The listen process "listens" to a network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any connection-oriented network (more precisely, with any connection-oriented transport provider) that conforms to the Transport Layer Interface (TLI) Specification.

The listener internally generates a pathname for the minor device for each connection; it is this pathname that is used in the utmpx entry for a service, if one is created. By default, this pathname is the concatenation of the prefix /dev/netspec with the decimal representation of the minor device number. In either case, the representation of the minor device number will be at least two digits (for example, 05 or 27), or longer when it is necessary to accommodate minor device numbers larger than 99.

When a connection indication is received, the listener creates a new transport endpoint and accepts the connection on that endpoint. Before giving the file descriptor for this new connection to the server, any designated STREAMS modules are pushed and the configuration script is executed, (if one exists). This file descriptor is appropriate for use with either TLI (see t_sync(3NSL)) or the sockets interface library.

By default, a new instance of the server is invoked for each connection. When the server is invoked, file descriptor 0 refers to the transport endpoint, and is open for reading and writing. File descriptors 1 and 2 are copies of file descriptor 0; no other file descriptors are open. The service is invoked with the user and group IDs of the user name under which the service was registered with the listener, and with the current directory set to the HOME directory of that user.

Alternatively, a service may be registered so that the listener will pass connections to a standing server process through a FIFO or a named stream, instead of invoking the server anew for each connection. In this case, the connection is passed in the form of a file descriptor that refers to the new transport endpoint. Before the file descriptor is sent to the server, the listener interprets any configuration script registered for that service using doconfig(3NSL), although doconfig is invoked with both the NORUN and NOASSIGN flags. The server receives the file descriptor for the connection in a strrecvfd structure using an I_RECVFD ioctl(2).

For more details about the listener and its administration, see nlsadmin(1M).

Options

-m_devstem  The listener will use devstem as the prefix for the pathname.

Files

/etc/saf/pmtag/*

Attributes  See attributes(5) for descriptions of the following attributes:
<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

*nlsadmin(1M), pmadm(1M), sac(1M), sacadm(1M), ioctl(2), doconfig(3NSL), nlsgetcall(3NSL), nlsprovider(3NSL), t_sync(3NSL), attributes(5), streamio(7)*

*System Administration Guide: Basic Administration*

Notes  
When passing a connection to a standing server, the user and group IDs contained in the `strrecvfd` structure will be those for the listener (that is, they will both be 0); the user name under which the service was registered with the listener is not reflected in these IDs.

When operating multiple instances of the listener on a single transport provider, there is a potential race condition in the binding of addresses during initialization of the listeners, if any of their services have dynamically assigned addresses. This condition would appear as an inability of the listener to bind a static-address service to its otherwise valid address, and would result from a dynamic-address service having been bound to that address by a different instance of the listener.
llc2_loop(1M)

Name  llc2_loop – loopback diagnostics to test the driver, adapter and network.

Synopsis  

/usr/lib/llc2/llc2_loop2 [-v] ppa
/usr/lib/llc2/llc2_loop3 ppa sap frames
/usr/lib/llc2/llc2_loop3 ppa type frames
/usr/lib/llc2/llc2_loop4 [-v] ppa

Description

Loop 2  The loop2 test sends a NULL XID frame to the broadcast (all 1’s) destination MAC address. The source SAP (Service Access Point) value used is 0x04 (SNA’s SAP). Therefore, if SNA is running on the system, the loop2 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed, since the loop2 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The most likely error is:

Unexpected DLPI primitive x, expected y.

where \(x = 5\) and \(y = 6\). From /usr/include/sys/dlpi.h, the expected return value from one of the DLPI primitives is 6 (DL_OK_ACK), but instead a 5 (DL_ERROR_ACK) was received. This can occur for two reasons:

- The loop2 command was issued to a non-existent PPA (Physical Point of Attachment).
- The SAP (0x04) is already in use (for example, the SNA subsystem is up).

Loop 3  The loop3 test sends 1,495 byte Unnumbered Information (UI) framesto the NULL (all 0’s) destination MAC address. This should be used along with data capture either on the local node or another node on the same LAN to verify the transmission of data. The ppa argument specifies the adapter on which to run the test. The ppa is the relative physical position of the adapter and may be ascertained by viewing the adapter configuration (see llc2_config(1)). For Token Ring or Ethernet, specify an even sap value from 2 through 254, or, for Ethernet only, any type value from 1519 (0x05ef) through 65535 (0xffff). It is advised to pick a value that is easily recognized when the data capture output is viewed. frames is the decimal number of 1,495 bytes packets to transmit. The test will only display a message if a failure occurs.

Loop 4  The loop4 test sends a TEST frame (no information field) to the broadcast (all 1’s) destination MAC address. The source SAP value used is 0x04 (SNA’s SAP). Therefore, if SNA is running on the system, the loop4 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed since the loop4 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The loop4 test displays information similar to the following example if other nodes are listening and respond (verbose mode):

- Attaching
- Binding
-Sending TEST
-Responders
  1-0000c0c12449
  2-080000e14290
  3-080000e142a51
  4-0000c0450044
  5-0000c0199e46
-Unbinding
-Detaching
5 nodes responding

The errors displayed are the same as for loop2.

Notes  For information about how to start the service, see llc2(7D)
localeadm(1M)

Name
localeadm – query and configure locales

Synopsis
localeadm [-lcst] [-q locale | region] [-h] [-d device]...
localeadm -r locale | region [-t] [-v] [-m] [-R root_path]
localeadm -a locale | region [-t] [-v] [-m] [-d device]...
[-R root_path]
localeadm -f locale | region [-t] [-v] [-m] [-d device]...
[-R root_path]
localeadm -h
localeadm -C

Description
The localeadm utility queries and configures Solaris locales through a command line interface.

In query (-q) or list (-l) modes, localeadm displays information about locale packages that are installed on the system or that reside on a particular device or directory.

To make it easier for users to pick out locales, the output from localeadm consists of a list of country or region names rather than a list of packages. Users can use the output to determine which locales or regions to add or remove.

When the user specifies a locale or region to add or remove using the name given by the output of the list mode, localeadm calculates which locale packages need to be changed and add or remove them. localeadm uses pkgadd(1M) or pkgrm(1M) to add or remove packages.

If the locales changed were Asian locales, then extra processes such as input method server daemons might need to be started before the new locales work properly. Once the locales are installed, the user is prompted to either reboot the machine or manually start the daemons. The user is also given a list of daemons which need to be started.

All locales are part of a set geographic region. A locale is an indivisible part of a region. You cannot have a locale which doesn’t exist in a region, or a region without locales. If you choose to add or remove a particular locale, all of the locales in the region to which it belongs will be added or removed. Likewise, if you query a locale, localeadm checks the system for the region of which the local is part.

Options
The following options are supported:

-a locale | region     Add the packages for locale (locale) or geographic region region to the system.

Specify locale or region as the short name displayed by the -l option. For example, the -l option outputs Australasia (aua), therefore, the argument for -a is aua.
This option requires the `-d` option with arguments. If necessary packages are already installed, `localeadm` does not overwrite them. It simply skips such packages.

If you use the `-a` and `-m` options with a locale that has already been added without desktop translated message packages, it adds the desktop translated message packages for that locale to the system.

Only superusers or others who have been assigned package administration access through role-based access control can use this option. See `rbac(5)` for information on adding and removing packages. See `smc(1M)` for information on setting up and adding users to a package manager role.

`-c` Display the locale name with codeset in `locale(1)` format.

Use this option in conjunction with the `-l` option to display the locale name with codeset in the format shown by the `locale(1)` command. For example, it displays `fr_FR.ISO8859-1` as opposed to `french`.

`-C` Enable user to recreate the `Locale_config` file based on the images available to them. This attempts to ensure that any inaccuracies (more likely for non-GA versions) in the bundled configuration file are addressed.

`-d device` Install or list locales from packages located in `device`. Specify `device` as a full path name to a directory containing Solaris packages or the path to the top directory of a complete Solaris image. You can also specify `device` as a device alias such as `/cdrom/cdrom0`, a device nickname as defined by `eject(1)`, or an alternative device nickname such as `cdrom`, `dvd` or `dvdrom`. If the packages are to be installed from a series of CDROM images, then multiple images can be specified in a comma separated list. The same device or nickname can be repeated to indicate multiple loadings of different media at the same device.

`-f` Check the pkgs modified by a previous add or remove operation to ensure all pkgs were added or removed properly. If a pkg was incorrectly added due to a pkgadd or pkgrm failure, the pkg is backed out and reinstalled.

Only superusers or others who have been assigned package administration access through role-based access control can use this option. See `rbac(5)` for information on adding and removing packages. See `smc(1M)` for information on setting up and adding users to a package manager role.
localeadm(1M)

- h  Print a short help message. The help message lists all the flags and their usage.

- l  List all the locales that are installed on the system or available on an install media. The list is sorted by geographic region.

When you specify the -d option with -l, localeadm lists all of the locales or regions available on the device pointed to by the -d option arguments.

When you do not specify the -d option, localeadm -l lists all of the locales or regions installed on the current system.

When you specify the -t option with -l, localeadm lists all of the locales or regions that could possibly be added to the system.

- m  Deselect translated message packages.

By default, with the -a option, localeadm adds the translated desktop message packages for the locale or region specified in the -a option argument. If you use the -a option with the -m option, the desktop translated message packages for the locale or region will not be added, thus effectively disabling the desktop translated messages support for that locale or region. If used with the -r option, localeadm will remove only the translated desktop message packages for the locale or region specified in the -r option argument.

If you use the -m option with a locale that has already been added without the translated desktop message packages it adds the translated desktop message packages for that locale to the system.

- q locale | region  Query the system to see if the locale (locale) or geographic region (region) are already installed. The expected input for a locale or region name is the name displayed by the -l option.

- r locale | region  Remove the packages for locale (locale) or geographic region (region) from the system.

Specify locale or region as the short name displayed by the -l option. For example, the -l option outputs Australasia (aua), therefore, the argument for -a is aua.

Only superusers or others who have been assigned package administration access through role-based access control can use this option. See rbac(5) for information on adding and removing packages. See smc(1M) for information on setting up and adding users to a package manager role.
Definethe full pathname of a directory to use as the root path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path. You can specify root_path when you install to a client from a server.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

-s Display only the geographic regions of specific locales or regions.

Use this option in conjunction with the -l option to display listed regions or locales.

-t Test mode.

Use this option with -a, -f or -r to list all operations to be done. It will not actually add or remove packages.

Use the this option with -l to list all of the locales or regions that could possibly be added to the system.

-v Print out messages produced during a pkgadd or pkgrm command.

This option works on localeadm add and remove commands. It does not work on individual pkgadd or pkgrm commands. It displays additional information, but only as part of the larger program.

Examples

**EXAMPLE 1** Listing All of the Locales and Codesets

The following example lists all of the geographic regions installed on the machine. All locales in the regions are listed by their codesets:

```
example% localeadm -lc
```

**EXAMPLE 2** Listing the Regions Available on a Solaris CD or DVD

The following example command checks the Solaris_10/Product directory of the CD or DVD mounted on /cdrom/cdrom0. It also lists the names of the regions that can be installed from packages in that directory. The -s option displays the region names without any locales.

```
example% localeadm -ls -d /cdrom/cdrom0
```

**EXAMPLE 3** Querying for a Locale

The following example queries whether the Central European region called ceu on the current machine.

```
example% localeadm -q ceu
```
EXAMPLE 4  Removing Western European Locales

The following example removes all packages associated with the Western Europe region from
the system, except for those packages needed by other regions.

example% localeadm -r weu

EXAMPLE 5  Adding Russian Locales

The following example installs the Eastern Europe region, of which Russian locale is a part,
from packages located in /net/sparc_images/export/pkgs.

example# localeadm -a ru_RU -d /net/sparc_images/export/pkgs

EXAMPLE 6  Adding the Traditional Chinese Locale

The following example adds the Traditional Chinese region to the system. This differs from
the previous example in that Traditional Chinese is installed as a geographic region rather
than just a locale. This is the case for all Asian languages, for example, zh_TW, zh_CN, zh_HK,
hi_IN, th_TH, ko_KR, ja.

# localeadm -a zh_TW -d /net/sparc_images/export/pkgs

Exit Status  The following exit values are returned when you invoke localeadm without the -q (query)
option:

0  Successful completion.
1  An error occurred.

The following exit values are returned when you invoke localeadm with the -q (query)
option:

0  Successful search. The locale or region was found.
1  Unsuccessful search. The locale or region was not found.
2  An error occurred.

Files  /var/sadm/install/logs/localeadmin_install.date
/var/sadm/install/logs/localeadmin_uninstall.date
Log files for installation and removal operations.

date is specified in YYYY_MM_DD format. If a particular day has multiple installs, date
has a period (.) followed by a number appended to it, for example, 2003_10_20.1,
2003_10_20.2.

/tmp/locales.list
File that contains the output of the -l option.

*International Language Environments Guide*
The `localectr` utility allows new locales to be customized and built. The output of `localectr` is an installable package containing the compiled shared object binary which contains the locale data information as well as a number of other supporting files that are required to have a fully working locale on the system.

Once generated, the package can be added to the system by using the `pkgadd(1M)` command and removed with `pkgrm(1M)`.

Depending on your default system login, you might have to reset your user environment after you add a locale. If `dtlogin(1X)` (for the CDE user environment) is the default system login, you need to restart `dtlogin`. No action is required if `gdm(1)` (for the Gnome user environment) is the default login.

There are two interfaces to `localectr`, command line (CLI) and graphical user interface (GUI). To customize the locale data, you must use the GUI. To create locales with standard locale data according to Unicode's Common Locale Data Repository (CLDR), the CLI is sufficient.

With the CLI it is also possible to generate several locales in a single step, with a separate package being generated for each locale. With the GUI, a single locale is processed at a time.

To launch the GUI, run the `localectr` command with no options. To run from the CLI, use the appropriate options as described below.

`localectr` uses the `localedef(1)` utility to build the locale data binary shared object. Therefore, access to a C compiler is required in order to run `localectr` successfully, as this is also required by `localedef`.

`localectr` is mainly concerned with locale data. However, in order to create a fully working locale on the system with `localectr`, many features, such as fonts, translations and input methods, are also required. Depending on what locales are already installed on the system, the relevant features might or might not be present on the system. If they are not present, then `localeadm(1M)` should be used to add the relevant packages before adding packages created by `localectr`. `localectr` bundles locale data for the latest set of locales available in Unicode's CLDR. A user can also create a locale not available in CLDR by supplying her own data in the `localectr` GUI.
Options
The following options are supported:

- c compiler_path
  Specify the path to the C compiler that is used to compile the locale data into a shared object binary. Not required if the compiler is already in the user's PATH.

- d destination_path
  Specify the path to the directory where the created package is to be stored.

- h
  Displays the usage message.

- l template_file
  The full path to user defined pkginfo(4) template file.

- l locale1,locale2...
  Specify a comma-separated list of locale(s) to generate. Locale names are in the form: locale.codeset@variant, where codeset and variant are optional. The default and only allowed codeset is UTF-8. The default variant is localectr.

- p
  The package name prefix

- q
  Queries localectr for a complete list of locales for which locale data is defined in localectr. When localectr is run from the CLI, the locale(s) specified with the -l option must be on this list in order for an installable locale package to be generated.

- r
  Specify the range of Unicode characters for which locale data rules in the LC_CTYPE and LC_COLLATE categories are to be generated. There are three valid options:

  0
  Locale data rules are restricted to the exemplar or to commonly used characters of the locale in question.

  1
  Locale data rules are restricted to the Unicode plane 0 characters, whose codepoints fall in the range u0000-uFFFF.

  2
  Locale data rules are generated for all codepoints defined in the latest version of Unicode that is supported by the system on which localectr is being run.

- V
  Shows the version of this software.

Examples
EXAMPLE 1   Launching the GUI
The following example launches the localectr GUI.

example% localectr
EXAMPLE 2 Generating Locale for Afrikaans (South Africa) with Default Locale Data

The following example generates a package in the specified destination directory, which can be used to install the Afrikaans (af_ZA.UTF-8) locale on the system. The package name is composed of a prefix followed by the hyphen separated ISO-639 language code, the ISO-3166 country code, the locale encoding and an optional user-defined tag. The resulting package can then be added to the system using pkgadd(1M).

```sh
example% localectr -l af_ZA -d /tmp
```

EXAMPLE 3 Generating Several South Africa Locales with Full Unicode Range of Characters

The following example generates an installable package for each of the specified locales.

```sh
example% localectr -l af_ZA,en_ZA,xh_ZA,zu_ZA -d /tmp -r 2
```

EXAMPLE 4 Generating the Irish Locale with a User-Specified Tag

The following example will generate a locale whose full name is ga_IE.UTF-8@mycompanyname.

```sh
example% localectr -l ga_IE@mycompanyname -d /tmp
```

Exit Status

The following exit codes are returned:

- **0**
  - Successful completion
- **>0**
  - An error occurred.

Files

- `/usr/bin/localectr`
  - Wrapper script that launches locale creator.
- `/usr/lib/localectr`
  - Jar files, scripts, and locale data repository needed to run the application.

*International Language Environments Guide*
Name  locator – location indicator control  

Synopsis  
/usr/sbin/locator [-f | -n]

Description  The locator command sets or queries the state of the system locator if such a device exists. Without options, the locator command reports the current state of the system. The privileges required to use this command are hardware dependent. Typically, only the super user can get or set a locator.

Options  The following options are supported:
- f  Turns the locator off.
- n  Turns the locator on.

Examples  EXAMPLE 1  Using the locator Command on a Platform Which Has a System Locator LED
When issued on a platform which has a system locator LED, the following command turns the locator on:

```
# locator -n
# locator
```
The ‘system’ locator is on

EXAMPLE 2  Using the locator Command on a Platform Which Does Not Have a System Locator LED
When issued on a platform which does not have a system locator LED, the following command attempts to turn the locator on. The command returns an error message.

```
# locator -n
'system' locator not found
```

Exit Status  The following exit values are returned:
0  Successful completion.
1  Invalid command line input.
2  The requested operation failed.

The lockd utility is part of the NFS lock manager, which supports record locking operations on NFS files. See fcntl(2) and lockf(3C). The lock manager provides the following two functions:

- It forwards fcntl(2) locking requests for NFS mounted file systems to the lock manager on the NFS server.
- It generates local file locking operations in response to requests forwarded from lock managers running on NFS client machines.

State information kept by the lock manager about these locking requests can be lost if the lockd is killed or the operating system is rebooted. Some of this information can be recovered as follows. When the server lock manager restarts, it waits for a grace period for all client-site lock managers to submit reclaim requests. Client-site lock managers, on the other hand, are notified by the status monitor daemon, statd(1M), of the restart and promptly resubmit previously granted lock requests. If the lock daemon fails to secure a previously granted lock at the server site, then it sends SIGLOST to a process.

Administrators can make changes to the startup parameters for lockd by logging in as root and editing the /etc/default/nfs file (See nfs(4)).

**Options**

The following options are supported:

- `-g graceperiod` Deprecated in favor of GRACE_PERIOD. Specify the number of seconds that all clients (both NLM and NFSv4) have to reclaim locks after the server reboots. It also controls the NFSv4 lease interval. This option is equivalent to the LOCKD_GRACE_PERIOD parameter.

- `-l listen_min_backlog` Specify the listener backlog (listen_min_backlog). `listen_min_backlog` is the number connect requests that are queued and waiting to be processed before new connect requests start to get dropped.

- `-t timeout` Specify the number of seconds to wait before retransmitting a lock request to the remote server. The default value is 5 seconds. Equivalent of the LOCKD_RETRANSMIT_TIMEOUT parameter in the nfs file.

**Operands**

`nthreads` Specify the maximum number of concurrent threads that the server can handle. This concurrency is achieved by up to `nthreads` threads created as needed in the kernel. `nthreads` should be based on the load expected on this server. If `nthreads` is not specified, the maximum number of concurrent threads will default to 20. Equivalent of the LOCKD_SERVERS parameter in the nfs file.
**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnfscu</td>
</tr>
</tbody>
</table>

**See Also**  svcs(1), automountd(1M), clear_locks(1M), mount_nfs(1M), share(1M), share_nfs(1M), statd(1M), svcadm(1M), fcntl(2), lockf(3C), nfs(4), attributes(5), smf(5)

**Notes**  The lockd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/nfs/nlockmgr
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If it is disabled, it will be enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M) unless its application/auto_enable property is set to false.

This daemon might not exist in a future release of Solaris.
lockfs – change or report file system locks

/usr/sbin/lockfs [-adefhnuw] [-c string] [file-system] ...

Description
lockfs is used to change and report the status of file system locks. lockfs reports the lock status and unlocks the file systems that were improperly left locked.

Using lockfs to lock a file system is discouraged because this requires extensive knowledge of SunOS internals to be used effectively and correctly.

When invoked with no arguments, lockfs lists the UFS file systems that are locked. If file-system is not specified, and -a is specified, lockfs is run on all mounted, UFS type file systems.

Options
The options are mutually exclusive: wndheuf. If you do specify more than one of these options on a lockfs command line, the utility does not protest and invokes only the last option specified. In particular, you cannot specify a flush (-f) and a lock (for example, -w) on the same command line. However, all locking operations implicitly perform a flush, so the -f is superfluous when specifying a lock.

You must be super-user to use any of the following options, with the exception of -a, -f and -v.

The following options are supported.

- a
  Apply command to all mounted, UFS type file systems. file-system is ignored when -a is specified.

- c string
  Accept a string that is passed as the comment field. The -c only takes affect when the lock is being set using the -d, -h, -n, -u, or -w options.

- d
  Delete-lock (dlock) the specified file-system. dlock suspends access that could remove directory entries.

- e
  Error-lock (elock) the specified file-system. elock blocks all local access to the locked file system and returns EWOULDBLOCK on all remote access. File systems are elocked by UFS on detection of internal inconsistency. They may only be unlocked after successful repair by fsck, which is usually done automatically (see mount_ufs(1M)). elocked file systems can be unmounted.

- f
  Force a synchronous flush of all data that is dirty at the time fsflush is run to its backing store for the named file system (or for all file systems.)
It is a more reliable method than using `sync(1M)` because it does not return until all possible data has been pushed. In the case of UFS filesystems with logging enabled, the log is also rolled before returning. Additional data can be modified by the time `fsflush` exits, so using one of the locking options is more likely to be of general use.

- **h**
  Hard-lock (`hlock`) the specified `file-system`. hlock returns an error on every access to the locked file system, and cannot be unlocked. hlocked file systems can be unmounted.

- **n**
  Name-lock (`nlock`) the specified `file-system`. nlock suspends accesses that could change or remove existing directories entries.

- **u**
  Unlock (`ulock`) the specified `file-system`. ulock awakens suspended accesses.

- **v**
  Enable verbose output.

- **w**
  Write-lock (`wlock`) the specified `file-system`. wlock suspends writes that would modify the file system. Access times are not kept while a file system is write-locked.

### Operands

The following operands are supported.

- **file-system**
  A list of path names separated by whitespace. Note that `file-system` can be a directory rather than the specific name of a file system, such as `/` or `/usr`. For example, if you specify `/export/home` as an argument to a `lockfs` command and `/export/home` is mounted on the root (`/`) file system, the `lockfs` command will take effect on the root file system.

### Usage

See `largefile(5)` for the description of the behavior of `lockfs` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

### Examples

**EXAMPLE 1** Using `lockfs -a`

In the following examples, `filesystem` is the pathname of the mounted-on directory (mount point). Locktype is one of “write,” “name,” “delete,” “hard,” or “unlock”. When enclosed in parenthesis, the lock is being set. Comment is a string set by the process that last issued a lock command.

