changes to data will need to be written back to the database. This is achieved through a `MySqlDataAdapter` method, the `Update` method.

```
daCountry.Update(dsCountry, "Country");
```

Again, the Data Set and the table within the Data Set to update are specified.

Working Example

The interactions between the `DataSet`, `MySqlDataAdapter` and `MySqlCommandBuilder` classes can be a little confusing, so their operation can perhaps be best illustrated by working code.

In this example, data from the World database is read into a Data Grid View control. Here, the data can be viewed and changed before clicking an update button. The update button then activates code to write changes back to the database. The code uses the principles explained above. The application was built using the Microsoft Visual Studio in order to place and create the user interface controls, but the main code that uses the key classes descibed above is shown below, and is portable.

```
using System;
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Linq;
using System.Text;
using System.Windows.Forms;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace WindowsFormsApplication5
{
    public partial class Form1 : Form
    {
        MySqlDataAdapter daCountry;
        DataSet dsCountry;

        public Form1()
        {
            InitializeComponent();
        }

        private void Form1_Load(object sender, EventArgs e)
        {

            string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                label2.Text = "Connecting to MySQL...";

                string sql = "SELECT Code, Name, HeadOfState FROM Country WHERE Continent='North America'";
                daCountry = new MySqlDataAdapter (sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(daCountry);

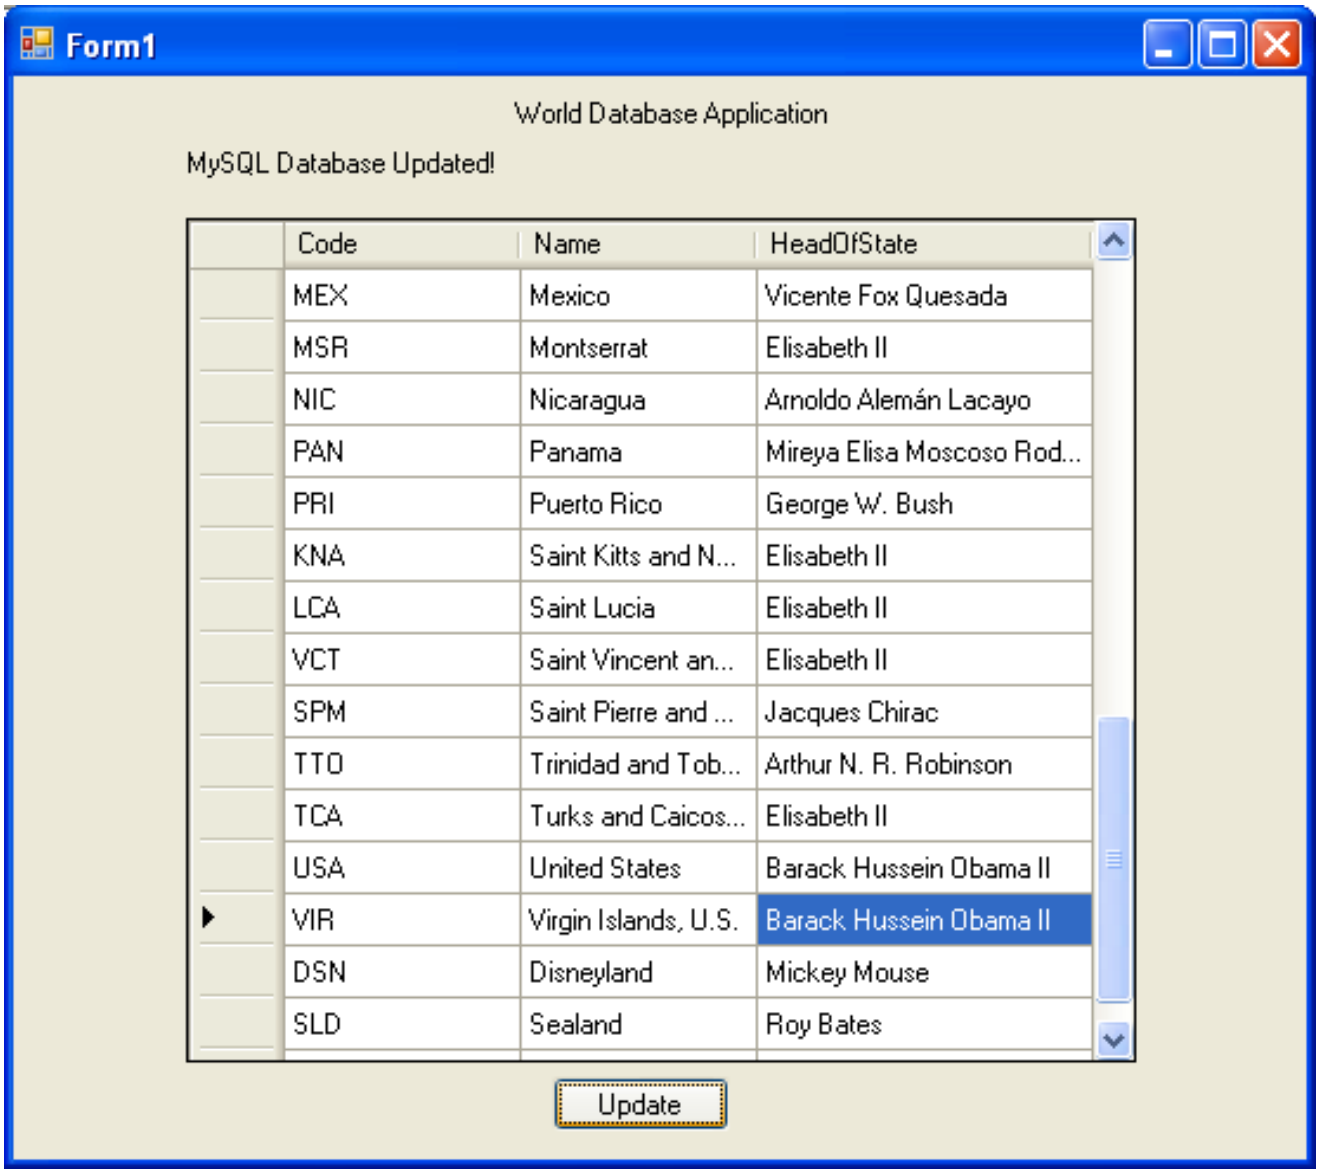
                dsCountry = new DataSet();
                daCountry.Fill(dsCountry, "Country");
                dataGridView1.DataSource = dsCountry;
                dataGridView1.DataMember = "Country";
            }
            catch (Exception ex)
            {
                label2.Text = ex.ToString();
            }
        }

        private void button1_Click(object sender, EventArgs e)
        {
            daCountry.Update(dsCountry, "Country");
```

```
            label2.Text = "MySQL Database Updated!";
        }
    }
}
```

The application running is shown below:

Figure 20.28. World Database Application



20.2.4.1.4. Working with Parameters

This part of the tutorial shows you how to use parameters in your Connector/NET application.

Although it is possible to build SQL query strings directly from user input, this is not advisable as it does not prevent erroneous or malicious information being entered. It is safer to use parameters as they will be processed as field data only. For example, imagine the following query was contructed from user input:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = "+user_continent;
```

If the string `user_continent` came from a Text Box control, there would potentially be no control over the string entered by the user. The user could enter a string that generates a run time error, or in the worst case actually harms the system. When using parameters it is not possible to do this because a parameter is only ever treated as a field parameter, rather than an arbitrary piece of SQL code.

The same query written user a parameter for user input would be:

```
string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent = @Continent";
```

Note that the parameter is preceded by an '@' symbol to indicate it is to be treated as a parameter.

As well as marking the position of the parameter in the query string, it is necessary to add a parameter to the Command object. This is illustrated by the following code snippet:

```
cmd.Parameters.AddWithValue("@Continent", "North America");
```

In this example the string "North America" is supplied as the parameter value statically, but in a more practical example it would come from a user input control.

A further example illustrates the complete process:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial5
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent=@Continent";
            MySqlCommand cmd = new MySqlCommand(sql, conn);

            Console.WriteLine("Enter a continent e.g. 'North America', 'Europe': ");
            string user_input = Console.ReadLine();

            cmd.Parameters.AddWithValue("@Continent", user_input);

            MySqlDataReader rdr = cmd.ExecuteReader();

            while (rdr.Read())
            {
                Console.WriteLine(rdr["Name"]+" --- "+rdr["HeadOfState"]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

In this part of the tutorial you have see how to use parameters to make your code more secure.

20.2.4.1.5. Working with Stored Procedures

In this section you will see how to work with Stored Procedures. This section assumes you have a basic understanding of what a Stored Procedure is, and how to create one.

For the purposes of this tutorial, you will create a simple Stored Procedure to see how it can be called from Connector/NET. In the MySQL Client program, connect to the World database and enter the following Stored Procedure:

```
DELIMITER //
CREATE PROCEDURE country_hos
(IN con CHAR(20))
```

```
BEGIN
  SELECT Name, HeadOfState FROM Country
  WHERE Continent = con;
END //
DELIMITER ;
```

Test the Stored Procedure works as expected by typing the following into the MySQL Client program:

```
CALL country_hos('Europe');
```

Note that The Stored Routine takes a single parameter, which is the continent you wish to restrict your search to.

Having confirmed that the Stored Procedure is present and correct you can now move on to seeing how it can be accessed from Connector/NET.

Calling a Stored Procedure from your Connector/NET application is similar to techniques you have seen earlier in this tutorial. A `MySqlCommand` object is created, but rather than taking a SQL query as a parameter it takes the name of the Stored Procedure to call. The `MySqlCommand` object also needs to be set to the type of Stored Procedure. This is illustrated by the following code snippet:

```
string rtn = "country_hos";
MySqlCommand cmd = new MySqlCommand(rtn, conn);
cmd.CommandType = CommandType.StoredProcedure;
```

In this case you also need to pass a parameter to the Stored Procedure. This can be achieved using the techniques seen in the previous section on parameters, Section 20.2.4.1.4, “Working with Parameters”. This is shown in the following code snippet:

```
cmd.Parameters.AddWithValue("@con", "Europe");
```

The value of the parameter `@con` could more realistically have come from a user input control, but for simplicity it is set as a static string in this example.

At this point everything is set up and all that now needs to be done is to call the routine. This can be achieved using techniques also learned in earlier sections, but in this case the `ExecuteReader` method of the `MySqlCommand` object is used.

Complete working code for the Stored Procedure example is shown below:

```
using System;
using System.Data;

using MySql.Data;
using MySql.Data.MySqlClient;

public class Tutorial6
{
    public static void Main()
    {
        string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to MySQL...");
            conn.Open();

            string rtn = "country_hos";
            MySqlCommand cmd = new MySqlCommand(rtn, conn);
            cmd.CommandType = CommandType.StoredProcedure;

            cmd.Parameters.AddWithValue("@con", "Europe");

            MySqlDataReader rdr = cmd.ExecuteReader();
            while (rdr.Read())
            {
                Console.WriteLine(rdr[0] + " --- " + rdr[1]);
            }
            rdr.Close();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
        }

        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

In this section you have seen how to call a Stored Procedure from Connector/NET. For the moment, this concludes our introductory tutorial on programming with Connector/NET.

20.2.4.2. Tutorial: MySQL Connector/NET ASP.NET Membership and Role Provider

Many web sites feature the facility for the user to create a user account. They can then log into the web site and enjoy a personalized experience. This requires that the developer creates database tables to store user information, along with code to gather and process this data. This represents a burden on the developer, and there is the possibility for security issues to creep into the developed code. However, ASP.NET 2.0 introduced the Membership system. This system is designed around the concept of Membership, Profile and Role Providers, which together provide all of the functionality to implement a user system, that previously would have to have been created by the developer from scratch.

Currently, MySQL Connector/NET provides Membership, Role, Profile and Session State Providers.

This tutorial shows you how to set up your ASP.NET web application to use the MySQL Connector/NET Membership and Role Providers. It assumes that you have MySQL Server installed, along with MySQL Connector/NET and Microsoft Visual Studio. This tutorial was tested with MySQL Connector/NET 6.0.4 and Microsoft Visual Studio 2008 Professional Edition. It is recommmended you use 6.0.4 or above for this tutorial.

1. Create a new database in the MySQL Server using the MySQL Command Line Client program (`mysql`), or other suitable tool. It does not matter what name is used for the database, but it should be noted down so that it can be specified in the connection string constructed later in this tutorial. This database will contain the tables, automatically created for you later, used to store data about users and roles.

2. Create a new ASP.NET Web Site in Visual Studio. If you are not sure how to do this, refer to the following tutorial: Section 20.2.4.6, “Tutorial: Databinding in ASP.NET using LINQ on Entities”, which demonstrates how to create a simple ASP.NET web site.

3. Add References to `MySql.Data` and `MySql.Web` to the web site project.

4. Locate the `machine.config` file on your system, which is the configuration file for the .NET Framework.

5. Search the `machine.config` file to find the membership provider `MySQLMembershipProvider`.

6. Add the attribute `autogenerateschema="true"`. The appropriate section should now resemble the following (note: for the sake of brevity some information has been excluded):

```
<membership>
 <providers>
   <add name="AspNetSqlMembershipProvider"
     type="System.Web.Security.SqlMembershipProvider"
     ...
     connectionStringName="LocalSqlServer"
     ... />
   <add name="MySQLMembershipProvider"
     autogenerateschema="true"
     type="MySql.Web.Security.MySQLMembershipProvider, MySql.Web, Version=6.0.4.0, Culture=neutral, PublicKeyToken=c56
     connectionStringName="LocalMySqlServer"
     ... />
 </providers>
</membership>
```

   Note that the name for the connection string to be used to connect to the server that contains the membership database is `LocalMySqlServer`.

   The `autogenerateschema="true"` attribute will cause MySQL Connector/NET to silently create, or upgrade, the schema on the database server, to contain the required tables for storing membership information.

7. It is now necessary to create the connection string referenced in the previous step. Load the web site's `web.config` file into Visual Studio.

8. Locate the section marked `<connectionStrings>`. Add the following connection string information:

```
<connectionStrings>
  <remove name="LocalMySqlServer"/>
  <add name="LocalMySqlServer"
       connectionString="Datasource=localhost;Database=users;uid=root;pwd=password;"
       providerName="MySql.Data.MySqlClient"/>
</connectionStrings>
```

The database specified is the one created in the first step. You could alternatively have used an existing database.

9. At this point build the solution to ensure no errors are present. This can be done by selecting BUILD, BUILD SOLUTION from the main menu, or pressing **F6**.

10. ASP.NET supports the concept of locally and remotely authenticated users. With local authentication the user is validated using their Windows credentials when they attempt to access the web site. This can be useful in an Intranet environment. With remote authentication a user is prompted for their login details when accessing the web site, and these credentials are checked aganst the membership information stored in a database server such as MySQL Server. You will now see how to choose this form of authentication.

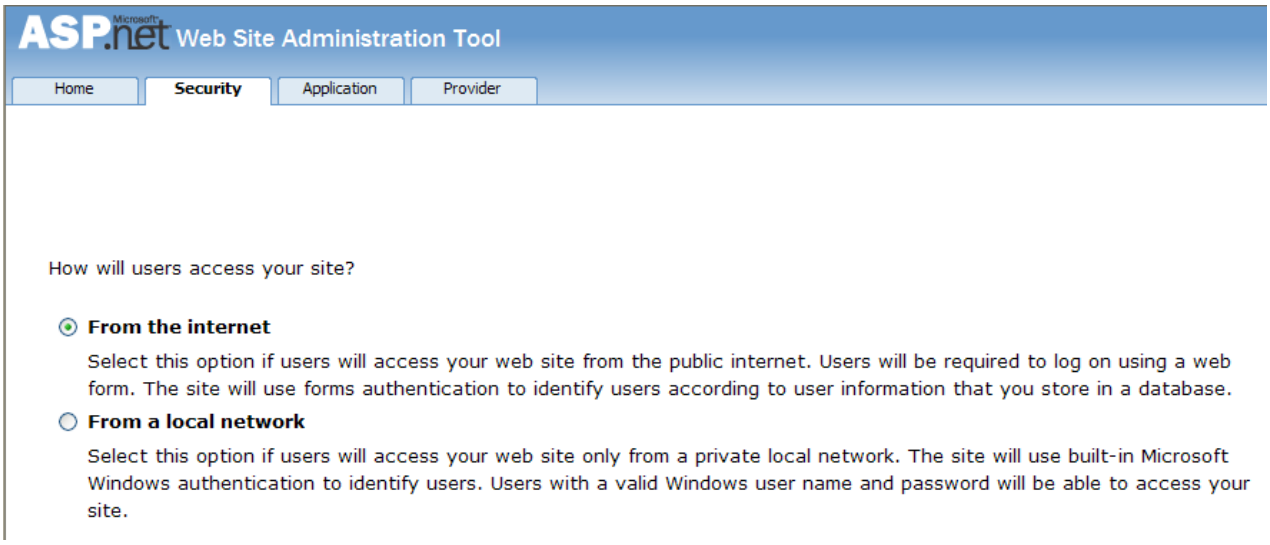
    Start the ASP.NET Web Site Administration Tool. This can be done quickly by clicking the small hammer/Earth icon in the Solution Explorer. You can also launch this tool by selecting WEBSITE, ASP.NET CONFIGURATION from the main menu.

11. In the ASP.NET Web Site Administration Tool click the **SECURITY** tab.

12. Now click the **USER AUTHENTICATION TYPE** link.

13. Select the **FROM THE INTERNET** radio button. The web site will now need to provide a form to allow the user to enter their login details. These will be checked against membership information stored in the MySQL database.

Figure 20.29. Authentication Type

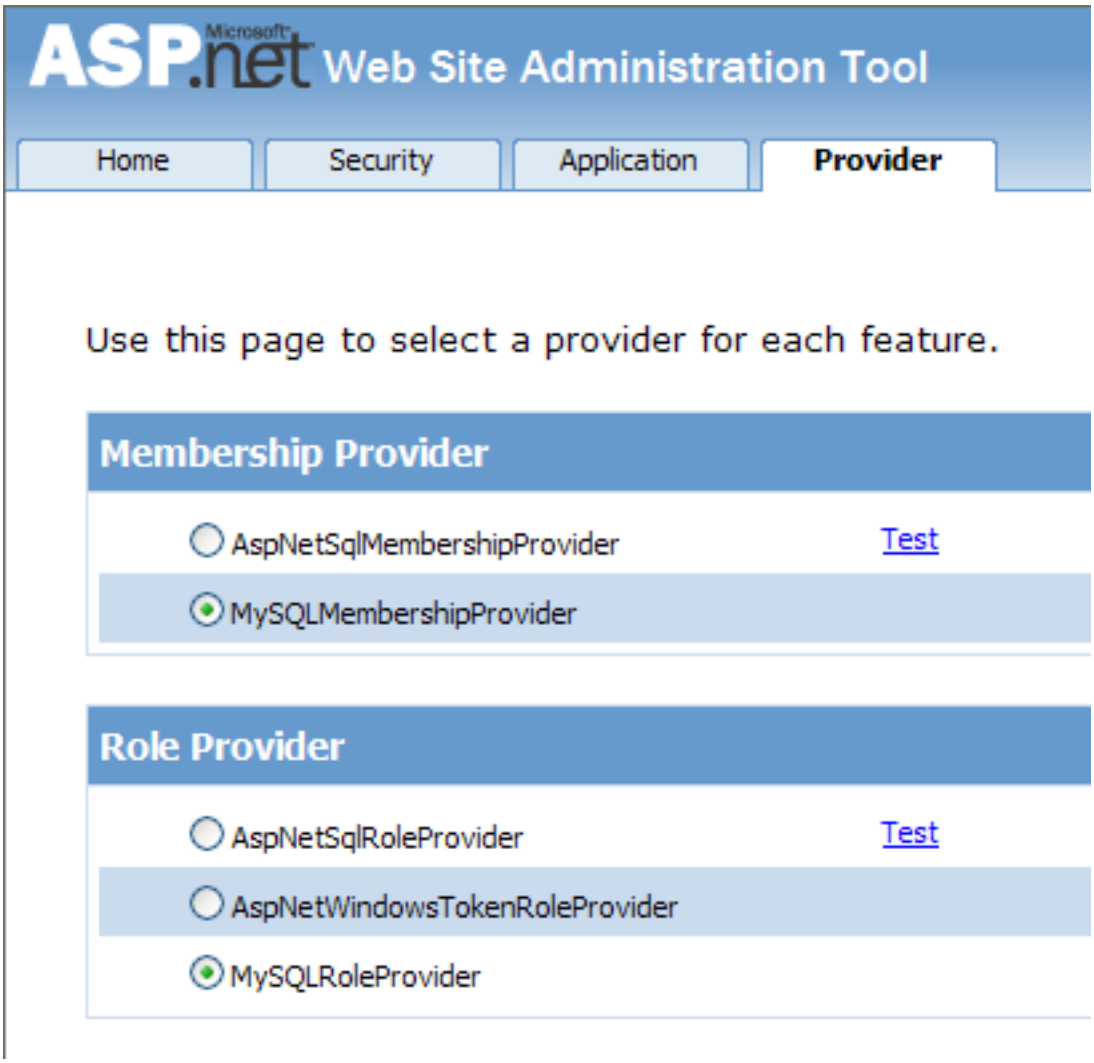


14. You now need to specify the Role and Membership Provider to be used. Click the **PROVIDER** tab.

15. Click the **SELECT A DIFFERENT PROVIDER FOR EACH FEATURE (ADVANCED)** link.

16. Now select the **MYSQLMEMBERSHIPPROVIDER** and the **MYSQLROLEPROVIDER** radio buttons.

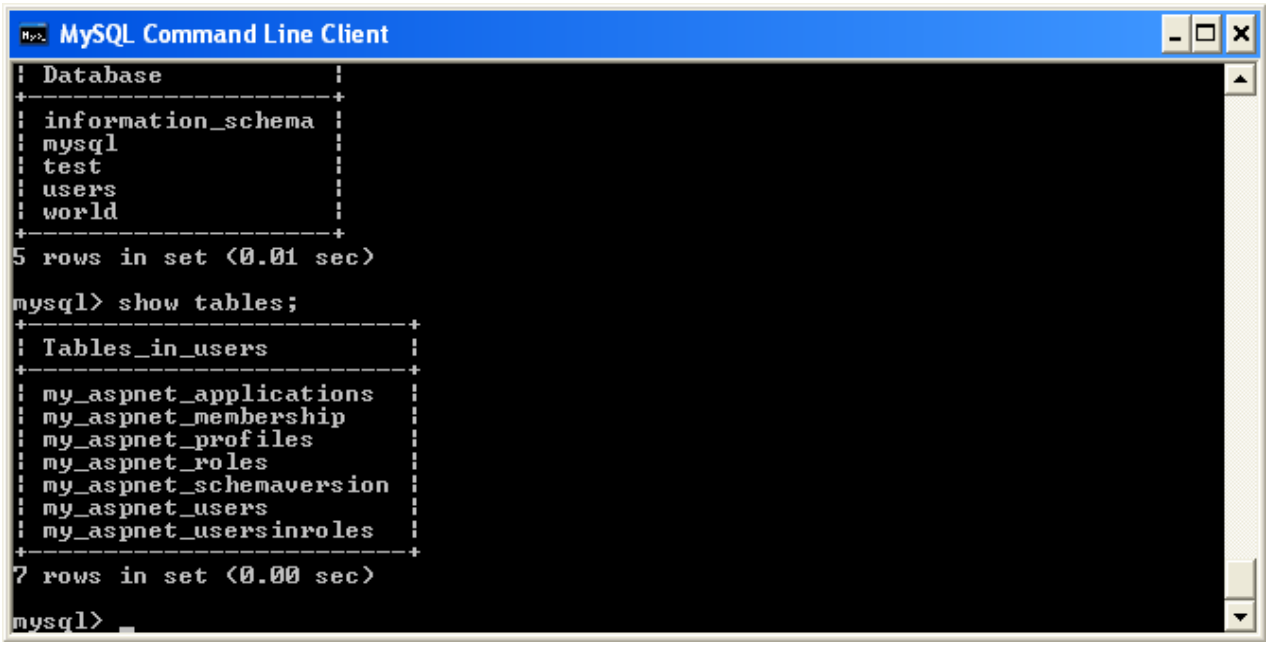
Figure 20.30. Select Membership and Role Provider



17. In Visual Studio rebuild the solution by selecting BUILD, REBUILD SOLUTION from the main menu.

18. Check that the necessary schema has been created. This can be achieved using the MySQL Command Line Client program.

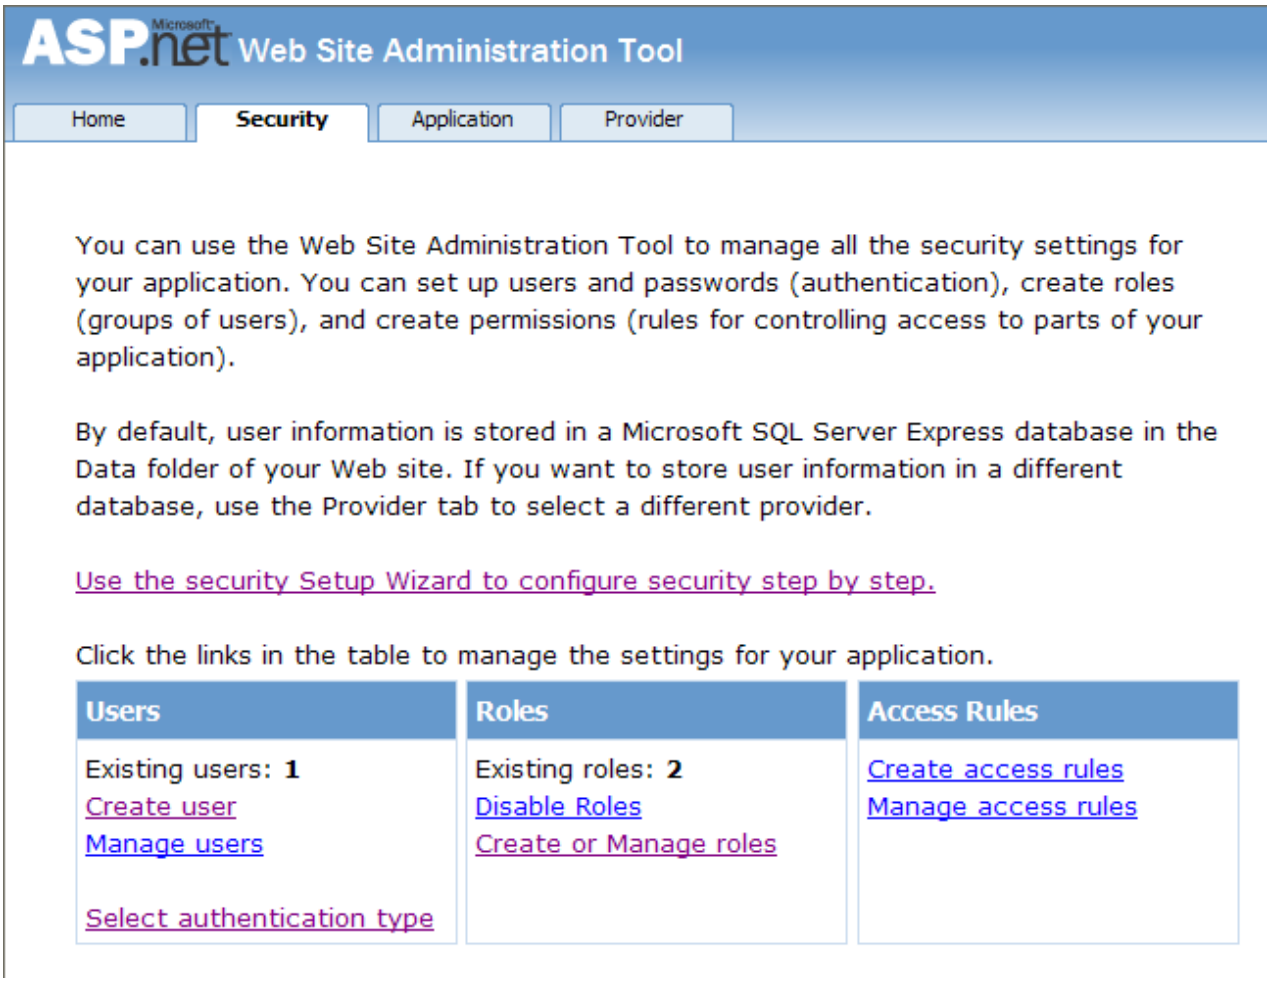
Figure 20.31. Membership and Role Provider Tables



19. Assuming all is present and correct you can now create users and roles for your web application. The easiest way to do this is with the ASP.NET Web Site Administration Tool. However, many web applications contain their own modules for creating roles and users. For simplicity the ASP.NET Web Site Administration Tool will be used in this tutorial.

20. In the ASP.NET Web Site Administration Tool, click the **SECURITY** tab. Now that both the Membership and Role Provider are enabled you will see links for creating roles and users. Click the **CREATE OR MANAGE ROLES** link.

Figure 20.32. Security Tab

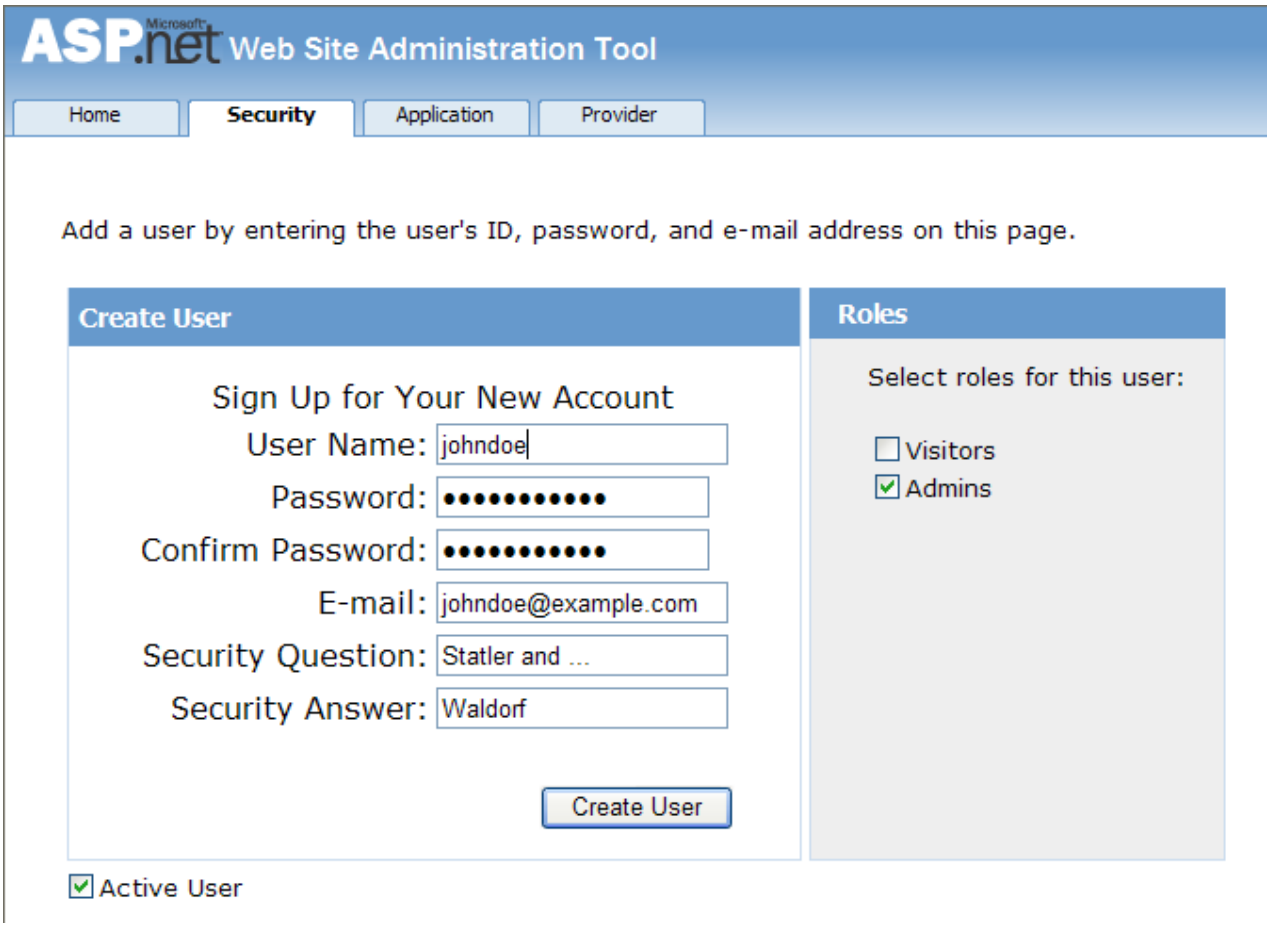


21. You can now enter the name of a new Role and click ADD ROLE to create the new Role. Create new Roles as required.

22. Click the BACK button.

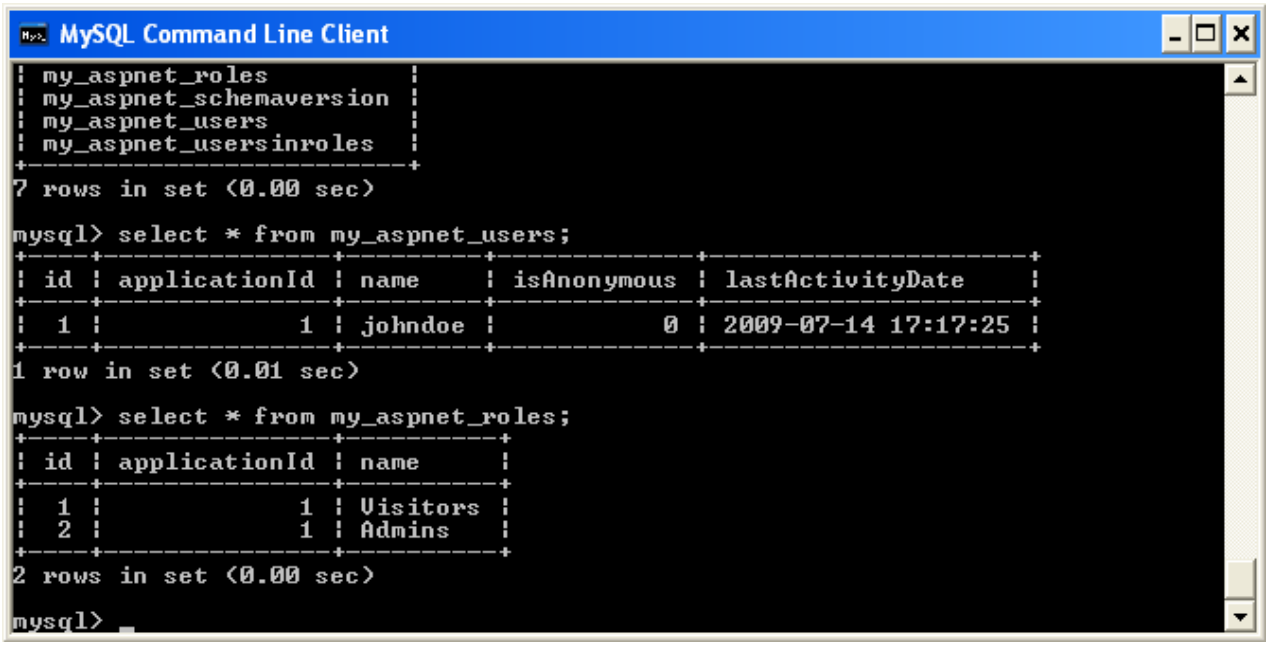
23. Click the **CREATE USER** link. You can now fill in information about the user to be created, and also allocate that user to one or more Roles.

Figure 20.33. Create User



24. Using the MySQL Command Line Client program you can check that your database has been correctly populated with the Membership and Role data.

Figure 20.34. Membership and Roles Table Contents



In this tutorial you have seen how to set up the MySQL Connector/NET Membership and Role Providers for use in your ASP.NET web application.

20.2.4.3. Tutorial: MySQL Connector/NET ASP.NET Session State Provider

MySQL Connector/NET from version 6.1 has included a MySQL Session State Provider. This provider allows you to store session state in a MySQL database. The following tutorial shows you how to prepare to use the MySQL Session State Provider, and then store session data into the MySQL database. This tutorial uses Microsoft Visual Studio 2008 Professional Edition, MySQL Connector/NET 6.1.1 and MySQL Server 5.1. This tutorial also assumes you have created an empty database, for example `test`, where you will store session data. You could do this using the MySQL Command Line Client tool.

1. In Visual Studio create a new ASP.NET web site. If you are not sure how to do this refer to the tutorial Section 20.2.4.6, “Tutorial: Databinding in ASP.NET using LINQ on Entities” which demonstrates how to do this.

2. Launch the MySQL MySQL Website Configuration tool. Due to a bug in 6.1.1 this may not appear unless you are connected to a server in the Server Explorer. If you are unfamiliar with the MySQL Website Configuration tool it is suggested that you first work through the following tutorial Section 20.2.3.10, “MySQL Website Configuration Tool”.

3. Navigate through the wizard to the Session State page. Make sure the checkbox **USE MYSQL TO MANAGE MY ASP.NET SESSION DATA** is seected.

4. On the same page configure the connection string to the database that will contain your session data. This database can be empty as MySQL Connector/NET will create the schema required to store session data.

5. Ensure that the checkbox **AUTOGENERATE SCHEMA** is selected so that MySQL Connector/NET will create the schema in your database to store the session data correctly.

6. Enter the name of your application.

7. Click FINISH. The MySQL Website Configuration tool will now update your application's `web.config` file with information about the connection string and default providers to be used. In this case we have selected the MySQL Session State Provider.

At this point you are ready to use the MySQL database to store session data. To test that the set up has worked you can write a simple program that uses session variables.

1. Open `Default.aspx.cs`. In the Page_Load method add the following code:

```
Session["SessionVariable1"] = "Test string";
```

2. Build your solution.

3. Run the solution (without debugging). When the application runs, the provider will autogenerate tables required in the database you chose when setting up the application.

4. Check that the schema was in fact created. Using the MySQL Command Line Client use the target database and then type `SHOW TABLES;`. You will see that MySQL Connector/NET has created the required schema automatically, as we selected this to happen in the MySQL Website Configuration tool.

5. Now view the contents of these tables by typing `SELECT * FROM my_aspnet_sessions;` in the MySQL Command Line Client. This will display the session data our application used. Note that this is stored in binary format so some data may not display as expected.

At this point you have installed the Session State Provider and carried out a preliminary test of the installation. You will now work a bit more with the Session State Provider.

In this part of the tutorial you will set and retrieve a session variable. You can work with your existing project.

1. Select the `Default.aspx` and switch to Design View. Add a text box and three buttons. Change the text property for the buttons to “Store Session Variable”, “Clear Textbox”, and “Show Session Variable”. These will be `Button1`, `Button2` and `Button3` respectively. Build your solution to ensure that no errors have been introduced.

2. Still in the Design View, double-click `Button1`. Now to the `Button1_Click` event handler add code some the handler resembles the following:

```
protected void Button1_Click(object sender, EventArgs e)
{
    Session["SessionString"] = TextBox1.Text;
}
```

   You have created a new Session variable accessed using the key “SessionString”. This will be set to the text that was entered into the text box when `Button1` is clicked.

3. In Design View double-click `Button2` to add its click event handler. This button needs to clear text from the text box. The code to do this is as follows:

```
protected void Button2_Click(object sender, EventArgs e)
{
    TextBox1.Text = "";
}
```

   The code simply assigns an empty string to the `Text` property of the text box.

4. In the Design View double-click `Button3` and modify the click handler as follows:

```
protected void Button3_Click(object sender, EventArgs e)
{
    TextBox1.Text = (String)Session["SessionString"];
}
```

   This will retrieve the session string and display it in the text box.

5. Now modify the `Page_Load` method as follows:

```
protected void Page_Load(object sender, EventArgs e)
{
    if (!IsPostBack)
    {
       TextBox1.Text = "Enter some text";
    }
}
```

This ensures that when the page loads the text box `Text` property is reset.

6. Ensure that the solution is saved and then rebuild the solution.

7. Run the solution without debugging.

8. The form will be displayed. Enter some text into the text box. Now click STORE SESSION VARIABLE. At this point you have stored the string in a session variable.

9. Now click CLEAR TEXT to clear the text box.

10. Now click SHOW SESSION VARIABLE to retrieve and display the session variable.

11. Refresh the page to destroy the form and display a new form.

12. Click SHOW SESSION VARIABLE the text box will display the stored session variable, demonstrating that the refreshing the page does not destroy the session variable.

This illustrates that the session state data is not destroyed when a page is reloaded.

20.2.4.4. Tutorial: MySQL Connector/NET ASP.NET Profile Provider

This tutorial shows you how to use the MySQL Profile Provider to store user profile information in a MySQL database. The tutorial uses MySQL Connector/NET 6.1.1, MySQL Server 5.1 and Microsoft Visual Studio 2008 Professional Edition.

Many modern web sites allow the user to create a personal profile. This requires a significant amount of code, but ASP.NET reduces this considerable by including the functionality in its Profile classes. The Profile Provider provides an abstraction between these classes and a data source. The MySQL Profile Provider allows profile data to be stored in a MySQL database. This allows the profile properties to be written to a persistent store, and be retrieved when required. The Profile Provider also allows profile data to be managed effectively, for example it allows profiles that have not been accessed since a specific date to be deleted.

The following steps show you how you can select the MySQL Profile Provider.

1. Create a new ASP.NET web project.

2. Select the MySQL Website Configuration tool. Due to a bug in 6.1.1 you may have to first connect to a server in Server Explorer before the tool's icon will display in the toolbar of the Solution Explorer.

3. In the MySQL Website Configuration tool navigate through the tool to the Profiles page.

4. Select the **USE MYSQL TO MANAGE MY PROFILES** checkbox.

5. Select the **AUTOGENERATE SCHEMA** checkbox.

6. Click the EDIT... button and configure a connection string for the database that will be used to store user profile information.

7. Navigate to the last page of the tool and click FINISH to save your changes and exit the tool.

At this point you are now ready to start using the MySQL Profile Provider. With the following steps you can carry out a preliminary test of your installation.

1. Open your `web.config` file.

2. Add a simple profile such as the following:

```
<system.web>
  <anonymousIdentification enabled="true"/>
  <profile defaultProvider="MySQLProfileProvider">
    ...
    <properties>
      <add name="Name" allowAnonymous="true"/>
      <add name="Age" allowAnonymous="true" type="System.UInt16"/>
      <group name="UI">
        <add name="Color" allowAnonymous="true" defaultValue="Blue"/>
```

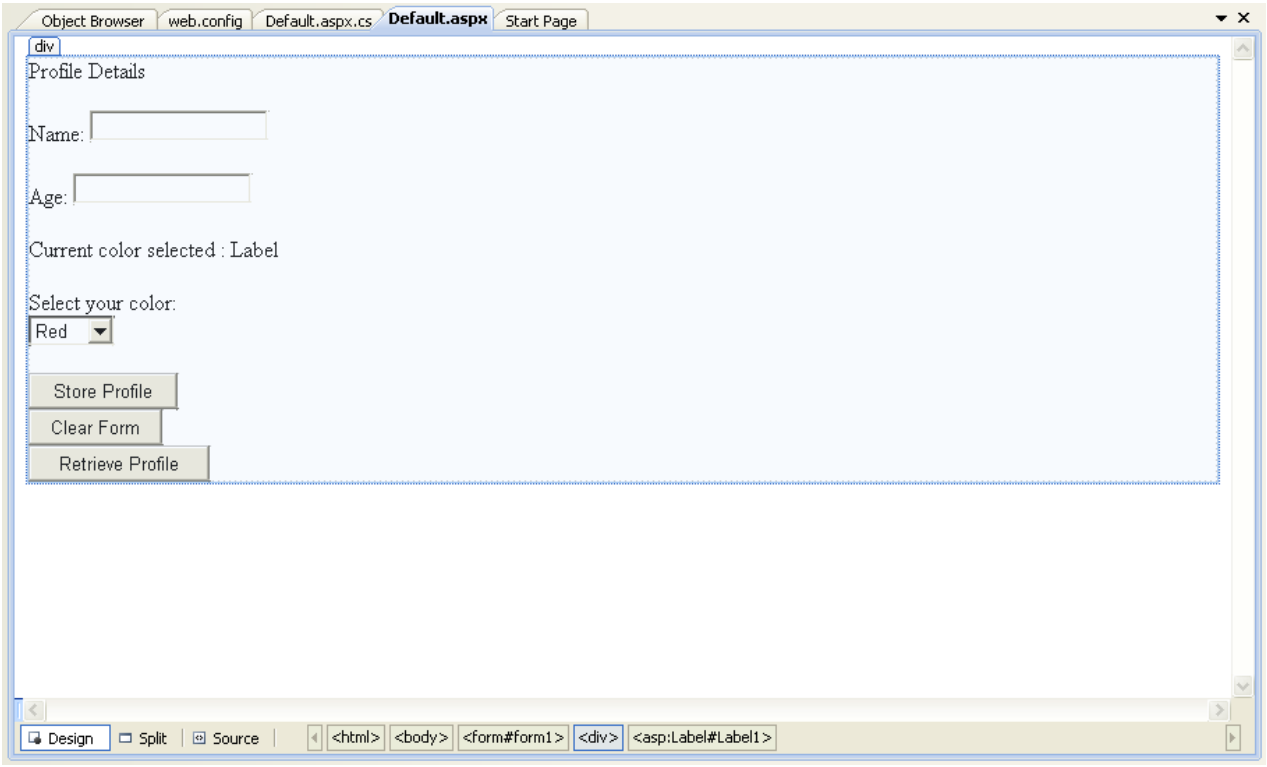
```
        <add name="Style" allowAnonymous="true" defaultValue="Plain"/>
      </group>
    </properties>
  </profile>
  ...
```

Note that `anonymousIdentification` has been set to true. This allows users who have not been authenticated to use profiles. They are identified by a GUID in a cookie rather than by user name.

Now that the simple profile has been defined in `web.config`, the next step is to write some code to test the profile.

1. In Design View design a simple page with the following controls:

Figure 20.35. Simple Profile Application



These will allow the user to enter some profile information. The user can also use the buttons to save their profile, clear the page, and restore their profile data.

2. In the Code View add code as follows:

```
...
protected void Page_Load(object sender, EventArgs e)
{
    if (!IsPostBack)
    {
        TextBox1.Text = Profile.Name;
        TextBox2.Text = Profile.Age.ToString();
        Label1.Text = Profile.UI.Color;
    }
}

// Store Profile
protected void Button1_Click(object sender, EventArgs e)
{
    Profile.Name = TextBox1.Text;
    Profile.Age = UInt16.Parse(TextBox2.Text);
```

```
}

// Clear Form
protected void Button2_Click(object sender, EventArgs e)
{
    TextBox1.Text = "";
    TextBox2.Text = "";
    Label1.Text = "";
}

// Retrieve Profile
protected void Button3_Click(object sender, EventArgs e)
{
    TextBox1.Text = Profile.Name;
    TextBox2.Text = Profile.Age.ToString();
    Label1.Text = Profile.UI.Color;
}

protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
{
    Profile.UI.Color = DropDownList1.SelectedValue;
}
...
```

3. Save all files and build the solution to check that no errors have been introduced.
4. Run the application.
5. Enter your name, age and select a color from the listbox. Now store this information in your profile by clicking STORE PROFILE. Note that if you do not select a color from the listbox your profile will use the default color `Blue` that was specified in the `web.config` file.
6. Click CLEAR FORM to clear text from the textboxes and the label that displays your chosen color.
7. Now click RETRIEVE PROFILE to restore your profile data from the MySQL database.
8. Now exit the browser to terminate the application.
9. Run the application again. Note that when the page loads your profile information is restored from the MySQL database.

In this tutorial you have seen how to using the MySQL Profile Provider with MySQL Connector/NET.

20.2.4.5. Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source

In this tutorial you will learn how to create a Windows Forms Data Source from an Entity in an Entity Data Model. This tutorial assumes that you have installed the World example database, which can be downloaded from the MySQL Documentation page. You can also find details on how to install the database on the same page. It will also be convenient for you to create a connection to the World database after it is installed. For instructions on how to do this see Section 20.2.3.1, “Making a connection”.

Creating a new Windows Forms application

The first step is to create a new Windows Forms application.

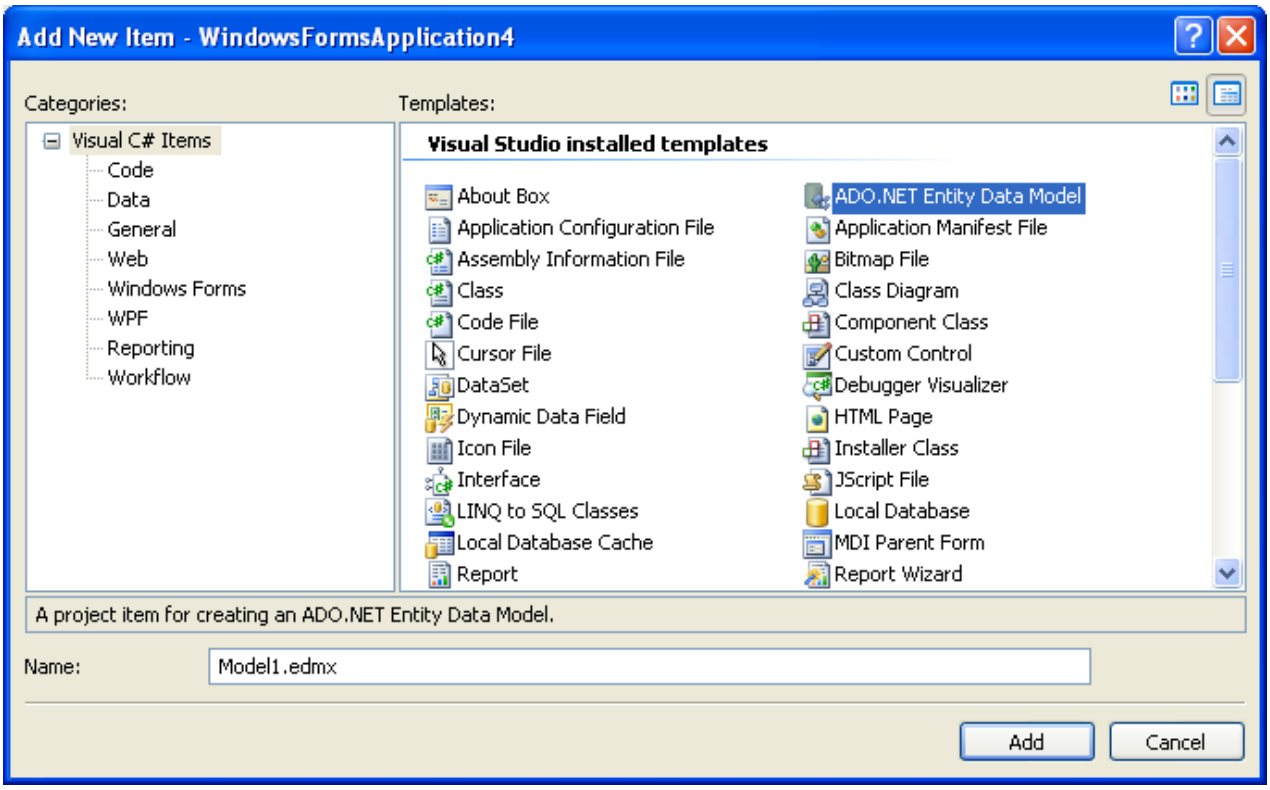
1. In Visual Studio, select FILE, NEW, PROJECT from the main menu.
2. Choose the **WINDOWS FORMS APPLICATION** installed template. Click OK. The solution is created.

Adding an Entity Data Model

You will now add an Entity Data Model to your solution.

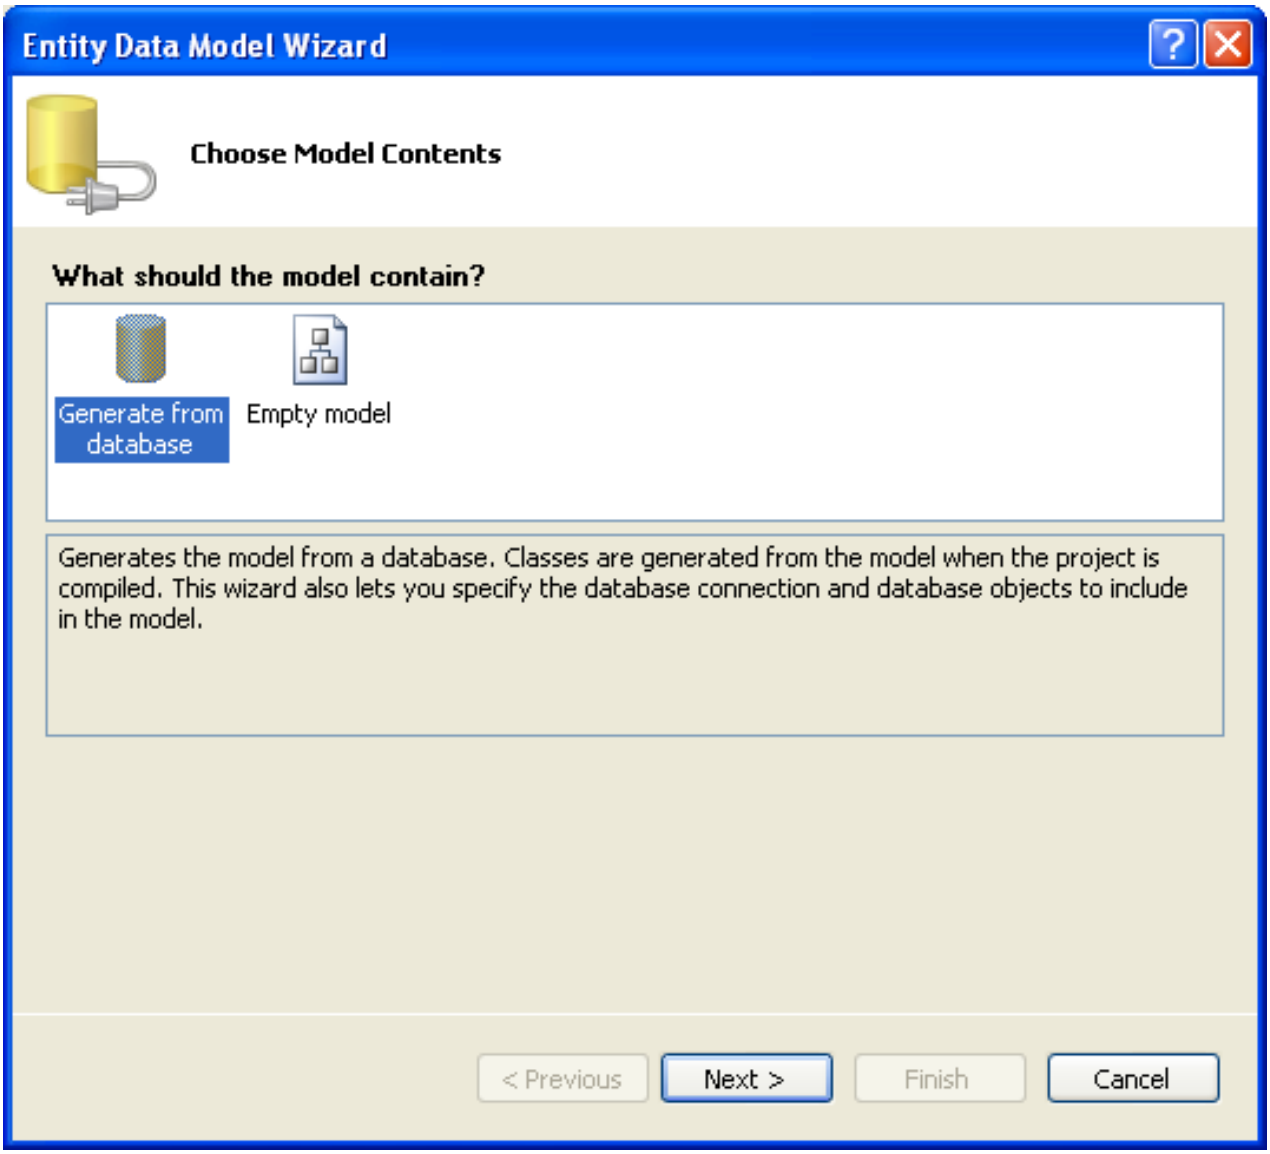
1. In the Solution Explorer, right-click your application and select ADD, NEW ITEM.... From **VISUAL STUDIO INSTALLED TEMPLATES** select **ADO.NET ENTITY DATA MODEL**. Click ADD.

Figure 20.36. Add Entity Data Model



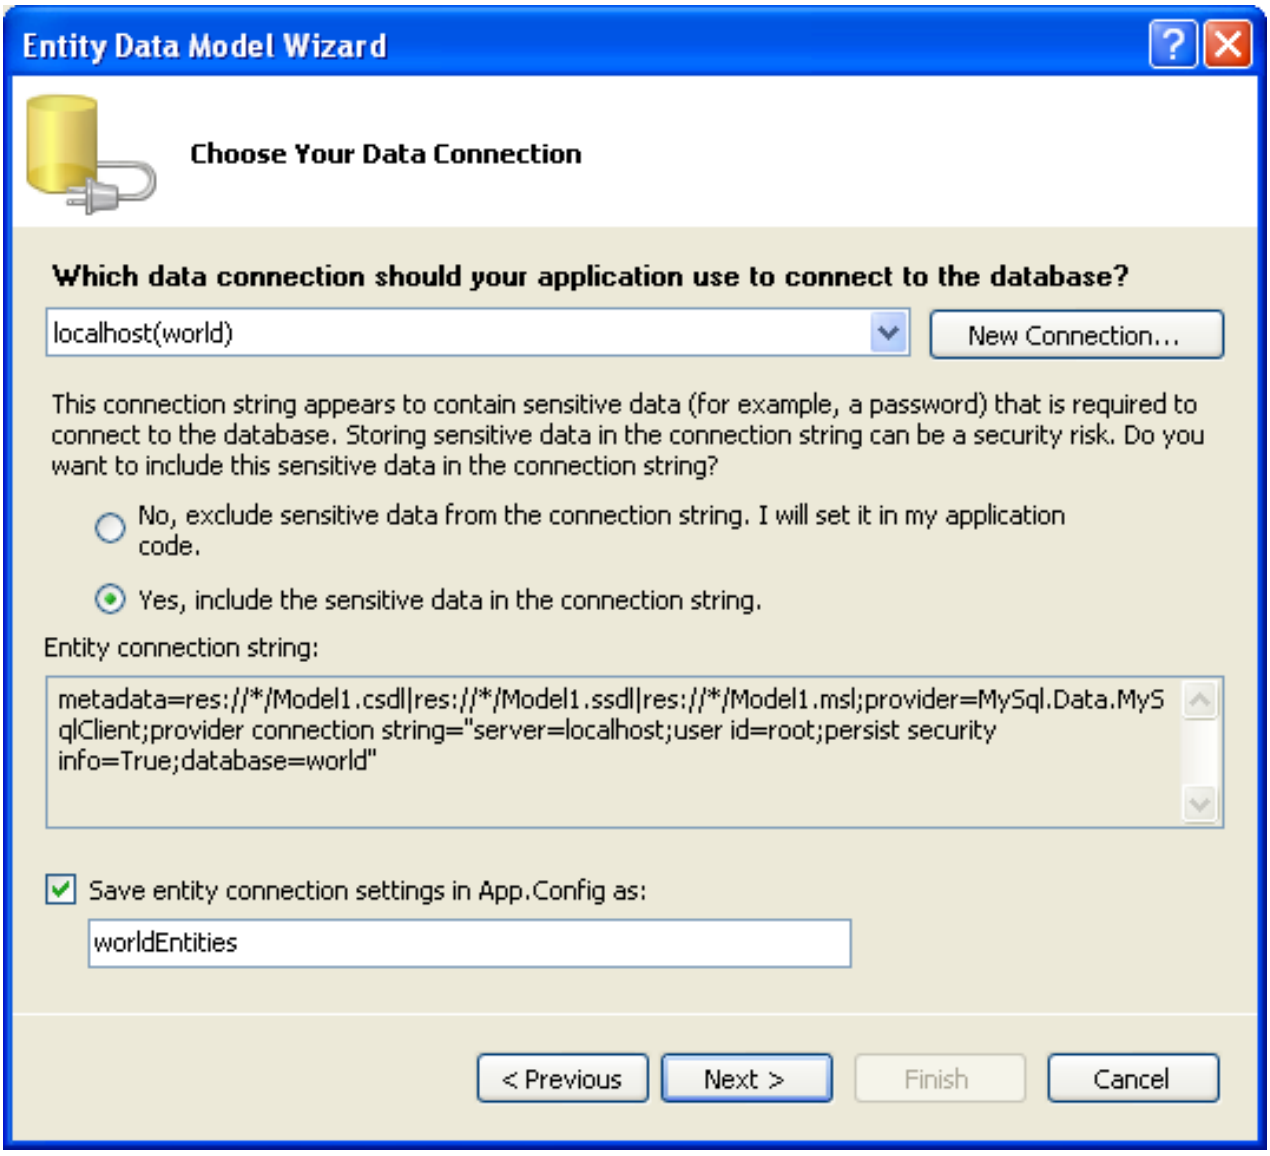
2. You will now see the Entity Data Model Wizard. You will use the wizard to generate the Entity Data Model from the world example database. Select the icon **GENERATE FROM DATABASE**. Click NEXT.

Figure 20.37. Entity Data Model Wizard Screen 1



3. You can now select the connection you made earlier to the World database. If you have not already done so, you can create the new connection at this time by clicking NEW CONNECTION.... For further instructions on creating a connection to a database see Section 20.2.3.1, “Making a connection”.

Figure 20.38. Entity Data Model Wizard Screen 2

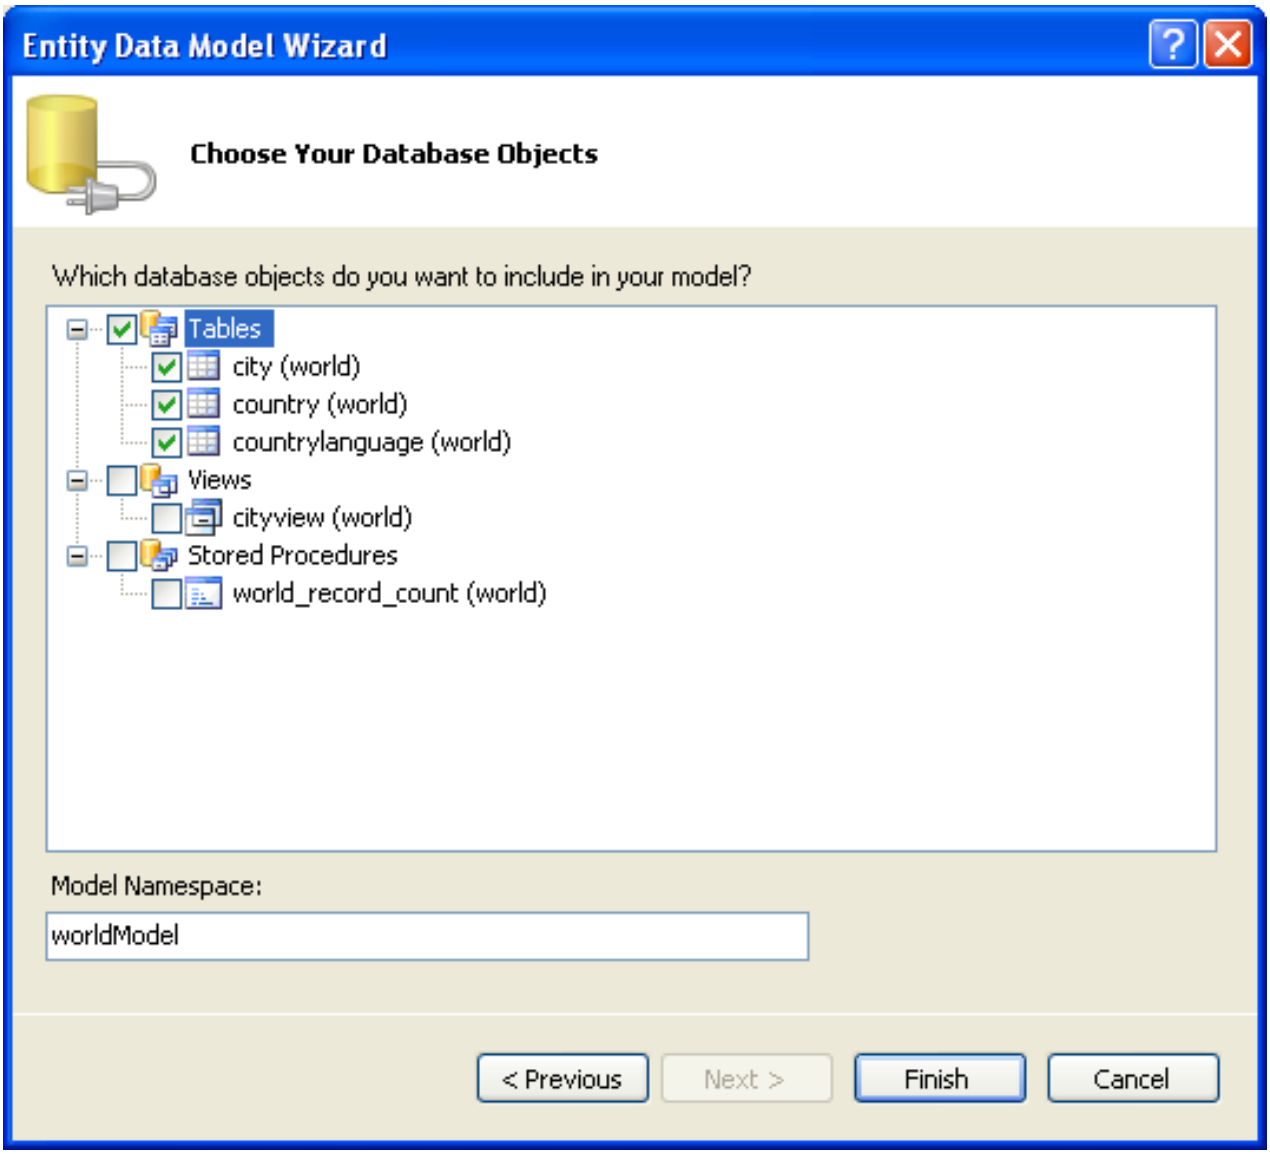


4. Make a note of the entity connection settings to be used in App.Config, as these will be used later to write the necessary control code.

5. Click NEXT.

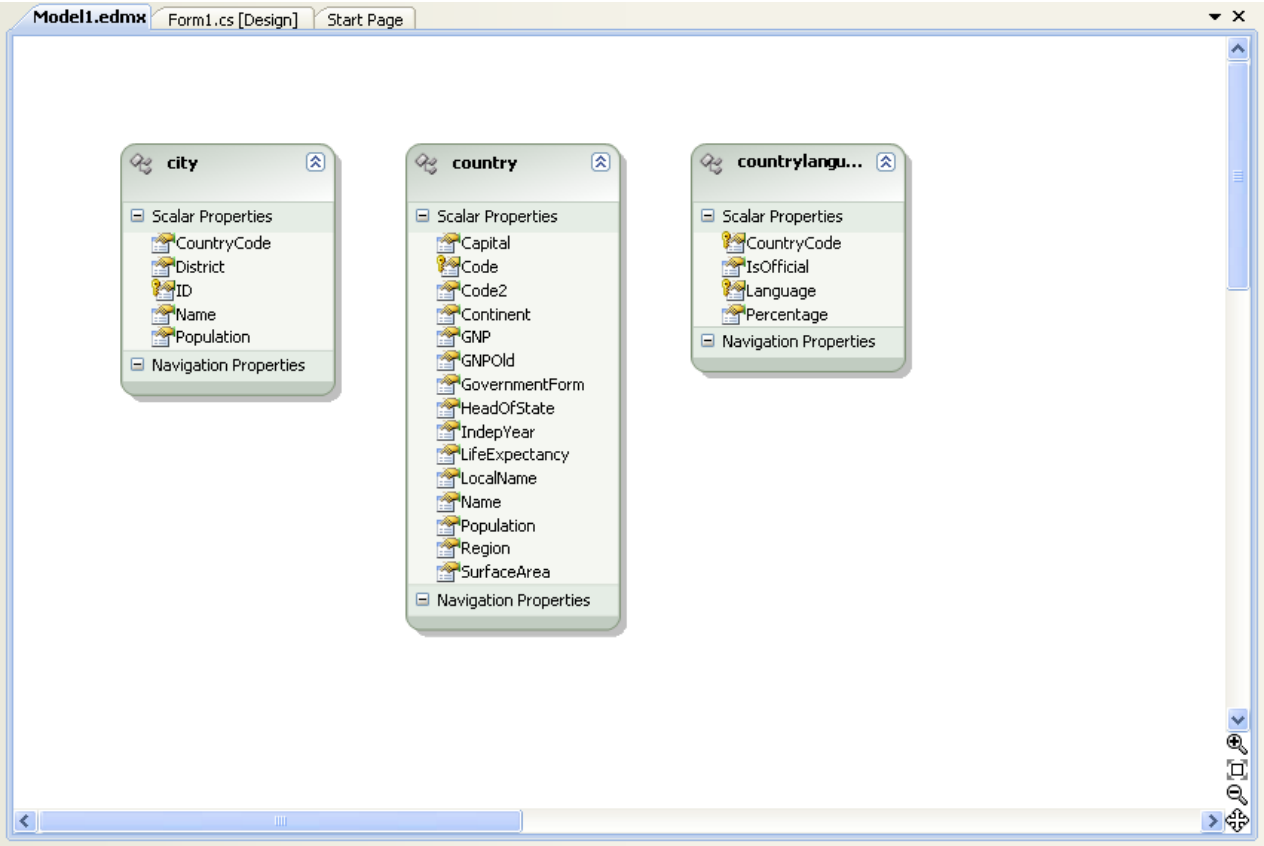
6. The Entity Data Model Wizard connects to the database. You are then presented with a tree structure of the database. From this you can select the object you would like to include in your model. If you had created Views and Stored Routines these will be displayed along with any tables. In this example you just need to select the tables. Click FINISH to create the model and exit the wizard.

Figure 20.39. Entity Data Model Wizard Screen 3



7. Visual Studio will generate the model and then display it.

Figure 20.40. Entity Data Model Diagram



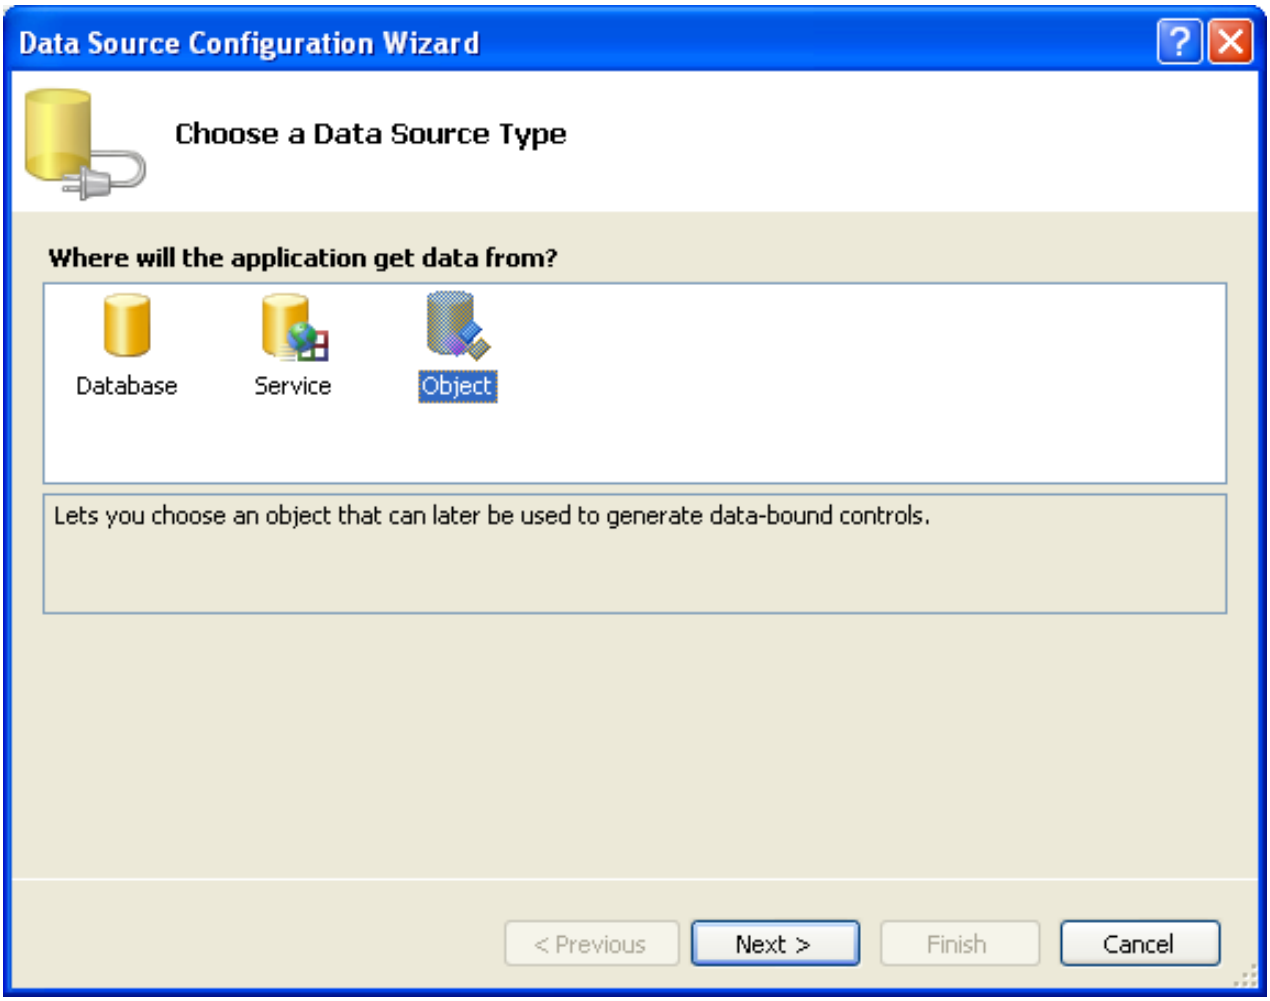
8. From the Visual Studio main menu select BUILD, BUILD SOLUTION, to ensure that everything compiles correctly so far.

Adding a new Data Source

You will now add a new Data Source to your project and see how it can be used to read and write to the database.

1. From the Visual Studio main menu select DATA, ADD NEW DATA SOURCE.... You will be presented with the Data Source Configuration Wizard.

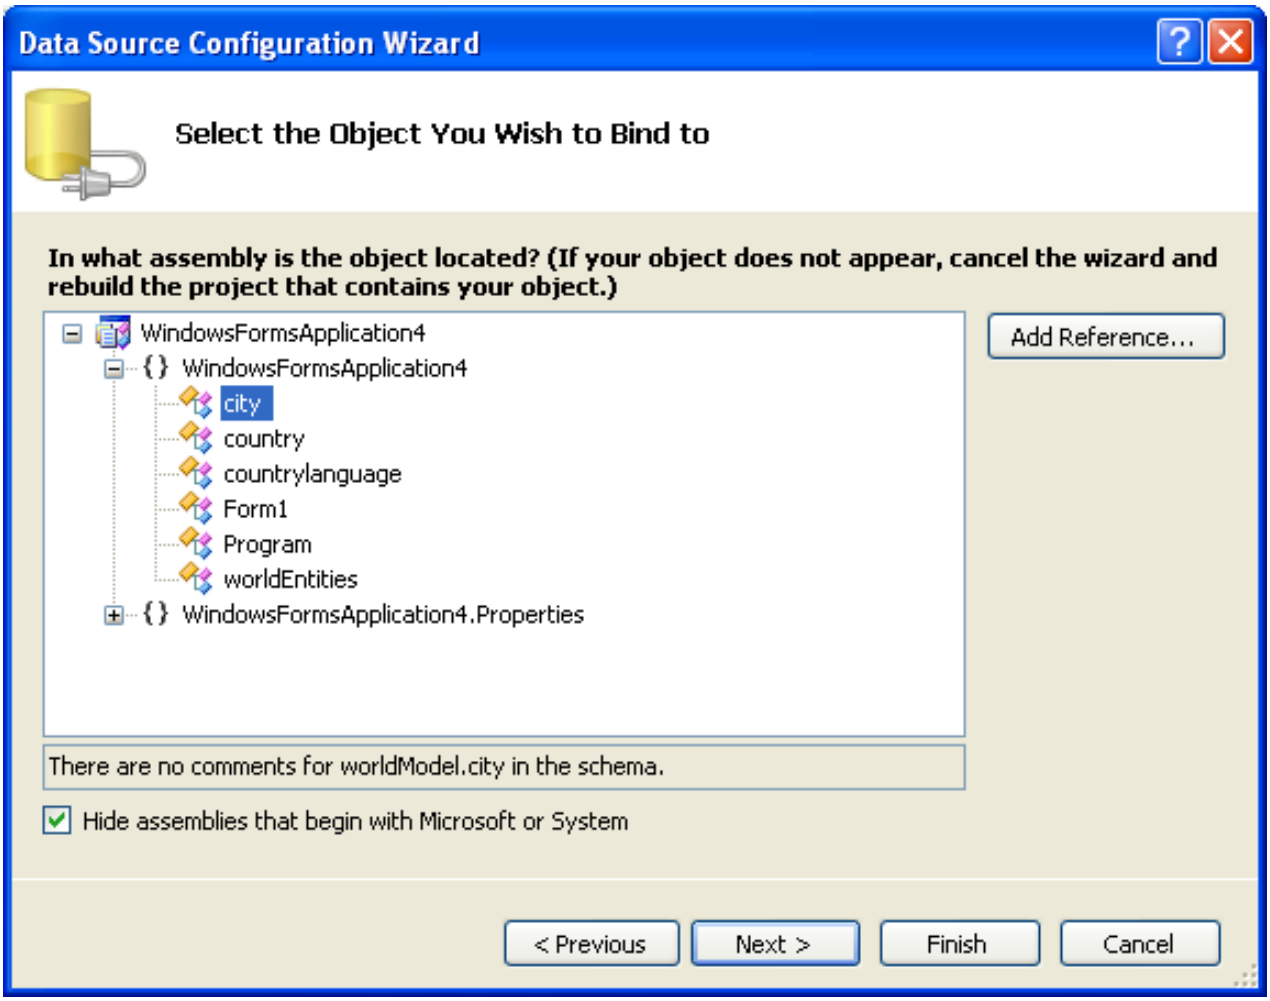
Figure 20.41. Entity Data Source Configuration Wizard Screen 1



2. Select the **OBJECT** icon. Click NEXT.

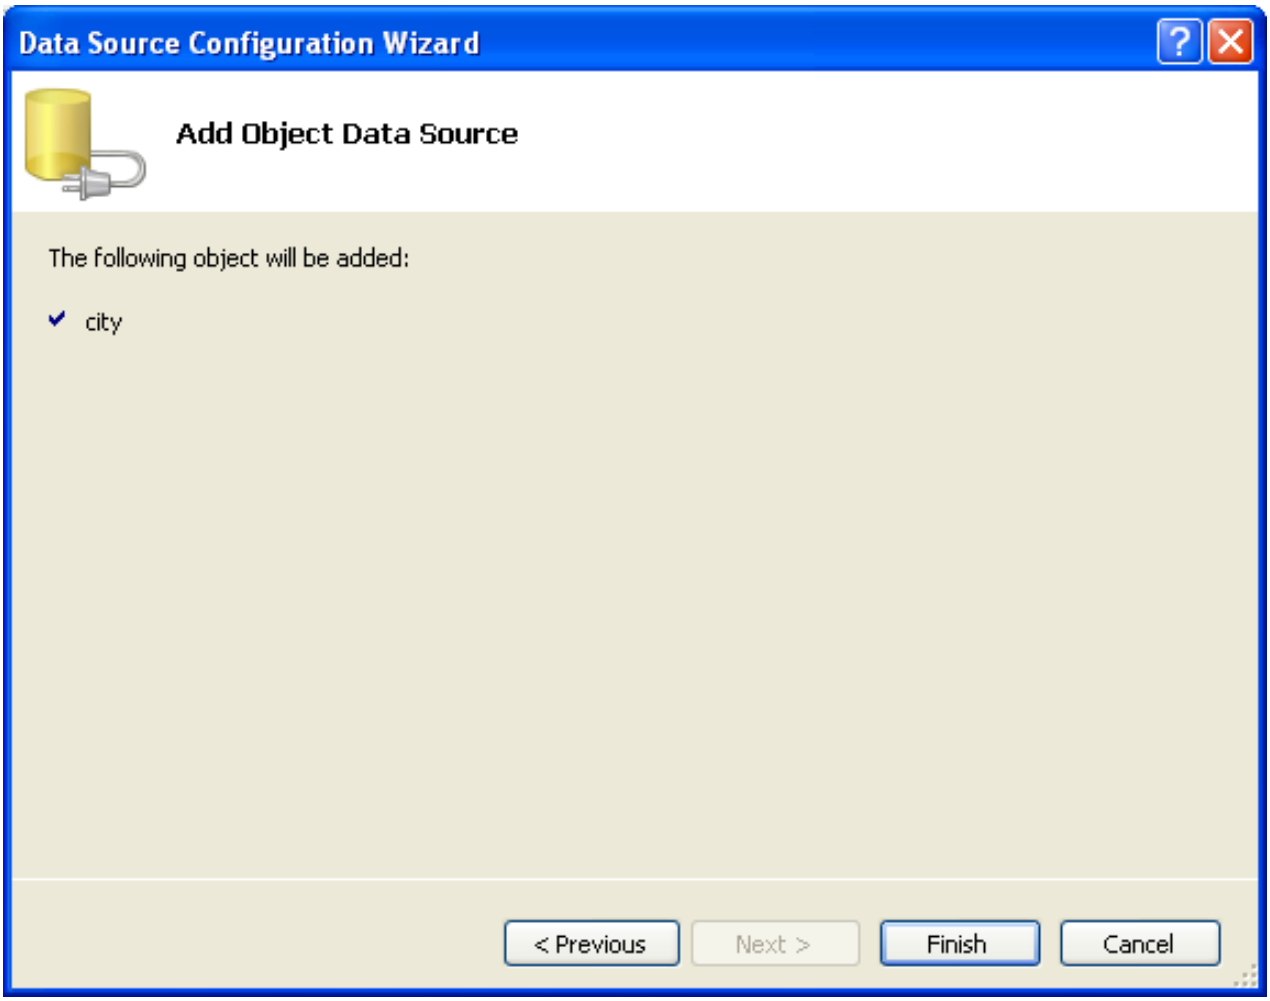
3. You will now select the Object you wish to bind to. Expand the tree. In this tutorial you will select the city table. Once the city table has been selected click NEXT.