The following example shows the `lockfs` output when only the `-a` option is specified.

```bash
example# /usr/sbin/lockfs -a

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Locktype</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>unlock</td>
<td></td>
</tr>
</tbody>
</table>
```
EXAMPLE 1 Using lockfs -a (Continued)

/var unlock

example#

EXAMPLE 2 Using lockfs -w

The following example shows the lockfs output when the -w option is used to write lock the /var file system and the comment string is set using the -c option. The -a option is then specified on a separate command line.

example# /usr/sbin/lockfs -w -c "lockfs: write lock example" /var
example# /usr/sbin/lockfs -a

             Filesystem | Locktype | Comment
-------------|-----------|---------
            / | unlock    |          
           /var | write     | lockfs: write lock example

example#

EXAMPLE 3 Using lockfs -u

The following example shows the lockfs output when the -u option is used to unlock the /var file system and the comment string is set using the -c option.

example# /usr/sbin/lockfs -uc "lockfs: unlock example" /var
example# /usr/sbin/lockfs /var

             Filesystem | Locktype | Comment
-------------|-----------|---------
            /var | unlock    | lockfs: unlock example

example#

System Administration Guide: Basic Administration
Diagnostics

file system: Not owner
You must be root to use this command.

file system: Deadlock condition detected/avoided
A file is enabled for accounting or swapping, on file system.

file system: Device busy
Another process is setting the lock on file system.
lockstat(1M)

Name
lockstat – report kernel lock and profiling statistics

Synopsis
lockstat [-ACEHI] [-e event_list] [-i rate]
[-b | -t | -h | -s depth] [-n nrecords]
[-l lock [size]] [-d duration]
[-f function [size]] [-T] [-ckgwRP] [-D count]
[-o filename] [-x opt [=val]] command [args]

Description
The lockstat utility gathers and displays kernel locking and profiling statistics. 
No event selection options are specified, the default is -C.

-A
Watch all lock events. -A is equivalent to -CH.

-C
Watch contention events.

-E
Watch error events.

-e event_list
Only watch the specified events. event list is a comma-separated list of events or ranges of
events such as 1,4-7,35. Run lockstat with no arguments to get a brief description of all
events.

The lockstat utility gathers and displays kernel locking and profiling statistics. 
Lockstat allows you to specify which events to watch (for example, spin on adaptive mutex, block on
read access to rwlock due to waiting writers, and so forth) how much data to gather for each
event, and how to display the data. By default, lockstat monitors all lock contention events,
gathers frequency and timing data about those events, and displays the data in decreasing
frequency order, so that the most common events appear first.

Lockstat gathers data until the specified command completes. For example, to gather
statistics for a fixed-time interval, use sleep(1) as the command, as follows:

example# lockstat sleep 5

When the -I option is specified, lockstat establishes a per-processor high-level periodic
interrupt source to gather profiling data. The interrupt handler simply generates a lockstat
event whose caller is the interrupted PC (program counter). The profiling event is just like any
other lockstat event, so all of the normal lockstat options are applicable.

Lockstat relies on DTrace to modify the running kernel’s text to intercept events of interest.
This imposes a small but measurable overhead on all system activity, so access to lockstat is
restricted to super-user by default. The system administrator can permit other users to use
lockstat by granting them additional DTrace privileges. Refer to the Solaris Dynamic Tracing
Guide for more information about DTrace security features.

Options
The following options are supported:

Event Selection
If no event selection options are specified, the default is -C.

-A
Watch all lock events. -A is equivalent to -CH.

-C
Watch contention events.

-E
Watch error events.

-e event_list
Only watch the specified events. event list is a comma-separated list of events or ranges of
events such as 1,4-7,35. Run lockstat with no arguments to get a brief description of all
events.
-H
Watch hold events.

-I
Watch profiling interrupt events.

-i rate
Interrupt rate (per second) for -I. The default is 97 Hz, so that profiling doesn’t run in lockstep with the clock interrupt (which runs at 100 Hz).

-x arg[=val]
Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the Solaris Dynamic Tracing Guide. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).

Data Gathering

-b
Basic statistics: lock, caller, number of events.

-h
Histogram: Timing plus time-distribution histograms.

-s depth
Stack trace: Histogram plus stack traces up to depth frames deep.

-t
Timing: Basic plus timing for all events [default].

Data Filtering

-d duration
Only watch events longer than duration.

-f func[size]
Only watch events generated by func, which can be specified as a symbolic name or hex address. size defaults to the ELF symbol size if available, or 1 if not.

-l lock[size]
Only watch lock, which can be specified as a symbolic name or hex address. size defaults to the ELF symbol size or 1 if the symbol size is not available.

-n records
Maximum number of data records.

Data Reporting

-c
Coalesce lock data for lock arrays (for example, pse_mutex[]).

-D count
Only display the top count events of each type.
-g
Show total events generated by function. For example, if \texttt{foo()} calls \texttt{bar()} in a loop, the work done by \texttt{bar()} counts as work generated by \texttt{foo()} (along with any work done by \texttt{foo()} itself). The -g option works by counting the total number of stack frames in which each function appears. This implies two things: (1) the data reported by -g can be misleading if the stack traces are not deep enough, and (2) functions that are called recursively might show greater than 100% activity. In light of issue (1), the default data gathering mode when using -g is -s 50.

-k
Coalesce PCs within functions.

-o \texttt{filename}
Direct output to \texttt{filename}.

-P
Sort data by \texttt{(count * time)} product.

-p
Parsable output format.

-R
Display rates (events per second) rather than counts.

-W
Whichever: distinguish events only by caller, not by lock.

-w
Wherever: distinguish events only by lock, not by caller.

### Display Formats

The following headers appear over various columns of data.

**Count or ops/s**
Number of times this event occurred, or the rate (times per second) if -R was specified.

**indv**
Percentage of all events represented by this individual event.

**genr**
Percentage of all events generated by this function.

**cuml**
Cumulative percentage; a running total of the individuals.

**rcnt**
Average reference count. This will always be 1 for exclusive locks (mutexes, spin locks, rwlocks held as writer) but can be greater than 1 for shared locks (rwlocks held as reader).

**nsec**
Average duration of the events in nanoseconds, as appropriate for the event. For the profiling event, duration means interrupt latency.
Lock
Address of the lock; displayed symbolically if possible.

CPU+PIL
CPU plus processor interrupt level (PIL). For example, if CPU 4 is interrupted while at PIL 6, this will be reported as cpu[4]+6.

Caller
Address of the caller; displayed symbolically if possible.

**Examples**

**EXAMPLE 1**  Measuring Kernel Lock Contention

```bash
example# lockstat sleep 5
```

Adaptive mutex spin: 2210 events in 5.055 seconds (437 events/sec)

EXAMPLE 4  Basic Kernel Profiling

For basic profiling, we don’t care whether the profiling interrupt sampled foo()+0x4c or foo()+0x78; we care only that it sampled somewhere in foo(), so we use `-k`. The CPU and PIL aren’t relevant to basic profiling because we are measuring the system as a whole, not a particular CPU or interrupt level, so we use `-W`.

example# lockstat -kIW -D 20 ./polltest

Profiling interrupt: 82 events in 0.424 seconds (194 events/sec)

### EXAMPLE 5  Generated-load Profiling

In the example above, 5% of the samples were in `poll()`. This tells us how much time was spent inside `poll()` itself, but tells us nothing about how much work was generated by `poll()`, that is, how much time we spent in functions called by `poll()`. To determine that, we use the `-g` option. The example below shows that although `polltest` spends only 5% of its time in `poll()` itself, `poll()`-induced work accounts for 34% of the load.

Note that the functions that generate the profiling interrupt (`lockstat_intr()`, `cyclic_fire()`, and so forth) appear in every stack trace, and therefore are considered to have generated 100% of the load. This illustrates an important point: the generated load percentages do not add up to 100% because they are not independent. If 72% of all stack traces contain both `foo()` and `bar()`, then both `foo()` and `bar()` are 72% load generators.

```
exampel# lockstat -kgIW -D 20 ./polltest
Profiling interrupt: 80 events in 0.412 seconds (194 events/sec)

EXAMPLE 6  Gathering Lock Contention and Profiling Data for a Specific Module

In this example we use the -f option not to specify a single function, but rather to specify the entire text space of the sbus module. We gather both lock contention and profiling statistics so that contention can be correlated with overall load on the module.

example# modinfo | grep sbus
24 102a8b6f b8b4 59 1 sbus (SBus (sysio) nexus driver)

*Solaris Dynamic Tracing Guide*

**Notes**
The profiling support provided by `lockstat -I` replaces the old (and undocumented) `/usr/bin/kgmon` and `/dev/profile`.

Tail-call elimination can affect call sites. For example, if `foo()+0x50` calls `bar()` and the last thing `bar()` does is call `mutex_exit()`, the compiler can arrange for `bar()` to branch to `mutex_exit()` with a return address of `foo()+0x58`. Thus, the `mutex_exit()` in `bar()` will appear as though it occurred at `foo()+0x58`.

The PC in the stack frame in which an interrupt occurs can be bogus because, between function calls, the compiler is free to use the return address register for local storage.

When using the `-I` and `-s` options together, the interrupted PC will usually not appear anywhere in the stack since the interrupt handler is entered asynchronously, not by a function call from that PC.

The `lockstat` technology is provided on an as-is basis. The format and content of `lockstat` output reflect the current Solaris kernel implementation and are therefore subject to change in future releases.
lofiadm

**Name**
lofiadm – administer files available as block devices through lofi

**Synopsis**

```
/usr/sbin/lofiadm -a file [device]
/usr/sbin/lofiadm -d file | device
/usr/sbin/lofiadm [ file | device]
```

**Description**

`lofiadm` administers `lofi(7D)`, the loopback file driver. `lofi(7D)` allows a file to be associated with a block device. That file can then be accessed through the block device. This is useful when the file contains an image of some filesystem (such as a floppy or CD-ROM image), because the block device can then be used with the normal system utilities for mounting, checking or repairing filesystems. See `fsck(1M)` and `mount(1M)`.

Use `lofiadm` to add a file as a loopback device, remove such an association, or print information about the current associations.

The `lofi(7D)` driver is not available and will not work inside a zone.

**Options**
The following options are supported:

- `-a file [device]`
  Add file as a block device.

  If `device` is not specified, an available device is picked.

  If `device` is specified, `lofiadm` attempts to assign it to `file`. `device` must be available or `lofiadm` will fail. The ability to specify a device is provided for use in scripts that wish to re-establish a particular set of associations.

- `-d file | device`
  Remove an association by `file` or `device` name, if the associated block device is not busy, and deallocates the block device.

**Operands**
The following operands are supported:

- `file`
  Print the block device associated with `file`.

- `device`
  Print the file name associated with the block device `device`.

  Without arguments, print a list of the current associations. Filenames must be valid absolute pathnames.

  When a file is added, it is opened for reading or writing by root. Any restrictions apply (such as restricted root access over NFS). The file is held open until the association is removed. It is not actually accessed until the block device is used, so it will never be written to if the block device is only opened read-only.
EXAMPLE 1  Mounting an Existing CD-ROM Image

You should ensure that Solaris understands the image before creating the CD. `lofi` allows you to mount the image and see if it works.

This example mounts an existing CD-ROM image (`sparc.iso`), of the Red Hat 6.0 CD which was downloaded from the Internet. It was created with the `mkisofs` utility from the Internet.

Use `lofiadm` to attach a block device to it:

```
# lofiadm -a /home/mike_s/RH6.0/sparc.iso
/dev/lofi/1
```

`lofiadm` picks the device and prints the device name to the standard output. You can run `lofiadm` again by issuing the following command:

```
# lofiadm
Block Device File
/dev/lofi/1 /home/mike_s/RH6.0/sparc.iso
```

Or, you can give it one name and ask for the other, by issuing the following command:

```
# lofiadm /dev/lofi/1
/home/mike_s/RH6.0/sparc.iso
```

Use the `mount` command to mount the image:

```
# mount -F hsfs -o ro /dev/lofi/1 /mnt
```

Check to ensure that Solaris understands the image:

```
# df -k /mnt
Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 512418 512418 0 100% /mnt
```

Solaris can mount the CD-ROM image, and understand the filenames. The image was created properly, and you can now create the CD-ROM with confidence.

As a final step, unmount and detach the images:

```
# umount /mnt
# lofiadm -d /dev/lofi/1
# lofiadm
Block Device File
```

EXAMPLE 2  Mounting a Floppy Image

This is similar to Example 1.

Using `lofi` to help you mount files that contain floppy images is helpful if a floppy disk contains a file that you need, but the machine which you are on does not have a floppy drive. It is also helpful if you do not want to take the time to use the `dd` command to copy the image to a floppy.

This is an example of getting to MDB floppy for Solaris on an x86 platform:

```bash
# lofiadm -a /export/s28/MDB_s28x_wos/latest/boot.3 /dev/lofi/1
# mount -F pcfs /dev/lofi/1 /mnt
# ls /mnt
./ COMMENT.BAT* RC.D/ SOLARIS.MAP*
../ IDENT* REPLACE.BAT* X/
APPEND.BAT* MAKDIR.BAT* SOLARIS/
# umount /mnt
# lofiadm -d /export/s28/MDB_s28x_wos/latest/boot.3
```

EXAMPLE 3  Making a UFS Filesystem on a File

Making a UFS filesystem on a file can be useful, particularly if a test suite requires a scratch filesystem. It can be painful (or annoying) to have to re-partition a disk just for the test suite, but you do not have to. You can `newfs` a file with `lofi`.

Create the file:

```bash
# mkfile 35m /export/home/test
```

Attach it to a block device. You also get the character device that `newfs` requires, so `newfs` that:

```bash
# lofiadm -a /export/home/test /dev/lofi/1
# newfs /dev/rlofi/1
```

`newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1: 71638 sectors in 119 cylinders of 1 tracks, 602 sectors
35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,
```

Note that `ufs` might not be able to use the entire file. Mount and use the filesystem:

```bash
# mount /dev/lofi/1 /mnt
# df -k /mnt
Filesystem kbytes used avail capacity Mounted on
/dev/lofi/1 33455 9 30101 1% /mnt
# ls /mnt
./ ../ lost+found/
# umount /mnt
```
EXAMPLE 3  Making a UFS Filesystem on a File  (Continued)

# lofiadm -d /dev/lofi/1

EXAMPLE 4  Creating a PC (FAT) File System on a Unix File

The following series of commands creates a FAT file system on a Unix file. The file is associated with a block device created by lofiadm.

# mkfile 10M /export/test/testfs
# lofiadm -a /export/test testfs
/dev/lofi/1

Note use of rlofi, not lofi, in following command.
# mkfs -F pcfs -o nofdisk,size=20480 /dev/rlofi/1
Construct a new FAT file system on /dev/rlofi/1: (y/n)? y
# cd /mnt
# df -k.
Filesystem  kbytes used  avail  capacity  Mounted on
/dev/lofi/1  10142  0  10142   0%   /mnt

See environ(5) for descriptions of the following environment variables that affect the execution of lofiadm: LC_CTYPE, LC_MESSAGES and NLSPATH.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  fsck(1M), mount(1M), mount_ufs(1M), newfs(1M), attributes(5), lofi(7D), lofs(7FS)

Notes  Just as you would not directly access a disk device that has mounted file systems, you should not access a file associated with a block device except through the lofi file driver. It might also be appropriate to ensure that the file has appropriate permissions to prevent such access.

Associations are not persistent across reboots. A script can be used to re-establish them if required.

The abilities of lofiadm, and who can use them, are controlled by the permissions of /dev/loficntl. Read-access allows query operations, such as listing all the associations. Write-access is required to do any state-changing operations, like adding an association. As
shipped, /dev/lofictl is owned by root, in group sys, and mode 0644, so all users can do query operations but only root can change anything. The administrator can give users write-access, allowing them to add or delete associations, but that is very likely a security hole and should probably only be given to a trusted group.

When mounting a filesystem image, take care to use appropriate mount options. In particular, the nosuid mount option might be appropriate for UFS images whose origin is unknown. Also, some options might not be useful or appropriate, like logging or forcedirectio for UFS. For compatibility purposes, a raw device is also exported along with the block device. For example, newfs(1M) requires one.

The output of lofiadm (without arguments) might change in future releases.
# Name

logadm – manage endlessly growing log files

# Synopsis

```bash
logadm [ -options ] logname...
```

# Description

logadm is a general log rotation tool that is suitable for running from `cron(1M)`.

Without arguments, `logadm` reads the `/etc/logadm.conf` file, and, for every entry found in that file, checks the corresponding log file to see if it should be rotated. Typically this check is done each morning by an entry in the root's `crontab(1)`.

If the `logname` argument is specified, `logadm` renames the corresponding log file by adding a suffix so that the most recent log file ends with `.0` (that is, `logfile.0`), the next most recent ends with `.1` (that is, `logfile.1`), and so forth. By default, ten versions of old log files are kept (that is, `logfile.0` through `logfile.9`). At the point when what would be the eleventh file is logged, `logadm` automatically deletes the oldest version to keep the count of files at ten.

`logadm` takes a number of `options`. You can specify these options on the command line or in the `/etc/logadm.conf` file. The `logadm` command searches `/etc/logadm.conf` for lines of the form `logname options`

`logname`  
Identifies an entry in `/etc/logadm.conf`. This can be a name or the pathname of the log file. If you specify a log file, rather than a name, for this field, it must be a fully qualified pathname.

`options`  
Identifies command line options exactly as they would be entered on the command line. This allows commonly used log rotation policies to be stored in the `/etc/logadm.conf` file. See EXAMPLES.

If `options` are specified both in `/etc/logadm.conf` and on the command line, those in the `/etc/logadm.conf` file are applied first. Therefore, the command line options override those in `/etc/logadm.conf`.

Log file names specified in `/etc/logadm.conf` can contain filename substitution characters such as * and ?, that are supported by `csh(1)`.

Two options control when a log file is rotated. They are: `-s size -p period`.

When using more than one of these options at a time, there is an implied `and` between them. This means that all conditions must be met before the log is rotated.

If neither of these two options are specified, the default conditions for rotating a log file are: `-s 1b -p 1w`, which means the log file is only rotated if the size is non-zero and if at least 1 week has passed since the last time it was rotated.
By specifying `-p never` as a rotation condition, any other rotation conditions are ignored and `logadm` moves on to the expiration of old log files. By specifying `-p now` as a rotation condition, a log rotation is forced.

Unless specified by the `-o`, `-q`, or `-m` options, `logadm` replaces the log file (after renaming it) by creating an empty file whose owner, group ID, and permissions match the original file.

Three options control when old log files are expired: `-A age` `-C count` `-S size`. These options expire the oldest log files until a particular condition or conditions are met. For example, the combination `-C 5` and the `-S 10m` options expires old log files until there are no more than 5 of the and their combined disk usage is no more than 10 megabytes. If none of these options are specified, the default expiration `-C 10` which keeps ten old log files. If no files are to be expired, use `-C 0` to prevent expiration by default.

**Options**

The following options are supported:

- `-a post_command`
  Execute the `post_command` after renaming the log file. `post_command` is passed to `sh -c`.

  Specify `post_command` as a valid shell command. Use quotes to protect spaces or shell metacharacters in `post_command`.

  This option can be used to restart a daemon that is writing to the file. When rotating multiple logs with one `logadm` command, `post_command` is executed only once after all the logs are rotated, not once per rotated log.

- `-A age`
  Delete any versions that have not been modified for the amount of time specified by `age`.

  Specify `age` as a number followed by an `h` (hours), `d` (days), `w` (weeks), `m` (months), or `y` (years).

- `-b pre_command`
  Execute `pre_command` before renaming the log file. `pre_command` is passed to `sh -c`.

  Specify `pre_command` as a valid shell command. Use quotes to protect spaces or shell metacharacters in `pre_command`.

  This option can be used to stop a daemon that is writing to the file. When rotating multiple logs with one `logadm` command, `pre_command` is executed only once before all the logs are rotated, not once per rotated log.

- `-C count`
  Rotate the log file by copying it and truncating the original log file to zero length, rather than renaming the file.

  `C count` Delete the oldest versions until there are not more than `count` files left.
If no expire options (-A, -C, or -S) are specified, -C 10 is the default. To prevent the default expire rule from being added automatically, specify -C 0.

-e mail_addr
Send error messages by email to mail_addr.

As logadm is typically run from crontab(1M), error messages are captured by cron and mailed to the owner of the crontab.

This option is useful if you want the mail regarding error messages to go to another address instead. If no errors are encountered, no mail message is generated.

-E cmd
Execute cmd to expire the file, rather than deleting the old log file to expire it.

cmd is passed to sh -c. The file is considered expired after cmd completes. If the old log file is not removed or renamed by the cmd, logadm considers it for expiration the next time that it runs on the specified log file. If present, the keyword $file in the specified cmd is expanded in the name of the file being expired.

This option is useful for tasks such as mailing old log files to administrators, or copying old log files to long term storage.

-f conf_file
Use conf_file instead of /etc/logadm.conf.

This option allows non-root users to keep their own logadm configuration files.

-g group
Create a new empty file with the ID specified by group, instead of preserving the group ID of the log file.

Specify group by name or by numeric group ID, as accepted by chgrp(1).

This option requires the ability to change file group ownership using the chgrp(1) command.

-h
Print a help message that describes logadm's options.

-l
Use local time rather than the Coordinated Universal Time (UTC) when naming rotated log files (see the discussion of percent sequences in the templates supplied with the -t option).

-m mode
Create a new empty file with the mode specified by mode, instead of preserving the mode of the log file.

Specify mode in any form that is accepted by the chmod(1) command.
-M cmd
   Use cmd to rename the log file. If the keyword $file is specified, it is expanded to the name of the log file. Similarly, the keyword $nfile is expanded to the new name of the log file. The $nfile keyword is only available with commands provided with the -M option. After the command completes, the log file is replaced by the rotate file. The default cmd is "/bin/mv $file $nfile".

-n
   Print the actions that the logadm command will perform without actually performing them.

   This option is useful for checking arguments before making any changes to the system.

   It is important to remember, however, that since log rotating actions are only printed with this option, logadm might not find files that need expiring, but if run without the -n logadm might create a file that needs expiring by performing the log rotating actions. Therefore, if you see no files being expired with the -n option, files still might be expired without it.

-N
   Prevent an error message if the specified logfile does not exist. Normally, logadm produces an error message if the log file is not found. With -N, if the log file doesn’t exist logadm moves on to the expire rules (if any) and then to the next log file (if any), without creating the empty replacement log file.

-o owner
   Create the new empty file with owner, instead of preserving the owner of the log file.

   Specify owner in any form that is accepted by the chown(1) command.

-p period
   Rotate a log file after the specified time period (period).

   Specify period as a number followed by d for days, h for hours, w for weeks (really 30 days) or y for years. There are also two special values for period: now and never. -p now forces log rotation. -p never forces no log rotation.

-P timestamp
   Used by logadm to record the last time the log was rotated in /etc/logadm.conf.

   This option uses timestamp to determine if the log rotation period has passed. The format of timestamp matches the format generated by ctime(3C), with quotes around it to protect embedded spaces. timestamp is always recorded in the Coordinated Universal Time (UTC) timezone.

-r
   Remove any entries corresponding to the specified logname from the /etc/logadm.conf.
-R cmd
Run the cmd when an old log file is created by a log rotation. If the keyword $file is embedded in the specified command, it is expanded to the name of the old log file just created by log rotation.

This option is useful for processing log file contents after rotating the log. cmd is executed by passing it to sh - c. When rotating multiple logs with one logadm command, the command supplied with -R is executed once every time a log is rotated. This is useful for post-processing a log file (that is, sorting it, removing uninteresting lines, etc.). The -a option is a better choice for restarting daemons after log rotation.

-s size
Rotate the log file only if its size is greater than or equal to size.

Specify size as a number followed by the letter b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.