Figure 20.42. Entity Data Source Configuration Wizard Screen 2



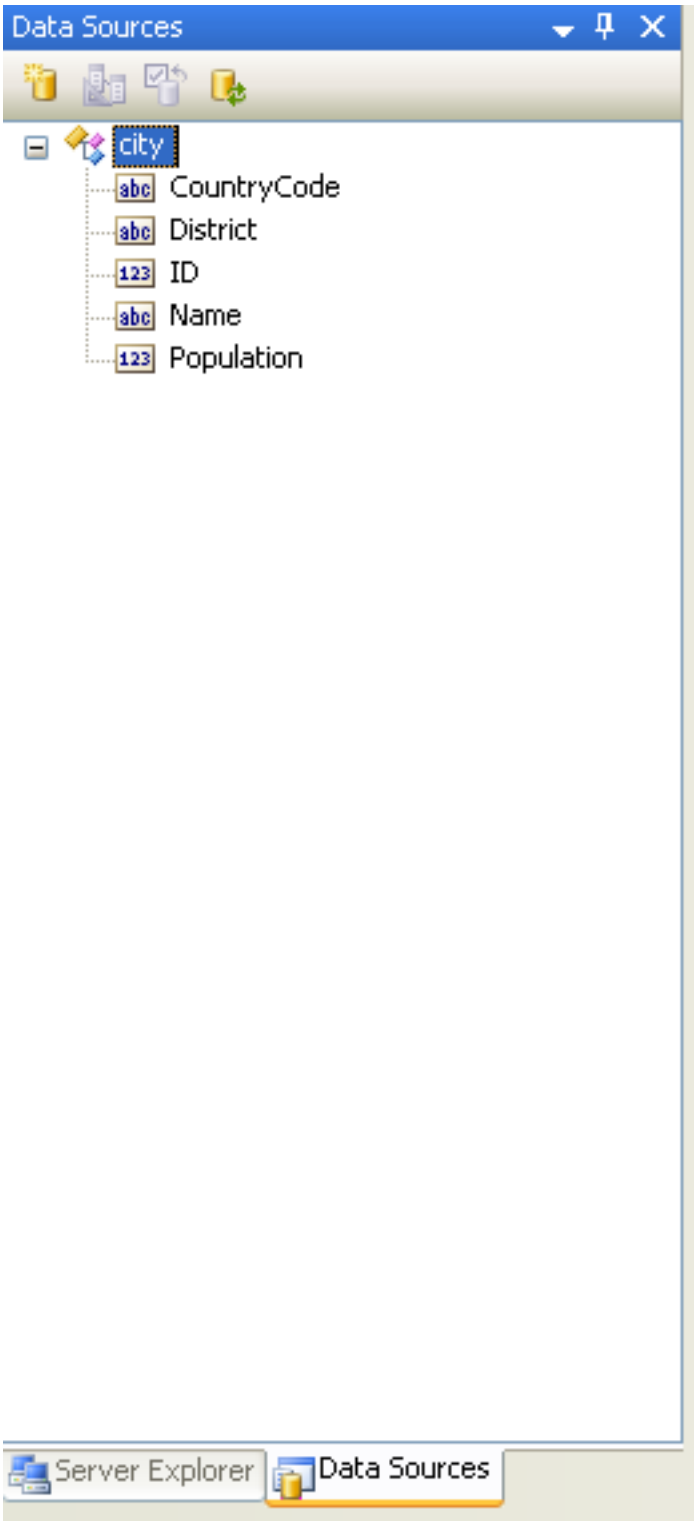
4. The wizard will confirm that the city object is to be added. Click FINISH.

Figure 20.43. Entity Data Source Configuration Wizard Screen 3



5. The city object will be display in the Data Sources panel. If the Data Sources panel is not displayed, select DATA, SHOW DATA SOURCES from the Visual Studio main menu. The docked panel will then be displayed.

Figure 20.44. Data Sources

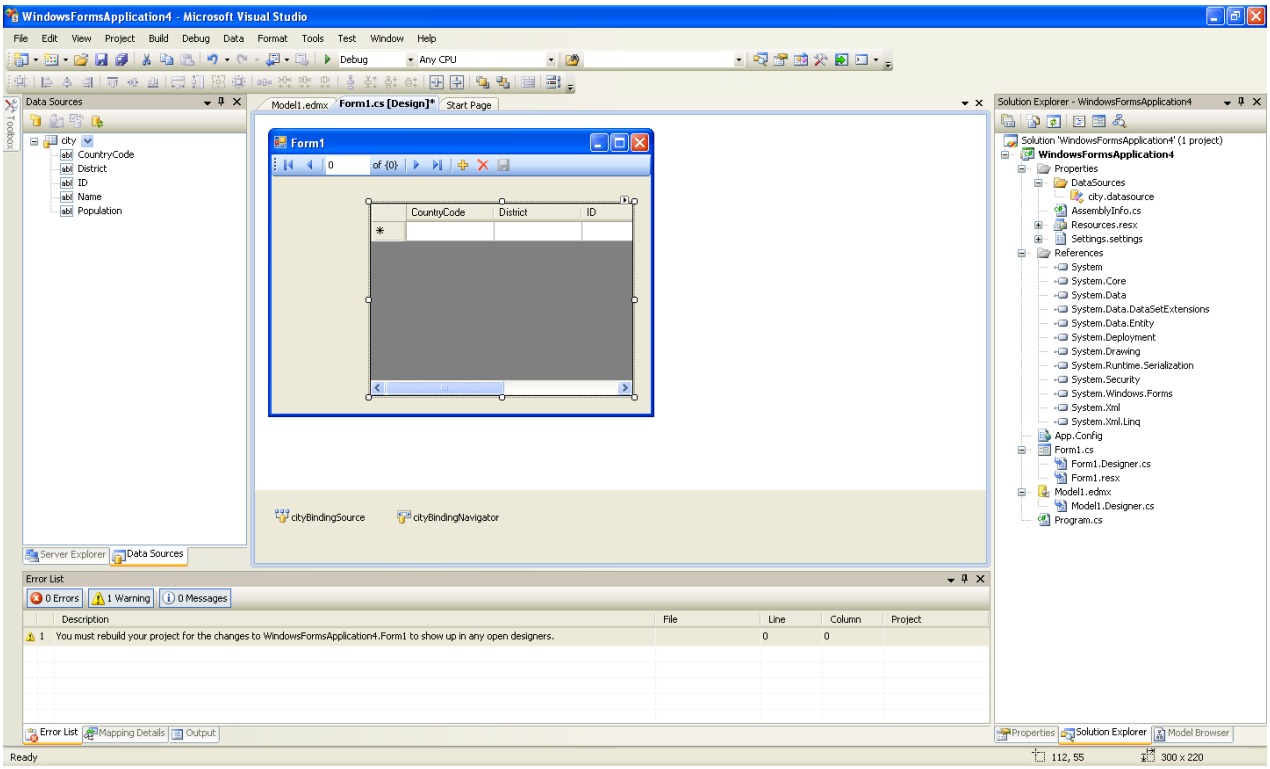


Using the Data Source in a Windows Form

You will now learn how to use the Data Source in a Windows Form.

1. In the Data Sources panel select the Data Source you just created and drag and drop it onto the Form Designer. By default the Data Source object will be added as a Data Grid View control. Note that the Data Grid View control is bound to the `cityBindingSource` and the Navigator control is bound to `cityBindingNavigator`.

Figure 20.45. Data Form Designer



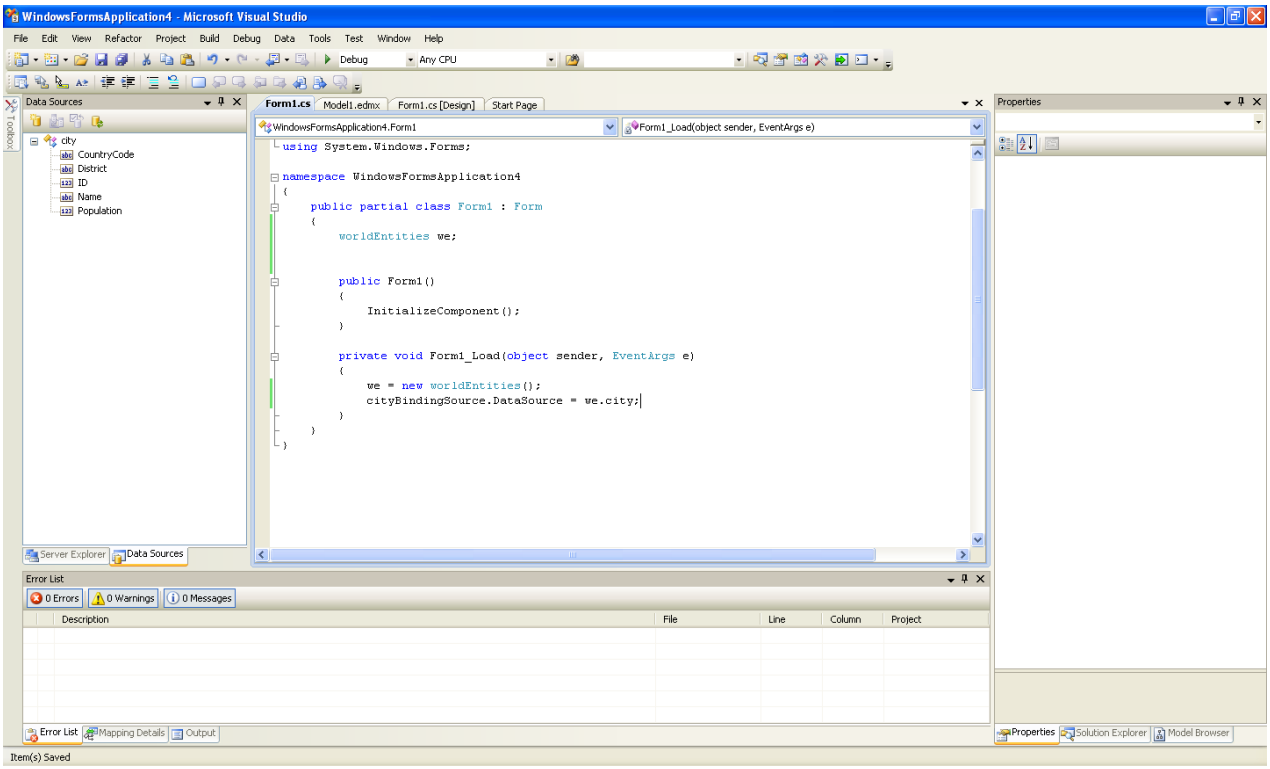
2. Save and rebuild the solution before continuing.

Adding Code to Populate the Data Grid View

You are now ready to add code to ensure that the Data Grid View control will be populated with data from the City database table.

1. Double-click the form to access its code.
2. Add code to instatiate the Entity Data Model's EntityContainer object and retrieve data from the database to populate the control.

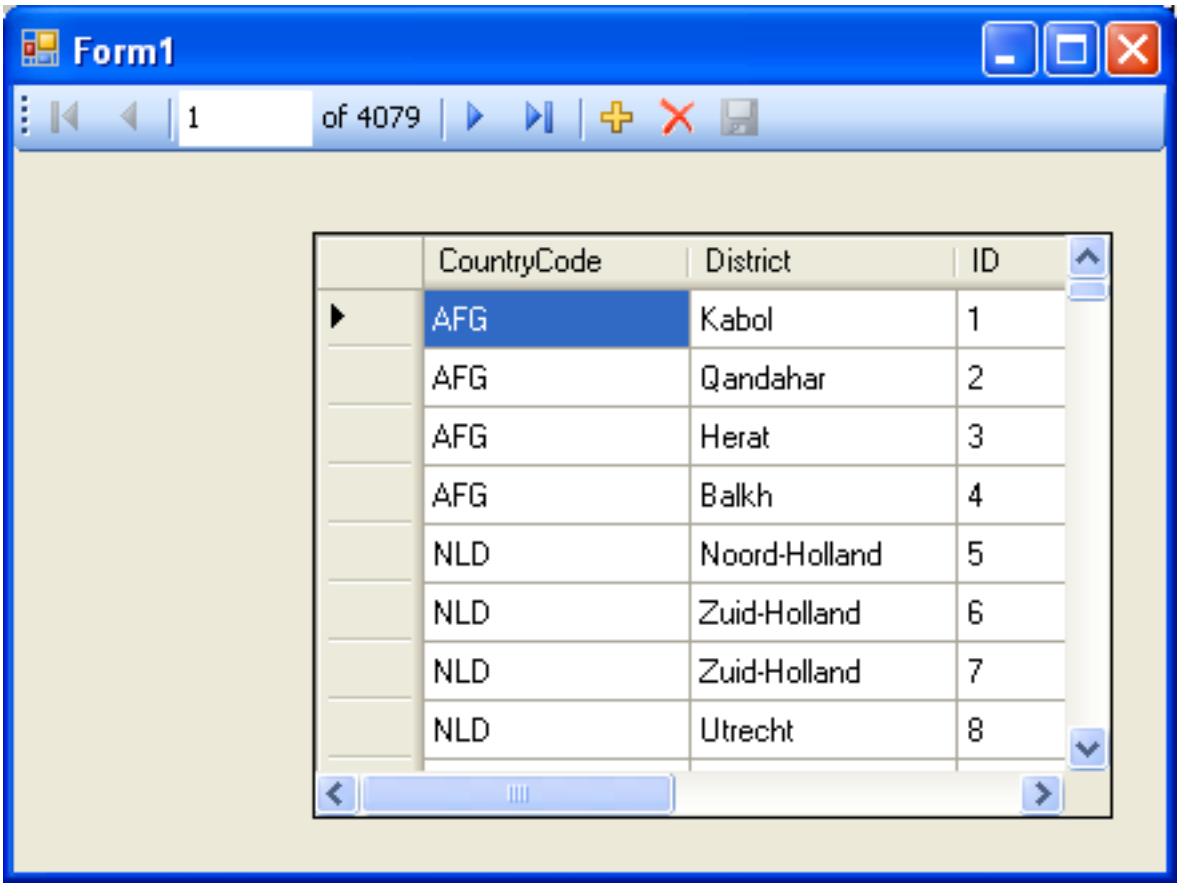
Figure 20.46. Adding Code to the Form



3. Save and rebuild the solution.

4. Run the solution. Ensure the grid is populated and you can navigate the database.

Figure 20.47. The Populated Grid Control



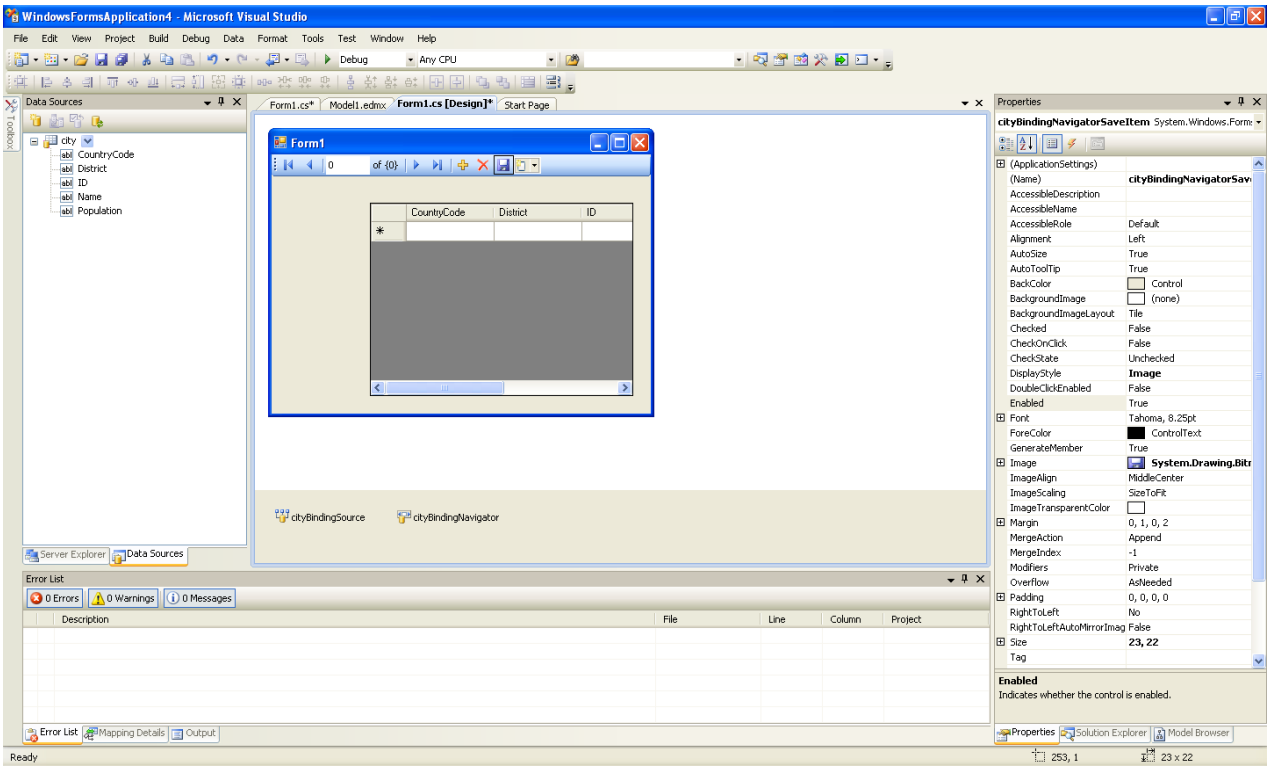
Adding Code to Save Changes to the Database

You will now add code to enable you to save changes to the database.

The Binding source component ensures that changes made in the Data Grid View control are also made to the Entity classes bound to it. However, that data needs to be saved back from the entities to the database itself. This can be achieved by the enabling of the Save button in the Navigator control, and the addition of some code.

1. In the Form Designer, click the Save icon in the Form toolbar and ensure that its Enabled property is set to True.

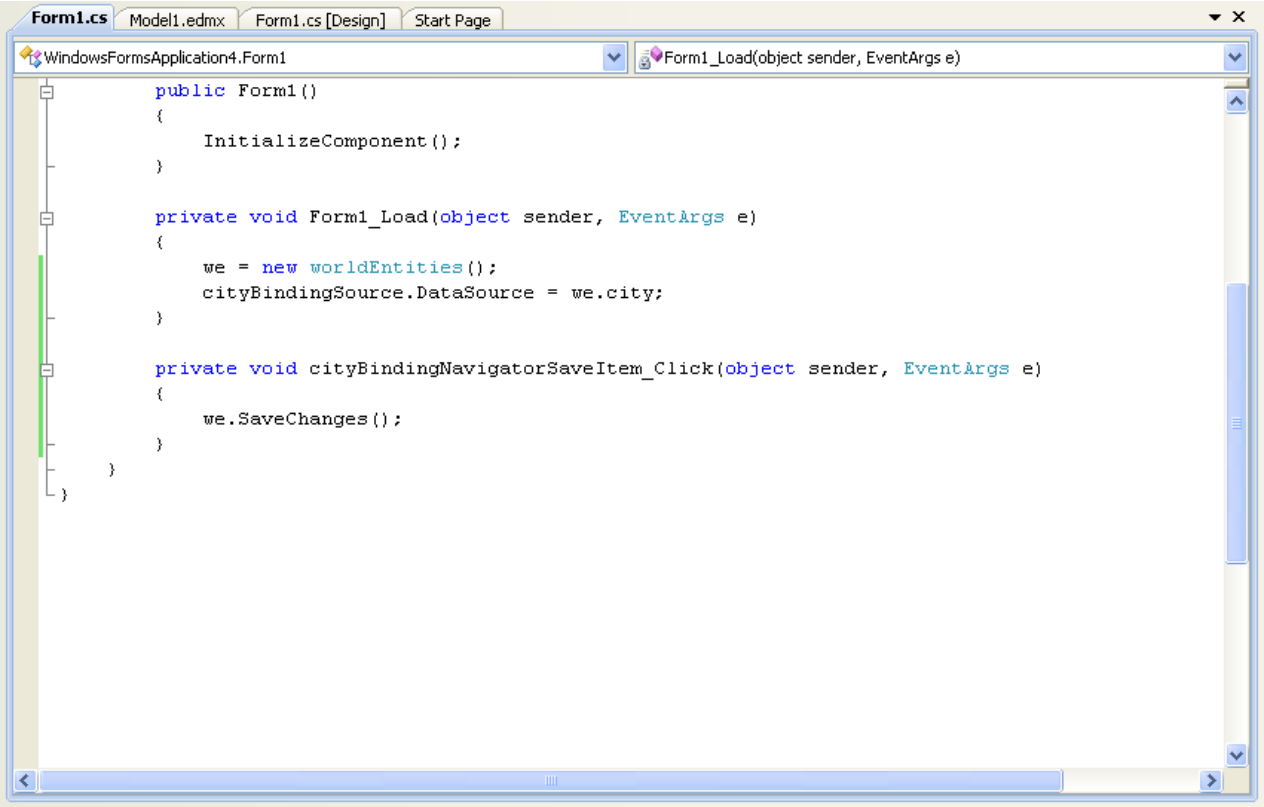
Figure 20.48. Save Button Enabled



2. Double-click the Save icon in the Form toolbar to display its code.

3. You now need to add code to ensure that data is saved to the database when the save button is clicked in the application.

Figure 20.49. Adding Save Code to the Form



4. Once the code has been added, save the solution and rebuild it. Run the application and verify that changes made in the grid are saved.

20.2.4.6. Tutorial: Databinding in ASP.NET using LINQ on Entities

In this tutorial you create an ASP.NET web page that binds LINQ queries to entities using the Entity Framework mapping.

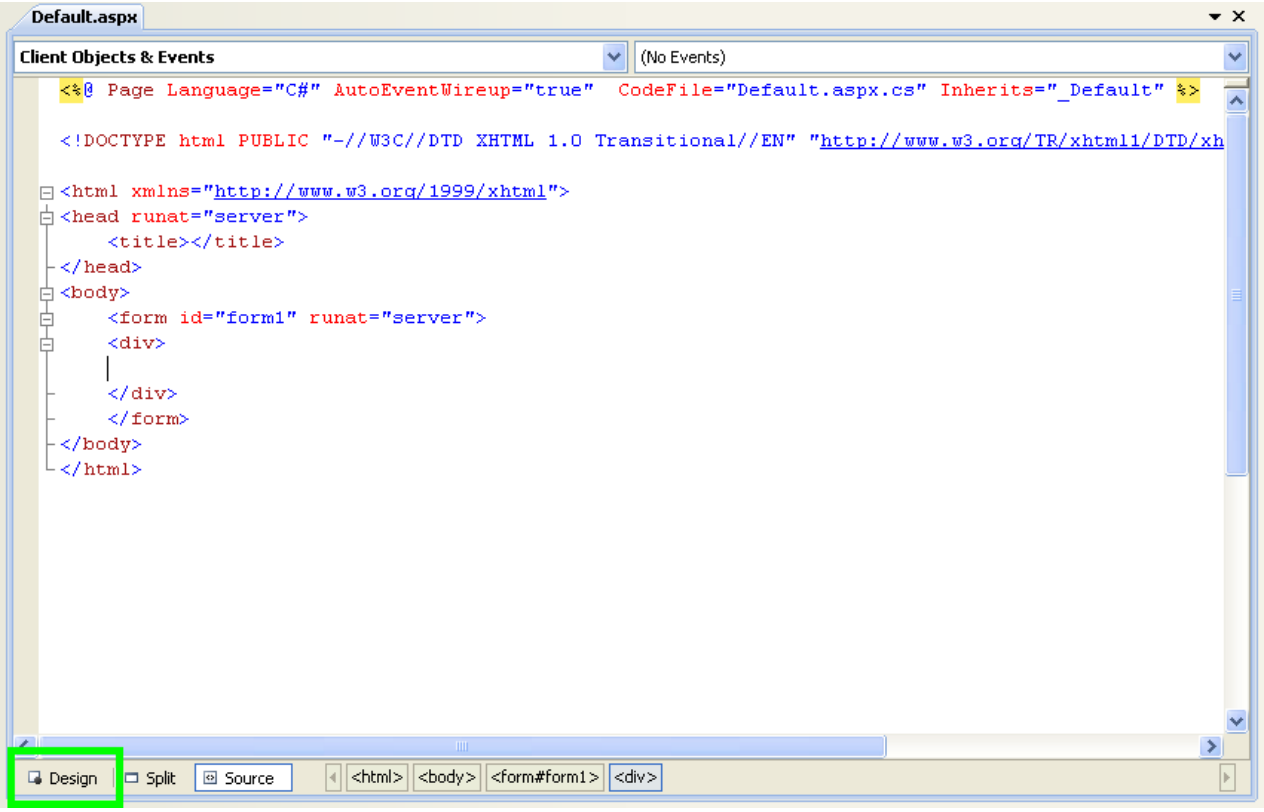
If you have not already done so, you should install the World example database prior to attempting this tutorial. Instructions on where to obtain the database and instructions on how to install it where given in the tutorial Section 20.2.4.5, “Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source”.

Creating an ASP.NET web site

In this part of the tutorial you will create an ASP.NET web site. The web site will use the World database. The main web page will feature a drop down list from which you can select a country, data about that country's cities will then be displayed in a grid view control.

1. From the Visual Studio main menu select FILE, NEW, WEB SITE....
2. From the Visual Studio installed templates select **ASP.NET WEB SITE**. Click OK. You will be presented with the Source view of your web page by default.
3. Click the Design view tab situated underneath the Source view panel.

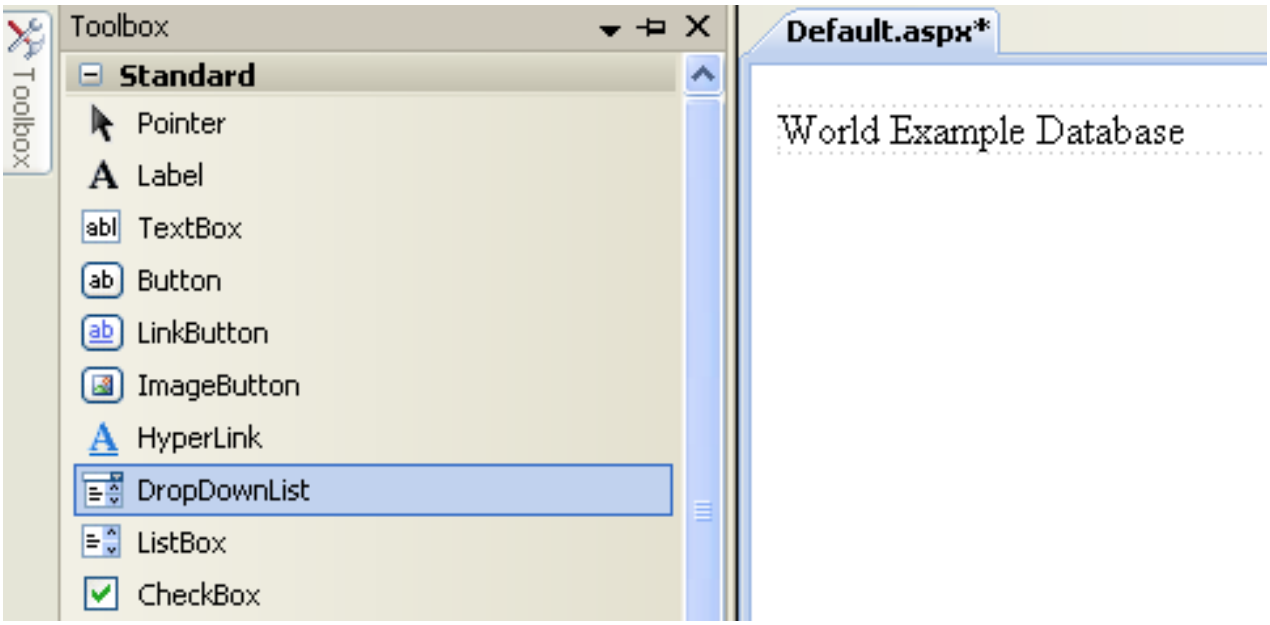
Figure 20.50. The Design Tab



4. In the Design view panel, enter some text to decorate the blank web page.

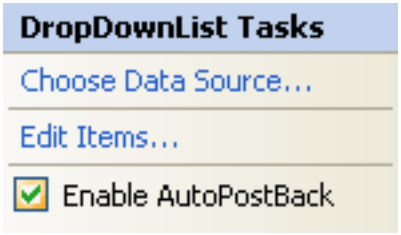
5. Click Toolbox. From the list of controls select **DROPDOWNLIST**. Drag and drop the control to a location beneath the text on your web page.

Figure 20.51. Drop Down List



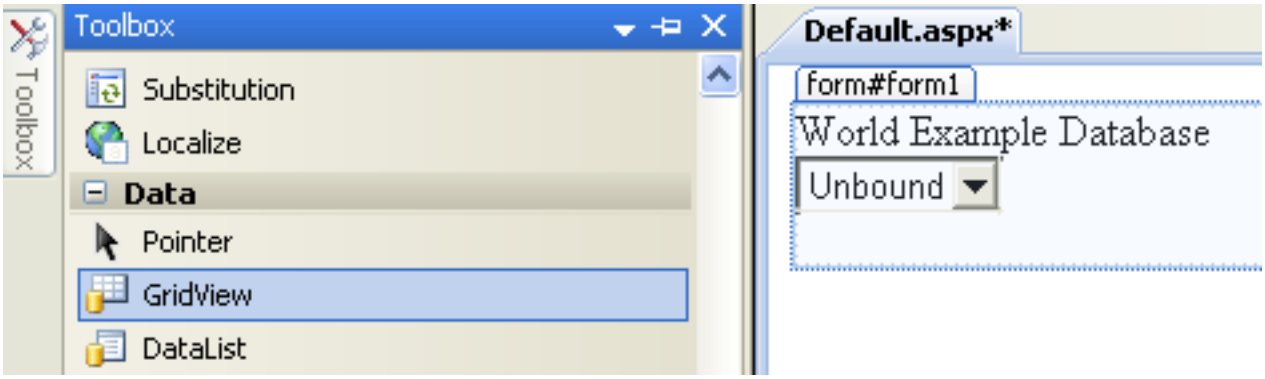
6. From the **DROPDOWNLIST** control's context menu, ensure that the **ENABLE AUTOPOSTBACK** check box is enabled. This will ensure the control's event handler is called when an item is selected. The user's choice will in turn be used to populate the **GRIDVIEW** control.

Figure 20.52. Enable AutoPostBack



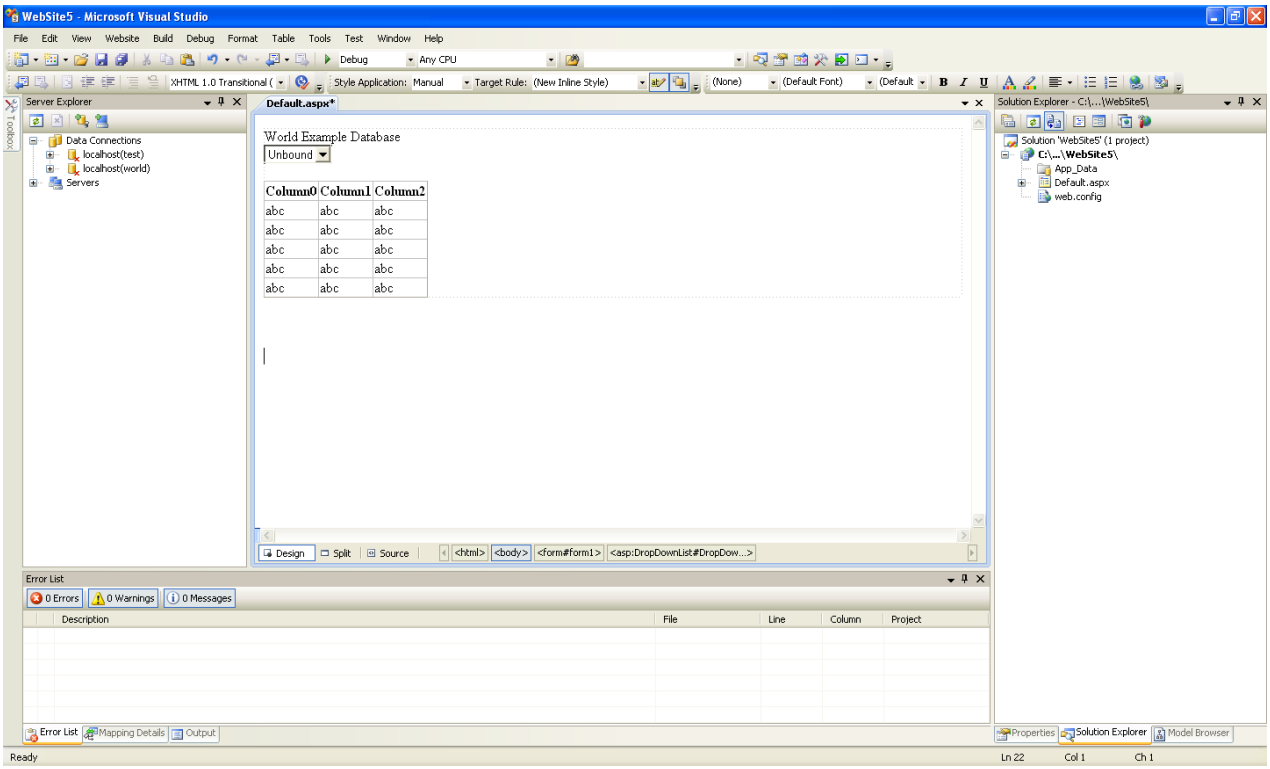
7. From the Toolbox select the **GRIDVIEW** control.

Figure 20.53. Grid View Control



Drag and drop the Grid Vew control to a location just below the Drop Down List you already placed.

Figure 20.54. Placed Grid Vew Control



8. At this point it is recommended that you save your solution, and build the solution to ensure that there are no errors.

9. If you run the solution you will see that the text and drop down list are displayed, but the list is empty. Also, the grid view does not appear at all. Adding this functionality is described in the following sections.

At this stage you have a web site that will build, but further functionality is required. The next step will be to use the Entity Framework to create a mapping from the World database into entities that you can control programmatically.

Creating an ADO.NET Entity Data Model

In this stage of the tutorial you will add an ADO.NET Entity Data Model to your project, using the World database at the storage level. The procedure for doing this is described in the tutorial Section 20.2.4.5, “Tutorial: Using an Entity Framework Entity as a Windows Forms Data Source”, and so will not be repeated here.

Populating a Drop Data List Box with using the results of a entity LINQ query

In this part of the tutorial you will write code to populate the DropDownList control. When the web page loads the data to populate the list will be achieved by using the results of a LINQ query on the model created previously.

1. In the Design view panel, double-click any blank area. This brings up the `Page_Load` method.

2. Modify the relevant section of code according to the following listing:

```
...
public partial class _Default : System.Web.UI.Page
{
    worldModel.worldEntities we;

    protected void Page_Load(object sender, EventArgs e)
    {
        we = new worldModel.worldEntities();

        if (!IsPostBack)
        {
            var countryQuery = from c in we.country
                               orderby c.Name
```

```
                                select new { c.Code, c.Name };
            DropDownList1.DataValueField = "Code";
            DropDownList1.DataTextField = "Name";
            DropDownList1.DataSource = countryQuery;
            DataBind();
        }
    }
...
```

Note that the list control only needs to be populated when the page first loads. The conditional code ensures that if the page is subsequently reloaded, the list control is not repopulated, which would cause the user selection to be lost.

3. Save the solution, build it and run it. You should see the list control has been populated. You can select an item, but as yet the grid view control does not apear.

At this point you have a working Drop Down List control, populated by a LINQ query on your entity data model.

Populating a Grid View control using an entity LINQ query

In the last part of this tutorial you will populate the Grid View Control using a LINQ query on your entity data model.

1. In the Design view, double-click the **DROPDOWNLIST** control. This causes its `SelectedIndexChanged` code to be displayed. This method is called when a user selects an item in the list control and thus fires an AutoPostBack event.

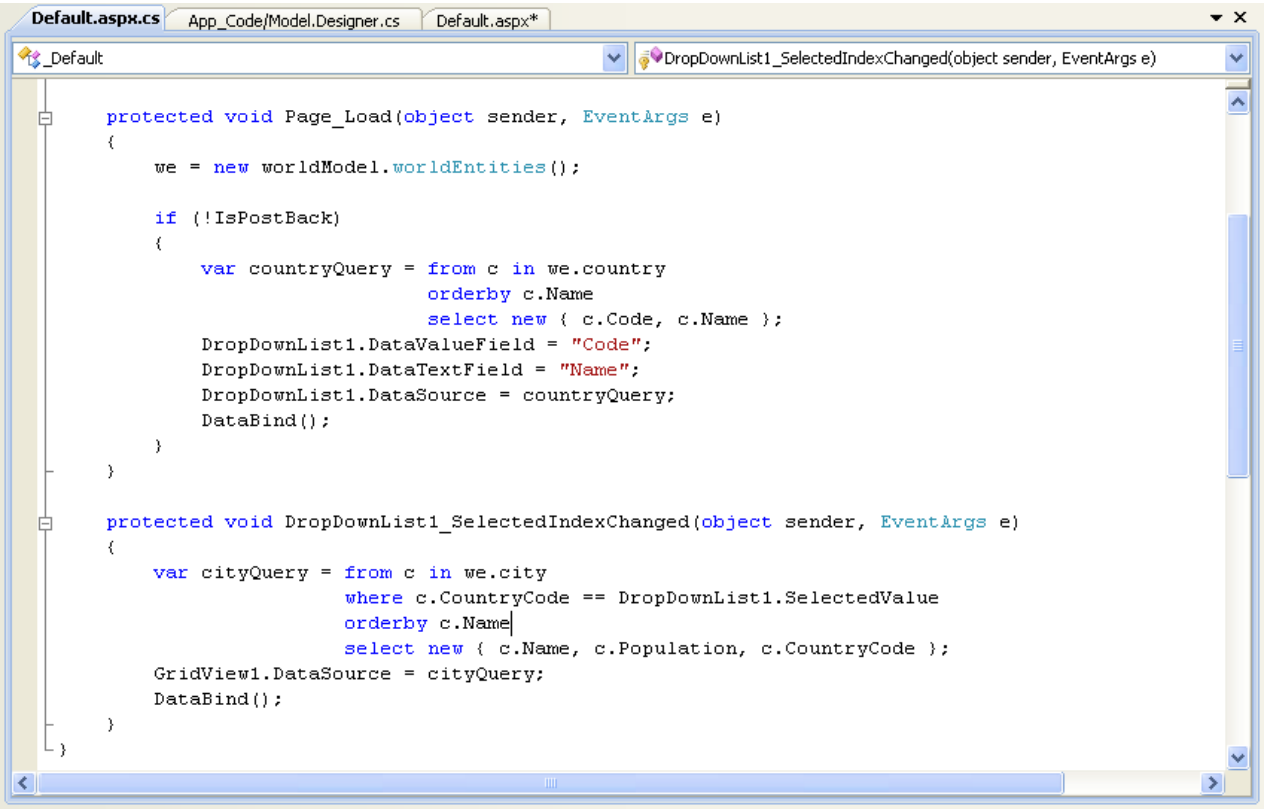
2. Modify the relevant section of code accordingly to the following listing:

```
...
    protected void DropDownList1_SelectedIndexChanged(object sender, EventArgs e)
    {
        var cityQuery = from c in we.city
                        where c.CountryCode == DropDownList1.SelectedValue
                        orderby c.Name
                        select new { c.Name, c.Population, c.CountryCode };
        GridView1.DataSource = cityQuery;
        DataBind();
    }
...
```

The grid view control is populated from the result of the LINQ query on the entity data model.

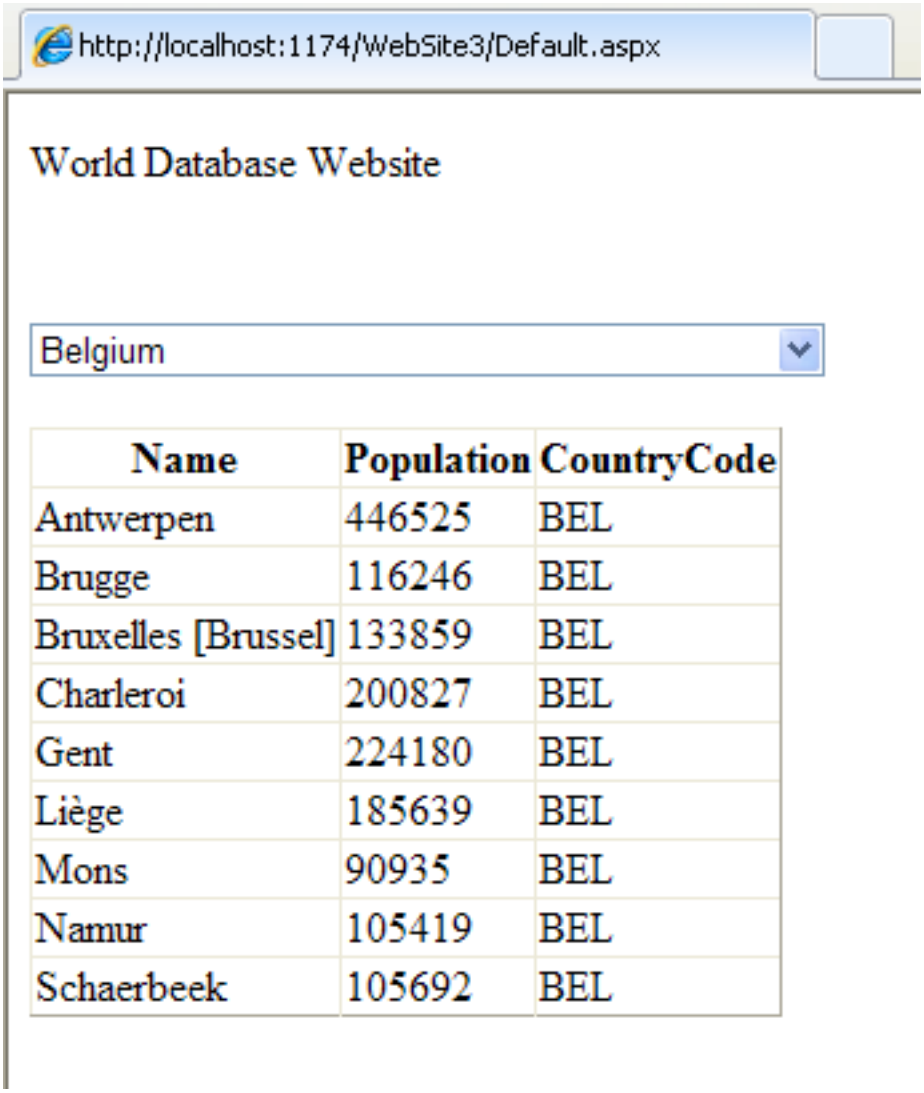
3. As a check compare your code to that shown in the following screenshot:

Figure 20.55. Source Code



4. Save, build and run the solution. As you select a country you will see its cities are displayed in the grid view control.

Figure 20.56. The Working Web Site



In this tutorial you have seen how to create an ASP.NET web site, you have also seen how you can access a MySQL database via LINQ queries on an entity data model.

20.2.4.7. Tutorial: Using SSL with MySQL Connector/NET

In this tutorial you will learn how you can use MySQL Connector/NET to connect to a MySQL server configured to use SSL. Support for SSL client certificates was added with MySQL Connector/NET 6.2.

MySQL Server uses the PEM format for certificates and private keys. This tutorial will use the test certificates from the server test suite by way of example. You can obtain the MySQL Server source code from MySQL Downloads. The certificates can be found in the directory `./mysql-test/std_data`.

To carry out the steps in this tutorial you will also need to have Open SSL installed. This can be downloaded for Microsoft Windows at no charge from Shining Light Productions.

Further details on the connection string options used in this tutorial can be found at Section 20.2.6, “Connector/NET Connection String Options Reference”.

Configuring the MySQL Server to use SSL

1. In the MySQL Server configuration file, set the SSL parameters as follows:

```
ssl-ca=path/to/repo/mysql-test/std_data/cacert.pem
ssl-cert=path/to/repo/mysql-test/std_data/server-cert.pem
ssl-key=path/to/repo/mysql-test/std_data/server-key.pem
```

   Adjust the directories according to the location in which you installed the MySQL source code.

2. In this step you create a test user and set the user to require SSL.

   Using the MySQL Command Line Client, connect as root and create the user `sslclient`.

3. To set privileges and requirements, issue the following command:

```
GRANT ALL PRIVILEGES ON *.* TO sslclient@'%' REQUIRE SSL;
```

Creating a certificate file to use with the .NET client

1. The .NET client does not use the PEM file format, as .NET does not support this format natively. You will be using test client certificates from the same server repository, for the purposes of this example. You will need to convert these to PFX format first. This format is also known as PKCS#12. An article describing this procedure can be found at the Citrix website. From the directory *`server-repository-root`*`/mysql-test/std_data`, issue the following command:

```
openssl pkcs12 -export -in client-cert.pem -inkey client-key.pem -certfile cacert.pem -out client.pfx
```

2. When asked for an export password, enter the password “pass”. The file `client.pfx` will be generated. This file is used in the remainder of the tutorial.

Connecting to the server using a file-based certificate

1. You will use PFX file, `client.pfx` you created in the previous step to authenticate the client. The following example demonstrates how to connect using the `SSL Mode`, `CertificateFile` and `CertificatePassword` connection string options:

```
using (MySqlConnection connection = new MySqlConnection(
  "database=test;user=sslclient;" +
  "CertificateFile=H:\\bzr\\mysql-trunk\\mysqlest\\std_data\\client.pfx" +
  "CertificatePassword=pass;" +
  "SSL Mode=Required "))
{
    connection.Open();
}
```

   The path to the certificate file will need to be changed to reflect your individual installation.

Connecting to the server using a store-based certificate

1. The first step is to import the PFX file, `client.pfx`, into the Personal Store. Double-click the file in Windows explorer. This launches the Certificate Import Wizard.

2. Follow the steps dictated by the wizard, and when prompted for the password for the PFX file, enter “pass”.

3. Click FINISH to close the wizard and import the certificate into the personal store.

Examine certificates in the Personal Store

1. Start the Microsoft Management Console by entering `mmc.exe` at a command prompt.

2. Select FILE, ADD/REMOVE SNAP-IN. Click ADD. Select **CERTIFICATES** from the list of available snap-ins in the dialog.

3. Click ADD button in the dialog, and select the **MY USER ACCOUNT** radio button. This is used for personal certificates.

4. Click the FINISH button.

5. Click OK to close the Add/Remove Snap-in dialog.

6. You will now have **CERTIFICATES – CURRENT USER** displayed in the left panel of the Microsoft Management Console. Expand the Certificates - Current User tree item and select **PERSONAL**, **CERTIFICATES**. The right-hand panel will display a certificate issued to MySQL. This is the certificate that was previously imported. Double-click the certificate to display its details.

7. After you have imported the certificate to the Personal Store, you can use a more succint connection string to connect to the database, as illustrated by the following code:

```
using (MySqlConnection connection = new MySqlConnection(
   "database=test;user=sslclient;" +
   "Certificate Store Location=CurrentUser;" +
   "SSL Mode=Required"))
{
   connection.Open();
}
```

Certificate Thumbprint Parameter

If you have a large number of certificates in your store, and many have the same Issuer, this can be a source of confusion and result in the wrong certificate being used. To alleviate this situation, there is an optional Certificate Thumbprint parameter that can additionally be specified as part of the connection string. As mentioned before, you can double-click a certificate in the Microsoft Management Console to display the certificate's details. When the Certificate dialog is displayed click the **DETAILS** tab and scroll down to see the thumbprint. The thumbprint will typically be a number such as `47 94 36 00 9a 40 f3 01 7a 14 5c f8 47 9e 76 94 d7 aa de f0`. This thumbprint can be used in the connection string, as the following code illustrates:

```
using (MySqlConnection connection = new MySqlConnection(
      "database=test;user=sslclient;" +
      "Certificate Store Location=CurrentUser;" +
      "Certificate Thumbprint=479436009a40f3017a145cf8479e7694d7aadef0;"+
      "SSL Mode=Required"))
{
    connection.Open();
}
```

Spaces in the thumbprint parameter are optional and the value is case-insensitive.

20.2.4.8. Tutorial: Using MySqlScript

In this tutorial you will learn how to use the `MySqlScript` class. This class allows you to execute a series of statements. Depending on the circumstances, this can be more convenient than using the `MySqlCommand` approach.

Further details of the `MySqlScript` class can be found in the reference documentation supplied with MySQL Connector/NET.

If you wish to run the example programs in this tutorial, you will need to set up a simple test database and table. This can be achived using the MySQL Command Line Client or MySql Workbench. Commands for the MySQL Command Line Client are given here:

1. `CREATE DATABASE TestDB;`

2. `USE TestDB;`

3. `CREATE TABLE TestTable (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, name VARCHAR(100));`

The main method of the `MySqlScript` class is the `Execute` method. This method causes the script (sequence of statements) assigned to the Query property of the MySqlScript object to be executed. Note the Query property can be set through the `MySqlScript` constructor or via the Query property. `Execute` returns the number of statements executed.

The `MySqlScript` object will execute the specified script on the connection set via the Connection property. Again, this property can be set directly or through the `MySqlScript` constructor. The following code snipets illustrate this:

```
string sql = "SELECT * FROM TestTable";
...
```

```
MySqlScript script = new MySqlScript(conn, sql);
...
MySqlScript script = new MySqlScript();
script.Query = sql;
script.Connection = conn;
...
script.Execute();
```

The MySqlScript class has several events associated with it. There are:

1. Error - generated in an error occurs.
2. ScriptCompleted - generated when the script successfully completes execution.
3. StatementExecuted - generated after each statement is executed.

It is possible to assign event handlers to each of these events. These user-provided routies will be called back should the connected event occur. The following code shows how the event handlers are set up.

```
script.Error += new MySqlScriptErrorEventHandler(script_Error);
script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
script.StatementExecuted += new MySqlStatementExecutedEventHandler(script_StatementExecuted);
```

In VisualStudio you can use tab completion to fill out stub routines for you, to save typing. To do this start by typing, for example, “script.Error +=”. Then press **TAB**, and then press **TAB** again. The assignment will be completed, and a stub event handler created. A complete working example is shown below:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace MySqlScriptTest
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "INSERT INTO TestTable(name) VALUES ('Superman');" +
                             "INSERT INTO TestTable(name) VALUES ('Batman');" +
                             "INSERT INTO TestTable(name) VALUES ('Wolverine');" +
                             "INSERT INTO TestTable(name) VALUES ('Storm');";

                MySqlScript script = new MySqlScript(conn, sql);

                script.Error += new MySqlScriptErrorEventHandler(script_Error);
                script.ScriptCompleted += new EventHandler(script_ScriptCompleted);
                script.StatementExecuted += new MySqlStatementExecutedEventHandler(script_StatementExecuted);

                int count = script.Execute();

                Console.WriteLine("Executed " + count + " statement(s).");
                Console.WriteLine("Delimiter: " + script.Delimiter);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }

        static void script_StatementExecuted(object sender, MySqlScriptEventArgs args)
        {
            Console.WriteLine("script_StatementExecuted");
        }
```

```
        static void script_ScriptCompleted(object sender, EventArgs e)
        {
            /// EventArgs e will be EventArgs.Empty for this method
            Console.WriteLine("script_ScriptCompleted!");
        }

        static void script_Error(Object sender, MySqlScriptErrorEventArgs args)
        {
            Console.WriteLine("script_Error: " + args.Exception.ToString());
        }
    }
}
```

Note that in the `script_ScriptCompleted` event handler, the `EventArgs` parameter `e` will be `EventArgs.Empty`. In the case of the `ScriptCompleted` event there is no additional data to be obtained, which is why the event object is `EventArgs.Empty`.

20.2.4.8.1. Using Delimiters with MySqlScript

Depending on the nature of the script, you made need control of the delimiter used to separate the statements that will make up a script. The most common example of this is where you have a multi-statement stored routine as part of your script. In this case if the default delimiter of ";" is used you will get an error when you attempt to execute the script. For example, consider the following stored routine:

```
CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;
    SELECT COUNT(name) FROM TestTable;
END
```

This routine actually needs to be executed on the MySQL Server as a single statement. However, with the default delimiter of ";", the `MySqlScript` class would interpret the above as two statements, the first being:

```
CREATE PROCEDURE test_routine()
BEGIN
    SELECT name FROM TestTable ORDER BY name;
```

Executing this as a statement would generate an error. To solve this problem `MySqlScript` supports the ability to set a different delimiter. This is achieved through the Delimiter property. For example, you could set the delimiter to "??", in which case the above stored routine would no longer generate an error when executed. Multiple statements can be delimited in the script, so for example, you could have a three statement script such as:

```
string sql = "DROP PROCEDURE IF EXISTS test_routine??" +
             "CREATE PROCEDURE test_routine() " +
             "BEGIN " +
             "SELECT name FROM TestTable ORDER BY name;" +
             "SELECT COUNT(name) FROM TestTable;" +
             "END??" +
             "CALL test_routine()";
```

You can change the delimiter back at any point by setting the Delimiter property. The following code shows a complete working example:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication8
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql =    "DROP PROCEDURE IF EXISTS test_routine??" +
```

```
                                "CREATE PROCEDURE test_routine() " +
                                "BEGIN " +
                                "SELECT name FROM TestTable ORDER BY name;" +
                                "SELECT COUNT(name) FROM TestTable;" +
                                "END??" +
                                "CALL test_routine()";

                MySqlScript script = new MySqlScript(conn);

                script.Query = sql;
                script.Delimiter = "??";
                int count = script.Execute();
                Console.WriteLine("Executed " + count + " statement(s)");
                script.Delimiter = ";";
                Console.WriteLine("Delimiter: " + script.Delimiter);
                Console.WriteLine("Query: " + script.Query);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

20.2.4.9. Tutorial: Generating MySQL DDL from an Entity Framework Model

In this tutorial you will learn how to create MySQL DDL from an Entity Framework model. You will need to use Visual Studio 2010 and MySQL Connector/NET 6.3 to carry out this tutorial.

1. Create a new console application in Visual Studio 2010.
2. Using the **Solution Explorer** add a reference to `MySql.Data.Entity`.
3. From the **Solution Explorer** select Add, New Item. In the **Add New Item** dialog select **Online Templates**. Select **ADO.NET Entity Data Model** and click Add. The **Entity Data Model** dialog will be displayed.
4. In the **Entity Data Model** dialog select **Empty Model**. Click Finish. A blank model will be created.
5. Create a simple model. A single Entity will do for the purposes of this tutorial.
6. In the **Properties** panel select ConceptualEntityModel from the drop-down listbox.
7. In the **Properties** panel, locate the **DDL Generation Template** in the category **Database Script Generation**.
8. For the **DDL Generation** property select SSDLToMySQL.tt(VS) from the drop-down listbox.
9. Save the solution.
10. Right-click an empty space in the model design area. The context-sensitive menu will be displayed.
11. From the context-sensitive menu select Generate Database from Model. The **Generate Database Wizard** dialog will be displayed.
12. In the **Generate Database Wizard** dialog select an existing connection, or create a new connection to a server. Select an appropriate radio button to show or hide sensitive data. For the purposes of this tutorial you can select **Yes** (although you may not want to do this for commercial applications).
13. Click Next. MySQL compatible DDL code will be generated. Click Finish to exit the wizard.

You have seen how to create MySQL DDL code from an Entity Framework model.

20.2.5. Connector/NET Programming

Connector/NET comprises several classes that are used to connect to the database, execute queries and statements, and manage query results.

The following are the major classes of Connector/NET:

- `MySqlCommand`: Represents an SQL statement to execute against a MySQL database.
- `MySqlCommandBuilder`: Automatically generates single-table commands used to reconcile changes made to a DataSet with the associated MySQL database.
- `MySqlConnection`: Represents an open connection to a MySQL Server database.
- `MySqlDataAdapter`: Represents a set of data commands and a database connection that are used to fill a data set and update a MySQL database.
- `MySqlDataReader`: Provides a means of reading a forward-only stream of rows from a MySQL database.
- `MySqlException`: The exception that is thrown when MySQL returns an error.
- `MySqlHelper`: Helper class that makes it easier to work with the provider.
- `MySqlTransaction`: Represents an SQL transaction to be made in a MySQL database.

In the following sections you will learn about some common use cases for Connector/NET, including BLOB handling, date handling, and using Connector/NET with common tools such as Crystal Reports.

20.2.5.1. Connecting to MySQL Using Connector/NET

Introduction

All interaction between a .NET application and the MySQL server is routed through a `MySqlConnection` object. Before your application can interact with the server, a `MySqlConnection` object must be instanced, configured, and opened.

Even when using the `MySqlHelper` class, a `MySqlConnection` object is created by the helper class.

In this section, we will describe how to connect to MySQL using the `MySqlConnection` object.

20.2.5.2. Creating a Connection String

The `MySqlConnection` object is configured using a connection string. A connection string contains sever key/value pairs, separated by semicolons. Each key/value pair is joined with an equal sign.

The following is a sample connection string:

```
Server=127.0.0.1;Uid=root;Pwd=12345;Database=test;
```

In this example, the `MySqlConnection` object is configured to connect to a MySQL server at `127.0.0.1`, with a user name of `root` and a password of `12345`. The default database for all statements will be the `test` database.

The following options are available:

> **Note**
>
> Using the '@' symbol for parameters is now the preferred approach although the old pattern of using '?' is still supported.
>
> Please be aware however that using '@' can cause conflicts when user variables are also used. To help with this situation please see the documentation on the `Allow User Variables` connection string option, which can be found here: Section 20.2.5.2, “Creating a Connection String”. The `Old Syntax` connection string option has now been deprecated.

20.2.5.2.1. Opening a Connection

Once you have created a connection string it can be used to open a connection to the MySQL server.

The following code is used to create a `MySqlConnection` object, assign the connection string, and open the connection.

Visual Basic Example

```
Dim conn As New MySql.Data.MySqlClient.MySqlConnection
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
            & "uid=root;" _
            & "pwd=12345;" _
            & "database=test;"

Try
  conn.ConnectionString = myConnectionString
  conn.Open()

Catch ex As MySql.Data.MySqlClient.MySqlException
  MessageBox.Show(ex.Message)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection();
    conn.ConnectionString = myConnectionString;
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

You can also pass the connection string to the constructor of the `MySqlConnection` class:

Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
             & "uid=root;" _
             & "pwd=12345;" _
             & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
   MessageBox.Show(ex.Message)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message);
}
```

Once the connection is open it can be used by the other Connector/NET classes to communicate with the MySQL server.

20.2.5.2.2. Handling Connection Errors

Because connecting to an external server is unpredictable, it is important to add error handling to your .NET application. When there is an error connecting, the `MySqlConnection` class will return a `MySqlException` object. This object has two properties that are of

interest when handling errors:

- `Message`: A message that describes the current exception.
- `Number`: The MySQL error number.

When handling errors, you can your application's response based on the error number. The two most common error numbers when connecting are as follows:

- `0`: Cannot connect to server.
- `1045`: Invalid user name and/or password.

The following code shows how to adapt the application's response based on the actual error:

Visual Basic Example

```
Dim myConnectionString as String

myConnectionString = "server=127.0.0.1;" _
          & "uid=root;" _
          & "pwd=12345;" _
          & "database=test;"

Try
    Dim conn As New MySql.Data.MySqlClient.MySqlConnection(myConnectionString)
    conn.Open()
Catch ex As MySql.Data.MySqlClient.MySqlException
    Select Case ex.Number
        Case 0
            MessageBox.Show("Cannot connect to server. Contact administrator")
        Case 1045
            MessageBox.Show("Invalid username/password, please try again")
    End Select
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
string myConnectionString;

myConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    conn = new MySql.Data.MySqlClient.MySqlConnection(myConnectionString);
    conn.Open();
}
    catch (MySql.Data.MySqlClient.MySqlException ex)
{
    switch (ex.Number)
    {
        case 0:
            MessageBox.Show("Cannot connect to server.  Contact administrator");
        case 1045:
            MessageBox.Show("Invalid username/password, please try again");
    }
}
```

> **Important**
>
> Note that if you are using multilanguage databases you must specify the character set in the connection string. If you do not specify the character set, the connection defaults to the `latin1` charset. You can specify the character set as part of the connection string, for example:

```
MySqlConnection myConnection = new MySqlConnection("server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;Charset=latin1;");
```

20.2.5.2.3. Using GetSchema on a Connection

The `GetSchema()` method of the connection object can be used to retrieve schema information about the database currently connected to. The schema information is returned in the form of a `DataTable`. The schema information is organised into a number of collections. Different forms of the `GetSchema()` method can be used depending on the information required. There are three forms of the `GetSchema()` method:

- `GetSchema()` - This call will return a list of available collections.
- `GetSchema(String)` - This call returns information about the collection named in the string parameter. If the string "MetaDataCollections" is used then a list of all available collections is returned. This is the same as calling `GetSchema()` without any parameters.
- `GetSchema(String, String[])` - In this call the first string parameter represents the collection name, and the second parameter represents a string array of restriction values. Restriction values limit the amount of data that will be returned. Restriction values are explained in more detail in the Microsoft .NET documentation.

20.2.5.2.3.1. Collections

The collections can be broadly grouped into two types: collections that are common to all data providers, and collections specific to a particular provider.

Common

The following collections are common to all data providers:

- MetaDataCollections
- DataSourceInformation
- DataTypes
- Restrictions
- ReservedWords

Provider-specific

The following are the collections currently provided by MySQL Connector/NET, in addition to the common collections above:

- Databases
- Tables
- Columns
- Users
- Foreign Keys
- IndexColumns
- Indexes
- Foreign Key Columns
- UDF
- Views
- ViewColumns
- Procedure Parameters

- Procedures
- Triggers

Example Code

A list of available collections can be obtained using the following code:

```
using System;
using System.Data;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication2
{
    class Program
    {

        private static void DisplayData(System.Data.DataTable table)
        {
            foreach (System.Data.DataRow row in table.Rows)
            {
                foreach (System.Data.DataColumn col in table.Columns)
                {
                    Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
                }
                Console.WriteLine("============================");
            }
        }

        static void Main(string[] args)
        {

            string connStr = "server=localhost;user=root;database=world;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                DataTable table = conn.GetSchema("MetaDataCollections");
                //DataTable table = conn.GetSchema("UDF");
                DisplayData(table);

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}
```

Further information on the `GetSchema()` method and schema collections can be found in the Microsoft .NET documentation.

20.2.5.3. Using MySqlCommand

A MySqlCommand has the `CommandText` and `CommandType` properties associated with it. The `CommandText` will be handled differently depending on the setting of `CommandType`. `CommandType` can be one of:

1. Text - A SQL text command (default)
2. StoredProcedure - The name of a Stored Procedure
3. TableDirect - The name of a table (new in Connector/NET 6.2)

The default `CommandType`, `Text`, is used for executing queries and other SQL commands. Some example of this can be found in the following section Section 20.2.4.1.2, “The MySqlCommand Object”.

If `CommandType` is set to `StoredProcedure`, `CommandText` should be set to the name of the Stored Procedure to access.

If `CommandType` is set to `TableDirect`, all rows and columns of the named table will be returned when you call one of the Execute methods. In effect, this command performs a `SELECT *` on the table specified. The `CommandText` property is set to the name of the table you wish to query. This is illustrated by the following code snippet:

```
...
MySqlCommand cmd = new MySqlCommand();
cmd.CommandText = "mytable";
cmd.Connection = someConnection;
cmd.CommandType = CommandType.TableDirect;
SqlDataReader reader = cmd.ExecuteReader();
while (reader.Read())
{
   Console.WriteLn(reader[0], reader[1]...);
}
...
```

Examples of using the CommandType of StoredProcedure can be found in the section Section 20.2.5.6, “Accessing Stored Procedures with Connector/NET”.

Commands can have a timeout associated with them. This is useful as you may not want a situation were a command takes up an excessive amount of time. A timeout can be set using the `CommandTimeout` property. The following code snippet sets a timeout of one minute:

```
MySqlCommand cmd = new MySqlCommand();
cmd.CommandTimeout = 60;
```

The default value is 30 secs. A value of 0 indicates an indefinite wait and should be avoided. Note the default command timeout can be changed using the connection string option `Default Command Timeout`.

Prior to MySQL Connector/NET 6.2, `MySqlCommand.CommandTimeout` included user processing time, that is processing time not related to direct use of the connector. Timeout was implemented through a .NET Timer, that triggered after `CommandTimeout` seconds. This timer consumed a thread.

MySQL Connector/NET 6.2 introduced timeouts that are aligned with how Microsoft handles `SqlCommand.CommandTimeout`. This property is the cumulative timeout for all network reads and writes during command execution or processing of the results. A timeout can still occur in the `MySqlReader.Read` method after the first row is returned, and does not include user processing time, only IO operations. The 6.2 implementation uses the underlying stream timeout facility, so is more efficient in that it does not require the additional timer thread as was the case with the previous implementation.

Further details on this can be found in the relevant Microsoft documentation.

20.2.5.4. Using Connector/NET with Connection Pooling

The Connector/NET supports connection pooling. This is enabled by default, but can be turned off via connection string options. See Section 20.2.5.2, “Creating a Connection String” for further information.

Connection pooling works by keeping the native connection to the server live when the client disposes of a `MySqlConnection`. Subsequently, if a new `MySqlConnection` object is opened, it will be created from the connection pool, rather than creating a new native connection. This improves performance.

To work as designed, it is best to let the connection pooling system manage all connections. You should not create a globally accessible instance of `MySqlConnection` and then manually open and close it. This interferes with the way the pooling works and can lead to unpredictable results or even exceptions.

One approach that simplifies things is to avoid manually creating a `MySqlConnection` object. Instead use the overloaded methods that take a connection string as an argument. Using this approach, Connector/NET will automatically create, open, close and destroy connections, using the connection pooling system for best performance.

Typed Datasets and the `MembershipProvider` and `RoleProvider` classes use this approach. Most classes that have methods that take a `MySqlConnection` as an argument, also have methods that take a connection string as an argument. This includes `MySqlDataAdapter`.

Instead of manually creating `MySqlCommand` objects, you can use the static methods of the `MySqlHelper` class. These take a connection string as an argument, and they fully support connection pooling.

Starting with MySQL Connector/NET 6.2, there is a background job that runs every three minutes and removes connections from pool that have been idle (unused) for more than three minutes. The pool cleanup frees resources on both client and server side. This is be-

cause on the client side every connection uses a socket, and on the server side every connection uses a socket and a thread.

Prior to this change, connections were never removed from the pool, and the pool always contained the peak number of open connections. For example, a web application that peaked at 1000 concurrent database connections would consume 1000 threads and 1000 open sockets at the server, without ever freeing up those resources from the connection pool. Note, connections, no matter how old, will not be closed if the number of connections in the pool is less than or equal to the value set by the `Min Pool Size` connection string parameter.

20.2.5.5. Using the Connector/NET with Prepared Statements

Introduction

As of MySQL 4.1, it is possible to use prepared statements with Connector/NET. Use of prepared statements can provide significant performance improvements on queries that are executed more than once.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

20.2.5.5.1. Preparing Statements in Connector/NET

To prepare a statement, create a command object and set the `.CommandText` property to your query.

After entering your statement, call the `.Prepare` method of the `MySqlCommand` object. After the statement is prepared, add parameters for each of the dynamic elements in the query.

After you enter your query and enter parameters, execute the statement using the `.ExecuteNonQuery()`, `.ExecuteScalar()`, or `.ExecuteReader` methods.

For subsequent executions, you need only modify the values of the parameters and call the execute method again, there is no need to set the `.CommandText` property or redefine the parameters.

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

conn.ConnectionString = strConnection

Try
   conn.Open()
   cmd.Connection = conn

   cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)"
   cmd.Prepare()

   cmd.Parameters.AddWithValue("@number", 1)
   cmd.Parameters.AddWithValue("@text", "One")

   For i = 1 To 1000
       cmd.Parameters["@number"].Value = i
       cmd.Parameters["@text"].Value = "A string value"

       cmd.ExecuteNonQuery()
     Next
Catch ex As MySqlException
    MessageBox.Show("Error " & ex.Number & " has occurred: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.E
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

conn.ConnectionString = strConnection;

try
```

```
{
    conn.Open();
    cmd.Connection = conn;

    cmd.CommandText = "INSERT INTO myTable VALUES(NULL, @number, @text)";
    cmd.Prepare();

    cmd.Parameters.AddWithValue("@number", 1);
    cmd.Parameters.AddWithValue("@text", "One");

    for (int i=1; i <= 1000; i++)
    {
        cmd.Parameters["@number"].Value = i;
        cmd.Parameters["@text"].Value = "A string value";

        cmd.ExecuteNonQuery();
    }
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

20.2.5.6. Accessing Stored Procedures with Connector/NET

Introduction

With the release of MySQL version 5 the MySQL server now supports stored procedures with the SQL 2003 stored procedure syntax.

A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients do not need to keep reissuing the individual statements but can refer to the stored procedure instead.

Stored procedures can be particularly useful in situations such as the following:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Connector/NET supports the calling of stored procedures through the `MySqlCommand` object. Data can be passed in and out of a MySQL stored procedure through use of the `MySqlCommand.Parameters` collection.

> **Note**
>
> When you call a stored procedure, the command object makes an additional `SELECT` call to determine the parameters of the stored procedure. You must ensure that the user calling the procedure has the `SELECT` privilege on the `mysql.proc` table to enable them to verify the parameters. Failure to do this will result in an error when calling the procedure.

This section will not provide in-depth information on creating Stored Procedures. For such information, please refer to http://dev.mysql.com/doc/mysql/en/stored-routines.html.

A sample application demonstrating how to use stored procedures with Connector/NET can be found in the `Samples` directory of your Connector/NET installation.

20.2.5.6.1. Using Stored Routines from Connector/NET

Stored procedures in MySQL can be created using a variety of tools. First, stored procedures can be created using the `mysql` command-line client. Second, stored procedures can be created using MySQL Workbench. Finally, stored procedures can be created using the `.ExecuteNonQuery` method of the `MySqlCommand` object.

It should be noted that, unlike the command-line and GUI clients, you are not required to specify a special delimiter when creating stored procedures in Connector/NET.

To call a stored procedure using Connector/NET, you create a `MySqlCommand` object and pass the stored procedure name as the `.CommandText` property. You then set the `.CommandType` property to `CommandType.StoredProcedure`.

After the stored procedure is named, you create one `MySqlCommand` parameter for every parameter in the stored procedure. `IN` parameters are defined with the parameter name and the object containing the value, `OUT` parameters are defined with the parameter name and the datatype that is expected to be returned. All parameters need the parameter direction defined.

After defining the parameters, you call the stored procedure by using the `MySqlCommand.ExecuteNonQuery()` method.

Once the stored procedure is called, the values of the output parameters can be retrieved by using the `.Value` property of the `MySqlConnector.Parameters` collection.

The following C# example code demonstrates the use of stored procedures. It assumes the database 'employees' has already been created:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace UsingStoredRoutines
{
    class Program
    {
        static void Main(string[] args)
        {
            MySqlConnection conn = new MySqlConnection();
            conn.ConnectionString = "server=localhost;user=root;database=employees;port=3306;password=******;";
            MySqlCommand cmd = new MySqlCommand();

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
                cmd.Connection = conn;
                cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp";
                cmd.ExecuteNonQuery();
                cmd.CommandText = "DROP TABLE IF EXISTS emp";
                cmd.ExecuteNonQuery();
                cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY, first_name VA
                cmd.ExecuteNonQuery();

                cmd.CommandText = "CREATE PROCEDURE add_emp(" +
                                  "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME, OUT empno INT)" +
                                  "BEGIN INSERT INTO emp(first_name, last_name, birthdate) " +
                                  "VALUES(fname, lname, DATE(bday)); SET empno = LAST_INSERT_ID(); END";

                cmd.ExecuteNonQuery();
            }
            catch (MySqlException ex)
            {
                Console.WriteLine ("Error " + ex.Number + " has occurred: " + ex.Message);
            }
            conn.Close();
            Console.WriteLine("Connection closed.");
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();
                cmd.Connection = conn;

                cmd.CommandText = "add_emp";
                cmd.CommandType = CommandType.StoredProcedure;

                cmd.Parameters.AddWithValue("@lname", "Jones");
                cmd.Parameters["@lname"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@fname", "Tom");
                cmd.Parameters["@fname"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@bday", "1940-06-07");
                cmd.Parameters["@bday"].Direction = ParameterDirection.Input;

                cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32);
                cmd.Parameters["@empno"].Direction = ParameterDirection.Output;

                cmd.ExecuteNonQuery();

                Console.WriteLine("Employee number: "+cmd.Parameters["@empno"].Value);
                Console.WriteLine("Birthday: " + cmd.Parameters["@bday"].Value);
            }
            catch (MySql.Data.MySqlClient.MySqlException ex)
            {
                Console.WriteLine("Error " + ex.Number + " has occurred: " + ex.Message);
```

```
            }
            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

The following code shows the same application in Visual Basic:

```
Imports System
Imports System.Collections.Generic
Imports System.Linq
Imports System.Text

Imports System.Data
Imports MySql.Data
Imports MySql.Data.MySqlClient

Module Module1

    Sub Main()
        Dim conn As New MySqlConnection()
        conn.ConnectionString = "server=localhost;user=root;database=world;port=3306;password=******;"
        Dim cmd As New MySqlCommand()

        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn
            cmd.CommandText = "DROP PROCEDURE IF EXISTS add_emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "DROP TABLE IF EXISTS emp"
            cmd.ExecuteNonQuery()
            cmd.CommandText = "CREATE TABLE emp (empno INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY, first_name VARCHA
            cmd.ExecuteNonQuery()

            cmd.CommandText = "CREATE PROCEDURE add_emp(" & "IN fname VARCHAR(20), IN lname VARCHAR(20), IN bday DATETIME,

            cmd.ExecuteNonQuery()
        Catch ex As MySqlException
            Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
        End Try
        conn.Close()
        Console.WriteLine("Connection closed.")
        Try
            Console.WriteLine("Connecting to MySQL...")
            conn.Open()
            cmd.Connection = conn

            cmd.CommandText = "add_emp"
            cmd.CommandType = CommandType.StoredProcedure

            cmd.Parameters.AddWithValue("@lname", "Jones")
            cmd.Parameters("@lname").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@fname", "Tom")
            cmd.Parameters("@fname").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@bday", "1940-06-07")
            cmd.Parameters("@bday").Direction = ParameterDirection.Input

            cmd.Parameters.AddWithValue("@empno", MySqlDbType.Int32)
            cmd.Parameters("@empno").Direction = ParameterDirection.Output

            cmd.ExecuteNonQuery()

            Console.WriteLine("Employee number: " & cmd.Parameters("@empno").Value)
            Console.WriteLine("Birthday: " & cmd.Parameters("@bday").Value)
        Catch ex As MySql.Data.MySqlClient.MySqlException
            Console.WriteLine(("Error " & ex.Number & " has occurred: ") + ex.Message)
        End Try
        conn.Close()
        Console.WriteLine("Done.")

    End Sub

End Module
```

20.2.5.7. Handling BLOB Data With Connector/NET

Introduction

One common use for MySQL is the storage of binary data in `BLOB` columns. MySQL supports four different BLOB datatypes: `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`.

Data stored in a BLOB column can be accessed using Connector/NET and manipulated using client-side code. There are no special requirements for using Connector/NET with BLOB data.

Simple code examples will be presented within this section, and a full sample application can be found in the `Samples` directory of the Connector/NET installation.

20.2.5.7.1. Preparing the MySQL Server

The first step is using MySQL with BLOB data is to configure the server. Let's start by creating a table to be accessed. In my file tables, I usually have four columns: an AUTO_INCREMENT column of appropriate size (UNSIGNED SMALLINT) to serve as a primary key to identify the file, a VARCHAR column that stores the file name, an UNSIGNED MEDIUMINT column that stores the size of the file, and a MEDIUMBLOB column that stores the file itself. For this example, I will use the following table definition:

```
CREATE TABLE file(
file_id SMALLINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
file_name VARCHAR(64) NOT NULL,
file_size MEDIUMINT UNSIGNED NOT NULL,
file MEDIUMBLOB NOT NULL);
```

After creating a table, you may need to modify the max_allowed_packet system variable. This variable determines how large of a packet (that is, a single row) can be sent to the MySQL server. By default, the server will only accept a maximum size of 1MB from our client application. If you do not intend to exceed 1MB, this should be fine. If you do intend to exceed 1MB in your file transfers, this number has to be increased.

The max_allowed_packet option can be modified using MySQL Administrator's Startup Variables screen. Adjust the Maximum allowed option in the Memory section of the Networking tab to an appropriate setting. After adjusting the value, click the APPLY CHANGES button and restart the server using the `Service Control` screen of MySQL Administrator. You can also adjust this value directly in the my.cnf file (add a line that reads max_allowed_packet=xxM), or use the SET max_allowed_packet=xxM; syntax from within MySQL.

Try to be conservative when setting max_allowed_packet, as transfers of BLOB data can take some time to complete. Try to set a value that will be adequate for your intended use and increase the value if necessary.

20.2.5.7.2. Writing a File to the Database

To write a file to a database we need to convert the file to a byte array, then use the byte array as a parameter to an `INSERT` query.

The following code opens a file using a FileStream object, reads it into a byte array, and inserts it into the `file` table:

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand

Dim SQL As String

Dim FileSize As UInt32
Dim rawData() As Byte
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

Try
    fs = New FileStream("c:\image.png", FileMode.Open, FileAccess.Read)
    FileSize = fs.Length

    rawData = New Byte(FileSize) {}
    fs.Read(rawData, 0, FileSize)
    fs.Close()

    conn.Open()

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)"

    cmd.Connection = conn
    cmd.CommandText = SQL
    cmd.Parameters.AddWithValue("@FileName", strFileName)
    cmd.Parameters.AddWithValue("@FileSize", FileSize)
```

```
    cmd.Parameters.AddWithValue("@File", rawData)

    cmd.ExecuteNonQuery()

    MessageBox.Show("File Inserted into database successfully!", _
    "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", _
        MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    fs = new FileStream(@"c:\image.png", FileMode.Open, FileAccess.Read);
    FileSize = fs.Length;

    rawData = new byte[FileSize];
    fs.Read(rawData, 0, FileSize);
    fs.Close();

    conn.Open();

    SQL = "INSERT INTO file VALUES(NULL, @FileName, @FileSize, @File)";

    cmd.Connection = conn;
    cmd.CommandText = SQL;
    cmd.Parameters.AddWithValue("@FileName", strFileName);
    cmd.Parameters.AddWithValue("@FileSize", FileSize);
    cmd.Parameters.AddWithValue("@File", rawData);

    cmd.ExecuteNonQuery();

    MessageBox.Show("File Inserted into database successfully!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    conn.Close();
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The `Read` method of the `FileStream` object is used to load the file into a byte array which is sized according to the `Length` property of the FileStream object.

After assigning the byte array as a parameter of the `MySqlCommand` object, the `ExecuteNonQuery` method is called and the BLOB is inserted into the `file` table.

20.2.5.7.3. Reading a BLOB from the Database to a File on Disk

Once a file is loaded into the `file` table, we can use the `MySqlDataReader` class to retrieve it.

The following code retrieves a row from the `file` table, then loads the data into a `FileStream` object to be written to disk:

Visual Basic Example

```
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myData As MySqlDataReader
Dim SQL As String
```

```
Dim rawData() As Byte
Dim FileSize As UInt32
Dim fs As FileStream

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=test"

SQL = "SELECT file_name, file_size, file FROM file"

Try
    conn.Open()

    cmd.Connection = conn
    cmd.CommandText = SQL

    myData = cmd.ExecuteReader

    If Not myData.HasRows Then Throw New Exception("There are no BLOBs to save")

    myData.Read()

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"))
    rawData = New Byte(FileSize) {}

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize)

    fs = New FileStream("C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write)
    fs.Write(rawData, 0, FileSize)
    fs.Close()

    MessageBox.Show("File successfully written to disk!", "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk)

    myData.Close()
    conn.Close()
Catch ex As Exception
    MessageBox.Show("There was an error: " & ex.Message, "Error", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataReader myData;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();

string SQL;
UInt32 FileSize;
byte[] rawData;
FileStream fs;

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

SQL = "SELECT file_name, file_size, file FROM file";

try
{
    conn.Open();

    cmd.Connection = conn;
    cmd.CommandText = SQL;

    myData = cmd.ExecuteReader();

    if (! myData.HasRows)
        throw new Exception("There are no BLOBs to save");

    myData.Read();

    FileSize = myData.GetUInt32(myData.GetOrdinal("file_size"));
    rawData = new byte[FileSize];

    myData.GetBytes(myData.GetOrdinal("file"), 0, rawData, 0, FileSize);

    fs = new FileStream(@"C:\newfile.png", FileMode.OpenOrCreate, FileAccess.Write);
    fs.Write(rawData, 0, FileSize);
    fs.Close();

    MessageBox.Show("File successfully written to disk!",
        "Success!", MessageBoxButtons.OK, MessageBoxIcon.Asterisk);

    myData.Close();
    conn.Close();
```

```
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show("Error " + ex.Number + " has occurred: " + ex.Message,
        "Error", MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

After connecting, the contents of the `file` table are loaded into a `MySqlDataReader` object. The `GetBytes` method of the MySqlDataReader is used to load the BLOB into a byte array, which is then written to disk using a FileStream object.

The `GetOrdinal` method of the MySqlDataReader can be used to determine the integer index of a named column. Use of the GetOrdinal method prevents errors if the column order of the `SELECT` query is changed.

20.2.5.8. Using Connector/NET with Crystal Reports

Introduction

Crystal Reports is a common tool used by Windows application developers to perform reporting and document generation. In this section we will show how to use Crystal Reports XI with MySQL and Connector/NET.

20.2.5.8.1. Creating a Data Source

When creating a report in Crystal Reports there are two options for accessing the MySQL data while designing your report.

The first option is to use Connector/ODBC as an ADO data source when designing your report. You will be able to browse your database and choose tables and fields using drag and drop to build your report. The disadvantage of this approach is that additional work must be performed within your application to produce a data set that matches the one expected by your report.

The second option is to create a data set in VB.NET and save it as XML. This XML file can then be used to design a report. This works quite well when displaying the report in your application, but is less versatile at design time because you must choose all relevant columns when creating the data set. If you forget a column you must re-create the data set before the column can be added to the report.