-S size
Delete the oldest versions until the total disk space used by the old log files is less than the specified size.

Specify size as a number followed by the letter b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.

-t template
Specify the template to use when renaming log files.

template can be a simple name, such as /var/adm/oldfile, or it can contain special keywords which are expanded by logadm and are in the form $word. Allowed sequences are:

$file
The full path name of the file to be rotated

$dirname
The directory of the file to be rotated

$basename
The log file name, without the directory name

$n
The version number, 0 is most recent, 1 is next most recent, and so forth

$N
The same as $n, but starts at 1 instead of zero

$secs
The number of seconds since 00:00:00 UTC, January 1, 1970

$nodename
Expands to the output of uname -n
$platform
   Expands to the output of uname -i

$isa
   Expands to the output of uname -p

$release
   Expands to the output of uname -r

$machine
   Expands to the output of uname -m

$domain
   Expands to the output of domainname

To actually have the dollar sign character in the file name, use $$.
Any percent sequences allowed by strftime(3C) are also allowed, for example, %d expands to the day of the
month. To actually have a percent sign character in the file name, use %%. Both dollar-sign
keywords and percent sequences can appear anywhere in the template. If the template
results in a pathname with non-existent directories, they are created as necessary when
rotating the log file.

If no -t option is specified, the default template is $file.$n. Actual rotation of log files,
where each version is shifted up until it expires is done using the $n keyword. If the
template does not contain the $n keyword, the log file is simply renamed to the new name
and then the expire rules, if any, are applied.

-T pattern
   Normally logadm looks for a list of old log files by turning the template (specified with the
   -t option) into a pattern and finding existing files whose names match that pattern. The -T
   option causes the given pattern to be used instead.

   This option is useful if another program fiddles with the old log file names, like a cron job
to compress them over time. The pattern is in the form of a pathname with special
characters such as * and ? as supported by csh(1) filename substitution.

-v
   Print information about the actions being executed in verbose mode.

-V
   Validate the configuration file.

   This option validates that an entry for the specified logname exists in the
   /etc/logadm.conf file and is syntactically correct. If logname is not specified, all entries in
   the configuration file are validated. If a logname argument is specified, the command
   validates the syntax of that entry. If the entry is found, it is printed and the exit value of the
   command is true. Otherwise the exit value is false.
Write an entry into the config file (that is, /etc/logadm.conf) that corresponds to the current command line arguments. If an entry already existed for the specified entryname, it is removed first. This is the preferred method for updating /etc/logadm.conf, because it prevents syntax errors in that file. The entryname is an argument to an invocation of logadm. The entryname might be chosen as something easy to remember or it can be the pathname of the log file.

If no log file name is provided on a logadm command line, the entry name is assumed to be the same as the log file name. For example, the following two lines achieve the same result, keeping two copies of rotated log files:

```bash
% logadm -C2 -w mylog /my/really/long/log/file/name
% logadm -C2 -w /my/really/long/log/file/name
```

Compress old log files as they are created. count of the most recent log files are left uncompressed, therefore making the count most recent files easier to peruse. Use count of zero to compress all old logs.

The compression is done with gzip(1) and the resulting log file has the suffix of .gz.

Operands

The following operands are supported:

logname

Identifies the name of the entry in /etc/logadm.conf. If the log file name is specified in the logname field, it is assumed that logname is the same as the actual log file name.

Examples

**EXAMPLE 1  Rotating a File and Keeping Previous Versions**

The following example rotates the /var/adm/exacct/proc file, keeping ten previous versions in /var/adm/exacct/proc.0 through /var/adm/exacct/proc.9.

Tell logadm to copy the file and truncate it.

```bash
% logadm -c /var/adm/exacct/proc
```

**EXAMPLE 2  Rotating syslog**

The following example rotates syslog and keeps eight log files. Old log files are put in the directory /var/oldlogs instead of /var/log:

```bash
% logadm -C8 -t"/var/oldlogs/syslog.$n" /var/log/syslog
```

**EXAMPLE 3  Rotating /var/adm/sulog and Expiring Based on Age**

The following entry in the /etc/logadm.conf file rotates the /var/adm/sulog file and expires any copies older than 30 days.

```
/var/adm/sulog -A 30d
```
EXAMPLE 4  Rotating Files and Expiring Based on Disk Usage
The following entry in the /etc/logadm.conf file rotates the /var/adm/sulog file and expires old log files when more than 100 megabytes are used by the sum of all the rotated log files.

/var/adm/sulog -S 100m

EXAMPLE 5  Creating an Entry that Stores the Logfile Name
This example creates an entry storing the log file name and the fact that we want to keep 20 copies in /etc/logadm.conf, but the -p never means the entry is ignored by the normal logadm run from root's crontab every morning.

% logadm -w locallog /usr/local/logfile -C20 -p never

Use the following entry on the command line to override the -p never option:

% logadm -p now locallog

EXAMPLE 6  Rotating the apache Error and Access Logs
The following example rotates the apache error and access logs monthly to filenames based on current year and month. It keeps the 24 most recent copies and tells apache to restart after renaming the logs.

This command is run once, and since the -w option is specified, an entry is made in /etc/logadm.conf so the apache logs are rotated from now on.

% logadm -w apache -p 1m -C 24\
   -t '/var/apache/old-logs/$basename.%Y-%m'\
   -a '/usr/apache/bin/apachectl graceful'\
   '/var/apache/logs/*{access,error}_log'

This example also illustrates that the entry name supplied with the -w option doesn't have to match the log file name. In this example, the entry name is apache and once the line has been run, the entry in /etc/logadm.conf can be forced to run by executing the following command:

% logadm -p now apache

Because the expression matching the apache log file names was enclosed in quotes, the expression is stored in /etc/logadm.conf, rather than the list of files that it expands to. This means that each time logadm runs from cron it expands that expression and checks all the log files in the resulting list to see if they need rotating.

The following command is an example without the quotes around the log name expression. The shell expands the last argument into a list of log files that exist at the time the command is entered, and writes an entry to /etc/logadm.conf that rotates the files.

logadm -w apache /var/apache/logs/*_log
Files
/etc/logadm.conf
configuration file for logadm command

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also chgrp(1), chmod(1), chown(1), crontab(1), csh(1), gzip(1), cron(1M), ctime(3C), strftime(3C), logadm.conf(4), attributes(5)

Notes When logadm applies expire conditions (supplied by the -A, -C, and -S options), it deletes files, the oldest first, until the conditions are satisfied. If the template used for naming the old logs contained $n or $N, logadm picks the highest value of $n or $N found in the old log file names first. If the template used is something else, logadm uses the modification time to determine which files to expire first. This might not be the expected behavior if an old log file has been modified since it was rotated.

Note that, depending on log file sizes and number of log files, log file rotations can be very time-consuming.

By default, logadm works in GMT. Therefore, all entries written to the /etc/logadm.conf file (see logadm.conf(4)) will have a GMT timestamp. Users can use the -l option to set logadm to local time.
logins(1M)

Name
logins – list user and system login information

Synopsis
/usr/bin/logins [-admopstux] [-g group...] [-l login_name...]

Description
This command displays information on user and system logins known to the system. Contents of the output is controlled by the command options and can include the following: user or system login, user id number, passwd account field value (user name or other information), primary group name, primary group id, multiple group names, multiple group ids, home directory, login shell, and four password aging parameters. The default information is the following: login id, user id, primary group name, primary group id and the account field value. Output is sorted by user id, system logins, followed by user logins.

Options
Options may be used together. If so, any login that matches any criteria are displayed.

The following options are supported:

- a
  Add two password expiration fields to the display. The fields show how many days a password can remain unused before it automatically becomes inactive, and the date that the password expires.

- d
  Selects logins with duplicate uids.

- g group
  Selects all users belonging to group, sorted by login. Multiple groups can be specified as a comma-separated list. When the -l and -g options are combined, a user is only listed once, even if the user belongs to more than one of the selected groups.

- l login_name...
  Selects the requested login. Multiple logins can be specified as a comma-separated list. Depending on the nameservice lookup types set in /etc/nsswitch.conf, the information can come from the /etc/passwd and /etc/shadow files and other nameservices. When the -l and -g options are combined, a user is only listed once, even if the user belongs to more than one of the selected groups.

- m
  Displays multiple group membership information.

- o
  Formats output into one line of colon-separated fields.

- p
  Selects logins with no passwords.

- s
  Selects all system logins.

- t
  Sorts output by login instead of by uid.
Selects all user logins.

- x
Prints an extended set of information about each selected user. The extended information includes home directory, login shell and password aging information, each displayed on a separate line. The password information currently consists of password status:

NP
Account has no password

LK
Account is locked for UNIX authentication

NL
Account is a no login account

UP
This account has not yet been activated by the administrator and cannot be used.

PS
Account probably has a valid password

UN
Account password status is unknown. That is, it is not a recognizable hashed password or any of the above entries. See crypt(3C) for valid password hashes.

If the login is passworded, status is followed by the date the password was last changed, the number of days required between changes, and the number of days allowed before a change is required. The password aging information shows the time interval that the user receives a password expiration warning message (when logging on) before the password expires.

**lpadmin** – configure the LP print service

**Synopsis**

`lpadmin -p printer {options}`

`lpadmin -x dest`

`lpadmin -d [dest]`

`lpadmin -S print-wheel -T [-A alert-type] [-W minutes] [ -Q requests]`

**Description**

lpadmin configures the LP print service by defining printers and devices. It is used to add and change printers, to remove printers from service, to set or change the system default destination, to define alerts for printer faults, and to mount print wheels.

**Options**

The `lpadmin` command has options for:

- Adding or changing a printer
- Removing a printer destination
- Setting or changing the system default destination
- Setting an alert for a print wheel

The options for each of the above categories are specified in the following subsections.

Several options support the use of lists. A list might contain, for example, user names, printers, printer forms, or content types. A list of multiple items can have the form of either comma-separated names or have the entire list enclosed by double quotes with a space between each name. For example, both lists below are acceptable:

```
one, two, three
"one two three"
```

**Adding or Changing a Printer**

The first form of the `lpadmin` command (`lpadmin -p printer {options}`) configures a new printer or changes the configuration of an existing printer. It also starts the print scheduler.

When creating a new printer, one of three options (-v, -U, or -s) must be supplied. In addition, only one of the following can be supplied: -e, -i, or -m; if none of these three options is supplied, the model standard is used. The -h and -l options are mutually exclusive. Printer and class names must be no longer than 14 characters and must consist entirely of the characters A-Z, a-z, 0-9, dash (-) and underscore (_). If -s is specified, the following options are invalid: -A, -e, -F, -h, -i, -l, -M, -m, -o, -U, -v, and -W.

The following options can appear in any order.

`-A alert-type [-W minutes]`

The -A option is used to define an alert that informs the administrator when a printer fault is detected, and periodically thereafter, until the printer fault is cleared by the administrator. The alert-types are:

```
mail Send the alert message using mail (see mail(1)) to the administrator.
```
**write**

Write the message to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is chosen arbitrarily.

**quiet**

Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the fault has been cleared and printing resumes, messages are sent again when another fault occurs with the printer.

**showfault**

Attempt to execute a fault handler on each system that has a print job in the queue. The fault handler is `/etc/lp/alerts/printer`. It is invoked with three parameters: `printer_name`, `date`, `file_name`. The `file_name` is the name of a file containing the fault message.

**none**

Do not send messages; any existing alert definition for the printer is removed. No alert is sent when the printer faults until a different alert-type (except `quiet`) is used.

**shell-command**

Run the `shell-command` each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Notice that the `mail` and `write` values for this option are equivalent to the values `mail user-name` and `write user-name` respectively, where `user-name` is the current name for the administrator. This is the login name of the person submitting this command unless he or she has used the `su` command to change to another user ID. If the `su` command has been used to change the user ID, then the `user-name` for the new ID is used.

**list**

Display the type of the alert for the printer fault. No change is made to the alert.

When a fault occurs, the printing subsystem displays a message indicating that printing for a specified printer has stopped and the reason for the stoppage. The message also indicates that printing will restart in a few minutes and that you can enter an `enable` command if you want to restart sooner than that.

Following a fault that occurs in the middle of a print job, the job is reprinted from the beginning. An exception to this occurs when you enter a command, such as the one shown below, that changes the page list to be printed.

```
% lp -i request-id -p ...
```

For a given print request, the presence of multiple reasons for failure indicate multiple attempts at printing.
The LP print service can detect printer faults only through an adequate fast filter and only when the standard interface program or a suitable customized interface program is used. Furthermore, the level of recovery after a fault depends on the capabilities of the filter.

If, instead of a single printer, the keyword `all` is displayed in an alert, the alert applies to all printers.

If the `-W` option is not used to arrange fault alerting for `printer`, the default procedure is to mail one message to the administrator of `printer` per fault. This is equivalent to specifying `-W once` or `-W 0`. If `minutes` is a number greater than zero, an alert is sent at intervals specified by `minutes`.

- `c class`
  Insert `printer` into the specified `class`. `class` is created if it does not already exist. This option requires the `-U dial-info` or `-v device` options.

- `D comment`
  Save this `comment` for display whenever a user asks for a full description of `printer` (see `lpstat(1)`). The LP print service does not interpret this comment.

- `e printer`
  Copy the interface program of an existing `printer` to be the interface program for `printer`. (Options `-i` and `-m` must not be specified with this option.)

- `-f allow:form-list`
- `-f deny:form-list`
  Allow or deny the forms in `form-list` to be printed on `printer`. By default no forms are allowed on a new printer.

For each printer, the LP print service keeps two lists of forms: an “allow-list” of forms that can be used with the printer, and a “deny-list” of forms that cannot be used with the printer. With the `-f allow` option, the forms listed are added to the allow-list and removed from the deny-list. With the `-f deny` option, the forms listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the forms in the list can be used on the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the forms in the deny-list cannot be used with the printer. All forms can be excluded from a printer by specifying `-f deny:all`. All forms can be used on a printer (provided the printer can handle all the characteristics of each form) by specifying `-f allow:all`.

The LP print service uses this information as a set of guidelines for determining where a form can be mounted. Administrators, however, are not restricted from mounting a form on any printer. If mounting a form on a particular printer is in disagreement with the information in the allow-list or deny-list, the administrator is warned but the mount is accepted. Nonetheless, if a user attempts to issue a print or change request for a form and printer combination that is in disagreement with the information, the request is accepted.
only if the form is currently mounted on the printer. If the form is later unmounted before the request can print, the request is canceled and the user is notified by mail.

If the administrator tries to specify a form as acceptable for use on a printer that does not have the capabilities needed by the form, the command is rejected.

Notice the other use of `-f`, with the `-h` option, below.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-f` option can be used.

- **-f fault-recovery**
  This option specifies the recovery to be used for any print request that is stopped because of a printer fault, according to the value of `fault-recovery`:

  - `continue` Continue printing on the top of the page where printing stopped. This requires a filter to wait for the fault to clear before automatically continuing.
  - `beginning` Start printing the request again from the beginning.
  - `wait` Disable printing on `printer` and wait for the administrator or a user to enable printing again.

  During the wait, the administrator or the user who submitted the stopped print request can issue a change request that specifies where printing should resume. (See the `-i` option of the `lp` command.) If no change request is made before printing is enabled, printing resumes at the top of the page where stopped, if the filter allows; otherwise, the request is printed from the beginning.

- **-h**
  Indicate that the device associated with the printer is hardwired. If neither of the mutually exclusive options, `-h` and `-l`, is specified, `-h` is assumed.

- **-i interface**
  Establish a new interface program for `printer`. `interface` is the pathname of the new program. (The `-e` and `-m` options must not be specified with this option.)

- **-I content-type-list**
  Allow `printer` to handle print requests with the content types listed in a `content-type-list`.

  The type `simple` is recognized as the default content type for files in the UNIX system. A `simple` type of file is a data stream containing only printable ASCII characters and the following control characters:

<table>
<thead>
<tr>
<th>Control Char</th>
<th>Octal Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACKSPACE</td>
<td>10</td>
<td>Move back one char, except...</td>
</tr>
</tbody>
</table>
To prevent the print service from considering `simple` a valid type for the printer, specify either an explicit value (such as the printer type) in the `content-type-list`, or an empty list. If you do want `simple` included along with other types, you must include `simple` in the `content-type-list`.

In addition to content types defined by the print administrator, the type `PostScript` is recognized and supported by the Solaris print subsystem. This includes filters to support `PostScript` as the printer content type.

The type `any` is recognized as a special content type for files. When declared as the input type for a printer, it signals the print sub-system not to do any filtering on the file before sending it to the printer.

Except for `simple` and `any`, each `content-type` name is determined by the administrator. If the printer type is specified by the `-T` option, then the printer type is implicitly considered to be also a valid content type.

- `l`
  Indicate that the device associated with `printer` is a login terminal. The LP scheduler (`lpsched`) disables all login terminals automatically each time it is started. (The `-h` option must not be specified with this option.)

- `m model`
  Select `model` interface program, provided with the LP print service, for the printer. (Options `-e` and `-i` must not be specified with this option.)

- `M -f form-name [-a [-o filebreak]] [-t tray-number]`
  Mount the form `form-name` on `printer`. Print requests that need the pre-printed form `form-name` is printed on `printer`. If more than one printer has the form mounted and the user has specified `any` (with the `-d` option of the `lp` command) as the printer destination, then the print request is printed on the one printer that also meets the other needs of the request.
The page length and width, and character and line pitches needed by the form are compared with those allowed for the printer, by checking the capabilities in the `terminfo` database for the type of printer. If the form requires attributes that are not available with the printer, the administrator is warned but the mount is accepted. If the form lists a print wheel as mandatory, but the print wheel mounted on the printer is different, the administrator is also warned but the mount is accepted.

If the `-a` option is given, an alignment pattern is printed, preceded by the same initialization of the physical printer that precedes a normal print request, with one exception: no banner page is printed. Printing is assumed to start at the top of the first page of the form. After the pattern is printed, the administrator can adjust the mounted form in the printer and press return for another alignment pattern (no initialization this time), and can continue printing as many alignment patterns as desired. The administrator can quit the printing of alignment patterns by typing `q`.

If the `-o filebreak` option is given, a formfeed is inserted between each copy of the alignment pattern. By default, the alignment pattern is assumed to correctly fill a form, so no formfeed is added.

If the `-t tray-number` option is specified, printer tray `tray-number` is used.

A form is “unmounted” either by mounting a new form in its place or by using the `-f none` option. By default, a new printer has no form mounted.

Notice the other use of `-f` without the `-M` option above.

**-M print-wheel**

Mount the `print-wheel` on `printer`. Print requests that need the `print-wheel` are printed on `printer`. If more than one printer has `print-wheel` mounted and the user has specified any (with the `-d` option of the `lp` command) as the printer destination, then the print request is printed on the one printer that also meets the other needs of the request.

If the `print-wheel` is not listed as acceptable for the printer, the administrator is warned but the mount is accepted. If the printer does not take print wheels, the command is rejected.

A print wheel is “unmounted” either by mounting a new print wheel in its place or by using the option `-S none`. By default, a new printer has no print wheel mounted.

Notice the other uses of the `-S` option without the `-M` option described below.

**-n ppdfilename**

Specify a PPD file for creating and modifying printer queues. `ppdfilename` is the full path and file name to the PPD file. Used in conjunction with the `-p`, `-d`, `-x`, or `-S` options.

**-o option**

The `-o` option defines default printer configuration values given to an interface program. The default can be explicitly overwritten for individual requests by the user (see `lp(1)`), or taken from a preprinted form description (see `lpforms(1M)` and `lp(1)`).
There are several options which are predefined by the system. In addition, any number of key-value pairs can be defined. See the section “Predefined Options Used with the -o Option”, below.

- **-P** **paper-name**
  Specify a paper type list that the printer supports.

- **-r** **class**
  Remove printer from the specified class. If printer is the last member of class, then class is removed.

- **-S** **list**
  Allow either the print wheels or aliases for character sets named in list to be used on the printer.

  If the printer is a type that takes print wheels, then list is a comma or space separated list of print wheel names. These are the only print wheels considered mountable on the printer. (You can always force a different print wheel to be mounted.) Until the option is used to specify a list, no print wheels are considered mountable on the printer, and print requests that ask for a particular print wheel with this printer are rejected.

  If the printer is a type that has selectable character sets, then list is a list of character set name “mappings” or aliases. Each “mapping” is of the form known-name=alias The known-name is a character set number preceded by cs (such as cs3 for character set three) or a character set name from the terminfo database entry csnm. See terminfo(4). If this option is not used to specify a list, only the names already known from the terminfo database or numbers with a prefix of cs is acceptable for the printer. If list is the word none, any existing print wheel lists or character set aliases are removed.

Notice the other uses of the -S with the -M option described above.

The -T option must be invoked first with lpadmin to identify the printer type before the -S option can be used.

- **-s** **system-name**
  The -s option can be used for both remote or local printers. For remote printers:

  - **-s** **system-name[!printer-name]** (UUCP format)
  - **-s** **printer-name@system-name** (RCMD format)

  Make a remote printer (one that must be accessed through another system) accessible to users on your system. system-name is the name of the remote system on which the remote printer is located. printer-name is the name used on the remote system for that printer. For example, if you
want to access printer1 on system1 and you want it called printer2 on your system:

- p printer2 - s system1!printer1
- p printer2 - s printer1@system1

- s scheme://end-point (URI format) Make a remote printer (one that must be accessed through another system) accessible to users on your system. The supported schemes include lpd and ipp. Specify URI's using the lpd format as follows:

lpd://server/printers/queue[#Solaris]

URI's using the ipp format are defined by the remote print server. They are generally of the format:

ipp://server/printers/queue

In either case, server specifies the hostname or IP address of the remote print server, queue specifies the name of the print queue on the remote print server, and the optional #Solarisspecifies that the remote print server is a Solaris server when lpd URI format is being used.

For example:

- p printer - s lpd://server/printers/queue#Solaris
- p printer - s ipp://server/printers/queue

For local printers:

- s "localhost” Use localhost for the system-name to be used by the print service. In an environment where the nodename is variable, print queues are invalidated when the nodename changes. Using localhost as the system-name allows print queues to be maintained across changing nodenames. The system-name, as used by the print service, is only set to localhost when explicitly set with this option; by default, ladmin sets system-name to nodename. For example, if you want to configure a new printer on the local system, and want it called printer3:

- p printer3 - s localhost - v device
This option should never be used when creating name service maps.

- T printer-type-list
Identify the printer as being of one or more printer-types. Each printer-type is used to extract data from the terminfo database; this information is used to initialize the printer before printing each user's request. Some filters might also use a printer-type to convert content for the printer. If this option is not used, the default printer-type is unknown. No information is extracted from terminfo so each user request is printed without first initializing the printer. Also, this option must be used if the following are to work: -o cp1, -o lpi, -o width, and -o length options of the lpadmin and lp commands, and the -S and -f options of the lpadmin command.

If the printer-type-list contains more than one type, then the content-type-list of the -I option must either be specified as simple, as empty (-I ""), or not specified at all.

- t number-of-trays
Specify the number of trays when creating the printer.

- u allow: login-ID-list
- u deny: login-ID-list
Allow or deny the users in login-ID-list access to the printer. By default all users are allowed on a new printer. The login-ID-list argument can include any or all of the following constructs:

  login-ID           a user on any system
  system-name!login-ID    a user on system system-name
  system-name!all          all users on system system-name
  all!login-ID         a user on all systems
  all                  all users on all systems

For each printer, the LP print service keeps two lists of users: an “allow-list” of people allowed to use the printer, and a “deny-list” of people denied access to the printer. With the -u allow option, the users listed are added to the allow-list and removed from the deny-list. With the -u deny option, the users listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the users in the list can use the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the users in the deny-list cannot use the printer. All users can be denied access to the printer by specifying -u deny: all. All users can use the printer by specifying -u allow: all.