The following code can be used to create a data set from a query and write it to disk:

Visual Basic Example

```
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myData.WriteXml("C:\dataset.xml", XmlWriteMode.WriteSchema)
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
```

```
  "pwd=12345;database=test;";

try
{
  cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
  "country.name, country.population, country.continent " +
  "FROM country, city ORDER BY country.continent, country.name";
  cmd.Connection = conn;

  myAdapter.SelectCommand = cmd;
  myAdapter.Fill(myData);

  myData.WriteXml(@"C:\dataset.xml", XmlWriteMode.WriteSchema);
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
  MessageBox.Show(ex.Message, "Report could not be created",
  MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

The resulting XML file can be used as an ADO.NET XML datasource when designing your report.

If you choose to design your reports using Connector/ODBC, it can be downloaded from dev.mysql.com.

20.2.5.8.2. Creating the Report

For most purposes the Standard Report wizard should help with the initial creation of a report. To start the wizard, open Crystal Reports and choose the New > Standard Report option from the File menu.

The wizard will first prompt you for a data source. If you are using Connector/ODBC as your data source, use the OLEDB provider for ODBC option from the OLE DB (ADO) tree instead of the ODBC (RDO) tree when choosing a data source. If using a saved data set, choose the ADO.NET (XML) option and browse to your saved data set.

The remainder of the report creation process is done automatically by the wizard.

After the report is created, choose the Report Options... entry of the File menu. Un-check the Save Data With Report option. This prevents saved data from interfering with the loading of data within our application.

20.2.5.8.3. Displaying the Report

To display a report we first populate a data set with the data needed for the report, then load the report and bind it to the data set. Finally we pass the report to the crViewer control for display to the user.

The following references are needed in a project that displays a report:

- CrytalDecisions.CrystalReports.Engine
- CrystalDecisions.ReportSource
- CrystalDecisions.Shared
- CrystalDecisions.Windows.Forms

The following code assumes that you created your report using a data set saved using the code shown in Section 20.2.5.8.1, “Creating a Data Source”, and have a crViewer control on your form named `myViewer`.

Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = _
    "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
```

```
    & "database=test"

Try
    conn.Open()

    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " _
        & "country.name, country.population, country.continent " _
        & "FROM country, city ORDER BY country.continent, country.name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.SetDataSource(myData)
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT city.name AS cityName, city.population AS CityPopulation, " +
        "country.name, country.population, country.continent " +
        "FROM country, city ORDER BY country.continent, country.name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.SetDataSource(myData);
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

A new data set it generated using the same query used to generate the previously saved data set. Once the data set is filled, a ReportDocument is used to load the report file and bind it to the data set. The ReportDocument is the passed as the ReportSource of the crViewer.

This same approach is taken when a report is created from a single table using Connector/ODBC. The data set replaces the table used in the report and the report is displayed properly.

When a report is created from multiple tables using Connector/ODBC, a data set with multiple tables must be created in our application. This allows each table in the report data source to be replaced with a report in the data set.

We populate a data set with multiple tables by providing multiple `SELECT` statements in our MySqlCommand object. These `SELECT` statements are based on the SQL query shown in Crystal Reports in the Database menu's Show SQL Query option. Assume the following query:

```
SELECT `country`.`Name`, `country`.`Continent`, `country`.`Population`, `city`.`Name`, `city`.`Population`
FROM `world`.`country` `country` LEFT OUTER JOIN `world`.`city` `city` ON `country`.`Code`=`city`.`CountryCode`
ORDER BY `country`.`Continent`, `country`.`Name`, `city`.`Name`
```

This query is converted to two `SELECT` queries and displayed with the following code:

Visual Basic Example

```
Imports CrystalDecisions.CrystalReports.Engine
Imports System.Data
Imports MySql.Data.MySqlClient

Dim myReport As New ReportDocument
Dim myData As New DataSet
Dim conn As New MySqlConnection
Dim cmd As New MySqlCommand
Dim myAdapter As New MySqlDataAdapter

conn.ConnectionString = "server=127.0.0.1;" _
    & "uid=root;" _
    & "pwd=12345;" _
    & "database=world"

Try
    conn.Open()
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER BY countrycode, name; " _
        & "SELECT name, population, code, continent FROM country ORDER BY continent, name"
    cmd.Connection = conn

    myAdapter.SelectCommand = cmd
    myAdapter.Fill(myData)

    myReport.Load(".\world_report.rpt")
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0))
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1))
    myViewer.ReportSource = myReport
Catch ex As Exception
    MessageBox.Show(ex.Message, "Report could not be created", MessageBoxButtons.OK, MessageBoxIcon.Error)
End Try
```

C# Example

```
using CrystalDecisions.CrystalReports.Engine;
using System.Data;
using MySql.Data.MySqlClient;

ReportDocument myReport = new ReportDocument();
DataSet myData = new DataSet();
MySql.Data.MySqlClient.MySqlConnection conn;
MySql.Data.MySqlClient.MySqlCommand cmd;
MySql.Data.MySqlClient.MySqlDataAdapter myAdapter;

conn = new MySql.Data.MySqlClient.MySqlConnection();
cmd = new MySql.Data.MySqlClient.MySqlCommand();
myAdapter = new MySql.Data.MySqlClient.MySqlDataAdapter();

conn.ConnectionString = "server=127.0.0.1;uid=root;" +
    "pwd=12345;database=test;";

try
{
    cmd.CommandText = "SELECT name, population, countrycode FROM city ORDER " +
        "BY countrycode, name; SELECT name, population, code, continent FROM " +
        "country ORDER BY continent, name";
    cmd.Connection = conn;

    myAdapter.SelectCommand = cmd;
    myAdapter.Fill(myData);

    myReport.Load(@".\world_report.rpt");
    myReport.Database.Tables(0).SetDataSource(myData.Tables(0));
    myReport.Database.Tables(1).SetDataSource(myData.Tables(1));
    myViewer.ReportSource = myReport;
}
catch (MySql.Data.MySqlClient.MySqlException ex)
{
    MessageBox.Show(ex.Message, "Report could not be created",
        MessageBoxButtons.OK, MessageBoxIcon.Error);
}
```

It is important to order the `SELECT` queries in alphabetical order, as this is the order the report will expect its source tables to be in. One SetDataSource statement is needed for each table in the report.

This approach can cause performance problems because Crystal Reports must bind the tables together on the client-side, which will be slower than using a pre-saved data set.

20.2.5.9. Handling Date and Time Information in Connector/NET

Introduction

MySQL and the .NET languages handle date and time information differently, with MySQL allowing dates that cannot be represented by a .NET data type, such as '`0000-00-00 00:00:00`'. These differences can cause problems if not properly handled.

In this section we will demonstrate how to properly handle date and time information when using Connector/NET.

20.2.5.9.1. Problems when Using Invalid Dates

The differences in date handling can cause problems for developers who use invalid dates. Invalid MySQL dates cannot be loaded into native .NET `DateTime` objects, including `NULL` dates.

Because of this issue, .NET `DataSet` objects cannot be populated by the `Fill` method of the `MySqlDataAdapter` class as invalid dates will cause a `System.ArgumentOutOfRangeException` exception to occur.

20.2.5.9.2. Restricting Invalid Dates

The best solution to the date problem is to restrict users from entering invalid dates. This can be done on either the client or the server side.

Restricting invalid dates on the client side is as simple as always using the .NET `DateTime` class to handle dates. The `DateTime` class will only allow valid dates, ensuring that the values in your database are also valid. The disadvantage of this is that it is not useful in a mixed environment where .NET and non .NET code are used to manipulate the database, as each application must perform its own date validation.

Users of MySQL 5.0.2 and higher can use the new `traditional` SQL mode to restrict invalid date values. For information on using the `traditional` SQL mode, see Section 5.1.7, “Server SQL Modes”.

20.2.5.9.3. Handling Invalid Dates

Although it is strongly recommended that you avoid the use of invalid dates within your .NET application, it is possible to use invalid dates by means of the `MySqlDateTime` datatype.

The `MySqlDateTime` datatype supports the same date values that are supported by the MySQL server. The default behavior of Connector/NET is to return a .NET DateTime object for valid date values, and return an error for invalid dates. This default can be modified to cause Connector/NET to return `MySqlDateTime` objects for invalid dates.

To instruct Connector/NET to return a `MySqlDateTime` object for invalid dates, add the following line to your connection string:

```
Allow Zero Datetime=True
```

Please note that the use of the `MySqlDateTime` class can still be problematic. The following are some known issues:

1. Data binding for invalid dates can still cause errors (zero dates like 0000-00-00 do not seem to have this problem).
2. The `ToString` method return a date formatted in the standard MySQL format (for example, `2005-02-23 08:50:25`). This differs from the `ToString` behavior of the .NET DateTime class.
3. The `MySqlDateTime` class supports NULL dates, while the .NET DateTime class does not. This can cause errors when trying to convert a MySQLDateTime to a DateTime if you do not check for NULL first.

Because of the known issues, the best recommendation is still to use only valid dates in your application.

20.2.5.9.4. Handling NULL Dates

The .NET `DateTime` datatype cannot handle `NULL` values. As such, when assigning values from a query to a `DateTime` variable, you must first check whether the value is in fact `NULL`.

When using a `MySqlDataReader`, use the `.IsDBNull` method to check whether a value is `NULL` before making the assignment:

Visual Basic Example

```
If Not myReader.IsDBNull(myReader.GetOrdinal("mytime")) Then
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"))
Else
    myTime = DateTime.MinValue
```

```
End If
```

C# Example

```
if (! myReader.IsDBNull(myReader.GetOrdinal("mytime")))
    myTime = myReader.GetDateTime(myReader.GetOrdinal("mytime"));
else
    myTime = DateTime.MinValue;
```

`NULL` values will work in a data set and can be bound to form controls without special handling.

20.2.5.10. ASP.NET Provider Model

MySQL Connector/NET provides support for the ASP.NET 2.0 provider model. This model allows application developers to focus on the business logic of their application instead of having to recreate such boilerplate items as membership and roles support.

MySQL Connector/NET supplies the following providers:

- Membership Provider
- Role Provider
- Profile Provider
- Session State Provider (MySQL Connector/NET 6.1 and later)

The following tables show the supported providers, their default provider and the corresponding MySQL provider.

Membership Provider

Default Provider	MySQL Provider
System.Web.Security.SqlMembershipProvider	MySql.Web.Security.MySQLMembershipProvider

Role Provider

Default Provider	MySQL Provider
System.Web.Security.SqlRoleProvider	MySql.Web.Security.MySQLRoleProvider

Profile Provider

Default Provider	MySQL Provider
System.Web.Profile.SqlProfileProvider	MySql.Web.Profile.MySQLProfileProvider

SessionState Provider

Default Provider	MySQL Provider
System.Web.SessionState.InProcSessionStateStore	MySql.Web.SessionState.MySqlSessionStateStore

> **Note**
>
> The MySQL Session State provider uses slightly different capitalization on the class name compared to the other MySQL providers.

Installing The Providers

The installation of Connector/Net 5.1 or later will install the providers and register them in your machine's .NET configuration file, `machine.config`. The additional entries created will result in the `system.web` section appearing similar to the following code:

```
<system.web>
  <processModel autoConfig="true" />
  <httpHandlers />
  <membership>
    <providers>
      <add name="AspNetSqlMembershipProvider" type="System.Web.Security.SqlMembershipProvider, System.Web, Version=2.0.0.0
      <add name="MySQLMembershipProvider" type="MySql.Web.Security.MySQLMembershipProvider, MySql.Web, Version=6.1.1.0, Cu
    </providers>
  </membership>
  <profile>
    <providers>
      <add name="AspNetSqlProfileProvider" connectionStringName="LocalSqlServer" applicationName="/" type="System.Web.Profi
      <add name="MySQLProfileProvider" type="MySql.Web.Profile.MySQLProfileProvider, MySql.Web, Version=6.1.1.0, Culture=ne
    </providers>
  </profile>
  <roleManager>
    <providers>
      <add name="AspNetSqlRoleProvider" connectionStringName="LocalSqlServer" applicationName="/" type="System.Web.Security
      <add name="AspNetWindowsTokenRoleProvider" applicationName="/" type="System.Web.Security.WindowsTokenRoleProvider, Sy
      <add name="MySQLRoleProvider" type="MySql.Web.Security.MySQLRoleProvider, MySql.Web, Version=6.1.1.0, Culture=neutra
    </providers>
  </roleManager>
</system.web>
```

Each provider type can have multiple provider implementations. The default provider can also be set here using the `defaultProvider` attribute, but usually this is set in the `web.config` file either manually or by using the ASP.NET configuration tool.

At time of writing the `MySqlSessionStateStore` is not added to `machine.config` at install time, and so you would need to add the following:

```
<sessionState>
  <providers>
    <add name="MySqlSessionStateStore" type="MySql.Web.SessionState.MySqlSessionStateStore, MySql.Web, Version=6.1.1.0, Cu
  </providers>
</sessionState>
```

It should be pointed out that the SessionState Provider uses the `customProvider` attribute, rather than `defaultProvider`, in order to set the provider as the default. A typical `web.config` file might contain:

```
   <system.web>
        <membership defaultProvider="MySQLMembershipProvider" />
        <roleManager defaultProvider="MySQLRoleProvider" />
        <profile defaultProvider="MySQLProfileProvider" />
        <sessionState customProvider="MySqlSessionStateStore" />
        <compilation debug="false">
          ...
```

This sets the MySQL Providers as the defaults to be used in this web application.

The providers are implemented in the file `mysql.web.dll` and this file can be found in your MySQL Connector/NET installation folder. There is no need to run any type of SQL script to set up the database schema as the providers create and maintain the proper schema automatically.

Using The Providers

The easiest way to start using the providers is to use the ASP.NET configuration tool that is available on the Solution Explorer toolbar when you have a website project loaded.

In the web pages that open you will be able to select the MySQL membership and roles providers by indicating that you want to pick a custom provider for each area.

When the provider is installed, it creates a dummy connection string named `LocalMySqlServer`. This has to be done so that the provider will work in the ASP.NET configuration tool. However, you will want to override this connection string in your `web.config` file. You do this by first removing the dummy connection string and then adding in the proper one, as shown in the following example:

```
<connectionStrings>
  <remove name="LocalMySqlServer"/>
  <add name="LocalMySqlServer" connectionString="server=xxx;uid=xxx;pwd=xxx;database=xxx;"/>
</connectionStrings>
```

Note the database you want to connect to must be specified.

Rather than manually editing configuration files it is recommended that you use the MySQL Website Configuration tool to config your desired provider setup. From MySQL Connector/NET 6.1.1 onwards all providers can be selected and configured from this wizard. The tool will modify your `website.config` file to the desired configuration. A tutorial on doing this is available in the following section Section 20.2.3.10, “MySQL Website Configuration Tool”.

A tutorial demonstrating how to use the Membership and Role Providers can be found in the following section Section 20.2.4.2, “Tutorial: MySQL Connector/NET ASP.NET Membership and Role Provider”.

Deployment

To use the providers on a production server you will need to distribute the `MySql.Data` and the `MySql.Web` assemblies and either register them in the remote systems Global Assembly Cache or keep them in your application's `bin/` directory.

20.2.5.11. Binary/Nonbinary Issues

There are certain situations where MySQL will return incorrect metadata about one or more columns. More specifically, the server will sometimes report that a column is binary when it is not and vice versa. In these situations, it becomes practically impossible for the connector to be able to correctly identify the correct metadat.

Some examples of situations that may return incorrect metadata are:

- Execution of `SHOW PROCESSLIST`. Some of the columns will be returned as binary even though they only hold string data.
- When a temp table is used to process a resultset, some columns may be returned with incorrect binary flags.
- Some server functions such `DATE_FORMAT` will incorrectly return the column as binary.

With the availability of `BINARY` and `VARBINARY` data types it is important that we respect the metadata returned by the sever. However, we are aware that some existing applications may break with this change so we are creating a connection string option to enable or disable it. By default, Connector/Net 5.1 will respect the binary flags returned by the server. This will mean that you may need to make small changes to your application to accomodate this change.

In the event that the changes required to your application would be too large, you can add 'respect binary flags=false' to your connection string. This will cause the connector to use the prior behavior. In a nutshell, that behavior was that any column that is marked as string, regardless of binary flags, will be returned as string. Only columns that are specifically marked as a `BLOB` will be returned as `BLOB`.

20.2.5.12. Character Sets

Treating Binary Blobs As UTF8

MySQL doesn't currently support 4 byte UTF8 sequences. This makes it difficult to represent some multi-byte languages such as Japanese. To try and alleviate this, Connector/Net now supports a mode where binary blobs can be treated as strings.

To do this, you set the 'Treat Blobs As UTF8' connection string keyword to yes. This is all that needs to be done to enable conversion of all binary blobs to UTF8 strings. If you wish to convert only some of your blob columns, then you can make use of the 'BlobAsUTF8IncludePattern' and 'BlobAsUTF8ExcludePattern' keywords. These should be set to the regular expression pattern that matches the column names you wish to include or exlude respectively.

One thing to note is that the regular expression patterns can both match a single column. When this happens, the include pattern is applied before the exclude pattern. The result, in this case, would be that the column would be excluded. You should also be aware that this mode does not apply to columns of type `BINARY` or `VARBINARY` and also do not apply to nonbinary `BLOB` columns.

Currently this mode only applies to reading strings out of MySQL. To insert 4-byte UTF8 strings into blob columns you will need to use the .NET `Encoding.GetBytes` function to convert your string to a series of bytes. You can then set this byte array as a parameter for a `BLOB` column.

20.2.5.13. Working with medium trust

.NET applications operate under a given trust level. Normal desktop applications operate under full trust while web applications that are hosted in shared environments are normally run under the medium trust level. Some hosting providers host shared applications in their own app pools and allow the application to run under full trust, but this seems to be the exception rather than the rule.

Connector/Net versions prior to 5.0.8 and 5.1.3 were not compatible with medium trust hosting. Starting with these versions, Connector/Net can be used under medium trust hosting that has been modified to allow the use of sockets for communication. By default, medium trust does not include `SocketPermission`. Connector/Net uses sockets to talk with the MySQL server so it is required that a new trust level be created that is an exact clone of medium trust but that has `SocketPermission` added.

20.2.5.14. Using the MySQL Connector/NET Trace Source Object

MySQL Connector/NET 6.2 introduced support for .NET 2.0 compatible tracing, using `TraceSource` objects.

The .NET 2.0 tracing architecture consists of four main parts:

- *Source* - This is the originator of the trace information. The source is used to send trace messages. The name of the source provided by MySQL Connector/NET is `mysql`.
- *Switch* - This defines the level of trace information to emit. Typically, this is specified in the `app.config` file, so that it is not necessary to recompile an application in order to change the trace level.
- *Listener* - Trace listeners define where the trace information will be written to. Supported listeners include, for example, the Visual Studio Output window, the Windows Event Log, and the console.
- *Filter* - Filters can be attached to listeners. Filters determine the level of trace information that will be written. While a switch defines the level of information that will be written to all listeners, a filter can be applied on a per-listener basis, giving finer grained control of trace information.

To use tracing a `TraceSource` object first needs to be created. To create a `TraceSource` object in MySQL Connector/NET you would use code similar to the following:

```
TraceSource ts = new TraceSource("mysql");
```

To enable trace messages you also need to configure a trace switch. There are three main switch classes, `BooleanSwitch`, `SourceSwitch`, and `TraceSwitch`. Trace switches also have associated with them a trace level enumeration, these are `Off`, `Error`, `Warning`, `Info`, and `Verbose`. The following code snippet illustrates creating a switch:

```
ts.Switch = new SourceSwitch("MySwitch", "Verbose");
```

This creates a `SourceSwitch`, called `MySwitch`, and sets the trace level to `Verbose`, meaning that all trace messages will be written.

It is convenient to be able to change the trace level without having to recompile the code. This is achieved by specifying the trace level in application configuration file, `app.config`. You then simply need to specify the desired trace level in the configuration file and restart the application. The trace source is configured within the `system.diagnostics` section of the file. The following XML snippet illustrates this:

```
<configuration>
  ...
  <system.diagnostics>
    <sources>
      <source name="mysql" switchName="MySwitch"
              switchType="System.Diagnostics.SourceSwitch" />
      ...
    </sources>
    <switches>
      <add name="MySwitch" value="Verbose"/>
      ...
    </switches>
  </system.diagnostics>
  ...
</configuration>
```

By default trace information is written to the Output window of Microsoft Visual Studio. However, there are a wide range of listeners than can be attached to the trace source, so that trace messages can be written out to various destinations. It is also possible to create custom listeners to allow trace messages to be written to other destinations as mobile devices and web services. A commonly used example of a listener is `ConsoleTraceListener`, which writes trace messages to the console.

To add a listener at run time you can use code such as the following:

```
ts.Listeners.Add(new ConsoleTraceListener());
```

You can then call methods on trace source object to generate trace information. For example, the `TraceInformation()`, `TraceEvent()`, or `TraceData()` methods can be used.

The `TraceInformation()` method simply prints a string passed as a parameter. The `TraceEvent()` method, as well as the optional informational string, requires a `TraceEventType` value to be passed to indicate the trace message type, and also an application specific ID. The `TraceEventType` can have a value of `Verbose`, `Information`, `Warning`, `Error`, and `Critical`. Using the `TraceData()` method you can pass any object, for example an exception object, instead of a message.

To ensure than these generated trace messages gets flushed from the trace source buffers to listeners, you need to invoke the `Flush()` method. When you are finished using a trace source, you should call the `Close()` method. The `Close()` method first calls `Flush()`, to ensure any remaining data is written out. It then frees up resources, and closes the listeners associated with the trace source.

```
ts.TraceInformation("Informational message");
ts.TraceEvent(TraceEventType.Error, 3, "Optional error message");
ts.TraceData(TraceEventType.Error, 3, ex); // pass exception object
ts.Flush();
...
ts.Close();
```

20.2.5.14.1. Viewing MySQL Trace Information

This section describes how to set up your application to view MySQL trace information.

The first thing you need to do is create a suitable `app.config` file for your application. An example is shown in the following code:

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <system.diagnostics>
    <sources>
      <source name="mysql" switchName="SourceSwitch"
        switchType="System.Diagnostics.SourceSwitch" >
        <listeners>
          <add name="console" />
          <remove name ="Default" />
        </listeners>
      </source>
    </sources>
    <switches>
      <!-- You can set the level at which tracing is to occur -->
      <add name="SourceSwitch" value="Verbose" />
      <!-- You can turn tracing off -->
      <!--add name="SourceSwitch" value="Off" -->
    </switches>
    <sharedListeners>
      <add name="console"
        type="System.Diagnostics.ConsoleTraceListener"
        initializeData="false"/>
    </sharedListeners>
  </system.diagnostics>
</configuration>
```

This ensures a suitable trace source is created, along with a switch. The switch level in this case is set to `Verbose` to display the maximum amount of information.

In the application the only other step required is to add `logging=true` to the connection string. An example application could be:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Diagnostics;
using MySql.Data;
using MySql.Data.MySqlClient;
using MySql.Web;

namespace ConsoleApplication1
{
    class Program
```

```
    {
        static void Main(string[] args)
        {

            string connStr = "server=localhost;user=root;database=world;port=3306;password=******;logging=true;";
            MySqlConnection conn = new MySqlConnection(connStr);
            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1]);
                }

                rdr.Close();

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}
```

Ths simple application will then generate the following output:

```
Connecting to MySQL...
mysql Information: 1 : 1: Connection Opened: connection string = 'server=localhost;User Id=root;database=world;port=3306
;password=******;logging=True'
mysql Information: 3 : 1: Query Opened: SHOW VARIABLES
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=272, skipped rows=0, size (bytes)=7058
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SHOW COLLATION
mysql Information: 4 : 1: Resultset Opened: field(s) = 6, affected rows = -1, inserted id = -1
mysql Information: 5 : 1: Resultset Closed. Total rows=127, skipped rows=0, size (bytes)=4102
mysql Information: 6 : 1: Query Closed
mysql Information: 3 : 1: Query Opened: SET character_set_results=NULL
mysql Information: 4 : 1: Resultset Opened: field(s) = 0, affected rows = 0, inserted id = 0
mysql Information: 5 : 1: Resultset Closed. Total rows=0, skipped rows=0, size (bytes)=0
mysql Information: 6 : 1: Query Closed
mysql Information: 10 : 1: Set Database: world
mysql Information: 3 : 1: Query Opened: SELECT Name, HeadOfState FROM Country WHERE Continent='Oceania'
mysql Information: 4 : 1: Resultset Opened: field(s) = 2, affected rows = -1, inserted id = -1
American Samoa -- George W. Bush
Australia -- Elisabeth II
...
Wallis and Futuna -- Jacques Chirac
Vanuatu -- John Bani
United States Minor Outlying Islands -- George W. Bush
mysql Information: 5 : 1: Resultset Closed. Total rows=28, skipped rows=0, size (bytes)=788
mysql Information: 6 : 1: Query Closed
Done.
mysql Information: 2 : 1: Connection Closed
```

The first number displayed in the trace message corresponds to the MySQL event type:

Event	Description
1	ConnectionOpened: connection string
2	ConnectionClosed:
3	QueryOpened: mysql server thread id, query text
4	ResultOpened: field count, affected rows (-1 if select), inserted id (-1 if select)
5	ResultClosed: total rows read, rows skipped, size of resultset in bytes
6	QueryClosed:
7	StatementPrepared: prepared sql, statement id
8	StatementExecuted: statement id, mysql server thread id
9	StatementClosed: statement id

10	NonQuery: [varies]
11	UsageAdvisorWarning: usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
12	Warning: level, code, message
13	Error: error number, error message

The second number displayed in the trace message is the connection count.

Although this example uses the `ConsoleTraceListener`, any of the other standard listeners could have been used. Another possibility is to create a custom listener that uses the information passed via the `TraceEvent` method. For example, a custom trace listener could be created to perform active monitoring of the MySQL event messages, rather than simply writing these to an output device.

It is also possible to add listeners to the MySQL Trace Source at run time. This can be done with the following code:

```
MySqlTrace.Listeners.Add(new ConsoleTraceListener());
```

MySQL Connector/NET 6.3.2 introduced the ability to switch tracing on and off at run time. This can be achieved using the calls `MySqlTrace.EnableQueryAnalyzer(string host, int postInterval)` and `MySqlTrace.DisableQueryAnalyzer()`. The parameter `host` is the URL of the MySQL Enterprise Monitor server to monitor. The parameter `postInterval` is how often the data should be periodically posted to MySQL Enterprise Monitor, in seconds.

20.2.5.14.2. Building Custom Listeners

In order to build custom listeners that work with the MySQL Connector/NET Trace Source, it is necessary to understand the key methods used, and the event data formats used.

The main method involved in passing trace messages is the `TraceSource.TraceEvent` method. This has the prototype:

```
public void TraceEvent(
    TraceEventType eventType,
    int id,
    string format,
    params Object[] args
)
```

This trace source method will process the list of attached listeners and call the listener's TraceListener.TraceEvent method. The prototype for the `TraceListener.TraceEvent` method is as follows:

```
public virtual void TraceEvent(
    TraceEventCache eventCache,
    string source,
    TraceEventType eventType,
    int id,
    string format,
    params Object[] args
)
```

The first three parameters are used in the standard as defined by Microsoft. The last three parameters contain MySQL-specifc trace information. Each of these parameters is now discussed in more detail.

`int id`

This is a MySQL-specific identifier. It identifies the MySQL event type that has occurred, resulting in a trace message being generated. This value is defined by the `MySqlTraceEventType` public enum contained in the MySQL Connector/NET code:

```
public enum MySqlTraceEventType : int
{
    ConnectionOpened = 1,
    ConnectionClosed,
    QueryOpened,
    ResultOpened,
    ResultClosed,
    QueryClosed,
    StatementPrepared,
    StatementExecuted,
    StatementClosed,
    NonQuery,
    UsageAdvisorWarning,
```

```
    Warning,
    Error
}
```

The MySQL event type also determines the contents passed via the parameter `params Object[] args`. The nature of the `args` parameters are described in further detail in the following material.

`string format`

This is the format string that contains zero or more format items, which correspond to objects in the args array. This would be used by a listener such as `ConsoleTraceListener` to write a message to the output device.

`params Object[] args`

This is a list of objects that depends on the MySQL event type, `id`. However, the first parameter passed via this list is always the driver id. The driver id is a unique number that is incremented each time the connector is opened. This allows groups of queries on the same connection to be identified. The parameters that follow driver id depend of the MySQL event id, and are as follows:

MySQL-specific event type	Arguments (params Object[] args)
ConnectionOpened	Connection string
ConnectionClosed	No additional parameters
QueryOpened	mysql server thread id, query text
ResultOpened	field count, affected rows (-1 if select), inserted id (-1 if select)
ResultClosed	total rows read, rows skipped, size of resultset in bytes
QueryClosed	No additional parameters
StatementPrepared	prepared sql, statement id
StatementExecuted	statement id, mysql server thread id
StatementClosed	statement id
NonQuery	Varies
UsageAdvisorWarning	usage advisor flag. NoIndex = 1, BadIndex = 2, SkippedRows = 3, SkippedColumns = 4, FieldConversion = 5.
Warning	level, code, message
Error	error number, error message

This information will allow you to create custom trace listeners that can actively monitor the MySQL-specific events.

20.2.5.15. Using the Bulk Loader

MySQL Connector/NET features a bulk loader class that wraps the MySQL statement `LOAD DATA INFILE`. This gives MySQL Connector/NET the ability to load a data file from a local or remote host to the server. The class concerned is `MySqlBulkLoader`. This class has various methods, the main one being `load` to cause the specified file to be loaded to the server. Various parameters can be set to control how the data file is processed. This is achieved through setting various properties of the class. For example, the field separator used, such as comma or tab, can be specified, along with the record terminator, such as newline.

The following code shows a simple example of using the `MySqlBulkLoader` class. First an empty table needs to be created, in this case in the `test` database:

```
CREATE TABLE Career (
       Name VARCHAR(100) NOT NULL,
       Age INTEGER,
       Profession VARCHAR(200)
);
```

A simple tab-delimited data file is also created (it could use any other field delimiter such as comma):

```
Table Career in Test Database
Name Age Profession

Tony 47 Technical Writer
Ana 43 Nurse
```

```
Fred 21 IT Specialist
Simon 45 Hairy Biker
```

Note that with this test file the first three lines will need to be ignored, as they do not contain table data. This can be achieved using the `NumberOfLinesToSkip` property. This file can then be loaded and used to populate the `Career` table in the `test` database:

```
using System;
using System.Text;
using MySql.Data;
using MySql.Data.MySqlClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {

            string connStr = "server=localhost;user=root;database=test;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            MySqlBulkLoader bl = new MySqlBulkLoader(conn);
            bl.TableName = "Career";
            bl.FieldTerminator = "\t";
            bl.LineTerminator = "\n";
            bl.FileName = "c:/career_data.txt";
            bl.NumberOfLinesToSkip = 3;

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                // Upload data from file
                int count = bl.Load();
                Console.WriteLine(count + " lines uploaded.");

                string sql = "SELECT Name, Age, Profession FROM Career";
                MySqlCommand cmd = new MySqlCommand(sql, conn);
                MySqlDataReader rdr = cmd.ExecuteReader();

                while (rdr.Read())
                {
                    Console.WriteLine(rdr[0] + " -- " + rdr[1] + " -- " + rdr[2]);
                }

                rdr.Close();

                conn.Close();
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }
            Console.WriteLine("Done.");
        }
    }
}
```

Further information on `LOAD DATA INFILE` can be found in Section 12.2.6, “`LOAD DATA INFILE` Syntax”. Further information on `MySqlBulkLoader` can be found in the reference documentation that was included with your connector.

20.2.6. Connector/NET Connection String Options Reference

Name	Default	Description
`Allow Batch`	true	When true, multiple SQL statements can be sent with one command execution. -Note- Starting with MySQL 4.1.1, batch statements should be separated by the server-defined separator character. Commands sent to earlier versions of MySQL should be separated with ';'.
`Allow User Variables`	false	Setting this to `true` indicates that the provider expects user variables in the SQL. This option was added in Connector/NET version 5.2.2.
`Allow Zero Datetime`	false	If set to `True`, `MySqlDataReader.GetValue()` will return a `MySqlDateTime` object for date or datetime columns that have illegal values, such as zero datetime values, and a `System.DateTime` object for legal values. If set to `False` (the default setting) it will cause a `System.DateTime` object to be returned for all legal values and an excep-

		tion to be thrown for illegal values, such as zero datetime values.
AutoEnlist	true	If AutoEnlist is set to true, which is the default, a connection opened using TransactionScope participates in this scope, it commits when the scope commits and rolls back if TransactionScope does not commit. However, this feature is considered security sensitive and therefore cannot be used in a medium trust environment.
BlobAsUTF8ExcludePattern	null	
BlobAsUTF8IncludePattern	null	
CertificateFile	null	This option specifies the path to a certificate file in PFX format. For an example of usage see Section 20.2.4.7, "Tutorial: Using SSL with MySQL Connector/NET". Was introduced with 6.2.1.
CertificatePassword	null	This option allows you to specify a password which is used in conjunction with a certificate specified using the option CertificateFile. For an example of usage see Section 20.2.4.7, "Tutorial: Using SSL with MySQL Connector/NET". Was introduced with 6.2.1.
Certificate Store Location	null	This option allows you to access a certificate held in a personal store, rather than use a certificate file and password combination. For an example of usage see Section 20.2.4.7, "Tutorial: Using SSL with MySQL Connector/NET". Was introduced with 6.2.1.
Certificate Thumbprint	null	This option allows you to specify a certificate thumbprint to ensure correct identifcation of a certificate contained within a personal store. For an example of usage see Section 20.2.4.7, "Tutorial: Using SSL with MySQL Connector/NET". Was introduced with 6.2.1.
CharSet, Character Set		Specifies the character set that should be used to encode all queries sent to the server. Resultsets are still returned in the character set of the data returned.
Connect Timeout, Connection Timeout	15	The length of time (in seconds) to wait for a connection to the server before terminating the attempt and generating an error.
Connection Reset	false	
Convert Zero Datetime	false	True to have MySqlDataReader.GetValue() and MySqlDataReader.GetDateTime() return DateTime.MinValue for date or datetime columns that have illegal values.
Default Command Timeout	30	Sets the default value of the command timeout to be used. This does not supercede the individual command timeout property on an individual command object. If you set the command timeout property, that will be used. This option was added in Connector/NET 5.1.4
Encrypt, UseSSL	false	For Connector/NET 5.0.3 and later, when true, SSL encryption is used for all data sent between the client and server if the server has a certificate installed. Recognized values are true, false, yes, and no. In versions before 5.0.3, this option had no effect. From version 6.2.1 this option is deprecated and is replaced by SSL Mode. However, the option is still supported if used. If this option is set to true it is equivalent to SSL Mode = Preferred.
FunctionsReturnString	false	This will cause the connector to return binary/varbinary values as strings, if they do not have a tablename in the metadata.
Host, Server, Data Source, DataSource, Address, Addr, Network Address	localhost	The name or network address of the instance of MySQL to which to connect. Multiple hosts can be specified separated by &. This can be useful where multiple MySQL servers are configured for replication and you are not concerned about the precise server you are connecting to. No attempt is made by the provider to synchronize writes to the database so care should be taken when using this option. In Unix environment with Mono, this can be a fully qualified path to MySQL socket file name. With this configuration, the Unix socket will be used instead of TCP/IP socket. Currently only a single socket name can be given so accessing MySQL in a replicated environment using Unix sockets is not currently supported.
Ignore Prepare	true	When true, instructs the provider to ignore any calls to MySqlCommand.Prepare(). This option is provided to prevent issues with cor-

		ruption of the statements when use with server side prepared statements. If you want to use server-side prepare statements, set this option to false. This option was added in Connector/NET 5.0.3 and Connector/NET 1.0.9.
`Initial Catalog`, `Database`	mysql	The name of the database to use intially
`Interactive, InteractiveSession`	false	If set to true the client is interactive. An interactive client is one where the server variable `CLIENT_INTERACTIVE` is set. If an interactive client is set, the `wait_timeout` variable is set to the value of `interactive_timeout`. The client will then timeout after this period of inactivity. More details can be found in the server manual Section 5.1.4, "Server System Variables".
`Logging`	false	When true, various pieces of information is output to any configured TraceListeners. See Section 20.2.5.14, "Using the MySQL Connector/NET Trace Source Object" for further details.
`Old Guids`	false	This option was introduced in Connector/NET 6.1.1. The backend representation of a GUID type was changed from `BINARY(16)` to `CHAR(36)`. This was done to allow developers to use the server function `UUID()` to populate a GUID table - `UUID()` generates a 36-character string. Developers of older applications can add 'Old Guids=true' to the connection string in order to use a GUID of data type `BINARY(16)`.
`Old Syntax`, `OldSyntax`	false	This option was deprecated in Connector/NET 5.2.2. All code should now be written using the '@' symbol as the parameter marker.
`Password`, `pwd`		The password for the MySQL account being used.
`Persist Security Info`	false	When set to `false` or `no` (strongly recommended), security-sensitive information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. Resetting the connection string resets all connection string values including the password. Recognized values are `true`, `false`, `yes`, and `no`.
`Pipe Name`, `Pipe`	mysql	When set to the name of a named pipe, the `MySqlConnection` will attempt to connect to MySQL on that named pipe.This settings only applies to the Windows platform.
`Port`	3306	The port MySQL is using to listen for connections. This value is ignored if Unix socket is used.
`Procedure Cache Size`	25	Sets the size of the stored procedure cache. By default, Connector/NET will store the metadata (input/output datatypes) about the last 25 stored procedures used. To disable the stored procedure cache, set the value to zero (0). This option was added in Connector/NET 5.0.2 and Connector/NET 1.0.9.
`Protocol`	socket	Specifies the type of connection to make to the server. Values can be: `socket` or `tcp` for a socket connection, `pipe` for a named pipe connection, `unix` for a Unix socket connection, `memory` to use MySQL shared memory.
`Respect Binary Flags`	true	Setting this option to `false` means that Connector/NET will ignore a column's binary flags as set by the server. This option was added in Connector/NET version 5.1.3.
`Shared Memory Name`	MYSQL	The name of the shared memory object to use for communication if the connection protocol is set to memory.
`Sql Server Mode`	false	Allow SQL Server syntax. When set to `true` allows Connector/NET to support square brackets around symbols instead of backticks. This allows Visual Studio wizards that bracket symbols with [] to work with Connector/NET. This option incurs a performance hit, so should only be used if necessary. This option was added in version 6.3.1.
`SSL Mode`	None	This option has the following values: • **None** - do not use SSL. • **Preferred** - use SSL if the server supports it, but allow connection in

		all cases. • **Required** - Always use SSL. Deny connection if server does not support SSL. • **VerifyCA** - Always use SSL. Validate the CA but tolerate name mismatch. • **VerifyFull** - Always use SSL. Fail if the host name is not correct. This option was introduced in MySQL Connector/NET 6.2.1.
`TreatBlobsAsUTF8`	false	
`Treat Tiny As Boolean`	true	Setting this value to `false` indicates that `TINYINT(1)` will be treated as an `INT`. See also Section 10.1.1, "Overview of Numeric Types" for a further explanation of the `TINYINT` and `BOOL` data types.
`Use Affected Rows`	false	When `true` the connection will report changed rows instead of found rows. This option was added in Connector/NET version 5.2.6.
`Use Procedure Bodies`	true	When set to `true`, the default value, MySQL Connector/NET expects the body of the procedure to be viewable. This enables it to determine the parameter types and order. The option should be set to `false` when the user connecting to the database does not have the `SELECT` privileges for the `mysql.proc` (stored procedures) table, or cannot view `I_S.ROUTINES`. In this case, MySQL Connector/NET will not be able to determine the types and order of the parameters, and must be alerted to this fact by setting this option to `false`. When set to `false`, MySQL Connector/NET will not rely on this information being available when the procedure is called. Because MySQL Connector/NET will not be able to determine this information, you should explicitly set the types of all the parameters before the call and the parameters should be added to the command in the same order as they appear in the procedure definition. This option was added in MySQL Connector/NET 5.0.4 and MySQL Connector/NET 1.0.10.
`User Id`, `Username`, `Uid`, `User name`		The MySQL login account being used.
`Use Compression`	false	Setting this option to `true` enables compression of packets exchanged between the client and the server. This exchange is defined by the MySQL client-server protocol. Compression is used if both client and server support ZLIB compression, and the client has requested compression using this option. A compressed packet header is: packet length (3 bytes), packet number (1 byte), and Uncompressed Packet Length (3 bytes). The Uncompressed Packet Length is the number of bytes in the original, uncompressed packet. If this is zero then the data in this packet has not been compressed. When the compression protocol is in use, either the client or the server may compress packets. However, compression will not occur if the compressed length is greater than the original length. Thus, some packets will contain compressed data while other packets will not.
`Use Usage Advisor`	false	
`Use Performance Monitor`	false	

The following table lists the valid names for connection pooling values within the `ConnectionString`. For more information about connection pooling, see Connection Pooling for the MySQL Data Provider.

Name	Default	Description
`Cache Server Configuration`, `CacheServerConfiguration`,	false	Specifies whether server variables should be updated when a pooled connection is returned. Turning this on will yield faster opens but will also

`CacheServerConfig`		not catch any server changes made by other connections.
`Connection Lifetime`	0	When a connection is returned to the pool, its creation time is compared with the current time, and the connection is destroyed if that time span (in seconds) exceeds the value specified by `Connection Lifetime`. This is useful in clustered configurations to force load balancing between a running server and a server just brought online. A value of zero (0) causes pooled connections to have the maximum connection timeout.
`Max Pool Size`	100	The maximum number of connections allowed in the pool.
`Min Pool Size`	0	The minimum number of connections allowed in the pool.
`Pooling`	true	When `true`, the `MySqlConnection` object is drawn from the appropriate pool, or if necessary, is created and added to the appropriate pool. Recognized values are `true`, `false`, `yes`, and `no`.
`Reset Pooled Connections`, `ResetConnections`, `ResetPooledConnections`	true	Specifies whether a ping and a reset should be sent to the server before a pooled connection is returned. Not resetting will yield faster connection opens but also will not clear out session items such as temp tables.

20.2.7. Connector/NET API Reference

This section of the manual contains a complete reference to the Connector/NET ADO.NET component, automatically generated from the embedded documentation.

20.2.7.1. `MySql.Data.MySqlClient`

Namespace hierarchy

Classes

Class	Description
MySqlCommand	
MySqlCommandBuilder	
MySqlConnection	
MySqlDataAdapter	
MySqlDataReader	Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.
MySqlError	Collection of error codes that can be returned by the server
MySqlException	The exception that is thrown when MySQL returns an error. This class cannot be inherited.
MySqlHelper	Helper class that makes it easier to work with the provider.
MySqlInfoMessageEventArgs	Provides data for the InfoMessage event. This class cannot be inherited.
MySqlParameter	Represents a parameter to a MySqlCommand , and optionally, its mapping to DataSetcolumns. This class cannot be inherited.
MySqlParameterCollection	Represents a collection of parameters relevant to a MySqlCommand as well as their respective mappings to columns in a DataSet. This class cannot be inherited.
MySqlRowUpdatedEventArgs	Provides data for the RowUpdated event. This class cannot be inherited.
MySqlRowUpdatingEventArgs	Provides data for the RowUpdating event. This class cannot be inherited.
MySqlTransaction	

Delegates

Delegate	Description
MySqlInfoMessageEventHandler	Represents the method that will handle the InfoMessage event of a MySqlConnection.
MySqlRowUpdatedEventHandler	Represents the method that will handle the RowUpdatedevent of a MySqlDataAdapter .
MySqlRowUpdatingEventHandler	Represents the method that will handle the RowUpdatingevent of a MySqlDataAdapter .

Enumerations

Enumeration	Description
MySqlDbType	Specifies MySQL specific data type of a field, property, for use in a MySqlParameter .
MySqlErrorCode

20.2.7.1.2.1. `MySqlCommand` Members

MySqlCommand overview

Public Instance Constructors

MySqlCommand	Overloaded. Initializes a new instance of the MySqlCommand class.

Public Instance Properties

CommandText	
CommandTimeout	
CommandType	
Connection	
Container(inherited from Component)	Gets the IContainerthat contains the Component.
IsPrepared	
Parameters	
Site(inherited from Component)	Gets or sets the ISiteof the Component.
Transaction	
UpdatedRowSource	

Public Instance Methods

Cancel	Attempts to cancel the execution of a MySqlCommand. This operation is not supported.
CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
CreateParameter	Creates a new instance of a MySqlParameter object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
ExecuteNonQuery	
ExecuteReader	Overloaded.
ExecuteScalar	
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Prepare	
ToString(inherited from Component)	Returns a Stringcontaining the name of the Component, if any. This method should not be overridden.

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Disposedevent on the component.

MySqlConnection overview

Public Instance Constructors

MySqlConnection	Overloaded. Initializes a new instance of the MySqlConnection class.

Public Instance Properties

ConnectionString	
ConnectionTimeout	
Container(inherited from Component)	Gets the IContainerthat contains the Component.
Database	
DataSource	Gets the name of the MySQL server to which to connect.
ServerThread	Returns the id of the server thread this connection is executing on
ServerVersion	
Site(inherited from Component)	Gets or sets the ISiteof the Component.
State	
UseCompression	Indicates if this connection should use compression when communicating with the server.

Public Instance Methods

BeginTransaction	Overloaded.

ChangeDatabase	
Close	
CreateCommand	
CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Open	
Ping	Ping
ToString(inherited from Component)	Returns a Stringcontaining the name of the Component, if any. This method should not be overridden.

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Disposedevent on the component.
InfoMessage	
StateChange

20.2.7.1.2.1.1.3.1.1.10.1.1.1. `MySqlTransaction` Members

MySqlTransaction overview

Public Instance Properties

Connection	Gets the MySqlConnection object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.
IsolationLevel	Specifies the IsolationLevelfor this transaction.

Public Instance Methods

Commit	
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Typeof the current instance.
Rollback	
ToString(inherited from Object)	Returns a Stringthat represents the current Object.

See Also

MySqlTransaction Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.1.3.1.1.10.1.1.1.1. Connection Property

Gets the MySqlConnection object associated with the transaction, or a null reference (Nothing in Visual Basic) if the transaction is no longer valid.

Syntax: Visual Basic

```
Public ReadOnly Property Connection As MySqlConnection
```

Syntax: C#

```
public MySqlConnection Connection {get;}
```

Property Value

The MySqlConnection object associated with this transaction.

Remarks

A single application may have multiple database connections, each with zero or more transactions. This property enables you to determine the connection object associated with a particular transaction created by BeginTransaction .

See Also

MySqlTransaction Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.1.3.1.1.10.1.1.1.2. IsolationLevel Property

Specifies the IsolationLevelfor this transaction.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsolationLevel As IsolationLevel _
_  Implements IDbTransaction.IsolationLevel
```

Syntax: C#

```
public System.Data.IsolationLevel IsolationLevel {get;}
```

Property Value

The IsolationLevel for this transaction. The default is ReadCommitted.

Implements

IDbTransaction.IsolationLevel

Remarks

Parallel transactions are not supported. Therefore, the IsolationLevel applies to the entire transaction.

MySqlInfoMessageEventArgs overview

Public Instance Constructors

MySqlInfoMessageEventArgs Constructor	Initializes a new instance of the MySqlInfoMessageEventArgs class.

Public Instance Fields

errors	

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Typeof the current instance.
ToString(inherited from Object)	Returns a Stringthat represents the current Object.

Protected Instance Methods

Finalize(inherited from Object)	Allows an Objectto attempt to free resources and perform other cleanup operations before the Objectis reclaimed by garbage collection.
MemberwiseClone(inherited from Object)	Creates a shallow copy of the current Object.

MySqlParameterCollection overview

Public Instance Constructors

MySqlParameterCollection Constructor	Initializes a new instance of the MySqlParameterCollection class.

Public Instance Properties

Count	Gets the number of MySqlParameter objects in the collection.
Item	Overloaded. Gets the MySqlParameter with a specified attribute. In C#, this property is the indexer for the MySqlParameterCollection class.

Public Instance Methods

Add	Overloaded. Adds the specified MySqlParameter object to the MySqlParameterCollection .
Clear	Removes all items from the collection.
Contains	Overloaded. Gets a value indicating whether a MySqlParameter exists in the collection.
CopyTo	Copies MySqlParameter objects from the MySqlParameterCollection to the specified array.
CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
IndexOf	Overloaded. Gets the location of a MySqlParameter in the collection.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
Insert	Inserts a MySqlParameter into the collection at the specified index.
Remove	Removes the specified MySqlParameter from the collection.

RemoveAt	Overloaded. Removes the specified MySqlParameter from the collection.
ToString(inherited from Object)	Returns a Stringthat represents the current Object.

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.1. `MySqlParameterCollection` Constructor

Initializes a new instance of the MySqlParameterCollection class.

Syntax: Visual Basic

```
Public Sub New()
```

Syntax: C#

```
public MySqlParameterCollection();
```

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.2. Count Property

Gets the number of MySqlParameter objects in the collection.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Count As Integer _
_  Implements ICollection.Count
```

Syntax: C#

```
public int Count {get;}
```

Implements

ICollection.Count

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3. Item Property

Gets the MySqlParameter with a specified attribute. In C#, this property is the indexer for the MySqlParameterCollection class.

Overload List

Gets the MySqlParameter at the specified index.

- public MySqlParameter this[int] {get; set;}

Gets the MySqlParameter with the specified name.

- public MySqlParameter this[string] {get; set;}

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1. `MySqlParameter` Class

Represents a parameter to a MySqlCommand , and optionally, its mapping to DataSetcolumns. This class cannot be inherited.

For a list of all members of this type, see MySqlParameter Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlParameter_
  Inherits MarshalByRefObject_
  Implements IDataParameter, IDbDataParameter, ICloneable
```

Syntax: C#

```
public sealed class MySqlParameter : MarshalByRefObject, IDataParameter, IDbDataParameter, ICloneable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlParameter Members , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1. `MySqlParameter` Members

MySqlParameter overview

Public Instance Constructors

MySqlParameter	Overloaded. Initializes a new instance of the MySqlParameter class.

Public Instance Properties

DbType	Gets or sets the DbTypeof the parameter.
Direction	Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.
IsNullable	Gets or sets a value indicating whether the parameter accepts null values.
IsUnsigned	
MySqlDbType	Gets or sets the MySqlDbType of the parameter.
ParameterName	Gets or sets the name of the MySqlParameter.
Precision	Gets or sets the maximum number of digits used to represent the Value property.
Scale	Gets or sets the number of decimal places to which Value is resolved.

Size	Gets or sets the maximum size, in bytes, of the data within the column.
SourceColumn	Gets or sets the name of the source column that is mapped to the DataSetand used for loading or returning the Value .
SourceVersion	Gets or sets the DataRowVersionto use when loading Value .
Value	Gets or sets the value of the parameter.

Public Instance Methods

CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ToString	Overridden. Gets a string containing the ParameterName .

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.1. `MySqlParameter` Constructor

Initializes a new instance of the MySqlParameter class.

Overload List

Initializes a new instance of the MySqlParameter class.

- public MySqlParameter();

Initializes a new instance of the MySqlParameter class with the parameter name and the data type.

- public MySqlParameter(string,MySqlDbType);

Initializes a new instance of the MySqlParameter class with the parameter name, the MySqlDbType , and the size.

- public MySqlParameter(string,MySqlDbType,int);

Initializes a new instance of the MySqlParameter class with the parameter name, the type of the parameter, the size of the parameter, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersionto use, and the value of the parameter.

- public MySqlParameter(string,MySqlDbType,int,ParameterDirection,bool,byte,byte,string,DataRowVersion,object);

Initializes a new instance of the MySqlParameter class with the parameter name, the MySqlDbType , the size, and the source column name.

- public MySqlParameter(string,MySqlDbType,int,string);

Initializes a new instance of the MySqlParameter class with the parameter name and a value of the new MySqlParameter.

- public MySqlParameter(string,object);

Specifies MySQL specific data type of a field, property, for use in a MySqlParameter .

Syntax: Visual Basic

```
Public Enum MySqlDbType
```

Syntax: C#

```
public enum MySqlDbType
```

Members

Member Name	Description
Newdate	Obsolete. Use Datetime or Date type.
Timestamp	A timestamp. The range is '1970-01-01 00:00:01' to sometime in the year 2038.
Time	The range is '-838:59:59' to '838:59:59'
Date	Date The supported range is '1000-01-01' to '9999-12-31'
Datetime	The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'
Year	A year in 2- or 4-digit format (default is 4-digit). The allowable values are 1901 to 2155, 0000 in the 4-digit year format, and 1970-2069 if you use the 2-digit format (70-69).
TinyBlob	A BLOB column with a maximum length of 255 (2^8 - 1) characters
Blob	A BLOB column with a maximum length of 65535 (2^16 - 1) characters
MediumBlob	A BLOB column with a maximum length of 16777215 (2^24 - 1) characters
LongBlob	A BLOB column with a maximum length of 4294967295 or 4G (2^32 - 1) characters
Int16	A 16-bit signed integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535
Int24	Specifies a 24 (3 byte) signed or unsigned value
Int32	A 32-bit signed integer
Int64	A 64-bit signed integer
Byte	The signed range is -128 to 127. The unsigned range is 0 to 255.
Float	A small (single-precision) floating-point number. Allowable values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38.
Double	A normal-size (double-precision) floating-point number. Allowable values are -1.7976931348623157E+308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308.
UByte	An 8-bit unsigned value
UInt16	A 16-bit unsigned value
UInt24	A 24-bit unsigned value
UInt32	A 32-bit unsigned value
UInt64	A 64-bit unsigned value

Decimal	A fixed precision and scale numeric value between -1038 -1 and 10 38 -1
NewDecimal	New Decimal
Set	A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... A SET can have a maximum of 64 members.
String	Obsolete Use VarChar type
VarChar	A variable-length string containing 0 to 255 characters
VarString	A variable-length string containing 0 to 65535 characters
Enum	An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special "" error value. An ENUM can have a maximum of 65535 distinct values.
Geometry	
Bit	Bit-field data type
TinyText	A nonbinary string column supporting a maximum length of 255 (2^8 - 1) characters
Text	A nonbinary string column supporting a maximum length of 65535 (2^16 - 1) characters
MediumText	A nonbinary string column supporting a maximum length of 16777215 (2^24 - 1) characters
LongText	A nonbinary string column supporting a maximum length of 4294967295 (2^32 - 1) characters

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.1.3. `MySqlParameter` Constructor (String, MySqlDbType, Int32)

Initializes a new instance of the MySqlParameter class with the parameter name, the MySqlDbType , and the size.

Syntax: Visual Basic

```
Overloads Public Sub New( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer _
)
```

Syntax: C#

```
public MySqlParameter(
stringparameterName,
MySqlDbTypedbType,
intsize
);
```

Parameters

- `parameterName`: The name of the parameter to map.

- `dbType`: One of the MySqlDbType values.
- `size`: The length of the parameter.

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace , MySqlParameter Constructor Overload List

20.2.7.1.2.1.7.1.1.3.1.1.1.4. `MySqlParameter` Constructor

Initializes a new instance of the MySqlParameter class with the parameter name, the type of the parameter, the size of the parameter, a ParameterDirection, the precision of the parameter, the scale of the parameter, the source column, a DataRowVersionto use, and the value of the parameter.

Syntax: Visual Basic

```
Overloads Public Sub New( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer, _
   ByVal direction As ParameterDirection, _
   ByVal isNullable As Boolean, _
   ByVal precision As Byte, _
   ByVal scale As Byte, _
   ByVal sourceColumn As String, _
   ByVal sourceVersion As DataRowVersion, _
   ByVal value As Object _
)
```

Syntax: C#

```
public MySqlParameter(
stringparameterName,
MySqlDbTypedbType,
intsize,
ParameterDirectiondirection,
boolisNullable,
byteprecision,
bytescale,
stringsourceColumn,
DataRowVersionsourceVersion,
objectvalue
);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `dbType`: One of the MySqlDbType values.
- `size`: The length of the parameter.
- `direction`: One of the ParameterDirectionvalues.
- `isNullable`: true if the value of the field can be null, otherwise false.
- `precision`: The total number of digits to the left and right of the decimal point to which Value is resolved.
- `scale`: The total number of decimal places to which Value is resolved.
- `sourceColumn`: The name of the source column.
- `sourceVersion`: One of the DataRowVersionvalues.
- `value`: An Objectthat is the value of the MySqlParameter .

Exceptions

);
```

Parameters

- `parameterName`: The name of the parameter to map.
- `value`: An Objectthat is the value of the MySqlParameter .

MySqlParameter Class , MySql.Data.MySqlClient Namespace , MySqlParameter Constructor Overload List

20.2.7.1.2.1.7.1.1.3.1.1.2. DbType Property

Gets or sets the DbTypeof the parameter.

Syntax: Visual Basic

```
NotOverridable Public Property DbType As DbType _
_
  Implements IDataParameter.DbType
```

Syntax: C#

```
public System.Data.DbType DbType {get; set;}
```

Implements

IDataParameter.DbType

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.3. Direction Property

Gets or sets a value indicating whether the parameter is input-only, output-only, bidirectional, or a stored procedure return value parameter. As of MySQL version 4.1 and earlier, input-only is the only valid choice.

Syntax: Visual Basic

```
NotOverridable Public Property Direction As ParameterDirection _
_
  Implements IDataParameter.Direction
```

Syntax: C#

```
public System.Data.ParameterDirection Direction {get; set;}
```

Implements

IDataParameter.Direction

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.4. IsNullable Property

Gets or sets a value indicating whether the parameter accepts null values.

Syntax: Visual Basic

```
NotOverridable Public Property IsNullable As Boolean _
_  Implements IDataParameter.IsNullable
```

Syntax: C#

```
public bool IsNullable {get; set;}
```

Implements

IDataParameter.IsNullable

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.5. IsUnsigned Property

Syntax: Visual Basic

```
Public Property IsUnsigned As Boolean
```

Syntax: C#

```
public bool IsUnsigned {get; set;}
```

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.6. `MySqlDbType` Property

Gets or sets the MySqlDbType of the parameter.

Syntax: Visual Basic

```
Public Property MySqlDbType As MySqlDbType
```

Syntax: C#

```
public MySqlDbType MySqlDbType {get; set;}
```

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.7. ParameterName Property

Gets or sets the name of the MySqlParameter.

Syntax: Visual Basic

```
NotOverridable Public Property ParameterName As String _
_ Implements IDataParameter.ParameterName
```

Syntax: C#

```
public string ParameterName {get; set;}
```

Implements

IDataParameter.ParameterName

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.8. Precision Property

Gets or sets the maximum number of digits used to represent the Value property.

Syntax: Visual Basic

```
NotOverridable Public Property Precision As Byte _
_ Implements IDbDataParameter.Precision
```

Syntax: C#

```
public byte Precision {get; set;}
```

Implements

IDbDataParameter.Precision

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.9. Scale Property

Gets or sets the number of decimal places to which Value is resolved.

Syntax: Visual Basic

```
NotOverridable Public Property Scale As Byte _
_ Implements IDbDataParameter.Scale
```

Syntax: C#

```
public byte Scale {get; set;}
```

Implements

IDbDataParameter.Scale

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.10. Size Property

Gets or sets the maximum size, in bytes, of the data within the column.

Syntax: Visual Basic

```
NotOverridable Public Property Size As Integer _
_ Implements IDbDataParameter.Size
```

Syntax: C#

```
public int Size {get; set;}
```

Implements

IDbDataParameter.Size

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.11. SourceColumn Property

Gets or sets the name of the source column that is mapped to the DataSetand used for loading or returning the Value .

Syntax: Visual Basic

```
NotOverridable Public Property SourceColumn As String _
_ Implements IDataParameter.SourceColumn
```

Syntax: C#

```
public string SourceColumn {get; set;}
```

Implements

IDataParameter.SourceColumn

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.12. SourceVersion Property

Gets or sets the DataRowVersionto use when loading Value .

Syntax: Visual Basic

```
NotOverridable Public Property SourceVersion As DataRowVersion _
_ Implements IDataParameter.SourceVersion
```

Syntax: C#

```
public System.Data.DataRowVersion SourceVersion {get; set;}
```

Implements

IDataParameter.SourceVersion

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.1.1.13. `MySqlParameter.ToString` Method

Overridden. Gets a string containing the ParameterName .

Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

Syntax: C#

```
public override string ToString();
```

Return Value

See Also

MySqlParameter Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.3.2. Item Property (Int32)

Gets the MySqlParameter at the specified index.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _
   ByVal index As Integer _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter this[
intindex
] {get; set;}
```

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Item Overload List

20.2.7.1.2.1.7.1.1.3.3. Item Property (String)

Gets the MySqlParameter with the specified name.

Syntax: Visual Basic

```
Overloads Public Default Property Item( _
   ByVal name As String _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter this[
stringname
] {get; set;}
```

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Item Overload List

20.2.7.1.2.1.7.1.1.4. Add Method

Adds the specified MySqlParameter object to the MySqlParameterCollection .

Overload List

Adds the specified MySqlParameter object to the MySqlParameterCollection .

- public MySqlParameter Add(MySqlParameter);

Adds the specified MySqlParameter object to the MySqlParameterCollection .

- public int Add(object);

Adds a MySqlParameter to the MySqlParameterCollection given the parameter name and the data type.

- public MySqlParameter Add(string,MySqlDbType);

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, and the column length.

- public MySqlParameter Add(string,MySqlDbType,int);

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, the column length, and the source column name.

- public MySqlParameter Add(string,MySqlDbType,int,string);

Adds a MySqlParameter to the MySqlParameterCollection given the specified parameter name and value.

- public MySqlParameter Add(string,object);

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.4.1. `MySqlParameterCollection.Add` Method

Adds the specified MySqlParameter object to the MySqlParameterCollection .

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal value As MySqlParameter _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
MySqlParametervalue
);
```

Parameters

- `value`: The MySqlParameter to add to the collection.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Add Overload List

20.2.7.1.2.1.7.1.1.4.2. `MySqlParameterCollection.Add` Method

Adds the specified MySqlParameter object to the MySqlParameterCollection .

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Add( _
   ByVal value As Object _
) As Integer _
_
  Implements IList.Add
```

Syntax: C#

```
public int Add(
objectvalue
);
```

Parameters

- `value`: The MySqlParameter to add to the collection.

Return Value

The index of the new MySqlParameter object.

Implements

IList.Add

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Add Overload List

20.2.7.1.2.1.7.1.1.4.3. `MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection given the parameter name and the data type.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
MySqlDbTypedbType
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the MySqlDbType values.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Add Overload List

20.2.7.1.2.1.7.1.1.4.4. `MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, and the column length.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
MySqlDbTypedbType,
intsize
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the MySqlDbType values.
- `size`: The length of the column.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Add Overload List

20.2.7.1.2.1.7.1.1.4.5. `MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection with the parameter name, the data type, the column length, and the source column name.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal dbType As MySqlDbType, _
   ByVal size As Integer, _
   ByVal sourceColumn As String _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
MySqlDbTypedbType,
intsize,
stringsourceColumn
);
```

Parameters

- `parameterName`: The name of the parameter.
- `dbType`: One of the MySqlDbType values.
- `size`: The length of the column.

- `sourceColumn`: The name of the source column.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Add Overload List

20.2.7.1.2.1.7.1.1.4.6. `MySqlParameterCollection.Add` Method

Adds a MySqlParameter to the MySqlParameterCollection given the specified parameter name and value.

Syntax: Visual Basic

```
Overloads Public Function Add( _
   ByVal parameterName As String, _
   ByVal value As Object _
) As MySqlParameter
```

Syntax: C#

```
public MySqlParameter Add(
stringparameterName,
objectvalue
);
```

Parameters

- `parameterName`: The name of the parameter.
- `value`: The Value of the MySqlParameter to add to the collection.

Return Value

The newly added MySqlParameter object.

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Add Overload List

20.2.7.1.2.1.7.1.1.5. `MySqlParameterCollection.Clear` Method

Removes all items from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Clear() _
_
  Implements IList.Clear
```

Syntax: C#

```
public void Clear();
```

Implements

IList.Clear

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.6. Contains Method

Gets a value indicating whether a MySqlParameter exists in the collection.

Overload List

Gets a value indicating whether a MySqlParameter exists in the collection.

- public bool Contains(object);

Gets a value indicating whether a MySqlParameter with the specified parameter name exists in the collection.

- public bool Contains(string);

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.6.1. `MySqlParameterCollection.Contains` Method

Gets a value indicating whether a MySqlParameter exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _
   ByVal value As Object _
) As Boolean _
_
  Implements IList.Contains
```

Syntax: C#

```
public bool Contains(
objectvalue
);
```

Parameters

- `value`: The value of the MySqlParameter object to find.

Return Value

true if the collection contains the MySqlParameter object; otherwise, false.

Implements

IList.Contains

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Contains Overload List

20.2.7.1.2.1.7.1.1.6.2. `MySqlParameterCollection.Contains` Method

Gets a value indicating whether a MySqlParameter with the specified parameter name exists in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function Contains( _
   ByVal name As String _
) As Boolean _
_
  Implements IDataParameterCollection.Contains
```

Syntax: C#

```
public bool Contains(
stringname
);
```

Parameters

- `name`: The name of the MySqlParameter object to find.

Return Value

true if the collection contains the parameter; otherwise, false.

Implements

IDataParameterCollection.Contains

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.Contains Overload List

20.2.7.1.2.1.7.1.1.7. `MySqlParameterCollection.CopyTo` Method

Copies MySqlParameter objects from the MySqlParameterCollection to the specified array.

Syntax: Visual Basic

```
NotOverridable Public Sub CopyTo( _
   ByVal array As Array, _
   ByVal index As Integer _
) _
_
  Implements ICollection.CopyTo
```

Syntax: C#

```
public void CopyTo(
Arrayarray,
intindex
);
```

Parameters

- `array`:
- `index`:

Implements

ICollection.CopyTo

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.8. IndexOf Method

Gets the location of a MySqlParameter in the collection.

Overload List

Gets the location of a MySqlParameter in the collection.

- public int IndexOf(object);

Gets the location of the MySqlParameter in the collection with a specific parameter name.

- public int IndexOf(string);

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.8.1. `MySqlParameterCollection.IndexOf` Method

Gets the location of a MySqlParameter in the collection.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _
   ByVal value As Object _
) As Integer _
_
  Implements IList.IndexOf
```

Syntax: C#

```
public int IndexOf(
objectvalue
);
```

Parameters

- `value`: The MySqlParameter object to locate.

Return Value

The zero-based location of the MySqlParameter in the collection.

Implements

IList.IndexOf

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.IndexOf Overload List

20.2.7.1.2.1.7.1.1.8.2. `MySqlParameterCollection.IndexOf` Method

Gets the location of the MySqlParameter in the collection with a specific parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Function IndexOf( _
   ByVal parameterName As String _
) As Integer _
_
  Implements IDataParameterCollection.IndexOf
```

Syntax: C#

```
public int IndexOf(
stringparameterName
);
```

Parameters

- `parameterName`: The name of the MySqlParameter object to retrieve.

Return Value

The zero-based location of the MySqlParameter in the collection.

Implements

IDataParameterCollection.IndexOf

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.IndexOf Overload List

20.2.7.1.2.1.7.1.1.9. `MySqlParameterCollection.Insert` Method

Inserts a MySqlParameter into the collection at the specified index.

Syntax: Visual Basic

```
NotOverridable Public Sub Insert( _
   ByVal index As Integer, _
   ByVal value As Object _
) _
_
  Implements IList.Insert
```

Syntax: C#

```
public void Insert(
intindex,
objectvalue
);
```

Parameters

- `index`:
- `value`:

Implements

IList.Insert

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.10. `MySqlParameterCollection.Remove` Method

Removes the specified MySqlParameter from the collection.

Syntax: Visual Basic

```
NotOverridable Public Sub Remove( _
   ByVal value As Object _
) _
_
  Implements IList.Remove
```

Syntax: C#

```
public void Remove(
objectvalue
);
```

Parameters

- `value`:

Implements

IList.Remove

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.11. RemoveAt Method

Removes the specified MySqlParameter from the collection.

Overload List

Removes the specified MySqlParameter from the collection using a specific index.

- public void RemoveAt(int);

Removes the specified MySqlParameter from the collection using the parameter name.

- public void RemoveAt(string);

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.7.1.1.11.1. `MySqlParameterCollection.RemoveAt` Method

Removes the specified MySqlParameter from the collection using a specific index.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _
   ByVal index As Integer _
) _
_
  Implements IList.RemoveAt
```

Syntax: C#

```
public void RemoveAt(
intindex
);
```

Parameters

- `index`: The zero-based index of the parameter.

Implements

IList.RemoveAt

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.RemoveAt Overload List

20.2.7.1.2.1.7.1.1.11.2. `MySqlParameterCollection.RemoveAt` Method

Removes the specified MySqlParameter from the collection using the parameter name.

Syntax: Visual Basic

```
NotOverridable Overloads Public Sub RemoveAt( _
   ByVal name As String _
) _
_
  Implements IDataParameterCollection.RemoveAt
```

Syntax: C#

```
public void RemoveAt(
stringname
);
```

Parameters

- `name`: The name of the MySqlParameter object to retrieve.

Implements

IDataParameterCollection.RemoveAt

See Also

MySqlParameterCollection Class , MySql.Data.MySqlClient Namespace , MySqlParameterCollection.RemoveAt Overload List

20.2.7.1.2.1.8. Transaction Property

Syntax: Visual Basic

```
Public Property Transaction As MySqlTransaction
```

Syntax: C#

```
public MySqlTransaction Transaction {get; set;}
```

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.9. UpdatedRowSource Property

Syntax: Visual Basic

```
NotOverridable Public Property UpdatedRowSource As UpdateRowSource _
_
  Implements IDbCommand.UpdatedRowSource
```

Syntax: C#

```
public System.Data.UpdateRowSource UpdatedRowSource {get; set;}
```

Implements

IDbCommand.UpdatedRowSource

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.10. `MySqlCommand.Cancel` Method

Attempts to cancel the execution of a MySqlCommand. This operation is not supported.

Syntax: Visual Basic

```
NotOverridable Public Sub Cancel() _
_  Implements IDbCommand.Cancel
```

Syntax: C#

```
public void Cancel();
```

Implements

IDbCommand.Cancel

Remarks

Cancelling an executing command is currently not supported on any version of MySQL.

Exceptions

Exception Type	Condition
NotSupportedException	This operation is not supported.

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.11. `MySqlCommand.CreateParameter` Method

Creates a new instance of a MySqlParameter object.

Syntax: Visual Basic

```
Public Function CreateParameter() As MySqlParameter
```

Syntax: C#

```
public MySqlParameter CreateParameter();
```

Return Value

A MySqlParameter object.

Remarks

This method is a strongly-typed version of CreateParameter.

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.12. `MySqlCommand.ExecuteNonQuery` Method

Syntax: Visual Basic

```
NotOverridable Public Function ExecuteNonQuery() As Integer _
_  Implements IDbCommand.ExecuteNonQuery
```

Syntax: C#

```
public int ExecuteNonQuery();
```

Implements

IDbCommand.ExecuteNonQuery

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13. ExecuteReader Method

Overload List

- public MySqlDataReader ExecuteReader();
- public MySqlDataReader ExecuteReader(CommandBehavior);

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1. `MySqlCommand.ExecuteReader` Method

Syntax: Visual Basic

```
Overloads Public Function ExecuteReader() As MySqlDataReader
```

Syntax: C#

```
public MySqlDataReader ExecuteReader();
```

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace , MySqlCommand.ExecuteReader Overload List

20.2.7.1.2.1.13.1.1. `MySqlDataReader` Class

Provides a means of reading a forward-only stream of rows from a MySQL database. This class cannot be inherited.

For a list of all members of this type, see MySqlDataReader Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlDataReader_
  Inherits MarshalByRefObject_
  Implements IEnumerable, IDataReader, IDisposable, IDataRecord
```

Syntax: C#

```
public sealed class MySqlDataReader : MarshalByRefObject, IEnumerable, IDataReader, IDisposable, IDataRecord
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlDataReader Members , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1. `MySqlDataReader` Members

MySqlDataReader overview

Public Instance Properties

Depth	Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.
FieldCount	Gets the number of columns in the current row.
HasRows	Gets a value indicating whether the MySqlDataReader contains one or more rows.
IsClosed	Gets a value indicating whether the data reader is closed.
Item	Overloaded. Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Public Instance Methods

Close	Closes the MySqlDataReader object.
CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetBoolean	Gets the value of the specified column as a Boolean.
GetByte	Gets the value of the specified column as a byte.
GetBytes	Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.
GetChar	Gets the value of the specified column as a single character.
GetChars	Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.
GetDataTypeName	Gets the name of the source data type.
GetDateTime	
GetDecimal	
GetDouble	
GetFieldType	Gets the Type that is the data type of the object.
GetFloat	
GetGuid	
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetInt16	
GetInt32	
GetInt64	
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the life-

	time policy for this instance.
GetMySqlDateTime	
GetName	Gets the name of the specified column.
GetOrdinal	Gets the column ordinal, given the name of the column.
GetSchemaTable	Returns a DataTable that describes the column metadata of the MySqlDataReader.
GetString	
GetTimeSpan	
GetType(inherited from Object)	Gets the Typeof the current instance.
GetUInt16	
GetUInt32	
GetUInt64	
GetValue	Gets the value of the specified column in its native format.
GetValues	Gets all attribute columns in the collection for the current row.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
IsDBNull	Gets a value indicating whether the column contains non-existent or missing values.
NextResult	Advances the data reader to the next result, when reading the results of batch SQL statements.
Read	Advances the MySqlDataReader to the next record.
ToString(inherited from Object)	Returns a Stringthat represents the current Object.

20.2.7.1.2.1.13.1.1.1.1. Depth Property

Gets a value indicating the depth of nesting for the current row. This method is not supported currently and always returns 0.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property Depth As Integer _
_
  Implements IDataReader.Depth
```

Syntax: C#

```
public int Depth {get;}
```

Implements

IDataReader.Depth

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.2. FieldCount Property

Gets the number of columns in the current row.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property FieldCount As Integer _
_
```

```
  Implements IDataRecord.FieldCount
```

Syntax: C#

```
public int FieldCount {get;}
```

Implements

IDataRecord.FieldCount

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.3. HasRows Property

Gets a value indicating whether the MySqlDataReader contains one or more rows.

Syntax: Visual Basic

```
Public ReadOnly Property HasRows As Boolean
```

Syntax: C#

```
public bool HasRows {get;}
```

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.4. IsClosed Property

Gets a value indicating whether the data reader is closed.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property IsClosed As Boolean _
_
  Implements IDataReader.IsClosed
```

Syntax: C#

```
public bool IsClosed {get;}
```

Implements

IDataReader.IsClosed

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.5. Item Property

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

Overload List

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

- public object this[int] {get;}

Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

- public object this[string] {get;}

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.5.1. Item Property (Int32)

Overloaded. Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _
   ByVal i As Integer _
) _
_
  Implements IDataRecord.Item As Object _
_
  Implements IDataRecord.Item
```

Syntax: C#

```
public object this[
inti
] {get;}
```

Implements

IDataRecord.Item

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace , MySqlDataReader.Item Overload List

20.2.7.1.2.1.13.1.1.1.5.2. Item Property (String)

Gets the value of a column in its native format. In C#, this property is the indexer for the MySqlDataReader class.

Syntax: Visual Basic

```
NotOverridable Overloads Public Default ReadOnly Property Item( _
   ByVal name As String _
) _
_
  Implements IDataRecord.Item As Object _
_
  Implements IDataRecord.Item
```

Syntax: C#

```
public object this[
stringname
] {get;}
```

Implements

IDataRecord.Item

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace , MySqlDataReader.Item Overload List

20.2.7.1.2.1.13.1.1.1.6. RecordsAffected Property

Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.

Syntax: Visual Basic

```
NotOverridable Public ReadOnly Property RecordsAffected As Integer _
_
  Implements IDataReader.RecordsAffected
```

Syntax: C#

```
public int RecordsAffected {get;}
```

Implements

IDataReader.RecordsAffected

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.7. `MySqlDataReader.Close` Method

Closes the MySqlDataReader object.

Syntax: Visual Basic

```
NotOverridable Public Sub Close() _
_
  Implements IDataReader.Close
```

Syntax: C#

```
public void Close();
```

Implements

IDataReader.Close

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.8. `MySqlDataReader.GetBoolean` Method

Gets the value of the specified column as a Boolean.

Syntax: Visual Basic

```
NotOverridable Public Function GetBoolean( _
   ByVal i As Integer _
) As Boolean _
_
  Implements IDataRecord.GetBoolean
```

Syntax: C#

```
public bool GetBoolean(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetBoolean

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.9. `MySqlDataReader.GetByte` Method

Gets the value of the specified column as a byte.

Syntax: Visual Basic

```
NotOverridable Public Function GetByte( _
   ByVal i As Integer _
) As Byte _
_
  Implements IDataRecord.GetByte
```

Syntax: C#

```
public byte GetByte(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetByte

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.10. `MySqlDataReader.GetBytes` Method

Reads a stream of bytes from the specified column offset into the buffer an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetBytes( _
   ByVal i As Integer, _
   ByVal dataIndex As Long, _
   ByVal buffer As Byte(), _
   ByVal bufferIndex As Integer, _
   ByVal length As Integer _
) As Long _
_
  Implements IDataRecord.GetBytes
```

Syntax: C#

```
public long GetBytes(
inti,
longdataIndex,
byte[]buffer,
intbufferIndex,
intlength
);
```

Parameters

- `i`: The zero-based column ordinal.
- `dataIndex`: The index within the field from which to begin the read operation.
- `buffer`: The buffer into which to read the stream of bytes.
- `bufferIndex`: The index for buffer to begin the read operation.
- `length`: The maximum length to copy into the buffer.

Return Value

The actual number of bytes read.

Implements

IDataRecord.GetBytes

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.11. `MySqlDataReader.GetChar` Method

Gets the value of the specified column as a single character.

Syntax: Visual Basic

```
NotOverridable Public Function GetChar( _
   ByVal i As Integer _
) As Char _
_
  Implements IDataRecord.GetChar
```

Syntax: C#

```
public char GetChar(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetChar

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.12. `MySqlDataReader.GetChars` Method

Reads a stream of characters from the specified column offset into the buffer as an array starting at the given buffer offset.

Syntax: Visual Basic

```
NotOverridable Public Function GetChars( _
   ByVal i As Integer, _
   ByVal fieldOffset As Long, _
   ByVal buffer As Char(), _
   ByVal bufferoffset As Integer, _
   ByVal length As Integer _
```

```
) As Long _
_
  Implements IDataRecord.GetChars
```

Syntax: C#

```
public long GetChars(
inti,
longfieldOffset,
char[]buffer,
intbufferoffset,
intlength
);
```

Parameters

- `i`:
- `fieldOffset`:
- `buffer`:
- `bufferoffset`:
- `length`:

Return Value

Implements

IDataRecord.GetChars

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.13. `MySqlDataReader.GetDataTypeName` Method

Gets the name of the source data type.

Syntax: Visual Basic

```
NotOverridable Public Function GetDataTypeName( _
   ByVal i As Integer _
) As String _
_
  Implements IDataRecord.GetDataTypeName
```

Syntax: C#

```
public string GetDataTypeName(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetDataTypeName

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.14. `MySqlDataReader.GetDateTime` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDateTime( _
   ByVal index As Integer _
) As Date _
_
  Implements IDataRecord.GetDateTime
```

Syntax: C#

```
public DateTime GetDateTime(
intindex
);
```

Implements

IDataRecord.GetDateTime

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.15. `MySqlDataReader.GetDecimal` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDecimal( _
   ByVal index As Integer _
) As Decimal _
_
  Implements IDataRecord.GetDecimal
```

Syntax: C#

```
public decimal GetDecimal(
intindex
);
```

Implements

IDataRecord.GetDecimal

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.16. `MySqlDataReader.GetDouble` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetDouble( _
   ByVal index As Integer _
) As Double _
_
  Implements IDataRecord.GetDouble
```

Syntax: C#

```
public double GetDouble(
intindex
);
```

Implements

IDataRecord.GetDouble

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.17. `MySqlDataReader.GetFieldType` Method

Gets the Type that is the data type of the object.

Syntax: Visual Basic

```
NotOverridable Public Function GetFieldType( _
   ByVal i As Integer _
) As Type _
_
  Implements IDataRecord.GetFieldType
```

Syntax: C#

```
public Type GetFieldType(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetFieldType

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.18. `MySqlDataReader.GetFloat` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetFloat( _
   ByVal index As Integer _
) As Single _
_
  Implements IDataRecord.GetFloat
```

Syntax: C#

```
public float GetFloat(
intindex
);
```

Implements

IDataRecord.GetFloat

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.19. `MySqlDataReader.GetGuid` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetGuid( _
   ByVal index As Integer _
) As Guid _
_
  Implements IDataRecord.GetGuid
```

Syntax: C#

```
public Guid GetGuid(
intindex
);
```

Implements

IDataRecord.GetGuid

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.20. `MySqlDataReader.GetInt16` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt16( _
   ByVal index As Integer _
) As Short _
_
  Implements IDataRecord.GetInt16
```

Syntax: C#

```
public short GetInt16(
intindex
);
```

Implements

IDataRecord.GetInt16

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.21. `MySqlDataReader.GetInt32` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt32( _
   ByVal index As Integer _
) As Integer _
_
  Implements IDataRecord.GetInt32
```

Syntax: C#

```
public int GetInt32(
intindex
);
```

Implements

IDataRecord.GetInt32

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.22. `MySqlDataReader.GetInt64` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetInt64( _
   ByVal index As Integer _
) As Long _
_
  Implements IDataRecord.GetInt64
```

Syntax: C#

```
public long GetInt64(
intindex
);
```

Implements

IDataRecord.GetInt64

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.23. `MySqlDataReader.GetMySqlDateTime` Method

Syntax: Visual Basic

```
Public Function GetMySqlDateTime( _
   ByVal index As Integer _
) As MySqlDateTime
```

Syntax: C#

```
public MySqlDateTime GetMySqlDateTime(
intindex
);
```

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.24. `MySqlDataReader.GetName` Method

Gets the name of the specified column.

Syntax: Visual Basic

```
NotOverridable Public Function GetName( _
   ByVal i As Integer _
) As String _
_
  Implements IDataRecord.GetName
```

Syntax: C#

```
public string GetName(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetName

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.25. `MySqlDataReader.GetOrdinal` Method

Gets the column ordinal, given the name of the column.

Syntax: Visual Basic

```
NotOverridable Public Function GetOrdinal( _
   ByVal name As String _
) As Integer _
_
  Implements IDataRecord.GetOrdinal
```

Syntax: C#

```
public int GetOrdinal(
stringname
);
```

Parameters

- `name`:

Return Value

Implements

IDataRecord.GetOrdinal

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.26. `MySqlDataReader.GetSchemaTable` Method

Returns a DataTable that describes the column metadata of the MySqlDataReader.