The -U option allows your print service to access a remote printer. (It does not enable your print service to access a remote printer service.) Specifically, -U assigns the “dialing” information dial-info to the printer. dial-info is used with the dial routine to call the printer. Any network connection supported by the Basic Networking Utilities works.
`dial-info` can be either a phone number for a modem connection, or a system name for other kinds of connections. Or, if `-U direct` is given, no dialing takes place, because the name `direct` is reserved for a printer that is directly connected. If a system name is given, it is used to search for connection details from the file `/etc/uucp/Systems` or related files. The Basic Networking Utilities are required to support this option. By default, `-U direct` is assumed.

**-v device**
Associate a `device` with `printer`. The `device` is the path name of a file that is writable by `lp`. Notice that the same `device` can be associated with more than one printer.

**-v scheme://end-point**
Associate a network attached device with `printer`. The `scheme` is the method or protocol used to access the network attached device and `end-point` is the information necessary to contact that network attached device. Use of this device format requires the use of the `uri` interface script and can only be used with the `smb` scheme at this time.

For example:
```bash
# lpadmin -p queue -v smb://smb-service/printer -m uri
```

See the `/usr/sfw/man/man1m/smbspool.1m` man page for details.

**Removing a Printer Destination**

The `-x dest` option removes the destination `dest` (a printer or a class), from the LP print service. If `dest` is a printer and is the only member of a class, then the class is deleted, too. If `dest` is a `class`, all printers and classes are removed. If there are no remaining local printers and the scheduler is still running, the scheduler is shut down.

No other options are allowed with `-x`.

**Setting/Changing the System Default Destination**

The `-d [dest]` option makes `dest` (an existing printer or class) the new system default destination. If `dest` is not supplied, then there is no system default destination. No other options are allowed with `-d`.

**Setting an Alert for a Print Wheel**

The `-S print-wheel [-A alert-type] [-W minutes] [-Q requests] -T`

The `-S print-wheel` option is used with the `-A alert-type` option to define an alert to mount the print wheel when there are jobs queued for it. If this command is not used to arrange alerting for a print wheel, no alert is sent for the print wheel. Notice the other use of `-A`, with the `-p` option, above.

The `alert-types` are:

- `mail` Send the alert message using the `mail` command to the administrator.
- `write` Write the message, using the `write` command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.
quiet
Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the print-wheel has been mounted and subsequently unmounted, messages are sent again when the number of print requests reaches the threshold specified by the -Q option.

none
Do not send messages until the -A option is given again with a different alert-type (other than quiet).

shell-command
Run the shell-command each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blanks embedded in the command, enclose the command in quotes. Notice that the mail and write values for this option are equivalent to the values mail user-name and write user-name respectively, where user-name is the current name for the administrator. This is the login name of the person submitting this command unless he or she has used the su command to change to another user ID. If the su command has been used to change the user ID, then the user-name for the new ID is used.

list
Display the type of the alert for the print wheel on standard output. No change is made to the alert.

The message sent appears as follows:

The print wheel print-wheel needs to be mounted on the printer(s):
printer(integer1requests) integer2 print requests
await this print wheel.

The printers listed are those that the administrator had earlier specified were candidates for this print wheel. The number integer1 listed next to each printer is the number of requests eligible for the printer. The number integer2 shown after the printer list is the total number of requests awaiting the print wheel. It is less than the sum of the other numbers if some requests can be handled by more than one printer.

If the print-wheel is all, the alerting defined in this command applies to all print wheels already defined to have an alert.

If the -W option is not given, the default procedure is that only one message is sent per need to mount the print wheel. Not specifying the -W option is equivalent to specifying -W once or -W 0. If minutes is a number greater than zero, an alert is sent at intervals specified by minutes.

If the -Q option is also given, the alert is sent when a certain number (specified by the argument requests) of print requests that need the print wheel are waiting. If the -Q option is not given, or requests is 1 or any (which are both the default), a message is sent as soon as
anyone submits a print request for the print wheel when it is not mounted.

A number of options, described below, are predefined for use with -o. These options are used for adjusting printer capabilities, adjusting printer port characteristics, configuring network printers, and controlling the use of banner. The -o also supports an arbitrary keyword=value format, which is referred to below as an undefined option.

The length, width, cpi, and lpi parameters can be used in conjunction with the -o option to adjust printer capabilities. The format of the parameters and their values is as follows:

length=scaled-decimal-number
width=scaled-decimal-number
cpi=scaled-decimal-number
lpi=scaled-decimal-number

The term scaled-decimal-number refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number. Three types of scaled-decimal-numbers can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing c); numbers that show sizes in inches (marked with a trailing i); and numbers that show sizes in units appropriate to use (without a trailing letter), that is, lines, characters, lines per inch, or characters per inch.

The option values must agree with the capabilities of the type of physical printer, as defined in the terminfo database for the printer type. If they do not, the command is rejected.

The defaults are defined in the terminfo entry for the specified printer type. The defaults can be reset by:

lpadmin -p printername -o length=
lpadmin -p printername -o width=
lpadmin -p printername -o cpi=
lpadmin -p printername -o lpi=

You use the stty keyword in conjunction with the o option to adjust printer port characteristics. The general form of the stty portion of the command is:

stty="stty-option-list"

The stty-option-list is not checked for allowed values, but is passed directly to the stty program by the standard interface program. Any error messages produced by stty when a request is processed (by the standard interface program) are mailed to the user submitting the request.

The default for stty is:

stty="9600 cs8 -cstopb -parenb iixon
     -ixany opos -olcuc onlcr
     -ocrnl -onocr
     -onlret -ofill nl0 cr0 bs0 vt0 ff0"
The default can be reset by:

```
lpadmin -p printername -o stty=
```

### Configuring Network Printers

The `dest`, `protocol`, `bsdctrl`, and `timeout` parameters are used in conjunction with the `-o` option to configure network printers. The format of these keywords and their assigned values is as follows:

```
dest=string  protocol=string  bsdctrl=string  \n  timeout=non-negative-integer-seconds
```

These four options are provided to support network printing. Each option is passed directly to the interface program; any checking for allowed values is done there.

The value of `dest` is the name of the destination for the network printer; the semantics for value `dest` are dependent on the printer and the configuration. There is no default.

The value of option `protocol` sets the over-the-wire protocol to the printer. The default for option `protocol` is `bsd`. The value of option `bsdctrl` sets the print order of control and data files (BSD protocol only); the default for this option is `control file first`. The value of option `timeout` sets the seed value for backoff time when the printer is busy. The default value for the `timeout` option is 10 seconds. The defaults can be reset by:

```
lpadmin -p printername -o protocol=
lpadmin -p printername -o bsdctrl=
lpadmin -p printername -o timeout=
```

### Controlling the Use of the Banner Page

Use the following commands to control the use of the banner page:

```
lpadmin -p printer -o nobanner
lpadmin -p printer -o banner
lpadmin -p printer -o banner=always
lpadmin -p printer -o banner=never
lpadmin -p printer -o banner=optional
```

The first and fifth commands (`-o nobanner` and `-o banner=optional`) are equivalent. The default is to print the banner page, unless a user specifies `-o nobanner` on an `lp` command line.

The second and third commands (`-o banner` and `-o banner=always`) are equivalent. Both cause a banner page to be printed always, even if a user specifies `lp -o nobanner`. The root user can override this command.

The fourth command (`-o banner=never`) causes a banner page never to be printed, even if a user specifies `lp -o banner`. The root user can override this command.

### Undefined Options

The `-o` option supports the use of arbitrary, user-defined options with the following format:
key=value

Each key=value is passed directly to the interface program. Any checking for allowed values is done in the interface program.

Any default values for a given key=value option are defined in the interface program. If a default is provided, it can be reset by typing the key without any value:

```
lpadmin -p printername -o key=
```

Sets boolean values foo=true | foo=false.

**Examples**

In the following examples, prtr can be any name up to 14 characters and can be the same name as the ping(1M) name.

**EXAMPLE 1** Configuring an HP Postscript Printer with a Jet Direct Network Interface

The following example configures an HP postscript printer with a jet direct network interface:

```
example# lpadmin -p prtr -v /dev/null -m netstandard \n    -o dest=ping_name_of_prtr:9100 -o protocol=tcp -T PS -I \n    postscript
example# enable prtr
example# accept prtr
```

**EXAMPLE 2** Configuring a Standard Postscript Network Printer

The following example configures a standard postscript network printer:

```
example# lpadmin -p prtr -v /dev/null -m netstandard \n    -o dest=ping_name_of_prtr -T PS -I postscript
example# enable prtr
example# accept prtr
```

**Exit Status**

The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

System Administration Guide: Basic Administration

Notes  When using lpadmin to provide access to a remote printer, remote configuration data is stored in /etc/printers.conf. This data includes a bsdaddr and a printer-uri-supported attribute. The data in this file can be shared through the use of a network name service or replicated across multiple systems. If the data is shared, it is important to make sure that the bsdaddr and printer-uri-supported contain hostname information that is correctly resolved on all hosts sharing this data. Also, the printer-uri-supported is the preferred means of accessing remote print service. The bsdaddr is supplied for backward compatibility with Solaris 2.6-10 systems.
**Name**  
lpfilter – administer filters used with the LP print service

**Synopsis**  
/usr/sbin/lpfilter \(-f\) *filter-name*  
\{ \(\cdot\) | \(-i\) | \(-l\) | \(-x\) \(\cdot\) \(-F\) *pathname* \}

**Description**  
The `lpfilter` command is used to add, change, delete, or list a filter used with the LP print service. These filters convert the content of a file to have a content type acceptable to a printer.

**Options**  
Arguments consist of the `-f` *filter-name* option and exactly one of the arguments appearing within braces ({} in the SYNOPSIS.

- Adds or changes a filter as specified from standard input. The format of the input is specified below. If `-f all` is specified with the – option, the specified change is made to all existing filters. This is not useful.

- `-f` *filter-name*  
  Specifies the *filter-name* of the filter to be added, changed, reset, deleted, or listed. The filter name `all` is a special filter name defined below. The `-f` option is required.

- `-F` *pathname*  
  Adds or changes a filter as specified by the contents of the file *pathname*. The format of the file’s contents is specified below. If `-f all` is specified with the `-F` option, the specified change is made to all existing filters. This is not useful.

- `-i`  
  Resets a filter to its default settings. Using `-f all` with the `-i` option restores all filters for which predefined settings are available to their original settings.

- `-l`  
  Lists a filter description. Using `-f all` with the `-l` option produces a list of all filters.

- `-x`  
  Deletes a filter. Using `-f all` with the `-x` option results in all filters being deleted.

**Usage**  

### Adding or Changing a Filter  
The filter named in the `-f` option is added to the filter table. If the filter already exists, its description is changed to reflect the new information in the input.

When `–` is specified, standard input supplies the filter description. When `-F` is specified, the file *pathname* supplies the filter description. One of these two options must be specified to add or change a filter.

When an existing filter is changed with the `-F` or `–` option, lines in the filter description that are not specified in the new information are not changed. When a new filter is added with this command, unspecified lines receive default values. See below.

Filters are used to convert the content of a request from its initial type into a type acceptable to a printer. For a given print request, the LP print service knows the following:
The content type of the request (specified by `lp -T` or determined implicitly).

The name of the printer (specified by `lp -d`).

The printer type (specified by `lpadmin -T`).

The printer type is intended to be a printer model, but some people specify it with a content type even though `lpadmin -I` is intended for this purpose.

The content types acceptable to the printer (specified by `lpadmin -I`).

The values specified by the `lpadmin -T` are treated as if they were specified by the `-I` option as well.

The modes of printing asked for by the originator of the request (specified by various options to `lp`).

The system uses the above information to construct a list of one or more filters that converts the document's content type into a content type acceptable to the printer and consumes all `lp` arguments that invoke filters (`-y` and `-P`).

The contents of the file (specified by the `-F` option) and the input stream from standard input (specified by `−`) must consist of a series of lines, such that each line conforms to the syntax specified by one of the seven lines below. All lists are comma or space separated. Each item contains a description.

**Input types:** `content-type-list`

**Output types:** `content-type-list`

**Printer types:** `printer-type-list`

**Printers:** `printer-list`

**Filter type:** `filter-type`

**Command:** `shell-command`

**Options:** `template-list`

**Input types**: This gives the content types that can be accepted by the filter. The default is any. The document content type must be a member of this list for the initial filter in the sequence.

**Output types**: This gives the content types that the filter can produce from any of the input (content) types. The default is any. The intersection of the output types of this list and the content types acceptable to the printer (from `lpadmin -I` and `lpadmin -T`) must be non-null for the last filter in the sequence. For adjacent filters in the sequence, the intersection of output types of one and the input types of the next must be non-null.

**Printer types**: This gives the printer types for which this printer can be used. The LP print service will restrict the use of the filter to these printer types (from `lpadmin -T`). The default is any.
Printers
This gives the names of the printers for which the filter can be used. The LP print service will restrict the use of the filter to just the printers named. The default is any.

Filter type
This marks the filter as a slow filter or a fast filter. Slow filters are generally those that take a long time to convert their input (that is, minutes or hours). They are run before the job is scheduled for a printer, to keep the printers from being tied up while the filter is running. If a listed printer is on a remote system, the filter type for it must have the value slow. That is, if a client defines a filter, it must be a slow filter. Fast filters are generally those that convert their input quickly (that is, faster than the printer can process the data), or those that must be connected to the printer when run. Fast filters will be given to the interface program to run while connected to the physical printer.

Command
This specifies which program to run to invoke the filter. The full program pathname as well as fixed options must be included in the shell-command; additional options are constructed, based on the characteristics of each print request and on the Options field. A command must be given for each filter. The command must accept a data stream as standard input and produce the converted data stream on its standard output. This allows filter pipelines to be constructed to convert data not handled by a single filter.

Options
This is a comma-separated list of templates used by the LP print service to construct options to the filter from the characteristics of each print request listed in the table later. The -y and -P arguments to the lp command cause a filter sequence to be built even if there is no need for a conversion of content types.

In general, each template is of the following form:

```
keyword pattern = replacement
```

The keyword names the characteristic that the template attempts to map into a filter-specific option; each valid keyword is listed in the table below.

A pattern is one of the following: a literal pattern of one of the forms listed in the table, a single asterisk (*), or a regular expression. If pattern matches the value of the characteristic, the template fits and is used to generate a filter-specific option. The replacement is what will be used as the option.

Regular expressions are the same as those found on the regexp(5) manual page. This includes the \( \ldots \) and \n constructions, which can be used to extract portions of the pattern for copying into the replacement, and the &, which can be used to copy the entire pattern into the replacement.
The replacement can also contain a *; it too, is replaced with the entire pattern, just like the & of \texttt{regexp(5)}.

The keywords are:

### Resetting a Filter to Defaults

If the filter named is one originally delivered with the LP print service, the \texttt{-i} option restores the original filter description.

### Deleting a Filter

The \texttt{-x} option is used to delete the filter specified in filter-name from the LP filter table.

### Listing a Filter Description

The \texttt{-l} option is used to list the description of the filter named in filter-name. If the command is successful, the following message is sent to standard output:

\textit{Input types: content-type-list}
\textit{Output types: content-type-list}
\textit{Printer types: printer-type-list}
Printers: *printer-list*
Filter type: *filter-type*
Command: *shell-command*
Options: *template-list*

If the command fails, an error message is sent to standard error.

**Large File Behavior**
See [largefile(5)] for the description of the behavior of `lpfilter` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**Examples**

**EXAMPLE 1**  Printing with the landscape option
For example, the template

```plaintext
MODES landscape = -l
```

shows that if a print request is submitted with the `-y landscape` option, the filter will be given the option `-l`.

**EXAMPLE 2**  Selecting the printer type
As another example, the template

```plaintext
TERM * = -T *
```

shows that the filter will be given the option `-T printer-type` for whichever `printer-type` is associated with a print request using the filter.

**EXAMPLE 3**  Using the keywords table
Consider the template

```plaintext
MODES prwidth\=\((.*)\) = -w\1
```

Suppose a user gives the command

```plaintext
lp -y prwidth=10
```

From the table above, the LP print service determines that the `-y` option is handled by a `MODES` template. The `MODES` template here works because the pattern `prwidth\=\(` matches the `prwidth=10` given by the user. The replacement `-w1` causes the LP print service to generate the filter option `-w10`. If necessary, the LP print service will construct a filter pipeline by concatenating several filters to handle the user's file and all the print options. See `sh(1)` for a description of a pipeline. If the print service constructs a filter pipeline, the `INPUT` and `OUTPUT` values used for each filter in the pipeline are the types of input and output for that filter, not for the entire pipeline.

**Exit Status**  The following exit values are returned:

<table>

System Administration Guide: Basic Administration

Notes

If the lp command specifies more than one document, the filtering chain is determined by the first document. Other documents may have a different format, but they will print correctly only if the filter chain is able to handle their format.
Name

lpforms – administer forms used with the LP print service

Synopsis

lpforms [-f form-name] option

lpforms -f form-name -A alert-type [-P paper-name [-d]]
[-Q requests] [-W minutes]

Description

The lpforms command administers the use of preprinted forms, such as company letterhead paper, with the LP print service. A form is specified by its form-name. Users may specify a form when submitting a print request (see lp(1)). The argument all can be used instead of form-name with either of the command lines shown above. The first command line allows the administrator to add, change, and delete forms, to list the attributes of an existing form, and to allow and deny users access to particular forms. The second command line is used to establish the method by which the administrator is alerted that the form form-name must be mounted on a printer.

Options

The following options are supported:

- **-f form-name**  
  Specify a form.

The first form of lpforms requires that one of the following options (-, -l, -F, -x) must be used:

- **-F pathname**  
  To add or change form form-name, as specified by the information in pathname.

-  
  To add or change form form-name, as specified by the information from standard input.

- **-l**  
  To list the attributes of form form-name.

- **-x**  
  To delete form form-name (this option must be used separately; it may not be used with any other option).

The second form of the lpforms command requires the -A alert-type option. The other options are optional.

- **-A alert-type**  
  Defines an alert to mount the form when there are queued jobs which need it.

- **-P paper-name [-d]**  
  Specify the paper name when creating the form. If -d is specified, this paper is the default.

- **-Q requests**  
  An alert will be sent when a certain number of print requests that need the form are waiting.

- **-W minutes**  
  An alert will be sent at intervals specified by minutes.

Usage
Adding or Changing a Form

The `-F pathname` option is used to add a new form, `form-name`, to the LP print service, or to change the attributes of an existing form. The form description is taken from `pathname` if the `-F` option is given, or from the standard input if the `−` option is used. One of these two options must be used to define or change a form.

`pathname` is the path name of a file that contains all or any subset of the following information about the form.

- **Page length:** `scaled-decimal-number1`
- **Page width:** `scaled-decimal-number2`
- **Number of pages:** `integer`
- **Line pitch:** `scaled-decimal-number3`
- **Character pitch:** `scaled-decimal-number4`
- **Character set choice:** `character-set/print-wheel` [mandatory]
- **Ribbon color:** `ribbon-color`
- **Comment:** `comment`
- **Alignment pattern:** `[content-type]`  
  `content`

The term "scaled-decimal-number" refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a "trailing" letter attached to the number. Three types of scaled decimal numbers can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing `c`); numbers that show sizes in inches (marked with a trailing `i`); and numbers that show sizes in units appropriate to use (without a trailing letter); lines, characters, lines per inch, or characters per inch.

Except for the last two lines, the above lines may appear in any order. The `Comment:` and `comment` items must appear in consecutive order but may appear before the other items, and the `Alignment pattern:` and the `content` items must appear in consecutive order at the end of the file. Also, the `comment` item may not contain a line that begins with any of the key phrases above, unless the key phrase is preceded with a `>` sign. Any leading `>` sign found in the `comment` will be removed when the comment is displayed. There is no case distinction among the key phrases.

When this command is issued, the form specified by `form-name` is added to the list of forms. If the form already exists, its description is changed to reflect the new information. Once added, a form is available for use in a print request, except where access to the form has been restricted, as described under the `-u` option. A form may also be allowed to be used on certain printers only.

A description of each form attribute is below:

**Page length and Page Width**

Before printing the content of a print request needing this form, the generic interface program provided with the LP print service will initialize the physical printer to handle pages `scaled-decimal-number1` long, and
scaled-decimal-number2 wide using the printer type as a key into the \texttt{terminfo(4)} database. The page length and page width will also be passed, if possible, to each filter used in a request needing this form.

**Number of pages**

Each time the alignment pattern is printed, the LP print service will attempt to truncate the \textit{content} to a single form by, if possible, passing to each filter the page subset of \texttt{1\textdaggerDash integer}.

**Line pitch and Character pitch**

Before printing the content of a print request needing this form, the interface program provided with the LP print service will initialize the physical printer to handle these pitches, using the printer type as a key into the \texttt{terminfo(4)} database. Also, the pitches will be passed, if possible, to each filter used in a request needing this form. \texttt{scaled-decimal-number3} is in lines-per-centimeter if a \texttt{c} is appended, and lines-per-inch otherwise; similarly, \texttt{scaled-decimal-number4} is in characters-per-centimeter if a \texttt{c} is appended, and characters-per-inch otherwise. The character pitch can also be given as \texttt{elite} (12 characters-per-inch), \texttt{pica} (10 characters-per-inch), or \texttt{compressed} (as many characters-per-inch as possible).

**Character set choice**

When the LP print service alerts an administrator to mount this form, it will also mention that the print wheel \texttt{print-wheel} should be used on those printers that take print wheels. If printing with this form is to be done on a printer that has selectable or loadable character sets instead of print wheels, the interface programs provided with the LP print service will automatically select or load the correct character set. If \texttt{mandatory} is appended, a user is not allowed to select a different character set for use with the form; otherwise, the character set or print wheel named is a suggestion and a default only.

**Ribbon color**

When the LP print service alerts an administrator to mount this form, it will also mention that the color of the ribbon should be \texttt{ribbon-color}.

**Comment**

The LP print service will display the \textit{comment} unaltered when a user asks about this form (see \texttt{lpstat(1)}).
Alignment pattern

When mounting this form, an administrator can ask for the content to be printed repeatedly, as an aid in correctly positioning the preprinted form. The optional content-type defines the type of printer for which content had been generated. If content-type is not given, simple is assumed. Note that the content is stored as given, and will be readable only by the user lp.

When an existing form is changed with this command, items missing in the new information are left as they were. When a new form is added with this command, missing items will get the following defaults:

- Page Length: 66
- Page Width: 80
- Number of Pages: 1
- Line Pitch: 6
- Character Pitch: 10
- Character Set Choice: any
- Ribbon Color: any

LP print service: The -x option is used to delete the form form-name from the LP print service.

The -l option is used to list the attributes of the existing form form-name. The attributes listed are those described under Adding and Changing a Form, above. Because of the potentially sensitive nature of the alignment pattern, only the administrator can examine the form with this command. Other people may use the lpstat(1) command to examine the non-sensitive part of the form description.

The -u option, followed by the argument allow:login-ID-list or -u deny:login-ID-list lets you determine which users will be allowed to specify a particular form with a print request. This option can be used with the -F or – option, each of which is described above under Adding or Changing a Form.

The login-ID-list argument may include any or all of the following constructs:

- login-ID: A user on any system
- system_name!login-ID: A user on system system_name
- system_name!all: All users on system system_name
- all!login-ID: A user on all systems
- all: All users on all systems

The LP print service keeps two lists of users for each form: an “allow-list” of people allowed to use the form, and a “deny-list” of people that may not use the form. With the -u allow option, the users listed are added to the allow-list and removed from the deny-list. With the -u deny
option, the users listed are added to the deny-list and removed from the allow-list. (Both forms of the -u option can be run together with the -F or the − option.)