Syntax: Visual Basic

```
NotOverridable Public Function GetSchemaTable() As DataTable _
_
  Implements IDataReader.GetSchemaTable
```

Syntax: C#

```
public DataTable GetSchemaTable();
```

Return Value

Implements

IDataReader.GetSchemaTable

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.27. `MySqlDataReader.GetString` Method

Syntax: Visual Basic

```
NotOverridable Public Function GetString( _
   ByVal index As Integer _
) As String _
_
  Implements IDataRecord.GetString
```

Syntax: C#

```
public string GetString(
intindex
);
```

Implements

IDataRecord.GetString

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.28. `MySqlDataReader.GetTimeSpan` Method

Syntax: Visual Basic

```
Public Function GetTimeSpan( _
   ByVal index As Integer _
) As TimeSpan
```

Syntax: C#

```
public TimeSpan GetTimeSpan(
intindex
);
```

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.29. `MySqlDataReader.GetUInt16` Method

Syntax: Visual Basic

```
Public Function GetUInt16( _
   ByVal index As Integer _
) As UInt16
```

Syntax: C#

```
public ushort GetUInt16(
intindex
);
```

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.30. `MySqlDataReader.GetUInt32` Method

Syntax: Visual Basic

```
Public Function GetUInt32( _
   ByVal index As Integer _
) As UInt32
```

Syntax: C#

```
public uint GetUInt32(
intindex
);
```

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.31. `MySqlDataReader.GetUInt64` Method

Syntax: Visual Basic

```
Public Function GetUInt64( _
   ByVal index As Integer _
) As UInt64
```

Syntax: C#

```
public ulong GetUInt64(
intindex
);
```

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.32. `MySqlDataReader.GetValue` Method

Gets the value of the specified column in its native format.

Syntax: Visual Basic

```
NotOverridable Public Function GetValue( _
   ByVal i As Integer _
) As Object _
_
  Implements IDataRecord.GetValue
```

Syntax: C#

```
public object GetValue(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.GetValue

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.33. `MySqlDataReader.GetValues` Method

Gets all attribute columns in the collection for the current row.

Syntax: Visual Basic

```
NotOverridable Public Function GetValues( _
   ByVal values As Object() _
```

```
) As Integer _
_
  Implements IDataRecord.GetValues
```

Syntax: C#

```
public int GetValues(
object[]values
);
```

Parameters

- `values`:

Return Value

Implements

IDataRecord.GetValues

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.34. `MySqlDataReader.IsDBNull` Method

Gets a value indicating whether the column contains non-existent or missing values.

Syntax: Visual Basic

```
NotOverridable Public Function IsDBNull( _
   ByVal i As Integer _
) As Boolean _
_
  Implements IDataRecord.IsDBNull
```

Syntax: C#

```
public bool IsDBNull(
inti
);
```

Parameters

- `i`:

Return Value

Implements

IDataRecord.IsDBNull

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.35. `MySqlDataReader.NextResult` Method

Advances the data reader to the next result, when reading the results of batch SQL statements.

Syntax: Visual Basic

```
NotOverridable Public Function NextResult() As Boolean _
_
```

```
  Implements IDataReader.NextResult
```

Syntax: C#

```
public bool NextResult();
```

Return Value

Implements

IDataReader.NextResult

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.1.1.1.36. `MySqlDataReader.Read` Method

Advances the MySqlDataReader to the next record.

Syntax: Visual Basic

```
NotOverridable Public Function Read() As Boolean _
_
  Implements IDataReader.Read
```

Syntax: C#

```
public bool Read();
```

Return Value

Implements

IDataReader.Read

See Also

MySqlDataReader Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.13.2. `MySqlCommand.ExecuteReader` Method

Syntax: Visual Basic

```
Overloads Public Function ExecuteReader( _
   ByVal behavior As CommandBehavior _
) As MySqlDataReader
```

Syntax: C#

```
public MySqlDataReader ExecuteReader(
CommandBehaviorbehavior
);
```

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace , MySqlCommand.ExecuteReader Overload List

20.2.7.1.2.1.14. `MySqlCommand.ExecuteScalar` Method

Syntax: Visual Basic

```

_
  Implements IDbCommand.ExecuteScalar
```

Syntax: C#

```
public object ExecuteScalar();
```

Implements

IDbCommand.ExecuteScalar

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.2.1.15. `MySqlCommand.Prepare` Method

Syntax: Visual Basic

```
NotOverridable Public Sub Prepare() _
_
  Implements IDbCommand.Prepare
```

Syntax: C#

```
public void Prepare();
```

Implements

IDbCommand.Prepare

See Also

MySqlCommand Class , MySql.Data.MySqlClient Namespace

20.2.7.1.3. `MySqlCommandBuilder` Class

For a list of all members of this type, see MySqlCommandBuilder Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlCommandBuilder_
  Inherits Component
```

Syntax: C#

```
public sealed class MySqlCommandBuilder : Component
```

Thread Safety

Public static (Sharedin Visual Basic) members of this type are safe for multithreaded operations. Instance members are notguaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlCommandBuilder Members , MySql.Data.MySqlClient Namespace

20.2.7.1.3.1. `MySqlCommandBuilder` Members

MySqlCommandBuilder overview

Public Static (Shared) Methods

DeriveParameters	Overloaded. Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

Public Instance Constructors

MySqlCommandBuilder	Overloaded. Initializes a new instance of the MySqlCommandBuilder class.

Public Instance Properties

Container(inherited from Component)	Gets the IContainerthat contains the Component.
DataAdapter	
QuotePrefix	
QuoteSuffix	
Site(inherited from Component)	Gets or sets the ISiteof the Component.

Public Instance Methods

CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetDeleteCommand	
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetInsertCommand	
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
GetUpdateCommand	
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
RefreshSchema	
ToString(inherited from Component)	Returns a Stringcontaining the name of the Component, if any. This method should not be overridden.

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Disposedevent on the component.

See Also

MySqlCommandBuilder Class , MySql.Data.MySqlClient Namespace

20.2.7.1.3.1.1. DeriveParameters Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

Overload List

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

- public static void DeriveParameters(MySqlCommand);
- public static void DeriveParameters(MySqlCommand,bool);

See Also

MySqlCommandBuilder Class , MySql.Data.MySqlClient Namespace

20.2.7.1.3.1.1.1. `MySqlCommandBuilder.DeriveParameters` Method

Retrieves parameter information from the stored procedure specified in the MySqlCommand and populates the Parameters collection of the specified MySqlCommand object. This method is not currently supported since stored procedures are not available in MySql.

Syntax: Visual Basic

```
Overloads Public Shared Sub DeriveParameters( _
   ByVal command As MySqlCommand _
)
```

Syntax: C#

```
public static void DeriveParameters(
MySqlCommandcommand
);
```

Parameters

- `command`: The MySqlCommand referencing the stored procedure from which the parameter information is to be derived. The derived parameters are added to the Parameters collection of the MySqlCommand.

Exceptions

Exception Type	Condition
InvalidOperationException	The command text is not a valid stored procedure name.

20.2.7.1.3.1.2.2.1. `MySqlDataAdapter` Class

For a list of all members of this type, see MySqlDataAdapter Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlDataAdapter_
  Inherits DbDataAdapter
```

Syntax: C#

```
public sealed class MySqlDataAdapter : DbDataAdapter
```

Thread Safety

Public static (Sharedin Visual Basic) members of this type are safe for multithreaded operations. Instance members are notguaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlDataAdapter Members , MySql.Data.MySqlClient Namespace

20.2.7.1.3.1.2.2.1.1. `MySqlDataAdapter` Members

MySqlDataAdapter overview

Public Instance Constructors

MySqlDataAdapter	Overloaded. Initializes a new instance of the MySqlDataAdapter class.

Public Instance Properties

AcceptChangesDuringFill(inherited from DataAdapter)	Gets or sets a value indicating whether AcceptChangesis called on a DataRowafter it is added to the DataTableduring any of the Fill operations.
AcceptChangesDuringUpdate(inherited from DataAdapter)	Gets or sets whether AcceptChangesis called during a Update.
Container(inherited from Component)	Gets the IContainerthat contains the Component.
ContinueUpdateOnError(inherited from DataAdapter)	Gets or sets a value that specifies whether to generate an exception when an error is encountered during a row update.
DeleteCommand	Overloaded.
FillLoadOption(inherited from DataAdapter)	Gets or sets the LoadOptionthat determines how the adapter fills the DataTablefrom the DbDataReader.
InsertCommand	Overloaded.
MissingMappingAction(inherited from DataAdapter)	Determines the action to take when incoming data does not have a matching table or column.
MissingSchemaAction(inherited from DataAdapter)	Determines the action to take when existing DataSetschema does not match incoming data.
ReturnProviderSpecificTypes(inherited from DataAdapter)	Gets or sets whether the Fillmethod should return provider-specific values or common CLS-compliant values.
SelectCommand	Overloaded.
Site(inherited from Component)	Gets or sets the ISiteof the Component.
TableMappings(inherited from DataAdapter)	Gets a collection that provides the master mapping between a source table and a DataTable.

UpdateBatchSize(inherited from DbDataAdapter)	Gets or sets a value that enables or disables batch processing support, and specifies the number of commands that can be executed in a batch.
UpdateCommand	Overloaded.

Public Instance Methods

CreateObjRef(inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
Dispose(inherited from Component)	Releases all resources used by the Component.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
Fill(inherited from DbDataAdapter)	Overloaded. Adds or refreshes rows in the DataSetto match those in the data source using the DataSetname, and creates a DataTablenamed "Table."
FillSchema(inherited from DbDataAdapter)	Overloaded. Configures the schema of the specified DataTablebased on the specified SchemaType.
GetFillParameters(inherited from DbDataAdapter)	Gets the parameters set by the user when executing an SQL `SELECT` statement.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService(inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetType(inherited from Object)	Gets the Typeof the current instance.
InitializeLifetimeService(inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
ResetFillLoadOption(inherited from DataAdapter)	Resets FillLoadOptionto its default state and causes Fillto honor AcceptChangesDuringFill.
ShouldSerializeAcceptChangesDuringFill(inherited from DataAdapter)	Determines whether the AcceptChangesDuringFillproperty should be persisted.
ShouldSerializeFillLoadOption(inherited from DataAdapter)	Determines whether the FillLoadOptionproperty should be persisted.
ToString(inherited from Component)	Returns a Stringcontaining the name of the Component, if any. This method should not be overridden.
Update(inherited from DbDataAdapter)	Overloaded. Calls the respective INSERT, UPDATE, or DELETE statements for each inserted, updated, or deleted row in the specified DataSet.

Public Instance Events

Disposed(inherited from Component)	Adds an event handler to listen to the Disposedevent on the component.
FillError(inherited from DataAdapter)	Returned when an error occurs during a fill operation.
RowUpdated	Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.
RowUpdating	Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

Protected Internal Instance Properties

FillCommandBehavior(inherited from DbDataAdapter)	Gets or sets the behavior of the command used to fill the data ad-

	apter.

20.2.7.1.3.1.2.2.1.1.6. `MySqlDataAdapter.RowUpdated` Event

Occurs during Update after a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdated As MySqlRowUpdatedEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatedEventHandler RowUpdated;
```

Event Data

The event handler receives an argument of type MySqlRowUpdatedEventArgs containing data related to this event. The following MySqlRowUpdatedEventArgsproperties provide information specific to this event.

Property	Description
Command	Gets or sets the MySqlCommand executed when Update is called.
Errors	Gets any errors generated by the .NET Framework data provider when the Commandwas executed.
RecordsAffected	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row	Gets the DataRowsent through an Update.
RowCount	Gets the number of rows processed in a batch of updated records.
StatementType	Gets the type of SQL statement executed.
Status	Gets the UpdateStatusof the Commandproperty.
TableMapping	Gets the DataTableMappingsent through an Update.

20.2.7.1.3.1.2.2.1.1.6.1. `MySqlRowUpdatedEventHandler` Delegate

Represents the method that will handle the RowUpdatedevent of a MySqlDataAdapter .

Syntax: Visual Basic

```
Public Delegate Sub MySqlRowUpdatedEventHandler( _
   ByVal sender As Object, _
   ByVal e As MySqlRowUpdatedEventArgs _
)
```

Syntax: C#

```
public delegate void MySqlRowUpdatedEventHandler(
objectsender,
MySqlRowUpdatedEventArgse
);
```

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySql.Data.MySqlClient Namespace

20.2.7.1.3.1.2.2.1.1.6.1.1. `MySqlRowUpdatedEventArgs` Class

Provides data for the RowUpdated event. This class cannot be inherited.

For a list of all members of this type, see MySqlRowUpdatedEventArgs Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlRowUpdatedEventArgs_
  Inherits RowUpdatedEventArgs
```

Syntax: C#

```
public sealed class MySqlRowUpdatedEventArgs : RowUpdatedEventArgs
```

Thread Safety

Public static (Sharedin Visual Basic) members of this type are safe for multithreaded operations. Instance members are notguaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

MySqlRowUpdatedEventArgs overview

Public Instance Constructors

MySqlRowUpdatedEventArgs Constructor	Initializes a new instance of the MySqlRowUpdatedEventArgs class.

Public Instance Properties

Command	Overloaded. Gets or sets the MySqlCommand executed when Update is called.
Errors(inherited from RowUpdatedEventArgs)	Gets any errors generated by the .NET Framework data provider when the Commandwas executed.
RecordsAffected(inherited from RowUpdatedEventArgs)	Gets the number of rows changed, inserted, or deleted by execution of the SQL statement.
Row(inherited from RowUpdatedEventArgs)	Gets the DataRowsent through an Update.
RowCount(inherited from RowUpdatedEventArgs)	Gets the number of rows processed in a batch of updated records.
StatementType(inherited from RowUpdatedEventArgs)	Gets the type of SQL statement executed.
Status(inherited from RowUpdatedEventArgs)	Gets the UpdateStatusof the Commandproperty.
TableMapping(inherited from RowUpdatedEventArgs)	Gets the DataTableMappingsent through an Update.

Public Instance Methods

CopyToRows(inherited from RowUpdatedEventArgs)	Overloaded. Copies references to the modified rows into the provided array.
Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Typeof the current instance.
ToString(inherited from Object)	Returns a Stringthat represents the current Object.

20.2.7.1.3.1.2.2.1.1.6.1.1.1.1. `MySqlRowUpdatedEventArgs` Constructor

Initializes a new instance of the MySqlRowUpdatedEventArgs class.

Syntax: Visual Basic

```
Public Sub New( _
   ByVal row As DataRow, _
   ByVal command As IDbCommand, _
   ByVal statementType As StatementType, _
   ByVal tableMapping As DataTableMapping _
)
```

Syntax: C#

```
public MySqlRowUpdatedEventArgs(
DataRowrow,
IDbCommandcommand,
StatementTypestatementType,
DataTableMappingtableMapping
);
```

Parameters

- `row`: The DataRowsent through an Update.
- `command`: The IDbCommandexecuted when Updateis called.
- `statementType`: One of the StatementTypevalues that specifies the type of query executed.
- `tableMapping`: The DataTableMappingsent through an Update.

20.2.7.1.3.1.2.2.1.1.7. `MySqlDataAdapter.RowUpdating` Event

Occurs during Update before a command is executed against the data source. The attempt to update is made, so the event fires.

Syntax: Visual Basic

```
Public Event RowUpdating As MySqlRowUpdatingEventHandler
```

Syntax: C#

```
public event MySqlRowUpdatingEventHandler RowUpdating;
```

Event Data

The event handler receives an argument of type MySqlRowUpdatingEventArgs containing data related to this event. The following MySqlRowUpdatingEventArgsproperties provide information specific to this event.

Property	Description
Command	Gets or sets the MySqlCommand to execute when performing the Update.
Errors	Gets any errors generated by the .NET Framework data provider when the Commandexecutes.
Row	Gets the DataRowthat will be sent to the server as part of an insert, update, or delete operation.
StatementType	Gets the type of SQL statement to execute.
Status	Gets or sets the UpdateStatusof the Commandproperty.
TableMapping	Gets the DataTableMappingto send through the Update.

Syntax: Visual Basic

```
Public Function GetUpdateCommand() As MySqlCommand
```

Syntax: C#

```
public MySqlCommand GetUpdateCommand();
```

See Also

MySqlCommandBuilder Class , MySql.Data.MySqlClient Namespace

20.2.7.1.3.1.9. `MySqlCommandBuilder.RefreshSchema` Method

Syntax: Visual Basic

```
Public Sub RefreshSchema()
```

Syntax: C#

```
public void RefreshSchema();
```

See Also

MySqlCommandBuilder Class , MySql.Data.MySqlClient Namespace

20.2.7.1.4. `MySqlException` Class

The exception that is thrown when MySQL returns an error. This class cannot be inherited.

For a list of all members of this type, see MySqlException Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlException_
  Inherits SystemException
```

Syntax: C#

```
public sealed class MySqlException : SystemException
```

Thread Safety

Public static (Sharedin Visual Basic) members of this type are safe for multithreaded operations. Instance members are notguaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlException Members , MySql.Data.MySqlClient Namespace

20.2.7.1.4.1. `MySqlException` Members

MySqlException overview

Public Instance Properties

Data(inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.

HelpLink(inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException(inherited from Exception)	Gets the Exceptioninstance that caused the current exception.
Message(inherited from Exception)	Gets a message that describes the current exception.
Number	Gets a number that identifies the type of error. This number corresponds to the error numbers given in Section B.3, “Server Error Codes and Messages”.
Source(inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace(inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite(inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetBaseException(inherited from Exception)	When overridden in a derived class, returns the Exceptionthat is the root cause of one or more subsequent exceptions.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData(inherited from Exception)	When overridden in a derived class, sets the SerializationInfowith information about the exception.
GetType(inherited from Exception)	Gets the runtime type of the current instance.
ToString(inherited from Exception)	Creates and returns a string representation of the current exception.

MySqlException Class , MySql.Data.MySqlClient Namespace

20.2.7.1.4.1.1. Number Property

Gets a number that identifies the type of error.

Syntax: Visual Basic

```
Public ReadOnly Property Number As Integer
```

Syntax: C#

```
public int Number {get;}
```

See Also

MySqlException Class , MySql.Data.MySqlClient Namespace

20.2.7.1.5. `MySqlHelper` Class

Helper class that makes it easier to work with the provider.

For a list of all members of this type, see MySqlHelper Members .

Syntax: Visual Basic

```
NotInheritable Public Class MySqlHelper
```

Syntax: C#

```
public sealed class MySqlHelper
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.MySqlClient

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlHelper Members , MySql.Data.MySqlClient Namespace

20.2.7.1.5.1. `MySqlHelper` Members

MySqlHelper overview

Public Static (Shared) Methods

ExecuteDataRow	Executes a single SQL statement and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.
ExecuteDataset	Overloaded. Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.
ExecuteNonQuery	Overloaded. Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.
ExecuteReader	Overloaded. Executes a single command against a MySQL database.
ExecuteScalar	Overloaded. Execute a single command against a MySQL database.
UpdateDataSet	Updates the given table with data from the given DataSet

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Typeof the current instance.
ToString(inherited from Object)	Returns a Stringthat represents the current Object.

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace

20.2.7.1.5.1.1. `MySqlHelper.ExecuteDataRow` Method

Executes a single SQL statement and returns the first row of the resultset. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Public Shared Function ExecuteDataRow( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray parms As MySqlParameter() _
) As DataRow
```

Syntax: C#

```
public static DataRow ExecuteDataRow(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]parms
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute
- `parms`: Parameters to use for the command

Return Value

DataRow containing the first row of the resultset

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace

20.2.7.1.5.1.2. ExecuteDataset Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

Overload List

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

- public static DataSet ExecuteDataset(MySqlConnection,string);

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

- public static DataSet ExecuteDataset(MySqlConnection,string,params MySqlParameter[]);

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- public static DataSet ExecuteDataset(string,string);

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

- public static DataSet ExecuteDataset(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace

20.2.7.1.5.1.2.1. `MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
MySqlConnectionconnection,
stringcommandText
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command to execute

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteDataset Overload List

20.2.7.1.5.1.2.2. `MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. The state of the MySqlConnection object remains unchanged after execution of this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
MySqlConnectionconnection,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteDataset Overload List

20.2.7.1.5.1.2.3. `MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connectionString As String, _
   ByVal commandText As String _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
stringconnectionString,
stringcommandText
);
```

Parameters

- `connectionString`: Settings to be used for the connection
- `commandText`: Command to execute

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteDataset Overload List

20.2.7.1.5.1.2.4. `MySqlHelper.ExecuteDataset` Method

Executes a single SQL statement and returns the resultset in a DataSet. A new MySqlConnection object is created, opened, and closed during this method.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteDataset( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As DataSet
```

Syntax: C#

```
public static DataSet ExecuteDataset(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connectionString`: Settings to be used for the connection

- `commandText`: Command to execute
- `commandParameters`: Parameters to use for the command

Return Value

DataSetcontaining the resultset

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteDataset Overload List

20.2.7.1.5.1.3. ExecuteNonQuery Method

Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.

Overload List

Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.

- public static int ExecuteNonQuery(MySqlConnection,string,params MySqlParameter[]);

Executes a single command against a MySQL database. A new MySqlConnection is created using the ConnectionString given.

- public static int ExecuteNonQuery(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace

20.2.7.1.5.1.3.1. `MySqlHelper.ExecuteNonQuery` Method

Executes a single command against a MySQL database. The MySqlConnection is assumed to be open when the method is called and remains open after the method completes.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As Integer
```

Syntax: C#

```
public static int ExecuteNonQuery(
MySqlConnectionconnection,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: SQL statement to be executed
- `commandParameters`: Array of MySqlParameter objects to use with the command.

Return Value

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteNonQuery Overload List

20.2.7.1.5.1.3.2. `MySqlHelper.ExecuteNonQuery` Method

Executes a single command against a MySQL database. A new MySqlConnection is created using the ConnectionString given.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteNonQuery( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray parms As MySqlParameter() _
) As Integer
```

Syntax: C#

```
public static int ExecuteNonQuery(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]parms
);
```

Parameters

- `connectionString`: ConnectionString to use
- `commandText`: SQL statement to be executed
- `parms`: Array of MySqlParameter objects to use with the command.

Return Value

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteNonQuery Overload List

20.2.7.1.5.1.4. ExecuteReader Method

Executes a single command against a MySQL database.

Overload List

Executes a single command against a MySQL database.

- public static MySqlDataReader ExecuteReader(string,string);

Executes a single command against a MySQL database.

- public static MySqlDataReader ExecuteReader(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace

20.2.7.1.5.1.4.1. `MySqlHelper.ExecuteReader` Method

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _
   ByVal connectionString As String, _
   ByVal commandText As String _
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(
stringconnectionString,
stringcommandText
);
```

Parameters

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use

Return Value

MySqlDataReader object ready to read the results of the command

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteReader Overload List

20.2.7.1.5.1.4.2. `MySqlHelper.ExecuteReader` Method

Executes a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteReader( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As MySqlDataReader
```

Syntax: C#

```
public static MySqlDataReader ExecuteReader(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connectionString`: Settings to use for this command
- `commandText`: Command text to use
- `commandParameters`: Array of MySqlParameter objects to use with the command

Return Value

MySqlDataReader object ready to read the results of the command

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteReader Overload List

20.2.7.1.5.1.5. ExecuteScalar Method

Execute a single command against a MySQL database.

Overload List

Execute a single command against a MySQL database.

- public static object ExecuteScalar(MySqlConnection,string);

Execute a single command against a MySQL database.

- public static object ExecuteScalar(MySqlConnection,string,params MySqlParameter[]);

Execute a single command against a MySQL database.

- public static object ExecuteScalar(string,string);

Execute a single command against a MySQL database.

- public static object ExecuteScalar(string,string,params MySqlParameter[]);

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace

20.2.7.1.5.1.5.1. `MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
MySqlConnectionconnection,
stringcommandText
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command text to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteScalar Overload List

20.2.7.1.5.1.5.2. `MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connection As MySqlConnection, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
MySqlConnectionconnection,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connection`: MySqlConnection object to use
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteScalar Overload List

20.2.7.1.5.1.5.3. `MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connectionString As String, _
   ByVal commandText As String _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
stringconnectionString,
stringcommandText
);
```

Parameters

- `connectionString`: Settings to use for the update
- `commandText`: Command text to use for the update

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteScalar Overload List

20.2.7.1.5.1.5.4. `MySqlHelper.ExecuteScalar` Method

Execute a single command against a MySQL database.

Syntax: Visual Basic

```
Overloads Public Shared Function ExecuteScalar( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ParamArray commandParameters As MySqlParameter() _
) As Object
```

Syntax: C#

```
public static object ExecuteScalar(
stringconnectionString,
stringcommandText,
   params MySqlParameter[]commandParameters
);
```

Parameters

- `connectionString`: Settings to use for the command
- `commandText`: Command text to use for the command
- `commandParameters`: Parameters to use for the command

Return Value

The first column of the first row in the result set, or a null reference if the result set is empty.

See Also

MySqlHelper Class , MySql.Data.MySqlClient Namespace , MySqlHelper.ExecuteScalar Overload List

20.2.7.1.5.1.6. `MySqlHelper.UpdateDataSet` Method

Updates the given table with data from the given DataSet

Syntax: Visual Basic

```
Public Shared Sub UpdateDataSet( _
   ByVal connectionString As String, _
   ByVal commandText As String, _
   ByVal ds As DataSet, _
   ByVal tablename As String _
)
```

Syntax: C#

```
public static void UpdateDataSet(
stringconnectionString,
stringcommandText,
DataSetds,
stringtablename
);
```

Parameters

- `connectionString`: Settings to use for the update

- `commandText`: Command text to use for the update
- `ds`: DataSetcontaining the new data to use in the update
- `tablename`: Tablename in the data set to update

See Also

MySqlConversionException overview

Public Instance Constructors

MySqlConversionException Constructor	Ctor

Public Instance Properties

Data(inherited from Exception)	Gets a collection of key/value pairs that provide additional, user-defined information about the exception.
HelpLink(inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException(inherited from Exception)	Gets the Exceptioninstance that caused the current exception.
Message(inherited from Exception)	Gets a message that describes the current exception.
Source(inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace(inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite(inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.

GetBaseException(inherited from Exception)	When overridden in a derived class, returns the Exceptionthat is the root cause of one or more subsequent exceptions.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData(inherited from Exception)	When overridden in a derived class, sets the SerializationInfowith information about the exception.
GetType(inherited from Exception)	Gets the runtime type of the current instance.
ToString(inherited from Exception)	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult(inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize(inherited from Object)	Allows an Objectto attempt to free resources and perform other cleanup operations before the Objectis reclaimed by garbage collection.
MemberwiseClone(inherited from Object)	Creates a shallow copy of the current Object.

20.2.7.2.3. `MySqlDateTime` Class

Summary description for MySqlDateTime.

For a list of all members of this type, see MySqlDateTime Members .

Syntax: Visual Basic

```
Public Class MySqlDateTime_
  Inherits MySqlValue_
  Implements IConvertible, IComparable
```

Syntax: C#

```
public class MySqlDateTime : MySqlValue, IConvertible, IComparable
```

Thread Safety

Public static (Shared in Visual Basic) members of this type are safe for multithreaded operations. Instance members are not guaranteed to be thread-safe.

Requirements

Namespace: MySql.Data.Types

Assembly: MySql.Data (in MySql.Data.dll)

See Also

MySqlDateTime Members , MySql.Data.Types Namespace

20.2.7.2.3.1. `MySqlDateTime` Members

MySqlDateTime overview

Public Static (Shared) Type Conversions

Explicit MySqlDateTime to DateTime Conversion	

Public Instance Properties

Day	Returns the day portion of this datetime
Hour	Returns the hour portion of this datetime
IsNull (inherited from MySqlValue)	
IsValidDateTime	Indicates if this object contains a value that can be represented as a DateTime
Minute	Returns the minute portion of this datetime
Month	Returns the month portion of this datetime
Second	Returns the second portion of this datetime
ValueAsObject (inherited from MySqlValue)	Returns the value of this field as an object
Year	Returns the year portion of this datetime

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetDateTime	Returns this value as a DateTime
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Typeof the current instance.
ToString	Returns a MySQL specific string representation of this value

Protected Instance Fields

classType (inherited from MySqlValue)	The system type represented by this value
dbType (inherited from MySqlValue)	The generic dbtype of this value
isNull (inherited from MySqlValue)	Is this value null
mySqlDbType (inherited from MySqlValue)	The specific MySQL db type
mySqlTypeName (inherited from MySqlValue)	The MySQL specific typename of this value

objectValue (inherited from MySqlValue)	

Protected Instance Methods

Finalize(inherited from Object)	Allows an Objectto attempt to free resources and perform other cleanup operations before the Objectis reclaimed by garbage collection.
MemberwiseClone(inherited from Object)	Creates a shallow copy of the current Object.

MySqlValue overview

Protected Static (Shared) Fields

numberFormat	

Public Instance Constructors

MySqlValue Constructor	Initializes a new instance of the MySqlValue class.

Public Instance Properties

IsNull	
ValueAsObject	Returns the value of this field as an object

Public Instance Methods

Equals(inherited from Object)	Determines whether the specified Objectis equal to the current Object.
GetHashCode(inherited from Object)	Serves as a hash function for a particular type. GetHashCodeis suitable for use in hashing algorithms and data structures like a hash table.
GetType(inherited from Object)	Gets the Typeof the current instance.
ToString	Returns a string representation of this value

Protected Instance Fields

classType	The system type represented by this value
dbType	The generic dbtype of this value
isNull	Is this value null
mySqlDbType	The specific MySQL db type
mySqlTypeName	The MySQL specific typename of this value
objectValue	

Protected Instance Methods

Finalize(inherited from Object)	Allows an Objectto attempt to free resources and perform other cleanup operations before the Objectis reclaimed by garbage collection.
MemberwiseClone(inherited from Object)	Creates a shallow copy of the current Object.

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.4.1.1.3. ValueAsObject Property

Returns the value of this field as an object

Syntax: Visual Basic

```
Public ReadOnly Property ValueAsObject As Object
```

Syntax: C#

```
public object ValueAsObject {get;}
```

See Also

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.4.1.1.4. `MySqlValue.ToString` Method

Returns a string representation of this value

Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

Syntax: C#

```
public override string ToString();
```

See Also

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.4.1.1.5. `MySqlValue.classType` Field

The system type represented by this value

Syntax: Visual Basic

```
Protected classType As Type
```

Syntax: C#

```
protected Type classType;
```

See Also

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.4.1.1.6. `MySqlValue.dbType` Field

The generic dbtype of this value

Syntax: Visual Basic

```
Protected dbType As DbType
```

Syntax: C#

```
protected DbType dbType;
```

See Also

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.4.1.1.7. `MySqlValue.mySqlDbType` Field

The specific MySQL db type

Syntax: Visual Basic

```
Protected mySqlDbType As MySqlDbType
```

Syntax: C#

```
protected MySqlDbType mySqlDbType;
```

See Also

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.4.1.1.8. `MySqlValue.mySqlTypeName` Field

The MySQL specific typename of this value

Syntax: Visual Basic

```
Protected mySqlTypeName As String
```

Syntax: C#

```
protected string mySqlTypeName;
```

See Also

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.4.1.1.9. `MySqlValue.objectValue` Field

```
Protected objectValue As Object
```

Syntax: C#

```
protected object objectValue;
```

See Also

MySqlValue Class , MySql.Data.Types Namespace

20.2.7.2.3.1.5. IsValidDateTime Property

Indicates if this object contains a value that can be represented as a DateTime

Syntax: Visual Basic

```
Public ReadOnly Property IsValidDateTime As Boolean
```

Syntax: C#

```
public bool IsValidDateTime {get;}
```

See Also

MySqlDateTime Class , MySql.Data.Types Namespace

20.2.7.2.3.1.6. Minute Property

Returns the minute portion of this datetime

Syntax: Visual Basic

```
Public Property Minute As Integer
```

Syntax: C#

```
public int Minute {get; set;}
```

See Also

MySqlDateTime Class , MySql.Data.Types Namespace

20.2.7.2.3.1.7. Month Property

Returns the month portion of this datetime

Syntax: Visual Basic

```
Public Property Month As Integer
```

Syntax: C#

```
public int Month {get; set;}
```

See Also

MySqlDateTime Class , MySql.Data.Types Namespace

20.2.7.2.3.1.8. Second Property

Returns the second portion of this datetime

Syntax: Visual Basic

```
Public Property Second As Integer
```

Syntax: C#

```
public int Second {get; set;}
```

See Also

MySqlDateTime Class , MySql.Data.Types Namespace

20.2.7.2.3.1.9. Year Property

Returns the year portion of this datetime

Syntax: Visual Basic

```
Public Property Year As Integer
```

Syntax: C#

```
public int Year {get; set;}
```

See Also

MySqlDateTime Class , MySql.Data.Types Namespace

20.2.7.2.3.1.10. `MySqlDateTime.GetDateTime` Method

Returns this value as a DateTime

Syntax: Visual Basic

```
Public Function GetDateTime() As Date
```

Syntax: C#

```
public DateTime GetDateTime();
```

See Also

MySqlDateTime Class , MySql.Data.Types Namespace

20.2.7.2.3.1.11. `MySqlDateTime.ToString` Method

Returns a MySQL specific string representation of this value

Syntax: Visual Basic

```
Overrides Public Function ToString() As String
```

Syntax: C#

```
public override string ToString();
```

See Also

20.2.8. Connector/NET Support

The developers of Connector/NET greatly value the input of our users in the software development process. If you find Connector/NET lacking some feature important to you, or if you discover a bug and need to file a bug report, please use the instructions in Section 1.7, “How to Report Bugs or Problems”.

20.2.8.1. Connector/NET Community Support

- Community support for Connector/NET can be found through the forums at http://forums.mysql.com.
- Community support for Connector/NET can also be found through the mailing lists at http://lists.mysql.com.
- Paid support is available from Sun Microsystems, Inc. Additional information is available at http://dev.mysql.com/support/.

20.2.8.2. How to report Connector/NET Problems or Bugs

If you encounter difficulties or problems with Connector/NET, contact the Connector/NET community Section 20.2.8.1, “Connector/NET Community Support”.

You should first try to execute the same SQL statements and commands from the `mysql` client program or from `admndemo`. This helps you determine whether the error is in Connector/NET or MySQL.

If reporting a problem, you should ideally include the following information with the email:

- Operating system and version
- Connector/NET version
- MySQL server version
- Copies of error messages or other unexpected output
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through http://bugs.mysql.com/.

20.2.8.3. Connector/NET Change History

The Connector/NET Change History (Changelog) is located with the main Changelog for MySQL. See Section C.4, "MySQL Connector/NET Change History".

20.2.9. Connector/NET FAQ

Questions

- 21.2.9.1: How do I obtain the value of an auto-incremented column?

Questions and Answers

21.2.9.1: How do I obtain the value of an auto-incremented column?

When using `CommandBuilder`, setting `ReturnGeneratedIdentifiers` property to `true` no longer works, as `CommandBuilder` does not add `last_insert_id()` by default.

CommandBuilder hooks up to the `DataAdapter.RowUpdating` event handler, which means it will get called for every row. It examines the command object and, if it is the same referenced object, it essentially rebuilds the object, thereby destroying your command text changes.

One approach to solving this problem is to clone the command object so you have a different actual reference:

```
dataAdapter.InsertCommand = cb.GetInsertCommand().Clone()
```

This will work, but since the CommandBuilder is still connected to the DataAdapter, the RowUpdating event will still fire and performance will be hit. To stop that, once all your commands have been added you need to disconnect the CommandBuilder from the DataAdapter:

```
cb.DataAdapter = null;
```

The last requirement is to make sure the `id` that is returned by `last_insert_id()` has the correct name. For example:

```
SELECT last_insert_id() AS id
```

A complete working example is shown here:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
```

```
namespace GetAutoIncId
{
    class Program
    {
        static void Main(string[] args)
        {
            string connStr = "server=localhost;user=root;database=TestDB;port=3306;password=******;";
            MySqlConnection conn = new MySqlConnection(connStr);

            try
            {
                Console.WriteLine("Connecting to MySQL...");
                conn.Open();

                string sql = "SELECT * FROM TestTable";

                MySqlDataAdapter da = new MySqlDataAdapter(sql, conn);
                MySqlCommandBuilder cb = new MySqlCommandBuilder(da);

                MySqlCommand cmd = new MySqlCommand();
                cmd.Connection = conn;
                cmd.CommandText = sql;
                // use Cloned object to avoid .NET rebuilding the object, and
                // thereby throwing away our command text additions.
                MySqlCommand insertCmd = cb.GetInsertCommand().Clone();
                insertCmd.CommandText = insertCmd.CommandText + ";SELECT last_insert_id() AS id";
                insertCmd.UpdatedRowSource = UpdateRowSource.FirstReturnedRecord;
                da.InsertCommand = insertCmd;
                cb.DataAdapter = null; // Unhook RowUpdating event handler

                DataTable dt = new DataTable();
                da.Fill(dt);

                DataRow row = dt.NewRow();
                row["name"] = "Joe Smith";

                dt.Rows.Add(row);
                da.Update(dt);

                System.Console.WriteLine("ID after update: " + row["id"]);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.ToString());
            }

            conn.Close();
            Console.WriteLine("Done.");
        }
    }
}
```

20.3. MySQL Connector/J

MySQL provides connectivity for client applications developed in the Java programming language via a JDBC driver, which is called MySQL Connector/J.

MySQL Connector/J is a JDBC Type 4 driver. Different versions are available that are compatible with the JDBC 3.0 and JDBC 4.0 specifications. The Type 4 designation means that the driver is pure-Java implementation of the MySQL protocol and does not rely on the MySQL client libraries.

Although JDBC is useful by itself, we would hope that if you are not familiar with JDBC that after reading the first few sections of this manual, that you would avoid using naked JDBC for all but the most trivial problems and consider using one of the popular persistence frameworks such as Hibernate, Spring's JDBC templates or Ibatis SQL Maps to do the majority of repetitive work and heavier lifting that is sometimes required with JDBC.

This section is not designed to be a complete JDBC tutorial. If you need more information about using JDBC you might be interested in the following online tutorials that are more in-depth than the information presented here:

- JDBC Basics: A tutorial from Sun covering beginner topics in JDBC
- JDBC Short Course: A more in-depth tutorial from Sun and JGuru

Key topics:

- For help with connection strings, connection options setting up your connection through JDBC, see Section 20.3.4.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”.
- For tips on using Connector/J and JDBC with generic J2EE toolkits, see Section 20.3.5.2, “Using Connector/J with J2EE and Other Java Frameworks”.
- Developers using the Tomcat server platform, see Section 20.3.5.2.2, “Using Connector/J with Tomcat”.
- Developers using JBoss, see Section 20.3.5.2.3, “Using Connector/J with JBoss”.
- Developers using Spring, see Section 20.3.5.2.4, “Using Connector/J with Spring”.

MySQL Enterprise
MySQL Enterprise subscribers will find more information about using JDBC with MySQL in the Knowledge Base articles about JDBC. Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

20.3.1. Connector/J Versions

There are currently four versions of MySQL Connector/J available:

- Connector/J 5.1 is the Type 4 pure Java JDBC driver, which conforms to the JDBC 3.0 and JDBC 4.0 specifications. It provides compatibility with all the functionality of MySQL, including 4.1, 5.0, 5.1, 5.4 and 5.5. Connector/J 5.1 provides ease of development features, including auto-registration with the Driver Manager, standardized validity checks, categorized SQLExceptions, support for the JDBC-4.0 XML processing, per connection client information, `NCHAR`, `NVARCHAR` and `NCLOB` types. This release also includes all bug fixes up to and including Connector/J 5.0.6.
- Connector/J 5.0 provides support for all the functionality offered by Connector/J 3.1 and includes distributed transaction (XA) support.
- Connector/J 3.1 was designed for connectivity to MySQL 4.1 and MySQL 5.0 servers and provides support for all the functionality in MySQL 5.0 except distributed transaction (XA) support.
- Connector/J 3.0 provides core functionality and was designed with connectivity to MySQL 3.x or MySQL 4.1 servers, although it will provide basic compatibility with later versions of MySQL. Connector/J 3.0 does not support server-side prepared statements, and does not support any of the features in versions of MySQL later than 4.1.

The following table summarizes the Connector/J versions available:

Connector/J version	Driver Type	JDBC version	MySQL Server version	Status
5.1	4	3.0, 4.0	4.1, 5.0, 5.1, 5.4, 5.5	Recommended version
5.0	4	3.0	4.1, 5.0	Released version
3.1	4	3.0	4.1, 5.0	Obsolete
3.0	4	3.0	3.x, 4.1	Obsolete

The current recommended version for Connector/J is 5.1. This guide covers all four connector versions, with specific notes given where a setting applies to a specific option.

20.3.1.1. Java Versions Supported

The following table summarizes Connector/J Java dependencies:

Connector/J version	Java RTE required	JDK required (to build source code)
5.1	1.4.x, 1.5.x, 1.6.x	1.6.x and 1.5.x (or older)
5.0	1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x

3.1	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x
3.0	1.2.x, 1.3.x, 1.4.x, 1.5.x, 1.6.x	1.4.2, 1.5.x, 1.6.x

MySQL Connector/J does not support JDK-1.1.x or JDK-1.0.x.

Because of the implementation of `java.sql.Savepoint`, Connector/J 3.1.0 and newer will not run on a Java runtime older than 1.4 unless the class verifier is turned off (by setting the `-Xverify:none` option to the Java runtime). This is because the class verifier will try to load the class definition for `java.sql.Savepoint` even though it is not accessed by the driver unless you actually use savepoint functionality.

Caching functionality provided by Connector/J 3.1.0 or newer is also not available on JVMs older than 1.4.x, as it relies on `java.util.LinkedHashMap` which was first available in JDK-1.4.0.

If you are building Connector/J from source code using the source distribution (see Section 20.3.2.4, "Installing from the Development Source Tree") then you must use JDK 1.4.2 or newer to compile the Connector package. For Connector/J 5.1 you must have both JDK-1.6.x. and JDK-1.5.x installed in order to be able to build the source code.

20.3.2. Connector/J Installation

You can install the Connector/J package using either the binary or source distribution. The binary distribution provides the easiest method for installation; the source distribution enables you to customize your installation further. With either solution, you must manually add the Connector/J location to your Java `CLASSPATH`.

If you are upgrading from a previous version, read the upgrade information before continuing. See Section 20.3.2.3, "Upgrading from an Older Version".

Connector/J is also available as part of the Maven project. More information, and the Connector/J JAR files can be found at the Maven repository.

20.3.2.1. Installing Connector/J from a Binary Distribution

The easiest method of installation is to use the binary distribution of the Connector/J package. The binary distribution is available either as a Tar/Gzip or Zip file which you must extract to a suitable location and then optionally make the information about the package available by changing your `CLASSPATH` (see Section 20.3.2.2, "Installing the Driver and Configuring the `CLASSPATH`").

MySQL Connector/J is distributed as a .zip or .tar.gz archive containing the sources, the class files, and the JAR archive named `mysql-connector-java-[version]-bin.jar`, and starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar`.

Starting with Connector/J 3.1.9, the `.class` files that constitute the JAR files are only included as part of the driver JAR file.

You should not use the debug build of the driver unless instructed to do so when reporting a problem or a bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the Aspect/J runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

You will need to use the appropriate graphical or command-line utility to extract the distribution (for example, WinZip for the .zip archive, and `tar` for the .tar.gz archive). Because there are potentially long file names in the distribution, we use the GNU tar archive format. You will need to use GNU tar (or an application that understands the GNU tar archive format) to unpack the .tar.gz variant of the distribution.

20.3.2.2. Installing the Driver and Configuring the `CLASSPATH`

Once you have extracted the distribution archive, you can install the driver by placing `mysql-connector-java-[version]-bin.jar` in your classpath, either by adding the full path to it to your `CLASSPATH` environment variable, or by directly specifying it with the command line switch -cp when starting your JVM.

If you are going to use the driver with the JDBC DriverManager, you would use `com.mysql.jdbc.Driver` as the class that implements `java.sql.Driver`.

You can set the `CLASSPATH` environment variable under UNIX, Linux or Mac OS X either locally for a user within their `.profile`, `.login` or other login file. You can also set it globally by editing the global `/etc/profile` file.

For example, under a C shell (csh, tcsh) you would add the Connector/J driver to your `CLASSPATH` using the following:

```
shell> setenv CLASSPATH /path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Or with a Bourne-compatible shell (sh, ksh, bash):

```
shell> export set CLASSPATH=/path/mysql-connector-java-[ver]-bin.jar:$CLASSPATH
```

Within Windows 2000, Windows XP, Windows Server 2003 and Windows Vista, you must set the environment variable through the System Control Panel.

If you want to use MySQL Connector/J with an application server such as GlassFish, Tomcat or JBoss, you will have to read your vendor's documentation for more information on how to configure third-party class libraries, as most application servers ignore the `CLASSPATH` environment variable. For configuration examples for some J2EE application servers, see Section 20.3.5.2, "Using Connector/J with J2EE and Other Java Frameworks". However, the authoritative source for JDBC connection pool configuration information for your particular application server is the documentation for that application server.

If you are developing servlets or JSPs, and your application server is J2EE-compliant, you can put the driver's .jar file in the WEB-INF/lib subdirectory of your webapp, as this is a standard location for third party class libraries in J2EE web applications.

You can also use the `MysqlDataSource` or `MysqlConnectionPoolDataSource` classes in the `com.mysql.jdbc.jdbc2.optional` package, if your J2EE application server supports or requires them. Starting with Connector/J 5.0.0, the `javax.sql.XADataSource` interface is implemented via the `com.mysql.jdbc.jdbc2.optional.MysqlXADataSource` class, which supports XA distributed transactions when used in combination with MySQL server version 5.0.

The various `MysqlDataSource` classes support the following parameters (through standard set mutators):

- user
- password
- serverName (see the previous section about fail-over hosts)
- databaseName
- port

20.3.2.3. Upgrading from an Older Version

We try to keep the upgrade process as easy as possible, however as is the case with any software, sometimes changes need to be made in new versions to support new features, improve existing functionality, or comply with new standards.

This section has information about what users who are upgrading from one version of Connector/J to another (or to a new version of the MySQL server, with respect to JDBC functionality) should be aware of.

20.3.2.3.1. Upgrading from MySQL Connector/J 3.0 to 3.1

Connector/J 3.1 is designed to be backward-compatible with Connector/J 3.0 as much as possible. Major changes are isolated to new functionality exposed in MySQL-4.1 and newer, which includes Unicode character sets, server-side prepared statements, SQLState codes returned in error messages by the server and various performance enhancements that can be enabled or disabled via configuration properties.

- **Unicode Character Sets**: See the next section, as well as Section 9.1, "Character Set Support", for information on this new feature of MySQL. If you have something misconfigured, it will usually show up as an error with a message similar to `Illegal mix of collations`.
- **Server-side Prepared Statements**: Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer).

  Starting with version 3.1.7, the driver scans SQL you are preparing via all variants of `Connection.prepareStatement()` to determine if it is a supported type of statement to prepare on the server side, and if it is not supported by the server, it instead prepares it as a client-side emulated prepared statement. You can disable this feature by passing emulateUnsupportedPstmts=false in your JDBC URL.

If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the connection property useServerPrepStmts=false

- **Datetimes** with all-zero components (`0000-00-00 ...`): These values can not be represented reliably in Java. Connector/J 3.0.x always converted them to `NULL` when being read from a ResultSet.

  Connector/J 3.1 throws an exception by default when these values are encountered as this is the most correct behavior according to the JDBC and SQL standards. This behavior can be modified using the zeroDateTimeBehavior configuration property. The allowable values are:

  - `exception` (the default), which throws an SQLException with an SQLState of `S1009`.
  - `convertToNull`, which returns `NULL` instead of the date.
  - `round`, which rounds the date to the nearest closest value which is `0001-01-01`.

  Starting with Connector/J 3.1.7, `ResultSet.getString()` can be decoupled from this behavior via noDatetimeStringSync=true (the default value is `false`) so that you can retrieve the unaltered all-zero value as a String. It should be noted that this also precludes using any time zone conversions, therefore the driver will not allow you to enable noDatetimeStringSync and useTimezone at the same time.

- **New SQLState Codes**: Connector/J 3.1 uses SQL:1999 SQLState codes returned by the MySQL server (if supported), which are different from the legacy X/Open state codes that Connector/J 3.0 uses. If connected to a MySQL server older than MySQL-4.1.0 (the oldest version to return SQLStates as part of the error code), the driver will use a built-in mapping. You can revert to the old mapping by using the configuration property useSqlStateCodes=false.

- **`ResultSet.getString()`**: Calling `ResultSet.getString()` on a `BLOB` column will now return the address of the `byte[]` array that represents it, instead of a `String` representation of the `BLOB`. `BLOB` values have no character set, so they cannot be converted to `java.lang.String`s without data loss or corruption.

  To store strings in MySQL with LOB behavior, use one of the `TEXT` types, which the driver will treat as a `java.sql.Clob`.

- **Debug builds**: Starting with Connector/J 3.1.8 a debug build of the driver in a file named `mysql-connector-java-[version]-bin-g.jar` is shipped alongside the normal binary jar file that is named `mysql-connector-java-[version]-bin.jar`.

  Starting with Connector/J 3.1.9, we do not ship the .class files unbundled, they are only available in the JAR archives that ship with the driver.

  You should not use the debug build of the driver unless instructed to do so when reporting a problem or bug, as it is not designed to be run in production environments, and will have adverse performance impact when used. The debug binary also depends on the AspectJ runtime library, which is located in the `src/lib/aspectjrt.jar` file that comes with the Connector/J distribution.

20.3.2.3.2. Upgrading to MySQL Connector/J 5.1.x

- In Connector/J 5.0.x and earlier, the alias for a table in a `SELECT` statement is returned when accessing the result set metadata using `ResultSetMetaData.getColumnName()`. This behavior however is not JDBC compliant, and in Connector/J 5.1 this behavior was changed so that the original table name, rather than the alias, is returned.

  The JDBC-compliant behavior is designed to let API users reconstruct the DML statement based on the metadata within `ResultSet` and `ResultSetMetaData`.

  You can get the alias for a column in a result set by calling `ResultSetMetaData.getColumnLabel()`. If you want to use the old noncompliant behavior with `ResultSetMetaData.getColumnName()`, use the `useOldAliasMetadataBehavior` option and set the value to `true`.

  In Connector/J 5.0.x the default value of `useOldAliasMetadataBehavior` was true, but in Connector/J 5.1 this was changed to a default value of false.

20.3.2.3.3. JDBC-Specific Issues When Upgrading to MySQL Server 4.1 or Newer

- *Using the UTF-8 Character Encoding* - Prior to MySQL server version 4.1, the UTF-8 character encoding was not supported by the server, however the JDBC driver could use it, allowing storage of multiple character sets in latin1 tables on the server.

  Starting with MySQL-4.1, this functionality is deprecated. If you have applications that rely on this functionality, and can not upgrade them to use the official Unicode character support in MySQL server version 4.1 or newer, you should add the following property to your connection URL:

  ```
  useOldUTF8Behavior=true
  ```

- *Server-side Prepared Statements* - Connector/J 3.1 will automatically detect and use server-side prepared statements when they are available (MySQL server version 4.1.0 and newer). If your application encounters issues with server-side prepared statements, you can revert to the older client-side emulated prepared statement code that is still presently used for MySQL servers older than 4.1.0 with the following connection property:

  ```
  useServerPrepStmts=false
  ```

20.3.2.4. Installing from the Development Source Tree

> **Caution**
>
> You should read this section only if you are interested in helping us test our new code. If you just want to get MySQL Connector/J up and running on your system, you should use a standard binary release distribution.

To install MySQL Connector/J from the development source tree, make sure that you have the following prerequisites:

- A Bazaar client, to check out the sources from our Launchpad repository (available from http://bazaar-vcs.org/).
- Apache Ant version 1.7 or newer (available from http://ant.apache.org/).
- JDK 1.4.2 or later. Although MySQL Connector/J can be be used with older JDKs, to compile it from source you must have at least JDK 1.4.2. If you are building Connector/J 5.1 you will need JDK 1.6.x and an older JDK such as JDK 1.5.x. You will then need to point your JAVA_HOME environment variable at the older installation.

The source code repository for MySQL Connector/J is located on Launchpad at https://code.launchpad.net/connectorj.

To check out and compile a specific branch of MySQL Connector/J, follow these steps:

1. Check out the latest code from the branch that you want with one of the following commands.

   To check out the latest development branch use:

   ```
   shell> bzr branch lp:connectorj
   ```

   This creates a `connectorj` subdirectory in the current directory that contains the latest sources for the requested branch.

   To check out the latest 5.1 code use:

   ```
   shell> bzr branch lp:connectorj/5.1
   ```

   This will create a `5.1` subdirectory in the current directory containing the latest 5.1 code.

2. If you are building Connector/J 5.1 make sure that you have both JDK 1.6.x installed and an older JDK such as JDK 1.5.x. This is because Connector/J supports both JDBC 3.0 (which was prior to JDK 1.6.x) and JDBC 4.0. Set your JAVA_HOME environment variable to the path of the older JDK installation.

3. Change location to either the `connectorj` or `5.1` directory, depending on which branch you want to build, to make it your current working directory. For example:

   ```
   shell> cd connectorj
   ```

4. If you are building Connector/J 5.1 you need to edit the `build.xml` to reflect the location of your JDK 1.6.x installation. The

lines that you need to change are:

```
            <property name="com.mysql.jdbc.java6.javac" value="C:\jvms\jdk1.6.0\bin\javac.exe" />
            <property name="com.mysql.jdbc.java6.rtjar" value="C:\jvms\jdk1.6.0\jre\lib\rt.jar" />
```

Alternatively, you can set the value of these property names through the Ant `-D` option.

5. Issue the following command to compile the driver and create a `.jar` file suitable for installation:

```
shell> ant dist
```

This creates a `build` directory in the current directory, where all build output will go. A directory is created in the `build` directory that includes the version number of the sources you are building from. This directory contains the sources, compiled `.class` files, and a `.jar` file suitable for deployment. For other possible targets, including ones that will create a fully packaged distribution, issue the following command:

```
shell> ant -projecthelp
```

6. A newly created `.jar` file containing the JDBC driver will be placed in the directory `build/mysql-connector-java-[version]`.

   Install the newly created JDBC driver as you would a binary `.jar` file that you download from MySQL by following the instructions in Section 20.3.2.2, “Installing the Driver and Configuring the CLASSPATH”.

A package containing both the binary and source code for Connector/J 5.1 can also be found at the following location: Connector/J 5.1 Download

20.3.3. Connector/J Examples

Examples of using Connector/J are located throughout this document, this section provides a summary and links to these examples.

- Example 20.1, “Connector/J: Obtaining a connection from the `DriverManager`”
- Example 20.2, “Connector/J: Using java.sql.Statement to execute a `SELECT` query”
- Example 20.3, “Connector/J: Calling Stored Procedures”
- Example 20.4, “Connector/J: Using `Connection.prepareCall()`”
- Example 20.5, “Connector/J: Registering output parameters”
- Example 20.6, “Connector/J: Setting `CallableStatement` input parameters”
- Example 20.7, “Connector/J: Retrieving results and output parameter values”
- Example 20.8, “Connector/J: Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`”
- Example 20.9, “Connector/J: Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`”
- Example 20.10, “Connector/J: Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`”
- Example 20.11, “Connector/J: Using a connection pool with a J2EE application server”
- Example 20.12, “Connector/J: Example of transaction with retry logic”

20.3.4. Connector/J (JDBC) Reference

This section of the manual contains reference material for MySQL Connector/J, some of which is automatically generated during the Connector/J build process.

20.3.4.1. Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J

The name of the class that implements java.sql.Driver in MySQL Connector/J is `com.mysql.jdbc.Driver`. The `org.gjt.mm.mysql.Driver` class name is also usable to remain backward-compatible with MM.MySQL. You should use this class name when registering the driver, or when otherwise configuring software to use MySQL Connector/J.

The JDBC URL format for MySQL Connector/J is as follows, with items in square brackets ([,]) being optional:

```
jdbc:mysql://[host][,failoverhost...][:port]/[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

If the host name is not specified, it defaults to 127.0.0.1. If the port is not specified, it defaults to 3306, the default port number for MySQL servers.

```
jdbc:mysql://[host:port],[host:port].../[database] »
[?propertyName1][=propertyValue1][&propertyName2][=propertyValue2]...
```

If the database is not specified, the connection will be made with no default database. In this case, you will need to either call the `setCatalog()` method on the Connection instance or fully specify table names using the database name (that is, `SELECT dbname.tablename.colname FROM dbname.tablename...`) in your SQL. Not specifying the database to use upon connection is generally only useful when building tools that work with multiple databases, such as GUI database managers.

MySQL Connector/J has fail-over support. This allows the driver to fail-over to any number of slave hosts and still perform read-only queries. Fail-over only happens when the connection is in an `autoCommit(true)` state, because fail-over can not happen reliably when a transaction is in progress. Most application servers and connection pools set `autoCommit` to `true` at the end of every transaction/connection use.

The fail-over functionality has the following behavior:

- If the URL property autoReconnect is false: Failover only happens at connection initialization, and failback occurs when the driver determines that the first host has become available again.
- If the URL property autoReconnect is true: Failover happens when the driver determines that the connection has failed (before *every* query), and falls back to the first host when it determines that the host has become available again (after `queriesBeforeRetryMaster` queries have been issued).

In either case, whenever you are connected to a "failed-over" server, the connection will be set to read-only state, so queries that would modify data will have exceptions thrown (the query will **never** be processed by the MySQL server).

Configuration properties define how Connector/J will make a connection to a MySQL server. Unless otherwise noted, properties can be set for a DataSource object or for a Connection object.

Configuration Properties can be set in one of the following ways:

- Using the set*() methods on MySQL implementations of java.sql.DataSource (which is the preferred method when using implementations of java.sql.DataSource):
  - com.mysql.jdbc.jdbc2.optional.MysqlDataSource
  - com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource
- As a key/value pair in the java.util.Properties instance passed to `DriverManager.getConnection()` or `Driver.connect()`
- As a JDBC URL parameter in the URL given to `java.sql.DriverManager.getConnection()`, `java.sql.Driver.connect()` or the MySQL implementations of the `javax.sql.DataSource` `setURL()` method.

> **Note**
>
> If the mechanism you use to configure a JDBC URL is XML-based, you will need to use the XML character literal & to separate configuration parameters, as the ampersand is a reserved character for XML.

The properties are listed in the following tables.

Connection/Authentication.

Property Name	Definition	Default Value	Since Version
user	The user to connect as		all versions
password	The password to use when connecting		all versions
socketFactory	The name of the class that the driver should use for creating socket connections to the server. This class must implement the interface 'com.mysql.jdbc.SocketFactory' and have public no-args constructor.	com.mysql.jdbc.StandardSocketFactory	3.0.3
connectTimeout	Timeout for socket connect (in milliseconds), with 0 being no timeout. Only works on JDK-1.4 or newer. Defaults to '0'.	0	3.0.1
socketTimeout	Timeout on network socket operations (0, the default means no timeout).	0	3.0.1
connectionLifecycleInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.ConnectionLifecycleInterceptor" that should notified of connection lifecycle events (creation, destruction, commit, rollback, setCatalog and setAutoCommit) and potentially alter the execution of these commands. ConnectionLifecycleInterceptors are "stackable", more than one interceptor may be specified via the configuration property as a comma-delimited list, with the interceptors executed in order from left to right.		5.1.4
useConfigs	Load the comma-delimited list of configuration properties before parsing the URL or applying user-specified properties. These configurations are explained in the 'Configurations' of the documentation.		3.1.5
interactiveClient	Set the CLIENT_INTERACTIVE flag, which tells MySQL to timeout connections based on INTERACTIVE_TIMEOUT instead of WAIT_TIMEOUT	false	3.1.0
localSocketAddress	Hostname or IP address given to explicitly configure the interface that the driver will bind the client side of the TCP/IP connection to when connecting.		5.0.5
propertiesTransform	An implementation of com.mysql.jdbc.ConnectionPropertiesTransform that the driver will use to modify URL properties passed to the driver before attempting a connection		3.1.4
useCompression	Use zlib compression when communicating with the server (true/false)? Defaults to 'false'.	false	3.0.17

Networking.

Property Name	Definition	Default Value	Since Version
maxAllowedPacket	Maximum allowed packet size to send to server. If not set, the value of system variable 'max_allowed_packet' will be used to initialize this upon connecting. This value will not take effect if set larger than the value of 'max_allowed_packet'.	-1	5.1.8
tcpKeepAlive	If connecting using TCP/IP, should the driver set SO_KEEPALIVE?	true	5.0.7
tcpNoDelay	If connecting using TCP/IP, should the driver set SO_TCP_NODELAY (disabling the Nagle Algorithm)?	true	5.0.7
tcpRcvBuf	If connecting using TCP/IP, should the driver set SO_RCV_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7

tcpSndBuf	If connecting using TCP/IP, shuold the driver set SO_SND_BUF to the given value? The default value of '0', means use the platform default value for this property)	0	5.0.7
tcpTrafficClass	If connecting using TCP/IP, should the driver set traffic class or type-of-service fields ?See the documentation for java.net.Socket.setTrafficClass() for more information.	0	5.0.7

High Availability and Clustering.

Property Name	Definition	Default Value	Since Version
autoReconnect	Should the driver try to re-establish stale and/or dead connections? If enabled the driver will throw an exception for a queries issued on a stale or dead connection, which belong to the current transaction, but will attempt reconnect before the next query issued on the connection in a new transaction. The use of this feature is not recommended, because it has side effects related to session state and data consistency when applications don't handle SQLExceptions properly, and is only designed to be used when you are unable to configure your application to handle SQLExceptions resulting from dead and stale connections properly. Alternatively, investigate setting the MySQL server variable "wait_timeout" to some high value rather than the default of 8 hours.	false	1.1
autoReconnectForPools	Use a reconnection strategy appropriate for connection pools (defaults to 'false')	false	3.1.3
failOverReadOnly	When failing over in autoReconnect mode, should the connection be set to 'read-only'?	true	3.0.12
maxReconnects	Maximum number of reconnects to attempt if autoReconnect is true, default is '3'.	3	1.1
reconnectAtTxEnd	If autoReconnect is set to true, should the driver attempt reconnections at the end of every transaction?	false	3.0.10
retriesAllDown	When using loadbalancing, the number of times the driver should cycle through available hosts, attempting to connect. Between cycles, the driver will pause for 250ms if no servers are available.	120	5.1.6
initialTimeout	If autoReconnect is enabled, the initial time to wait between reconnect attempts (in seconds, defaults to '2').	2	1.1
roundRobinLoadBalance	When autoReconnect is enabled, and failoverReadonly is false, should we pick hosts to connect to on a round-robin basis?	false	3.1.2
queriesBeforeRetryMaster	Number of queries to issue before falling back to master when failed over (when using multi-host failover). Whichever condition is met first, 'queriesBeforeRetryMaster' or 'secondsBeforeRetryMaster' will cause an attempt to be made to reconnect to the master. Defaults to 50.	50	3.0.2
secondsBeforeRetryMaster	How long should the driver wait, when failed over, before attempting	30	3.0.2
selfDestructOnPingMaxOperations	=If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connnection's count of commands sent to the server exceeds this value.	0	5.1.6
selfDestructOnPingSecondsLifetime	If set to a non-zero value, the driver will report close the connection and report failure when Connection.ping() or Connection.isValid(int) is called if the connnection's lifetime exceeds this value.	0	5.1.6
resourceId	A globally unique name that identifies the resource that this datasource or connection is connected to, used for XAResource.isSameRM() when the driver can't determine this value based on hostnames used in the URL		5.0.1

Security.

Property Name	Definition	Default Value	Since Version
allowMultiQueries	Allow the use of ';' to delimit multiple queries during one statement (true/false), defaults to 'false'	false	3.1.1
useSSL	Use SSL when communicating with the server (true/false), defaults to 'false'	false	3.0.2
requireSSL	Require SSL connection if useSSL=true? (defaults to 'false').	false	3.1.0
verifyServerCertificate	If "useSSL" is set to "true", should the driver verify the server's certificate? When using this feature, the keystore parameters should be specified by the "clientCertificateKeyStore*" properties, rather than system properties.	true	5.1.6
clientCertificateKeyStoreUrl	URL to the client certificate KeyStore (if not specified, use defaults)		5.1.0
clientCertificateKeyStoreType	KeyStore type for client certificates (NULL or empty means use default, standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		5.1.0
clientCertificateKeyStorePassword	Password for the client certificates KeyStore		5.1.0
trustCertificateKeyStoreUrl	URL to the trusted root certificate KeyStore (if not specified, use defaults)		5.1.0
trustCertificateKeyStoreType	KeyStore type for trusted root certificates (NULL or empty means use default, standard keystore types supported by the JVM are "JKS" and "PKCS12", your environment may have more available depending on what security products are installed and available to the JVM.		5.1.0
trustCertificateKeyStorePassword	Password for the trusted root certificates KeyStore		5.1.0
allowLoadLocalInfile	Should the driver allow use of 'LOAD DATA LOCAL INFILE...' (defaults to 'true').	true	3.0.3
allowUrlInLocalInfile	Should the driver allow URLs in 'LOAD DATA LOCAL INFILE' statements?	false	3.1.4
paranoid	Take measures to prevent exposure sensitive information in error messages and clear data structures holding sensitive data when possible? (defaults to 'false')	false	3.0.1
passwordCharacterEncoding	What character encoding is used for passwords? Leaving this set to the default value (null), uses the platform character set, which works for ISO8859_1 (i.e. "latin1") passwords. For passwords in other character encodings, the encoding will have to be specified with this property, as it's not possible for the driver to auto-detect this.		5.1.7

Performance Extensions.

Property Name	Definition	Default Value	Since Version
callableStmtCacheSize	If 'cacheCallableStmts' is enabled, how many callable statements should be cached?	100	3.1.2
metadataCacheSize	The number of queries to cache ResultSetMetadata for if cacheResultSetMetaData is set to 'true' (default 50)	50	3.1.1
useLocalSessionState	Should the driver refer to the internal values of autocommit and transaction isolation that are set by Connection.setAutoCommit() and Connection.setTransactionIsolation() and transaction state as maintained by the protocol, rather than querying the database or blindly sending commands to the database for commit() or roll-	false	3.1.7

	back() method calls?		
useLocalTransactionState	Should the driver use the in-transaction state provided by the MySQL protocol to determine if a commit() or rollback() should actually be sent to the database?	false	5.1.7
prepStmtCacheSize	If prepared statement caching is enabled, how many prepared statements should be cached?	25	3.0.10
prepStmtCacheSqlLimit	If prepared statement caching is enabled, what's the largest SQL the driver will cache the parsing for?	256	3.0.10
alwaysSendSetIsolation	Should the driver always communicate with the database when Connection.setTransactionIsolation() is called? If set to false, the driver will only communicate with the database when the requested transaction isolation is different than the whichever is newer, the last value that was set via Connection.setTransactionIsolation(), or the value that was read from the server when the connection was established.	true	3.1.7
maintainTimeStats	Should the driver maintain various internal timers to enable idle time calculations as well as more verbose error messages when the connection to the server fails? Setting this property to false removes at least two calls to System.getCurrentTimeMillis() per query.	true	3.1.9
useCursorFetch	If connected to MySQL > 5.0.2, and setFetchSize() > 0 on a statement, should that statement use cursor-based fetching to retrieve rows?	false	5.0.0
blobSendChunkSize	Chunk to use when sending BLOB/CLOBs via ServerPreparedStatements	1048576	3.1.9
cacheCallableStmts	Should the driver cache the parsing stage of CallableStatements	false	3.1.2
cachePrepStmts	Should the driver cache the parsing stage of PreparedStatements of client-side prepared statements, the "check" for suitability of server-side prepared and server-side prepared statements themselves?	false	3.0.10
cacheResultSetMetadata	Should the driver cache ResultSetMetaData for Statements and PreparedStatements? (Req. JDK-1.4+, true/false, default 'false')	false	3.1.1
cacheServerConfiguration	Should the driver cache the results of 'SHOW VARIABLES' and 'SHOW COLLATION' on a per-URL basis?	false	3.1.5
defaultFetchSize	The driver will call setFetchSize(n) with this value on all newly-created Statements	0	3.1.9
dontTrackOpenResources	The JDBC specification requires the driver to automatically track and close resources, however if your application doesn't do a good job of explicitly calling close() on statements or result sets, this can cause memory leakage. Setting this property to true relaxes this constraint, and can be more memory efficient for some applications.	false	3.1.7
dynamicCalendars	Should the driver retrieve the default calendar when required, or cache it per connection/session?	false	3.1.5
elideSetAutoCommits	If using MySQL-4.1 or newer, should the driver only issue 'set autocommit=n' queries when the server's state doesn't match the requested state by Connection.setAutoCommit(boolean)?	false	3.1.3
enableQueryTimeouts	When enabled, query timeouts set via Statement.setQueryTimeout() use a shared java.util.Timer instance for scheduling. Even if the timeout doesn't expire before the query is processed, there will be memory used by the TimerTask for the given timeout which won't be reclaimed until the time the timeout would have expired if it hadn't been cancelled by the driver. High-load environments might want to consider disabling this functionality.	true	5.0.6
holdResultsOpenOverStatementClose	Should the driver leave the result sets open on Statement.close() (enabling violates JDBC specification)	false	3.1.7

largeRowSizeThreshold	What size result set row should the JDBC driver consider "large", and thus use a more memory-efficient way of representing the row internally?	2048	5.1.1
loadBalanceStrategy	If using a load-balanced connection to connect to SQL nodes in a MySQL Cluster/NDB configuration (by using the URL prefix "jdbc:mysql:loadbalance://"), which load balancing algorithm should the driver use: (1) "random" - the driver will pick a random host for each request. This tends to work better than round-robin, as the randomness will somewhat account for spreading loads where requests vary in response time, while round-robin can sometimes lead to overloaded nodes if there are variations in response times across the workload. (2) "bestResponseTime" - the driver will route the request to the host that had the best response time for the previous transaction.	random	5.0.6
locatorFetchBufferSize	If 'emulateLocators' is configured to 'true', what size buffer should be used when fetching BLOB data for getBinaryInputStream?	1048576	3.2.1
rewriteBatchedStatements	Should the driver use multiqueries (irregardless of the setting of "allowMultiQueries") as well as rewriting of prepared statements for INSERT into multi-value inserts when executeBatch() is called? Notice that this has the potential for SQL injection if using plain java.sql.Statements and your code doesn't sanitize input correctly. Notice that for prepared statements, server-side prepared statements can not currently take advantage of this rewrite option, and that if you don't specify stream lengths when using PreparedStatement.set*Stream(), the driver won't be able to determine the optimum number of parameters per batch and you might receive an error from the driver that the resultant packet is too large. Statement.getGeneratedKeys() for these rewritten statements only works when the entire batch includes INSERT statements.	false	3.1.13
useDirectRowUnpack	Use newer result set row unpacking code that skips a copy from network buffers to a MySQL packet instance and instead reads directly into the result set row data buffers.	true	5.1.1
useDynamicCharsetInfo	Should the driver use a per-connection cache of character set information queried from the server when necessary, or use a built-in static mapping that is more efficient, but isn't aware of custom character sets or character sets implemented after the release of the JDBC driver?	true	5.0.6
useFastDateParsing	Use internal String->Date/Time/Timestamp conversion routines to avoid excessive object creation?	true	5.0.5
useFastIntParsing	Use internal String->Integer conversion routines to avoid excessive object creation?	true	3.1.4
useJvmCharsetConverters	Always use the character encoding routines built into the JVM, rather than using lookup tables for single-byte character sets?	false	5.0.1
useReadAheadInput	Use newer, optimized non-blocking, buffered input stream when reading from the server?	true	3.1.5

Debugging/Profiling.

Property Name	**Definition**	**Default Value**	**Since Version**
logger	The name of a class that implements "com.mysql.jdbc.log.Log" that will be used to log messages to. (default is "com.mysql.jdbc.log.StandardLogger", which logs to STDERR)	com.mysql.jdbc.log.StandardLogger	3.1.1
gatherPerfMetrics	Should the driver gather performance metrics, and report them via the configured logger every 'reportMetricsIntervalMillis' milliseconds?	false	3.1.2
profileSQL	Trace queries and their execution/fetch times to the configured	false	3.1.0

	logger (true/false) defaults to 'false'		
profileSql	Deprecated, use 'profileSQL' instead. Trace queries and their execution/fetch times on STDERR (true/false) defaults to 'false'		2.0.14
reportMetricsIntervalMillis	If 'gatherPerfMetrics' is enabled, how often should they be logged (in ms)?	30000	3.1.2
maxQuerySizeToLog	Controls the maximum length/size of a query that will get logged when profiling or tracing	2048	3.1.3
packetDebugBufferSize	The maximum number of packets to retain when 'enablePacketDebug' is true	20	3.1.3
slowQueryThresholdMillis	If 'logSlowQueries' is enabled, how long should a query (in ms) before it is logged as 'slow'?	2000	3.1.2
slowQueryThresholdNanos	If 'useNanosForElapsedTime' is set to true, and this property is set to a non-zero value, the driver will use this threshold (in nanosecond units) to determine if a query was slow.	0	5.0.7
useUsageAdvisor	Should the driver issue 'usage' warnings advising proper and efficient usage of JDBC and MySQL Connector/J to the log (true/false, defaults to 'false')?	false	3.1.1
autoGenerateTestcaseScript	Should the driver dump the SQL it is executing, including server-side prepared statements to STDERR?	false	3.1.9
autoSlowLog	Instead of using slowQueryThreshold* to determine if a query is slow enough to be logged, maintain statistics that allow the driver to determine queries that are outside the 99th percentile?	true	5.1.4
clientInfoProvider	The name of a class that implements the com.mysql.jdbc.JDBC4ClientInfoProvider interface in order to support JDBC-4.0's Connection.get/setClientInfo() methods	com.mysql.jdbc.JDBC4CommentClientInfoProvider	5.1.0
dumpMetadataOnColumnNotFound	Should the driver dump the field-level metadata of a result set into the exception message when ResultSet.findColumn() fails?	false	3.1.13
dumpQueriesOnException	Should the driver dump the contents of the query sent to the server in the message for SQLExceptions?	false	3.1.3
enablePacketDebug	When enabled, a ring-buffer of 'packetDebugBufferSize' packets will be kept, and dumped when exceptions are thrown in key areas in the driver's code	false	3.1.3
explainSlowQueries	If 'logSlowQueries' is enabled, should the driver automatically issue an 'EXPLAIN' on the server and send the results to the configured log at a WARN level?	false	3.1.2
includeInnodbStatusInDeadlockExceptions	Include the output of "SHOW ENGINE INNODB STATUS" in exception messages when deadlock exceptions are detected?	false	5.0.7
logSlowQueries	Should queries that take longer than 'slowQueryThresholdMillis' be logged?	false	3.1.2
logXaCommands	Should the driver log XA commands sent by MysqlXaConnection to the server, at the DEBUG level of logging?	false	5.0.5
profilerEventHandler	Name of a class that implements the interface com.mysql.jdbc.profiler.ProfilerEventHandler that will be used to handle profiling/tracing events.	com.mysql.jdbc.profiler.LoggingProfilerEventHandler	5.1.6
resultSetSizeThreshold	If the usage advisor is enabled, how many rows should a result set contain before the driver warns that it is suspiciously large?	100	5.0.5
traceProtocol	Should trace-level network protocol be logged?	false	3.1.2
useNanosForElapsedTime	For profiling/debugging functionality that measures elapsed time, should the driver try to use nanoseconds resolution if available	false	5.0.7

	(JDK >= 1.5)?		

Miscellaneous.

Property Name	Definition	Default Value	Since Version
useUnicode	Forces the driver to use Unicode character encodings. Should only be set to false either when the driver can't determine the character set mapping (in which case, specify the Java character encoding in the characterEncoding property), or you are trying to force the driver to use a character set that MySQL doesn't natively support. Should be 'true' for all versions of MySQL 4.1 or higher unless you are trying to emulate the character set handling support provided in MySQL 4.0. Value is true/false, defaults to 'true'	true	1.1g
characterEncoding	If 'useUnicode' is set to true, what Java character encoding should the driver use when dealing with strings? (defaults is to 'autodetect'). If the encoding cannot be determined, then an exception will be raised.		1.1g
characterSetResults	Character set to tell the server to return results as.		3.0.13
connectionCollation	If set, tells the server to use this collation via 'set collation_connection'		3.0.13
useBlobToStoreUTF8OutsideBMP	Tells the driver to treat [MEDIUM/LONG]BLOB columns as [LONG]VARCHAR columns holding text encoded in UTF-8 that has characters outside the BMP (4-byte encodings), which MySQL server can't handle natively.	false	5.1.3
utf8OutsideBmpExcludedColumnNamePattern	When "useBlobToStoreUTF8OutsideBMP" is set to "true", column names matching the given regex will still be treated as BLOBs unless they match the regex specified for "utf8OutsideBmpIncludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3
utf8OutsideBmpIncludedColumnNamePattern	Used to specify exclusion rules to "utf8OutsideBmpExcludedColumnNamePattern". The regex must follow the patterns used for the java.util.regex package.		5.1.3
loadBalanceEnableJMX	Enables JMX-based management of load-balanced connection groups, including live addition/removal of hosts from load-balancing pool.	false	5.1.13
sessionVariables	A comma-separated list of name/value pairs to be sent as SET SESSION ... to the server when the driver connects.		3.1.8
useColumnNamesInFindColumn	Prior to JDBC-4.0, the JDBC specification had a bug related to what could be given as a "column name" to ResultSet methods like findColumn(), or getters that took a String property. JDBC-4.0 clarified "column name" to mean the label, as given in an "AS" clause and returned by ResultSetMetaData.getColumnLabel(), and if no AS clause, the column name. Setting this property to "true" will give behavior that is congruent to JDBC-3.0 and earlier versions of the JDBC specification, but which because of the specification bug could give unexpected results. This property is preferred over "useOldAliasMetadataBehavior" unless you need the specific behavior that it provides with respect to ResultSetMetadata.	false	5.1.7
allowNanAndInf	Should the driver allow NaN or +/- INF values in PreparedStatement.setDouble()?	false	3.1.5
autoClosePStmtStreams	Should the driver automatically call .close() on streams/readers passed as arguments via set*() methods?	false	3.1.12
autoDeserialize	Should the driver automatically detect and de-serialize objects stored in BLOB fields?	false	3.1.5
blobsAreStrings	Should the driver always treat BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP	false	5.0.8

	BY clauses?		
capitalizeTypeNames	Capitalize type names in DatabaseMetaData? (usually only useful when using WebObjects, true/false, defaults to 'false')	true	2.0.7
clobCharacterEncoding	The character encoding to use for sending and retrieving TEXT, MEDIUMTEXT and LONGTEXT values instead of the configured connection characterEncoding		5.0.0
clobberStreamingResults	This will cause a 'streaming' ResultSet to be automatically closed, and any outstanding data still streaming from the server to be discarded if another query is executed before all the data has been read from the server.	false	3.0.9
compensateOnDuplicateKeyUpdateCounts	Should the driver compensate for the update counts of "ON DUPLICATE KEY" INSERT statements (2 = 1, 0 = 1) when using prepared statements?	false	5.1.7
continueBatchOnError	Should the driver continue processing batch commands if one statement fails. The JDBC spec allows either way (defaults to 'true').	true	3.0.3
createDatabaseIfNotExist	Creates the database given in the URL if it doesn't yet exist. Assumes the configured user has permissions to create databases.	false	3.1.9
emptyStringsConvertToZero	Should the driver allow conversions from empty string fields to numeric values of '0'?	true	3.1.8
emulateLocators	Should the driver emulate java.sql.Blobs with locators? With this feature enabled, the driver will delay loading the actual Blob data until the one of the retrieval methods (getInputStream(), getBytes(), and so forth) on the blob data stream has been accessed. For this to work, you must use a column alias with the value of the column to the actual name of the Blob. The feature also has the following restrictions: The SELECT that created the result set must reference only one table, the table must have a primary key; the SELECT must alias the original blob column name, specified as a string, to an alternate name; the SELECT must cover all columns that make up the primary key.	false	3.1.0
emulateUnsupportedPstmts	Should the driver detect prepared statements that are not supported by the server, and replace them with client-side emulated versions?	true	3.1.7
exceptionInterceptors	Comma-delimited list of classes that implement com.mysql.jdbc.ExceptionInterceptor. These classes will be instantiated one per Connection instance, and all SQLExceptions thrown by the driver will be allowed to be intercepted by these interceptors, in a chained fashion, with the first class listed as the head of the chain.		5.1.8
functionsNeverReturnBlobs	Should the driver always treat data from functions returning BLOBs as Strings - specifically to work around dubious metadata returned by the server for GROUP BY clauses?	false	5.0.8
generateSimpleParameterMetadata	Should the driver generate simplified parameter metadata for PreparedStatements when no metadata is available either because the server couldn't support preparing the statement, or server-side prepared statements are disabled?	false	5.0.5
ignoreNonTxTables	Ignore non-transactional table warning for rollback? (defaults to 'false').	false	3.0.9
jdbcCompliantTruncation	This sets whether Connector/J should throw java.sql.DataTruncation exceptions when data is truncated. This is required by the JDBC specification when connected to a server that supports warnings (MySQL 4.1.0 and newer). This property has no effect if the server sql-mode includes STRICT_TRANS_TABLES. Note that if STRICT_TRANS_TABLES is not set, it will be set as a result of using this connection string option.	true	3.1.2
loadBalanceBlacklistTimeout	Time in milliseconds between checks of servers which are unavail-	0	5.1.0

	able.		
loadBalanceConnectionGroup	Logical group of load-balanced connections within a classloader, used to manage different groups independently. If not specified, live management of load-balanced connections is disabled.		5.1.13
loadBalanceExceptionChecker	Fully-qualified class name of custom exception checker. The class must implement com.mysql.jdbc.LoadBalanceExceptionChecker interface, and is used to inspect SQLExceptions and determine whether they should trigger fail-over to another host in a load-balanced deployment.	com.mysql.jdbc.StandardLoadBalanceExceptionChecker	5.1.13
loadBalancePingTimeout	Time in milliseconds to wait for ping response from each of load-balanced physical connections when using load-balanced Connection.	0	5.1.13
loadBalanceSQLExceptionSubclassFailover	Comma-delimited list of classes/interfaces used by default load-balanced exception checker to determine whether a given SQLException should trigger failover. The comparison is done using Class.isInstance(SQLException) using the thrown SQLException.		5.1.13
loadBalanceSQLStateFailover	Comma-delimited list of SQLState codes used by default load-balanced exception checker to determine whether a given SQLException should trigger failover. The SQLState of a given SQLException is evaluated to determine whether it begins with any value in the comma-delimited list.		5.1.13
loadBalanceValidateConnectionOnSwapServer	Should the load-balanced Connection explicitly check whether the connection is live when swapping to a new physical connection at commit/rollback?	false	5.1.13
maxRows	The maximum number of rows to return (0, the default means return all rows).	-1	all versions
netTimeoutForStreamingResults	What value should the driver automatically set the server setting 'net_write_timeout' to when the streaming result sets feature is in use? (value has unit of seconds, the value '0' means the driver will not try and adjust this value)	600	5.1.0
noAccessToProcedureBodies	When determining procedure parameter types for CallableStatements, and the connected user can't access procedure bodies through "SHOW CREATE PROCEDURE" or select on mysql.proc should the driver instead create basic metadata (all parameters reported as IN VARCHARs, but allowing registerOutParameter() to be called on them anyway) instead of throwing an exception?	false	5.0.3
noDatetimeStringSync	Don't ensure that ResultSet.getDatetimeType().toString().equals(ResultSet.getString())	false	3.1.7
noTimezoneConversionForTimeType	Don't convert TIME values using the server timezone if 'useTimezone'='true'	false	5.0.0
nullCatalogMeansCurrent	When DatabaseMetadataMethods ask for a 'catalog' parameter, does the value null mean use the current catalog? When nullCatalogMeansCurrent is true the current catalog will be used if the catalog parameter is null. If nullCatalogMeansCurrent is false and the catalog parameter is null then the catalog parameter is not used to restrict the catalog search. (This is not JDBC-compliant, but follows legacy behavior from earlier versions of the driver)	true	3.1.8
nullNamePatternMatchesAll	Should DatabaseMetaData methods that accept *pattern parameters treat null the same as '%' (this is not JDBC-compliant, however older versions of the driver accepted this departure from the specification)	true	3.1.8
overrideSupportsIntegrityEnhancementFacility	Should the driver return "true" for DatabaseMetaData.supportsIntegrityEnhancementFacility() even if the database doesn't support it to workaround applications that require this method to return "true" to signal support of foreign keys, even though the SQL specification states that this facility contains much more than just foreign key support (one such application being	false	3.1.12

	OpenOffice)?		
padCharsWithSpace	If a result set column has the CHAR type and the value does not fill the amount of characters specified in the DDL for the column, should the driver pad the remaining characters with space (for ANSI compliance)?	false	5.0.6
pedantic	Follow the JDBC spec to the letter.	false	3.0.0
pinGlobalTxToPhysicalConnection	When using XAConnections, should the driver ensure that operations on a given XID are always routed to the same physical connection? This allows the XAConnection to support "XA START ... JOIN" after "XA END" has been called	false	5.0.1
populateInsertRowWithDefaultValues	When using ResultSets that are CONCUR_UPDATABLE, should the driver pre-populate the "insert" row with default values from the DDL for the table used in the query so those values are immediately available for ResultSet accessors? This functionality requires a call to the database for metadata each time a result set of this type is created. If disabled (the default), the default values will be populated by the an internal call to refreshRow() which pulls back default values and/or values changed by triggers.	false	5.0.5
processEscapeCodesForPrepStmts	Should the driver process escape codes in queries that are prepared?	true	3.1.12
queryTimeoutKillsConnection	If the timeout given in Statement.setQueryTimeout() expires, should the driver forcibly abort the Connection instead of attempting to abort the query?	false	5.1.9
relaxAutoCommit	If the version of MySQL the driver connects to does not support transactions, still allow calls to commit(), rollback() and setAutoCommit() (true/false, defaults to 'false')?	false	2.0.13
retainStatementAfterResultSetClose	Should the driver retain the Statement reference in a ResultSet after ResultSet.close() has been called. This is not JDBC-compliant after JDBC-4.0.	false	3.1.11
rollbackOnPooledClose	Should the driver issue a rollback() when the logical connection in a pool is closed?	true	3.0.15
runningCTS13	Enables workarounds for bugs in Sun's JDBC compliance testsuite version 1.3	false	3.1.7
serverTimezone	Override detection/mapping of timezone. Used when timezone from server doesn't map to Java timezone		3.0.2
statementInterceptors	A comma-delimited list of classes that implement "com.mysql.jdbc.StatementInterceptor" that should be placed "in between" query execution to influence the results. StatementInterceptors are "chainable", the results returned by the "current" interceptor will be passed on to the next in in the chain, from left-to-right order, as specified in this property.		5.1.1
strictFloatingPoint	Used only in older versions of compliance test	false	3.0.0
strictUpdates	Should the driver do strict checking (all primary keys selected) of updatable result sets (true, false, defaults to 'true')?	true	3.0.4
tinyInt1isBit	Should the driver treat the datatype TINYINT(1) as the BIT type (because the server silently converts BIT -> TINYINT(1) when creating tables)?	true	3.0.16
transformedBitIsBoolean	If the driver converts TINYINT(1) to a different type, should it use BOOLEAN instead of BIT for future compatibility with MySQL-5.0, as MySQL-5.0 has a BIT type?	false	3.1.9
treatUtilDateAsTimestamp	Should the driver treat java.util.Date as a TIMESTAMP for the purposes of PreparedStatement.setObject()?	true	5.0.5
ultraDevHack	Create PreparedStatements for prepareCall() when required, because UltraDev is broken and issues a prepareCall() for _all_ statements? (true/false, defaults to 'false')	false	2.0.3
useAffectedRows	Don't set the CLIENT_FOUND_ROWS flag when connecting to	false	5.1.7

	the server (not JDBC-compliant, will break most applications that rely on "found" rows vs. "affected rows" for DML statements), but does cause "correct" update counts from "INSERT ... ON DUPLICATE KEY UPDATE" statements to be returned by the server.		
useGmtMillisForDatetimes	Convert between session timezone and GMT before creating Date and Timestamp instances (value of "false" is legacy behavior, "true" leads to more JDBC-compliant behavior.	false	3.1.12
useHostsInPrivileges	Add '@hostname' to users in DatabaseMetaData.getColumn/TablePrivileges() (true/false), defaults to 'true'.	true	3.0.2
useInformationSchema	When connected to MySQL-5.0.7 or newer, should the driver use the INFORMATION_SCHEMA to derive information used by DatabaseMetaData?	false	5.0.0
useJDBCCompliantTimezoneShift	Should the driver use JDBC-compliant rules when converting TIME/TIMESTAMP/DATETIME values' timezone information for those JDBC arguments which take a java.util.Calendar argument? (Notice that this option is exclusive of the "useTimezone=true" configuration option.)	false	5.0.0
useLegacyDatetimeCode	Use code for DATE/TIME/DATETIME/TIMESTAMP handling in result sets and statements that consistently handles timezone conversions from client to server and back again, or use the legacy code for these datatypes that has been in the driver for backwards-compatibility?	true	5.1.6
useOldAliasMetadataBehavior	Should the driver use the legacy behavior for "AS" clauses on columns and tables, and only return aliases (if any) for ResultSetMetaData.getColumnName() or ResultSetMetaData.getTableName() rather than the original column/table name? In 5.0.x, the default value was true.	false	5.0.4
useOldUTF8Behavior	Use the UTF-8 behavior the driver did when communicating with 4.0 and older servers	false	3.1.6
useOnlyServerErrorMessages	Don't prepend 'standard' SQLState error messages to error messages returned by the server.	true	3.0.15
useSSPSCompatibleTimezoneShift	If migrating from an environment that was using server-side prepared statements, and the configuration property "useJDBCCompliantTimeZoneShift" set to "true", use compatible behavior when not using server-side prepared statements when sending TIMESTAMP values to the MySQL server.	false	5.0.5
useServerPrepStmts	Use server-side prepared statements if the server supports them?	false	3.1.0
useSqlStateCodes	Use SQL Standard state codes instead of 'legacy' X/Open/SQL state codes (true/false), default is 'true'	true	3.1.3
useStreamLengthsInPrepStmts	Honor stream length parameter in PreparedStatement/ResultSet.setXXXStream() method calls (true/false, defaults to 'true')?	true	3.0.2
useTimezone	Convert time/date types between client and server timezones (true/false, defaults to 'false')?	false	3.0.2
useUnbufferedInput	Don't use BufferedInputStream for reading data from the server	true	3.0.11
yearIsDateType	Should the JDBC driver treat the MySQL type "YEAR" as a java.sql.Date, or as a SHORT?	true	3.1.9
zeroDateTimeBehavior	What should happen when the driver encounters DATETIME values that are composed entirely of zeros (used by MySQL to represent invalid dates)? Valid values are "exception", "round" and "convertToNull".	exception	3.1.4

Connector/J also supports access to MySQL via named pipes on Windows NT/2000/XP using the NamedPipeSocketFactory as a plugin-socket factory via the socketFactory property. If you do not use a namedPipePath property, the default of '\\.\pipe\MySQL' will be used. If you use the `NamedPipeSocketFactory`, the host name and port number values in the JDBC url will be ignored. You can

enable this feature using:

```
socketFactory=com.mysql.jdbc.NamedPipeSocketFactory
```

Named pipes only work when connecting to a MySQL server on the same physical machine as the one the JDBC driver is being used on. In simple performance tests, it appears that named pipe access is between 30%-50% faster than the standard TCP/IP access. However, this varies per system, and named pipes are slower than TCP/IP in many Windows configurations.

You can create your own socket factories by following the example code in `com.mysql.jdbc.NamedPipeSocketFactory`, or `com.mysql.jdbc.StandardSocketFactory`.

20.3.4.2. JDBC API Implementation Notes

MySQL Connector/J passes all of the tests in the publicly available version of Sun's JDBC compliance test suite. However, in many places the JDBC specification is vague about how certain functionality should be implemented, or the specification allows leeway in implementation.

This section gives details on a interface-by-interface level about how certain implementation decisions may affect how you use MySQL Connector/J.

- **Blob**

  Starting with Connector/J version 3.1.0, you can emulate Blobs with locators by adding the property 'emulateLocators=true' to your JDBC URL. Using this method, the driver will delay loading the actual Blob data until you retrieve the other data and then use retrieval methods (`getInputStream()`, `getBytes()`, and so forth) on the blob data stream.

  For this to work, you must use a column alias with the value of the column to the actual name of the Blob, for example:

  ```
  SELECT id, 'data' as blob_data from blobtable
  ```

  For this to work, you must also follow these rules:

  - The `SELECT` must also reference only one table, the table must have a primary key.
  - The `SELECT` must alias the original blob column name, specified as a string, to an alternate name.
  - The `SELECT` must cover all columns that make up the primary key.

  The Blob implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, you should use the corresponding `PreparedStatement.setBlob()` or `ResultSet.updateBlob()` (in the case of updatable result sets) methods to save changes back to the database.

  > **MySQL Enterprise**
  > MySQL Enterprise subscribers will find more information about type conversion in the Knowledge Base article, Type Conversions Supported by MySQL Connector/J. To subscribe to MySQL Enterprise see http://www.mysql.com/products/enterprise/advisors.html.

- **CallableStatement**

  Starting with Connector/J 3.1.1, stored procedures are supported when connecting to MySQL version 5.0 or newer via the `CallableStatement` interface. Currently, the `getParameterMetaData()` method of `CallableStatement` is not supported.

- **Clob**

  The Clob implementation does not allow in-place modification (they are copies, as reported by the `DatabaseMetaData.locatorsUpdateCopies()` method). Because of this, you should use the `PreparedStatement.setClob()` method to save changes back to the database. The JDBC API does not have a `ResultSet.updateClob()` method.

- **Connection**

  Unlike older versions of MM.MySQL the `isClosed()` method does not ping the server to determine if it is alive. In accordance

with the JDBC specification, it only returns true if `closed()` has been called on the connection. If you need to determine if the connection is still valid, you should issue a simple query, such as `SELECT 1`. The driver will throw an exception if the connection is no longer valid.

- **DatabaseMetaData**

  Foreign Key information (`getImportedKeys()`/`getExportedKeys()` and `getCrossReference()`) is only available from InnoDB tables. However, the driver uses `SHOW CREATE TABLE` to retrieve this information, so when other storage engines support foreign keys, the driver will transparently support them as well.

- **PreparedStatement**

  PreparedStatements are implemented by the driver, as MySQL does not have a prepared statement feature. Because of this, the driver does not implement `getParameterMetaData()` or `getMetaData()` as it would require the driver to have a complete SQL parser in the client.

  Starting with version 3.1.0 MySQL Connector/J, server-side prepared statements and binary-encoded result sets are used when the server supports them.

  Take care when using a server-side prepared statement with **large** parameters that are set via `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()`, or `setClob()`. If you want to re-execute the statement with any large parameter changed to a nonlarge parameter, it is necessary to call `clearParameters()` and set all parameters again. The reason for this is as follows:

  - During both server-side prepared statements and client-side emulation, large data is exchanged only when `PreparedStatement.execute()` is called.
  - Once that has been done, the stream used to read the data on the client side is closed (as per the JDBC spec), and cannot be read from again.
  - If a parameter changes from large to nonlarge, the driver must reset the server-side state of the prepared statement to allow the parameter that is being changed to take the place of the prior large value. This removes all of the large data that has already been sent to the server, thus requiring the data to be re-sent, via the `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()`, `setBlob()` or `setClob()` methods.

  Consequently, if you want to change the type of a parameter to a nonlarge one, you must call `clearParameters()` and set all parameters of the prepared statement again before it can be re-executed.

- **ResultSet**

  By default, ResultSets are completely retrieved and stored in memory. In most cases this is the most efficient way to operate, and due to the design of the MySQL network protocol is easier to implement. If you are working with ResultSets that have a large number of rows or large values, and can not allocate heap space in your JVM for the memory required, you can tell the driver to stream the results back one row at a time.

  To enable this functionality, you need to create a Statement instance in the following manner:

  ```
  stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                java.sql.ResultSet.CONCUR_READ_ONLY);
  stmt.setFetchSize(Integer.MIN_VALUE);
  ```

  The combination of a forward-only, read-only result set, with a fetch size of `Integer.MIN_VALUE` serves as a signal to the driver to stream result sets row-by-row. After this any result sets created with the statement will be retrieved row-by-row.

  There are some caveats with this approach. You will have to read all of the rows in the result set (or close it) before you can issue any other queries on the connection, or an exception will be thrown.

  The earliest the locks these statements hold can be released (whether they be `MyISAM` table-level locks or row-level locks in some other storage engine such as `InnoDB`) is when the statement completes.

  If the statement is within scope of a transaction, then locks are released when the transaction completes (which implies that the statement needs to complete first). As with most other databases, statements are not complete until all the results pending on the statement are read or the active result set for the statement is closed.

  Therefore, if using streaming results, you should process them as quickly as possible if you want to maintain concurrent access to the tables referenced by the statement producing the result set.

- **ResultSetMetaData**

  The `isAutoIncrement()` method only works when using MySQL servers 4.0 and newer.

- **Statement**

  When using versions of the JDBC driver earlier than 3.2.1, and connected to server versions earlier than 5.0.3, the `setFetchSize()` method has no effect, other than to toggle result set streaming as described above.

  Connector/J 5.0.0 and later include support for both `Statement.cancel()` and `Statement.setQueryTimeout()`. Both require MySQL 5.0.0 or newer server, and require a separate connection to issue the `KILL QUERY` statement. In the case of `setQueryTimeout()`, the implementation creates an additional thread to handle the timeout functionality.

  > **Note**
  >
  > Failures to cancel the statement for `setQueryTimeout()` may manifest themselves as `RuntimeException` rather than failing silently, as there is currently no way to unblock the thread that is executing the query being cancelled due to timeout expiration and have it throw the exception instead.

  MySQL does not support SQL cursors, and the JDBC driver doesn't emulate them, so "setCursorName()" has no effect.

  Connector/J 5.1.3 and later include two additional methods:

  - `setLocalInfileInputStream()` sets an `InputStream` instance that will be used to send data to the MySQL server for a `LOAD DATA LOCAL INFILE` statement rather than a `FileInputStream` or `URLInputStream` that represents the path given as an argument to the statement.

    This stream will be read to completion upon execution of a `LOAD DATA LOCAL INFILE` statement, and will automatically be closed by the driver, so it needs to be reset before each call to `execute*()` that would cause the MySQL server to request data to fulfill the request for `LOAD DATA LOCAL INFILE`.

    If this value is set to `NULL`, the driver will revert to using a `FileInputStream` or `URLInputStream` as required.

  - `getLocalInfileInputStream()` returns the `InputStream` instance that will be used to send data in response to a `LOAD DATA LOCAL INFILE` statement.

    This method returns `NULL` if no such stream has been set via `setLocalInfileInputStream()`.

20.3.4.3. Java, JDBC and MySQL Types

MySQL Connector/J is flexible in the way it handles conversions between MySQL data types and Java data types.

In general, any MySQL data type can be converted to a java.lang.String, and any numerical type can be converted to any of the Java numerical types, although round-off, overflow, or loss of precision may occur.

Starting with Connector/J 3.1.0, the JDBC driver will issue warnings or throw DataTruncation exceptions as is required by the JDBC specification unless the connection was configured not to do so by using the property jdbcCompliantTruncation and setting it to `false`.

The conversions that are always guaranteed to work are listed in the following table:

Connection Properties - Miscellaneous.

These MySQL Data Types	Can always be converted to these Java types
`CHAR, VARCHAR, BLOB, TEXT, ENUM, and SET`	`java.lang.String, java.io.InputStream, java.io.Reader, java.sql.Blob, java.sql.Clob`
`FLOAT, REAL, DOUBLE PRECISION, NUMERIC, DECIMAL, TINYINT, SMALLINT, MEDIUMINT, INTEGER, BIGINT`	`java.lang.String, java.lang.Short, java.lang.Integer, java.lang.Long, java.lang.Double, java.math.BigDecimal`
`DATE, TIME, DATETIME, TIMESTAMP`	`java.lang.String, java.sql.Date, java.sql.Timestamp`

> **Note**

Round-off, overflow or loss of precision may occur if you choose a Java numeric data type that has less precision or capacity than the MySQL data type you are converting to/from.

The `ResultSet.getObject()` method uses the type conversions between MySQL and Java types, following the JDBC specification where appropriate. The value returned by `ResultSetMetaData.GetColumnClassName()` is also shown below. For more information on the `java.sql.Types` classes see Java 2 Platform Types.

MySQL Types to Java Types for ResultSet.getObject().

MySQL Type Name	Return value of `GetColumnClassName`	Returned as Java Class
BIT(1) (new in MySQL-5.0)	BIT	`java.lang.Boolean`
BIT(> 1) (new in MySQL-5.0)	BIT	`byte[]`
TINYINT	TINYINT	`java.lang.Boolean` if the configuration property `tinyInt1isBit` is set to `true` (the default) and the storage size is 1, or `java.lang.Integer` if not.
BOOL, BOOLEAN	TINYINT	See TINYINT, above as these are aliases for TINYINT(1), currently.
SMALLINT[(M)] [UNSIGNED]	SMALLINT [UNSIGNED]	`java.lang.Integer` (regardless if UNSIGNED or not)
MEDIUMINT[(M)] [UNSIGNED]	MEDIUMINT [UNSIGNED]	`java.lang.Integer`, if UNSIGNED `java.lang.Long` (C/J 3.1 and earlier), or `java.lang.Integer` for C/J 5.0 and later
INT,INTEGER[(M)] [UNSIGNED]	INTEGER [UNSIGNED]	`java.lang.Integer`, if UNSIGNED `java.lang.Long`
BIGINT[(M)] [UNSIGNED]	BIGINT [UNSIGNED]	`java.lang.Long`, if UNSIGNED `java.math.BigInteger`
FLOAT[(M,D)]	FLOAT	`java.lang.Float`
DOUBLE[(M,B)]	DOUBLE	`java.lang.Double`
DECIMAL[(M[,D])]	DECIMAL	`java.math.BigDecimal`
DATE	DATE	`java.sql.Date`
DATETIME	DATETIME	`java.sql.Timestamp`
TIMESTAMP[(M)]	TIMESTAMP	`java.sql.Timestamp`
TIME	TIME	`java.sql.Time`
YEAR[(2|4)]	YEAR	If `yearIsDateType` configuration property is set to false, then the returned object type is `java.sql.Short`. If set to true (the default) then an object of type `java.sql.Date` (with the date set to January 1st, at midnight).
CHAR(M)	CHAR	`java.lang.String` (unless the character set for the column is BINARY, then `byte[]` is returned.
VARCHAR(M) [BINARY]	VARCHAR	`java.lang.String` (unless the character set for the column is BINARY, then `byte[]` is returned.
BINARY(M)	BINARY	`byte[]`
VARBINARY(M)	VARBINARY	`byte[]`
TINYBLOB	TINYBLOB	`byte[]`
TINYTEXT	VARCHAR	`java.lang.String`
BLOB	BLOB	`byte[]`
TEXT	VARCHAR	`java.lang.String`
MEDIUMBLOB	MEDIUMBLOB	`byte[]`
MEDIUMTEXT	VARCHAR	`java.lang.String`
LONGBLOB	LONGBLOB	`byte[]`
LONGTEXT	VARCHAR	`java.lang.String`

ENUM('value1','value2',...)	CHAR	`java.lang.String`
SET('value1','value2',...)	CHAR	`java.lang.String`

20.3.4.4. Using Character Sets and Unicode

All strings sent from the JDBC driver to the server are converted automatically from native Java Unicode form to the client character encoding, including all queries sent via `Statement.execute()`, `Statement.executeUpdate()`, `Statement.executeQuery()` as well as all `PreparedStatement` and `CallableStatement` parameters with the exclusion of parameters set using `setBytes()`, `setBinaryStream()`, `setAsciiStream()`, `setUnicodeStream()` and `setBlob()`.

Prior to MySQL Server 4.1, Connector/J supported a single character encoding per connection, which could either be automatically detected from the server configuration, or could be configured by the user through the *`useUnicode`* and *`characterEncoding`* properties.

Starting with MySQL Server 4.1, Connector/J supports a single character encoding between client and server, and any number of character encodings for data returned by the server to the client in `ResultSets`.

The character encoding between client and server is automatically detected upon connection. The encoding used by the driver is specified on the server via the `character_set` system variable for server versions older than 4.1.0 and `character_set_server` for server versions 4.1.0 and newer. For more information, see Section 9.1.3.1, “Server Character Set and Collation”.

To override the automatically detected encoding on the client side, use the *`characterEncoding`* property in the URL used to connect to the server.

When specifying character encodings on the client side, Java-style names should be used. The following table lists Java-style names for MySQL character sets:

MySQL to Java Encoding Name Translations.

MySQL Character Set Name	Java-Style Character Encoding Name
ascii	US-ASCII
big5	Big5
gbk	GBK
sjis	SJIS (or Cp932 or MS932 for MySQL Server < 4.1.11)
cp932	Cp932 or MS932 (MySQL Server > 4.1.11)
gb2312	EUC_CN
ujis	EUC_JP
euckr	EUC_KR
latin1	Cp1252
latin2	ISO8859_2
greek	ISO8859_7
hebrew	ISO8859_8
cp866	Cp866
tis620	TIS620
cp1250	Cp1250
cp1251	Cp1251
cp1257	Cp1257
macroman	MacRoman
macce	MacCentralEurope
utf8	UTF-8
ucs2	UnicodeBig

> **Warning**
>
> Do not issue the query 'set names' with Connector/J, as the driver will not detect that the character set has changed, and will continue to use the character set detected during the initial connection setup.

To allow multiple character sets to be sent from the client, the UTF-8 encoding should be used, either by configuring `utf8` as the default server character set, or by configuring the JDBC driver to use UTF-8 through the *`characterEncoding`* property.

20.3.4.5. Connecting Securely Using SSL

SSL in MySQL Connector/J encrypts all data (other than the initial handshake) between the JDBC driver and the server. The performance penalty for enabling SSL is an increase in query processing time between 35% and 50%, depending on the size of the query, and the amount of data it returns.

For SSL Support to work, you must have the following:

- A JDK that includes JSSE (Java Secure Sockets Extension), like JDK-1.4.1 or newer. SSL does not currently work with a JDK that you can add JSSE to, like JDK-1.2.x or JDK-1.3.x due to the following JSSE bug: http://developer.java.sun.com/developer/bugParade/bugs/4273544.html
- A MySQL server that supports SSL and has been compiled and configured to do so, which is MySQL-4.0.4 or later, see Section 5.5.6, “Using SSL for Secure Connections”, for more information.
- A client certificate (covered later in this section)

The system works through two Java truststore files, one file contains the certificate information for the server (`truststore` in the examples below). The other file contains the certificate for the client (`keystore` in the examples below). All Java truststore files are password protected by supplying a suitable password to the `keytool` when you create the files. You need the file names and associated passwords to create an SSL connection.

You will first need to import the MySQL server CA Certificate into a Java truststore. A sample MySQL server CA Certificate is located in the `SSL` subdirectory of the MySQL source distribution. This is what SSL will use to determine if you are communicating with a secure MySQL server. Alternatively, use the CA Certificate that you have generated or been provided with by your SSL provider.

To use Java's `keytool` to create a truststore in the current directory , and import the server's CA certificate (`cacert.pem`), you can do the following (assuming that `keytool` is in your path. The `keytool` should be located in the `bin` subdirectory of your JDK or JRE):

```
shell> keytool -import -alias mysqlServerCACert \
                                -file cacert.pem -keystore truststore
```

You will need to enter the password when prompted for the keystore file. Interaction with `keytool` will look like this:

```
Enter keystore password:  *********
Owner: EMAILADDRESS=walrus@example.com, CN=Walrus,
       O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Issuer: EMAILADDRESS=walrus@example.com, CN=Walrus,
       O=MySQL AB, L=Orenburg, ST=Some-State, C=RU
Serial number: 0
Valid from:
   Fri Aug 02 16:55:53 CDT 2002 until: Sat Aug 02 16:55:53 CDT 2003
Certificate fingerprints:
    MD5:  61:91:A0:F2:03:07:61:7A:81:38:66:DA:19:C4:8D:AB
    SHA1: 25:77:41:05:D5:AD:99:8C:14:8C:CA:68:9C:2F:B8:89:C3:34:4D:6C
Trust this certificate? [no]:  yes
Certificate was added to keystore
```

You then have two options, you can either import the client certificate that matches the CA certificate you just imported, or you can create a new client certificate.

To import an existing certificate, the certificate should be in DER format. You can use `openssl` to convert an existing certificate into the new format. For example:

```
shell> openssl x509 -outform DER -in client-cert.pem -out client.cert
```

You now need to import the converted certificate into your keystore using `keytool`:

```
shell> keytool -import -file client.cert -keystore keystore -alias mysqlClientCertificate
```

To generate your own client certificate, use `keytool` to create a suitable certificate and add it to the `keystore` file:

```
 shell> keytool -genkey -keyalg rsa \
     -alias mysqlClientCertificate -keystore keystore
```

Keytool will prompt you for the following information, and create a keystore named `keystore` in the current directory.

You should respond with information that is appropriate for your situation:

```
Enter keystore password:  *********
What is your first and last name?
  [Unknown]:  Matthews
What is the name of your organizational unit?
  [Unknown]:  Software Development
What is the name of your organization?
  [Unknown]:  MySQL AB
What is the name of your City or Locality?
  [Unknown]:  Flossmoor
What is the name of your State or Province?
  [Unknown]:  IL
What is the two-letter country code for this unit?
  [Unknown]:  US
Is <CN=Matthews, OU=Software Development, O=MySQL AB,
 L=Flossmoor, ST=IL, C=US> correct?
  [no]:  y

Enter key password for <mysqlClientCertificate>
        (RETURN if same as keystore password):
```

Finally, to get JSSE to use the keystore and truststore that you have generated, you need to set the following system properties when you start your JVM, replacing path_to_keystore_file with the full path to the keystore file you created, path_to_truststore_file with the path to the truststore file you created, and using the appropriate password values for each property. You can do this either on the command line:

```
-Djavax.net.ssl.keyStore=path_to_keystore_file
-Djavax.net.ssl.keyStorePassword=password
-Djavax.net.ssl.trustStore=path_to_truststore_file
-Djavax.net.ssl.trustStorePassword=password
```

Or you can set the values directly within the application:

```
 System.setProperty("javax.net.ssl.keyStore","path_to_keystore_file");
System.setProperty("javax.net.ssl.keyStorePassword","password");
System.setProperty("javax.net.ssl.trustStore","path_to_truststore_file");
System.setProperty("javax.net.ssl.trustStorePassword","password");
```

You will also need to set useSSL to `true` in your connection parameters for MySQL Connector/J, either by adding `useSSL=true` to your URL, or by setting the property useSSL to `true` in the `java.util.Properties` instance you pass to `DriverManager.getConnection()`.

You can test that SSL is working by turning on JSSE debugging (as detailed below), and look for the following key events:

```

JSSE provides debugging (to STDOUT) when you set the following system property: `-Djavax.net.debug=all` This will tell you what keystores and truststores are being used, as well as what is going on during the SSL handshake and certificate exchange. It will be helpful when trying to determine what is not working when trying to get an SSL connection to happen.

20.3.4.6. Using Master/Slave Replication with ReplicationConnection

Starting with Connector/J 3.1.7, we've made available a variant of the driver that will automatically send queries to a read/write master, or a failover or round-robin loadbalanced set of slaves based on the state of `Connection.getReadOnly()` .

An application signals that it wants a transaction to be read-only by calling `Connection.setReadOnly(true)`, this replication-aware connection will use one of the slave connections, which are load-balanced per-vm using a round-robin scheme (a given connection is sticky to a slave unless that slave is removed from service). If you have a write transaction, or if you have a read that is time-sensitive (remember, replication in MySQL is asynchronous), set the connection to be not read-only, by calling `Connection.setReadOnly(false)` and the driver will ensure that further calls are sent to the master MySQL server. The driver takes care of propagating the current state of autocommit, isolation level, and catalog between all of the connections that it uses to accomplish this load balancing functionality.

To enable this functionality, use the " `com.mysql.jdbc.ReplicationDriver` " class when configuring your application server's connection pool or when creating an instance of a JDBC driver for your standalone application. Because it accepts the same URL format as the standard MySQL JDBC driver, `ReplicationDriver` does not currently work with `java.sql.DriverManager` -based connection creation unless it is the only MySQL JDBC driver registered with the `DriverManager` .

Here is a short, simple example of how ReplicationDriver might be used in a standalone application.

```
import java.sql.Connection;
import java.sql.ResultSet;
import java.util.Properties;

import com.mysql.jdbc.ReplicationDriver;

public class ReplicationDriverDemo {

  public static void main(String[] args) throws Exception {
    ReplicationDriver driver = new ReplicationDriver();

    Properties props = new Properties();

    // We want this for failover on the slaves
    props.put("autoReconnect", "true");

    // We want to load balance between the slaves
    props.put("roundRobinLoadBalance", "true");

    props.put("user", "foo");
    props.put("password", "bar");

    //
    // Looks like a normal MySQL JDBC url, with a
    // comma-separated list of hosts, the first
    // being the 'master', the rest being any number
    // of slaves that the driver will load balance against
    //

    Connection conn =
        driver.connect("jdbc:mysql:replication://master,slave1,slave2,slave3/test",
            props);

    //
    // Perform read/write work on the master
    // by setting the read-only flag to "false"
    //
```

```
    conn.setReadOnly(false);
    conn.setAutoCommit(false);
    conn.createStatement().executeUpdate("UPDATE some_table ....");
    conn.commit();

    //
    // Now, do a query from a slave, the driver automatically picks one
    // from the list
    //

    conn.setReadOnly(true);

    ResultSet rs =
      conn.createStatement().executeQuery("SELECT a,b FROM alt_table");

     .......
  }
}
```

You may also want to investigate the Load Balancing JDBC Pool (lbpol) tool, which provides a wrapper around the standard JDBC driver and allows you to use DB connection pools that includes checks for system failures and uneven load distribution. For more information, see Load Balancing JDBC Pool (lbpool).

20.3.4.7. Mapping MySQL Error Numbers to SQLStates

The table below provides a mapping of the MySQL Error Numbers to `SQL States`

Table 20.3. Mapping of MySQL Error Numbers to SQLStates

MySQL Error Number	MySQL Error Name	Legacy (X/Open) SQLState	SQL Standard SQLState
1022	ER_DUP_KEY	S1000	23000
1037	ER_OUTOFMEMORY	S1001	HY001
1038	ER_OUT_OF_SORT-MEMORY	S1001	HY001

20.3.5. Connector/J Notes and Tips

20.3.5.1. Basic JDBC Concepts

This section provides some general JDBC background.

20.3.5.1.1. Connecting to MySQL Using the `DriverManager` Interface

When you are using JDBC outside of an application server, the `DriverManager` class manages the establishment of Connections.

The `DriverManager` needs to be told which JDBC drivers it should try to make Connections with. The easiest way to do this is to use `Class.forName()` on the class that implements the `java.sql.Driver` interface. With MySQL Connector/J, the name of this class is `com.mysql.jdbc.Driver`. With this method, you could use an external configuration file to supply the driver class name and driver parameters to use when connecting to a database.

The following section of Java code shows how you might register MySQL Connector/J from the `main()` method of your application. If testing this code please ensure you read the installation section first at Section 20.3.2, “Connector/J Installation”, to make sure you have connector installed correctly and the `CLASSPATH` set up. Also, ensure that MySQL is configured to accept external TCP/IP connections.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

// Notice, do not import com.mysql.jdbc.*
// or you will have problems!

public class LoadDriver {
    public static void main(String[] args) {
        try {
            // The newInstance() call is a work around for some
```

```
            // broken Java implementations

            Class.forName("com.mysql.jdbc.Driver").newInstance();
        } catch (Exception ex) {
            // handle the error
        }
    }
}
```

After the driver has been registered with the `DriverManager`, you can obtain a `Connection` instance that is connected to a particular database by calling `DriverManager.getConnection()`:

Example 20.1. Connector/J: Obtaining a connection from the `DriverManager`

If you have not already done so, please review the section Section 20.3.5.1.1, "Connecting to MySQL Using the `DriverManager` Interface" before working with these examples.

This example shows how you can obtain a `Connection` instance from the `DriverManager`. There are a few different signatures for the `getConnection()` method. You should see the API documentation that comes with your JDK for more specific information on how to use them.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;

Connection conn = null;
...
try {
    conn =
       DriverManager.getConnection("jdbc:mysql://localhost/test?" +
                                   "user=monty&password=greatsqldb");

    // Do something with the Connection

   ...
} catch (SQLException ex) {
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
```

Once a `Connection` is established, it can be used to create `Statement` and `PreparedStatement` objects, as well as retrieve metadata about the database. This is explained in the following sections.

20.3.5.1.2. Using Statements to Execute SQL

`Statement` objects allow you to execute basic SQL queries and retrieve the results through the `ResultSet` class which is described later.

To create a `Statement` instance, you call the `createStatement()` method on the `Connection` object you have retrieved via one of the `DriverManager.getConnection()` or `DataSource.getConnection()` methods described earlier.

Once you have a `Statement` instance, you can execute a `SELECT` query by calling the `executeQuery(String)` method with the SQL you want to use.

To update data in the database, use the `executeUpdate(String SQL)` method. This method returns the number of rows matched by the update statement, not the number of rows that were modified.

If you do not know ahead of time whether the SQL statement will be a `SELECT` or an `UPDATE`/`INSERT`, then you can use the `execute(String SQL)` method. This method will return true if the SQL query was a `SELECT`, or false if it was an `UPDATE`, `INSERT`, or `DELETE` statement. If the statement was a `SELECT` query, you can retrieve the results by calling the `getResultSet()` method. If the statement was an `UPDATE`, `INSERT`, or `DELETE` statement, you can retrieve the affected rows count by calling `getUpdateCount()` on the `Statement` instance.

Example 20.2. Connector/J: Using java.sql.Statement to execute a `SELECT` query

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;

// assume that conn is an already created JDBC connection (see previous examples)

Statement stmt = null;
ResultSet rs = null;

try {
    stmt = conn.createStatement();
    rs = stmt.executeQuery("SELECT foo FROM bar");

    // or alternatively, if you don't know ahead of time that
    // the query will be a SELECT...

    if (stmt.execute("SELECT foo FROM bar")) {
        rs = stmt.getResultSet();
    }

    // Now do something with the ResultSet ....
}
catch (SQLException ex){
    // handle any errors
    System.out.println("SQLException: " + ex.getMessage());
    System.out.println("SQLState: " + ex.getSQLState());
    System.out.println("VendorError: " + ex.getErrorCode());
}
finally {
    // it is a good idea to release
    // resources in a finally{} block
    // in reverse-order of their creation
    // if they are no-longer needed

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException sqlEx) { } // ignore

        rs = null;
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException sqlEx) { } // ignore

        stmt = null;
    }
}
```

20.3.5.1.3. Using `CallableStatements` to Execute Stored Procedures

Starting with MySQL server version 5.0 when used with Connector/J 3.1.1 or newer, the `java.sql.CallableStatement` interface is fully implemented with the exception of the `getParameterMetaData()` method.

For more information on MySQL stored procedures, please refer to http://dev.mysql.com/doc/mysql/en/stored-routines.html.

Connector/J exposes stored procedure functionality through JDBC's `CallableStatement` interface.

> **Note**
>
> Current versions of MySQL server do not return enough information for the JDBC driver to provide result set metadata for callable statements. This means that when using `CallableStatement`, `ResultSetMetaData` may return `NULL`.

The following example shows a stored procedure that returns the value of `inOutParam` incremented by 1, and the string passed in via `inputParam` as a `ResultSet`:

Example 20.3. Connector/J: Calling Stored Procedures

```
CREATE PROCEDURE demoSp(IN inputParam VARCHAR(255), \
                                      INOUT inOutParam INT)
BEGIN
    DECLARE z INT;
    SET z = inOutParam + 1;
    SET inOutParam = z;
```

```
    SELECT inputParam;

    SELECT CONCAT('zyxw', inputParam);
END
```

To use the `demoSp` procedure with Connector/J, follow these steps:

1. Prepare the callable statement by using `Connection.prepareCall()` .

   Notice that you have to use JDBC escape syntax, and that the parentheses surrounding the parameter placeholders are not optional:

   Example 20.4. Connector/J: Using `Connection.prepareCall()`

   ```
   import java.sql.CallableStatement;

   ...

       //
       // Prepare a call to the stored procedure 'demoSp'
       // with two parameters
       //
       // Notice the use of JDBC-escape syntax ({call ...})
       //

       CallableStatement cStmt = conn.prepareCall("{call demoSp(?, ?)}");

       cStmt.setString(1, "abcdefg");
   ```

   > **Note**
   >
   > `Connection.prepareCall()` is an expensive method, due to the metadata retrieval that the driver performs to support output parameters. For performance reasons, you should try to minimize unnecessary calls to `Connection.prepareCall()` by reusing `CallableStatement` instances in your code.

2. Register the output parameters (if any exist)

   To retrieve the values of output parameters (parameters specified as `OUT` or `INOUT` when you created the stored procedure), JDBC requires that they be specified before statement execution using the various `registerOutputParameter()` methods in the `CallableStatement` interface:

   Example 20.5. Connector/J: Registering output parameters

   ```
   import java.sql.Types;
   ...
   //
   // Connector/J supports both named and indexed
   // output parameters. You can register output
   // parameters using either method, as well
   // as retrieve output parameters using either
   // method, regardless of what method was
   // used to register them.
   //
   // The following examples show how to use
   // the various methods of registering
   // output parameters (you should of course
   // use only one registration per parameter).
   //

   //
   // Registers the second parameter as output, and
   // uses the type 'INTEGER' for values returned from
   // getObject()
   //

   cStmt.registerOutParameter(2, Types.INTEGER);

   //
   // Registers the named parameter 'inOutParam', and
   // uses the type 'INTEGER' for values returned from
   ```

```
// getObject()
//

cStmt.registerOutParameter("inOutParam", Types.INTEGER);
...
```

3. Set the input parameters (if any exist)

   Input and in/out parameters are set as for `PreparedStatement` objects. However, `CallableStatement` also supports setting parameters by name:

Example 20.6. Connector/J: Setting `CallableStatement` input parameters

```
...
    //
    // Set a parameter by index
    //

    cStmt.setString(1, "abcdefg");

    //
    // Alternatively, set a parameter using
    // the parameter name
    //

    cStmt.setString("inputParameter", "abcdefg");

    //
    // Set the 'in/out' parameter using an index
    //

    cStmt.setInt(2, 1);

    //
    // Alternatively, set the 'in/out' parameter
    // by name
    //

    cStmt.setInt("inOutParam", 1);

...
```

4. Execute the `CallableStatement`, and retrieve any result sets or output parameters.

   Although `CallableStatement` supports calling any of the `Statement` execute methods (`executeUpdate()`, `executeQuery()` or `execute()`), the most flexible method to call is `execute()`, as you do not need to know ahead of time if the stored procedure returns result sets:

Example 20.7. Connector/J: Retrieving results and output parameter values

```
...
    boolean hadResults = cStmt.execute();

    //
    // Process all returned result sets
    //

    while (hadResults) {
        ResultSet rs = cStmt.getResultSet();

        // process result set
        ...

        hadResults = cStmt.getMoreResults();
    }

    //
    // Retrieve output parameters
    //
    // Connector/J supports both index-based and
    // name-based retrieval
    //
```

```
    int outputValue = cStmt.getInt(2); // index-based

    outputValue = cStmt.getInt("inOutParam"); // name-based

...
```

20.3.5.1.4. Retrieving `AUTO_INCREMENT` Column Values

Before version 3.0 of the JDBC API, there was no standard way of retrieving key values from databases that supported auto increment or identity columns. With older JDBC drivers for MySQL, you could always use a MySQL-specific method on the `Statement` interface, or issue the query `SELECT LAST_INSERT_ID()` after issuing an `INSERT` to a table that had an `AUTO_INCREMENT` key. Using the MySQL-specific method call isn't portable, and issuing a `SELECT` to get the `AUTO_INCREMENT` key's value requires another round-trip to the database, which isn't as efficient as possible. The following code snippets demonstrate the three different ways to retrieve `AUTO_INCREMENT` values. First, we demonstrate the use of the new JDBC-3.0 method `getGeneratedKeys()` which is now the preferred method to use if you need to retrieve `AUTO_INCREMENT` keys and have access to JDBC-3.0. The second example shows how you can retrieve the same value using a standard `SELECT LAST_INSERT_ID()` query. The final example shows how updatable result sets can retrieve the `AUTO_INCREMENT` value when using the `insertRow()` method.

Example 20.8. Connector/J: Retrieving `AUTO_INCREMENT` column values using `Statement.getGeneratedKeys()`

```
Statement stmt = null;
ResultSet rs = null;

try {

 //
 // Create a Statement instance that we can use for
 // 'normal' result sets assuming you have a
 // Connection 'conn' to a MySQL database already
 // available

 stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                             java.sql.ResultSet.CONCUR_UPDATABLE);

 //
 // Issue the DDL queries for the table for this example
 //

 stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
 stmt.executeUpdate(
         "CREATE TABLE autoIncTutorial ("
         + "priKey INT NOT NULL AUTO_INCREMENT, "
         + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

 //
 // Insert one row that will generate an AUTO INCREMENT
 // key in the 'priKey' field
 //

 stmt.executeUpdate(
         "INSERT INTO autoIncTutorial (dataField) "
         + "values ('Can I Get the Auto Increment Field?')",
         Statement.RETURN_GENERATED_KEYS);

 //
 // Example of using Statement.getGeneratedKeys()
 // to retrieve the value of an auto-increment
 // value
 //

 int autoIncKeyFromApi = -1;

 rs = stmt.getGeneratedKeys();

 if (rs.next()) {
     autoIncKeyFromApi = rs.getInt(1);
 } else {

     // throw an exception from here
 }

 rs.close();

 rs = null;
```

```
    System.out.println("Key returned from getGeneratedKeys():"
        + autoIncKeyFromApi);
} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

Example 20.9. Connector/J: Retrieving `AUTO_INCREMENT` column values using `SELECT LAST_INSERT_ID()`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets.

    stmt = conn.createStatement();

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Insert one row that will generate an AUTO INCREMENT
    // key in the 'priKey' field
    //

    stmt.executeUpdate(
            "INSERT INTO autoIncTutorial (dataField) "
            + "values ('Can I Get the Auto Increment Field?')");

    //
    // Use the MySQL LAST_INSERT_ID()
    // function to do the same thing as getGeneratedKeys()
    //

    int autoIncKeyFromFunc = -1;
    rs = stmt.executeQuery("SELECT LAST_INSERT_ID()");

    if (rs.next()) {
        autoIncKeyFromFunc = rs.getInt(1);
    } else {
        // throw an exception from here
    }

    rs.close();

    System.out.println("Key returned from " +
                       "'SELECT LAST_INSERT_ID()': " +
                       autoIncKeyFromFunc);

} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
```

```
    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
            // ignore
        }
    }
}
```

Example 20.10. Connector/J: Retrieving `AUTO_INCREMENT` column values in `Updatable ResultSets`

```
   Statement stmt = null;
   ResultSet rs = null;

   try {

    //
    // Create a Statement instance that we can use for
    // 'normal' result sets as well as an 'updatable'
    // one, assuming you have a Connection 'conn' to
    // a MySQL database already available
    //

    stmt = conn.createStatement(java.sql.ResultSet.TYPE_FORWARD_ONLY,
                                java.sql.ResultSet.CONCUR_UPDATABLE);

    //
    // Issue the DDL queries for the table for this example
    //

    stmt.executeUpdate("DROP TABLE IF EXISTS autoIncTutorial");
    stmt.executeUpdate(
            "CREATE TABLE autoIncTutorial ("
            + "priKey INT NOT NULL AUTO_INCREMENT, "
            + "dataField VARCHAR(64), PRIMARY KEY (priKey))");

    //
    // Example of retrieving an AUTO INCREMENT key
    // from an updatable result set
    //

    rs = stmt.executeQuery("SELECT priKey, dataField "
       + "FROM autoIncTutorial");

    rs.moveToInsertRow();

    rs.updateString("dataField", "AUTO INCREMENT here?");
    rs.insertRow();

    //
    // the driver adds rows at the end
    //

    rs.last();

    //
    // We should now be on the row we just inserted
    //

    int autoIncKeyFromRS = rs.getInt("priKey");

    rs.close();

    rs = null;

    System.out.println("Key returned for inserted row: "
        + autoIncKeyFromRS);

} finally {

    if (rs != null) {
        try {
            rs.close();
        } catch (SQLException ex) {
            // ignore
        }
    }

    if (stmt != null) {
        try {
            stmt.close();
        } catch (SQLException ex) {
```

```
            // ignore
        }
    }
}
```

When you run the preceding example code, you should get the following output: Key returned from `getGeneratedKeys()`: 1 Key returned from `SELECT LAST_INSERT_ID()`: 1 Key returned for inserted row: 2 You should be aware, that at times, it can be tricky to use the `SELECT LAST_INSERT_ID()` query, as that function's value is scoped to a connection. So, if some other query happens on the same connection, the value will be overwritten. On the other hand, the `getGeneratedKeys()` method is scoped by the `Statement` instance, so it can be used even if other queries happen on the same connection, but not on the same `Statement` instance.

20.3.5.2. Using Connector/J with J2EE and Other Java Frameworks

This section describes how to use Connector/J in several contexts.

20.3.5.2.1. General J2EE Concepts

This section provides general background on J2EE concepts that pertain to use of Connector/J.

20.3.5.2.1.1. Understanding Connection Pooling

Connection pooling is a technique of creating and managing a pool of connections that are ready for use by any thread that needs them.

This technique of pooling connections is based on the fact that most applications only need a thread to have access to a JDBC connection when they are actively processing a transaction, which usually take only milliseconds to complete. When not processing a transaction, the connection would otherwise sit idle. Instead, connection pooling allows the idle connection to be used by some other thread to do useful work.

In practice, when a thread needs to do work against a MySQL or other database with JDBC, it requests a connection from the pool. When the thread is finished using the connection, it returns it to the pool, so that it may be used by any other threads that want to use it.

When the connection is loaned out from the pool, it is used exclusively by the thread that requested it. From a programming point of view, it is the same as if your thread called `DriverManager.getConnection()` every time it needed a JDBC connection, however with connection pooling, your thread may end up using either a new, or already-existing connection.

Connection pooling can greatly increase the performance of your Java application, while reducing overall resource usage. The main benefits to connection pooling are:

- Reduced connection creation time

  Although this is not usually an issue with the quick connection setup that MySQL offers compared to other databases, creating new JDBC connections still incurs networking and JDBC driver overhead that will be avoided if connections are recycled.

- Simplified programming model

  When using connection pooling, each individual thread can act as though it has created its own JDBC connection, allowing you to use straight-forward JDBC programming techniques.

- Controlled resource usage

  If you do not use connection pooling, and instead create a new connection every time a thread needs one, your application's resource usage can be quite wasteful and lead to unpredictable behavior under load.

Remember that each connection to MySQL has overhead (memory, CPU, context switches, and so forth) on both the client and server side. Every connection limits how many resources there are available to your application as well as the MySQL server. Many of these resources will be used whether or not the connection is actually doing any useful work!

Connection pools can be tuned to maximize performance, while keeping resource utilization below the point where your application will start to fail rather than just run slower.

Luckily, Sun has standardized the concept of connection pooling in JDBC through the JDBC-2.0 Optional interfaces, and all major application servers have implementations of these APIs that work fine with MySQL Connector/J.

Generally, you configure a connection pool in your application server configuration files, and access it via the Java Naming and Directory Interface (JNDI). The following code shows how you might use a connection pool from an application deployed in a J2EE application server:

Example 20.11. Connector/J: Using a connection pool with a J2EE application server

```
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;

import javax.naming.InitialContext;
import javax.sql.DataSource;

public class MyServletJspOrEjb {

    public void doSomething() throws Exception {
        /*
         * Create a JNDI Initial context to be able to
         *  lookup  the DataSource
         *
         * In production-level code, this should be cached as
         * an instance or static variable, as it can
         * be quite expensive to create a JNDI context.
         *
         * Note: This code only works when you are using servlets
         * or EJBs in a J2EE application server. If you are
         * using connection pooling in standalone Java code, you
         * will have to create/configure datasources using whatever
         * mechanisms your particular connection pooling library
         * provides.
         */

        InitialContext ctx = new InitialContext();

         /*
          * Lookup the DataSource, which will be backed by a pool
          * that the application server provides. DataSource instances
          * are also a good candidate for caching as an instance
          * variable, as JNDI lookups can be expensive as well.
          */

        DataSource ds =
          (DataSource)ctx.lookup("java:comp/env/jdbc/MySQLDB");

        /*
         * The following code is what would actually be in your
         * Servlet, JSP or EJB 'service' method...where you need
         * to work with a JDBC connection.
         */

        Connection conn = null;
        Statement stmt = null;

        try {
            conn = ds.getConnection();

            /*
             * Now, use normal JDBC programming to work with
             * MySQL, making sure to close each resource when you're
             * finished with it, which allows the connection pool
             * resources to be recovered as quickly as possible
             */

            stmt = conn.createStatement();
            stmt.execute("SOME SQL QUERY");

            stmt.close();
            stmt = null;

            conn.close();
            conn = null;
        } finally {
            /*
             * close any jdbc instances here that weren't
             * explicitly closed during normal code path, so
             * that we don't 'leak' resources...
             */

            if (stmt != null) {
                try {
                    stmt.close();
```

```
                } catch (sqlexception sqlex) {
                    // ignore -- as we can't do anything about it here
                }

                stmt = null;
            }

            if (conn != null) {
                try {
                    conn.close();
                } catch (sqlexception sqlex) {
                    // ignore -- as we can't do anything about it here
                }

                conn = null;
            }
        }
    }
}
```

As shown in the example above, after obtaining the JNDI InitialContext, and looking up the DataSource, the rest of the code should look familiar to anyone who has done JDBC programming in the past.

The most important thing to remember when using connection pooling is to make sure that no matter what happens in your code (exceptions, flow-of-control, and so forth), connections, and anything created by them (such as statements or result sets) are closed, so that they may be re-used, otherwise they will be stranded, which in the best case means that the MySQL server resources they represent (such as buffers, locks, or sockets) may be tied up for some time, or worst case, may be tied up forever.

What Is the Best Size for my Connection Pool?

As with all other configuration rules-of-thumb, the answer is: it depends. Although the optimal size depends on anticipated load and average database transaction time, the optimum connection pool size is smaller than you might expect. If you take Sun's Java Petstore blueprint application for example, a connection pool of 15-20 connections can serve a relatively moderate load (600 concurrent users) using MySQL and Tomcat with response times that are acceptable.

To correctly size a connection pool for your application, you should create load test scripts with tools such as Apache JMeter or The Grinder, and load test your application.

An easy way to determine a starting point is to configure your connection pool's maximum number of connections to be unbounded, run a load test, and measure the largest amount of concurrently used connections. You can then work backward from there to determine what values of minimum and maximum pooled connections give the best performance for your particular application.

20.3.5.2.2. Using Connector/J with Tomcat

The following instructions are based on the instructions for Tomcat-5.x, available at http://tomcat.apache.org/tomcat-5.5-doc/jndi-datasource-examples-howto.html which is current at the time this document was written.

First, install the .jar file that comes with Connector/J in `$CATALINA_HOME/common/lib` so that it is available to all applications installed in the container.

Next, Configure the JNDI DataSource by adding a declaration resource to `$CATALINA_HOME/conf/server.xml` in the context that defines your web application:

```
<Context ....>

  ...

  <Resource name="jdbc/MySQLDB"
              auth="Container"
              type="javax.sql.DataSource"/>

  <!-- The name you used above, must match _exactly_ here!

       The connection pool will be bound into JNDI with the name
       "java:/comp/env/jdbc/MySQLDB"
  -->

  <ResourceParams name="jdbc/MySQLDB">
    <parameter>
      <name>factory</name>
      <value>org.apache.commons.dbcp.BasicDataSourceFactory</value>
    </parameter>

    <!-- Don't set this any higher than max_connections on your
         MySQL server, usually this should be a 10 or a few 10's
         of connections, not hundreds or thousands -->
```

```
  <parameter>
    <name>maxActive</name>
    <value>10</value>
  </parameter>

  <!-- You don't want to many idle connections hanging around
       if you can avoid it, only enough to soak up a spike in
       the load -->

  <parameter>
    <name>maxIdle</name>
    <value>5</value>
  </parameter>

  <!-- Don't use autoReconnect=true, it's going away eventually
       and it's a crutch for older connection pools that couldn't
       test connections. You need to decide whether your application
       is supposed to deal with SQLExceptions (hint, it should), and
       how much of a performance penalty you're willing to pay
       to ensure 'freshness' of the connection -->

  <parameter>
    <name>validationQuery</name>
    <value>SELECT 1</value> <-- See discussion below for update to this option -->
  </parameter>

 <!-- The most conservative approach is to test connections
       before they're given to your application. For most applications
       this is okay, the query used above is very small and takes
       no real server resources to process, other than the time used
       to traverse the network.

       If you have a high-load application you'll need to rely on
       something else. -->

  <parameter>
    <name>testOnBorrow</name>
    <value>true</value>
  </parameter>

 <!-- Otherwise, or in addition to testOnBorrow, you can test
       while connections are sitting idle -->

  <parameter>
    <name>testWhileIdle</name>
    <value>true</value>
  </parameter>

  <!-- You have to set this value, otherwise even though
       you've asked connections to be tested while idle,
       the idle evicter thread will never run -->

  <parameter>
    <name>timeBetweenEvictionRunsMillis</name>
    <value>10000</value>
  </parameter>

  <!-- Don't allow connections to hang out idle too long,
       never longer than what wait_timeout is set to on the
       server...A few minutes or even fraction of a minute
       is sometimes okay here, it depends on your application
       and how much spikey load it will see -->

  <parameter>
    <name>minEvictableIdleTimeMillis</name>
    <value>60000</value>
  </parameter>

  <!-- Username and password used when connecting to MySQL -->

  <parameter>
   <name>username</name>
   <value>someuser</value>
  </parameter>

  <parameter>
   <name>password</name>
   <value>somepass</value>
  </parameter>

  <!-- Class name for the Connector/J driver -->

  <parameter>
     <name>driverClassName</name>
     <value>com.mysql.jdbc.Driver</value>
  </parameter>

  <!-- The JDBC connection url for connecting to MySQL, notice
       that if you want to pass any other MySQL-specific parameters
```

```
         you should pass them here in the URL, setting them using the
         parameter tags above will have no effect, you will also
         need to use &amp;amp; to separate parameter values as the
         ampersand is a reserved character in XML -->

    <parameter>
      <name>url</name>
      <value>jdbc:mysql://localhost:3306/test</value>
    </parameter>

  </ResourceParams>
</Context>
```

Note that Connector/J 5.1.3 introduced a facility whereby, rather than use a `validationQuery` value of `SELECT 1`, it is possible to use `validationQuery` with a value set to `/* ping */`. This sends a ping to the server which then returns a fake result set. This is a lighter weight solution. It also has the advantage that if using `ReplicationConnection` or `LoadBalancedConnection` type connections, the ping will be sent across all active connections. The following XML snippet illustrates how to select this option:

```
<parameter>
 <name>validationQuery</name>
 <value>/* ping */</value>
</parameter>
```

Note that `/* ping */` has to be specified exactly.

In general, you should follow the installation instructions that come with your version of Tomcat, as the way you configure datasources in Tomcat changes from time-to-time, and unfortunately if you use the wrong syntax in your XML file, you will most likely end up with an exception similar to the following:

```
Error: java.sql.SQLException: Cannot load JDBC driver class 'null ' SQL
state: null
```

20.3.5.2.3. Using Connector/J with JBoss

These instructions cover JBoss-4.x. To make the JDBC driver classes available to the application server, copy the .jar file that comes with Connector/J to the `lib` directory for your server configuration (which is usually called `default`). Then, in the same configuration directory, in the subdirectory named deploy, create a datasource configuration file that ends with "-ds.xml", which tells JBoss to deploy this file as a JDBC Datasource. The file should have the following contents:

```
<datasources>
    <local-tx-datasource>
        <!-- This connection pool will be bound into JNDI with the name
             "java:/MySQLDB" -->

        <jndi-name>MySQLDB</jndi-name>
        <connection-url>jdbc:mysql://localhost:3306/dbname</connection-url>
        <driver-class>com.mysql.jdbc.Driver</driver-class>
        <user-name>user</user-name>
        <password>pass</password>

        <min-pool-size>5</min-pool-size>

        <!-- Don't set this any higher than max_connections on your
         MySQL server, usually this should be a 10 or a few 10's
         of connections, not hundreds or thousands -->

        <max-pool-size>20</max-pool-size>

        <!-- Don't allow connections to hang out idle too long,
         never longer than what wait_timeout is set to on the
         server...A few minutes is usually okay here,
         it depends on your application
         and how much spikey load it will see -->

        <idle-timeout-minutes>5</idle-timeout-minutes>

        <!-- If you're using Connector/J 3.1.8 or newer, you can use
             our implementation of these to increase the robustness
             of the connection pool. -->

        <exception-sorter-class-name>
  com.mysql.jdbc.integration.jboss.ExtendedMysqlExceptionSorter
        </exception-sorter-class-name>
        <valid-connection-checker-class-name>
  com.mysql.jdbc.integration.jboss.MysqlValidConnectionChecker
        </valid-connection-checker-class-name>
```

```
    </local-tx-datasource>
</datasources>
```

20.3.5.2.4. Using Connector/J with Spring

The Spring Framework is a Java-based application framework designed for assisting in application design by providing a way to configure components. The technique used by Spring is a well known design pattern called Dependency Injection (see Inversion of Control Containers and the Dependency Injection pattern). This article will focus on Java-oriented access to MySQL databases with Spring 2.0. For those wondering, there is a .NET port of Spring appropriately named Spring.NET.

Spring is not only a system for configuring components, but also includes support for aspect oriented programming (AOP). This is one of the main benefits and the foundation for Spring's resource and transaction management. Spring also provides utilities for integrating resource management with JDBC and Hibernate.

For the examples in this section the MySQL world sample database will be used. The first task is to set up a MySQL data source through Spring. Components within Spring use the "bean" terminology. For example, to configure a connection to a MySQL server supporting the world sample database you might use:

```
<util:map id="dbProps">
    <entry key="db.driver" value="com.mysql.jdbc.Driver"/>
    <entry key="db.jdbcurl" value="jdbc:mysql://localhost/world"/>
    <entry key="db.username" value="myuser"/>
    <entry key="db.password" value="mypass"/>
</util:map>
```

In the above example we are assigning values to properties that will be used in the configuration. For the datasource configuration:

```
<bean id="dataSource"
       class="org.springframework.jdbc.datasource.DriverManagerDataSource">
    <property name="driverClassName" value="${db.driver}"/>
    <property name="url" value="${db.jdbcurl}"/>
    <property name="username" value="${db.username}"/>
    <property name="password" value="${db.password}"/>
</bean>
```

The placeholders are used to provide values for properties of this bean. This means that you can specify all the properties of the configuration in one place instead of entering the values for each property on each bean. We do, however, need one more bean to pull this all together. The last bean is responsible for actually replacing the placeholders with the property values.

```
<bean
 class="org.springframework.beans.factory.config.PropertyPlaceholderConfigurer">
    <property name="properties" ref="dbProps"/>
</bean>
```

Now that we have our MySQL data source configured and ready to go, we write some Java code to access it. The example below will retrieve three random cities and their corresponding country using the data source we configured with Spring.

```
// Create a new application context. this processes the Spring config
ApplicationContext ctx =
    new ClassPathXmlApplicationContext("ex1appContext.xml");
// Retrieve the data source from the application context
    DataSource ds = (DataSource) ctx.getBean("dataSource");
// Open a database connection using Spring's DataSourceUtils
Connection c = DataSourceUtils.getConnection(ds);
try {
    // retrieve a list of three random cities
    PreparedStatement ps = c.prepareStatement(
        "select City.Name as 'City', Country.Name as 'Country' " +
        "from City inner join Country on City.CountryCode = Country.Code " +
        "order by rand() limit 3");
    ResultSet rs = ps.executeQuery();
    while(rs.next()) {
        String city = rs.getString("City");
        String country = rs.getString("Country");
        System.out.printf("The city %s is in %s%n", city, country);
    }
} catch (SQLException ex) {
    // something has failed and we print a stack trace to analyse the error
    ex.printStackTrace();
    // ignore failure closing connection
    try { c.close(); } catch (SQLException e) { }
```

```
} finally {
    // properly release our connection
    DataSourceUtils.releaseConnection(c, ds);
}
```

This is very similar to normal JDBC access to MySQL with the main difference being that we are using DataSourceUtils instead of the DriverManager to create the connection.

While it may seem like a small difference, the implications are somewhat far reaching. Spring manages this resource in a way similar to a container managed data source in a J2EE application server. When a connection is opened, it can be subsequently accessed in other parts of the code if it is synchronized with a transaction. This makes it possible to treat different parts of your application as transactional instead of passing around a database connection.

20.3.5.2.4.1. Using `JdbcTemplate`

Spring makes extensive use of the Template method design pattern (see Template Method Pattern). Our immediate focus will be on the `JdbcTemplate` and related classes, specifically `NamedParameterJdbcTemplate`. The template classes handle obtaining and releasing a connection for data access when one is needed.

The next example shows how to use `NamedParameterJdbcTemplate` inside of a DAO (Data Access Object) class to retrieve a random city given a country code.

```
public class Ex2JdbcDao {
     /**
     * Data source reference which will be provided by Spring.
     */
     private DataSource dataSource;

     /**
     * Our query to find a random city given a country code. Notice
     * the ":country" parameter toward the end. This is called a
     * named parameter.
     */
     private String queryString = "select Name from City " +
        "where CountryCode = :country order by rand() limit 1";

     /**
     * Retrieve a random city using Spring JDBC access classes.
     */
     public String getRandomCityByCountryCode(String cntryCode) {
         // A template that allows using queries with named parameters
         NamedParameterJdbcTemplate template =
         new NamedParameterJdbcTemplate(dataSource);
         // A java.util.Map is used to provide values for the parameters
         Map params = new HashMap();
         params.put("country", cntryCode);
         // We query for an Object and specify what class we are expecting
         return (String)template.queryForObject(queryString, params, String.class);
     }

    /**
    * A JavaBean setter-style method to allow Spring to inject the data source.
    * @param dataSource
    */
    public void setDataSource(DataSource dataSource) {
        this.dataSource = dataSource;
    }
}
```

The focus in the above code is on the `getRandomCityByCountryCode()` method. We pass a country code and use the `NamedParameterJdbcTemplate` to query for a city. The country code is placed in a Map with the key "country", which is the parameter is named in the SQL query.

To access this code, you need to configure it with Spring by providing a reference to the data source.

```
<bean id="dao" class="code.Ex2JdbcDao">
    <property name="dataSource" ref="dataSource"/>
</bean>
```

At this point, we can just grab a reference to the DAO from Spring and call `getRandomCityByCountryCode()`.

```
// Create the application context
    ApplicationContext ctx =
    new ClassPathXmlApplicationContext("ex2appContext.xml");
    // Obtain a reference to our DAO
    Ex2JdbcDao dao = (Ex2JdbcDao) ctx.getBean("dao");
```

```
    String countryCode = "USA";

    // Find a few random cities in the US
    for(int i = 0; i < 4; ++i)
        System.out.printf("A random city in %s is %s%n", countryCode,
            dao.getRandomCityByCountryCode(countryCode));
```

This example shows how to use Spring's JDBC classes to completely abstract away the use of traditional JDBC classes including `Connection` and `PreparedStatement`.

20.3.5.2.4.2. Transactional JDBC Access

You might be wondering how we can add transactions into our code if we do not deal directly with the JDBC classes. Spring provides a transaction management package that not only replaces JDBC transaction management, but also allows declarative transaction management (configuration instead of code).

In order to use transactional database access, we will need to change the storage engine of the tables in the world database. The downloaded script explicitly creates MyISAM tables which do not support transactional semantics. The InnoDB storage engine does support transactions and this is what we will be using. We can change the storage engine with the following statements.

```
ALTER TABLE City ENGINE=InnoDB;
ALTER TABLE Country ENGINE=InnoDB;
ALTER TABLE CountryLanguage ENGINE=InnoDB;
```

A good programming practice emphasized by Spring is separating interfaces and implementations. What this means is that we can create a Java interface and only use the operations on this interface without any internal knowledge of what the actual implementation is. We will let Spring manage the implementation and with this it will manage the transactions for our implementation.

First you create a simple interface:

```
public interface Ex3Dao {
    Integer createCity(String name, String countryCode,
    String district, Integer population);
}
```

This interface contains one method that will create a new city record in the database and return the id of the new record. Next you need to create an implementation of this interface.

```
public class Ex3DaoImpl implements Ex3Dao {
    protected DataSource dataSource;
    protected SqlUpdate updateQuery;
    protected SqlFunction idQuery;

    public Integer createCity(String name, String countryCode,
        String district, Integer population) {
            updateQuery.update(new Object[] { name, countryCode,
                   district, population });
            return getLastId();
        }

    protected Integer getLastId() {
        return idQuery.run();
    }
}
```

You can see that we only operate on abstract query objects here and do not deal directly with the JDBC API. Also, this is the complete implementation. All of our transaction management will be dealt with in the configuration. To get the configuration started, we need to create the DAO.

```
<bean id="dao" class="code.Ex3DaoImpl">
    <property name="dataSource" ref="dataSource"/>
    <property name="updateQuery">...</property>
    <property name="idQuery">...</property>
</bean>
```

Now you need to set up the transaction configuration. The first thing you must do is create transaction manager to manage the data source and a specification of what transaction properties are required for the `dao` methods.

```
<bean id="transactionManager"
  class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
    <property name="dataSource" ref="dataSource"/>
</bean>
```

```
<tx:advice id="txAdvice" transaction-manager="transactionManager">
    <tx:attributes>
        <tx:method name="*"/>
    </tx:attributes>
</tx:advice>
```

The preceding code creates a transaction manager that handles transactions for the data source provided to it. The `txAdvice` uses this transaction manager and the attributes specify to create a transaction for all methods. Finally you need to apply this advice with an AOP pointcut.

```
<aop:config>
    <aop:pointcut id="daoMethods"
        expression="execution(* code.Ex3Dao.*(..))"/>
     <aop:advisor advice-ref="txAdvice" pointcut-ref="daoMethods"/>
</aop:config>
```

This basically says that all methods called on the `Ex3Dao` interface will be wrapped in a transaction. To make use of this, you only have to retrieve the `dao` from the application context and call a method on the `dao` instance.

```
Ex3Dao dao = (Ex3Dao) ctx.getBean("dao");
Integer id = dao.createCity(name,  countryCode, district, pop);
```

We can verify from this that there is no transaction management happening in our Java code and it is all configured with Spring. This is a very powerful notion and regarded as one of the most beneficial features of Spring.

20.3.5.2.4.3. Connection Pooling

In many sitations, such as web applications, there will be a large number of small database transactions. When this is the case, it usually makes sense to create a pool of database connections available for web requests as needed. Although MySQL does not spawn an extra process when a connection is made, there is still a small amount of overhead to create and set up the connection. Pooling of connections also alleviates problems such as collecting large amounts of sockets in the `TIME_WAIT` state.

Setting up pooling of MySQL connections with Spring is as simple as changing the data source configuration in the application context. There are a number of configurations that we can use. The first example is based on the Jakarta Commons DBCP library. The example below replaces the source configuration that was based on `DriverManagerDataSource` with DBCP's BasicDataSource.

```
<bean id="dataSource" destroy-method="close"
  class="org.apache.commons.dbcp.BasicDataSource">
    <property name="driverClassName" value="${db.driver}"/>
    <property name="url" value="${db.jdbcurl}"/>
    <property name="username" value="${db.username}"/>
    <property name="password" value="${db.password}"/>
    <property name="initialSize" value="3"/>
</bean>
```

The configuration of the two solutions is very similar. The difference is that DBCP will pool connections to the database instead of creating a new connection every time one is requested. We have also set a parameter here called `initialSize`. This tells DBCP that we want three connections in the pool when it is created.

Another way to configure connection pooling is to configure a data source in our J2EE application server. Using JBoss as an example, you can set up the MySQL connection pool by creating a file called `mysql-local-ds.xml` and placing it in the server/default/deploy directory in JBoss. Once we have this setup, we can use JNDI to look it up. With Spring, this lookup is very simple. The data source configuration looks like this.

```
<jee:jndi-lookup id="dataSource" jndi-name="java:MySQL_DS"/>
```

20.3.5.2.5. Using Connector/J with GlassFish

20.3.5.3. Connector/J: Common Problems and Solutions

There are a few issues that seem to be commonly encountered often by users of MySQL Connector/J. This section deals with their symptoms, and their resolutions.

Questions

- 21.3.5.3.1: When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

  What is going on? I can connect just fine with the MySQL command-line client.

- 21.3.5.3.2: My application throws an SQLException 'No Suitable Driver'. Why is this happening?

- 21.3.5.3.3: I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

- 21.3.5.3.4: I have a servlet/application that works fine for a day, and then stops working overnight

- 21.3.5.3.5: I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.

- 21.3.5.3.6: I cannot connect to the MySQL server using Connector/J, and I'm sure the connection paramters are correct.

- 21.3.5.3.7: I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```
java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

- 21.3.5.3.8: My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting a error and stack trace, but these only occur after a fixed period of heavy activity.

- 21.3.5.3.9: When using `gcj` an `java.io.CharConversionException` is raised when working with certain character sequences.

- 21.3.5.3.10: Updating a table that contains a primary key that is either `FLOAT` or compound primary key that uses `FLOAT` fails to update the table and raises an exception.

- 21.3.5.3.11: You get an `ER_NET_PACKET_TOO_LARGE` exception, even though the binary blob size you want to insert via JDBC is safely below the `max_allowed_packet` size.

Questions and Answers

21.3.5.3.1: When I try to connect to the database with MySQL Connector/J, I get the following exception:

```
SQLException: Server configuration denies access to data source
SQLState: 08001
VendorError: 0
```

What is going on? I can connect just fine with the MySQL command-line client.

MySQL Connector/J must use TCP/IP sockets to connect to MySQL, as Java does not support Unix Domain Sockets. Therefore, when MySQL Connector/J connects to MySQL, the security manager in MySQL server will use its grant tables to determine whether the connection should be allowed.

You must add the necessary security credentials to the MySQL server for this to happen, using the `GRANT` statement to your MySQL Server. See Section 12.4.1.3, “`GRANT` Syntax”, for more information.

> **Note**
>
> Testing your connectivity with the `mysql` command-line client will not work unless you add the `--host` flag, and use something other than `localhost` for the host. The `mysql` command-line client will use Unix domain sockets if you use the special host name `localhost`. If you are testing connectivity to `localhost`, use `127.0.0.1` as the host name instead.

> **Warning**
>
> Changing privileges and permissions improperly in MySQL can potentially cause your server installation to not have optimal security properties.

21.3.5.3.2: My application throws an SQLException 'No Suitable Driver'. Why is this happening?

There are three possible causes for this error:

- The Connector/J driver is not in your `CLASSPATH`, see Section 20.3.2, “Connector/J Installation”.
- The format of your connection URL is incorrect, or you are referencing the wrong JDBC driver.
- When using DriverManager, the `jdbc.drivers` system property has not been populated with the location of the Connector/J driver.

21.3.5.3.3: I'm trying to use MySQL Connector/J in an applet or application and I get an exception similar to:

```
SQLException: Cannot connect to MySQL server on host:3306.
Is there a MySQL server running on the machine/port you
are trying to connect to?

(java.security.AccessControlException)
SQLState: 08S01
VendorError: 0
```

Either you're running an Applet, your MySQL server has been installed with the "--skip-networking" option set, or your MySQL server has a firewall sitting in front of it.

Applets can only make network connections back to the machine that runs the web server that served the .class files for the applet. This means that MySQL must run on the same machine (or you must have some sort of port re-direction) for this to work. This also means that you will not be able to test applets from your local file system, you must always deploy them to a web server.

MySQL Connector/J can only communicate with MySQL using TCP/IP, as Java does not support Unix domain sockets. TCP/IP communication with MySQL might be affected if MySQL was started with the "--skip-networking" flag, or if it is firewalled.

If MySQL has been started with the "--skip-networking" option set (the Debian Linux package of MySQL server does this for example), you need to comment it out in the file /etc/mysql/my.cnf or /etc/my.cnf. Of course your my.cnf file might also exist in the `data` directory of your MySQL server, or anywhere else (depending on how MySQL was compiled for your system). Binaries created by us always look in /etc/my.cnf and [datadir]/my.cnf. If your MySQL server has been firewalled, you will need to have the firewall configured to allow TCP/IP connections from the host where your Java code is running to the MySQL server on the port that MySQL is listening to (by default, 3306).

21.3.5.3.4: I have a servlet/application that works fine for a day, and then stops working overnight

MySQL closes connections after 8 hours of inactivity. You either need to use a connection pool that handles stale connections or use the "autoReconnect" parameter (see Section 20.3.4.1, “Driver/Datasource Class Names, URL Syntax and Configuration Properties for Connector/J”).

Also, you should be catching SQLExceptions in your application and dealing with them, rather than propagating them all the way until your application exits, this is just good programming practice. MySQL Connector/J will set the SQLState (see `java.sql.SQLException.getSQLState()` in your APIDOCS) to "08S01" when it encounters network-connectivity issues during the processing of a query. Your application code should then attempt to re-connect to MySQL at this point.

The following (simplistic) example shows what code that can handle these exceptions might look like:

Example 20.12. Connector/J: Example of transaction with retry logic

```
public void doBusinessOp() throws SQLException {
    Connection conn = null;
    Statement stmt = null;
    ResultSet rs = null;

    //
    // How many times do you want to retry the transaction
    // (or at least _getting_ a connection)?
    //
    int retryCount = 5;

    boolean transactionCompleted = false;

    do {
        try {
            conn = getConnection(); // assume getting this from a
                                    // javax.sql.DataSource, or the
                                    // java.sql.DriverManager

            conn.setAutoCommit(false);

            //
            // Okay, at this point, the 'retry-ability' of the
            // transaction really depends on your application logic,
            // whether or not you're using autocommit (in this case
            // not), and whether you're using transacational storage
            // engines
            //
            // For this example, we'll assume that it's _not_ safe
            // to retry the entire transaction, so we set retry
            // count to 0 at this point
            //
            // If you were using exclusively transaction-safe tables,
            // or your application could recover from a connection going
            // bad in the middle of an operation, then you would not
            // touch 'retryCount' here, and just let the loop repeat
            // until retryCount == 0.
            //
            retryCount = 0;

            stmt = conn.createStatement();

            String query = "SELECT foo FROM bar ORDER BY baz";

            rs = stmt.executeQuery(query);

            while (rs.next()) {
            }

            rs.close();
            rs = null;

            stmt.close();
            stmt = null;

            conn.commit();
            conn.close();
            conn = null;

            transactionCompleted = true;
        } catch (SQLException sqlEx) {

            //
            // The two SQL states that are 'retry-able' are 08S01
            // for a communications error, and 40001 for deadlock.
            //
            // Only retry if the error was due to a stale connection,
            // communications problem or deadlock
            //

            String sqlState = sqlEx.getSQLState();

            if ("08S01".equals(sqlState) || "40001".equals(sqlState)) {
                retryCount--;
            } else {
                retryCount = 0;
            }
        } finally {
            if (rs != null) {
                try {
                    rs.close();
                } catch (SQLException sqlEx) {
                    // You'd probably want to log this . . .
                }
            }
```

```
            if (stmt != null) {
                try {
                    stmt.close();
                } catch (SQLException sqlEx) {
                    // You'd probably want to log this as well . . .
                }
            }

            if (conn != null) {
                try {
                    //
                    // If we got here, and conn is not null, the
                    // transaction should be rolled back, as not
                    // all work has been done

                    try {
                        conn.rollback();
                    } finally {
                        conn.close();
                    }
                } catch (SQLException sqlEx) {
                    //
                    // If we got an exception here, something
                    // pretty serious is going on, so we better
                    // pass it up the stack, rather than just
                    // logging it. . .

                    throw sqlEx;
                }
            }
        }
    } while (!transactionCompleted && (retryCount > 0));
}
```

> **Note**
>
> Use of the `autoReconnect` option is not recommended because there is no safe method of reconnecting to the MySQL server without risking some corruption of the connection state or database state information. Instead, you should use a connection pool which will enable your application to connect to the MySQL server using an available connection from the pool. The `autoReconnect` facility is deprecated, and may be removed in a future release.

21.3.5.3.5: I'm trying to use JDBC-2.0 updatable result sets, and I get an exception saying my result set is not updatable.

Because MySQL does not have row identifiers, MySQL Connector/J can only update result sets that have come from queries on tables that have at least one primary key, the query must select every primary key and the query can only span one table (that is, no joins). This is outlined in the JDBC specification.

Note that this issue only occurs when using updatable result sets, and is caused because Connector/J is unable to guarantee that it can identify the correct rows within the result set to be updated without having a unique reference to each row. There is no requirement to have a unique field on a table if you are using `UPDATE` or `DELETE` statements on a table where you can individually specify the criteria to be matched using a `WHERE` clause.

21.3.5.3.6: I cannot connect to the MySQL server using Connector/J, and I'm sure the connection paramters are correct.

Make sure that the `skip-networking` option has not been enabled on your server. Connector/J must be able to communicate with your server over TCP/IP, named sockets are not supported. Also ensure that you are not filtering connections through a Firewall or other network security system. For more information, see Section B.5.2.2, “`Can't connect to [local] MySQL server`”.

21.3.5.3.7: I am trying to connect to my MySQL server within my application, but I get the following error and stack trace:

```
java.net.SocketException
MESSAGE: Software caused connection abort: recv failed

STACKTRACE:

java.net.SocketException: Software caused connection abort: recv failed
at java.net.SocketInputStream.socketRead0(Native Method)
at java.net.SocketInputStream.read(Unknown Source)
at com.mysql.jdbc.MysqlIO.readFully(MysqlIO.java:1392)
at com.mysql.jdbc.MysqlIO.readPacket(MysqlIO.java:1414)
at com.mysql.jdbc.MysqlIO.doHandshake(MysqlIO.java:625)
at com.mysql.jdbc.Connection.createNewIO(Connection.java:1926)
at com.mysql.jdbc.Connection.<init>(Connection.java:452)
at com.mysql.jdbc.NonRegisteringDriver.connect(NonRegisteringDriver.java:411)
```

The error probably indicates that you are using a older version of the Connector/J JDBC driver (2.0.14 or 3.0.x) and you are trying to connect to a MySQL server with version 4.1x or newer. The older drivers are not compatible with 4.1 or newer of MySQL as they do not support the newer authentication mechanisms.

It is likely that the older version of the Connector/J driver exists within your application directory or your `CLASSPATH` includes the older Connector/J package.

21.3.5.3.8: My application is deployed through JBoss and I am using transactions to handle the statements on the MySQL database. Under heavy loads I am getting a error and stack trace, but these only occur after a fixed period of heavy activity.

This is a JBoss, not Connector/J, issue and is connected to the use of transactions. Under heavy loads the time taken for transactions to complete can increase, and the error is caused because you have exceeded the predefined timeout.

You can increase the timeout value by setting the `TransactionTimeout` attribute to the `TransactionManagerService` within the `/conf/jboss-service.xml` file (pre-4.0.3) or `/deploy/jta-service.xml` for JBoss 4.0.3 or later. See TransactionTimeoute within the JBoss wiki for more information.

21.3.5.3.9: When using `gcj` an `java.io.CharConversionException` is raised when working with certain character sequences.

This is a known issue with `gcj` which raises an exception when it reaches an unknown character or one it cannot convert. You should add `useJvmCharsetConverters=true` to your connection string to force character conversion outside of the `gcj` libraries, or try a different JDK.

21.3.5.3.10: Updating a table that contains a primary key that is either `FLOAT` or compound primary key that uses `FLOAT` fails to update the table and raises an exception.

Connector/J adds conditions to the `WHERE` clause during an `UPDATE` to check the old values of the primary key. If there is no match then Connector/J considers this a failure condition and raises an exception.

The problem is that rounding differences between supplied values and the values stored in the database may mean that the values never match, and hence the update fails. The issue will affect all queries, not just those from Connector/J.

To prevent this issue, use a primary key that does not use `FLOAT`. If you have to use a floating point column in your primary key use `DOUBLE` or `DECIMAL` types in place of `FLOAT`.

21.3.5.3.11: You get an `ER_NET_PACKET_TOO_LARGE` exception, even though the binary blob size you want to insert via JDBC is safely below the `max_allowed_packet` size.