If the allow-list is not empty, only the users in the list are allowed access to the form, regardless of the content of the deny-list. If the allow-list is empty but the deny-list is not, the users in the deny-list may not use the form, (but all others may use it). All users can be denied access to a form by specifying -f deny:all. All users can be allowed access to a form by specifying -f allow:all. (This is the default.)

The -f form-name option is used with the -A alert-type option to define an alert to mount the form when there are queued jobs which need it. If this option is not used to arrange alerting for a form, no alert will be sent for that form.

The method by which the alert is sent depends on the value of the alert-type argument specified with the -A option. The alert-types are:

- **mail** Send the alert message using the mail command to the administrator.

- **write** Write the message, using the write command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.

- **quiet** Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form form-name has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the -Q option.

- **showfault** Attempt to execute a form alert handler on each system that has a print job for that form in the queue. The fault handler is /etc/lp/alerts/form. It is invoked with three parameters: form_name, date, file_name. file_name is the name of a file containing the form alert message.

- **none** Do not send messages until the -A option is given again with a different alert-type (other than quiet).

- **shell-command** Run the shell-command each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the mail and write values for this option are equivalent to the values mail login-ID and write login-ID respectively, where login-ID is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the su command to change to another login-ID. If the su command has been used to change the user ID, then the user-name for the new ID is used.

- **list** Display the type of the alert for the form on standard output. No change is made to the alert.
The message sent appears as follows:

The form *form-name* needs to be mounted on the printer(s): *printer* (`integer1` requests).
`integer2` print requests await this form.
Use the *ribbon-color* ribbon. Use the *print-wheel* print wheel, if appropriate.

The printers listed are those that the administrator has specified as candidates for this form. The number `integer1` listed next to each printer is the number of requests eligible for the printer. The number `integer2` shown after the list of printers is the total number of requests awaiting the form. It will be less than the sum of the other numbers if some requests can be handled by more than one printer. The *ribbon-color* and *print-wheel* are those specified in the form description. The last line in the message is always sent, even if none of the printers listed use print wheels, because the administrator may choose to mount the form on a printer that does use a print wheel.

Where any color ribbon or any print wheel can be used, the statements above will read:

Use any ribbon.
Use any print-wheel.

If `form-name` is *any*, the *alert-type* defined in this command applies to any form for which an alert has not yet been defined. If `form-name` is *all*, the *alert-type* defined in this command applies to all forms.

If the `-W minutes` option is not given, the default procedure is that only one message will be sent per need to mount the form. Not specifying the `-W` option is equivalent to specifying `-W once` or `-W 0`. If `minutes` is a number greater than 0, an alert will be sent at intervals specified by `minutes`.

If the `-Q requests` option is also given, the alert will be sent when a certain number (specified by the argument `requests`) of print requests that need the form are waiting. If the `-Q` option is not given, or the value of `requests` is 1 or any (which are both the default), a message is sent as soon as anyone submits a print request for the form when it is not mounted.

The `-f` option, followed by the `-A` option and the argument `list` is used to list the *alert-type* that has been defined for the specified form `form-name`. No change is made to the alert. If `form-name` is recognized by the LP print service, one of the following lines is sent to the standard output, depending on the type of alert for the form.

- When `requests` requests are queued: alert with `shell-command` every `minutes` minutes
- When `requests` requests are queued: write to `user-name` every `minutes` minutes
- When `requests` requests are queued: mail to `user-name` every `minutes` minutes
- No alert
The phrase every minutes is replaced with once if minutes (-Wminutes) is 0.

Terminating an Active Alert
The -quiet option is used to stop messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form has been mounted and then unmounted, messages will again be sent when the number of print requests reaches the threshold requests.

Removing an Alert Definition
No messages will be sent after the -A none option is used until the -A option is given again with a different alert-type. This can be used to permanently stop further messages from being sent as any existing alert definition for the form will be removed.

Large File Behavior
See largefile(5) for the description of the behavior of lpforms when encountering files greater than or equal to 2 Gbyte (2\(^{31}\) bytes).

Exit Status
The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

Files
/etc/lp/alerts/form Fault handler for lpform.

System Administration Guide: Basic Administration
The `lpget` utility reads printing configuration information from the configuration databases in `$HOME/.printers`, `/etc/printers.conf`, `printers.conf.byname`, and `printers.org_dir` printer. This information, called a configuration report, is displayed to the standard output. See `printers(4)` and `printers.conf(4)` for information about the printer configuration databases.

`lpget` displays a configuration report for all keys for the specified destination or destinations by default. Use the `-k` option to display a configuration report for specific keys. Use the `list` operand to display a configuration report for all configured destinations.

**Options**
The following option is supported:

- `-k key` Displays a configuration report for `key`. See `printers.conf(4)` for information about specifying `key`.

**Operands**
The following operands are supported:

- `destination` Displays a configuration report for `destination`. Destination can be either a printer of a class of printers. See `lpadmin(1M)`. Specify `destination` using atomic or POSIX-style (`server:destination`) names. See `printers.conf(4)` for information regarding the naming conventions for atomic names and `standards(5)` for information concerning POSIX.

- `list` Displays a configuration report for all configured destinations.

**Examples**

**EXAMPLE 1** Displaying a Configuration Report for the `bsdaddr` Key

The following example displays a configuration report for the `bsdaddr` key for printer `catalpa`.

`example% lpget -k bsdaddr catalpa`

**EXAMPLE 2** A Configuration Report for all Keys for all Configured Destinations

The following example displays a configuration report for all keys for all configured destinations.

`example% lpget list`

**Exit Status**
The following exit values are returned:

- `0` Successful completion.
- non-zero An error occurred.

Notes

Be mindful of the following if the LDAP database is used as the name service. If the ldapclient(1M) server is a replica LDAP server, LDAP printer database updates may not appear immediately, as the replica server may not have been updated by the master server and can be out of sync. For example, a printer that you deleted by using lpset(1M) may still appear in the printer list you display with lpget until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. Refer to the System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP) for more information on LDAP replication.
lpmove(1M)

Name  lpmove – move print requests

Synopsis  lpmove  [request-ID]  destination
           lpmove  source  destination

Description  The lpmove command moves print requests queued by \( \texttt{lp}(1) \) or \( \texttt{lpr}(1B) \) between destinations.

The first form of \( \texttt{lpmove} \) moves specific print requests (request-ID) to a specific destination.

The second form of the \( \texttt{lpmove} \) command moves all print requests from one destination (destination1) to another (destination2). This form of \( \texttt{lpmove} \) also rejects new print requests for destination1.

\( \texttt{lpmove} \) moves individual requests or entire queues only within an instance of a print service, not between a local and a remote queue or local queues on different instances of a print service. Requests can only be moved if the print service or protocol supports it. The LP print server and IPP print protocol both support moving requests between queues. The BSD print protocol does not.

When moving requests, \( \texttt{lpmove} \) does not check the acceptance status of the destination to which the print requests are being moved (see \( \texttt{accept}(1M) \)). \( \texttt{lpmove} \) does not move requests that have options (for example, content type or requiring a special form) that cannot be handled by the new destination.

Operands  The following operands are supported:

request-ID  The specific print request to be moved. Specify request-ID as the identifier associated with a print request as reported by \( \texttt{lpstat} \). See \( \texttt{lpstat}(1) \).

destination  The name of the printer or class of printers (see \( \texttt{lpadmin}(1M) \)) to which \( \texttt{lpmove} \) moves a specified print request. Specify destination using atomic, URI-style (scheme://endpoint), POSIX-style (server:destination) syntax.

source  The name of the destination from which \( \texttt{lpmove} \) moves all print requests. Specify destination using atomic, URI-style (scheme://endpoint), POSIX-style (server:destination) syntax.

See \( \texttt{printers.conf}(4) \) for information regarding the naming conventions for atomic names and \( \texttt{standards}(5) \) for information regarding POSIX.

Exit Status  The following exit values are returned:

0  Successful completion.
non-zero  An error occurred.

Files  /etc/printers.conf  System printer configuration database
       \$HOME/.printers  User-configurable printer database
       ou=printers  LDAP version of /etc/printers.conf
printers.conf.byname  NIS version of /etc/printers.conf
printers.org_dir  NIS+ version of /etc/printers.conf

System Administration Guide: Printing

Notes
When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.
**Synopsis**
```
lpsched [-f num_filters] [-n num_notifiers] [-p fd_limit]
        [-r reserved_fds]
```

**Description**
The `lpsched` command starts or restarts the LP print service.

The `lpshut` command stops the LP print service. Printers that are restarted using `lpsched` reprint (in their entirety) print requests that were stopped by `lpshut`. See `lpshut(1M)`.

It is recommended that you start and stop the LP print service using `svcadm(1M)`. See `NOTES`.

**Options**
The following options are supported:

- `-f num_filters` Specifies the number of concurrent slow filters that may be run on a print server. A default value of 1 is used if none is specified. Depending on server configuration, a value of 1 may cause printers to remain idle while there are jobs queued to them.

- `-n num_notifiers` Specifies the number of concurrent notification processes that can run on a print server. A default value of 1 is used when none is specified.

- `-p fd_limit` Specifies the file descriptor resource limit for the `lpsched` process. A default value of 4096 is used if none is specified. On extremely large and active print servers, it may be necessary to increase this value.

- `-r reserved_fds` Specifies the number of file descriptors that the scheduler reserves for internal communications under heavy load. A default value of 2 is used when none is specified. It should not be necessary to modify this value unless instructed to do so when troubleshooting problems under high load.

**Exit Status**
The following exit values are returned:

- `0` Successful completion.
- `non-zero` An error occurred.

**Files**
`/var/spool/lp/*` LP print queue.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>

*System Administration Guide: Basic Administration*
The `lpsched` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/application/print/server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

**Notes**

The `lpsched` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/application/print/server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
Name

lpset – set printing configuration in /etc/printers.conf or other supported databases

Synopsis

lpset [-n system | nisplus | fnslsap] [-x]
[ [-D binddn] [-w passwd] [-h ldaphost]]
[-a key=value] [-d key] destination

Description

The lpset utility sets printing configuration information in the system configuration databases. Use lpset to create and update printing configuration in /etc/printers.conf, or printers.org_dir (NIS+). See nsswitch.conf(4) and printers.conf(4).

Only a superuser or a member of Group 14 may execute lpset.

Options

The following options are supported:

- n system|nisplus|ldap
  Create or update the configuration information for the destination entry in /etc/printers.conf, printers.org_dir (NIS+), or LDAP printer contexts. system specifies that the information is created or updated in /etc/printers.conf. nisplus specifies that the information is created or updated in the printers.org_dir NIS+ table. ldap specifies that the information is written to an LDAP server. See Notes.

  If -n is not specified, system is the default.

- x
  Remove all configuration for the destination entry from the database specified by the -n option.

- a key=value
  Configure the specified key=value pair for the destination. See printers.conf(4) for information regarding the specification of key=value pairs.

- d key
  Delete the configuration option specified by key for the destination entry. See printers.conf(4) for information regarding the specification of key and key=value pairs.

- D binddn
  Use the distinguished name (DN) binddn to bind to the LDAP directory server.

- w passwd
  Use passwd as the password for authentication to the LDAP directory server.

- h ldaphost
  Specify an alternate host on which the LDAP server is running. This option is only used when ldap is specified as the naming service. If this option is not specified, the default is the current host system.

Operands

The following operand is supported:

destination
  Specifies the entry in /etc/printers.conf, printers.org_dir, or LDAP, in which to create or modify information. destination names a printer of class of
printers. See \texttt{lpadmin(1M)}. Each entry in \texttt{printers.conf} describes one destination. Specify \texttt{destination} using atomic names. POSIX-style destination names are not acceptable. See \texttt{printers.conf(4)} for information regarding the naming conventions for atomic names and \texttt{standards(5)} for information regarding POSIX.

### Examples

**EXAMPLE 1** Removing All Existing Printing Configuration Information

The following example removes all existing printing configuration information for destination \texttt{dogs} from \texttt{/etc/printers.conf}:

```bash
example% lpset -x dogs
```

**EXAMPLE 2** Setting a key=value Pair

The following example sets the \texttt{user-equivalence =true} key=value pair for destination \texttt{tabloid} in the NIS+ context:

```bash
example% lpset -n nisplus -a user-equivalence=true tabloid
```

**EXAMPLE 3** Setting a key=value Pair in LDAP

```bash
example% lpset -n ldap -h ldap1.xyz.com -D "cn=Directory Manager" -w passwd -a key1=value1 printer1
```

### Exit Status

The following exit values are returned:

- **0** Successful completion.
- **non-zero** An error occurred.

### Files

- **/etc/printers.conf** System configuration database.
- **printer.org_dir** (NIS+) NIS+ version of \texttt{/etc/printers.conf}.

### Attributes

See \texttt{attributes(5)} for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTIIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpcu</td>

*System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*
Notes  If the `ldap` database is used, the printer administrator should be mindful of the following when updating printer information.

1. Because the domain information for the printer being updated is extracted from the `ldapclient(1M)` configuration, the LDAP server being updated must host the same domain that is used by the current `ldapclient(1M)` server.

2. If the LDAP server being updated is a replica LDAP server, the updates will be referred to the master LDAP server and completed there. The updates might be out of sync and not appear immediately, as the replica server may not have been updated by the master server. For example, a printer that you deleted by using `lpset` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. See *System Administration Guide: Printing* for information on LDAP server replication.

3. Although users can use the LDAP command line utilities `ldapadd(1)` and `ldapmodify(1)` to update printer entries in the directory, the preferred method is to use `lpset`. Otherwise, if the `ldapadd` and `ldapmodify` utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using `lpset` or the Solaris Print Manager, `printmgr(1M)` may be unpredictable.
Name
lpshut – stop the LP print service

Synopsis
lpshut

Description
The lpshut command stops the LP print service.
Printers that are printing when lpshut is invoked stop printing. Start or restart printers using lpsched(1M).

</tbody>
</table>

* This command could be removed at any time.

See Also  ladmin(1M), lpusers(1M), printers.conf(4), attributes(5)
The \texttt{lpusers} command sets limits to the queue priority level that can be assigned to jobs submitted by users of the LP print service.

The first form of the command (with \texttt{-d}) sets the system-wide priority default to \texttt{priority-level}, where \texttt{priority-level} is a value of 0 to 39, with 0 being the highest priority. If a user does not specify a priority level with a print request (see \texttt{lp(1)}), the default priority level is used. Initially, the default priority level is 20.

The second form of the command (with \texttt{-q} and \texttt{-u}) sets the default highest \texttt{priority-level} (0-39) that the users in \texttt{login-ID-list} can request when submitting a print request. The \texttt{login-ID-list} argument may include any or all of the following constructs:

- \texttt{login-ID} A user on any system
- \texttt{system_name!login-ID} A user on the system \texttt{system_name}
- \texttt{system_name!all} All users on system \texttt{system_name}
- \texttt{all!login-ID} A user on all systems
- \texttt{all} All users on all systems

Users that have been given a limit cannot submit a print request with a higher priority level than the one assigned, nor can they change a request that has already been submitted to have a higher priority. Any print requests submitted with priority levels higher than allowed will be given the highest priority allowed.

The third form of the command (with \texttt{-u}) removes any explicit priority level for the specified users.

The fourth form of the command (with \texttt{-q}) sets the default highest priority level for all users not explicitly covered by the use of the second form of this command.

The last form of the command (with \texttt{-l}) lists the default priority level and the priority limits assigned to users.

The following options are supported:

- \texttt{-d priority-level} Set the system-wide priority default to \texttt{priority-level}.  

List the default priority level and the priority limits assigned to users.

- q priority-level
  Set the default highest priority level for all users not explicitly covered.

- q priority-level -u login-ID-list
  Set the default highest priority-level that the users in login-ID-list can request when submitting a print request.

- u login-ID-list
  Remove any explicit priority level for the specified users.

**Exit Status**

The following exit values are returned:

0  Successful completion.

non-zero  An error occurred.

lu(1M)

Name
lu – FMLI-based interface to Live Upgrade functions

 Synopsis
/usr/sbin/lu

Description
Sun no longer recommends use of the `lu` command. The `lu` command displays a character
user interface (CUI). The underlying command sequence for the CUI—typically `lucreate`,
luupgrade, and `luactivate`—is straightforward to use. The SEE ALSO section below
highlights the full Solaris Live Upgrade command set.

The `lu` program is part of a suite of commands that make up the Live Upgrade feature of the
Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade
feature.

The `lu` program is a Forms and Menu Language Interpreter-based user interface. (See `fmli(1)`
for a description of the Forms and Menu Language Interpreter.) `lu` enables you to create and
upgrade boot environments (BEs) and perform other administrative tasks on BEs. The `lu`
program performs a subset of the functions provided by the Live Upgrade command-line
utilities.

Users of `lu` should be aware of the following:
- `lu` is a deprecated interface. It will be replaced in the future and should not be depended on
  for critical functionality.
- All new Live Upgrade features are being implemented in the Live Upgrade command-line
  utilities. No new features are being made available in `lu`.
- The `lu` command is not internationalized. It will not be internationalized in a future
  release.

`lu` should be used for learning or experimenting only. For any production use or to use the full
capabilities of Live Upgrade, use the Live Upgrade command-line utilities.

Invocation of the `lu` command requires root privileges.

The `lu` command accepts no arguments. After invoking `lu`, you receive a display with the
following options:

Activate Activate a boot environment. This option designates that the system boot from
the specified BE upon next reboot. This option is equivalent to the command-line
luactivate(1M) utility.

Cancel Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and
flash functions (all described below) at a later time. The cancel function enables
you to cancel a scheduled job. This function is equivalent to the command-line
lucancel(1M) utility.

Compare Compare the contents of BEs. Enables you to obtain a detailed comparison of two
BEs. Equivalent to the command-line lucompare(1M) utility.
Copy  Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line `lumake(1M)` utility. At any time, you can have only one Live Upgrade operation scheduled.

Create  Create a boot environment. Implements a subset of the functions performed by the command-line `lucreate(1M)` utility.

Current  Display the name of the current boot environment. Equivalent of the command-line `lucurr(1M)` utility.

Delete  Delete a boot environment. Equivalent of the command-line `ludelete(1M)` utility.

List  List the file systems of a boot environment. Equivalent of the command-line `lufslist(1M)` utility.

Rename  Change the name of a boot environment. Equivalent of the command-line `lurename(1M)` utility.

Status  List the status of all boot environments. Equivalent of the command-line `lustatus(1M)` utility.

Upgrade  Upgrade a boot environment or upgrade the OS on an inactive BE. This option enables you to upgrade to a new operating system or install new packages or patches on a specified BE. Implements a subset of the functions performed by the command-line `luupgrade(1M)` utility. Note that if you are performing an upgrade that requires more than one CD, you must use the `-i` option of `luupgrade`.

Flash  Flash a boot environment. This option enables you to install an operating system on a BE from a flash archive. You can perform the same function with `luupgrade(1M)`.

Help  Displays help information. There are also context-specific help screens for many of the options.

Exit  Exit `lu`.

Navigation  You navigate through `lu`'s various screens using arrow keys and function keys (usually F2 through F9 on the keyboard of a Sun desktop system). Available key functions are displayed at the base of the `lu` screen. You can use Ctrl-F, plus a number key, to duplicate a function key. For example, press Ctrl-F and the number key 2 to duplicate the F2 key.

In a screen for a given option, you can press Esc to obtain context-specific help.

Display Issues  When viewing the FMLI interface remotely, such as over a `tip` line, you might need to set the `TERM` environment variable to `VT220`. When using the FMLI interface in a CDE environment use `dtterm`, rather than `xterm`, as the value of the `TERM` variable.
The `lu` command supports only single-byte environments.

**Common Functions**

Most of the options listed above offer the following functions. These functions are accessible through function keys indicated at the base of the screen.

- **Choice**: Available to you whenever you have a field that can be filled in. Pressing the Choice function key gives you a popup screen displaying a list of alternatives. For example, for options involving copying or upgrading BEs, you receive a list of available BEs. You can then use arrow and function keys to make a selection from this popup. The choice function is useful because it prevents you from selecting an invalid alternative. In our example, it prevents you from choosing a BE that is not available for a copy or upgrade operation. Such non-availability might occur when a BE is in the midst of an upgrade.

- **Cancel**: Cancel an operation.
- **Save**: Proceed with an operation.

**Other Functions**

The “Create” option, described above, offers the following functions:

- **Split**: Split a file system. For example, you can split a `/` file system into `/`, `/usr`, and `/var`. To split a file system, you must have disk slices available on which to mount the separated file system(s). If you do not, `lu` invokes the `format(1M)` utility, in which you can use the partition option to create a new disk slice.

- **Merge**: Join one or more file systems with its (or their) parent file system. For example, using a source BE that has separate `/`, `/usr`, and `/var` file systems, you can merge these file systems under `/` on a target BE.

**Files**

- `/etc/lutab` list of BEs on the system

**Solaris Installation Guide**

**Warnings**

The `lu` command is a deprecated interface. See DESCRIPTION.
The `luactivate` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `luactivate` command, with no arguments, displays the name of the boot environment (BE) that will be active upon the next reboot of the system. When an argument (a BE) is specified, `luactivate` activates the specified BE.

`luactivate` activates a BE by making the BE's root partition bootable. On an x86 machine, this might require that you take steps following the completion of `luactivate`. If so, `luactivate` displays the correct steps to take.

To successfully activate a BE, that BE must meet the following conditions:

- The BE must have a status of “complete,” as reported by `lustatus(1M)`.
- If the BE is not the current BE, you cannot have mounted the partitions of that BE (using `lumount(1M)` or `mount(1M)`).
- The BE you want to activate cannot be involved in an `lucompare(1M)` operation.

After activating a specified BE, `luactivate` displays the steps to be taken for fallback in case of any problem on the next reboot. Make note of these instructions and follow them exactly, if necessary.

**Note** – Before booting a new BE, you must run `luactivate` to specify that BE as active. `luactivate` performs a number of tasks, described below, that ensure correct operation of the BE. In some cases, a BE is not bootable until after you have run the command.

The `luactivate` command performs the following tasks:

- The first time you boot from a newly created BE, Live Upgrade software synchronizes this BE with the BE that was last active. (This is not necessarily the BE that was the source for the newly created BE.) *Synchronize* here means that certain system files and directories are copied from the last-active BE to the BE being booted. (See `synclist(4)`.) Live Upgrade software does not perform this synchronization after a BE's initial boot, unless you use the `-s` option, described below.
- If `luactivate` detects conflicts between files that are subject to synchronization, it issues a warning and does not perform the synchronization for those files. Activation can complete successfully, in spite of such a conflict. A conflict can occur if you upgrade one BE or another to a new operating system version or if you modify system files (for example, `/etc/passwd`) on one of the BEs.
luactivate checks to see whether upgrade problems occurred. For example, packages required for the correct operation of the operating system might be missing. This package check is done for the global zone as well as all non-global zones inside of the BE. The command can issue a warning or, if a BE is incomplete, can refuse activation.

luactivate determines whether the bootstrap program requires updating and takes steps to update if necessary. If a bootstrap program changed from one operating release to another, an incorrect bootstrap program might render an upgraded BE unbootable. See installboot(1M).

luactivate modifies the root partition ID on a Solaris x86 disk to enable multiple BEs to reside on a single disk. In this configuration, if you do not run luactivate, booting of the BE will fail. See fmthard(1M) and dkio(7I).

The luactivate command requires root or equivalent privileges.

Options

The luactivate command has the following options:

- `error_log`  
  Error and status messages are sent to `error_log`, in addition to where they are sent in your current environment.

- `outfile`  
  All command output is sent to `outfile`, in addition to where it is sent in your current environment.

- `s`  
  Causes synchronization to occur (see DESCRIPTION) even if next boot of a specified BE is not the first boot of that BE. Use this option with great caution, because you might not be aware or in control of changes that might have occurred in the last-active BE.