This is because the `hexEscapeBlock()` method in `com.mysql.jdbc.PreparedStatement.streamToBytes()` may almost double the size of your data.

20.3.6. Connector/J Support

20.3.6.1. Connector/J Community Support

Sun Microsystems, Inc. provides assistance to the user community by means of its mailing lists. For Connector/J related issues, you can get help from experienced users by using the MySQL and Java mailing list. Archives and subscription information is available online at http://lists.mysql.com/java.

For information about subscribing to MySQL mailing lists or to browse list archives, visit http://lists.mysql.com/. See Section 1.6.1, “MySQL Mailing Lists”.

Community support from experienced users is also available through the JDBC Forum. You may also find help from other users in the other MySQL Forums, located at http://forums.mysql.com. See Section 1.6.2, “MySQL Community Support at the MySQL Forums”.

20.3.6.2. How to Report Connector/J Bugs or Problems

The normal place to report bugs is http://bugs.mysql.com/, which is the address for our bugs database. This database is public, and can be browsed and searched by anyone. If you log in to the system, you will also be able to enter new reports.

If you have found a sensitive security bug in MySQL, you can send email to `<security@mysql.com>`.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release.

This section will help you write your report correctly so that you do not waste your time doing things that may not help us much or at all.

If you have a repeatable bug report, please report it to the bugs database at http://bugs.mysql.com/. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

To report other problems, you can use one of the MySQL mailing lists.

Remember that it is possible for us to respond to a message containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter.

A good principle is this: If you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of Connector/J or MySQL used, and (b) not fully describing the platform on which Connector/J is installed (including the JVM version, and the platform type and version number that MySQL itself is installed on).

This is highly relevant information, and in 99 cases out of 100, the bug report is useless without it. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has already been fixed in newer MySQL versions.

Sometimes the error is platform-dependent; in such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If at all possible, you should create a repeatable, stanalone testcase that doesn't involve any third-party classes.

To streamline this process, we ship a base class for testcases with Connector/J, named '`com.mysql.jdbc.util.BaseBugReport`'. To create a testcase for Connector/J using this class, create your own class that inherits from `com.mysql.jdbc.util.BaseBugReport` and override the methods `setUp()`, `tearDown()` and `runTest()`.

In the `setUp()` method, create code that creates your tables, and populates them with any data needed to demonstrate the bug.

In the `runTest()` method, create code that demonstrates the bug using the tables and data you created in the `setUp` method.

In the `tearDown()` method, drop any tables you created in the `setUp()` method.

In any of the above three methods, you should use one of the variants of the `getConnection()` method to create a JDBC connection to MySQL:

- `getConnection()` - Provides a connection to the JDBC URL specified in `getUrl()`. If a connection already exists, that connection is returned, otherwise a new connection is created.
- `getNewConnection()` - Use this if you need to get a new connection for your bug report (that is, there is more than one connection involved).
- `getConnection(String url)` - Returns a connection using the given URL.
- `getConnection(String url, Properties props)` - Returns a connection using the given URL and properties.

If you need to use a JDBC URL that is different from 'jdbc:mysql:///test', override the method `getUrl()` as well.

Use the `assertTrue(boolean expression)` and `assertTrue(String failureMessage, boolean expression)` methods to create conditions that must be met in your testcase demonstrating the behavior you are expecting (vs. the behavior you are observing, which is why you are most likely filing a bug report).

Finally, create a `main()` method that creates a new instance of your testcase, and calls the `run` method:

```
public static void main(String[] args) throws Exception {
      new MyBugReport().run();
 }
```

Once you have finished your testcase, and have verified that it demonstrates the bug you are reporting, upload it with your bug report to http://bugs.mysql.com/.

20.3.6.3. Connector/J Change History

The Connector/J Change History (Changelog) is located with the main Changelog for MySQL. See Section C.6, “MySQL Connector/J Change History”.

20.4. MySQL Connector/MXJ

MySQL Connector/MXJ is a Java Utility package for deploying and managing a MySQL database. Deploying and using MySQL can be as easy as adding another parameter to the JDBC connection url, which will result in the database being started when the first connection is made. This makes it easy for Java developers to deploy applications which require a database by reducing installation barriers for their end-users.

MySQL Connector/MXJ makes the MySQL database appear to be a java-based component. It does this by determining what platform the system is running on, selecting the appropriate binary, and launching the executable. It will also optionally deploy an initial database, with any specified parameters.

Included are instructions for use with a JDBC driver and deploying as a JMX MBean to JBoss.

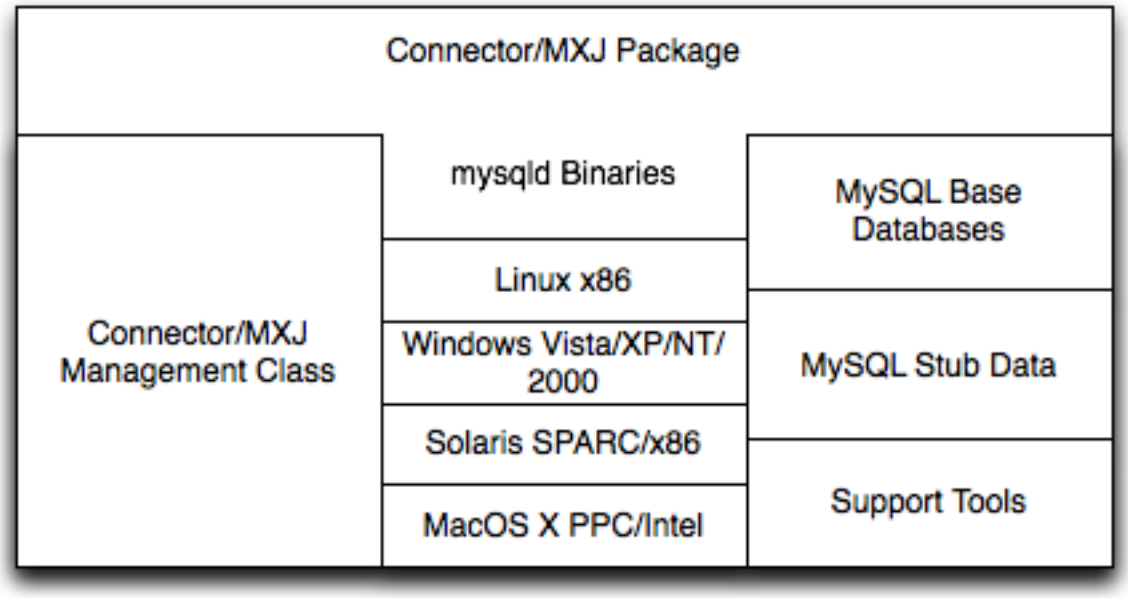
You can download sources and binaries from: http://dev.mysql.com/downloads/connector/mxj/

This a beta release and feedback is welcome and encouraged.

Please send questions or comments to the MySQL and Java mailing list.

20.4.1. Connector/MXJ Overview

Connector/MXJ consists of a Java class, a copy of the `mysqld` binary for a specific list of platforms, and associated files and support utilities. The Java class controls the initialization of an instance of the embedded `mysqld` binary, and the ongoing management of the `mysqld` process. The entire sequence and management can be controlled entirely from within Java using the Connector/MXJ Java classes. You can see an overview of the contents of the Connector/MXJ package in the figure below.



It is important to note that Connector/MXJ is not an embedded version of MySQL, or a version of MySQL written as part of a Java class. Connector/MXJ works through the use of an embedded, compiled binary of `mysqld` as would normally be used when deploying a standard MySQL installation.

It is the Connector/MXJ wrapper, support classes and tools, that enable Connector/MXJ to appear as a MySQL instance.

When Connector/MXJ is initialized, the corresponding `mysqld` binary for the current platform is extracted, along with a pre-

configured data directed. Both are contained within the Connector/MXJ JAR file. The `mysqld` instance is then started, with any additional options as specified during the initialization, and the MySQL database becomes accessible.

Because Connector/MXJ works in combination with Connector/J, you can access and integrate with the MySQL instance through a JDBC connection. When you have finished with the server, the instance is terminated, and, by default, any data created during the session is retained within the temporary directory created when the instance was started.

Connector/MXJ and the embedded `mysqld` instance can be deployed in a number of environments where relying on an existing database, or installing a MySQL instance would be impossible, including CD-ROM embedded database applications and temporary database requirements within a Java-based application environment.

20.4.2. Connector/MXJ Versions

- Connector/MXJ 5.x, currently in beta status, includes `mysqld` version 5.x and includes binaries for Linux x86, Mac OS X PPC, Windows XP/NT/2000 x86 and Solaris SPARC. Connector/MXJ 5.x requires the Connector/J 5.x package.

  The exact version of `mysqld` included depends on the version of Connector/MXJ

  1. Connector/MXJ v5.0.3 included MySQL v5.0.22
  2. Connector/MXJ v5.0.4 includes MySQL v5.0.27 (Community) or MySQL v5.0.32 (Enterprise)
  3. Connector/MXJ v5.0.6 includes MySQL 5.0.37 (Community)
  4. Connector/MXJ v5.0.7 includes MySQL 5.0.41 (Community) or MySQL 5.0.42 (Enterprise)
  5. Connector/MXJ v5.0.8 includes MySQL 5.0.45 (Community) or MySQL 5.0.46 (Enterprise)
  6. Connector/MXJ v5.0.9 includes MySQL 5.0.51a (Community) or MySQL 5.0.54 (Enterprise)

- Connector/MXJ 1.x includes `mysqld` version 4.1.13 and includes binaries for Linux x86, Windows XP/NT/2000 x86 and Solaris SPARC. Connector/MXJ 1.x requires the Connector/J 3.x package.

A summary of the different MySQL versions supplied with each Connector/MXJ release are shown in the table.

Connector/MXJ Version	MySQL Version(s)
5.0.8	5.0.45 (CS), 5.0.46 (ES)
5.0.7	5.0.41 (CS), 5.0.42 (ES)
5.0.6	5.0.37 (CS), 5.0.40 (ES)
5.0.5	5.0.37 (CS), 5.0.36 (ES)
5.0.4	5.0.27 (CS), 5.0.32 (ES)
5.0.3	5.0.22
5.0.2	5.0.19

This guide provides information on the Connector/MXJ 5.x release. For information on using the older releases, please see the documentation included with the appropriate distribution.

20.4.3. Connector/MXJ Installation

Connector/MXJ does not have a installation application or process, but there are some steps you can follow to make the installation and deployment of Connector/MXJ easier.

Before you start, there are some baseline requirements for

- Java Runtime Environment (v1.4.0 or newer) if you are only going to deploy the package.
- Java Development Kit (v1.4.0 or newer) if you want to build Connector/MXJ from source.

- Connector/J 5.0 or newer.

Depending on your target installation/deployment environment you may also require:

- JBoss - 4.0rc1 or newer
- Apache Tomcat - 5.0 or newer
- Sun's JMX reference implementation version 1.2.1 (from http://java.sun.com/products/JavaManagement/)

20.4.3.1. Supported Platforms

Connector/MXJ is compatible with any platform supporting Java and MySQL. By default, Connector/MXJ incorporates the `mysqld` binary for a select number of platforms which differs by version. The following platforms have been tested and working as deployment platforms. Support for all the platforms listed below is not included by default.

- Linux (i386)
- FreeBSD (i386)
- Windows NT (x86), Windows 2000 (x86), Windows XP (x86), Windows Vista (x86)
- Solaris 8, SPARC 32-bit (compatible with Solaris 8, Solaris 9 and Solaris 10 on SPARC 32-bit and 64-bit platforms)
- Mac OS X (PowerPC and Intel)

The Connector/MXJ 5.0.8 release includes `mysqld` binaries for the following platforms by as standard:

- Linux (i386)
- Windows (x86), compatible with Windows NT, Windows 2000, Windows XP , Windows Vista
- Solaris 8, SPARC 32-bit (compatible with Solaris 8, Solaris 9 and Solaris 10 on SPARC 32-bit and 64-bit platforms)
- Mac OS X (PowerPC and Intel)

For more information on packaging your own Connector/MXJ with the platforms you require, see Section 20.4.6.1, “Creating your own Connector/MXJ Package”

20.4.3.2. Connector/MXJ Base Installation

Because there is no formal installation process, the method, installation directory, and access methods you use for Connector/MXJ are entirely up to your individual requirements.

To perform a basic installation, choose a target directory for the files included in the Connector/MXJ package. On Unix/Linux systems you may opt to use a directory such as `/usr/local/connector-mxj`; On Windows, you may want to install the files in the base directory, `C:\Connector-MXJ`, or within the `Program Files` directory.

To install the files, for a Connector/MXJ 5.0.4 installation:

1. Download the Connector/MXJ package, either in Tar/Gzip format (ideal for Unix/Linux systems) or Zip format (Windows).
2. Extract the files from the package. This will create a directory `mysql-connector-mxj-gpl-[ver]`. Copy and optionally rename this directory to your desired location.
3. For best results, you should update your global `CLASSPATH` variable with the location of the required `jar` files.

   Within Unix/Linux you can do this globally by editing the global shell profile, or on a user by user basis by editing their individual

shell profile.

On Windows 2000, Windows NT and Windows XP, you can edit the global `CLASSPATH` by editing the `Environment Variables` configured through the `System` control panel.

For Connector/MXJ 5.0.6 and later you need the following JAR files in your `CLASSPATH`:

- `mysql-connector-mxj-gpl-[ver].jar`: contains the main Connector/MXJ classes.
- `mysql-connector-mxj-gpl-[ver]-db-files.jar`: contains the embedded `mysqld` and database files.
- `aspectjrt.jar`: the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
- `mysql-connector-java-[ver]-bin.jar`: Connector/J, see Section 20.3, "MySQL Connector/J".

For Connector/MXJ 5.0.4 and later you need the following JAR files in your `CLASSPATH`:

- `connector-mxj.jar`: contains the main Connector/MXJ classes.
- `connector-mxj-db-files.jar`: contains the embedded `mysqld` and database files.
- `aspectjrt.jar`: the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
- `mysql-connector-mxj-gpl-[ver].jar`: Connector/J, see Section 20.3, "MySQL Connector/J".

For Connector/MXJ 5.0.3 and earlier, you need the following JAR files:

- `connector-mxj.jar`
- `aspectjrt.jar`: the AspectJ runtime library, located in `lib/aspectjrt.jar` in the Connector/MXJ package.
- `mysql-connector-mxj-gpl-[ver].jar`: Connector/J, see Section 20.3, "MySQL Connector/J".

20.4.3.3. Connector/MXJ Quick Start Guide

Once you have extracted the Connector/MXJ and Connector/J components you can run one of the sample applications that initiates a MySQL instance. You can test the installation by running the `ConnectorMXJUrlTestExample`:

```
shell> java ConnectorMXJUrlTestExample
jdbc:mysql:mxj://localhost:3336/our_test_app?server.basedir»
    =/var/tmp/test-mxj&createDatabaseIfNotExist=true&server.initialize-user=true
[/var/tmp/test-mxj/bin/mysqld][--no-defaults][--port=3336][--socket=mysql.sock]»
    [--basedir=/var/tmp/test-mxj][--datadir=/var/tmp/test-mxj/data]»
    [--pid-file=/var/tmp/test-mxj/data/MysqldResource.pid]
[MysqldResource] launching mysqld (driver_launched_mysqld_1)
InnoDB: The first specified data file ./ibdata1 did not exist:
InnoDB: a new database to be created!
080220  9:40:20  InnoDB: Setting file ./ibdata1 size to 10 MB
InnoDB: Database physically writes the file full: wait...
080220  9:40:20  InnoDB: Log file ./ib_logfile0 did not exist: new to be created
InnoDB: Setting log file ./ib_logfile0 size to 5 MB
InnoDB: Database physically writes the file full: wait...
080220  9:40:20  InnoDB: Log file ./ib_logfile1 did not exist: new to be created
InnoDB: Setting log file ./ib_logfile1 size to 5 MB
InnoDB: Database physically writes the file full: wait...
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
080220  9:40:21  InnoDB: Started; log sequence number 0 0
080220  9:40:21 [Note] /var/tmp/test-mxj/bin/mysqld: ready for connections.
Version: '5.0.51a'  socket: 'mysql.sock'  port: 3336  MySQL Community Server (GPL)
[MysqldResource] mysqld running as process: 2238
------------------------
SELECT VERSION()
------------------------
```

```
5.0.51a
------------------------
[MysqldResource] stopping mysqld (process: 2238)
080220  9:40:27 [Note] /var/tmp/test-mxj/bin/mysqld: Normal shutdown

080220  9:40:27  InnoDB: Starting shutdown...
080220  9:40:29  InnoDB: Shutdown completed; log sequence number 0 43655
080220  9:40:29 [Note] /var/tmp/test-mxj/bin/mysqld: Shutdown complete

[MysqldResource] shutdown complete
```

The above output shows an instance of MySQL starting, the necessary files being created (log files, InnoDB data files) and the MySQL database entering the running state. The instance is then shutdown by Connector/MXJ before the example terminates.

> **Warning**
>
> You should avoid running your Connector/MXJ application as the `root` user, because this will cause the `mysqld` to also be executed with root privileges. For more information, see Section 5.3.6, “How to Run MySQL as a Normal User”.

20.4.3.4. Deploying Connector/MXJ using Driver Launch

Connector/MXJ and Connector/J work together to enable you to launch an instance of the `mysqld` server through the use of a keyword in the JDBC connection string. Deploying Connector/MXJ within a Java application can be automated through this method, making the deployment of Connector/MXJ a simple process:

1. Download and unzip Connector/MXJ, add `mysql-connector-mxj-gpl-[ver].jar` to the `CLASSPATH`.

   If you are using Connector/MXJ v5.0.4 or later you will also need to add the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file to your `CLASSPATH`.

2. To the JDBC connection string, embed the `mxj` keyword, for example: `jdbc:mysql:mxj://localhost:PORT/DBNAME`.

For more details, see Section 20.4.4, “Connector/MXJ Configuration”.

20.4.3.5. Deploying Connector/MXJ within JBoss

For deployment of Connector/MXJ within a JBoss environment, you must configure the JBoss environment to use the Connector/MXJ component within the JDBC parameters:

1. Download Connector/MXJ and copy the `mysql-connector-mxj-gpl-[ver].jar` file to the `$JBOSS_HOME/server/default/lib` directory.

   If you are using Connector/MXJ v5.0.4 or later you will also need to copy the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file to `$JBOSS_HOME/server/default/lib`.

2. Download Connector/J and copy the `mysql-connector-java-5.1.5-bin.jar` file to the `$JBOSS_HOME/server/default/lib` directory.

3. Create an MBean service xml file in the `$JBOSS_HOME/server/default/deploy` directory with any attributes set, for instance the `datadir` and `autostart`.

4. Set the JDBC parameters of your web application to use:

   ```
   String driver = "com.mysql.jdbc.Driver";
   String url = "jdbc:mysql:///test?propertiesTransform="+
                "com.mysql.management.jmx.ConnectorMXJPropertiesTransform";
   String user = "root";
   String password = "";
   Class.forName(driver);
   Connection conn = DriverManager.getConnection(url, user, password);
   ```

You may wish to create a separate users and database table spaces for each application, rather than using "root and test".

We highly suggest having a routine backup procedure for backing up the database files in the `datadir`.

20.4.3.6. Verifying Installation using JUnit

The best way to ensure that your platform is supported is to run the JUnit tests. These will test the Connector/MXJ classes and the associated components.

20.4.3.6.1. JUnit Test Requirements

The first thing to do is make sure that the components will work on the platform. The `MysqldResource` class is really a wrapper for a native version of MySQL, so not all platforms are supported. At the time of this writing, Linux on the i386 architecture has been tested and seems to work quite well, as does OS X v10.3. There has been limited testing on Windows and Solaris.

Requirements:

1. JDK-1.4 or newer (or the JRE if you aren't going to be compiling the source or JSPs).
2. MySQL Connector/J version 5.0 or newer (from http://dev.mysql.com/downloads/connector/j/) installed and available via your CLASSPATH.
3. The `javax.management` classes for JMX version 1.2.1, these are present in the following application servers:
   - JBoss - 4.0rc1 or newer.
   - Apache Tomcat - 5.0 or newer.
   - Sun's JMX reference implementation version 1.2.1 (from http://java.sun.com/products/JavaManagement/).
4. JUnit 3.8.1 (from http://www.junit.org/).

If building from source, All of the requirements from above, plus:

1. Ant version 1.5 or newer (download from http://ant.apache.org/).

20.4.3.6.2. Running the JUnit Tests

1. The tests attempt to launch MySQL on the port 3336. If you have a MySQL running, it may conflict, but this isn't very likely because the default port for MySQL is 3306. However, You may set the "c-mxj_test_port" Java property to a port of your choosing. Alternatively, you may wish to start by shutting down any instances of MySQL you have running on the target machine.

   The tests suppress output to the console by default. For verbose output, you may set the "c-mxj_test_silent" Java property to "false".
2. To run the JUnit test suite, the $CLASSPATH must include the following:
   - JUnit
   - JMX
   - Connector/J
   - MySQL Connector/MXJ
3. If `connector-mxj.jar` is not present in your download, unzip MySQL Connector/MXJ source archive.

   ```
   cd mysqldjmx
   ant dist
   ```

   Then add `$TEMP/cmxj/stage/connector-mxj/connector-mxj.jar` to the CLASSPATH.
4. If you have `junit`, execute the unit tests. From the command line, type:

```
java com.mysql.management.AllTestsSuite
```

The output should look something like this:

```
.....................................
.....................................
.........
Time: 259.438

OK (101 tests)
```

Note that the tests are a bit slow near the end, so please be patient.

20.4.4. Connector/MXJ Configuration

20.4.4.1. Running as part of the JDBC Driver

A feature of the MySQL Connector/J JDBC driver is the ability to specify a connection to an embedded Connector/MXJ instance through the use of the mxj keyword in the JDBC connection string.

In the following example, we have a program which creates a connection, executes a query, and prints the result to the System.out. The MySQL database will be deployed and started as part of the connection process, and shutdown as part of the finally block.

You can find this file in the Connector/MXJ package as `src/ConnectorMXJUrlTestExample.java`.

```
import java.io.File;
import java.sql.Connection;
import java.sql.DriverManager;

import com.mysql.management.driverlaunched.ServerLauncherSocketFactory;
import com.mysql.management.util.QueryUtil;

public class ConnectorMXJUrlTestExample {
  public static String DRIVER = "com.mysql.jdbc.Driver";

  public static String JAVA_IO_TMPDIR = "java.io.tmpdir";

  public static void main(String[] args) throws Exception {
    File ourAppDir = new File(System.getProperty(JAVA_IO_TMPDIR));
    File databaseDir = new File(ourAppDir, "test-mxj");
    int port = Integer.parseInt(System.getProperty("c-mxj_test_port", "3336"));
    String dbName = "our_test_app";

    String url = "jdbc:mysql:mxj://localhost:" + port + "/" + dbName //
      + "?" + "server.basedir=" + databaseDir //
      + "&" + "createDatabaseIfNotExist=true"//
      + "&" + "server.initialize-user=true" //
    ;

    System.out.println(url);

    String userName = "alice";
    String password = "q93uti0opwhkd";

    Class.forName(DRIVER);
    Connection conn = null;
    try {
      conn = DriverManager.getConnection(url, userName, password);
      String sql = "SELECT VERSION()";
      String queryForString = new QueryUtil(conn).queryForString(sql);

      System.out.println("-----------------------");
      System.out.println(sql);
      System.out.println("-----------------------");
      System.out.println(queryForString);
      System.out.println("-----------------------");
      System.out.flush();
      Thread.sleep(100); // wait for System.out to finish flush
    } finally {
      try {
        if (conn != null)
          conn.close();
      } catch (Exception e) {
        e.printStackTrace();
      }
```

```
      ServerLauncherSocketFactory.shutdown(databaseDir, null);
    }
  }
}
```

To run the above program, be sure to have connector-mxj.jar and Connector/J in the CLASSPATH. Then type:

```
java ConnectorMXJTestExample
```

20.4.4.2. Running within a Java Object

If you have a java application and wish to “embed” a MySQL database, make use of the `com.mysql.management.MysqldResource` class directly. This class may be instantiated with the default (no argument) constructor, or by passing in a java.io.File object representing the directory you wish the server to be "unzipped" into. It may also be instantiated with printstreams for "stdout" and "stderr" for logging.

Once instantiated, a `java.util.Map`, the object will be able to provide a `java.util.Map` of server options appropriate for the platform and version of MySQL which you will be using.

The `MysqldResource` enables you to "start" MySQL with a `java.util.Map` of server options which you provide, as well as "shutdown" the database. The following example shows a simplistic way to embed MySQL in an application using plain java objects.

You can find this file in the Connector/MXJ package as `src/ConnectorMXJObjectTestExample.java`.

```
import java.io.File;
import java.sql.Connection;
import java.sql.DriverManager;
import java.util.HashMap;
import java.util.Map;

import com.mysql.management.MysqldResource;
import com.mysql.management.MysqldResourceI;
import com.mysql.management.util.QueryUtil;

public class ConnectorMXJObjectTestExample {
    public static final String DRIVER = "com.mysql.jdbc.Driver";

    public static final String JAVA_IO_TMPDIR = "java.io.tmpdir";

    public static void main(String[] args) throws Exception {
        File ourAppDir = new File(System.getProperty(JAVA_IO_TMPDIR));
        File databaseDir = new File(ourAppDir, "mysql-mxj");
        int port = Integer.parseInt(System.getProperty("c-mxj_test_port",
                "3336"));
        String userName = "alice";
        String password = "q93uti0opwhkd";

        MysqldResource mysqldResource = startDatabase(databaseDir, port,
                userName, password);

        Class.forName(DRIVER);
        Connection conn = null;
        try {
            String dbName = "our_test_app";
            String url = "jdbc:mysql://localhost:" + port + "/" + dbName //
                    + "?" + "createDatabaseIfNotExist=true"//
            ;
            conn = DriverManager.getConnection(url, userName, password);
            String sql = "SELECT VERSION()";
            String queryForString = new QueryUtil(conn).queryForString(sql);

            System.out.println("------------------------");
            System.out.println(sql);
            System.out.println("------------------------");
            System.out.println(queryForString);
            System.out.println("------------------------");
            System.out.flush();
            Thread.sleep(100); // wait for System.out to finish flush
        } finally {
            try {
                if (conn != null) {
                    conn.close();
                }
            } catch (Exception e) {
                e.printStackTrace();
            }
            try {
                mysqldResource.shutdown();
            } catch (Exception e) {
```

```
                e.printStackTrace();
            }
        }
    }

    public static MysqldResource startDatabase(File databaseDir, int port,
            String userName, String password) {
        MysqldResource mysqldResource = new MysqldResource(databaseDir);

        Map database_options = new HashMap();
        database_options.put(MysqldResourceI.PORT, Integer.toString(port));
        database_options.put(MysqldResourceI.INITIALIZE_USER, "true");
        database_options.put(MysqldResourceI.INITIALIZE_USER_NAME, userName);
        database_options.put(MysqldResourceI.INITIALIZE_PASSWORD, password);

        mysqldResource.start("test-mysqld-thread", database_options);

        if (!mysqldResource.isRunning()) {
            throw new RuntimeException("MySQL did not start.");
        }

        System.out.println("MySQL is running.");

        return mysqldResource;
    }
}
```

20.4.4.3. Setting server options

Of course there are many options we may wish to set for a MySQL database. These options may be specified as part of the JDBC connection string simply by prefixing each server option with `server.`. In the following example we set two driver parameters and two server parameters:

```
        String url = "jdbc:mysql://" + hostColonPort + "/"
                + "?"
                + "cacheServerConfiguration=true"
                + "&"
                + "useLocalSessionState=true"
                + "&"
                + "server.basedir=/opt/myapp/db"
                + "&"
                + "server.datadir=/mnt/bigdisk/myapp/data";
```

Starting with Connector/MXJ 5.0.6 you can use the `initialize-user` property to a connection string. If set to true, the default anonymous and root users will be removed and the user/password combination from the connection URL will be used to create a new user. For example:

```
        String url = "jdbc:mysql:mxj://localhost:" + port
        + "/alice_db"
        + "?server.datadir=" + dataDir.getPath()
        + "&server.initialize-user=true"
        + "&createDatabaseIfNotExist=true"
        ;
```

20.4.5. Connector/MXJ Reference

The following sections include detailed information on the different API interfaces to Connector/MXJ.

20.4.5.1. MysqldResource Constructors

The `MysqldResource` class supports three different constructor forms:

- `public MysqldResource(File baseDir, File dataDir, String mysqlVersionString, PrintStream out, PrintStream err)`

  Enables you to set the base directory, data directory, select a server by its version string, standard out and standard error.

- `public MysqldResource(File baseDir, File dataDir, String mysqlVersionString)`

  Enables you to set the base directory, data directory and select a server by its version string. Output for standard out and standard err are directed to System.out and System.err.

- `public MysqldResource(File baseDir, File dataDir)`

  Enables you to set the base directory and data directory. The default MySQL version is selected, and output for standard out and standard err are directed to System.out and System.err.

- `public MysqldResource(File baseDir);`

  Allows the setting of the "basedir" to deploy the MySQL files to. Output for standard out and standard err are directed to System.out and System.err.

- `public MysqldResource();`

  The basedir is defaulted to a subdirectory of the java.io.tempdir. Output for standard out and standard err are directed to System.out and System.err;

20.4.5.2. MysqldResource Methods

MysqldResource API includes the following methods:

- `void start(String threadName, Map mysqldArgs);`

  Deploys and starts MySQL. The "threadName" string is used to name the thread which actually performs the execution of the MySQL command line. The map is the set of arguments and their values to be passed to the command line.

- `void shutdown();`

  Shuts down the MySQL instance managed by the MysqldResource object.

- `Map getServerOptions();`

  Returns a map of all the options and their current (or default, if not running) options available for the MySQL database.

- `boolean isRunning();`

  Returns true if the MySQL database is running.

- `boolean isReadyForConnections();`

  Returns true once the database reports that is ready for connections.

- `void setKillDelay(int millis);`

  The default “Kill Delay” is 30 seconds. This represents the amount of time to wait between the initial request to shutdown and issuing a “force kill” if the database has not shutdown by itself.

- `void addCompletionListenser(Runnable listener);`

  Allows for applications to be notified when the server process completes. Each "listener" will be fired off in its own thread.

- `String getVersion();`

  Returns the version of MySQL.

- `void setVersion(int MajorVersion, int minorVersion, int patchLevel);`

  The standard distribution comes with only one version of MySQL packaged. However, it is possible to package multiple versions, and specify which version to use.

20.4.6. Connector/MXJ Notes and Tips

This section contains notes and tips on using the Connector/MXJ component within your applications.

20.4.6.1. Creating your own Connector/MXJ Package

If you want to create a custom Connector/MXJ package that includes a specific `mysqld` version or platform then you must extract and rebuild the `mysql-connector-mxj.jar` (Connector/MXJ v5.0.3 or earlier) or `mysql-connector-mxj-gpl-[ver]-db-files.jar` (Connector/MXJ v5.0.4 or later) file.

First, you should create a new directory into which you can extract the current `connector-mxj.jar`:

```
shell> mkdir custom-mxj
shell> cd custom-mxj
shell> jar -xf connector-mxj.jar
shell> ls
5-0-22/
ConnectorMXJObjectTestExample.class
ConnectorMXJUrlTestExample.class
META-INF/
TestDb.class
com/
kill.exe
```

If you are using Connector/MXJ v5.0.4 or later, you should unpack the `connector-mxj-db-files.jar`:

```
shell> mkdir custom-mxj
shell> cd custom-mxj
shell> jar -xf connector-mxj-db-files.jar
shell> ls
5-0-51a/
META-INF/
connector-mxj.properties
```

The MySQL version directory, `5-0-22` or `5-0-51a` in the preceding examples, contains all of the files used to create an instance of MySQL when Connector/MXJ is executed. All of the files in this directory are required for each version of MySQL that you want to embed. Note as well the format of the version number, which uses hyphens instead of periods to separate the version number components.

Within the version specific directory are the platform specific directories, and archives of the `data` and `share` directory required by MySQL for the various platforms. For example, here is the listing for the default Connector/MXJ package:

```
shell>> ls
Linux-i386/
META-INF/
Mac_OS_X-ppc/
SunOS-sparc/
Win-x86/
com/
data_dir.jar
share_dir.jar
win_share_dir.jar
```

Platform specific directories are listed by their OS and platform - for example the `mysqld` for Mac OS X PowerPC is located within the `Mac_OS_X-ppc` directory. You can delete directories from this location that you do not require, and add new directories for additional platforms that you want to support.

To add a platform specific `mysqld`, create a new directory with the corresponding name for your operating system/platform. For example, you could add a directory for Mac OS X/Intel using the directory `Mac_OS_X-i386`.

On Unix systems, you can determine the platform using `uname`:

```
shell> uname -p
i386
```

In Connector/MXJ v5.0.9 and later, an additional `platform-map.properties` file is used to associate a specific platform and operating system combination with the directory in which the `mysqld` for that combination is located. The determined operating system and platform are on the left, and the directory name where the appropriate mysqld is located is on the right. You can see a sample of the file below:

```
Linux-i386=Linux-i386
Linux-x86=Linux-i386
Linux-i686=Linux-i386
Linux-x86_64=Linux-i386
Linux-ia64=Linux-i386
```

```
#Linux-ppc=Linux-ppc
#Linux-ppc64=Linux-ppc

Mac_OS_X-i386=Mac_OS_X-i386
Mac_OS_X-ppc=Mac_OS_X-ppc
Rhapsody-PowerPC=Mac_OS_X-ppc
#Mac_OS-PowerPC=
#macos-PowerPC=
#MacOS-PowerPC=

SunOS-sparc=SunOS-sparc
Solaris-sparc=SunOS-sparc
SunOS-x86=SunOS-x86
Solaris-x86=SunOS-x86

FreeBSD-x86=FreeBSD-x86

Windows_Vista-x86=Win-x86
Windows_2003-x86=Win-x86
Windows_XP-x86=Win-x86
Windows_2000-x86=Win-x86
Windows_NT-x86=Win-x86
Windows_NT_(unknown)-x86=Win-x86
```

Now you need to download or compile `mysqld` for the MySQL version and platform you want to include in your custom `connector-mxj.jar` package into the new directory.

Create a file called `version.txt` in the OS/platform directory you have just created that contains the version string/path of the mysqld binary. For example:

```
mysql-5.0.22-osx10.3-i386/bin/mysqld
```

You can now recreate the `connector-mxj.jar` file with the added `mysqld`:

```
shell> cd custom-mxj
shell> jar -cf ../connector-mxj.jar *
```

For Connector/MXJ v5.0.4 and later, you should repackage to the `connector-mxj-db-files.jar`:

```
shell> cd custom-mxj
shell> jar -cf ../mysql-connector-mxj-gpl-[ver]-db-files.jar *
```

You should test this package using the steps outlined in Section 20.4.3.3, “Connector/MXJ Quick Start Guide”.

> **Note**
>
> Because the `mysql-connector-mxj-gpl-[ver]-db-files.jar` file is separate from the main Connector/MXJ classes you can distribute different `mysql-connector-mxj-gpl-[ver]-db-files.jar` files to different hotsts or for different projects without having to create a completely new main `mysql-connector-mxj-gpl-[ver].jar` file for each one.

20.4.6.2. Deploying Connector/MXJ with a pre-configured database

To include a pre-configured/populated database within your Connector/MXJ JAR file you must create a custom `data_dir.jar` file, as included within the main `connector-mxj.jar` (Connector/MXJ 5.0.3 or earlier) or `mysql-connector-mxj-gpl-[ver]-db-files.jar` (Connector/MXJ 5.0.4 or later) file:

1. First extract the `connector-mxj.jar` or `mysql-connector-gpl-[ver]-db-files.jar` file, as outlined in the previous section (see Section 20.4.6.1, “Creating your own Connector/MXJ Package”).
2. First, create your database and populate the database with the information you require in an existing instance of MySQL - including Connector/MXJ instances. Data file formats are compatible across platforms.
3. Shutdown the instance of MySQL.
4. Create a JAR file of the data directory and databases that you want to include your Connector/MXJ package. You should include the `mysql` database, which includes user authentication information, in addition to the specific databases you want to include. For example, to create a JAR of the `mysql` and `mxjtest` databases:

```
shell> jar -cf ../data_dir.jar mysql mxjtest
```

5. For Connector/MXJ 5.0.3 or earlier, copy the `data_dir.jar` file into the extracted `connector-mxj.jar` directory, and then create an archive for `connector-mxj.jar`.

   For Connector/MXJ 5.0.4 or later, copy the `data_dir.jar` file into the extracted `mysql-connector-mxj-gpl-[ver]-db-files.jar` directory, and then create an archive for `mysql-connector-mxj-db-gpl-[ver]--files.jar`.

Note that if you are create databases using the InnoDB engine, you must include the `ibdata.*` and `ib_logfile*` files within the `data_dir.jar` archive.

20.4.6.3. Running within a JMX Agent (custom)

As a JMX MBean, MySQL Connector/MXJ requires a JMX v1.2 compliant MBean container, such as JBoss version 4. The MBean will uses the standard JMX management APIs to present (and allow the setting of) parameters which are appropriate for that platform.

If you are not using the SUN Reference implementation of the JMX libraries, you should skip this section. Or, if you are deploying to JBoss, you also may wish to skip to the next section.

We want to see the MysqldDynamicMBean in action inside of a JMX agent. In the `com.mysql.management.jmx.sunri` package is a custom JMX agent with two MBeans:

1. The MysqldDynamicMBean, and
2. A com.sun.jdmk.comm.HtmlAdaptorServer, which provides a web interface for manipulating the beans inside of a JMX agent.

When this very simple agent is started, it will allow a MySQL database to be started and stopped with a web browser.

1. Complete the testing of the platform as above.
   - Current JDK, JUnit, Connector/J, MySQL Connector/MXJ
   - This section *requires* the SUN reference implementation of JMX
   - `PATH`, `JAVA_HOME`, `ANT_HOME`, `CLASSPATH`
2. If not building from source, skip to next step

   Rebuild with the "sunri.present"

   ```
   ant -Dsunri.present=true dist
   re-run tests:
   java junit.textui.TestRunner com.mysql.management.AllTestsSuite
   ```

3. Launch the test agent from the command line:

   ```
   java com.mysql.management.jmx.sunri.MysqldTestAgentSunHtmlAdaptor &
   ```

4. From a browser:

   ```
   http://localhost:9092/
   ```

5. Under MysqldAgent,

   ```
   select "name=mysqld"
   ```

6. Observe the MBean View
7. Scroll to the bottom of the screen press the STARTMYSQLD button
8. Click `Back to MBean View`
9. Scroll to the bottom of the screen press STOPMYSQLD button
10. Kill the java process running the Test Agent (jmx server)

20.4.6.4. Deployment in a standard JMX Agent environment (JBoss)

Once there is confidence that the MBean will function on the platform, deploying the MBean inside of a standard JMX Agent is the next step. Included are instructions for deploying to JBoss.

1. Ensure a current version of java development kit (v1.4.x), see above.
   - Ensure `JAVA_HOME` is set (JBoss requires `JAVA_HOME`)
   - Ensure `JAVA_HOME/bin` is in the `PATH` (You will NOT need to set your CLASSPATH, nor will you need any of the jars used in the previous tests).
2. Ensure a current version of JBoss (v4.0RC1 or better)

```
http://www.jboss.org/index.html
select "Downloads"
select "jboss-4.0.zip"
pick a mirror
unzip ~/dload/jboss-4.0.zip
create a JBOSS_HOME environment variable set to the unzipped directory
unix only:
cd $JBOSS_HOME/bin
chmod +x *.sh
```

3. Deploy (copy) the `connector-mxj.jar` to `$JBOSS_HOME/server/default/lib`.
4. Deploy (copy) `mysql-connector-java-3.1.4-beta-bin.jar` to `$JBOSS_HOME/server/default/lib`.
5. Create a `mxjtest.war` directory in `$JBOSS_HOME/server/default/deploy`.
6. Deploy (copy) `index.jsp` to `$JBOSS_HOME/server/default/deploy/mxjtest.war`.
7. Create a `mysqld-service.xml` file in `$JBOSS_HOME/server/default/deploy`.

```
<?xml version="1.0" encoding="UTF-8"?>
 <server>
  <mbean code="com.mysql.management.jmx.jboss.JBossMysqldDynamicMBean"
     name="mysql:type=service,name=mysqld">
  <attribute name="datadir">/tmp/xxx_data_xxx</attribute>
  <attribute name="autostart">true</attribute>
  </mbean>
 </server>
```

8. Start jboss:
   - On unix: `$JBOSS_HOME/bin/run.sh`
   - On windows: `%JBOSS_HOME%\bin\run.bat`

   Be ready: JBoss sends a lot of output to the screen.
9. When JBoss seems to have stopped sending output to the screen, open a web browser to: `http://localhost:8080/jmx-console`
10. Scroll down to the bottom of the page in the `mysql` section, select the bulleted `mysqld` link.
11. Observe the JMX MBean View page. MySQL should already be running.

12. (If "autostart=true" was set, you may skip this step.) Scroll to the bottom of the screen. You may press the INVOKE button to stop (or start) MySQL observe `Operation completed successfully without a return value.` Click `Back to MBean View`

13. To confirm MySQL is running, open a web browser to `http://localhost:8080/mxjtest/` and you should see that

    ```
    SELECT 1
    ```

    returned with a result of

    ```
    1
    ```

14. Guided by the `$JBOSS_HOME/server/default/deploy/mxjtest.war/index.jsp` you will be able to use MySQL in your Web Application. There is a `test` database and a `root` user (no password) ready to experiment with. Try creating a table, inserting some rows, and doing some selects.

15. Shut down MySQL. MySQL will be stopped automatically when JBoss is stopped, or: from the browser, scroll down to the bottom of the MBean View press the stop service INVOKE button to halt the service. Observe `Operation completed successfully without a return value.` Using `ps` or `task manager` see that MySQL is no longer running

As of 1.0.6-beta version is the ability to have the MBean start the MySQL database upon start up. Also, we've taken advantage of the JBoss life-cycle extension methods so that the database will gracefully shut down when JBoss is shutdown.

20.4.7. Connector/MXJ Support

There are a wide variety of options available for obtaining support for using Connector/MXJ. You should contact the Connector/MXJ community for help before reporting a potential bug or problem. See Section 20.4.7.1, “Connector/MXJ Community Support”.

20.4.7.1. Connector/MXJ Community Support

Sun Microsystems, Inc. provides assistance to the user community by means of a number of mailing lists and web based forums.

You can find help and support through the MySQL and Java mailing list.

For information about subscribing to MySQL mailing lists or to browse list archives, visit http://lists.mysql.com/. See Section 1.6.1, “MySQL Mailing Lists”.

Community support from experienced users is also available through the MyODBC Forum. You may also find help from other users in the other MySQL Forums, located at http://forums.mysql.com. See Section 1.6.2, “MySQL Community Support at the MySQL Forums”.

20.4.7.2. How to Report Connector/MXJ Problems

If you encounter difficulties or problems with Connector/MXJ, contact the Connector/MXJ community Section 20.4.7.1, “Connector/MXJ Community Support”.

If reporting a problem, you should ideally include the following information with the email:

- Operating system and version
- Connector/MXJ version
- MySQL server version
- Copies of error messages or other unexpected output
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

If you believe the problem to be a bug, then you must report the bug through http://bugs.mysql.com/.

20.4.7.3. Connector/MXJ Change History

The Connector/MXJ Change History (Changelog) is located with the main Changelog for MySQL. See Section C.7, "MySQL Connector/MXJ Change History".

20.5. MySQL Connector/C++

MySQL Connector/C++ is a MySQL database connector for C++. The current version is 1.0.5 GA.

The MySQL Connector/C++ is licensed under the terms of the GPL, like most MySQL Connectors. There are special exceptions to the terms and conditions of the GPL as it is applied to this software, see FLOSS License Exception. If you need a non-GPL license for commercial distribution please contact us.

The MySQL Connector/C++ is compatible with the JDBC 4.0 API. However, MySQL Connector/C++ does not implement all of the JDBC 4.0 API. The MySQL Connector/C++ current version features the following classes:

- `Connection`
- `DatabaseMetaData`
- `Driver`
- `PreparedStatement`
- `ResultSet`
- `ResultSetMetaData`
- `Savepoint`
- `Statement`

The JDBC 4.0 API defines approximately 450 methods for the above mentioned classes. MySQL Connector/C++ implements around 80% of these and makes them available in the current release.

The release has been successfully compiled and tested on the following platforms:

AIX

- 5.2 (PPC32, PPC64)
- 5.3 (PPC32, PPC64)

FreeBSD

- 6.0 (x86, x86_64)

HPUX

- 11.11 (PA-RISC 32bit, PA-RISC 64bit)

Linux

- Debian 3.1 (PPC32, x86)
- FC4 (x86)

- RHEL 3 (ia64, x86, x86_64)
- RHEL 4 (ia64, x86, x86_64)
- RHEL 5 (ia64, x86, x86_64)
- SLES 9 (ia64, x86, x86_64)
- SLES 10 (ia64, x86_64)
- SuSE 10.3, (x86_64)
- Ubuntu 8.04 (x86)
- Ubuntu 8.10 (x86_64)

Mac

- MacOSX 10.3 (PPC32, PPC64)
- MacOSX 10.4 (PPC32, PPC64, x86)
- MacOSX 10.5 (PPC32, PPC64, x86, x86_64)

SunOS

- Solaris 8 (SPARC32, SPARC64, x86)
- Solaris 9 (SPARC32, SPARC64, x86)
- Solaris 10 (SPARC32, SPARC64, x86, x86_64)

Windows

- XP Professional (32bit)
- 2003 (64bit)

Future versions will run on all platforms supported by the MySQL Server.

> **Note**
>
> MySQL Connector/C++ supports MySQL 5.1 and later.

> **Note**
>
> MySQL Connector/C++ supports only Microsoft Visual Studio 2003 and above on Windows.

MySQL Connector/C++ Download

You can download the source code for the MySQL Connector/C++ current release at the MySQL Connector/C++ downloads.

MySQL Connector/C++ Source repository

The latest development version is also available through Launchpad.

Bazaar is used for the MySQL Connector/C++ code repository. You can check out the latest source code using the `bzr` command line tool:

```
shell> bzr branch lp:~mysql/mysql-connector-cpp/trunk .
```

Binary distributions

Starting with 1.0.4 Beta, binary distributions were made available in addition to source code releases. The releases available are shown below.

Microsoft Windows platform:

- Without installer, a Zip file
- MSI installer package

Other platforms:

- Compressed GNU TAR archive (tar.gz)

> **Note**
>
> Note that source packages are available for all platforms in the Compressed GNU TAR archive (tar.gz) format.

Binary and source packages can be obtained from MySQL Connector/C++ downloads.

MySQL Connector/C++ Advantages

Using MySQL Connector/C++ instead of the MySQL C API (MySQL Client Library) offers the following advantages for C++ users:

- Convenience of pure C++, no C function calls required
- Supports an industry standard API, JDBC 4.0
- Supports the object-oriented programming paradigm
- Reduces development time
- MySQL Connector/C++ is licensed under the GPL with the FLOSS License Exception
- MySQL Connector/C++ is available under a commercial license upon request

MySQL Connector/C++ Status

MySQL Connector/C++ is available as a GA version. We kindly ask users and developers to try it out and provide us with feedback.

Note that MySQL Workbench is successfully using MySQL Connector/C++.

If you have any queries please contact us.

20.5.1. MySQL Connector/C++ Binary Installation

> **Caution**
>
> One problem that can occur is when the tools you use to build your application are not compatible with the tools used to build the binary versions of MySQL Connector/C++. Ideally you need to build your application with the same tools that were used to build the MySQL Connector/C++ binaries. To help with this the following resources are provided.
>
> All distributions contain a `README` file, which contains platform-specific notes. At the end of the `README` file contained in the binary distribution you will find the settings used to build the binaries. If you experience build-related issues on a platform, it may help to check the settings used on the platform to build the binary.
>
> For your convenience the same information, but more frequently updated, can be found on the MySQL Forge site.
>
> A better solution is to build your MySQL Connector/C++ libraries from the source code, using the same tools that you use

for building your application. This ensures compatibility.

Downloading MySQL Connector/C++

Binary and source packages can be obtained from MySQL Connector/C++ downloads.

Archive Package

Unpack the archive into an appropriate directory. If you plan to use a dynamically linked version of MySQL Connector/C++, make sure that your system can reference the MySQL Client Library. Consult your operating system documentation on how do modify and expand the search path for libraries. In case you cannot modify the library search path it may help to copy your application, the MySQL Connector/C++ library and the MySQL Client Library into the same directory. Most systems search for libraries in the current directory.

Windows MSI Installer

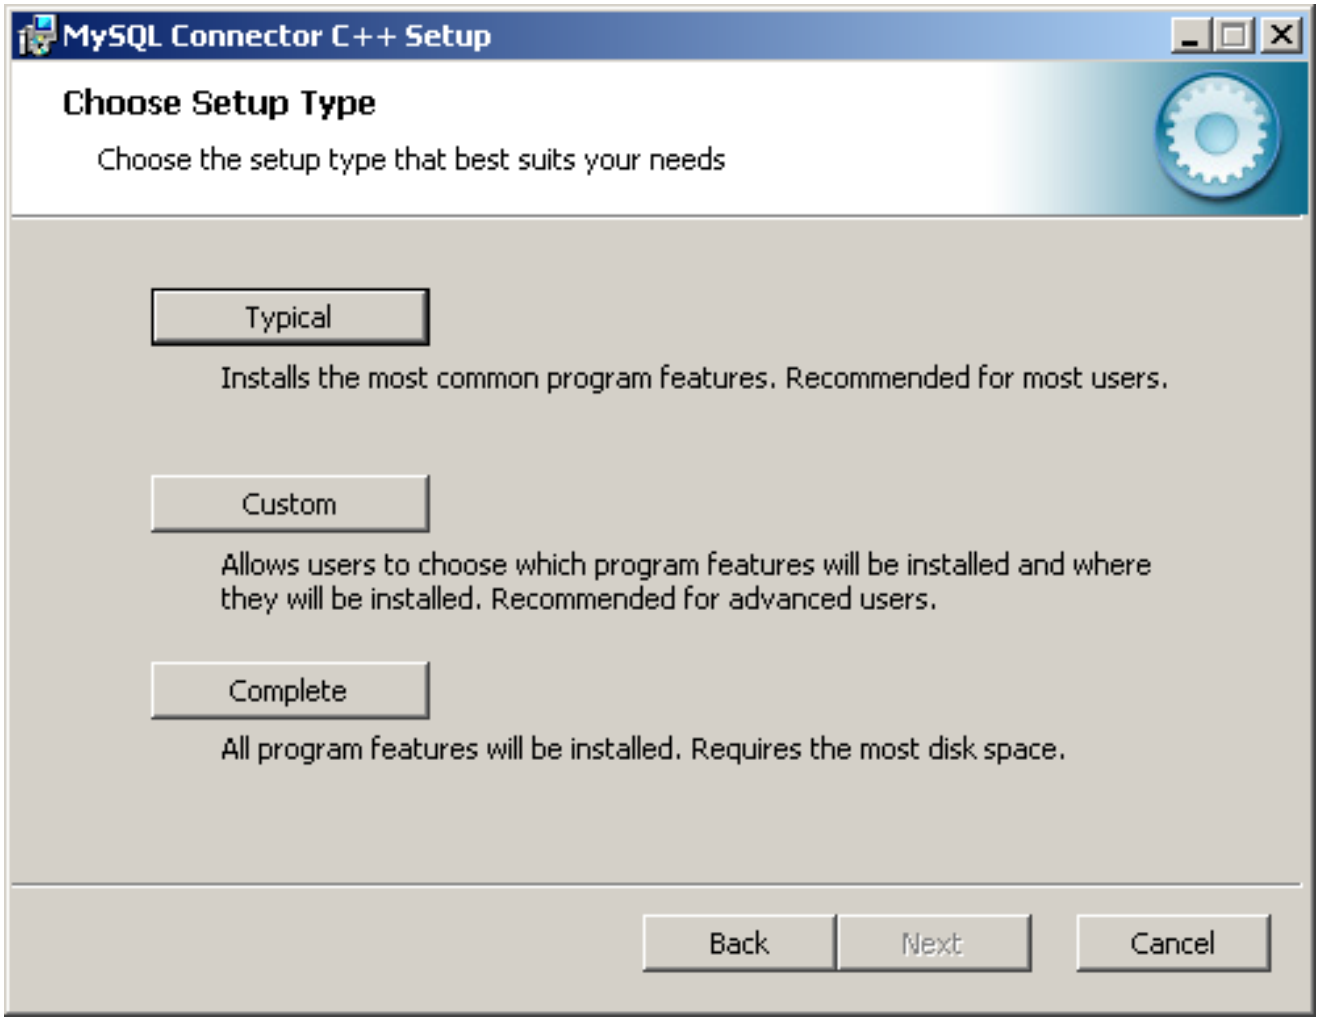
Windows users can choose between two binary packages:

1. Without installer (unzip in C:\)
2. Windows MSI Installer (x86)

Using the MSI Installer may be the easiest solution. Running the MSI Installer does not require any administrative permissions as it simply copies files.

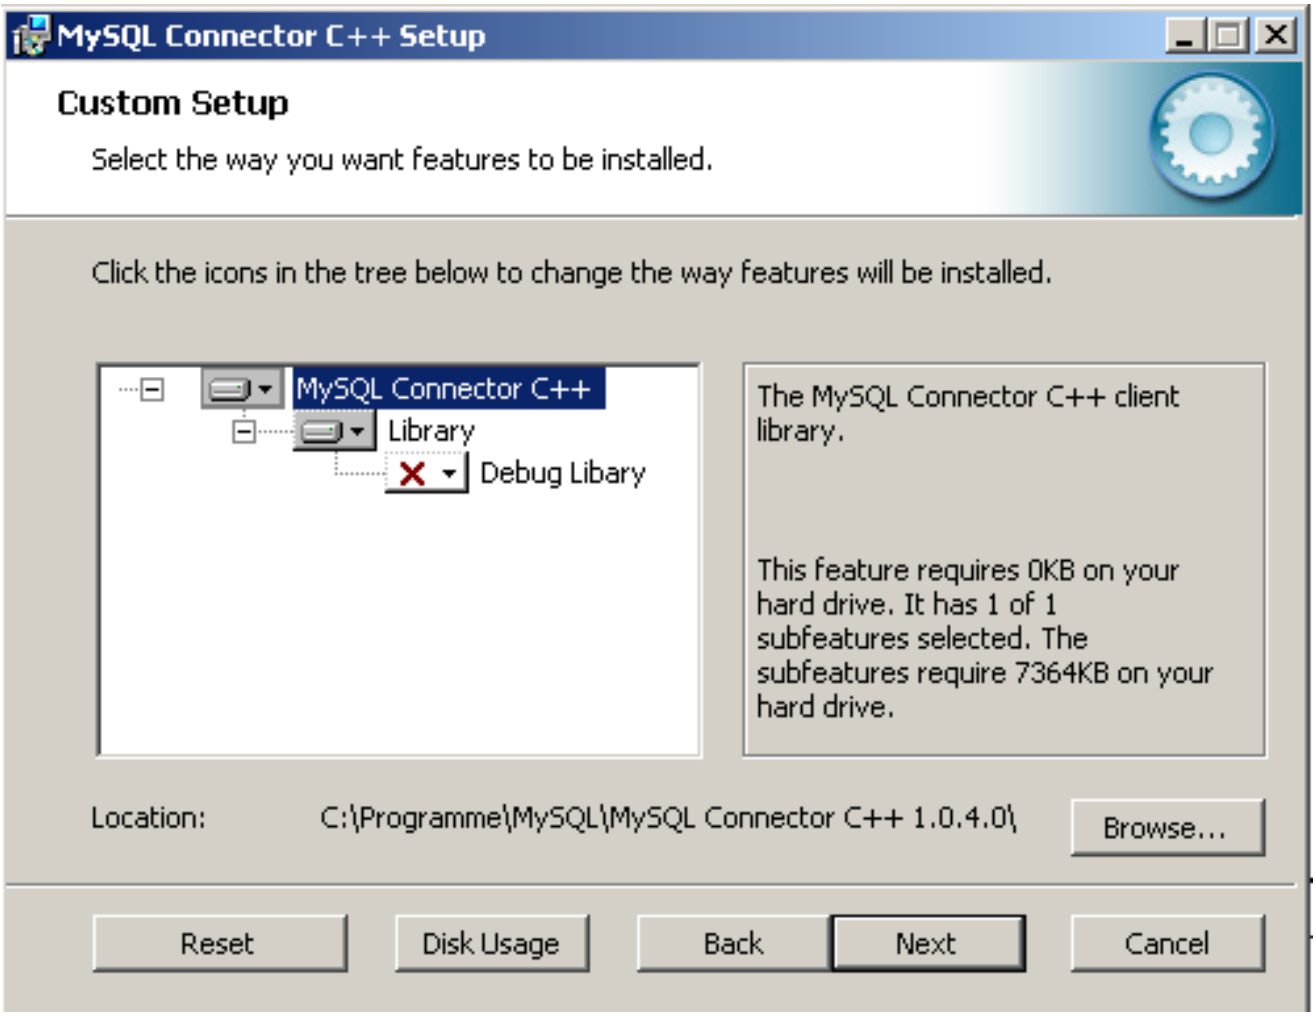
Figure 20.57. Windows Installer Welcome Screen

Figure 20.58. Windows Installer Overview Screen



The “Typical” installation consists of all required header files and the Release libraries. The only available “Custom” installation option allows you to install additional Debug versions of the connector libraries.

Figure 20.59. Windows Installer Custom Setup Screen



20.5.2. MySQL Connector/C++ Source Installation

The MySQL Connector/C++ is based on the MySQL Client Library (MySQL C API). MySQL Connector/C++ is linked against the MySQL Client Library. You need to have the MySQL Client Library installed in order to compile MySQL Connector/C++.

You also need to have the cross-platform build tool CMake 2.4, or newer, and GLib 2.2.3 or newer installed. Check the README file included with the distribution for platform specific notes on building for Windows and SunOS.

Typically the MySQL Client Library is installed when the MySQL Server is installed. However, check your operating system documentation for other installation options.

As of MySQL Connector/C++ version 1.1.0 it is necessary to have the Boost C++ libraries 1.34.0 or newer installed. Boost is only required to build the connector, it is not required in order to use the connector. You can obtain Boost from the official site and installation instructions can be obtained from the same site. Once Boost has been installed you will need to tell the make system where the Boost files are. This is done by setting the define `-DBOOST_ROOT:STRING=`. This can be done when initially invoking CMake, for example:

```
shell> CMake . -DBOOST_ROOT:STRING=/usr/local/boost_1_40_0
```

You may need to change */usr/local/boost_1_40_0/* to match your installation. See the Section 20.5.2.1, “Building source on Unix, Solaris and Mac OS X” and Section 20.5.2.2, “Building source on Windows” for further details.

20.5.2.1. Building source on Unix, Solaris and Mac OS X

1. Run CMake to build a Makefile:

```
shell> me@host:/path/to/mysql-connector-cpp> cmake .
-- Check for working C compiler: /usr/local/bin/gcc
-- Check for working C compiler: /usr/local/bin/gcc -- works
[...]
-- Generating done
-- Build files have been written to: /path/to/mysql-connector-cpp/
```

   On non-Windows systems, CMake first checks to see if the CMake variable `MYSQL_CONFIG_EXECUTABLE` is set. If it is not found CMake will try to locate `mysql_config` in the default locations.

   If you have any problems with the configure process please check the troubleshooting instructions below.

2. Use make to build the libraries. First make sure you have a clean build:

```
shell> me@host:/path/to/mysql-connector-cpp> make clean
```

   Then build the connector:

```
me@host:/path/to/mysql-connector-cpp> make
[  1%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_connection.o
[  3%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_constructed_resultset.o
[...]
[100%] Building CXX object examples/CMakeFiles/statement.dir/statement.o
Linking CXX executable statement
```

   If all goes well, you will find the MySQL Connector/C++ library in `/path/to/cppconn/libmysqlcppconn.so`.

3. Finally make sure the header and library files are installed to their correct locations:

```
make install
```

   Unless you have changed this in the configuration step, the header files will be copied to the directory `/usr/local/include`. The header files copied are `mysql_connection.h` and `mysql_driver.h`.

   Again, unless you have specified otherwise, the library files will be copied to `/usr/local/lib`. The files copied are `libmysqlcppcon.so`, the dynamic library, and `libmysqlcppconn-static.a`, the static library.

If you encounter any errors, please first carry out the checks shown below:

1. CMake options: MySQL installation path, debug version and more

   In case of configure and/or compile problems check the list of CMake options:

```
shell> me@host:/path/to/mysql-connector-cpp> cmake -L
[...]
CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
CMAKE_BUILD_TYPE:STRING=
CMAKE_INSTALL_PREFIX:PATH=/usr/local
EXECUTABLE_OUTPUT_PATH:PATH=
LIBRARY_OUTPUT_PATH:PATH=
MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
MYSQL_CONFIG_EXECUTABLE:FILEPATH=/usr/bin/mysql_config
```

   For example, if your MySQL Server installation path is not `/usr/local/mysql` and you want to build a debug version of the MySQL Connector/C++ use:

```
shell> me@host:/path/to/mysql-connector-cpp> cmake »
-D CMAKE_BUILD_TYPE:STRING=Debug »
-D MYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config .
```

2. Verify your settings with `cmake -L`:

```
shell> me@host:/path/to/mysql-connector-cpp> cmake -L
```

```
[...]
CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
CMAKE_BUILD_TYPE:STRING=
CMAKE_INSTALL_PREFIX:PATH=/usr/local
EXECUTABLE_OUTPUT_PATH:PATH=
LIBRARY_OUTPUT_PATH:PATH=
MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
MYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config
```

Proceed by carrying out a `make clean` command followed by a `make` command, as described above.

Once you have installed MySQL Connector/C++ you can carry out a quick test to check the installation. To do this you can compile and run one of the example programs, such as `examples/standalone_example.cpp`. This example is discussed in more detail later, but for now you can use it to test the connector has been correctly installed. This procedure assumes you have a working MySQL Server that you can connect to.

1. First compile the example. To do this change to the `examples` directory and type:

   ```
   shell> g++ -o test_install -I/usr/local/include -I/usr/local/include/cppconn -Wl,-Bdynamic -lmysqlcppconn standalone_e
   ```

2. You need to make sure the dynamic library which is used in this case can be found at run time. To do this enter:

   ```
   shell> export LD_LIBRARY_PATH=/usr/local/lib
   ```

3. Now run the program to test your installation, exchanging the host, user, password and database to be accessed given below to match your system:

   ```
   ./test_install localhost root password database
   ```

   You will see something similar to the following:

   ```
   Connector/C++ standalone program example...

   ... running 'SELECT 'Welcome to Connector/C++' AS _message'
   ... MySQL replies: Welcome to Connector/C++
   ... say it again, MySQL
   ....MySQL replies: Welcome to Connector/C++

   ... find more at http://www.mysql.com
   ```

   If you see any errors take note of them and go through the troubleshooting procedures discussed earlier.

20.5.2.2. Building source on Windows

> **Note**
>
> Please note the only compiler formally supported for Windows is Microsoft Visual Studio 2003 and above.

The basic steps for building the connector on Windows are the same as for Unix. It is important to use CMake 2.6.2 or newer to generate build files for your compiler and to invoke the compiler.

> **Note**
>
> On Windows, `mysql_config` is not present, so CMake will attempt to retrieve the location of MySQL from the environment variable `$ENV{MYSQL_DIR}`. If `MYSQL_DIR` is not set, CMake will then proceed to check for MySQL in the following locations: `$ENV{ProgramFiles}/MySQL/*/include`, and `$ENV{SystemDrive}/MySQL/*/include`.

CMake makes it easy for you to try other compilers. However, you may experience compile warnings, compile errors or linking issues not detected by Visual Studio. Patches are gratefully accepted to fix issues with other compilers.

Consult the CMake manual or check `cmake --help` to find out which build systems are supported by your CMake version:

```
C:\>cmake --help
cmake version 2.6-patch 2
Usage
[...]
Generators

The following generators are available on this platform:
  Borland Makefiles          = Generates Borland makefiles.
  MSYS Makefiles             = Generates MSYS makefiles.
  MinGW Makefiles            = Generates a make file for use with
                               mingw32-make.
  NMake Makefiles            = Generates NMake makefiles.
  Unix Makefiles             = Generates standard UNIX makefiles.
  Visual Studio 6            = Generates Visual Studio 6 project files.
  Visual Studio 7            = Generates Visual Studio .NET 2002 project
                               files.
  Visual Studio 7 .NET 2003  = Generates Visual Studio .NET 2003 project
                               files.
  Visual Studio 8 2005       = Generates Visual Studio .NET 2005 project
                               files.
  Visual Studio 8 2005 Win64 = Generates Visual Studio .NET 2005 Win64
                               project files.
  Visual Studio 9 2008       = Generates Visual Studio 9 2008 project fil
  Visual Studio 9 2008 Win64 = Generates Visual Studio 9 2008 Win64 proje
                               files.
[...]
```

It is likely that your CMake binary will support more compilers, known by CMake as *generators*, than supported by MySQL Connector/C++. We have built the connector using the following generators:

- Microsoft Visual Studio 8 (Visual Studio 2005)
- Microsoft Visual Studio 9 (Visual Studio 2008, Visual Studio 2008 Express)
- NMake

Please see the building instructions for Unix, Solaris and Mac OS X for troubleshooting and configuration hints.

The steps to build the connector are given below:

1. Run CMake to generate build files for your *generator*:

   Visual Studio

   ```
    C:\path_to_mysql_cpp>cmake -G "Visual Studio 9 2008"
   -- Check for working C compiler: cl
   -- Check for working C compiler: cl -- works
   -- Detecting C compiler ABI info
   -- Detecting C compiler ABI info - done
   -- Check for working CXX compiler: cl
   -- Check for working CXX compiler: cl -- works
   -- Detecting CXX compiler ABI info
   -- Detecting CXX compiler ABI info - done
   -- ENV{MYSQL_DIR} =
   -- MySQL Include dir: C:/Programme/MySQL/MySQL Server 5.1/include
   -- MySQL Library    : C:/Progams/MySQL/MySQL Server 5.1/lib/opt/mysqlclient.lib
   -- MySQL Library dir: C:/Progams/MySQL/MySQL Server 5.1/lib/opt
   -- MySQL CFLAGS:
   -- MySQL Link flags:
   -- MySQL Include dir: C:/Progams/MySQL/MySQL Server 5.1/include
   -- MySQL Library dir: C:/Progams/MySQL/MySQL Server 5.1/lib/opt
   -- MySQL CFLAGS:
   -- MySQL Link flags:
   -- Configuring cppconn
   -- Configuring test cases

   -- Looking for isinf - not found
   -- Looking for isinf
   -- Looking for isinf - not found.
   -- Looking for finite
   -- Looking for finite - not found.
   -- Configuring C/J junit tests port
   -- Configuring examples
   -- Configuring done
   -- Generating done
   -- Build files have been written to: C:\path_to_mysql_cpp
   C:\path_to_mysql_cpp>dir *.sln *.vcproj
   [...]
   19.11.2008  12:16            23.332 MYSQLCPPCONN.sln
   ```

```
[...]
19.11.2008  12:16            27.564 ALL_BUILD.vcproj
19.11.2008  12:16            27.869 INSTALL.vcproj
19.11.2008  12:16            28.073 PACKAGE.vcproj
19.11.2008  12:16            27.495 ZERO_CHECK.vcproj
```

NMake

```
 C:\path_to_mysql_cpp>cmake -G "NMake Makefiles"
-- The C compiler identification is MSVC
-- The CXX compiler identification is MSVC
[...]
-- Build files have been written to: C:\path_to_mysql_cpp
```

2. Use your compiler to build MySQL Connector/C++

Visual Studio - GUI

Open the newly generated project files in the Visual Studio GUI or use a Visual Studio command line to build the driver. The project files contain a variety of different configurations. Among them debug and nondebug versions.

Visual Studio - NMake

```
C:\path_to_mysql_cpp>nmake

Microsoft (R) Program Maintenance Utility Version 9.00.30729.01
Copyright (C) Microsoft Corporation.  All rights reserved.

Scanning dependencies of target mysqlcppconn
[  2%] Building CXX object driver/CMakeFiles/mysqlcppconn.dir/mysql_connection.obj
mysql_connection.cpp
[...]
Linking CXX executable statement.exe
[100%] Built target statement
```

20.5.2.3. Dynamically Linking MySQL Connector/C++ against the MySQL Client Library

> **Note**
>
> Note this section refers to dynamic linking of the MySQL Connector/C++ with the client library, not the dynamic linking of the application to MySQL Connector/C++.

An application that uses MySQL Connector/C++ can be either statically or dynamically linked to the MySQL Connector/C++ libraries. MySQL Connector/C++ is usually statically linked to the underlying MySQL Client Library (or Connector/C). Note, that unless otherwise stated, reference to the MySQL Client Library is also taken to include Connector/C, which is a separately packaged, stand alone version of the MySQL Client Library. From MySQL Connector/C++ version 1.1.0 it is possible to also dynamically link to the underlying MySQL Client Library. The ability of MySQL Connector/C++ to dynamically link to MySQL Client Library is not enabled by default, and enabling this feature is done through a compile time option, when compiling the MySQL Connector/C++ source code.

To use the ablity to dynamically link the client library to MySQL Connector/C++ the `MYSQLCLIENT_STATIC_BINDING:BOOL` needs to be defined when building the MySQL Connector/C++ source code:

```
rm CMakeCache.txt
cmake -DMYSQLCLIENT_STATIC_BINDING:BOOL=1 .
make clean
make
make install
```

Note that pre-compiled binaries of MySQL Connector/C++ use static binding with the client library by default.

Now, in your application, when creating a connection, MySQL Connector/C++ will select and load a client library at runtime. It will choose the client library by searching defined locations and environment variables depending on the host operating system. It also possible when creating a connection in an application to define an absolute path to the client library to be loaded at runtime. This can be convenient if you have defined a standard location from which you want the client library to be loaded. This is sometimes done to circumvent possible conflicts with other versions of the client library that may be located on the system.

20.5.3. MySQL Connector/C++ Building Windows applications with Microsoft

Visual Studio

MySQL Connector/C++ is available as a static or dynamic library to use with your application. This section looks at how to link the library to your application.

> **Note**
>
> To avoid potential crashes the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

Static library

The MySQL Connector/C++ static library file is `mysqlcppconn-static.lib`. This needs to be statically linked with your application. You also need to link against the files `libmysql.dll` and `libmysql.lib`. Once linking has been successfully completed, the application will require access to `libmysql.dll` at run time.

Dynamic library

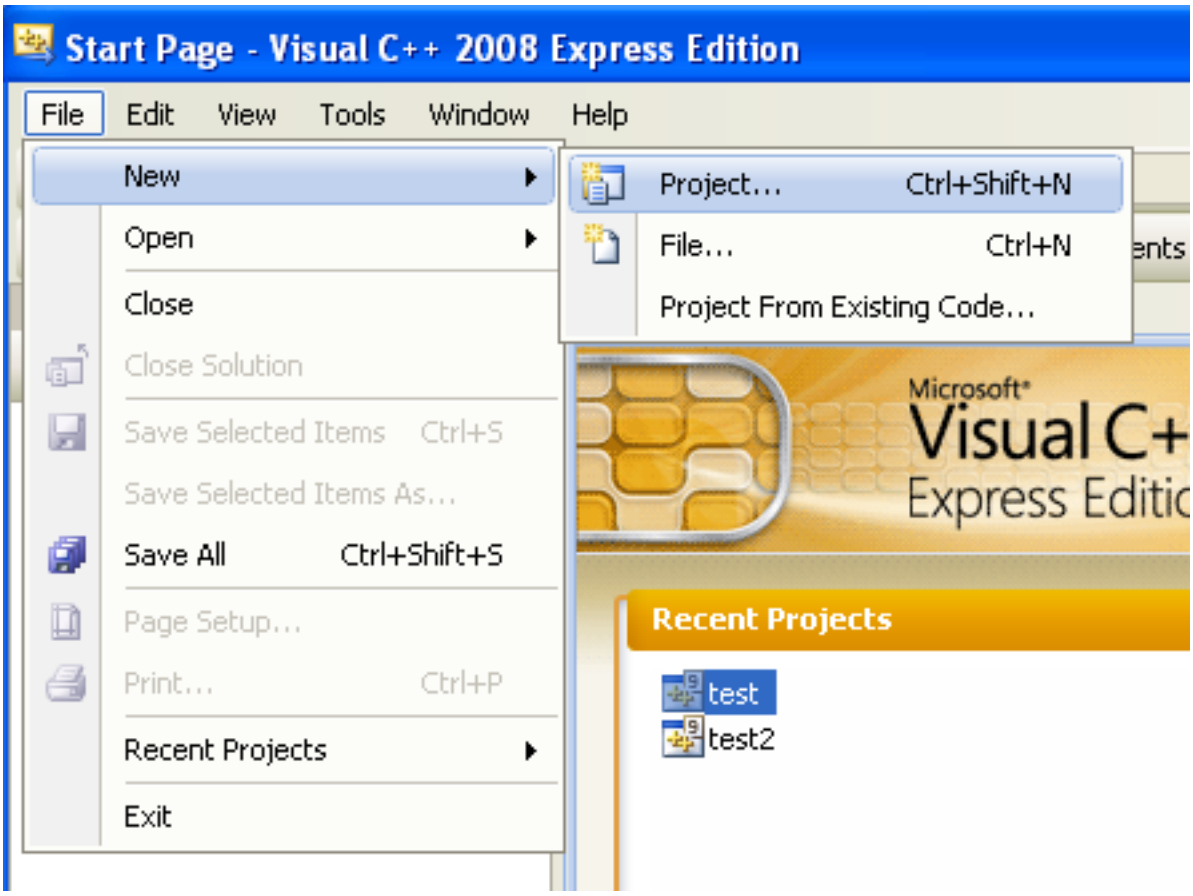
The MySQL Connector/C++ dynamic library file is `mysqlcppconn.dll`. In order to build your client application you need to link it with the file `mysqlcppconn.lib`. At run time the application will require access to the files `mysqlcppconn.dll` and `libmysql.dll`.

Building a MySQL Connector/C++ application with Microsoft Visual Studio

Initially, the procedure for building an application to use either the static or dynamic library is the same. You then carry out some additional steps depending on whether you want to build your application to use the static or dynamic library.

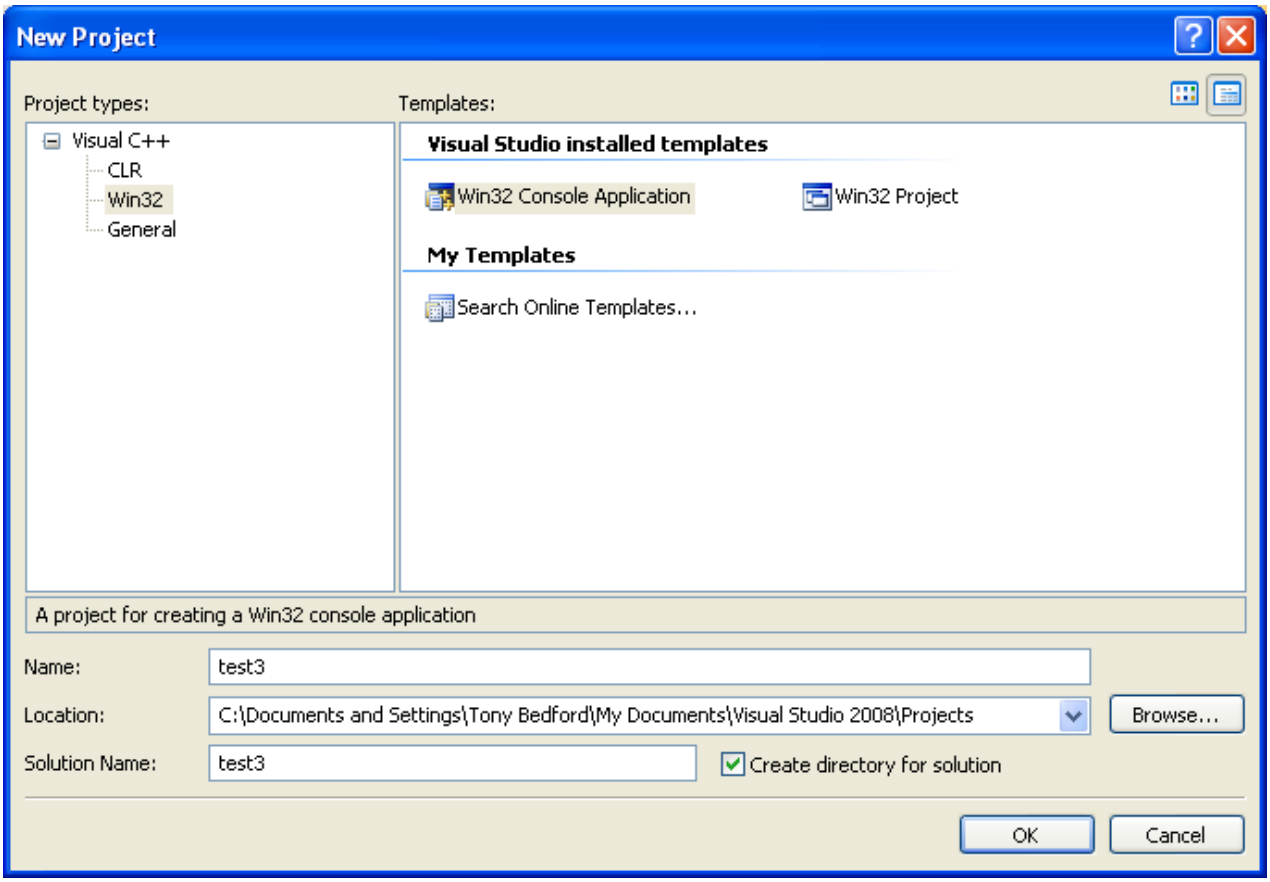
1. Select FILE, NEW, PROJECT from the main menu.

Figure 20.60. Creating a New Project



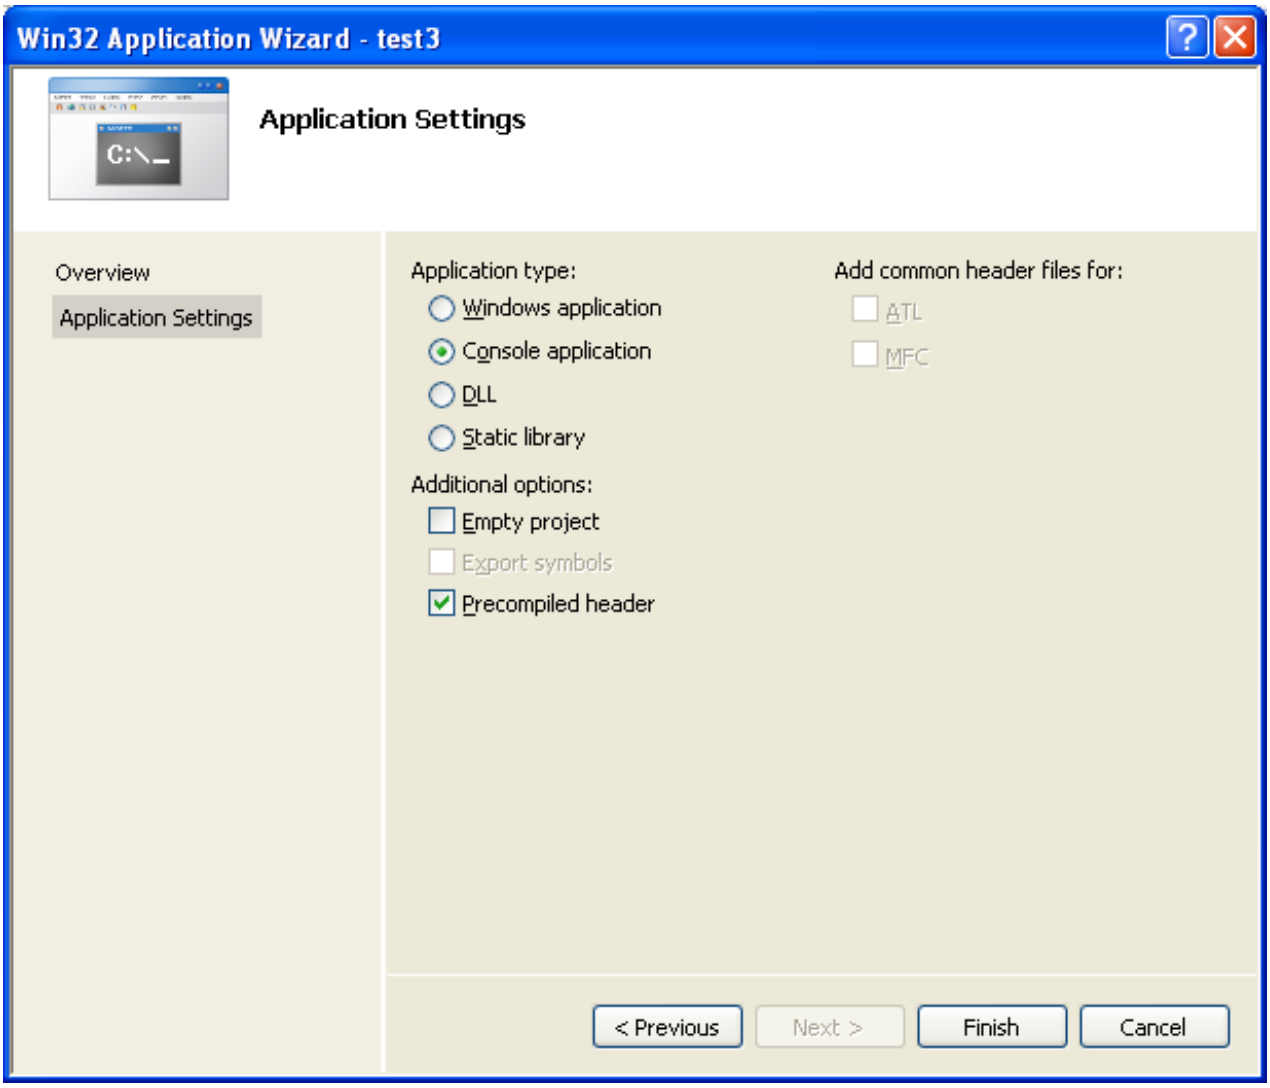
2. In the wizard select **VISUAL C++**, **WIN32**. From **VISUAL STUDIO INSTALLED TEMPLATES** select the application type **WIN32 CONSOLE APPLICATION**. Enter a name for the application, and then click OK, to move to the Win32 Application Wizard.