  If using `-s`, take special care when booting to an earlier release of Solaris than what is installed on the last-active BE. For example, consider that the last-active BE contains Solaris 9 and you want to activate a BE that contains Solaris 2.6. If you forced synchronization with the `-s` option, the BE containing Solaris 2.6 might be synchronized with files that, while compatible with Solaris 9, might not work under Solaris 2.6.

- `X`  
  Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Operands

`BE_name`  
Name of the BE to be activated.

Exit Status

The following exit values are returned:

0  
Successful completion.

>0  
An error occurred.
Files
/etc/lutab
/usr/share/lib/xml/dtd/lu_cli.dtd.<num>

current BE for possible obstacles.
lucancel(1M)

**Name**
lucancel – cancel a scheduled Live Upgrade copy/create procedure

**Synopsis**
/usr/sbin/lucancel [-l error_log] [-o outfile] [-X]

**Description**
The `lucancel` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lucancel` command cancels a boot environment (BE) creation or upgrade that was scheduled in the FMLI-based interface, `lu(1M)`, or the repopulation of a BE, scheduled with `lumake(1M)`. Note that Sun recommends against the use of the `lu` command.

`lucancel` does not cancel a job that is active (that is, in the process of creation or repopulation).

The `lucancel` command requires root privileges.

**Options**
The `lucancel` command has the following options:

- `-l error_log` Error and status messages are sent to `error_log`, in addition to where they are sent in your current environment.

- `-o outfile` All command output is sent to `outfile`, in addition to where it is sent in your current environment.

- `-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

**Exit Status**
The following exit values are returned:

- `0` Successful completion.

- `>0` An error occurred.

**Files**
/etc/lutab list of BEs on the system

Name  
lucompare – compare boot environments

Synopsis
/usr/sbin/lucompare [-i infile | -t] [-o outfile] BE_name [-X]

/usr/sbin/lucompare [-C file [-o outfile]] [-X]

Description
The lucompare command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See live_upgrade(5) for a description of the Live Upgrade feature.

The lucompare command compares the contents of the current boot environment (BE) with the contents of another BE. With the -C option, lucompare compares file statistics so that you can determine which files have changed on a BE since a specified time, such as the creation time of a BE. A specified BE must be inactive and in the complete state, as reported by the lustatus(1M) command. Also, a BE cannot have a copy job scheduled, which is also reported by lustatus(1M). A specified BE cannot have any partitions mounted with lumount(1M) or mount(1M).

For each file system defined for a specified BE, lucompare compares all files with the files with the same pathnames in the current BE. The files present in the active BE, but not in the specified BE, and vice-versa, are reported. You also have the option to specify a list of files to be compared.

If you specify the -C option, instead of doing an absolute comparison of the current BE with a target BE, lucompare compares the files in a specified BE with the list of files recorded in a file. When a BE is created, lucreate(1M) creates a file named :<BE_name> in /etc/lu/compare. You can use the -C option to compare the files in a specified BE to this snapshot in /etc/lu/compare or you can compare the BE to a file previously created with the -o option. Comparing a BE to its own snapshot in /etc/lu/compare enables you to determine which files have changed on the BE since its creation.

By default, the output of lucompare is written to stdout. With the -C option, you must use the -o option to specify an output file. The output for lucompare is a list of files that differ in permissions, owner, group, or sum, along with the reason for difference. The output format is shown below:

> active BE
< BE_name
reason
> file_name:owner:group:number_of_links:mode:type: size
or major_minor_number:checksum
< file_name:owner:group:number_of_links:mode:type: size
or major_minor_number:checksum

The above fields are obtained from the stat(2) structure of the file.

The type field can be one of the following:
SYMLINK symbolic link
lucompare computes checksums only if the file on the specified BE matches its counterpart on
the active BE in all of the fields described above. If the checksums differ, lucompare appends
the differing checksums to the entries for the compared files.

The lucompare command requires root privileges.

Options

The lucompare command has the following options:

- `-C file` Compare file statistics of BE with those recorded in file. file can be the snapshot
created at BE creation time, /etc/lu/compare/::<BE_name>, or a file
previously created with the -o option. You must use the -o option with this
option.

- `-i infile` Compare files listed in infile. The files to be compared should be an absolute
filename. If the entry in the file is a directory, then comparison is recursive with
respect to the directory. Mutually exclusive of -t.

- `-o outfile` Send output of differences to outfile. You must use this option if you use -C.

- `-t` Compare only nonbinary files. This is achieved by performing a file(1)
command on each file in the tree walk and only comparing text files. Mutually
exclusive of -i.

- `-X` Enable XML output. Characteristics of XML are defined in DTD, in
/usr/share/lib/xml/dtd/lu_cli.dtd.<num>, where <num> is the version
number of the DTD file.

Operands

BE_name Name of the BE to which the active BE will be compared. You cannot specify a
BE that is involved in another Live Upgrade operation, or specify a BE for which
you have mounted partitions (using lmount(1M) or mount(1M)).

Examples

EXAMPLE 1 Checking Differences Since BE Creation

The following command lists the differences in the BE s8u5 between its creation time and the
present.

    # lucompare -C /etc/lu/compare/::s8u5 -o /var/tmp/compare.out s8u5
EXAMPLE 1  Checking Differences Since BE Creation  (Continued)

Note that /etc/lu/compare/:s8u5 is the file created by lucreate upon creation of a BE. The list of differences is sent to /var/tmp/compare.out.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Files  /etc/lutab  list of BEs on the system

/usr/share/lib/xml/dtd/lu_cli.dtd.<num>  Live Upgrade DTD (see -X option)

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWlu</td>
</tr>
</tbody>
</table>

See Also  luactivate(1M), lucancel(1M), lucreate(1M), lucurr(1M), ludelete(1M), Ludesc(1M), lufslist(1M), lumake(1M), lumount(1M), lurename(1M), lustatus(1M), luupgrade(1M), lutab(4), attributes(5), live_upgrade(5)

Notes  The lucompare command makes no attempt to reconcile any differences it detects between BEs.
Name  lucreate – create a new boot environment

Synopsis  /usr/sbin/lucreate [-A BE_description] [-c BE_name]
          [-C ( boot_device | - )] -n BE_name
          [-D file_system]
          [-f exclude_list_file] [-I] [-\ error_log]
          [-o outfile] [-s ( - | source_BE_name )]
          [-M slice_list_file [-M]...]
          [-m mount_point:device [,volume]:fs_options[:zonename] [-m...]]
          [-p zfs_root_pool]
          [-x exclude [-x]...] [-X] [-y include [-y]...]
          [-Y include_list_file] [-z filter_list]

Description  The lucreate command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See live_upgrade(5) for a description of the Live Upgrade feature and its associated terminology.

The lucreate command offers a set of command line options that enable you to perform the following functions:

- Create a new boot environment (BE), based on the current BE.
- Create a new BE, based on a BE other than the current BE.
- Join or separate the file systems of a BE onto a new BE. For example, join /var and /opt under /, or separate these directories to be mounted under different disk slices.
- Specify separate file systems belonging to a particular zone inside of the new BE. (See zones(5).)
- Create the file systems for a BE, but leave those file systems unpopulated.

If lucreate is invoked without the -m, -M, or -p options (described below), it brings up an FMLI-based interface that provides curses-based screens for Live Upgrade administration. Note that the FMLI-based interface does not support all of the Live Upgrade features supported by the command-line version of lucreate. Also, Sun is not committed to ongoing development of the FMLI-based interface.

With the -p option, lucreate supports the creation of BEs on ZFS file systems. The source BE can be a UFS root file system on a disk slice or a ZFS file system in an existing ZFS storage pool. lucreate provides a convenient means of migrating a BE from a UFS root file system to a ZFS root file system. You cannot create a BE on a UFS file system from a source BE on a ZFS file system.

The creation of a BE includes selecting the disk or device slices for all the mount points of the BE. Slices can be physical disks or logical devices, such as Solaris Volume Manager volumes. You can also change the mount points of the BE using the SPLIT and MERGE functions of the FMLI-based configuration screen.
Upon successful creation of a BE, you can use `lustatus(1M)` to view the state of that BE and `lufslist(1M)` to view the BE's file systems. You can use `luupgrade(1M)` to upgrade the OS on that BE and `luactivate(1M)` to make a BE active, that is, designate it as the BE to boot from at the next reboot of the system.

**Note** – Before booting a new BE, you must run `luactivate` to specify that BE as active. `luactivate` performs a number of tasks that ensure correct operation of the BE. In some cases, a BE is not bootable until after you have run the command. See `luactivate(1M)` for a list of the operations performed by that command.

The `lucreate` command makes a distinction between the file systems that contain the OS—`/`, `/usr`, `/var`, and `/opt`—and those that do not, such as `/export`, `/home`, and other, user-defined file systems. The file systems in the first category cannot be shared between the source BE and the BE being created; they are always copied from the source BE to the target BE. By contrast, the user-defined file systems are shared by default. For Live Upgrade purposes, the file systems that contain the OS are referred to as non-shareable (or critical) file systems; other file systems are referred to as shareable. A non-shareable file system listed in the source BE's `vfstab` is copied to a new BE. For a shareable file system, if you specify a destination slice, the file system is copied. If you do not, the file system is shared.

When migrating from a UFS-based BE to a ZFS-based BE, you cannot migrate shared UFS file systems to ZFS. Also, when the source and destination BEs are both ZFS-based, you cannot copy shared file systems. Such file systems can only be shared.

The `lucreate` command copies all non-global zones from the current BE to the BE being created. For non-global zones residing in a non-shared file system, the new BE gets a copy of the zone in its non-shared file system. For non-global zones residing in a shared file system, `lucreate` makes a copy of the zone for the new BE in that shared file system and uses a different zonepath (see `zoneadm(1M)`) for the zone. The zonepath used is of the form `zonepath-newBE`. This prevents BEs from sharing the same non-global zone in the shared file system. When the new BE gets booted, the zone in the shared file system belonging to the new BE has its zonepath renamed to `zonepath` and the zone in the shared file system belonging to the original BE has its zonepath renamed to `zonepath-origBE`.

If a zone exists in a non-shared file system, the zone is automatically copied when the UFS root file system is migrated to a ZFS root file system. If a zone exists in a shared UFS file system, to migrate to a ZFS root file system, you must first upgrade the zone, as in previous Solaris releases. A zone in a non-shared file system within a ZFS BE is cloned when upgrading to a ZFS BE within the same ZFS pool.

The `lucreate` command supports a limited subset of Solaris Volume Manager functions. In particular, using `lucreate` with the `-m` option, you can:

- Create a mirror.
- Detach existing SVM concatenations from mirrors. Similarly, you can attach existing Solaris Volume Manager concatenations to mirrors. These can be mirrors that were created in Solaris Volume Manager or those created by `lucreate`.
- Create a single-slice concatenation and attach a single disk slice to it.
- Detach a single disk slice from a single-slice concatenation.
- Attach multiple single-slice concatenations to a mirror. `lucreate` can attach as many of these concatenations as are allowed by Solaris Volume Manager.

`lucreate` does not allow you to attach multiple disk slices or multiple storage devices to a concatenation. Similarly, it does not allow you to detach multiple slices or devices from a concatenation.

If you use Solaris Volume Manager volumes for boot environments, it is recommended that you use `lucreate` rather than Solaris Volume Manager commands to manipulate these volumes. The Solaris Volume Manager software has no knowledge of boot environments, whereas the `lucreate` command contains checks that prevent you from inadvertently destroying a boot environment by, for example, overwriting or deleting a Solaris Volume Manager volume.

If you have already used Solaris Volume Manager software to create complex Solaris Volume Manager volumes (for example, RAID-5 volumes), Live Upgrade will support the use of these. However, to create and manipulate these complex objects, you must use Solaris Volume Manager software. As described above, the use of Solaris Volume Manager software, rather than the `lucreate` command, entails the risk of destroying a boot environment. If you do use Solaris Volume Manager software, use `lufslist(1M)` to determine which devices are in use for boot environments.

Except for a special use of the `-s` option, described below, you must have a source BE for the creation of a new BE. By default, it is the current BE. You can use the `-s` option to specify a BE other than the current BE.

When creating a new BE on a UFS file system, `lucreate` enables you to exclude and include certain files from the source BE. You perform this inclusion or exclusion with the `-f`, `-x`, `-y`, `-F`, and `-z` options, described below. See the subsection on combining these options, following OPTIONS, below.

By default, all swap partitions on a UFS-based source BE are shared with a UFS-based target BE. For UFS-based target BEs, you can use the `-n` option (see below) to specify an additional or new set of swap partitions on the source BE for sharing with the target. When a UFS-based source BE is copied to a ZFS target BE, `lucreate` creates in the new BE a swap area and a dump device on separate ZFS volumes. When both the source and target BEs are ZFS-based and are in the same pool, both BEs use the same swap volume. If source and target are in different pools, a new swap volume is created in the pool of the target BE.

The `lucreate` command allows you to assign a description to a BE. A description is an optional attribute of a BE that can be of any format or length. It might be, for example, a text string or binary data. After you create a BE, you can change a BE description with the `ludesc(1M)` utility.
The `lucreate` command requires root privileges or that you assume the Primary Administrator role.

**Options**

The `lucreate` command has the options listed below. Note that a BE name must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the “Quoting” section of `sh(1)`. The BE name can contain only single-byte, 8–bit characters; it cannot contain whitespace characters.

Omission of `-m`, `-M`, and `-p` options (described below) in an `lucreate` command line invokes the FMLI-based interface, which allows you to select disk or device slices for a UFS-based BE.

- `-BE_description`
  
  Assigns the `BE_description` to a BE. `BE_description` can be a text string or other characters that can be entered on a Unix command line. See `ludesc(1M)` for additional information on BE descriptions.

- `-c BE_name`
  
  Assigns the name `BE_name` to the current BE. This option is not required and can be used only when the first BE is created. For the first time you run `lucreate`, for a UFS-based BE, if you omit `-c`, `lucreate` supplies a default name according to the following rules:

  1. If the physical boot device can be determined, the base name of that device is used to name the new boot environment. For example, if the physical boot device is `/dev/dsk/c0t0d0s0`, `lucreate` names the new boot environment `c0t0d0s0`.

  2. If the physical boot device cannot be determined, the operating system name (from `uname -s`) and operating system release level (from `uname -r`) are combined to produce the name of the new boot environment. For example, if `uname -s` returns `SunOS` and `uname -r` returns `5.9`, then `lucreate` assigns the name `SunOS5.9` to the new boot environment.

  3. If `lucreate` can determine neither boot device nor operating system name, it assigns the name `current` to the new boot environment.

For a ZFS-based BE, the default BE name is the base name of the root file system.

If you use the `-c` option after the first boot environment is created, the option is ignored if the name specified is the same as the current boot environment name. If the name is different, `lucreate` displays an error message and exits.

- `-C (boot_device | -)`
  
  Provided for occasions when `lucreate` cannot figure out which physical storage device is your boot device. This might occur, for example, when you have a mirrored root device on the source BE on an x86 machine. The `-C` specifies the physical boot device from which the source BE is booted. Without this option, `lucreate` attempts to determine the physical device from which a BE boots. If the device on which the root file system is located is not a physical disk (for example, if root is on a Solaris Volume Manager volume) and `lucreate` is able to make a reasonable guess as to the physical device, you receive the query:
Is the physical device `devname` the boot device for the logical device `devname`?

If you respond `y`, the command proceeds.

If you specify `-C boot_device`, `lucreate` skips the search for a physical device and uses the device you specify. The `-` (hyphen) with the `-C` option tells `lucreate` to proceed with whatever it determines is the boot device. If the command cannot find the device, you are prompted to enter it.

If you omit `-C` or specify `-C boot_device` and `lucreate` cannot find a boot device, you receive an error message.

Use of the `-C` form is a safe choice, because `lucreate` either finds the correct boot device or gives you the opportunity to specify that device in response to a subsequent query.

`-D file_system`

Specify a separate dataset for `/var` during UFS to ZFS migration. Valid values for `file_system` are `/var` or any other mount point not containing OS deliverables. For example, `/data`.

While the `-D` option is mainly intended for specifying a separate dataset for `/var`, it can also be used for other non-OS critical file systems. For example, you can create a separate dataset for `/data` under the root dataset in a ZFS root BE.

Note that all shareable filesystems in the UFS root BE that are not explicitly migrated to separate datasets with `-D` option continue to be shared with ZFS root BE.

See “Examples” for the migration and non-migration use of the `-D` option.

`-f exclude_list_file`

Use the contents of `exclude_list_file` to exclude specific files (including directories) from the newly created BE. `exclude_list_file` contains a list of files and directories, one per line. If a line item is a file, only that file is excluded; if a directory, that directory and all files beneath that directory, including subdirectories, are excluded.

This option is not supported when the source BE is on a ZFS file system.

`-I`

Ignore integrity check. Prior to creating a new BE, `lucreate` performs an integrity check, to prevent you from excluding important system files from the BE. Use this option to override this integrity check. The trade-off in use of this option is faster BE creation (with `-I`) versus the risk of a BE that does not function as you expect.

`-l error_log`

Error messages and other status messages are sent to `error_log`, in addition to where they are sent in your current environment.

`-m mount_point:device[,volume]:fs_option[:zonename]`  
`[-m mount_point:device:fs_option[:zonename]] ...`
Specifies the `vfstab(4)` information for a new UFS-based BE. The file systems specified as arguments to `-m` can be on the same disk or can be spread across multiple disks.

The `-m` option is not supported for BEs based on ZFS file systems. This option also does not support EFI-labeled disks.

`mount_point` can be any valid mount point or `–` (hyphen), indicating a swap partition. The `device` field can be one of the following:

- The name of a disk slice, of the form `/dev/dsk/cnumtnumsnumsnum`.
- The name of a Solaris Volume Manager volume, of the form `/dev/md/dsk/dnum`.
- The name of a Solaris Volume Manager disk set, of the form `/dev/md/setname/dsk/dnum`.
- The name of a Veritas volume, of the form `/dev/vx/dsk/dgname/volname`.
- The keyword `merged`, indicating that the file system at the specified mount point is to be merged with its parent.
- The keyword `shared`, indicating that all of the swap partitions in the source BE are to be shared with the new BE.

The `-m` option enables you to attach a physical disk device to a Solaris Volume Manager single-slice concatenation or attach a Solaris Volume Manager volume to a mirror. Both operations are accomplished with the `attach` keyword, described below. With this option, you have the choice of specifying a concatenation or mirror or allowing `lucreate` to select one for you. To specify a concatenation or mirror, append a comma and the name of the Solaris Volume Manager logical device to the device name to which the logical device is being attached. If you omit this specification, `lucreate` selects a concatenation or mirror from a list of free devices. See EXAMPLES.

The `fs_option` field can be one or more of the keywords listed below. The first two keywords specify types of file systems. The remaining keywords specify actions to be taken on a file system. When you specify multiple keywords, separate these with a comma.

- `ufs` Create the file system as a UFS volume.
- `vxfs` Create the file system as a Veritas device.
- `preserve` Preserve the file system contents of the specified physical storage device. Use of this keyword presumes that the device’s file system and its contents are appropriate for the specified mount point. For a given mount point, you can use `preserve` with only one device. This keyword enables you to bypass the default steps of creating a new file system on the specified storage device, then copying the file system contents from the source BE to the specified device. When you use `preserve`, `lucreate` checks that the storage device’s contents is suitable for a specified file system. This check is limited and cannot guarantee suitability.
**mirror**  
Create a mirror on the specified storage device. The specified storage device must be a correctly named (for example, `/dev/md/dsk/d10`) logical device that can serve as a mirror. In subsequent `-m` options, you must specify attach (see below) to attach at least one physical device to the new mirror.

**attach**  
Attach a physical storage device, contained by a volume, to the mirror or single-slice concatenation associated with a specified mount point. When using `attach`, if you want to attach a disk to a specific mirror or concatenation, you append a comma and the name of that logical device to the device name. If you omit the comma and the concatenation name, `lucreate` selects a free mirror or single-slice concatenation as the container volume for the storage device. See EXAMPLES.

`lucreate` allows you to create only concatenations that contain a single physical drive and allows you to attach up to four such concatenations to a mirror.

**detach**  
Detach a physical storage device from the mirror or concatenation associated with a specified mount point.

The optional `zonename` field specifies the name of an installed non-global zone. It is used to specify a separate file system that belongs to the particular zone, named `zonename`, that exists in the new BE being created.

At minimum, you must specify one disk or device slice, for root. You can do this with `-m`, `-M` (described below), or in the FMLI-based interface. You must specify an `-m` argument for each file system you want to create on a new BE. For example, if you have three file systems on a source BE (say, `/`, `/usr`, and `/var`) and want these three entities as separate file systems on a new BE, you must specify three `-m` arguments. If you were to specify only one, in our example, `/`, `/usr`, and `/var` would be merged on the new BE into a single file system, under `/`.

When using the `-m` option to specify swap partition(s), you can designate device(s) currently used for swap on any BE and any unused devices. Regarding swap assignments, you have the following choices:

- Omit any specification of swap devices, in which case all swap devices associated with the source BE will be used by the new BE.
- Specify one or more swap devices, in which case the new BE will use only the specified swap devices and not automatically share the swap devices associated with the source BE.
- Specify one or more swap devices and use the syntax `-m -:shared:swap`, in which case the new BE will use the specified swap devices and will share swap devices with the source BE.

See EXAMPLES, below.
-M slice_list
   List of -m options, collected in the file slice_list. Specify these arguments in the format specified for -m. Comment lines, beginning with a hash mark (#), are ignored. The -M option is useful where you have a long list of file systems for a BE. Note that you can combine -m and -M options. For example, you can store swap partitions in slice_list and specify / and /usr slices with -m.

   The -M option is not supported for BEs based on ZFS file systems.

   The -m and -M options support the listing of multiple slices for a given mount point. In processing these slices, lucreate skips any unavailable slices and selects the first available slice. See EXAMPLES.

-n BE_name
   The name of the BE to be created. BE_name must be unique on a given system.

-o outfile
   All command output is sent to outfile, in addition to where it is sent in your current environment.

-p zfs_root_pool
   Specifies the ZFS pool in which a new BE will reside.

   This option can be omitted if the source and target BEs are within the same pool.

   The -p option does not support the splitting and merging of file systems in a target BE that is supported by the -m option.

-s (–| BE_name)
   Source for the creation of the new BE. This option enables you to use a BE other than the current BE as the source for creation of a new BE.

   If you specify a hyphen (-) as an argument to -s, lucreate creates the new BE, but does not populate it. This variation of the -s option is intended for the subsequent installation of a flash archive on the unpopulated BE using luupgrade(1M). See flar(1M).

-x exclude
   Exclude the file or directory exclude from the newly created BE. If exclude is a directory, lucreate excludes that directory and all files beneath that directory, including subdirectories.

   This option is not supported when the source BE is on a ZFS file system.

-X
   Enable XML output. Characteristics of XML are defined in DTD, in /usr/share/lib/xml/dtd/lu_cli.dtd.<num>, where <num> is the version number of the DTD file.
-y include
Include the file or directory include in the newly created BE. If include is a directory, lude create includes that directory and all files beneath that directory, including subdirectories.

This option is not supported when the source BE is on a ZFS file system.

-Y include_list_file
Use the contents of include_list_file to include specific files (including directories) from the newly created BE. include_list_file contains a list of files and directories, one per line. If a line item is a file, only that file is included; if a directory, that directory and all files beneath that directory, including subdirectories, are included.

This option is not supported when the source BE is on a ZFS file system.

-z filter_list_file
filter_list_file contains a list of items, files and directories, one per line. Each item is preceded by either a +, indicating the item is to be included in the new BE, or -, indicating the item is to be excluded from the new BE.

This option is not supported when the source BE is on a ZFS file system.