Figure 20.61. The New Project Dialog Box



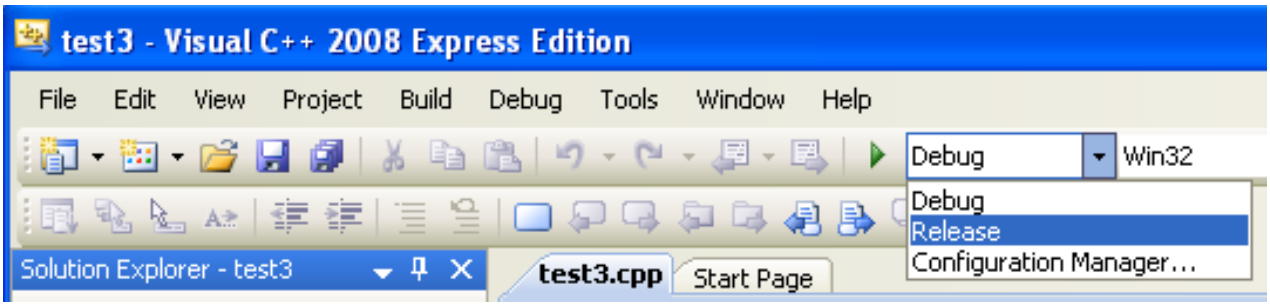
3. In the Win32 Application Wizard, click **APPLICATION SETTINGS** and ensure the defaults are selected. The radio button **CONSOLE APPLICATION**, and the checkbox **PRECOMPILED HEADERS** will be selected. Click FINISH to close the wizard.

Figure 20.62. The Win32 Application Wizard



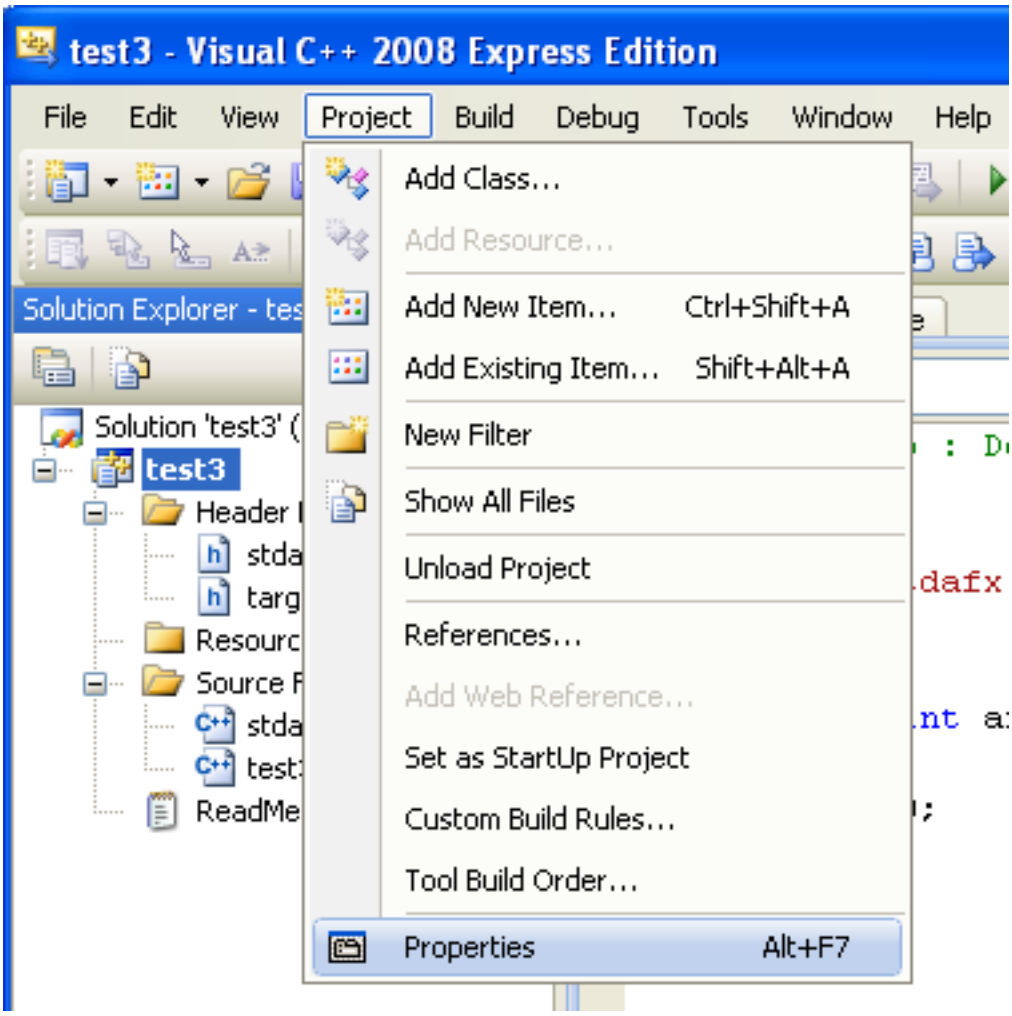
4. From the drop down list box on the toolbar, change from the default **DEBUG** build to the **RELEASE** build.

Figure 20.63. Selecting the Release Build



5. From the main menu select PROJECT, PROPERTIES. This can also be accessed using the hot key ALT + F7.

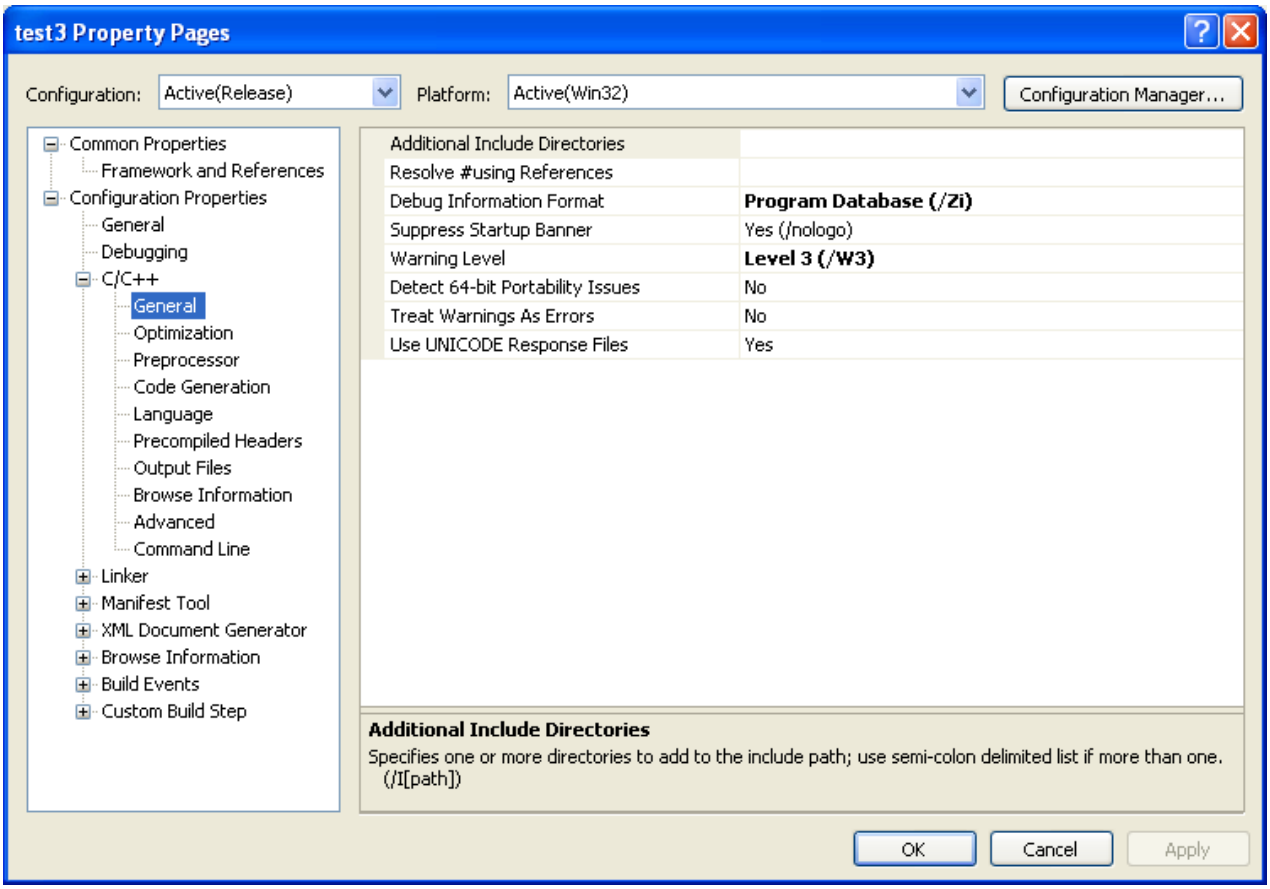
Figure 20.64. Selecting Project Properties from the Main Menu



6. Under **CONFIGURATION PROPERTIES**, open the tree view.

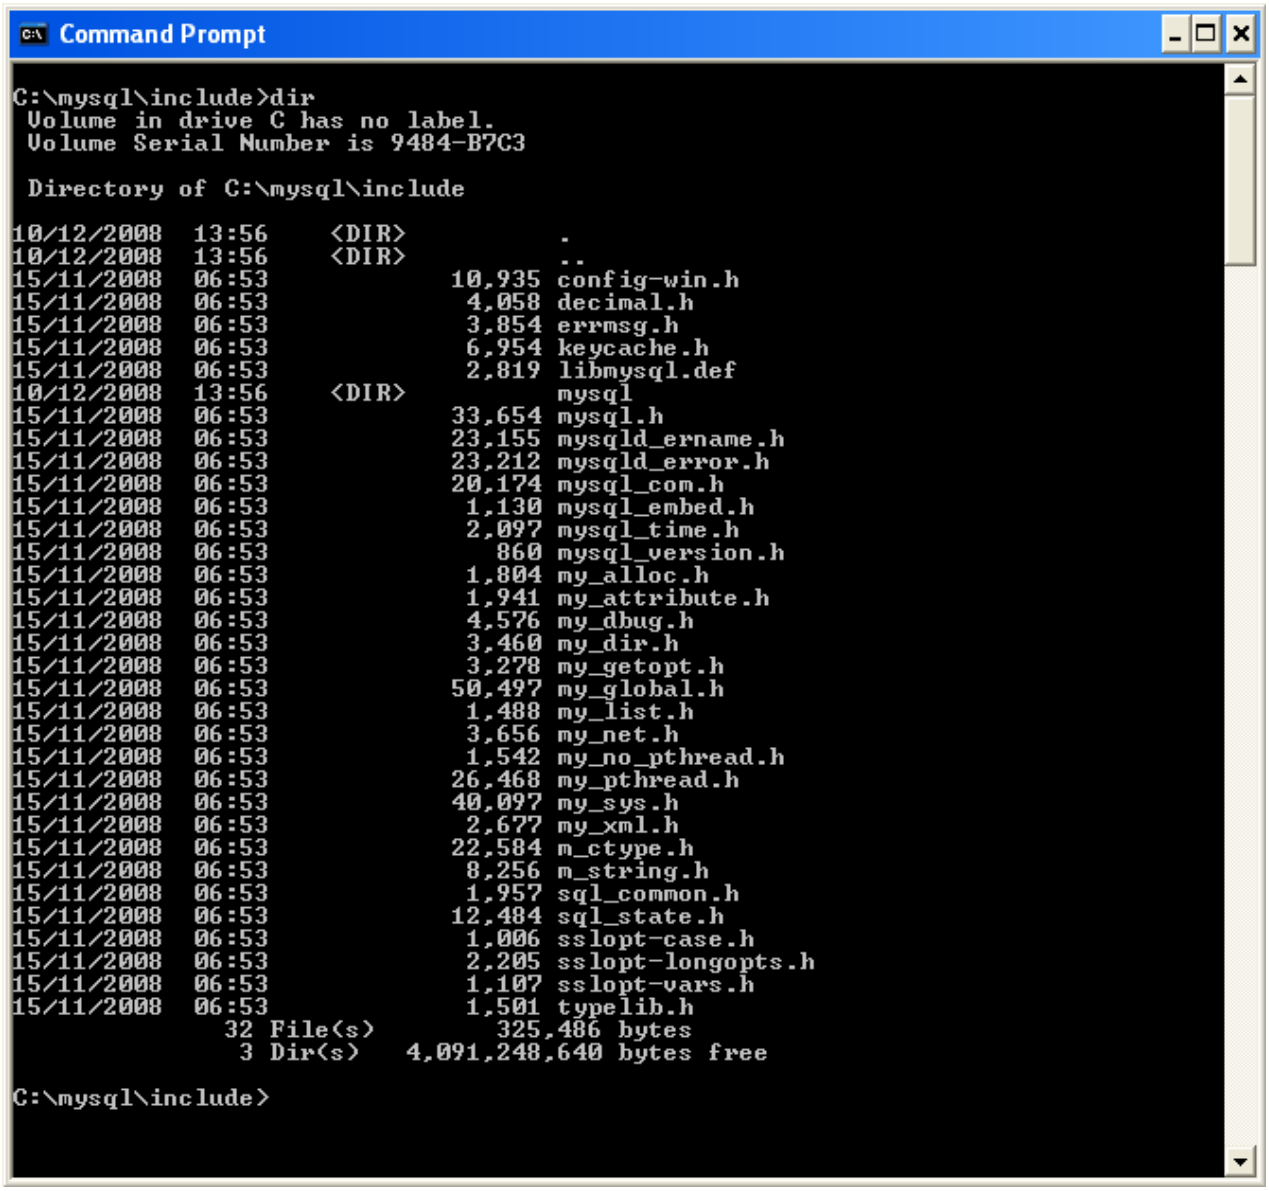
7. Select C++, **GENERAL** in the tree view.

Figure 20.65. Setting Properties



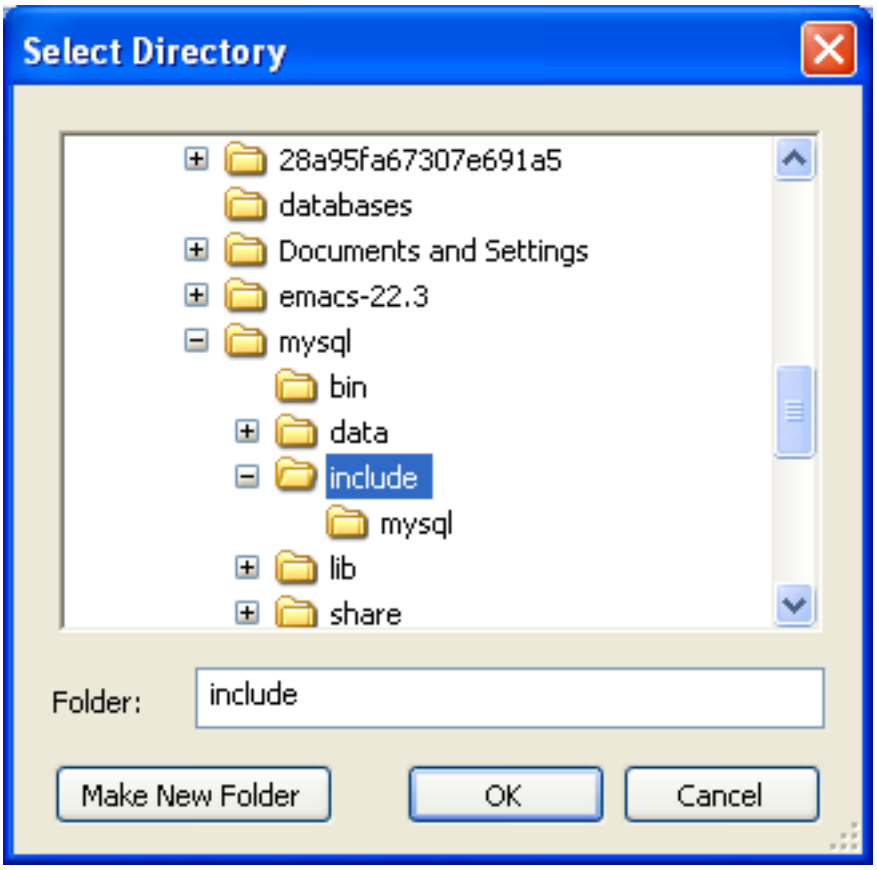
8. You now need to ensure that Visual Studio can find the MySQL include directory. This directory includes header files that can optionally be installed when installing MySQL Server.

Figure 20.66. MySQL Include Directory



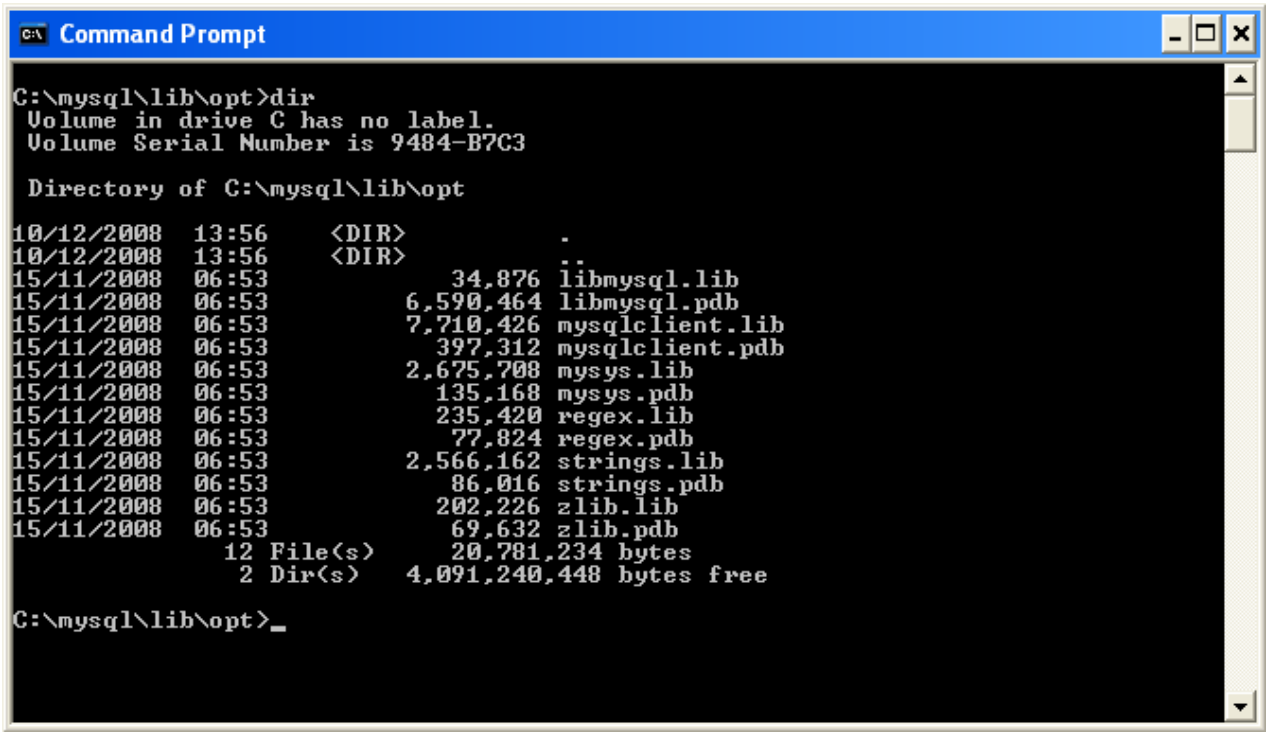
9. Then in the **Additional Include Directories** text field, add the MySQL `include/` directory.

Figure 20.67. Select Directory Dialog



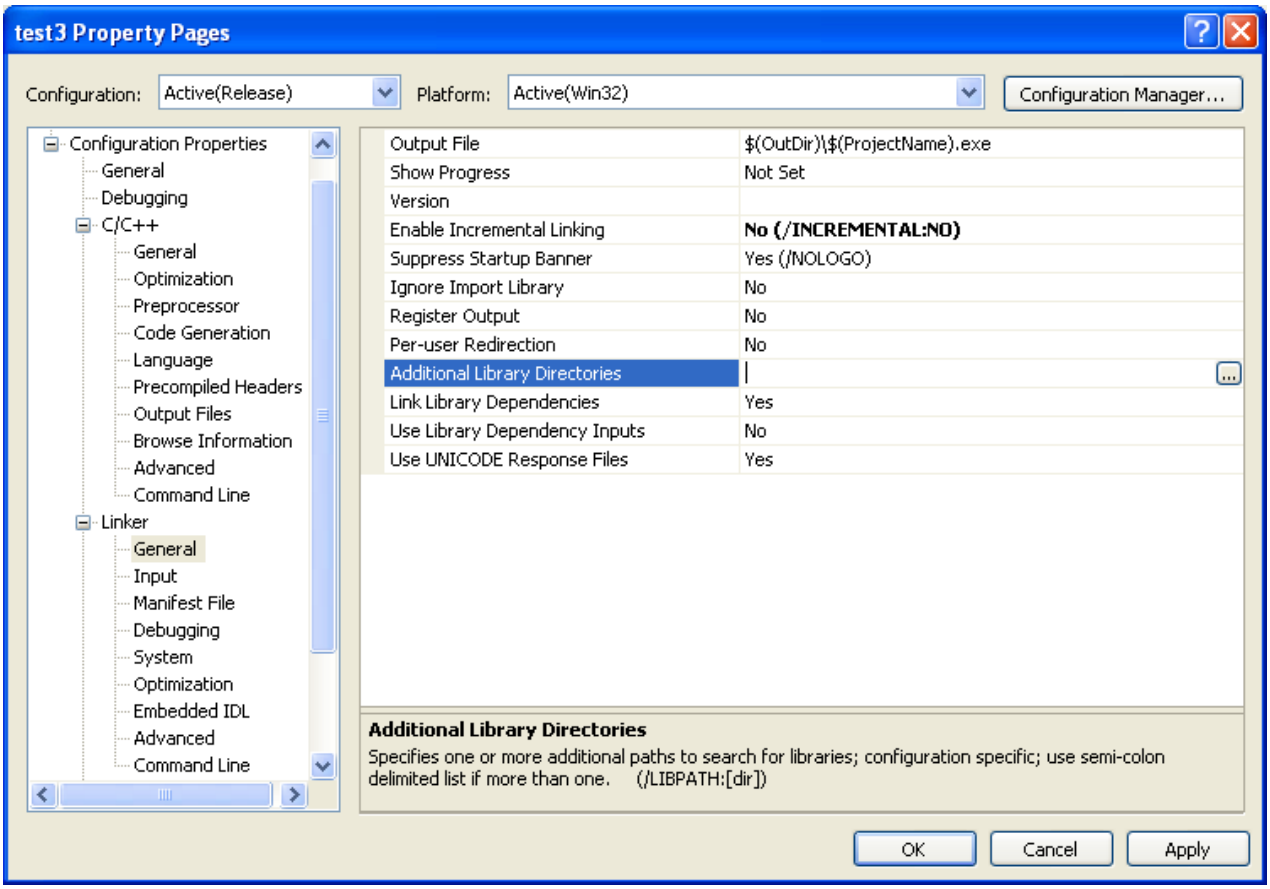
10. You will also need to set the location of additional libraries that Visual Studio will need in order to build the application. These are located in the MySQL `lib/opt` directory, a sub-directory of the MySQL Server installation directory.

Figure 20.68. Typical Contents of MySQL lib/opt Directory



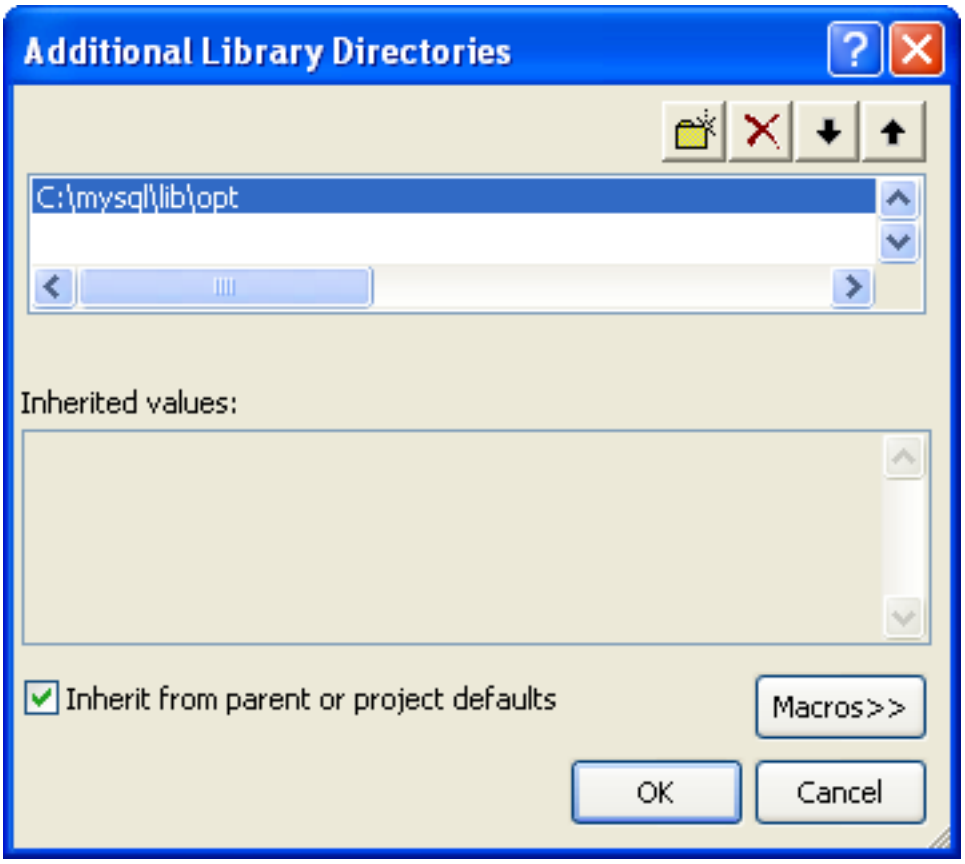
11. In the tree view open **Linker**, **General**, **Additional Library Directories**.

Figure 20.69. Additional Library Directories



12. Add the `lib/opt` directory into the **ADDITIONAL LIBRARY DIRECTORIES** text field. This allows the library file `libmysql.lib` to be found.

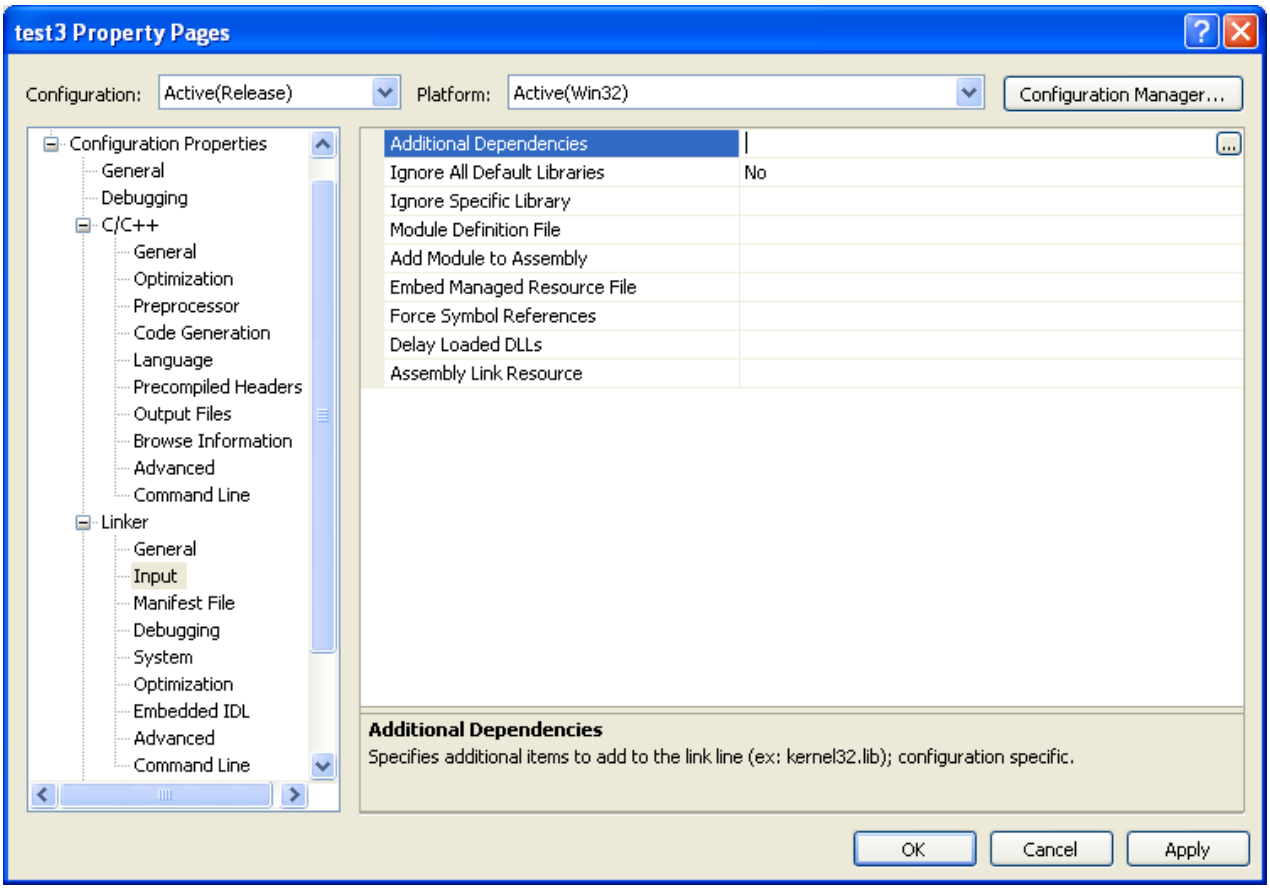
Figure 20.70. Additional Library Directories Dialog



The remaining steps depend on whether you are building an application to use the MySQL Connector/C++ static or dynamic library. If you are building your application to use the dynamic library go here. If you are building your application to use the static library, carry out the following steps:

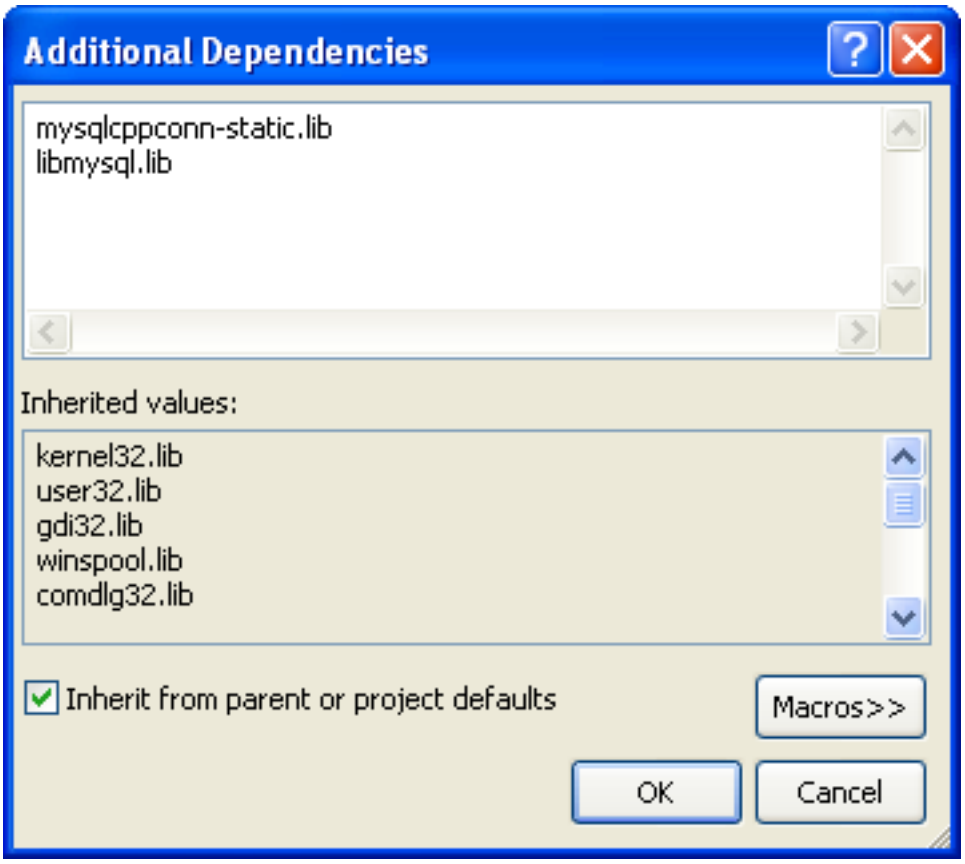
1. Then open **Linker**, **Input**, **Additional Dependencies**.

Figure 20.71.



2. Enter `mysqlcppconn-static.lib` and `libmysql.lib`.

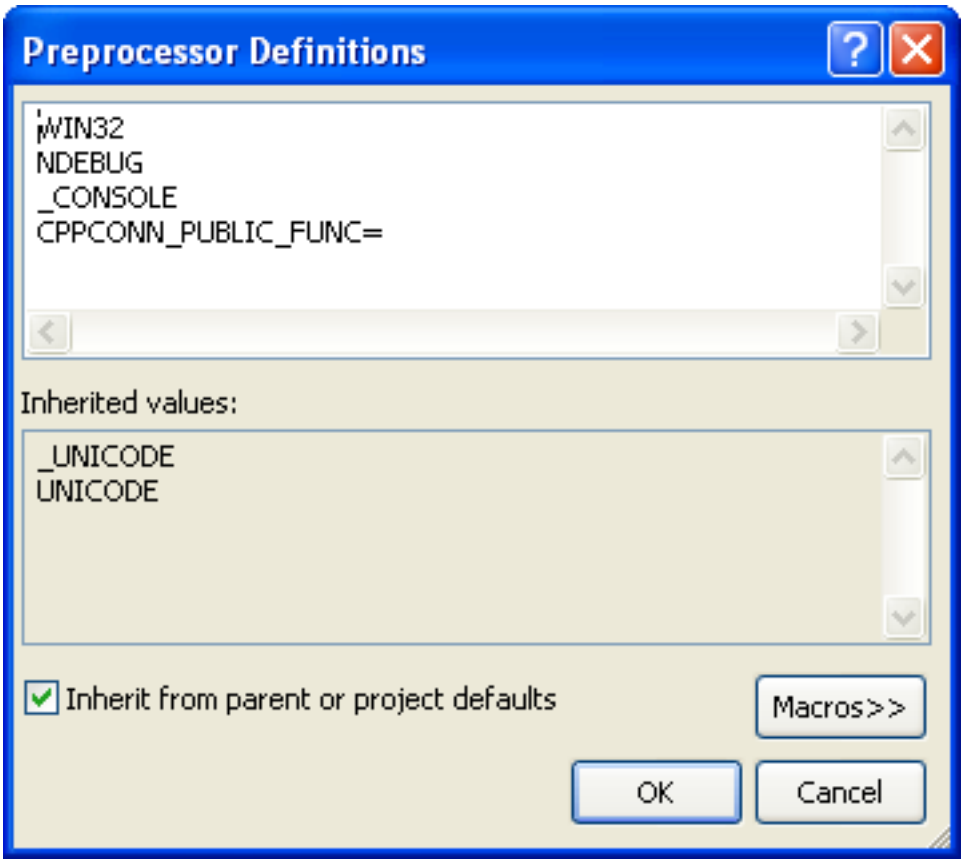
Figure 20.72. Adding Additional Dependencies



3. By default `CPPCONN_PUBLIC_FUNC` is defined to declare functions to be compatible with an application that calls a DLL. If building an application to call the static library, you must ensure that function prototypes are compatible with this. In this case `CPPCONN_PUBLIC_FUNC` needs to be defined to be an empty string, so that functions are declared with the correct prototype.

   In the **PROJECT**, **PROPERTIES** tree view, under **C++**, **PREPROCESSOR**, enter `CPPCONN_PUBLIC_FUNC=` into the PREPROCESSOR DEFINITIONS text field.

Figure 20.73. Setting the CPPCONN_PUBLIC_FUNC Define



Note

Make sure you enter `CPPCONN_PUBLIC_FUNC=` and not `CPPCONN_PUBLIC_FUNC`, as it needs to be defined as an empty string.

If building an application to use the MySQL Connector/C++ dynamically linked library carry out these steps:

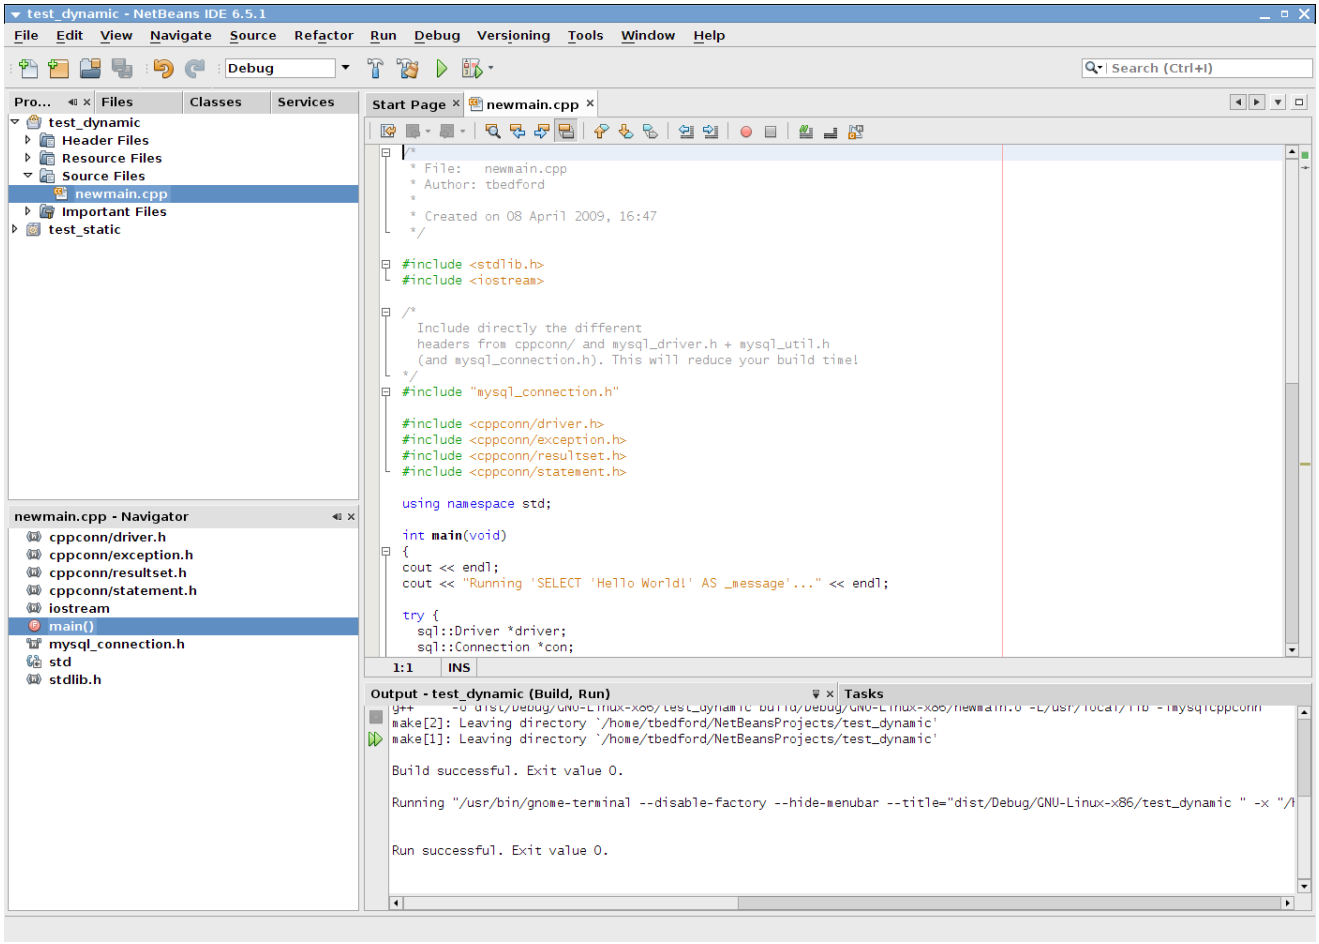
1. Under **Linker**, **Input**, add `mysqlcppconn.lib` into the **Additional Dependencies** text field.
2. The application will need to access the MySQL Connector/C++ Dynamic Linked Library at run time. Therefore, `mysqlcppconn.dll` needs to be in the same directory as the application executable, or somewhere on the system's path.

   Copy `mysqlcppconn.dll` to the same directory as the application. Alternatively, extend the `PATH` environment variable using `SET PATH=%PATH%;C:\path\to\cpp`. Alternatively, you can copy `mysqlcppconn.dll` to the Windows installation Directory, typically `c:\windows`.

20.5.4. MySQL Connector/C++ Building Linux applications with NetBeans

This section describes how you can build MySQL Connector/C++ applications for Linux using the NetBeans IDE.

Figure 20.74. The NetBeans IDE



> **Note**
>
> To avoid potential crashes the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

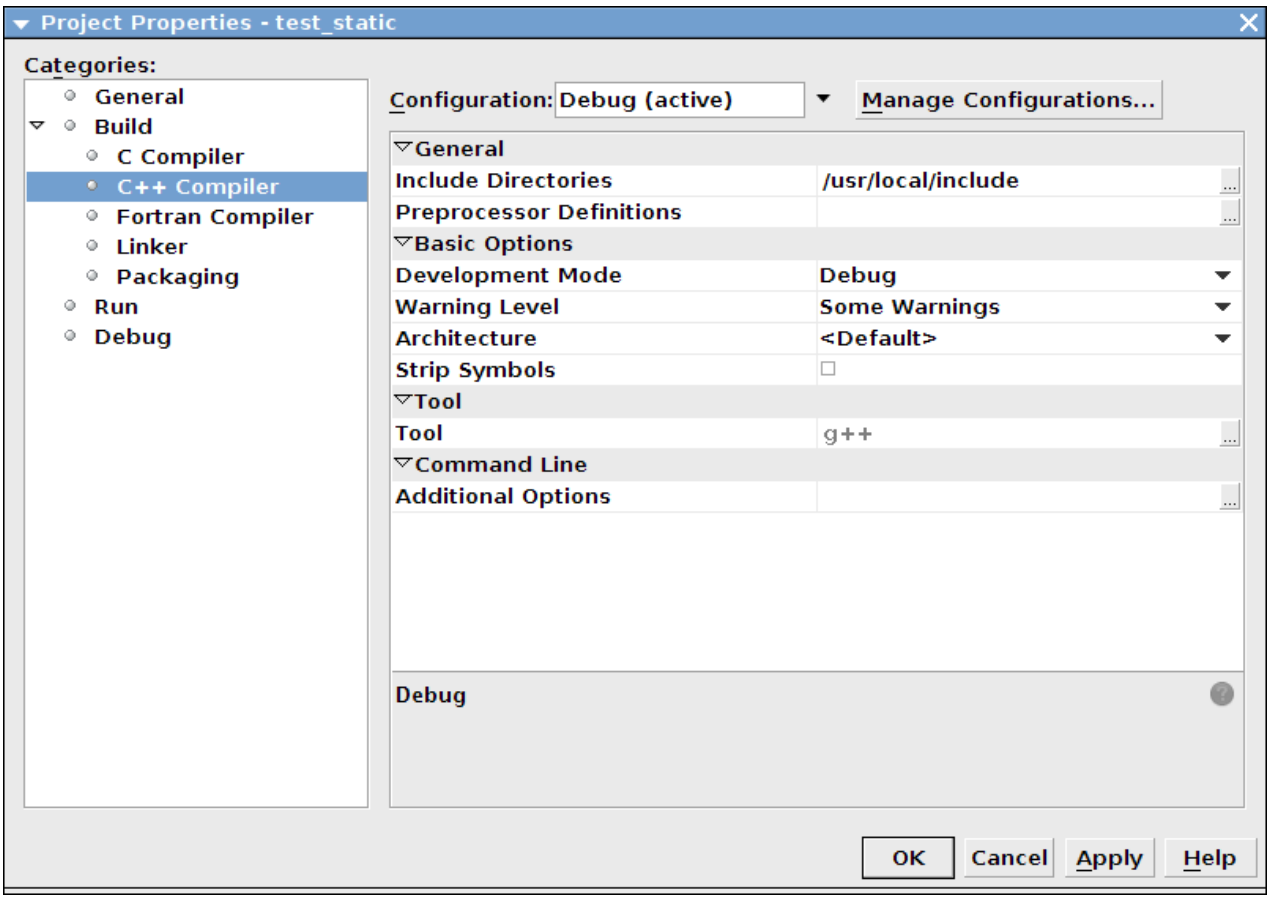
1. The first step of building your application is to create a new project. Select FILE, NEW PROJECT. Choose a **C/C++ APPLICATION** and click NEXT.
2. Give the project a name and click FINISH. A new project is created.
3. In the **PROJECTS** tab, right-click **SOURCE FILES** and select NEW, then MAIN C++ FILE....
4. Change the filename, or simply select the defaults and click FINISH to add the new file to the project.
5. You now need to add some working code to you main source file. Explore your MySQL Connector/C++ installation and navigate to the `examples` directory.
6. Select a suitable example such as `standalone_example_docs1.cpp`. Copy all the code in this file, and use it to replace the code in your existing main source file. Amend the code to reflect the connection properties required for your test database. You now have a working example that will access a MySQL database using MySQL Connector/C++.
7. You will notice that at this point NetBeans is showing some errors in the source code. This is because you need to direct NetBeans to the necessary header files that need to be included. Select FILE, PROJECT PROPERTIES from the main menu.
8. In the **CATEGORIES:** tree view panel, navigate to **BUILD**, **C++ COMPILER**.

9. In the **General** panel, select **Include Directories**.

10. Click the ... button.

11. Click Add and then navigate to the directory where the MySQL Connector/C++ header files are located. This will be `/usr/local/include` unless you have installed the files to a different location. Click Select. Click OK.

Figure 20.75. Setting the Header Include Directory



12. Click OK again to close the **Project Properties** dialog.

At this point you have created a NetBeans project, containing a single C++ source file. You have also ensured that the necessary include files are accessible. Before continuing, you need to decide whether your project is to use the MySQL Connector/C++ static or dynamic library. The project settings are slightly different in each case, as you need to link against a different library.

Using the static library

If you intend to use the static library you will need to link against two library files, `libmysqlcppconn-static.a` and `libmysqlclient.a`. The locations of the files will depend on your setup, but typically the former will be found in `/usr/local/lib` and the latter in `/usr/lib`. Note the file `libmysqlclient.a` is not part of MySQL Connector/C++, but is the MySQL Client Library file distributed with MySQL Server. Remember, the MySQL Client Library is an optional component as part of the MySQL Server installation process. Note the MySQL Client Library is also available as part of the new MySQL Connector/C distribution.

1. The first step is to set the project to link the necessary library files. Select File, Project Properties from the main menu.

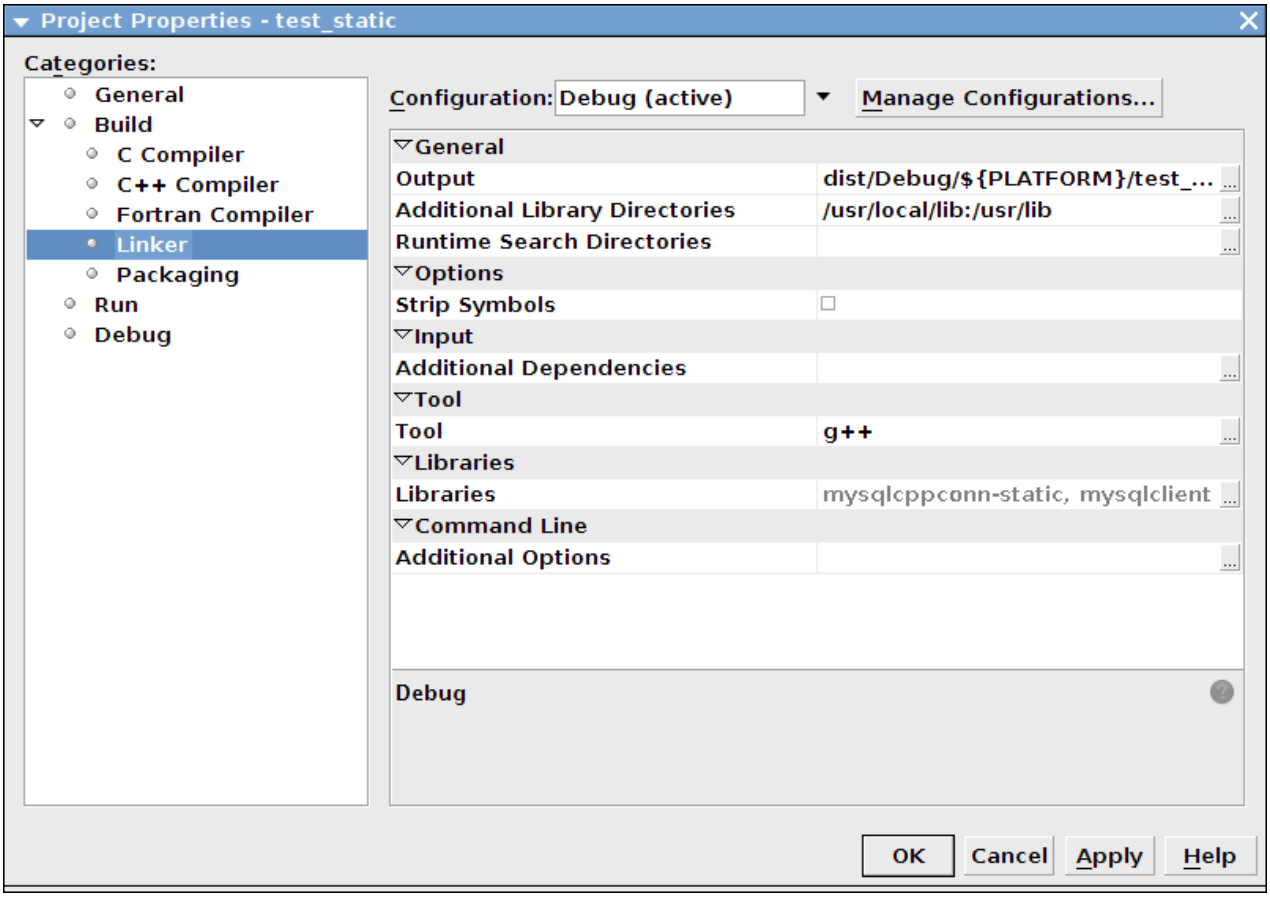
2. In the **Categores:** tree view navigate to **Linker**.

3. In the **General** panel select **Additional Library Directories**. Click the ... button.

4. Select and add the `/usr/lib` and `/usr/local/lib` directories.

5. In the same panel add the two library files required for static linking as discussed earlier. The properties panel should then look similar to the following screenshot:

Figure 20.76. Setting the Static Library Directories and File Names



6. Click OK to close the **Project Properties** dialog.

Using the dynamic library

If you require your application to use the MySQL Connector/C++ dynamic library, you simply need to link your project with a single library file, `libmysqlcppconn.so`. The location of this file will depend on how you configured your installation of MySQL Connector/C++, but will typically be `/usr/local/lib`.

1. The first step is to set the project to link the necessary library file. Select File, Project Properties from the main menu.

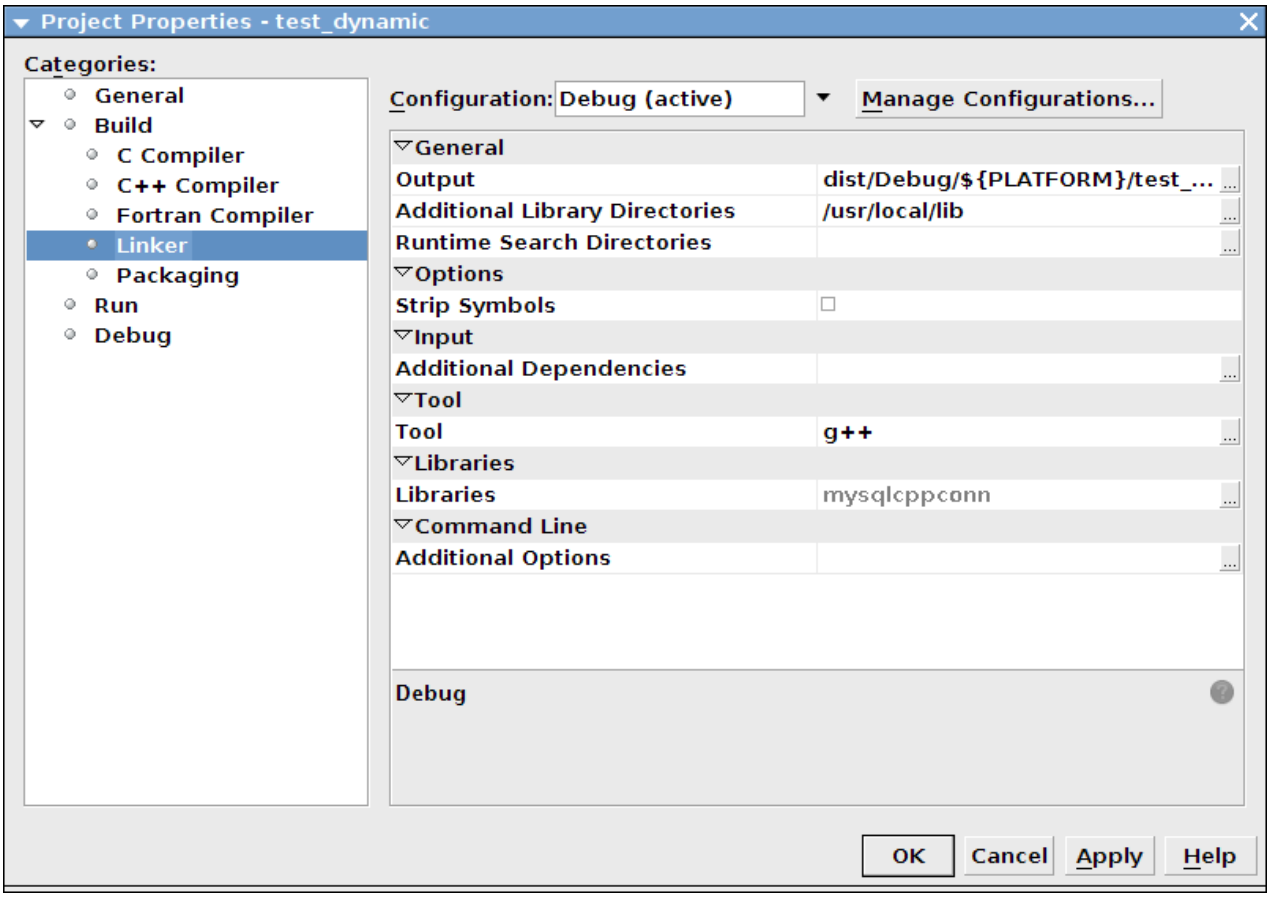
2. In the **Categories:** tree view navigate to **Linker**.

3. In the **General** panel select **Additional Library Directories**. Click the ... button.

4. Select and add the `/usr/local/lib` directories.

5. In the same panel add the library file required for static linking as discussed earlier. The properties panel should then look similar to the following screenshot:

Figure 20.77. Setting the Dynamic Library Directory and File Name

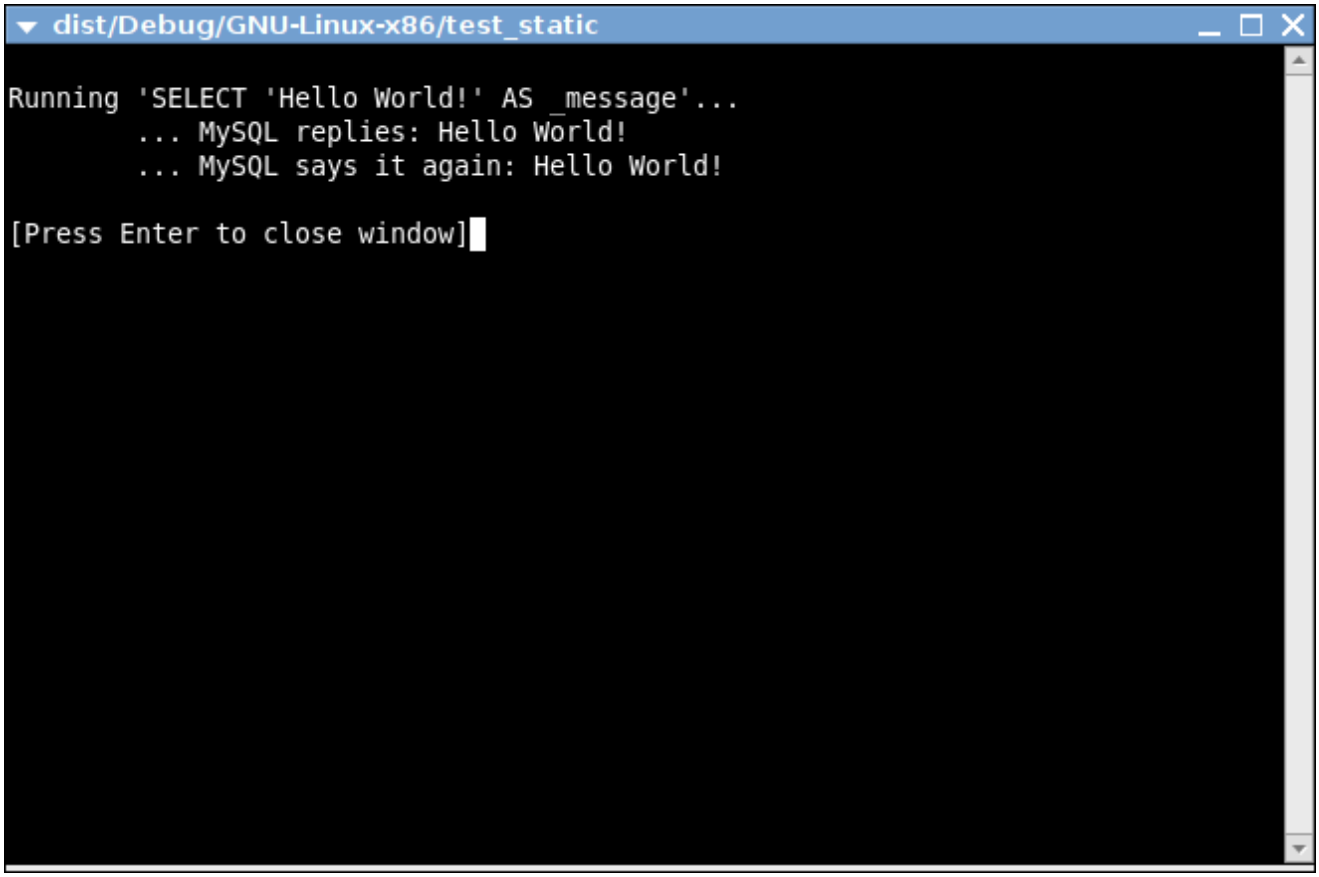


6. Click OK to close the Project Properties dialog.

Having configured your project you can build it by selecting RUN, BUILD MAIN PROJECT from the main menu. You can then run the project using RUN, RUN MAIN PROJECT.

On running the application you should see a screen similar to the following (this is actually the static version of the application shown):

Figure 20.78. The Example Application Running



> **Note**
>
> Note the above settings and procedures were carried out for the default `Debug` configuration. If you want to create a `Release` configuration you will need to select that configuration before setting the Project Properties.

20.5.5. MySQL Connector/C++ Getting Started: Usage Examples

The download package contains usage examples in the directory `examples/`. The examples explain the basic usage of the following classes:

- `Connection`
- `Driver`
- `PreparedStatement`
- `ResultSet`
- `ResultSetMetaData`
- `Statement`

The examples cover:

- Using the `Driver` class to connect to MySQL
- Creating tables, inserting rows, fetching rows using (simple) statements

- Creating tables, inserting rows, fetching rows using prepared statements
- Hints for working around prepared statement limitations
- Accessing result set meta data

The examples in this document are only code snippets. The code snippets provide a brief overview on the API. They are not complete programs. Please check the `examples/` directory of your MySQL Connector/C++ installation for complete programs. Please also read the `README` file in the `examples/` directory. Note to test the example code you will first need to edit the `examples.h` file in the `examples/` directory, to add your connection information. Then simply rebuild the code by issuing a `make` command.

The examples in the `examples/` directory include:

- `examples/connect.cpp`:

  How to create a connection, insert data into MySQL and handle exceptions.

- `examples/connection_meta_schemaobj.cpp`:

  How to obtain meta data associated with a connection object, for example, a list of tables, databases, MySQL version, connector version.

- `examples/debug.cpp`:

  How to activate and deactivate the MySQL Connector/C++ debug protocol.

- `examples/exceptions.cpp`:

  A closer look at the exceptions thrown by the connector and how to fetch error information.

- `examples/prepared_statements.cpp`:

  How to run Prepared Statements including an example how to handle SQL commands that cannot be prepared by the MySQL Server.

- `examples/resultset.cpp`:

  How to fetch data and iterate over the result set (cursor).

- `examples/resultset_meta.cpp`:

  How to obtain meta data associated with a result set, for example, number of columns and column types.

- `examples/resultset_types.cpp`:

  Result sets returned from meta data methods - this is more a test than much of an example.

- `examples/standalone_example.cpp`:

  Simple standalone program not integrated into regular CMake builds.

- `examples/statements.cpp`:

  How to run SQL commands without using Prepared Statements.

- `examples/cpp_trace_analyzer.cpp`:

  This example shows how to filter the output of the debug trace. Please see the inline comments for further documentation. This script is unsupported.

20.5.5.1. MySQL Connector/C++ Connecting to MySQL

A connection to MySQL is established by retrieving an instance of `sql::Connection` from a `sql::mysql::MySQL_Driver`

object. A `sql::mysql::MySQL_Driver` object is returned by `sql::mysql::MySQL_Driver::get_mysql_driver_instance()`.

```
sql::mysql::MySQL_Driver *driver;
sql::Connection *con;

driver = sql::mysql::MySQL_Driver::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");

delete con;
```

Make sure that you free the `sql::Connection` object as soon as you do not need it any more. But do not explicitly free the connector object!

20.5.5.2. MySQL Connector/C++ Running a simple query

For running simple queries you can use the methods `sql::Statement::execute()`, `sql::Statement::executeQuery()` and `sql::Statement::executeUpdate()`. The method `sql::Statement::execute()` should be used if your query does not return a result set or if your query returns more than one result set. See the `examples/` directory for more on this.

```
sql::mysql::MySQL_Driver *driver;
sql::Connection *con;
sql::Statement *stmt

driver = sql::mysql::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");

stmt = con->createStatement();
stmt->execute("USE " EXAMPLE_DB);
stmt->execute("DROP TABLE IF EXISTS test");
stmt->execute("CREATE TABLE test(id INT, label CHAR(1))");
stmt->execute("INSERT INTO test(id, label) VALUES (1, 'a')");

delete stmt;
delete con;
```

Note that you have to free `sql::Statement` and `sql::Connection` objects explicitly using delete.

20.5.5.3. MySQL Connector/C++ Fetching results

The API for fetching result sets is identical for (simple) statments and prepared statements. If your query returns one result set you should use `sql::Statement::executeQuery()` or `sql::PreparedStatement::executeQuery()` to run your query. Both methods return `sql::ResultSet` objects. The preview version does buffer all result sets on the client to support cursors.

```
// ...
sql::Connection *con;
sql::Statement *stmt
sql::ResultSet  *res;
// ...
stmt = con->createStatement();
// ...

res = stmt->executeQuery("SELECT id, label FROM test ORDER BY id ASC");
while (res->next()) {
  // You can use either numeric offsets...
  cout << "id = " <&;t; res->getInt(0);
  // ... or column names for accessing results. »
    The latter is recommended.
  cout << ", label = '" << »
    res->getString("label") << "'" << endl;
}

delete res;
delete stmt;
delete con;
```

Note that you have to free `sql::Statement`, `sql::Connection` and `sql::ResultSet` objects explicitly using delete.

The usage of cursors is demonstrated in the examples contained in the download package.

20.5.5.4. MySQL Connector/C++ Using Prepared Statements

If you are not familiar with Prepared Statements on MySQL have an extra look at the source code comments and explanations in the file `examples/prepared_statement.cpp`.

`sql::PreparedStatement` is created by passing a SQL query to `sql::Connection::prepareStatement()`. As `sql::PreparedStatement` is derived from `sql::Statement`, you will feel familiar with the API once you have learned how to use (simple) statements (`sql::Statement`). For example, the syntax for fetching results is identical.

```
// ...
sql::Connection *con;
sql::PreparedStatement *prep_stmt
// ...

prep_stmt = con->prepareStatement("INSERT INTO test(id, label) VALUES (?, ?)");

prep_stmt->setInt(1, 1);
prep_stmt->setString(2, "a");
prep_stmt->execute();

prep_stmt->setInt(1, 2);
prep_stmt->setString(2, "b");
prep_stmt->execute();

delete prep_stmt;
delete con;
```

As usual, you have to free `sql::PreparedStatement` and `sql::Connection` objects explicitly.

20.5.5.5. MySQL Connector/C++ Complete Example 1

The following code shows a complete example of how to use MySQL Connector/C++:

```
/* Copyright 2008 Sun Microsystems, Inc.

*/

/* Standard C++ includes */
#include <stdlib.h>
#include <iostream>

/*
  Include directly the different
  headers from cppconn/ and mysql_driver.h + mysql_util.h
  (and mysql_connection.h). This will reduce your build time!
*/
#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>

using namespace std;

int main(void)
{
cout << endl;
cout << "Running 'SELECT 'Hello World!' »
   AS _message'..." << endl;

try {
  sql::Driver *driver;
  sql::Connection *con;
  sql::Statement *stmt;
  sql::ResultSet *res;

  /* Create a connection */
  driver = get_driver_instance();
  con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
  /* Connect to the MySQL test database */
  con->setSchema("test");
```

```
  stmt = con->createStatement();
  res = stmt->executeQuery("SELECT 'Hello World!' AS _message");
  while (res->next()) {
    cout << "\t... MySQL replies: ";
    /* Access column data by alias or column name */
    cout << res->getString("_message") << endl;
    cout << "\t... MySQL says it again: ";
    /* Access column fata by numeric offset, 1 is the first column */
    cout << res->getString(1) << endl;
  }
  delete res;
  delete stmt;
  delete con;

} catch (sql::SQLException &e) {
  cout << "# ERR: SQLException in " << __FILE__;
  cout << "(" << __FUNCTION__ << ") on line " »
     << __LINE__ << endl;
  cout << "# ERR: " << e.what();
  cout << " (MySQL error code: " << e.getErrorCode();
  cout << ", SQLState: " << e.getSQLState() << " )" << endl;
}

cout << endl;

return EXIT_SUCCESS;
}
```

20.5.5.6. MySQL Connector/C++ Complete Example 2

The following code shows a complete example of how to use MySQL Connector/C++:

```
/* Copyright 2008 Sun Microsystems, Inc.

*/

/* Standard C++ includes */
#include <stdlib.h>
#include <iostream>

/*
  Include directly the different
  headers from cppconn/ and mysql_driver.h + mysql_util.h
  (and mysql_connection.h). This will reduce your build time!
*/
#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

using namespace std;

int main(void)
{
cout << endl;
cout << "Let's have MySQL count from 10 to 1..." << endl;

try {
  sql::Driver *driver;
  sql::Connection *con;
  sql::Statement *stmt;
  sql::ResultSet *res;
  sql::PreparedStatement *pstmt;

  /* Create a connection */
```

```
  driver = get_driver_instance();
  con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
  /* Connect to the MySQL test database */
  con->setSchema("test");

  stmt = con->createStatement();
  stmt->execute("DROP TABLE IF EXISTS test");
  stmt->execute("CREATE TABLE test(id INT)");
  delete stmt;

  /* '?' is the supported placeholder syntax */
  pstmt = con->prepareStatement("INSERT INTO test(id) VALUES (?)");
  for (int i = 1; i <= 10; i++) {
    pstmt->setInt(1, i);
    pstmt->executeUpdate();
  }
  delete pstmt;

  /* Select in ascending order */
  pstmt = con->prepareStatement("SELECT id FROM test ORDER BY id ASC");
  res = pstmt->executeQuery();

  /* Fetch in reverse = descending order! */
  res->afterLast();
  while (res->previous())
    cout << "\t... MySQL counts: " << res->getInt("id") << endl;
  delete res;

  delete pstmt;
  delete con;

} catch (sql::SQLException &e) {
  cout << "# ERR: SQLException in " << __FILE__;
  cout << "(" << __FUNCTION__ << ") on line " »
     << __LINE__ << endl;
  cout << "# ERR: " << e.what();
  cout << " (MySQL error code: " << e.getErrorCode();
  cout << ", SQLState: " << e.getSQLState() << »
     " )" << endl;
}

cout << endl;

return EXIT_SUCCESS;
}
```

20.5.6. MySQL Connector/C++ Tutorials

Here are some tutorials on using MySQL Connector/C++. You should also have a look at the examples which can be found in the following section Section 20.5.5, “MySQL Connector/C++ Getting Started: Usage Examples”.

Setting up the World database for use in the tutorials

These tutorials primarily use the `World` database, so you need to have that installed. You can download the `World` database, and documentation on how to install it, from the MySQL Documentation page - look for the section called “Example Databases”.

Tutorial framework code

Rather than repeating the same code, a framework is given here. You can reuse this framework with all the tutorials unless otherwise stated. This boiler plate code can then simply be reused for each tutorial.

The framework code is given here:

```
#include <stdlib.h>
#include <iostream>
#include <sstream>
#include <stdexcept>

#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

#define EXAMPLE_HOST "localhost"
#define EXAMPLE_USER "root"
#define EXAMPLE_PASS ""
#define EXAMPLE_DB "world"
```

```
using namespace std;

int main(int argc, const char **argv)
{

    string url(argc >= 2 ? argv[1] : EXAMPLE_HOST);
    const string user(argc >= 3 ? argv[2] : EXAMPLE_USER);
    const string pass(argc >= 4 ? argv[3] : EXAMPLE_PASS);
    const string database(argc >= 5 ? argv[4] : EXAMPLE_DB);

    cout << "Connector/C++ tutorial framework..." << endl;
    cout << endl;

    try {

        /* INSERT TUTORIAL CODE HERE! */

    } catch (sql::SQLException &e) {
        /*
          The MySQL Connector/C++ throws three different exceptions:

          - sql::MethodNotImplementedException (derived from sql::SQLException)
          - sql::InvalidArgumentException (derived from sql::SQLException)
          - sql::SQLException (derived from std::runtime_error)
        */
        cout << "# ERR: SQLException in " << __FILE__;
        cout << "(" << __FUNCTION__ << ") on line " << __LINE__ << endl;
        /* Use what() (derived from std::runtime_error) to fetch the error message */
        cout << "# ERR: " << e.what();
        cout << " (MySQL error code: " << e.getErrorCode();
        cout << ", SQLState: " << e.getSQLState() << " )" << endl;

        return EXIT_FAILURE;
    }

    cout << "Done." << endl;
    return EXIT_SUCCESS;
}
```

To compile and run the framework

First, copy and paste the framework code to a file such as `frmwk.cpp`. Edit the `#define` statements to reflect your connection details (server, user, password, database).

To compile the framework, for example on Mac OS X, type:

```
shell> g++ -o frmwk -I/usr/local/include -I/usr/local/include/cppconn -lmysqlcppconn frmwk.cpp
```

To run the framework, enter the following:

```
shell> ./frmwk
```

You will see a simple message. You are now ready to continue to the tutorials.

20.5.6.1. Tutorial: Calling Stored Procedures with Statements in MySQL Connector/C++

Stored Procedures can be called using both Statements and Prepared Statements. This tutorial looks at calling Stored Procedures using Statements. The following tutorial Section 20.5.6.2, “Tutorial: Calling Stored Procedures with Prepared Statements in MySQL Connector/C++” will cover the use of Prepared Statements.

When considering calling Stored Procedures there are several scenarios that can occur:

1. A Stored Procedure that does not return a result set.
2. A Stored Procedure that returns an output parameter.
3. A Stored Procedure that returns a result set.

Stored Procedures are given below that illustrate each of the above scenarios.

The following routine allows you to add a country into the World database, but does not return a result. This corresonds to Scenario 1

above.

```
CREATE PROCEDURE add_country (IN country_code CHAR(3), IN country_name CHAR(52), IN continent_name CHAR(30))
BEGIN
   INSERT INTO Country(Code, Name, Continent) VALUES (country_code, country_name, continent_name);
END
```

The next routine returns the population of a specified country, and corresponds to Scenario 2 above:

```
CREATE PROCEDURE get_pop (IN country_name CHAR(52), OUT country_pop INT(11))
BEGIN
   SELECT Population INTO country_pop FROM Country WHERE Name = country_name;
END
```

The next routine is an example of a procedure returning a result set containing multiple records. This routine corresponds to Scenario 3 above.

```
CREATE PROCEDURE get_data ()
BEGIN
        SELECT Code, Name, Population, Continent FROM Country WHERE Continent = "Oceania" AND Population < 10000;
        SELECT Code, Name, Population, Continent FROM Country WHERE Continent = "Europe" AND Population < 10000;
        SELECT Code, Name, Population, Continent FROM Country WHERE Continent = "North America" AND Population < 10000;
END
```

Enter and test the Stored Procedures to ensure no errors have been introduced. You are now ready to start writing routines to test out the use of Stored Procedures using Connector/C++.

Scenario 1 - Stored Procedure does not return a result set

In the first case you will examine Scenario 1, you call a Stored procedure that does not return a result set.

1. Make a copy of the tutorial framework code.
2. Insert the following code into the framework at the correct location (denoted by an INSERT HERE comment in the framework).

   ```
   sql::Driver* driver = get_driver_instance();
   std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
   con->setSchema(database);
   std::auto_ptr<sql::Statement> stmt(con->createStatement());

   // We don't need to check the return value explicitly, if it indicates
   // an error Connector/C++ will generate an exception.
   stmt->execute("CALL add_country(\"ATL\", \"Atlantis\", \"North America\")");
   ```

3. Compile the program using the following command:

   ```
   shell> g++ -o sp_scenario1 -I/usr/local/include/cppconn/ -lmysqlcppconn sp_scenario1.cpp
   ```

4. Run the program by typing:

   ```
   shell> ./sp_scenario1
   ```

5. Using the MySQL Command Line Client, or other suitable tool, check the World database to determine that it has been updated correctly. You can use a query such as:

   ```
   SELECT Code, Name, Continent FROM Country WHERE Code="ATL";
   ```

The code in this case simply creates a statement and then invokes the execute method on it, passing the call to the Stored Procedure as a parameter. The Stored Procedure itself does not return a value, although it is important to note there will always be a return value from the call - this is simply the call status. MySQL Connector/C++ handles this status for you, so you do not need code to handle it explicitly. If the call should fail for some reason an exception will be raised, and this will be handled by the `catch` statement in the code.

Scenario 2 - Stored Procedure returns an output parameter

You will now see how to handle a Stored Procedure that returns an output parameter.

1. Enter the following code into the tutorial framework code:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_pop(\"Uganda\", @pop)");

std::auto_ptr<sql::ResultSet> res(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
   cout << "Population of Uganda: " << res->getString("_reply") << endl;

stmt->execute("CALL get_pop_continent(\"Asia\", @pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of Asia: " << res->getString("_reply") << endl;

stmt->execute("CALL get_world_pop(@pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of World: " << res->getString("_reply") << endl;
```

2. Compile the program using the following command:

```
shell> g++ -o sp_scenario2 -I/usr/local/include/cppconn/ -lmysqlcppconn sp_scenario2.cpp
```

3. Run the program by typing:

```
shell> ./sp_scenario2
```

   Note the output generated by the program.

In this scenario the Stored Procedure sets an output parameter. This is not returned as such, but needs to be obtained via a query. If running the SQL statements directly this might be similar to the following:

```
CALL get_world_pop(@pop);
SELECT @pop;
```

In the C++ code a similar sequence is carried out. First, the `CALL` is executed as seen earlier. To obtain the output parameter an additional query must be executed. This query results in a `ResultSet` that can then be processed in a `while` loop. The simplest way to retrieve the data in this case is to use a getString method on the ResultSet, passing the name of the variable to access. In this example `_reply` is used as a placeholder for the variable and therefore is used as the key to access the correct element of the result dictionary.

Scenario 3 - Stored Procedure returns a Result Set

You will now see how to handle a Stored Procedure that returns a result set.

1. Enter the following code into the tutorial framework code:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_stats()");
std::auto_ptr< sql::ResultSet > res;
do {
   res.reset(stmt->getResultSet());
   while (res->next()) {
      cout << "Result: " << res->getString(1) << endl;
   }
} while (stmt->getMoreResults());
```

2. Compile the program using the following command:

```
shell> g++ -o sp_scenario3 -I/usr/local/include/cppconn/ -lmysqlcppconn sp_scenario3.cpp
```

3. Run the program by typing:

```
shell> ./sp_scenario3
```

   Note the output generated by the program.

The code is similar to the examples you have previously seen. The code of particular interest in this case is:

```
do {
   res.reset(stmt->getResultSet());
   while (res->next()) {
      cout << "Name: " << res->getString("Name")
           << " Population: " << res->getInt("Population")
           << endl;
   }
} while (stmt->getMoreResults());
```

The `CALL` is executed as before, with the results being returned into multiple `ResultSet`s. This is because the Stored Procedure in this case uses multiple `SELECT` statements. In this example the output shows that three Result Sets are processed, because there are three `SELECT` statements in the Stored Procedure. All of the Result Sets have more than one row.

Studying the code it should be noted that the results are processed using the pattern:

```
do {
   Get Result Set
   while (Get Result) {
      Process Result
   }
} while (Get More Result Sets);
```

> **Note**
>
> Note this pattern would be used even if the Stored Procedure carried out a single `SELECT` and you knew there was only one result set. This is a requirement of the underlying protocol.

20.5.6.2. Tutorial: Calling Stored Procedures with Prepared Statements in MySQL Connector/C++

Before working through this tutorial it is recommended you first work through the previous tutorial Section 20.5.6.1, “Tutorial: Calling Stored Procedures with Statements in MySQL Connector/C++”.

Scenario 1 - Using a Prepared Statement to prepare a Stored Procedure that does not return a result set

1. Add the following code to the `try` block of the tutorial framework:

```
vector<string> code_vector;
code_vector.push_back("SLD");
code_vector.push_back("DSN");
code_vector.push_back("ATL");

vector<string> name_vector;
name_vector.push_back("Sealand");
name_vector.push_back("Disneyland");
name_vector.push_back("Atlantis");

vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");
cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();
```

```
std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement >  pstmt;

pstmt.reset(con->prepareStatement("CALL add_country(?,?,?)"));
for (int i=0; i<3; i++)
{
   pstmt->setString(1,code_vector[i]);
   pstmt->setString(2,name_vector[i]);
   pstmt->setString(3,cont_vector[i]);

   pstmt->execute();
}
```

You will also need to add `#include <vector>` to the top of your code as vectors are used to store sample data.

2. Compile the code using the following command:

```
g++ -o ps_scenario1 -I/usr/local/include/cppconn/ -lmysqlcppconn ps_scenario1.cpp
```

3. Run the code using the command:

```
./ps_scenario1
```

4. You can test the dataase has been updated correctly by using a query such as:

```
SELECT Code, Name, Continent FROM Country WHERE Code = "DSN" OR Code="ATL" OR Code="SLD";
```

The code is relatively simple, as no processing is required to handle Result Sets. The procedure call, `CALL add_country(?,?,?)`, is made using placeholders for input parameters denoted by '?'. These placeholders are replaced by values using the Prepared Statement's `setString` method in this case. The `for` loop is set up to iterate 3 times, as there are three data sets in this example. The same Prepared Statement is executed three times, each time with different input parameters.

Scenario 2 - Using a Prepared Statement to prepare a Stored Procedure that uses an output parameter

In this scenario a different Stored Procedure is going to be used compared to the one use in the the tutorial Section 20.5.6.1, “Tutorial: Calling Stored Procedures with Statements in MySQL Connector/C++”. This is to illustrate passing an input parameter as well as fetching an output parameter. The stored routine is as follows:

```
CREATE PROCEDURE get_pop_continent (IN continent_name CHAR(30), OUT continent_pop INT(11))
BEGIN
       SELECT SUM(Population) INTO continent_pop FROM Country WHERE Continent = continent_name;
END
```

1. Copy the following code into the try block of the tutorial framework code:

```
vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");
cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::Statement > stmt(con->createStatement());
std::auto_ptr< sql::PreparedStatement >  pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_pop_continent(?,@pop)"));

for (int i=0; i<3; i++)
{
   pstmt->setString(1,cont_vector[i]);
   pstmt->execute();
   res.reset(stmt->executeQuery("SELECT @pop AS _population"));
   while (res->next())
      cout << "Population of " << cont_vector[i] << " is " << res->getString("_population") << endl;
```

```
}
```

You will also need to add the line `#include <vector>` to the top of the code, as vectors are used in this example.

2. Compile the code using:

```
shell> g++ -o ps_scenario2 -I/usr/local/include/cppconn/ -lmysqlcppconn ps_scenario2.cpp
```

3. Run the code using:

```
shell> ./ps_scenario2
```

4. Make a note of the output.

In this scenario a Prepared Statement is created that calls the Stored Procedure `get_pop_continent`. This procedure takes an input parameter, and also returns an output parameter. The approach used is to create another statement that can be used to fetch the output parameter using a `SELECT` query. Note that when the Prepared Statement is created, the input parameter to the Stored Procedure is denoted by '?'. Prior to execution of Prepared Statement it is necessary to replace this placeholder by an actual value. This is done using methods such as `setString` and `setInt`, for example:

```
pstmt->setString(1,cont_vector[i]);
```

Although for the query used to obtain the output parameter a single result set is expected, it is important to use the `while` loop to catch more than one result, to avoid the possibility of the connection becoming unstable.

Scenario 3 - Using a Prepared Statement to prepare a Stored Procedure that returns multiple Result Sets

> **Note**
>
> Note this scenario is not supported on versions of MySQL prior to 5.5.3. This is due to a limitation in the client-server protocol.

1. Enter the following code into the `try` block of the tutorial framework:

```
sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement >  pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_data()"));
res.reset(pstmt->executeQuery());

do {
   res.reset(pstmt->getResultSet());
   while (res->next()) {
      cout << "Name: " << res->getString("Name")
           << " Population: " << res->getInt("Population")
           << endl;
   }
} while (pstmt->getMoreResults());
```

2. Compile the code using the following command:

```
shell> g++ -o ps_scenario3 -I/usr/local/include/cppconn/ -lmysqlcppconn ps_scenario3.cpp
```

3. Run the program using the command:

```
shell> ./ps_scenario3
```

4. Make a note of the output generated.

The code executes the Stored Procedure using a Prepared Statement. The standard do-while construct is used to ensure that all Result Sets are fetched. In this case the returned values are fetched from the Result Sets using the `getInt` and `getString` methods.