When a source BE is on a UFS file system, the lude create command allows you to include or exclude specific files and directories when creating a new BE. You can include files and directories with:

- the -y include option
- the -Y include_list_file option
- items with a leading + in the file used with the -z filter_list option

You can exclude files and directories with:

- the -x exclude option
- the -f exclude_list_file option
- items with a leading – in the file used with the -z filter_list option

If the parent directory of an excluded item is included with include options (for example, -y include), then only the specific file or directory specified by exclude is excluded. Conversely, if the parent directory of an included file is specified for exclusion, then only the file include is included. For example, if you specify:

-x /a -y /a/b

all of /a except for /a/b is excluded. If you specify:

-y /a -x /a/b

all of /a except for /a/b is included.
Examples

The `lucreate` command produces copious output. In the following examples, this output is not reproduced, except where it is needed for clarity.

**EXAMPLE 1**  Creating a New Boot Environment for the First Time

The following command sequence creates a new boot environment on a machine on which a BE has never been created. All non-shareable (critical) file systems are mounted under `/`.

```
# lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The following command, like the preceding, creates a new boot environment on a machine on which a BE has never been created. However, the following command differs in two respects: the `-c` option is omitted and the `/usr` file system is mounted on its own disk slice, separate from `/`.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
lucreate: Please wait while your system configuration is determined.
many lines of output
lucreate: Creation of Boot Environment c0t4d0s0 successful.
```

In the absence of the `-c` option, `lucreate` assigns the name `c0t4d0s0`, the basename of the root device, to the new boot environment.

The same command is entered, with the addition of `-c`:

```
# lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following creation of a BE, you use `luupgrade(1M)` to upgrade the OS on the new BE and `luactivate(1M)` to make that BE the BE you will boot from upon the next reboot of your machine. Note that the swap partition and all shareable file systems for `first_disk` will be available to (shared with) `second_disk`.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
many lines of output
luupgrade: Upgrade of Boot Environment <second_disk> successful.
```

```
# luactivate second_disk
```

See `luupgrade(1M)` and `luactivate(1M)` for descriptions of those commands.

**EXAMPLE 2**  Creating a BE Using a Source Other than the Current BE

The following command uses the `-s` option to specify a source BE other than the current BE.
EXAMPLE 2  Creating a BE Using a Source Other than the Current BE  (Continued)

```bash
# lucreate -s third_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk

many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

EXAMPLE 3  Migrating a BE from a UFS Root File System to a ZFS Root File System

The following command creates a BE of a ZFS root file system from a UFS root file system. The current BE, c1t0d0s0, containing a UFS root file system, is identified by the `-c` option. The new BE, zfsBE, is identified by the `-n` option. A ZFS storage pool must exist before the `lucreate` operation and must be created with slices rather than whole disks to be upgradeable and bootable.

```bash
# zpool create rpool mirror c1t0d0s0 c2t0d0s0
# lucreate -c c1t0d0s0 -n zfsBE -p rpool

Note that if the current BE also resides on the ZFS pool rpool, the `-p` option could be omitted. For example:

```bash
# lucreate -n zfsBE
```

EXAMPLE 4  Creating a BE from a Flash Archive

Performing this task involves use of `lucreate` with the `-s` option and `luupgrade`.

```bash
# lucreate -s - -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk

brief messages
lucreate: Creation of Boot Environment <second_disk> successful.
```

With the `-s` option, the `lucreate` command completes it work within seconds. At this point, you can use `luupgrade` to install the flash archive:

```bash
# luupgrade -f -n second_disk \ 
-s /net/installmachine/export/solarisX/OS_image \ 
-J "archive_location http://example.com/myflash.flar"

See `luupgrade(1M)` for a description of that command.

EXAMPLE 5  Creating an Unpopulated BE from a ZFS Root

The following command uses the `-s` option to create an unpopulated BE from a ZFS root. You can subsequently use `luupgrade(1M)` to install a flash archive on the unpopulated BE, as in the previous example.

```bash
# lucreate -n second_disk -s - -p mypool
```
EXAMPLE 6  Sharing and Adding Swap Partitions

In the simplest case, if you do not specify any swap partitions in an lucreate command, all swap partitions in the source BE are shared with the new BE. For example, assume that the current BE uses /dev/dsk/c0t4d0s7 as its swap partition. You enter the command:

```
# lucreate -n second_disk -m /:/dev/dsk/c0t4d0s0:ufs
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon conclusion of the preceding command, the partition /dev/dsk/c0t4d0s7 will be used by the BE second_disk when that BE is activated and booted.

If you want a new BE to use a different swap partition from that used by the source BE, enter one or more -m options to specify a new partition or new partitions. Assume, once again, that the current BE uses /dev/dsk/c0t4d0s7 as its swap partition. You enter the command:

```
# lucreate -m /:/dev/dsk/c0t0d0s0:ufs -m -:shared:swap -m -:/dev/dsk/c0t4d0s1:swap -m -:/dev/dsk/c0t4d0s2:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon activation and boot, the new BE second_disk will use /dev/dsk/c0t4d0s1 and /dev/dsk/c0t4d0s2 and will not use /dev/dsk/c0t4d0s7, the swap partition used by the source BE.

Assume you want the new BE second_disk to share the source BE’s swap partition and have an additional swap partition. You enter:

```
# lucreate -m /:/dev/dsk/c0t0d0s0:ufs -m -:shared:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon activation and boot, the new BE second_disk will use for swapping /dev/dsk/c0t4d0s7, shared with the source BE, and, in addition, /dev/dsk/c0t4d0s1.

EXAMPLE 7  Using Swap Partitions on Multiple Disks

The command below creates a BE on a second disk and specifies swap partitions on both the first and second disks.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \
- m -:shared:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following completion of the preceding command, the BE second_disk will use both /dev/dsk/c0t4d0s1 and /dev/dsk/c0t4d0s1 as swap partitions. These swap assignments take effect only after booting from second_disk. If you have a long list of swap partitions, it is useful to use the -M option, as shown below.
EXAMPLE 8  Using a Combination of -m and -M Options

In this example, a list of swap partitions is collected in the file /etc/lu/swapslices. The location and name of this file is user-defined. The contents of /etc/lu/swapslices:

```
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t4d0s2:swap
-:/dev/dsk/c0t5d0s2:swap
-:/dev/dsk/c1t3d0s2:swap
-:/dev/dsk/c1t4d0s2:swap
-:/dev/dsk/c1t5d0s2:swap
```

This file is specified in the following command:

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs 
-M /etc/lu/swapslices -n second_disk
```

many lines of output

```
lucreate: Creation of Boot Environment <second_disk> successful.
```

The BE second_disk will swap onto the partitions specified in /etc/lu/swapslices.

EXAMPLE 9  Copying Versus Sharing

The following command copies the user file system /home (in addition to the non-shareable file systems / and /usr) from the current BE to the new BE:

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs 
-m /home:/dev/dsk/c0t4d0s4:ufs -n second_disk
```

The following command differs from the preceding in that the -m option specifying a destination for /home is omitted. The result of this is that /home will be shared between the current BE and the BE second_disk.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs 
-n second_disk
```

EXAMPLE 10  Using Solaris Volume Manager Volumes

The command shown below does the following:

1. Creates the mirror d10 and establishes this mirror as the receptacle for the root file system.
2. Attaches c0t0d0s0 and c0t1d0s0 to single-slice concatenations d1 and d2, respectively. 
   Note that the specification of these volumes is optional.
3. Attaches the concatenations associated with c0t0d0s0 and c0t1d0s0 to mirror d10.
4. Copies the current BE's root file system to mirror d10, overwriting any d10 contents.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror 
-m /:/dev/md/dsk/d1:d1:attach 
-m /:/dev/md/dsk/c0t0d0s0,d2:attach -n newBE
```

EXAMPLE 10  Using Solaris Volume Manager Volumes  (Continued)

The following command differs from the preceding only in that concatenations for the
physical storage devices are not specified. In this example, lucreate chooses concatenation
names from a list of free names and attaches these volumes to the mirror specified in the first
-m option.

# lucreate -m /:/dev/md/dsk/d10:ufs,mirror
   -m /:/dev/dsk/c0t0d0s0:attach
   -m /:/dev/dsk/c0t1d0s0:attach -n newBE

The following command differs from the preceding commands in that one of the physical
disks is detached from a mirror before being attached to the mirror you create. Also, the
contents of one of the physical disks is preserved. The command does the following:

1. Creates the mirror d10 and establishes this mirror as the receptacle for the root file system.
2. Detaches c0t0d0s0 from the mirror to which it is currently attached.
3. Attaches c0t0d0s0 and c0t1d0s0 to concatenations d1 and d2, respectively. Note that the
   specification of these concatenations is optional.
4. Preserves the contents of c0t0d0s0, which presumes that c0t0d0s0 contains a valid copy
   of the current BE's root file system.
5. Attaches the concatenations associated with c0t0d0s0 and c0t1d0s0 (d1 and d2) to mirror
d10.

# lucreate -m /:/dev/md/dsk/d10:ufs,mirror
   -m /:/dev/dsk/c0t0d0s0,d1:detach,attach,preserve
   -m /:/dev/dsk/c0t1d0s0,d2:attach -n nextBE

The following command is a follow-on to the first command in this set of examples. This
command detaches a concatenation (containing c0t0d0s0) from one mirror (d10, in the first
command) and attaches it to another (d20), preserving its contents.

# lucreate -m /:/dev/md/dsk/d20:ufs,mirror
   -m /:/dev/dsk/c0t0d0s0:detach,attach,preserve -n nextBE

The following command creates two mirrors, placing the / file system of the new BE on one
mirror and the /opt file system on the other.

# lucreate -m /:/dev/md/dsk/d10:ufs,mirror
   -m /:/dev/dsk/c0t0d0s0,d1:attach
   -m /:/dev/dsk/c1t0d0s0,d2:attach
   -m /opt:/dev/md/dsk/d11:ufs,mirror
   -m /opt:/dev/dsk/c2t0d0s1,d3:attach
   -m /opt:/dev/dsk/c3t1d0s1,d4:attach -n anotherBE

EXAMPLE 11  Invoking FMLI-based Interface

This example is included for historical purposes as the lu interface is now obsolete.
EXAMPLE 11  Invoking FMLI-based Interface  (Continued)

The command below, by omitting -m or -M options, invokes lu, the FMLI-based interface for Live Upgrade operations.

# lucreate -n second_disk

The preceding command uses the current BE as the source for the target BE second_disk. In the FMLI interface, you can specify the target disk slices for second_disk. The following command is a variation on the preceding:

# lucreate -n second_disk -s third_disk

In the preceding command, a source for the target BE is specified. As before, the FMLI interface comes up, enabling you to specify target disk slices for the new BE.

EXAMPLE 12  Merging File Systems

The command below merges the /usr/opt file system into the /usr file system. First, here are the disk slices in the BE first_disk, expressed in the format used for arguments to the -m option:

/::/dev/dsk/c0t4d0s0:ufs
/usr::/dev/dsk/c0t4d0s1:ufs
/usr/opt::/dev/dsk/c0t4d0s3:ufs

The following command creates a BE second_disk and performs the merge operation, merging /usr/opt with its parent, /usr.

# lucreate -m /::/dev/dsk/c0t4d0s0:ufs -m /usr::/dev/dsk/c0t4d0s1:ufs \
-m /usr/opt:merged:ufs -n second_disk

EXAMPLE 13  Splitting a File System

Assume a source BE with /, /usr, and /var all mounted on the same disk slice. The following command creates a BE second_disk that has /, /usr, and /var all mounted on different disk slices.

# lucreate -m /::/dev/dsk/c0t4d0s0:ufs -m /usr::/dev/dsk/c0t4d0s1:ufs \
/var::/dev/dsk/c0t4d0s3:ufs -n second_disk

This separation of a file system's (such as root's) components onto different disk slices is referred to as splitting a file system.

EXAMPLE 14  Specifying Alternative Slices

The following command uses multiple -m options as alternative disk slices for the new BE second_disk.

# lucreate -m /::/dev/dsk/c0t4d0s0:ufs -m /::/dev/dsk/c0t4d0s1:ufs \
-m /::/dev/dsk/c0t4d0s5:ufs -n second_disk
EXAMPLE 14  Specifying Alternative Slices (Continued)

many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.

The preceding command specifies three possible disk slices, $s0$, $s1$, and $s5$ for the / file system. `lucreate` selects the first one of these slices that is not being used by another BE. Note that the -s option is omitted, meaning that the current BE is the source BE for the creation of the new BE.

EXAMPLE 15  Specifying Separate File Systems for Non-Global Zones

The following command specifies a separate file system belonging to the zone, `zone1`, within the new BE, `second_disk`.

```
# lucreate -n second_disk -m /:/dev/dsk/c0d0s3:ufs 
  -m /export/home:/dev/dsk/c0d0s5:ufs:zone1
```

The zone named `zone1`, inside the new BE, has a separate disk slice allocated for its /export/home file system.

EXAMPLE 16  Specifying a Separate Dataset for /var Using -D

The following command specifies a separate dataset for /var during creation of a ZFS root boot environment from a parent boot environment with a UFS root.

```
# lucreate -n zfsroot_BE -p mypool -D /var
```

With the preceding command, the dataset shown below will be created under the root dataset. This dataset will be mounted as /var in the newly created boot environment. The dataset will be created with the `canmount=noauto` option and will inherit the `mountpoint` property from the root dataset.

```
mypool/ROOT/zfsroot_BE/var
```

If you were to exclude the -D option in the example command /var would be merged with / (root) in the ZFS root BE.

EXAMPLE 17  Specifying a Separate Dataset for /data Using -D

The following command creates a separate dataset for /data under the root dataset in a ZFS root BE.

```
# lucreate -n zfsroot_BE -p mypool -D /data
```

The preceding command presumes that /data resides in a UFS file system in the parent BE. The command creates the following dataset.

```
mypool/ROOT/zfsroot_BE/data
```
This dataset will be created with mountpoint=legacy and cnamount=noauto and an entry will be created for /data in /etc/vfstab of the newly created BE. Also, given that the dataset for /data resides under the root dataset in the ZFS root BE, /data will no longer be shared between the parent BE and the newly created ZFS root BE. If the ZFS root BE becomes the source BE in a subsequent lucreate operation, /data will be treated the same (for snapshot/cloning or copying) as other datasets under the root dataset holding OS-critical components.

**Exit Status**
The following exit values are returned:

- 0: Successful completion.
- >0: An error occurred.

**Files**
- /etc/lutab: list of BEs on the system
- /usr/share/lib/xml/dtd/lu_cli.dtd: Live Upgrade DTD (see -X option)

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWlu</td>
</tr>
</tbody>
</table>

**See Also**

**Notes**
As is true for any Solaris operating system upgrade (and not a feature of Live Upgrade), when splitting a directory into multiple mount points, hard links are not maintained across file systems. For example, if /usr/test1/buglist is hard linked to /usr/test2/buglist, and /usr/test1 and /usr/test2 are split into separate file systems, the link between the files will no longer exist. If lucreate encounters a hard link across file systems, the command issues a warning message and creates a symbolic link to replace the lost hard link.

lucreate cannot prevent you from making invalid configurations with respect to non-shareable file systems. For example, you could enter a lucreate command that would create separate file systems for / and /kernel—an invalid division of /. The resulting BE would be unbootable. When creating file systems for a boot environment, the rules are identical to the rules for creating file systems for the Solaris operating environment.

Mindful of the principle described in the preceding paragraph, consider the following:
- In a source BE, you must have valid vfstab entries for every file system you want to copy to or share with a new BE.
You cannot create a new BE on a disk with overlapping partitions (that is, partitions that share the same physical disk space). The `lucreate` command that specifies such a disk might complete, but the resulting BE would be unbootable.

**Note** – As stated in the description of the `-m` option, if you use Solaris Volume Manager volumes for boot environments, use `lucreate` rather than Solaris Volume Manager commands to manipulate these volumes. The Solaris Volume Manager software has no knowledge of boot environments; the `lucreate` command contains checks that prevent you from inadvertently destroying a boot environment by, for example, overwriting or deleting a Solaris Volume Manager volume.

For versions of the Solaris operating system prior to Solaris 10, Live Upgrade supports the release it is distributed on and up to three marketing releases back. For example, if you obtained Live Upgrade with Solaris 9 (including a Solaris 9 upgrade), that version of Live Upgrade supports Solaris versions 2.6, Solaris 7, and Solaris 8, in addition to Solaris 9. No version of Live Upgrade supports a Solaris version prior to Solaris 2.6.

Starting with version 10 of the Solaris operating system, Live Upgrade supports the release it is distributed on and up to two marketing releases back. For example, if you obtained Live Upgrade with Solaris 10 (including a Solaris 10 upgrade), that version of Live Upgrade supports Solaris 8 and Solaris 9, in addition to Solaris 10. For instructions on adding Live Upgrade packages for the release you want to install, see *Solaris 10 5/08 Installation Guide: Solaris Live Upgrade and Upgrade Planning*.

Correct operation of Solaris Live Upgrade requires that a limited set of patch revisions be installed for a given OS version. Before installing or running Live Upgrade, you are required to install the limited set of patch revisions. Make sure you have the most recently updated patch list by consulting `http://sunsolve.sun.com`. Search for the infodoc 72099 on the SunSolve web site.
lucurr(1M)

Name  lucurr – display the name of the active boot environment

Synopsis  /usr/sbin/lucurr [-l error_log] [-m mount_point]
           [-o outfile] [-X]

Description  The lucurr command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See live_upgrade(5) for a description of the Live Upgrade feature.

The lucurr command displays the name of the currently running boot environment (BE). If no BEs are configured on the system, lucurr displays the message "No Boot Environments are defined". Note that lucurr reports only the name of the current BE, not the BE that will be active upon the next reboot. Use lustatus(1M) or luactivate(1M) for this information.

The lucurr command requires root privileges.

Options  The lucurr command has the following options:
- l error_log  Error and status messages are sent to error_log, in addition to where they are sent in your current environment.
- m mount_point  Returns the name of the BE that owns mount_point, where mount_point is the mount point of a BE's root file system. This can be a mount point of the current BE or the mount point of a BE other than the current BE. If the latter, the file system of the BE must have been mounted with lumount(1M) or mount(1M) before entering this option.
- o outfile  All command output is sent to outfile, in addition to where it is sent in your current environment.
- X  Enable XML output. Characteristics of XML are defined in DTD, in /usr/share/lib/xml/dtd/lu_cli.dtd.<num>, where <num> is the version number of the DTD file.

Exit Status  The following exit values are returned:
0  Successful completion.
>0  An error occurred.

Files  /etc/lutab  list of BEs on the system
       /usr/share/lib/xml/dtd/lu_cli.dtd.<num>  Live Upgrade DTD (see -X option)

        ludesc(1M), lufslist(1M), lumake(1M), lumount(1M), lurename(1M), lustatus(1M),
        luupgrade(1M), lutab(4), attributes(5), live_upgrade(5)
ludelete (1M)

Name  ludelete – delete a boot environment

Synopsis  /usr/sbin/ludelete [-l error_log] [-o outfile] BE_name [-X]

Description  The ludelete command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See live_upgrade(5) for a description of the Live Upgrade feature.

The ludelete command deletes all records associated with a boot environment (BE) on all defined complete BEs. A complete BE is one that is not participating in an lucreate(1M), luupgrade(1M), or lucompare(1M) operation. Use lustatus(1M) to determine a BE’s status. You can delete neither the current BE, nor the BE that will become current upon the next reboot.

ludelete does not alter any files on the BE being deleted.

The ludelete command requires root privileges.

Options  The ludelete command has the following options:

- `-l error_log`  Error and status messages are sent to error_log in addition to where they are sent in your current environment.

- `-o outfile`  All command output is sent to outfile, in addition to where it is sent in your current environment.

- `-X`  Enable XML output. Characteristics of XML are defined in DTD, in
/usr/share/lib/xml/dtd/lu_cli.dtd.<num>, where <num> is the version number of the DTD file.

Operands  `BE_name`  Name of the BE to be deleted.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Files  `/etc/lutab`  list of BEs on the system

`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`  Live Upgrade DTD (see -X option)

The \texttt{ludesc} command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See \texttt{live\_upgrade(5)} for a description of the Live Upgrade feature.

The \texttt{ludesc} command allows you to manipulate boot environment (BE) descriptions. A BE description is an optional attribute of a BE. It can be text or binary data. For example, it might be a string such as "S9 beta test BE" or it might be a file that contains 8–bit multi-byte characters. The \texttt{ludesc} command in general and the options to manipulate binary-format descriptions in particular are suitable for use in programs.

You create a BE description using \texttt{ludesc} or \texttt{lucreate(1M)}. Only \texttt{ludesc} allows you to change a BE description or add a description following BE creation.

While a BE description is associated with a BE name, it is not interchangeable with that name. No Live Upgrade command allows you to specify a BE description instead of a BE name when performing an operation on a BE.

A shell might restrict what you enter for a BE description (in both \texttt{ludesc} and \texttt{lucreate(1M)}). In entering a description, use the following guidelines:

- Always enclose a description in single quotes (\textquoteleft\textquoteleft), unless the description includes a single quote.
- If your description includes a single quote, enclose the description in double quotes (\textquoteleft\textquoteright\textquoteleft). You then must use an escape sequence (usually a backslash [\textbackslash\textbackslash]) to enter a character that is special to the shell. See \texttt{sh(1)} for a list of special characters and a description of the escape sequence mechanism.

Descriptions that include many special characters might be more conveniently inserted in a file (\texttt{-f} option) than entered on a command line (\texttt{-A} option).

When \texttt{ludesc} outputs a BE description, it does so exactly as the description was entered. Because of this feature, a description that is a text string does not have a concluding newline, which means the system prompt immediately follows the last character of the description.

The \texttt{ludesc} command requires root privileges.
The `ludesc` command has the following options:

- **-A** *BE_description* Displays the BE name associated with *BE_description*.
- **-f** `{filename | -}` Specify the BE description contained in *filename* or read from stdin. When used without -n, displays the BE name associated with the specified BE description. Used with -n, changes the description for the specified BE to the description specified with -f.
- **-l** *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- **-n** *BE_name* With no other arguments, displays the BE description for the specified BE. With the -f option or the *BE_description* operand, changes the description for the specified BE to that specified with -f or *BE_description*.
- **-o** *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- **-X** Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd`. `<num>`, where `<num>` is the version number of the DTD file.

**Operands**

*BE_description* Used only with the -n option. *BE_description* replaces the current BE description for the specified BE.

**Examples**

The following are examples of the use of `ludesc`.

**EXAMPLE 1  Basic Use**

The first command, below, assigns a description to a BE. The second command returns the name of the BE associated with the specified description. The last command returns the description associated with a specified BE.

```
# ludesc -n first_disk 'Test disk'
Setting description for boot environment <first_disk>.
Propagating the change of BE description to all BEs.

# ludesc -A 'Test disk'
first_disk
#

# ludesc -n first_disk
Test disk#
```

As seen above and noted in the DESCRIPTION, `ludesc` does not append a newline to the display of BE description that is a text string.
EXAMPLE 2 Using Binary Files

The following commands are analogs of the preceding examples, substituting a binary file—here, a file containing a description in Russian, using the Cyrillic alphabet—for a text string. In the third command, note the use of a file to capture output. Sending output of a binary file to the console can produce erratic results.

```bash
# ludesc -n first_disk -f arrayBE.ru
Setting description for boot environment <first_disk>.
Propagating the change of BE description to all BEs.

# ludesc -f arrayBE.ru
first_disk

# ludesc -n first_disk > /tmp/arrayBE.out
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files

- `/etc/lutab` list of BEs on the system
- `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>` Live Upgrade DTD (see -X option)

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWluu</td>
</tr>
</tbody>
</table>

See Also `luactivate(1M), lucancel(1M), lucompare(1M), lucreate(1M), ludelete(1M), lufslist(1M), lumake(1M), lumount(1M), lurename(1M), lustatus(1M), luupgrade(1M), lutab(4), attributes(5), live_upgrade(5)`
The `lufslist` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lufslist` command lists the configuration of a boot environment (BE). The output contains the disk slice (file system), file system type, and file system size for each BE mount point. The output also notes any separate file systems that belong to a non-global zone inside the BE being displayed.

The following is an example of `lufslist` output, which shows a separate filesystem for the zone, zone1, within the BE being displayed.