20.5.7. MySQL Connector/C++ Debug Tracing

Although a debugger can be used to debug your application, you may find it beneficial to turn on the debug traces of the connector. Some problems happen randomly which makes them difficult to debug using a debugger. In such cases debug traces and protocol files are more useful because they allow you to trace the activities of all instances of your program.

DTrace is a very powerful technology to trace any application without having to develop an extra trace module for your application. Unfortunately, DTrace is currently only available on OpenSolaris, Solaris, MacOS 10.5 and FreeBSD.

The MySQL Connector/C++ can write two trace files:

1. Trace file generated by the MySQL Client Library
2. Trace file generated internally by MySQL Connector/C++

The first trace file can be generated by the underlying MySQL Client Library (libmysql). To enable this trace the connector will call the C-API function `mysql_debug()` internally. Only debug versions of the MySQL Client Library are capable of writing a trace file. Therefore you need to compile MySQL Connector/C++ against a debug version of the library, if you want utilize this trace. The trace shows the internal function calls and the addresses of internal objects as you can see below:

```
>mysql_stmt_init
| >_mymalloc
| | enter: Size: 816
| | exit: ptr: 0x68e7b8
| <_mymalloc | >init_alloc_root
| | enter: root: 0x68e7b8
| | >_mymalloc
| | | enter: Size: 2064
| | | exit: ptr: 0x68eb28
[...]
```

The second trace is the MySQL Connector/C++ internal trace. It is available with debug and nondebug builds of the connector as long as you have enabled the tracing module at compile time using `cmake -DMYSQLCPPCONN_TRACE_ENABLE:BOOL=1`. By default, the tracing functionality is not available and calls to trace functions are removed by the preprocessor.

Compiling the connector with tracing functionality enabled will cause two additional tracing function calls per each connector function call. You will need to run your own benchmark to find out how much this will impact the performance of your application.

A simple test using a loop running 30,000 INSERT SQL statements showed no significant real-time impact. The two variants of this application using a trace enabled and trace disabled version of the connector performed equally well. The run time measured in real-time was not significantly impacted as long as writing a debug trace was not enabled. However, there will be a difference in the time spent in the application. When writing a debug trace the IO subsystem may become a bottleneck.

In summary, use connector builds with tracing enabled carefully. Trace enabled versions may cause higher CPU usage even if the overall run time of your application is not impacted significantly.

```
|  INF: Tracing enabled
<MySQL_Connection::setClientOption
>MySQL_Prepared_Statement::setInt
|  INF: this=0x69a2e0
|  >MySQL_Prepared_Statement::checkClosed
|  <MySQL_Prepared_Statement::checkClosed
| <MySQL_Prepared_Statement::setInt
[...]
```

The example from `examples/debug.cpp` demonstrates how to activate the debug traces in your program. Currently they can only be activated through API calls. The traces are controlled on a per-connection basis. You can use the `setClientOptions()` method of a connection object to activate and deactivate the generation of a trace. The MySQL Client Library trace is always written into a file, whereas the connector's protocol messages are printed to standard out.

```
sql::Driver *driver;
int on_off = 1;

/* Using the Driver to create a connection */
driver = get_driver_instance();
```

```
std::auto_ptr< sql::Connection > con(driver->connect(host, user, pass));

/*
Activate debug trace of the MySQL Client Library (C-API)
Only available with a debug build of the MySQL Client Library!
*/
con->setClientOption("libmysql_debug", "d:t:O,client.trace");

/*
Tracing is available if you have compiled the driver using
cmake -DMYSQLCPPCONN_TRACE_ENABLE:BOOL=1
*/
con->setClientOption("client_trace", &on_off);
```

20.5.8. MySQL Connector/C++ Usage Notes

See the JDBC overview for information on JDBC 4.0. Please also check the `examples/` directory of the download package.

Notes on using the MySQL Connector/C++ API

- `DatabaseMetaData::supportsBatchUpdates()` returns `true` because MySQL supports batch updates in general. However, no API calls for batch updates are provided by the MySQL Connector/C++ API.
- Two non-JDBC methods have been introduced for fetching and setting unsigned integers: `getUInt64()` and `getUInt()`. These are available for `ResultSet` and `Prepared_Statement`:
  - `ResultSet::getUInt64()`
  - `ResultSet::getUInt()`
  - `Prepared_Statement::setUInt64()`
  - `Prepared_Statement::setUInt()`

  The corresponding `getLong()` and `setLong()` methods have been removed.
- The method `DatabaseMetaData::getColumns()` has 23 columns in its result set, rather than the 22 columns defined by JDBC. The first 22 columns are as described in the JDBC documentation, but column 23 is new:

  23. `IS_AUTOINCREMENT`: String which is “YES” if the column is an auto-increment column. Otherwise the string contains “NO”.
- MySQL Connector/C++ may return different metadata for the same column.

  When you have any column that accepts a charset and a collation in its specification and you specify a binary collation, such as:

  ```
  CHAR(250) CHARACTER SET 'latin1' COLLATE 'latin1_bin'
  ```

  The server sets the `BINARY` flag in the result set metadata of this column. The method `ResultSetMetadata::getColumnTypeName()` uses the metadata and will report, due to the `BINARY` flag, that the column type name is `BINARY`. This is illustrated below:

  ```
  mysql> create table varbin(a varchar(20) character set utf8 collate utf8_bin);
  Query OK, 0 rows affected (0.00 sec)

  mysql> select * from varbin;
  Field   1:  `a`
  Catalog:    `def`
  Database:   `test`
  Table:      `varbin`
  Org_table:  `varbin`
  Type:       VAR_STRING

```

However, `INFORMATION_SCHEMA` gives no hint in its `COLUMNS` table that metadata will contain the `BINARY` flag. `DatabaseMetaData::getColumns()` uses `INFORMATION_SCHEMA`. It will report the type name `CHAR` for the same column. Note, a different type code is also returned.

- The MySQL Connector/C++ class `sql::DataType` defines the following JDBC standard data types: `UNKNOWN`, `BIT`, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INTEGER`, `BIGINT`, `REAL`, `DOUBLE`, `DECIMAL`, `NUMERIC`, `CHAR`, `BINARY`, `VARCHAR`, `VARBINARY`, `LONGVARCHAR`, `LONGVARBINARY`, `TIMESTAMP`, `DATE`, `TIME`, `GEOMETRY`, `ENUM`, `SET`, `SQLNULL`.

  However, the following JDBC standard data types are *not* supported by MySQL Connector/C++: `ARRAY`, `BLOB`, `CLOB`, `DISTINCT`, `FLOAT`, `OTHER`, `REF`, `STRUCT`.

- When inserting or updating `BLOB` or `TEXT` columns, MySQL Connector/C++ developers are advised not to use `setString()`. Instead it is recommended that the dedicated API function `setBlob()` be used instead.

  The use of `setString()` can cause a Packet too large error message. The error will occur if the length of the string passed to the connector using `setString()` exceeds `max_allowed_packet` (minus a few bytes reserved in the protocol for control purposes). This situation is not handled in MySQL Connector/C++, as this could lead to security issues, such as extremely large memory allocation requests due to malevolently long strings.

  However, if `setBlob()` is used, this problem does not arise. This is because `setBlob()` takes a streaming approach based on `std::istream`. When sending the data from the stream to MySQL Server, MySQL Connector/C++ will split the stream into chunks appropriate for MySQL Server and observe the `max_allowed_packet` setting currently being used.

  > **Caution**
  >
  > When using `setString()` it is not possible to set `max_allowed_packet` to a value large enough for the string, prior to passing it to MySQL Connector/C++. The MySQL 5.1 documentation for `max_allowed_packet` states: “As of MySQL 5.1.31, the session value of this variable is read only. Before 5.1.31, setting the session value is allowed but has no effect.”

  This difference with the JDBC specification ensures that MySQL Connector/C++ is not vulnerable to memory flooding attacks.

- In general MySQL Connector/C++ works with MySQL 5.0, but it is not completely supported. Some methods may not be available when connecting to MySQL 5.0. This is because the Information Schema is used to obtain the requested information. There are no plans to improve the support for 5.0 because the current GA version of MySQL Server is 5.1. As a new product, MySQL Connector/C++ is primarily targeted at the MySQL Server GA version that was available on its release.

  The following methods will throw a `sql::MethodNotImplemented` exception when you connect to MySQL earlier than 5.1.0:

  - `DatabaseMetadata::getCrossReference()`
  - `DatabaseMetadata::getExportedKeys()`

- MySQL Connector/C++ includes a method `Connection::getClientOption()` which is not included in the JDBC API specification. The prototype is:

```
void getClientOption(const std::string & optionName, void * optionValue)
```

The method can be used to check the value of connection properties set when establishing a database connection. The values are returned through the `optionValue` argument passed to the method with the type `void *`.

Currently, `getClientOption()` supports fetching the `optionValue` of the following options:

- `metadataUseInfoSchema`
- `defaultStatementResultType`
- `defaultPreparedStatementResultType`

The connection option `metadataUseInfoSchema` controls whether to use the `Information_Schemata` for returning the meta data of `SHOW` commands. In the case of `metadataUseInfoSchema` the `optionValue` argument should be interpreted as a boolean upon return.

In the case of both `defaultStatementResultType` and `defaultPreparedStatementResultType`, the `optionValue` argument should be interpreted as an integer upon return.

The connection property can be either set when establishing the connection through the connection property map or using `void Connection::setClientOption(const std::string & optionName, const void * optionValue)` where `optionName` is assigned the value `metadataUseInfoSchema`.

Some examples are given below:

```
int defaultStmtResType;
int defaultPStmtResType;
conn->getClientOption("defaultStatementResultType", (void *) &defaultStmtResType);
conn->getClientOption("defaultPreparedStatementResultType", (void *) &defaultPStmtResType);

bool isInfoSchemaUsed;
conn->getClientOption("metadataUseInfoSchema", (void *) &isInfoSchemaUsed);
```

- MySQL Connector/C++ also supports the following methods not found in the JDBC API standard:

```
std::string MySQL_Connection::getSessionVariable(const std::string & varname)
```

```
void MySQL_Connection::setSessionVariable(const std::string & varname, const std::string & value)
```

Note that both methods are members of the `MySQL_Connection` class. The methods get and set MySQL session variables.

`setSessionVariable()` is equivalent to executing:

```
SET SESSION <varname> = <value>
```

`getSessionVariable()` is equivalent to executing the following and fetching the first return value:

```
SHOW SESSION VARIABLES LIKE "<varname>"
```

You can use “%” and other placeholders in <varname>, if the underlying MySQL server supports this.

- Fetching the value of a column can sometimes return different values depending on whether the call is made from a Statement or Prepared Statement. This is because the protocol used to communicate with the server differs depending on whether a Statement or Prepared Statement is used.

  To illustrate this, consider the case where a column has been defined as of type `BIGINT`. The most negative `BIGINT` value is then inserted into the column. If a Statement and Prepared Statement are created that perform a `GetUInt64()` call, then the results will be found to be different in each case. The Statement returns the maximum positive value for `BIGINT`. The Prepared Statement returns 0.

  The reason for the different results is due to the fact that Statements use a text protocol, and Prepared Statements use a binary protocol. With the binary protocol in this case, a binary value is returned from the server that can be interpreted as an `int64`. In the above scenario a very large negative value was fetched with `GetUInt64()`, which fetches unsigned integers. As the large negative value cannot be sensibly converted to an unsigned value 0 is returned.

  In the case of the Statement, which uses the text protocol, values are returned from the server as strings, and then converted as re-

quired. When a string value is returned from the server in the above scenario the large negative value will need to be converted by the runtime library function `strtoul()`, which `GetUInt64()` calls. The behavior of `strtoul()` is dependent upon the specific runtime and host operating system, so the results can be variable. In the case given a large positive value was actually returned.

Although it is very rare, there are some cases where Statements and Prepared Statements can return different values unexpectedly, but this usually only happens in extreme cases such as the one mentioned.

- The JDBC documentation lists many fields for the `DatabaseMetaData` class. JDBC also appears to define certain values for those fields. However, MySQL Connector/C++ does not define certain values for those fields. Internally enumerations are used and the compiler determines the values to assign to a field.

  To compare a value with the field, code such as the following should be used, rather than making assumptions about specific values for the attribute:

  ```
  // dbmeta is an instance of DatabaseMetaData
  if (myvalue == dbmeta->attributeNoNulls) {
      ...
  }
  ```

  Usually *`myvalue`* will be a column from a result set holding metadata information. MySQL Connector/C++ does not guarantee that `attributeNoNulls` is 0. It can be any value.

- When programming Stored Procedures JDBC has available an extra class, an extra abstraction layer for callable statements, the `CallableStatement` class. This is not present in MySQL Connector/C++. You therefore need to use the methods from the `Statement` and `Prepared Statement` classes to run a Stored Procedure using `CALL`.

20.5.9. MySQL Connector/C++ Known Bugs and Issues

> **Note**
>
> Please report bugs through MySQL Bug System .

Known bugs:

None.

Known issues:

- When linking against a static library for 1.0.3 on Windows you need to define `CPPDBC_PUBLIC_FUNC` either in the compiler options (preferable) or with `/D "CPPCONN_PUBLIC_FUNC="`. You can also explicitly define it in your code by placing `#define CPPCONN_PUBLIC_FUNC` before the header inclusions.

- Generally speaking C++ library binaries are less portable than C library binaries. Issues can be caused by name mangling, different Standard Template Library (STL) versions and using different compilers and linkers for linking against the libraries than were used for building the library itself.

  Even a small change in the compiler version can, but does not have to, cause problems. If you obtain error messages, that you suspect are related to binary incompatibilities, build MySQL Connector/C++ from source, using the same compiler and linker that you will use to build and link your application.

  Due to the variations between Linux distributions, compiler and linker versions and STL versions, it is not possible to provide binaries for each and every possible configuration. However, the MySQL Connector/C++ binary distributions contain a `README` file that describes the environment and settings used to build the binary versions of the libraries.

- To avoid potential crashes the build configuration of MySQL Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of MySQL Connector/C++ with a debug build of the client application.

See also the MySQL Connector/C++ Changelogs which can be found here Section C.8, “MySQL Connector/C++ Change History”.

20.5.10. MySQL Connector/C++ Feature requests

You can suggest new features in the first instance by joining the mailing list or forum and talking with the developers directly. See Section 20.5.11, “MySQL Connector/C++ Support”

The following feature requests are currently being worked on:

- C++ references for `Statements`, `ResultSets`, and exceptions, are being considered, instead of pointers to heap memory. This reduces the exception handling burden for the programmer.
- Adopt STL (suggestions are welcome).
- JDBC compliance: datatype interfaces and support through `ResultSet:getType()` and `PreparedStatement:bind()`. Introduce `sql::Blob`, `sql::Clob`, `sql::Date`, `sql::Time`, `sql::Timestamp`, `sql::URL`. Support `get|setBlob()`, `get|setClob()`, `get|setDate()`, `get|setTime()`, `get|setTimestamp()`, `get|setURL()`
- Add support for all C-API connection options. Improved support for `mysql_options`.
- Add connect method which supports passing options using HashMaps.
- Create Windows installer.

20.5.11. MySQL Connector/C++ Support

For general discussion of the MySQL Connector/C++ please use the C/C++ community forum or join the MySQL Connector/C++ mailing list.

Bugs can be reported at the MySQL bug Web site.

For Licensing questions, and to purchase MySQL Products and Services, please http://www.mysql.com/buy-mysql/

The MySQL Connector/C++ Changelogs can be found here Section C.8, “MySQL Connector/C++ Change History”

20.5.12. MySQL Connector/C++ FAQ

Questions

- 21.5.12.1: What is MySQL Connector/C++?
- 21.5.12.2: Which MySQL Server version(s) is MySQL Connector/C++ compatible with?
- 21.5.12.3: Does MySQL Connector/C++ implement the client-server protocol?
- 21.5.12.4: Are any MySQL products using MySQL Connector/C++?

Questions and Answers

21.5.12.1: What is MySQL Connector/C++?

MySQL Connector/C++ is a MySQL database connector for C++. It allows you develop applications in C++ that connect to the MySQL Server. MySQL Connector/C++ is compatible with the JDBC 4.0 API.

21.5.12.2: Which MySQL Server version(s) is MySQL Connector/C++ compatible with?

MySQL Connector/C++ fully supports MySQL Server version 5.1 and later.

21.5.12.3: Does MySQL Connector/C++ implement the client-server protocol?

No. MySQL Connector/C++ uses the MySQL Client Library for the client-server communication.

21.5.12.4: Are any MySQL products using MySQL Connector/C++?

Yes, MySQL Workbench and MySQL Connector/OpenOffice.org.

20.6. MySQL Connector/C

What is MySQL Connector/C?

MySQL Connector/C is a C client library for client-server communication. It is a standalone replacement for the MySQL Client Library shipped with the MySQL Server.

Why have a replacement for MySQL Client Library?

There is no need to compile or install the MySQL Server package if you only need the client library.

MySQL Connector/C does not rely on the MySQL Server release cycle, so bug fixes and new features are released more often.

MySQL Connector/C API documentation is available here Section 20.9.3, “C API Function Descriptions”.

Supported platforms include:

- Windows
- Windows x64
- Linux
- Solaris
- FreeBSD
- Mac OS X
- HP-UX
- IBM AIX
- IBM i5/OS

20.6.1. Building MySQL Connector/C from the Source Code

Obtaining the Source Code

A TAR file containing the source code can be downloaded from the MySQL Developers site. You will need to select the source code package from the drop down list.

The source code for development releases of the connector can be found at Launchpad. The project home page can be found here.

The source code for the 1.0 branch can be found here.

To obtain the code you will need to have Bazaar installed and use the command `bzr branch lp:libmysql`.

- **Building on Unix**

  Examples of supported Unix or Unix-like operating systems include:

  - Solaris
  - Linux
  - HP-UX
  - AIX
  - OS X

  Compiler Tools

Ideally, the native compiler tool set for the target platform is used for compilation. This would be SunStudio for Solaris and aCC for HP-UX for example. However, the GNU tool-chain can be used across all platforms.

You also need CMake 2.6 or newer, which is available online.

To Build

If using GNU AutoTools change to the MySQL Connector/C source directory and follow the procedure below.

1. To generate the makefile enter:

   ```
   shell> cmake -G "Unix Makefiles"
   ```

   or for a Debug build enter:

   ```
   shell> cmake -G "Unix Makefiles" -DCMAKE_BUILD_TYPE=Debug
   ```

2. Then build the project using:

   ```
   shell> make
   ```

To Install

By default make install will install the MySQL Connector/C files in the `/usr/local` directory. You can change this behavior by specifying another directory when generating the `makefile`:

```
shell> cmake -G "Unix Makefiles" -DCMAKE_INSTALL_PREFIX=/mypath
```

Now, in the root shell, enter the following to install the MySQL Connector/C libraries and tools:

```
root-shell> make install
```

At this point all of the MySQL Connector/C files will be in place.

- **Building on Microsoft Windows**

  Older versions of Microsoft Windows are not supported. Supported versions are Windows 2000, Windows XP, Windows Vista, Windows Server 2003, or Windows Server 2008.

  Compiler Tools

  Microsoft Visual Studio 8 and 9 are recommended. The Express Edition of Visual Studio and other compilers may work, but are untested.

  You also need CMake 2.6 or newer, available at http://www.cmake.org

  To Build

  You need to have the environment variables set for the Visual Studio toolchain. Visual Studio includes a batch file to set these for you, and installs a shortcut into the **START** menu to open a command prompt with these variables set.

  Build MySQL Connector/C using the CMake command-line tool by entering the following from the source root directory in a command prompt window:

  ```
  shell> cmake -G "Visual Studio 9 2008"
  ```

  This produces a project file that you can open with Visual Studio or build from the command line with either of:

  ```
  shell> devenv.com libmysql.sln /build Release
  ```

  ```
  shell> devenv.com libmysql.sln /build RelWithDebInfo
  ```

For other versions of Visual Studio or `nmake` based build, run the following command:

```
shell> cmake --help
```

to check the supported generators.

To compile the Debug build, you must run set the CMake build type so the correct version of external libraries are used:

```
shell> cmake -G "Visual Studio 8 2005" -DCMAKE_BUILD_TYPE=Debug
```

Followed by:

```
shell> devenv.com libmysql.sln /build Debug
```

To Install

To create a install package you can choose between two variants:

1. Creating a Zip package
2. Creating an MSI install package

- **Zip package**

  To create a Zip package, run the `cpack` command from the root of your MySQL Connector/C source directory.

- **MSI Install package**

  The required tools include Windows XML Installer toolset (WIX), which is available online.

  To create the MSI install package change to the subdirectory `win` and generate the `makefile`:

  ```
  shell> cmake -G "NMake Makefiles"
  ```

  Create the MSI install package by calling `nmake`:

  ```
  shell> nmake
  ```

Build Options

The following options can be used when building the MySQL Connector/C source code:

Build Option	Description
-DWITH_OPENSSL=1	Enables dynamic linking to the system OpenSSL library.
-DWITH_EXTERNAL_ZLIB=1	Enables dynamic linking to the system Zlib library.

20.6.2. Testing MySQL Connector/C

For testing MySQL Connector/C you will need a running MySQL server instance. Before you run the test suite you need to specify the following environment variables:

- `MYSQL_TEST_HOST` (default localhost)
- `MYSQL_TEST_USER`
- `MYSQL_TEST_PASSWD`
- `MYSQL_TEST_PORT`

- `MYSQL_TEST_SOCKET`
- `MYSQL_TEST_DB` (default test)

To run the test suite, execute `ctest` from the command line:

```
shell> ctest
```

20.6.3. MySQL Connector/C FAQ

Questions

- 21.6.3.1: What is “libmysqld”?
- 21.6.3.2: What is “libmysql”?
- 21.6.3.3: Does MySQL Connector/C replace any of “Native C API”, “libmysql” and “libmysqld”?
- 21.6.3.4: What is the difference between “Native C API”, “libmysql”, “libmysqld” and “MySQL Connector/C”?
- 21.6.3.5: What is “MySQL Connector/C”?
- 21.6.3.6: What is the “MySQL Native C API”? What are its typical benefits and use cases?

Questions and Answers

21.6.3.1: What is “libmysqld”?

`libmysqld` is an embedded database server with the same API as MySQL Connector/C. It is included with the MySQL Server distribution.

21.6.3.2: What is “libmysql”?

`libmysql` is the name of the library that MySQL Connector/C provides.

21.6.3.3: Does MySQL Connector/C replace any of “Native C API”, “libmysql” and “libmysqld”?

MySQL Connector/C contains `libmysql`, and implements a native C API. It does not include `libmysqld`, which can be found with the MySQL server distribution.

21.6.3.4: What is the difference between “Native C API”, “libmysql”, “libmysqld” and “MySQL Connector/C”?

MySQL Connector/C and `libmysql` are the “native C API for MySQL”, and all three terms can be used interchangeably. “libmysqld” is the embedded version of the MySQL Server, and is included in the server distribution.

21.6.3.5: What is “MySQL Connector/C”?

MySQL Connector/C is a standalone distribution of the `libmysql` library, which was previously only available as part of the MySQL Server distribution. The version of `libmysql` included with MySQL Connector/C and the version bundled with the server are functionally equivalent, but the cross-platform build system for MySQL Connector/C uses CMake.

21.6.3.6: What is the “MySQL Native C API”? What are its typical benefits and use cases?

MySQL Connector/C, also known as `libmysql`, or MySQL Native C API, is a standalone, C-based API and library that you can use in C applications to connect with the MySQL Server. It implements the same MySQL client API that has been in use for a decade.

It is also used as the foundation for drivers for standard database APIs such as ODBC, Perl's DBI, and Python's DB API.

20.7. MySQL Connector/OpenOffice.org

MySQL Connector/OpenOffice.org is a native MySQL database connector for OpenOffice.org. Currently, it is in preview status and supports OpenOffice.org 3.1 and above. It can be used to connect OpenOffice.org applications to a MySQL server.

Before MySQL Connector/OpenOffice.org became available you would have to use MySQL Connector/J (JDBC) or MySQL Connector/ODBC to connect to a MySQL server.

Connector/OpenOffice.org is a community project, although Sun Microsystems actively contributes code. The source code for Connector/OpenOffice.org is available under GPL with the FLOSS License Exception.

In the future a closed-source StarOffice version of Connector/OpenOffice.org will be made available.

Advantages

Using MySQL Connector/OpenOffice.org has the following advantages:

- Easy installation through the OpenOffice.org Extension Manager.
- Seamless integration into OpenOffice.org.
- No need to go through an additional Connector installation routine (ODBC/JDBC)
- No need to configure or register an additional Connector (ODBC)
- No need to install or configure a driver manager (ODBC)

Status

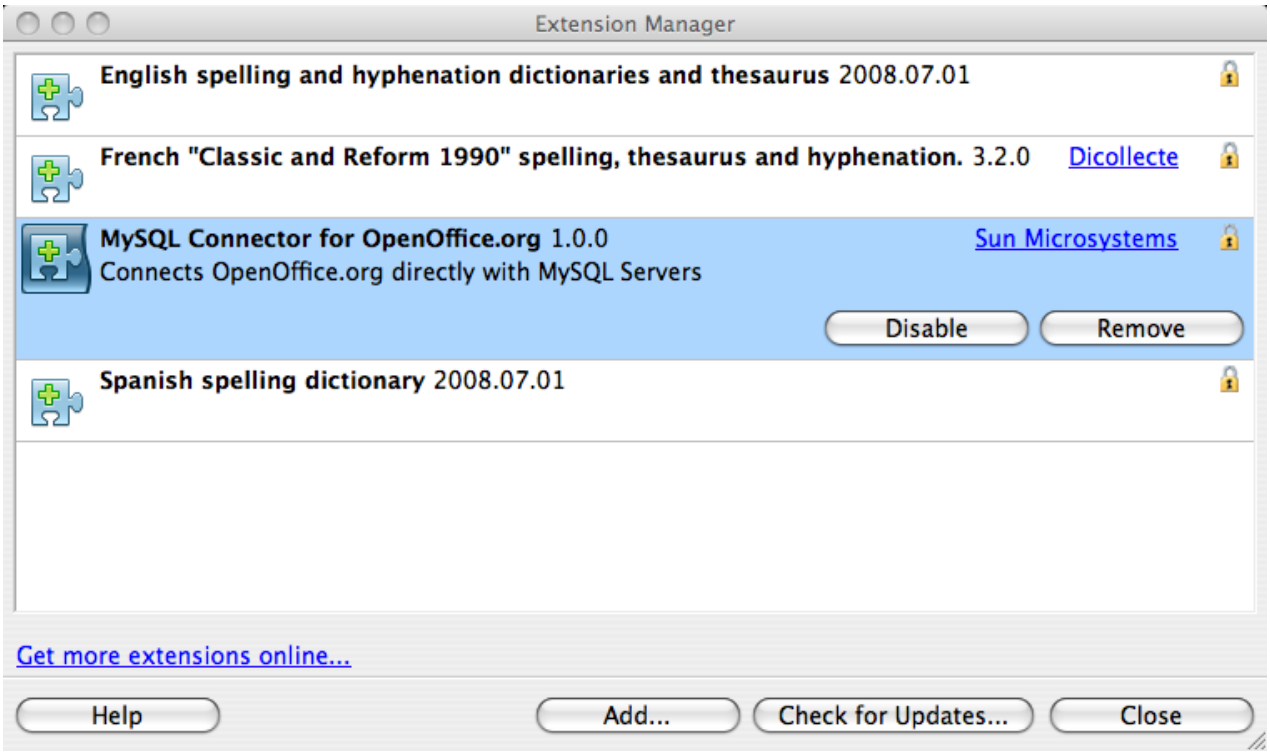
MySQL Connector/OpenOffice.org is currently at version 1.0 GA.

If you have any queries please contact us through our mailing list at `<users@dba.openoffice.org>`

20.7.1. Installation

1. Install or upgrade to OpenOffice.org 3.1.
2. Download MySQL Connector/OpenOffice.org from The OpenOffice.org extension download site. Save the file corresponding to your platform. Currently supported platforms are Windows, Linux, Linux x86-64, Mac OS X, Solaris x86 and Solaris SPARC.
3. Add the `.oxt` extension through the Extension Manager of OpenOffice.org. In OpenOffice.org, select TOOLS, EXTENSION MANAGER... and specify the `.oxt` file as a new extension. When done, MySQL Connector/OpenOffice.org will show up as a new extension in the Extension Manager.

Figure 20.79. Adding an Extension



4. Restart OpenOffice.org.

20.7.2. Getting Started: Connecting to MySQL

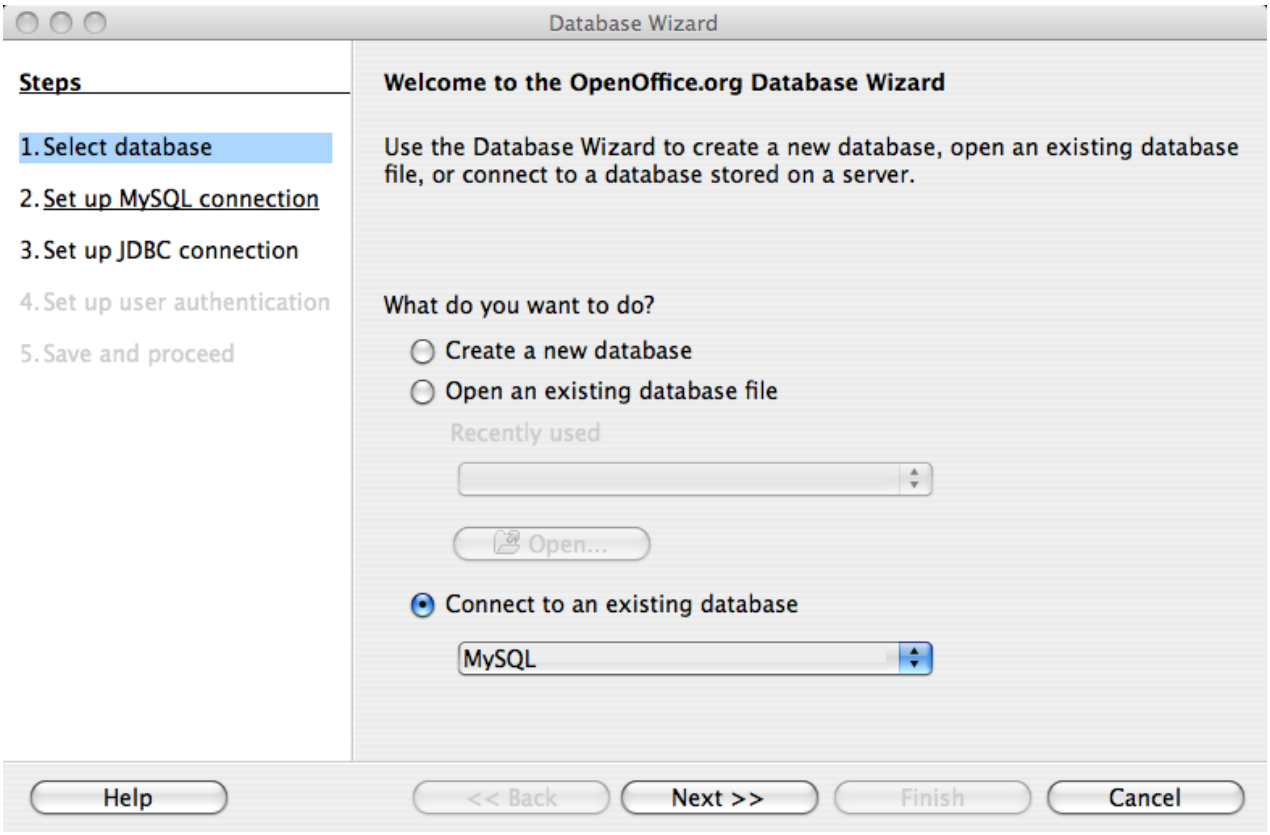
MySQL Connector/OpenOffice.org allows you to access the MySQL Server and its schemata from the OpenOffice.org suite.

The following example demonstrates the creation of a new OpenOffice.org Base database which uses a local MySQL Server for storage and the new connector for connecting.

1. **Select the database**

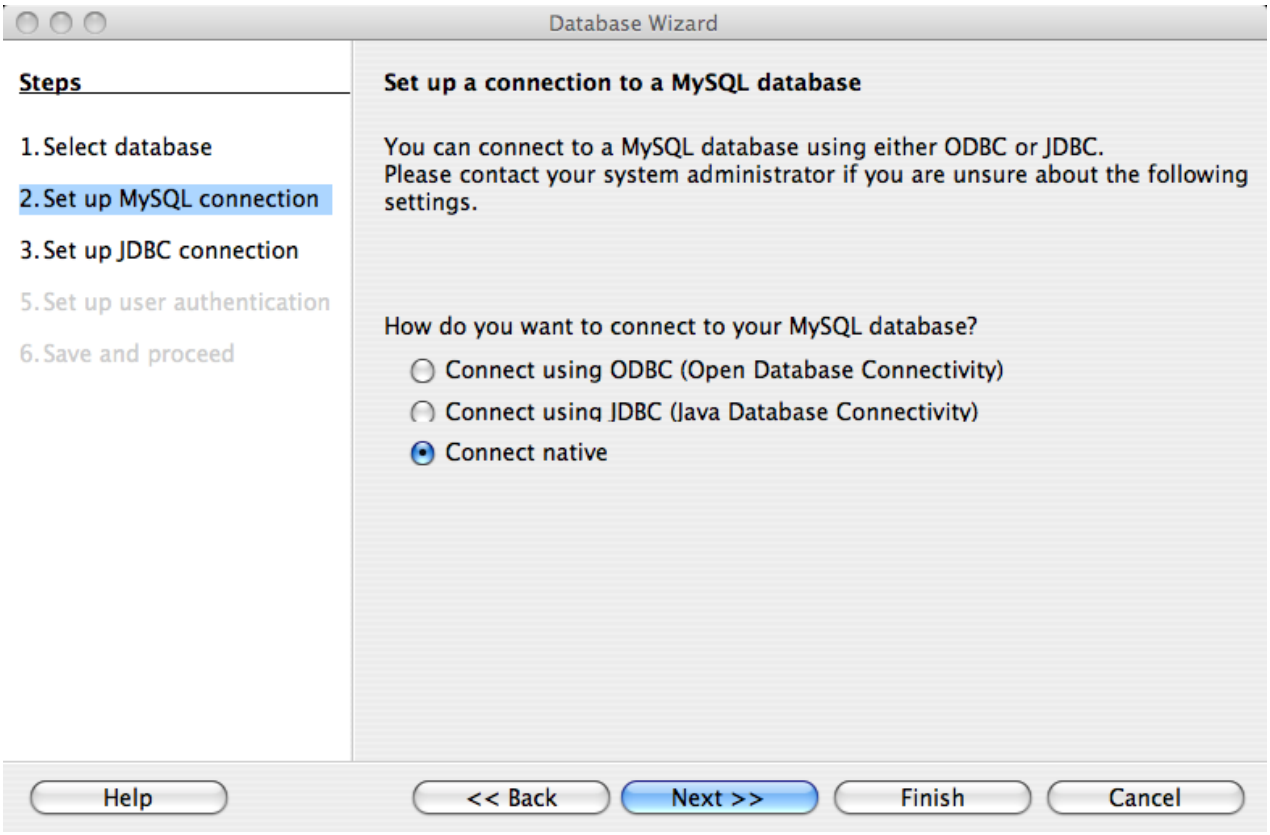
   Create a new database by selecting FILE, NEW, DATABASE. This starts a wizard that allows you to create a new database, open an existing database, or connect to an existing database. Select the **CONNECT TO EXISTING DATABASE** radio button. From the listbox select MySQL. Click NEXT >>.

Figure 20.80. Selecting the Database



2. You will be asked how you would like to connect to the database. Select the **CONNECT NATIVE** radio button.

Figure 20.81. Selecting the connection type



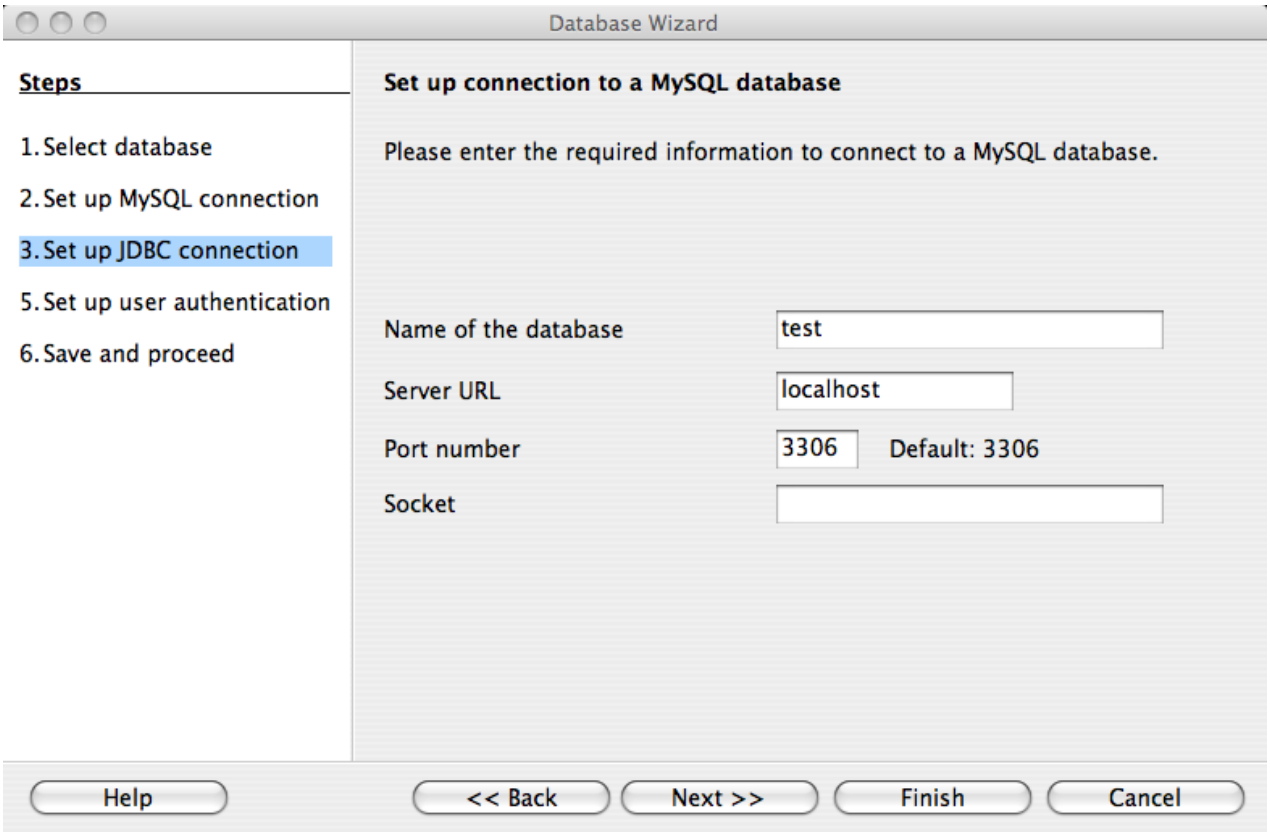
Click NEXT >>.

3. **Fill in the connection settings**

   Enter the name of the database, server URL, and optionally the socket to connect on (if not using the default).

   Note that if you do not specify a database all databases will be available for selection.

Figure 20.82. Entering Connection Settings

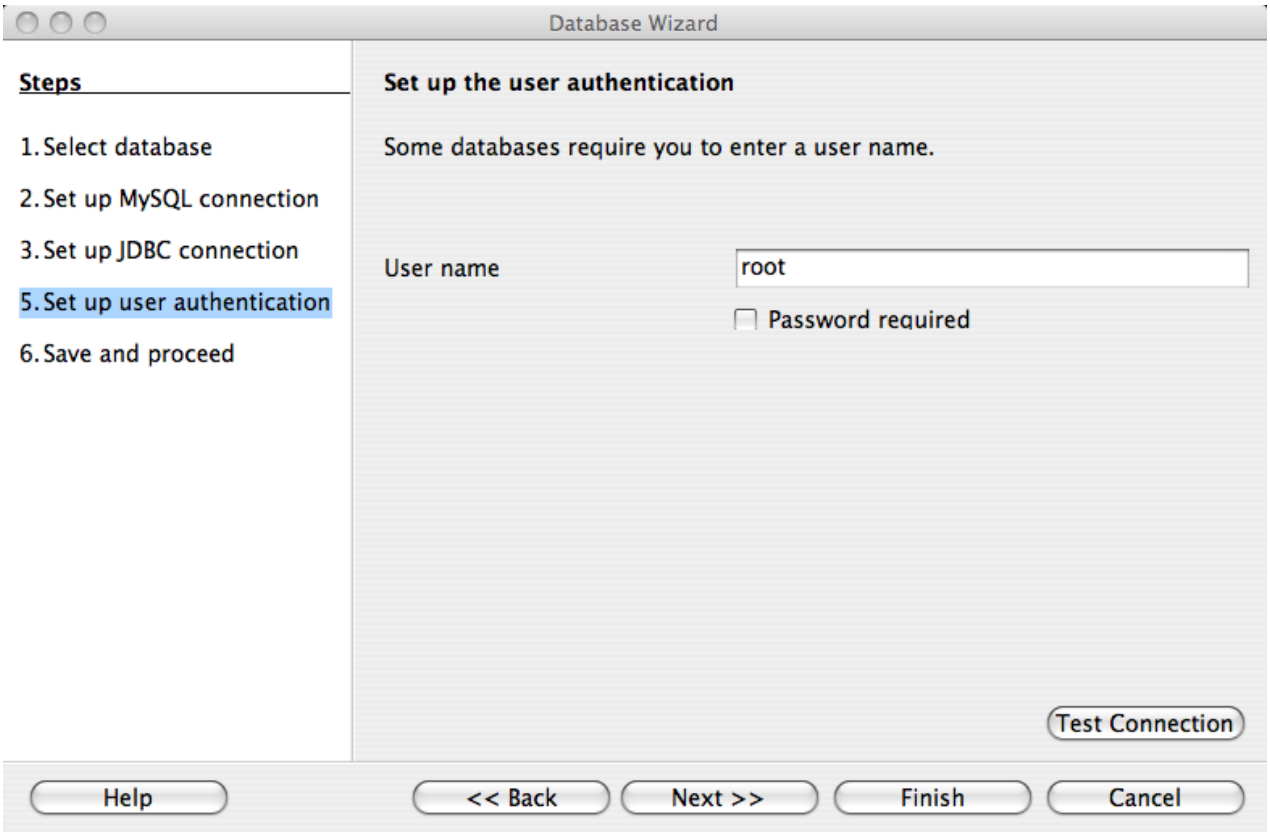


Click NEXT >>.

4. **Set up user authentication**

   If you are using MySQL server's anonymous account without a password, you do not have to fill in anything in this step. Otherwise, fill in your MySQL user name and check the password checkbox. Note, for security reasons, you should not normally use the anonymous account without a password.

Figure 20.83. Setting Up User Authentication

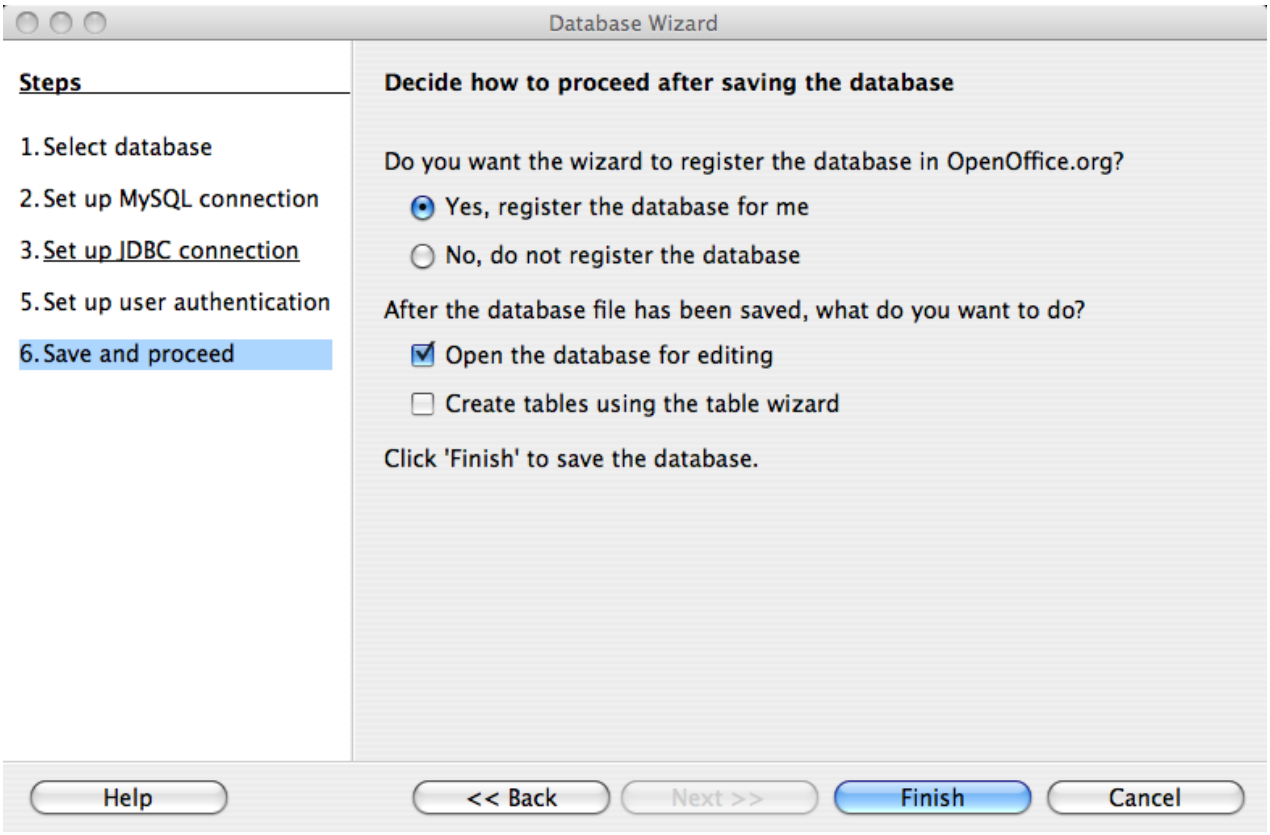


You can now test your connection to the MySQL database server by clicking the TEST CONNECTION button. Check the checkbox if you do not want OpenOffice.org to ask you for your password again in the current session. Testing the connection is optional, although recommended.

Click NEXT >>.

5. **Decide how to proceed after connecting to the database**

Figure 20.84. After Connecting to the Database

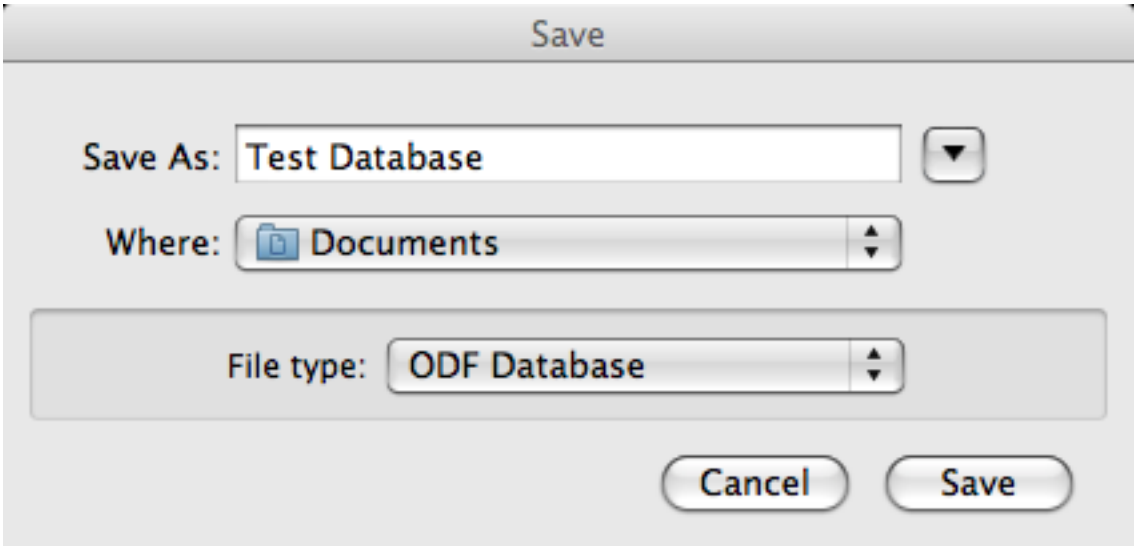


Keep the default settings.

Click FINISH.

6. You will then be prompted to save you database as a database file. Enter the name of the database and the location in which to save the file.

Figure 20.85. Entering the Database File Name



Click SAVE.

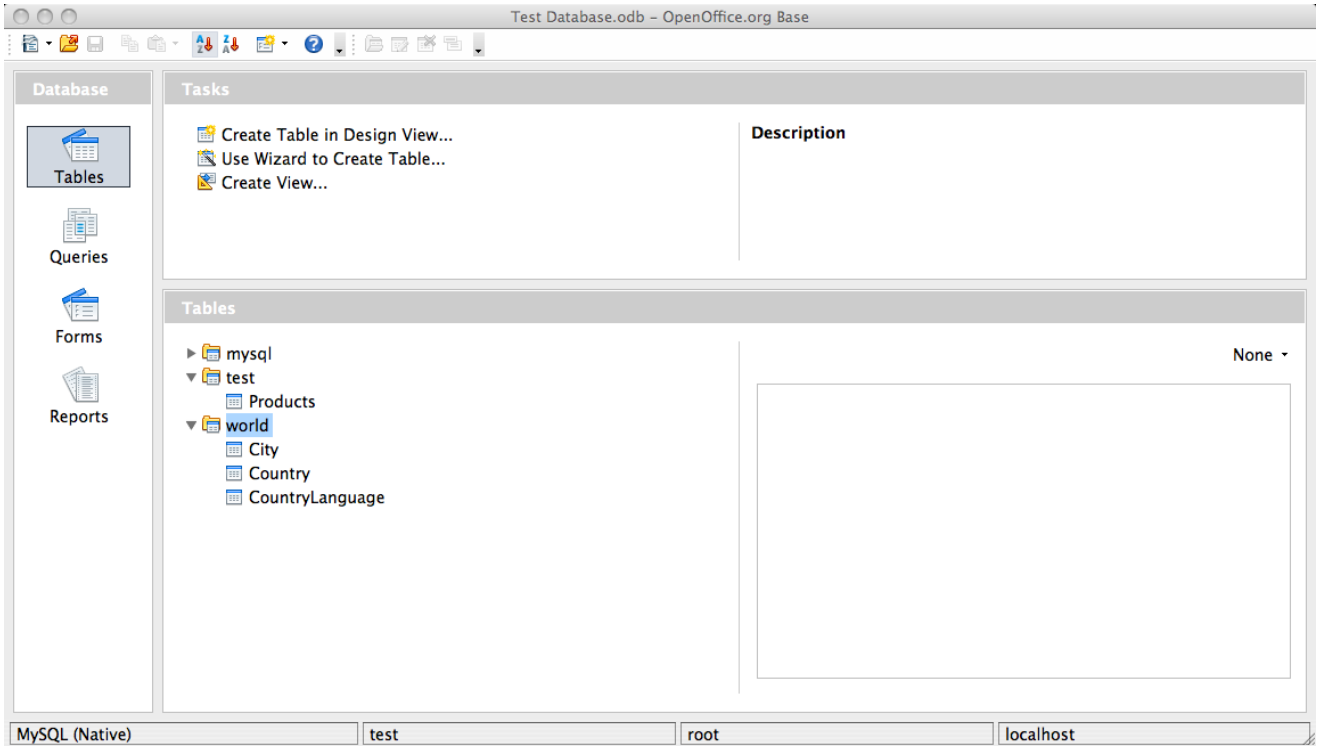
You will be located in the Base application with your database tables displayed.

20.7.3. Getting Started: Usage Examples

Listing Tables

In the **DATABASE** area of the **BASE** main window, select **TABLES**. If this is the first time you are accessing the database you will be prompted for your credentials (user name and password); you can store these settings for your current Base session.

Figure 20.86. Listing Tables



Depending on your connection settings you will now see all databases with all their tables, or just the database you have specified in the connection settings.

20.7.4. References

See the OpenOffice.org Web site for documentation of the office suite and its Extension Manager.

20.7.5. Known Bugs

If you discover a bug in Connector/OpenOffice.org please add it to this list and send an email to `<users@dba.openoffice.org>`. You need to be logged in with an OpenOffice.org account for both; see the project mailing list for details.

20.7.6. Contact

To discuss the new MySQL Connector/OpenOffice.org, please subscribe to the mailing list `<users@dba.openoffice.org>`. It is a low-volume list with less than 10 mails per day.

20.8. libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions.

Function	When to Call
`mysql_library_init()`	Should be called before any other MySQL function is called, preferably early in the `main()` function.
`mysql_library_end()`	Should be called before your program exits.
`mysql_thread_init()`	Should be called in each thread you create that accesses MySQL.
`mysql_thread_end()`	Should be called before calling `pthread_exit()`

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, be sure to compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 4.1 headers, do not compile your application against MySQL 5.1 headers, or vice versa.

The `mysql_library_xxx()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See Section 20.9.3.40, “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `--with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

20.8.1. Compiling Programs with `libmysqld`

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `--with-embedded-server` option. See Section 2.10.2, “Typical `configure` Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```
gcc mysql_test.c -o mysql_test -lz \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

20.8.2. Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- `InnoDB` is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the `event_scheduler` system variable is disabled.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

20.8.3. Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_library_init()` function. See Section 20.9.3.40, “mysql_library_init()”, for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See Section 4.2.3.3, “Using Option Files”.

20.8.4. Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

Example 1

`test1_libmysqld.c`

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
       { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",
                                 "libmysqld_client", NULL };

int main(void)
{
   mysql_library_init(num_elements, server_options, server_groups);
   mysql = mysql_init(NULL);
   mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
   mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

   mysql_real_connect(mysql, NULL,NULL,NULL, "database1", 0,NULL,0);
```

```
   mysql_query(mysql, "SELECT column1, column2 FROM table1");

   results = mysql_store_result(mysql);

   while((record = mysql_fetch_row(results))) {
      printf("%s - %s \n", record[0], record[1]);
   }

   mysql_free_result(results);
   mysql_close(mysql);
   mysql_library_end();

   return 0;
}
```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld -lz \
 `/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Example 2

To try the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

`test2_libmysqld.c`

```
/*
 * A simple example client, using the embedded MySQL server library
*/

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
  "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
  MYSQL *one, *two;

  /* mysql_library_init() must be called before any other mysql
   * functions.
   *
   * You can use mysql_library_init(0, NULL, NULL), and it
   * initializes the server using groups = {
   *   "server", "embedded", NULL
   *  }.
   *
   * In your $HOME/.my.cnf file, you probably want to put:

[test2_libmysqld_SERVER]
language = /path/to/source/of/mysql/sql/share/english

   * You could, of course, modify argc and argv before passing
   * them to this function.  Or you could create new ones in any
   * way you like.  But all of the arguments in argv (except for
   * argv[0], which is the program name) should be valid options
   * for the MySQL server.
   *
   * If you link this client against the normal mysqlclient
   * library, this function is just a stub that does nothing.
   */
  mysql_library_init(argc, argv, (char **)server_groups);

  one = db_connect("test");
  two = db_connect(NULL);

  db_do_query(one, "SHOW TABLE STATUS");
  db_do_query(two, "SHOW DATABASES");

  mysql_close(two);
  mysql_close(one);
```

```
  /* This must be called after all other mysql functions */
  mysql_library_end();

  exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
  va_list ap;
  va_start(ap, fmt);
  vfprintf(stderr, fmt, ap);
  va_end(ap);
  (void)putc('\n', stderr);
  if (db)
    db_disconnect(db);
  exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
  MYSQL *db = mysql_init(NULL);
  if (!db)
    die(db, "mysql_init failed: no memory");
  /*
   * Notice that the client and server use separate group names.
   * This is critical, because the server does not accept the
   * client's options, and vice versa.
   */
  mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
  if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
    die(db, "mysql_real_connect failed: %s", mysql_error(db));

  return db;
}

void
db_disconnect(MYSQL *db)
{
  mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
  if (mysql_query(db, query) != 0)
    goto err;

  if (mysql_field_count(db) > 0)
  {
    MYSQL_RES   *res;
    MYSQL_ROW    row, end_row;
    int num_fields;

    if (!(res = mysql_store_result(db)))
      goto err;
    num_fields = mysql_num_fields(res);
    while ((row = mysql_fetch_row(res)))
    {
      (void)fputs(">> ", stdout);
      for (end_row = row + num_fields; row < end_row; ++row)
        (void)printf("%s\t", row ? (char*)*row : "NULL");
      (void)fputc('\n', stdout);
    }
    (void)fputc('\n', stdout);
    mysql_free_result(res);
  }
  else
    (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

  return;

err:
  die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}
```

GNUmakefile

```
# This assumes the MySQL software is installed in /usr/local/mysql
inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc      := $(HOME)/mysql-5.4/include
#lib      := $(HOME)/mysql-5.4/libmysqld

CC       := gcc
```

```
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS   := -g -W -Wall
LDFLAGS  := -static
# You can change -lmysqld to -lmysqlclient to use the
# client/server library
LDLIBS    = -L$(lib) -lmysqld -lz -lm -ldl -lcrypt

ifneq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
# FreeBSD
LDFLAGS += -pthread
else
# Assume Linux
LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)

clean:
        rm -f $(targets) $(objects) *.core
```

20.8.5. Licensing the Embedded Server

We encourage everyone to promote free software by releasing code under the GPL or a compatible license. For those who are not able to do this, another option is to purchase a commercial license for the MySQL code from Oracle Corporation. For details, please see http://www.mysql.com/company/legal/licensing/.

20.9. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the `client` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J and Connector/NET) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See Chapter 4, *MySQL Programs*, for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See Section 7.5.3, “Tuning Server Parameters”.

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see Section 20.9.16.2, “How to Make a Threaded Client”. For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see Section 20.8, “libmysqld, the Embedded MySQL Server Library”.

> **Note**
>
> If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example from `libmysqlclient.so.15` to `libmysqlclient.so.16`.

MySQL Enterprise
MySQL Enterprise subscribers will find more information about using the C API in the Knowledge Base articles, The C API. Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

20.9.1. C API Data Structures

This section describes C API data structures other than those used for prepared statements. For information about the latter, see Section 20.9.5, "C API Prepared Statement Data Structures".

- `MYSQL`

  This structure represents a handle to one database connection. It is used for almost all MySQL functions. You should not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

  This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

  This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

  This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail later in this section. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

  This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

  The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of `0` to `1.84e19`.

  On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
        (unsigned long) mysql_num_rows(result));
```

- `my_bool`

  A boolean type, for values that are true (nonzero) or false (zero).

The `MYSQL_FIELD` structure contains the members described in the following list:

- `char * name`

  The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

  The name of the field, as a null-terminated string. Aliases are ignored.

- `char * table`

  The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string.

- `char * org_table`

  The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the underlying table. For a `UNION`, the value is the empty string.

- `char * db`

  The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a `UNION`, the value is the empty string.

- `char * catalog`

  The catalog name. This value is always `"def"`.

- `char * def`

  The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

  The width of the field. This corresponds to the display length, in bytes.

  The server determines the `length` value before it generates the result set, so this is the minimum length required for a data type capable of holding the largest possible value from the result column, without knowing in advance the actual values that will be produced by the query for the result set.

- `unsigned long max_length`

  The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

  The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the "widest" value is `-12.345`, `max_length` is 7 (the length of `'-12.345'`).

  If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See Section 20.9.5, "C API Prepared Statement Data Structures".) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See Section 20.9.7.3, "`mysql_stmt_attr_set()`", and Section 20.9.7.27, "`mysql_stmt_store_result()`".)

- `unsigned int name_length`

  The length of `name`.

- `unsigned int org_name_length`

  The length of `org_name`.

- `unsigned int table_length`

  The length of `table`.

- `unsigned int org_table_length`

  The length of `org_table`.

- `unsigned int db_length`

  The length of `db`.

- `unsigned int catalog_length`

  The length of `catalog`.

- `unsigned int def_length`

  The length of `def`.

- `unsigned int flags`

  Bit-flags that describe the field. The `flags` value may have zero or more of the following bits set.

Flag Value	Flag Description
`NOT_NULL_FLAG`	Field can't be `NULL`
`PRI_KEY_FLAG`	Field is part of a primary key
`UNIQUE_KEY_FLAG`	Field is part of a unique key
`MULTIPLE_KEY_FLAG`	Field is part of a nonunique key
`UNSIGNED_FLAG`	Field has the `UNSIGNED` attribute
`ZEROFILL_FLAG`	Field has the `ZEROFILL` attribute
`BINARY_FLAG`	Field has the `BINARY` attribute
`AUTO_INCREMENT_FLAG`	Field has the `AUTO_INCREMENT` attribute
`NUM_FLAG`	Field is numeric
`ENUM_FLAG`	Field is an `ENUM` (deprecated)
`SET_FLAG`	Field is a `SET` (deprecated)
`BLOB_FLAG`	Field is a `BLOB` or `TEXT` (deprecated)
`TIMESTAMP_FLAG`	Field is a `TIMESTAMP` (deprecated)
`NO_DEFAULT_VALUE_FLAG`	Field has no default value; see additional notes following table

  Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `MYSQL_TYPE_BLOB`, `MYSQL_TYPE_ENUM`, `MYSQL_TYPE_SET`, or `MYSQL_TYPE_TIMESTAMP` instead.

  `NUM_FLAG` indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

  `NO_DEFAULT_VALUE_FLAG` indicates that a column has no `DEFAULT` clause in its definition. This does not apply to `NULL` columns (because such columns have a default of `NULL`), or to `AUTO_INCREMENT` columns (which have an implied default value).

  The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

  You may use the following convenience macros to determine the boolean status of the `flags` value.

Flag Status	Description
`IS_NOT_NULL(flags)`	True if this field is defined as `NOT NULL`
`IS_PRI_KEY(flags)`	True if this field is a primary key
`IS_BLOB(flags)`	True if this field is a `BLOB` or `TEXT` (deprecated; test `field->type` instead)

- `unsigned int decimals`

  The number of decimals for numeric fields.

- `unsigned int charsetnr`

  An ID number that indicates the character set/collation pair for the field.

  To distinguish between binary and nonbinary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

  `charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+-----------+---------+----+---------+----------+---------+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----------+---------+----+---------+----------+---------+
| binary    | binary  | 63 | Yes     | Yes      |       1 |
+-----------+---------+----+---------+----------+---------+

mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
    -> FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
+-----------------+--------------------+
| COLLATION_NAME  | CHARACTER_SET_NAME |
+-----------------+--------------------+
| utf8_general_ci | utf8               |
+-----------------+--------------------+
```

- `enum enum_field_types type`

  The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

Type Value	Type Description
`MYSQL_TYPE_TINY`	`TINYINT` field
`MYSQL_TYPE_SHORT`	`SMALLINT` field
`MYSQL_TYPE_LONG`	`INTEGER` field
`MYSQL_TYPE_INT24`	`MEDIUMINT` field
`MYSQL_TYPE_LONGLONG`	`BIGINT` field
`MYSQL_TYPE_DECIMAL`	`DECIMAL` or `NUMERIC` field
`MYSQL_TYPE_NEWDECIMAL`	Precision math `DECIMAL` or `NUMERIC`
`MYSQL_TYPE_FLOAT`	`FLOAT` field
`MYSQL_TYPE_DOUBLE`	`DOUBLE` or `REAL` field
`MYSQL_TYPE_BIT`	`BIT` field
`MYSQL_TYPE_TIMESTAMP`	`TIMESTAMP` field
`MYSQL_TYPE_DATE`	`DATE` field
`MYSQL_TYPE_TIME`	`TIME` field
`MYSQL_TYPE_DATETIME`	`DATETIME` field
`MYSQL_TYPE_YEAR`	`YEAR` field
`MYSQL_TYPE_STRING`	`CHAR` or `BINARY` field
`MYSQL_TYPE_VAR_STRING`	`VARCHAR` or `VARBINARY` field
`MYSQL_TYPE_BLOB`	`BLOB` or `TEXT` field (use `max_length` to determine the maximum length)
`MYSQL_TYPE_SET`	`SET` field
`MYSQL_TYPE_ENUM`	`ENUM` field
`MYSQL_TYPE_GEOMETRY`	Spatial field
`MYSQL_TYPE_NULL`	`NULL`-type field

  You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

20.9.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See Section 20.9.3, “C API Function Descriptions”.

Function	Description
`my_init()`	Initialize global variables, and thread handler in thread-safe programs
`mysql_affected_rows()`	Returns the number of rows changed/deleted/inserted by the last `UPDATE`, `DELETE`, or `INSERT` query
`mysql_autocommit()`	Toggles autocommit mode on/off
`mysql_change_user()`	Changes user and database on an open connection
`mysql_character_set_name()`	Return default character set name for current connection
`mysql_close()`	Closes a server connection
`mysql_commit()`	Commits the transaction
`mysql_connect()`	Connects to a MySQL server (this function is deprecated; use `mysql_real_connect()` instead)
`mysql_create_db()`	Creates a database (this function is deprecated; use the SQL statement `CREATE DATABASE` instead)
`mysql_data_seek()`	Seeks to an arbitrary row number in a query result set
`mysql_debug()`	Does a `DBUG_PUSH` with the given string
`mysql_drop_db()`	Drops a database (this function is deprecated; use the SQL statement `DROP DATABASE` instead)
`mysql_dump_debug_info()`	Makes the server write debug information to the log
`mysql_eof()`	Determines whether the last row of a result set has been read (this function is deprecated; `mysql_errno()` or `mysql_error()` may be used instead)
`mysql_errno()`	Returns the error number for the most recently invoked MySQL function
`mysql_error()`	Returns the error message for the most recently invoked MySQL function
`mysql_escape_string()`	Escapes special characters in a string for use in an SQL statement
`mysql_fetch_field()`	Returns the type of the next table field
`mysql_fetch_field_direct()`	Returns the type of a table field, given a field number
`mysql_fetch_fields()`	Returns an array of all field structures
`mysql_fetch_lengths()`	Returns the lengths of all columns in the current row
`mysql_fetch_row()`	Fetches the next row from the result set
`mysql_field_count()`	Returns the number of result columns for the most recent statement
`mysql_field_seek()`	Puts the column cursor on a specified column
`mysql_field_tell()`	Returns the position of the field cursor used for the last `mysql_fetch_field()`
`mysql_free_result()`	Frees memory used by a result set
`mysql_get_character_set_info()`	Return information about default character set
`mysql_get_client_info()`	Returns client version information as a string
`mysql_get_client_version()`	Returns client version information as an integer
`mysql_get_host_info()`	Returns a string describing the connection
`mysql_get_proto_info()`	Returns the protocol version used by the connection
`mysql_get_server_info()`	Returns the server version number

`mysql_get_server_version()`	Returns version number of server as an integer
`mysql_get_ssl_cipher()`	Return current SSL cipher
`mysql_hex_string()`	Encode string in hexadecimal format
`mysql_info()`	Returns information about the most recently executed query
`mysql_init()`	Gets or initializes a `MYSQL` structure
`mysql_insert_id()`	Returns the ID generated for an `AUTO_INCREMENT` column by the previous query
`mysql_kill()`	Kills a given thread
`mysql_library_end()`	Finalize the MySQL C API library
`mysql_library_init()`	Initialize the MySQL C API library
`mysql_list_dbs()`	Returns database names matching a simple regular expression
`mysql_list_fields()`	Returns field names matching a simple regular expression
`mysql_list_processes()`	Returns a list of the current server threads
`mysql_list_tables()`	Returns table names matching a simple regular expression
`mysql_more_results()`	Checks whether any more results exist
`mysql_next_result()`	Returns/initiates the next result in multiple-result executions
`mysql_num_fields()`	Returns the number of columns in a result set
`mysql_num_rows()`	Returns the number of rows in a result set
`mysql_options()`	Sets connect options for `mysql_real_connect()`
`mysql_ping()`	Checks whether the connection to the server is working, reconnecting as necessary
`mysql_query()`	Executes an SQL query specified as a null-terminated string
`mysql_real_connect()`	Connects to a MySQL server
`mysql_real_escape_string()`	Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection
`mysql_real_query()`	Executes an SQL query specified as a counted string
`mysql_refresh()`	Flush or reset tables and caches
`mysql_reload()`	Tells the server to reload the grant tables
`mysql_rollback()`	Rolls back the transaction
`mysql_row_seek()`	Seeks to a row offset in a result set, using value returned from `mysql_row_tell()`
`mysql_row_tell()`	Returns the row cursor position
`mysql_select_db()`	Selects a database
`mysql_server_end()`	Finalize the MySQL C API library
`mysql_server_init()`	Initialize the MySQL C API library
`mysql_set_character_set()`	Set default character set for current connection
`mysql_set_local_infile_default()`	Set the `LOAD DATA LOCAL INFILE` handler callbacks to their default values
`mysql_set_local_infile_handler()`	Install application-specific `LOAD DATA LOCAL INFILE` handler callbacks
`mysql_set_server_option()`	Sets an option for the connection (like `multi-statements`)
`mysql_sqlstate()`	Returns the SQLSTATE error code for the last error
`mysql_shutdown()`	Shuts down the database server
`mysql_ssl_set()`	Prepare to establish SSL connection to server
`mysql_stat()`	Returns the server status as a string
`mysql_store_result()`	Retrieves a complete result set to the client
`mysql_thread_end()`	Finalize thread handler
`mysql_thread_id()`	Returns the current thread ID
`mysql_thread_init()`	Initialize thread handler

`mysql_thread_safe()`	Returns 1 if the clients are compiled as thread-safe
`mysql_use_result()`	Initiates a row-by-row result set retrieval
`mysql_warning_count()`	Returns the warning count for the previous SQL statement

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `mysqlclient` C client library and the `mysqld` embedded server library, so it is used whether you build a regular client program by linking with the `-libmysqlclient` flag, or an embedded server application by linking with the `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly via `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user name, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. They should be treated the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that is most appropriate for their re-

quirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is nonzero, the statement should have returned rows, but didn't. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

20.9.3. C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                  /* correct */
    ... error ...

if (result < 0)              /* incorrect */
    ... error ...

if (result == -1)            /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

> **MySQL Enterprise**
> MySQL Enterprise subscribers will find more information about the C API functions in the Knowledge Base articles, The C API. Access to the MySQL Knowledge Base collection of articles is one of the advantages of subscribing to MySQL Enterprise. For more information, see http://www.mysql.com/products/enterprise/advisors.html.

20.9.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

Description

`mysql_affected_rows()` may be called immediately after executing a statement with `mysql_query()` or `mysql_real_query()`. It returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows "found"; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value is 1 if the row is inserted as a new row and 2 if an existing row is updated.

Following a `CALL` statement for a stored procedure, `mysql_affected_rows()` returns the value that it would return for the last statement executed within the procedure, or `0` if that statement would return `-1`. Within the procedure, you can use `ROW_COUNT()` at the SQL level to obtain the affected-rows value for individual statements.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`.

Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

Errors

None.

Example

```
char *stmt = "UPDATE products SET cost=cost*1.25
              WHERE group=10";
mysql_query(&mysql,stmt);
printf("%ld products updated",
       (long) mysql_affected_rows(&mysql));
```

20.9.3.2. `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

Return Values

Zero if successful. Nonzero if an error occurred.

Errors

None.

20.9.3.3. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password, const char *db)
```

Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this

case, the user and database are not changed.

The `db` parameter may be set to `NULL` if you don't want to have a default database.

This command resets the state as if one had done a new connect. (See Section 20.9.11, "Controlling Automatic Reconnection Behavior".) It always performs a `ROLLBACK` of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and `HANDLER` variables are closed. Locks acquired with `GET_LOCK()` are released. These effects occur even if the user didn't change.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

- `ER_UNKNOWN_COM_ERROR`

  The MySQL server doesn't implement this command (probably an old server).

- `ER_ACCESS_DENIED_ERROR`

  The user or password was wrong.

- `ER_BAD_DB_ERROR`

  The database didn't exist.

- `ER_DBACCESS_DENIED_ERROR`

  The user did not have access rights to the database.

- `ER_WRONG_DB_NAME`

  The database name was too long.

Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
   fprintf(stderr, "Failed to change user.  Error: %s\n",
           mysql_error(&mysql));
}
```

20.9.3.4. `mysql_character_set_name()`

```
const char *mysql_character_set_name(MYSQL *mysql)
```

Description

Returns the default character set name for the current connection.

Return Values

The default character set name

Errors

None.

20.9.3.5. mysql_close()

```
void mysql_close(MYSQL *mysql)
```

Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

Return Values

None.

Errors

None.

20.9.3.6. mysql_commit()

```
my_bool mysql_commit(MYSQL *mysql)
```

Description

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

Return Values

Zero if successful. Nonzero if an error occurred.

Errors

None.

20.9.3.7. mysql_connect()

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

Description

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

Return Values

Same as for `mysql_real_connect()`.

Errors

Same as for `mysql_real_connect()`.

20.9.3.8. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

Return Values

Zero if the database was created successfully. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

Example

```
if(mysql_create_db(&mysql, "my_database"))
{
   fprintf(stderr, "Failed to create new database.  Error: %s\n",
           mysql_error(&mysql));
}
```

20.9.3.9. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number and should be in the range from `0` to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

None.

Errors

None.

20.9.3.10. mysql_debug()

```
void mysql_debug(const char *debug)
```

Description

Does a DBUG_PUSH with the given string. mysql_debug() uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See MySQL Internals: Porting.

Return Values

None.

Errors

None.

Example

The call shown here causes the client library to generate a trace file in /tmp/client.trace on the client machine:

```
mysql_debug("d:t:O,/tmp/client.trace");
```

20.9.3.11. mysql_drop_db()

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

Description

Drops the database named by the db parameter.

This function is deprecated. It is preferable to use mysql_query() to issue an SQL DROP DATABASE statement instead.

Return Values

Zero if the database was dropped successfully. Nonzero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

  The MySQL server has gone away.

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

Example

```
if(mysql_drop_db(&mysql, "my_database"))
  fprintf(stderr, "Failed to drop the database: Error: %s\n",
          mysql_error(&mysql));
```

20.9.3.12. mysql_dump_debug_info()

```
int mysql_dump_debug_info(MYSQL *mysql)
```

Description

Instructs the server to write some debug information to the log. For this to work, the connected user must have the `SUPER` privilege.

Return Values

Zero if the command was successful. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

  The MySQL server has gone away.

- `CR_SERVER_LOST`

  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

  An unknown error occurred.

20.9.3.13. `mysql_eof()`

```
my_bool mysql_eof(MYSQL_RES *result)
```

Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a `NULL` return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero if no error occurred. Nonzero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result))  // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql))  // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

20.9.3.14. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, *Errors, Error Codes, and Common Problems*.

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they succeed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where `1146` is the `mysql_errno()` value and `'42S02'` is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

Errors

None.

20.9.3.15. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, the following two tests are equivalent:

```
if(*mysql_error(&mysql))
{
```

```
  // an error occurred
}

if(mysql_error(&mysql)[0])
{
  // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently, you can choose error messages in several different languages. See Section 9.2, “Setting the Error Message Language”.

Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

Errors

None.

20.9.3.16. mysql_escape_string()

You should use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

20.9.3.17. mysql_fetch_field()

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

Errors

None.

Example

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

20.9.3.18. mysql_fetch_field_direct()

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int fieldnr)
```

Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. You may use this function to retrieve the definition for an arbitrary column. The value of `fieldnr` should be in the range from 0 to `mysql_num_fields(result)-1`.

Return Values

The `MYSQL_FIELD` structure for the specified column.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

20.9.3.19. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
   printf("Field %u is %s\n", i, fields[i].name);
}
```

20.9.3.20. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). NULL if an error occurred.

Errors

mysql_fetch_lengths() is valid only for the current row of the result set. It returns NULL if you call it before calling mysql_fetch_row() or after retrieving all rows in the result.

Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
         printf("Column %u is %lu bytes in length.\n",
                i, lengths[i]);
    }
}
```

20.9.3.21. mysql_fetch_row()

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

Description

Retrieves the next row of a result set. When used after mysql_store_result(), mysql_fetch_row() returns NULL when there are no more rows to retrieve. When used after mysql_use_result(), mysql_fetch_row() returns NULL when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by mysql_num_fields(result). If row holds the return value from a call to mysql_fetch_row(), pointers to the values are accessed as row[0] to row[mysql_num_fields(result)-1]. NULL values in the row are indicated by NULL pointers.

The lengths of the field values in the row may be obtained by calling mysql_fetch_lengths(). Empty fields and fields containing NULL both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is NULL, the field is NULL; otherwise, the field is empty.

Return Values

A MYSQL_ROW structure for the next row. NULL if there are no more rows to retrieve or if an error occurred.

Errors

Note that error is not reset between calls to mysql_fetch_row()

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
```

```
{
   unsigned long *lengths;
   lengths = mysql_fetch_lengths(result);
   for(i = 0; i < num_fields; i++)
   {
       printf("[%.*s] ", (int) lengths[i],
              row[i] ? row[i] : "NULL");
   }
   printf("\n");
}
```

20.9.3.22. mysql_field_count()

```
unsigned int mysql_field_count(MYSQL *mysql)
```

Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See Section 20.9.10.1, "Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success".

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result)  // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else  // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

20.9.3.23. mysql_field_seek()

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET offset)
```

Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

Return Values

The previous value of the field cursor.

Errors

None.

20.9.3.24. `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

Return Values

The current offset of the field cursor.

Errors

None.

20.9.3.25. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

Return Values

None.

Errors

None.

20.9.3.26. `mysql_get_character_set_info()`

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

Description

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

Example

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
```

```
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set+collation number: %d\n", cs.number);
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

20.9.3.27. mysql_get_client_info()

```
const char *mysql_get_client_info(void)
```

Description

Returns a string that represents the client library version.

Return Values

A character string that represents the MySQL client library version.

Errors

None.

20.9.3.28. mysql_get_client_version()

```
unsigned long mysql_get_client_version(void)
```

Description

Returns an integer that represents the client library version. The value has the format `XYYZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

Return Values

An integer that represents the MySQL client library version.

Errors

None.

20.9.3.29. mysql_get_host_info()

```
const char *mysql_get_host_info(MYSQL *mysql)
```

Description

Returns a string describing the type of connection in use, including the server host name.

Return Values

A character string representing the server host name and the connection type.

Errors

None.

20.9.3.30. mysql_get_proto_info()

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

Description

Returns the protocol version used by current connection.

Return Values

An unsigned integer representing the protocol version used by the current connection.

Errors

None.

20.9.3.31. mysql_get_server_info()

```
const char *mysql_get_server_info(MYSQL *mysql)
```

Description

Returns a string that represents the server version number.

Return Values

A character string that represents the server version number.

Errors

None.

20.9.3.32. mysql_get_server_version()

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

Description

Returns the version number of the server as an integer.

Return Values

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 5.1.5 is returned as 50105.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

Errors

None.

20.9.3.33. mysql_get_ssl_cipher()

```
const char *mysql_get_ssl_cipher(MYSQL *mysql)
```

Description

`mysql_get_ssl_cipher()` returns the SSL cipher used for the given connection to the server. `mysql` is the connection handler returned from `mysql_init()`.

Return Values

A string naming the SSL cipher used for the connection, or `NULL` if no cipher is being used.

20.9.3.34. mysql_hex_string()

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)
```

Description

This function is used to create a legal SQL string that you can use in an SQL statement. See Section 8.1.1, “Strings”.

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0x`*`value`* or `X'`*`value`*`'` format. However, the return value does not include the `0x` or `X'...'`. The caller must supply whichever of those is desired.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What is this",12);
end = strmov(end,",0x");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
   fprintf(stderr, "Failed to insert row, Error: %s\n",
           mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

20.9.3.35. `mysql_info()`

```
const char *mysql_info(MYSQL *mysql)
```

Description

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- `INSERT INTO ... SELECT ...`

  String format: `Records: 100 Duplicates: 0 Warnings: 0`

- `INSERT INTO ... VALUES (...),(...),(...)...`

  String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `LOAD DATA INFILE ...`

  String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`

- `ALTER TABLE`

  String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `UPDATE`

  String format: `Rows matched: 40 Changed: 40 Warnings: 0`

Note that `mysql_info()` returns a non-`NULL` value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

Return Values

A character string representing additional information about the most recently executed statement. `NULL` if no information is available for the statement.

Errors

None.

20.9.3.36. `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

Description

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

Return Values

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

Errors

In case of insufficient memory, `NULL` is returned.

20.9.3.37. `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(`*`expr`*`)`.

The return value of `mysql_insert_id()` is always zero unless explicitly updated under one of the following conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit nonspecial value.
- In the case of a multiple-row `INSERT` statement, the return value of `mysql_insert_id()` depends on the MySQL server version.

  `mysql_insert_id()` returns the *first* automatically generated `AUTO_INCREMENT` value that was *successfully* inserted.

  If no rows are successfully inserted, `mysql_insert_id()` returns 0.
- If an `INSERT ... SELECT` statement is executed, and no automatically generated value is successfully inserted, `mysql_insert_id()` returns the ID of the last inserted row.
- If an `INSERT ... SELECT` statement uses `LAST_INSERT_ID(`*`expr`*`)`, `mysql_insert_id()` returns *`expr`*.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(`*`expr`*`)` into any column or by updating any column to `LAST_INSERT_ID(`*`expr`*`)`.

- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

The return value of `mysql_insert_id()` can be simplified to the following sequence:

1. If there is an `AUTO_INCREMENT` column, and an automatically generated value was successfully inserted, return the first such value.
2. If `LAST_INSERT_ID(expr)` occurred in the statement, return *`expr`*, even if there was an `AUTO_INCREMENT` column in the affected table.
3. The return value varies depending on the statement used. When called after an `INSERT` statement:
   - If there is an `AUTO_INCREMENT` column in the table, and there were some explicit values for this column that were successfully inserted into the table, return the last of the explicit values.

   When called after an `INSERT ... ON DUPLICATE KEY UPDATE` statement:
   - If there is an `AUTO_INCREMENT` column in the table and there were some explicit succesfully inserted values, or some updated rows, return the last of the inserted or updated values.