```
# lufslist BE_name
Filesystem   fstype  size(Mb)  Mounted on
-----------------------------------------------
/dev/dsk/c0t0d0s1  swap   512.11  -
/dev/dsk/c0t4d0s3  ufs    3738.29  /
/dev/dsk/c0t4d0s4  ufs    510.24  /opt

zone zone1 within boot environment BE_name
/dev/dsk/c0t4d0s7  ufs    7000.48  /export
```

File system type can be ufs, swap, or vxfs, for a Veritas file system. Under the Filesystem heading can be a disk slice or a logical device, such as a disk metadevice used by volume management software.

The `lufslist` command requires root privileges or the Primary Administrator role.

**Options**

The `lufslist` command has the following options:

- `-l error_log`  Error and status messages are sent to `error_log`, in addition to where they are sent in your current environment.
- `-o outfile`  All command output is sent to `outfile`, in addition to where it is sent in your current environment.
- `-X`  Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd`, where `<num>` is the version number of the DTD file.

**Operands**

`BE_name`  Name of the BE for which file systems are to be reported. You cannot specify a BE that is involved in another Live Upgrade operation.
Exit Status  The following exit values are returned:

0       Successful completion.

>0      An error occurred.

Files  /etc/lutab                                  list of BEs on the system
       /usr/share/lib/xml/dtd/lu_cli.dtd.<num>     Live Upgrade DTD (see -X option)

ludelete(1M), ludesc(1M), lumake(1M), lumont(1M), lurename(1M), lustatus(1M),
luupgrade(1M), lutab(4), attributes(5), live_upgrade(5), zones(5)
**Name**  
lumake – populate a boot environment

**Synopsis**  
```
/usr/sbin/lumake [-l error_log] [-o outfile] [-s source_BE] -n BE_name [-X]
```
```
/usr/sbin/lumake [-l error_log] -t time [-o outfile]
[-s source_BE] -n BE_name [-m email_address] [-X]
```

**Description**  
The `lumake` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lumake` command populates (that is, copies files to) the file systems of a specified boot environment (BE) by copying files from the corresponding file systems of the active or a source (-s) BE. Any existing data on the target BE are destroyed. All file systems on the target BE are re-created.

The target BE must already exist. Use `lucreate(1M)` to create a new BE.

The `lumake` command requires root privileges.

**Options**  
The `lumake` command has the following options:

- `-n BE_name`  
  Name of the BE to be populated.

- `-s source_BE`  
  The optional name of a source BE. If you omit this option, `lumake` uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use `lustatus(1M)` to determine a BE's status.

- `-l error_log`  
  Error and status messages are sent to `error_log`, in addition to where they are sent in your current environment.

- `-o outfile`  
  All command output is sent to `outfile`, in addition to where it is sent in your current environment.

- `-t time`  
  Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the `at(1)` man page. At any time, you can have only one Live Upgrade operation scheduled. You can use `lucancel(1M)` to cancel a scheduled `lumake` operation.

- `-m email_address`  
  Allows you to email `lumake` output to a specified address upon command completion. There is no checking of `email_address`. Use this option in conjunction with `-t`, to obtain notification of batch command completion. If you use `-m` with options other than `-t`, no email is sent.

- `-X`  
  Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.
Exit Status  The following exit values are returned:

0      Successful completion.

>0     An error occurred.

Files  /etc/lutab                  list of BEs on the system
       /usr/share/lib/xml/dtd/lu_cli.dtd.<num>   Live Upgrade DTD (see -X option)

lumount, luumount – mount or unmount all file systems in a boot environment

Synopsis

/usr/sbin/lumount [-l error_log] [-o outfile] BE_name
    [mount_point] [-X]

    /usr/sbin/lumount

    /usr/sbin/luumount [-f]
    { [-n] BE_name | [-m] mount_point | block_device}
    [-l error_log] [-o outfile] [-X]

Description

The lumount and luumount commands are part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See live_upgrade(5) for a description of the Live Upgrade feature.

The lumount and luumount commands enable you to mount or unmount all of the file systems in a boot environment (BE). This allows you to inspect or modify the files in a BE while that BE is not active. By default, lumount mounts the file systems on a mount point of the form /.alt.BE_name, where BE_name is the name of the BE whose file systems are being mounted. See NOTES.

lumount and luumount also mount or unmount all installed non-global zones within the BE. For each running, mounted, or ready non-global zone in the current BE, lumount mounts all file systems in the mounted BE that belong to the non-global zone, at the specified mount point in the non-global zone. This provides the non-global zone administrator access to the corresponding file systems that exist in the mounted BE.

When invoked with no arguments, lumount returns the name(s) of the mounted BEs on a system.

The lumount and luumount commands require root privileges or the Primary Administrator role.

Options

The lumount and luumount commands have the following options:

- **-f**
  For luumount only, forcibly unmount a BE’s file systems after attempting (and failing) an unforced unmount. This option is analogous to the mount(1M) -f option.

- **-l error_log**
  Error and status messages are sent to error_log, in addition to where they are sent in your current environment.

- **-m mount_point**
  luumount unmounts the file systems of the BE that owns mount_point. See description of mount_point under OPERANDS, below. The use of -m is optional when specifying a mount point for luumount.

- **-n BE_name**
  Name of the BE whose file systems will be unmounted. See description of BE_name under OPERANDS, below. The use of -n is optional when specifying a BE name for luumount.
All command output is sent to outfile, in addition to where it is sent in your current environment.

Enable XML output. Characteristics of XML are defined in DTD, in /usr/share/lib/xml/dtd/lu_clia.dtd.<num>, where <num> is the version number of the DTD file.

For lumount, if you supply an argument and specify neither -m nor -n, the command determines whether your argument is a BE name, a mount point, or a block device. If it is one of these three and the argument is associated with a BE that has mounted file systems, lumount unmounts the file systems of that BE. Otherwise, lumount returns an error.

**Operands**

- **BE_name** Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an lumount or luumount command, the status of a BE must be complete, as reported by lstatus(1M). Also, none of the BE's disk slices can be mounted (through use of mount(1M)).

- **mount_point** For lumount, a mount point to use instead of the default / .alt. BE_name. If mount_point does not exist, lumount creates it. For luumount, the BE associated with mount_point will have its file systems unmounted. Note that default mount points are automatically deleted upon unmounting with luumount. Mount points that you specify are not deleted.

- **block_device** For luumount only, block_device is the root slice of a BE, such as /dev/dsk/c0t4d0s0. lumount unmounts the file systems of the BE associated with block_device.

**Examples**

**EXAMPLE 1** Specifying a Mount Point

The following command creates the mount point /test and mounts the file systems of the BE second_disk on /test.

```
# lumount second_disk /test
```

You can then cd to /test to view the file systems of second_disk. If you did not specify /test as a mount point, lumount would create a default mount point named / .alt. second_disk.

If you have installed non-global zones on your system, this command will also mount all non-global zones in second_disk inside their corresponding non-global zones in the currently running system at the mount point /test (or / .alt. second_disk if a mount point was not specified).

**EXAMPLE 2** Unmounting File Systems

The following command unmounts the file systems of the BE second_disk. In this example, we cd to / to ensure we are not in any of the file systems in second_disk.
EXAMPLE 2  Unmounting File Systems  (Continued)

    # cd /
    # luumount second_disk
    #

If /dev/dsk/c0t4d0s0 were the root slice for second_disk, you could enter the following
command to match the effect of the preceding command.

    # cd /
    # luumount /dev/dsk/c0t4d0s0
    #

**Exit Status**  The following exit values are returned:

0    Successful completion.

>0    An error occurred.

**Files**  /etc/lutab      list of BEs on the system
            /usr/share/lib/xml/dtd/lu_cli.dtd.<num>    Live Upgrade DTD (see -X option)

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWluu</td>
</tr>
</tbody>
</table>

**See Also**  luactivate(1M), lucancel(1M), lucompare(1M), lucreate(1M), lucurr(1M),
ludelete(1M), ludesc(1M), lufslist(1M), lumake(1M), lurename(1M), lusstatus(1M),
luupgrade(1M), lutab(4), attributes(5), live_upgrade(5), zones(5)

**Notes**  If a BE name contains slashes (/), luumount replaces those slashes with colons in a default
mount point name. For example:

    # luumount 'first/disk'
    /.alt.first:disk
The `lurename` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lurename` command renames the boot environment (BE) `BE_name` to `new_name`.

The string `new_name` must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the "Quoting" section of `sh(1)`. The BE name can contain only single-byte, 8-bit characters. It cannot contain whitespace characters. Also, `new_name` must be unique on the system.

A BE must have the status "complete" before you rename it. Use `lustatus(1M)` to determine a BE's status. Also, you cannot rename a BE that has file systems mounted with `lumount(1M)` or `mount(1M)`.

Renaming a BE is often useful when you upgrade the BE from one Solaris release to another. For example, following an operating system upgrade, you might rename the BE `solaris7` to `solaris8`.

The `lurename` command requires root privileges.

The `lurename` command has the options listed below.

- `-e BE_name` Name of the BE whose name you want to change.
- `-l error_log` Error and status messages are sent to `error_log`, in addition to where they are sent in your current environment.
- `-n new_name` New name of the BE. `new_name` must be unique on a given system.
- `-o outfile` All command output is sent to `outfile`, in addition to where it is sent in your current environment.
- `-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd`, where `<num>` is the version number of the DTD file.

The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.
lurename(1M)

ludelete(1M), ludesc(1M), lufslist(1M), lumake(1M), lumount(1M), lustatus(1M),
luupgrade(1M), lutab(4), attributes(5), live_upgrade(5)
The `lustatus` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lustatus` command displays the status information of the boot environment (BE) `BE_name`. If no BE is specified, the status information for all BEs on the system is displayed.

The headings in the `lustatus` information display are described as follows:

- **Boot Environment Name**: Name of the BE.
- **Is Complete**: Indicates whether a BE is able to be booted. Any current activity or failure in an `lucreate(1M)` or `luupgrade(1M)` operation causes a BE to be incomplete. For example, if there is a copy operation proceeding on or scheduled for a BE, that BE is considered incomplete.
- **Active Now**: Indicates whether the BE is currently active. The “active” BE is the one currently booted.
- **Active On Reboot**: Indicates whether the BE becomes active upon next reboot of the system.
- **Can Delete**: Indicates that no copy, compare, or upgrade operations are being performed on a BE. Also, none of that BE’s file systems are currently mounted. With all of these conditions in place, the BE can be deleted.
- **Copy Status**: Indicates whether the creation or repopulation of a BE is scheduled or active (that is, in progress). A status of ACTIVE, COMPARING (from `lucompare(1M)`), UPGRADING, or SCHEDULED prevents you performing Live Upgrade copy, rename, or upgrade operations.

The following is an example `lustatus` display:

<table>
<thead>
<tr>
<th>Boot Environment Name</th>
<th>Is Complete</th>
<th>Active Now</th>
<th>Active On Reboot</th>
<th>Can Delete</th>
<th>Copy Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>disk_a_S7</td>
<td>yes</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
<td>-</td>
</tr>
<tr>
<td>disk_b_S7db</td>
<td>yes</td>
<td>no</td>
<td>no</td>
<td>no</td>
<td>UPGRADING</td>
</tr>
<tr>
<td>disk_b_S8</td>
<td>no</td>
<td>no</td>
<td>no</td>
<td>no</td>
<td>-</td>
</tr>
<tr>
<td>S9itestbed</td>
<td>yes</td>
<td>no</td>
<td>no</td>
<td>yes</td>
<td>-</td>
</tr>
</tbody>
</table>
Note that you could not perform copy, rename, or upgrade operations on disk_b_S8, because it is not complete, nor on disk_b_S7db, because a Live Upgrade operation is pending.

The lustatus command requires root privileges.

**Options**

The lustatus command has the following options:

- `-l error_log` Error and status messages are sent to error_log, in addition to where they are sent in your current environment.
- `-o outfile` All command output is sent to outfile, in addition to where it is sent in your current environment.
- `-X` Enable XML output. Characteristics of XML are defined in DTD, in /usr/share/lib/xml/dtd/lu_cli.dtd.<num>, where <num> is the version number of the DTD file.

**Operands**

**BE_name** Name of the BE for which to obtain status. If BE_name is omitted, lustatus displays status for all BEs in the system.

**Exit Status**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Files**

/etc/lutab list of BEs on the system

/usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

luactivate(1M), lucancel(1M), lucompare(1M), lucreate(1M), lucurr(1M),
ludesc(1M), ludelete(1M), lufslist(1M), lumake(1M), lumount(1M), lurenamed(1M),
lupgrade(1M), lutab(4), attributes(5), live_upgrade(5)
The `luupgrade` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `luupgrade` command enables you to install software on a specified boot environment (BE). Specifically, `luupgrade` performs the following functions:

- Upgrades an operating system image on a BE (\(-u\) option). The source for the image can be any valid Solaris installation medium, including a Solaris Flash archive.
- Extract a Solaris Flash archive onto a BE (\(-f\) option). (See `flar(1M)`.)
- Add a package to (\(-p\)) or remove a package from (\(-P\)) a BE.
- Add a patch to (\(-t\)) or remove a patch from (\(-T\)) a BE.
- Check (\(-C\)) or obtain information about (\(-I\)) packages.
- Check an operating system installation medium (\(-c\)).

Before using `luupgrade`, you must have created a BE, using the `lucreate(1M)` command. You can upgrade only BEs other than the current BE.

The functions described in the preceding list each has its own set of options, which are described separately for each function.

Note that, for successful completion of an `luupgrade` operation, the status of a BE must be complete, as reported by `lustatus(1M)`. Also, the BE must not have any mounted disk slices, mounted either with `lumount(1M)` or `mount(1M)`.

`luupgrade` allows you to install an operating system image from a different marketing release of the Solaris operating system from the release running on the machine from which you invoke `luupgrade`. This feature has the following conditions:

- You can install Live Upgrade packages (`SUNWluu`, `SUNWlur`, and `SUNWlucfg`) from a given release of the Solaris operating system on a machine running a previous release. You can install these packages on a machine running a version of Solaris that is up to three releases prior to the release of the Live Upgrade packages. Live Upgrade is not supported on Solaris releases prior to Solaris 2.6. Thus, you can, for example, install Solaris 2.9 packages on Solaris 2.8, 2.7, and 2.6 machines.
- You can upgrade to a release of the Solaris operating system that is the same as the release of the Live Upgrade packages installed on a machine. This feature allows you to upgrade to Solaris upgrade releases within a marketing release. For example, if have the Solaris 9 FCS Live Upgrade packages installed on a machine, you can use `luupgrade` to upgrade a BE to the Solaris 9 update 3 release of the Solaris operating system.

See the `Solaris Installation Guide` for instructions on installing Live Upgrade packages.
The luupgrade command requires root privileges.

The following options are available for all uses of luupgrade:

- `-l error_log` Error and status messages are sent to `error_log`, in addition to where they are sent in your current environment.
- `-o outfile` All command output is sent to `outfile`, in addition to where it is sent in your current environment.
- `-N` Dry-run mode. Enables you to determine whether your command arguments are correctly formed. Does not apply to the `-c` (check medium) function.
- `-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

The luupgrade command uses `-u` to upgrade an operating system image. The syntax is as follows:

```
luupgrade -u -n BE_name -k autoreg_file [ -l error_log ]
 [ -o outfile ][-N] -s os_image_path [ -j profile_path [-D] ]
```

The first option, `-u`, indicates the function to perform—to install an OS image. The remaining options for this use of luupgrade, shown above, are described as follows:

- `-n BE_name` Name of the BE to receive an OS upgrade.
- `-k autoreg_file` Path to auto-registration information file. See `sysidcfg(4)` for a list of valid keywords for use in this file.
- `-s os_image_path` Path name of a directory containing an OS image. This can be a directory on an installation medium such as a DVD or CD, or can be an NFS or UFS directory.
- `-j profile_path` Path to a JumpStart profile. See the section "JumpStart Profile Keywords," below, for a list of valid keywords for use in a profile invoked by luupgrade. See `pinstall(1M)` and the Solaris installation documentation for information on the JumpStart software.
- `-D` Tests the profile values provided with `-j` against the disk configuration of the specified BE. The upgrade is not performed. The effect of this option is a dry run to test your profile. luupgrade creates log files, specified in its output, which allow you to examine the command's results.

Before upgrading a boot environment, do the following:

- Run `analyze_patches`.
- Install Live Upgrade packages for the operating system version to which you are upgrading.

The `analyze_patches` command is available in the `/Misc` directory on the Solaris software DVD (formerly the Solaris installation CD). This command determines which patches would be removed as a result of the upgrade. Then, following the upgrade, you can reinstall the list of patches provided by `analyze_patches`.

The Live Upgrade packages, `SUNWluu`, `SUNWlur`, and `SUNWlucfg`, are available on the Solaris software DVD (or CD, depending on the Solaris version). Before running `luupgrade` with the `-u` option, ensure that you have installed the packages from the version of Solaris to which you want to upgrade.

Note that if you are upgrading from a medium with multiple components, such as from multiple DVDs, use `luupgrade` with the `-i` option, as described in the section below, to install software from the second and any following media.

The `luupgrade` command uses `-i` to run an installer program. As discussed below, its primary use is following an invocation of `luupgrade` with the `-u` option. The syntax for `-i` is as follows:

```
luupgrade -i -n BE_name [-l error_log] [-o outfile] [-N] -s installation_medium [-O "installer_options"]
```

The first option, `-i`, indicates the function to perform—to run an installer program on the installation medium specified with `-s`. The remaining options for this use of `luupgrade`, shown above, are described as follows:

- `-n BE_name` Name of the BE on which software is to be installed.
- `-O "installer_options"` Options passed directly to the Solaris installer program. See `installer(1M)` for descriptions of the installer options.
- `-s installation_medium` Path name of an installation medium. This can be a DVD, CD, or an NFS or UFS directory.

With the `-i` option, `luupgrade` looks for an installation program on the specified medium and runs that program.

The primary use of the `-i` option is to upgrade an operating system image from a multiple-component medium, such as multiple DVDs. In this use, an `luupgrade` command with the `-i` option follows an invocation of `luupgrade` with `-u`. See EXAMPLES. The `-u` option is described above.

The `luupgrade` command uses `-f` to install an operating system from a Solaris Flash archive. Note that installing an archive overwrites all files on the target BE. The syntax is as follows:

```
luupgrade -f -n BE_name [-l error_log] [-o outfile] [-N] [-D] -s os_image_path (-a archive | -j profile_path | -J "profile")
```

Continuing an Upgrade by Running an Installer Program

Installing from a Solaris Flash Archive

System Administration Commands - Part 1
The first option, -f, indicates the function to perform—to install an OS from a Solaris Flash archive. The remaining options for this use of luupgrade, shown above, are described as follows:

- **n BE Name**: Name of the BE to receive an OS installation.
- **-D**
  - Tests the profile values provided with -j or -J against the disk configuration of the specified BE. The upgrade is not performed. The effect of this option is a dry run to test your profile. luupgrade creates log files, specified in its output, which allow you to examine the command's results.
- **s os_path**
  - Path name of a directory containing an OS image. This can be a directory on an installation medium, such as a DVD or CD, or can be an NFS or UFS directory.
- **-a archive**
  - Path to the Solaris Flash archive when the archive is available on the local file system. You must specify one of -a, -j, or -J.
- **-j profile_path**
  - Path to a JumpStart profile that is configured for a Solaris Flash installation. See the section "JumpStart Profile Keywords," below, for a list of valid keywords for use in a profile invoked by luupgrade. See pfinish(1M) and the Solaris installation documentation for information on the JumpStart software. You must specify one of -a, -j, or -J.
- **-J "profile"**
  - Entry from a JumpStart profile that is configured for a Solaris Flash installation. The only valid keyword for this option is archive location. See pfinish(1M) and the Solaris installation documentation for information on the JumpStart software. You must specify one of -a, -j, or -J.

Note that the version of the OS image specified with -s must be identical to the version of the OS contained in the Solaris Flash archive specified with the -a, -j, or -J options.

### Adding or Removing Packages

The luupgrade command uses -p to add a package and -P to remove a package. The syntax is as follows:

**For adding packages:**

```
luupgrade -p -n BE_name [-l error_log] [-o outfile] [-N] [-s packages_path] [-O "pkgadd_options"] [-a admin] [ pkginst [ pkginst...]]
```

**For removing packages:**

```
luupgrade -P -n BE_name [-l error_log] [-o outfile] [-N] [-O "pkgrm_options"] [ pkginst [ pkginst...]]
```
The first option, `-p`, to add packages, or `-P` to remove packages, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

- `-n `BE_name` Name of the BE to which packages will be added or from which packages will be removed.
- `-s `packages_path` (For adding packages only.) Path name of a directory containing packages to add. You can substitute `-d` for `-s`. The `-d` support is for `pkgadd(1M)` compatibility.
- `-d `packages_path` Identical to `-s`. Use of `-s` is recommended.
- `-O "pkgadd_options" or "pkgrm_options" Options passed directly to `pkgadd` (for `-p`) or `pkgrm` (for `-P`). See `pkgadd(1M)` and `pkgrm(1M)` for descriptions of the options for those commands.
- `-a `admin` (For adding packages only.) Path to an admin file. Identical to the `pkgadd -a` option. Use of the `-a` option here is identical to `-O -a admin`.

The `luupgrade` command uses `-t` to add a patch and `-T` to remove a patch. The syntax is as follows:

For adding patches:

```
luupgrade -t -n `BE_name` [ -l `error_log` ] [ -o `outfile` ] [ -N ]
-s `patch_path` [ -O "patchadd_options" ] [ `patch_name` [ `patch_name`... ] ]
```

For removing patches:

```
luupgrade -T -n `BE_name` [ -l `error_log` ] [ -o `outfile` ] [ -N ]
[ -O "patchrm_options" ] [ `patch_name` [ `patch_name`... ] ]
```

The first option, `-t`, to add patches, or `-T` to remove patches, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

It is critically important that any packages you add be compliant with the SVR4 Advanced Packaging Guidelines. See WARNINGS, below.
-n **BE_name**  
Name of the BE to which patches will be added or from which patches will be removed.

- **s patch_path**  
(For adding patches only.) Path name of a directory containing patches to add or path name of a patch_order file.

-0 "**patchadd_options" or "patchrm_options""  
Options passed directly to patchadd (for -p) or patchrm (for -P). See **patchadd(1M)** or **patchrm(1M)** for a description of these options.

**patch_name [ patch_name...]**  
Zero or more patches to add or remove. For adding patches, the default is to add all of the patches specified with the -s option, above. Separate multiple patch names with spaces.

It is critically important that any patches you add be compliant with the SVR4 Advanced Packaging Guidelines. See WARNINGS, below.

Use the `-C` to perform a **pkgchk(1M)** on all or the specified packages on a BE. Use the `-I` option to perform a **pkginfo(1)***.

For performing a pkgchk:

```
luupgrade -C -n BE_name [-l error_log] [-o outfile] [-N]
[-0 "pkgchk_options"] [ pkginst [ pkginst... ]]
```

For performing a pkginfo:

```
luupgrade -I -n BE_name [-l error_log] [-o outfile] [-N]
[-0 "pkginfo_options"] [ pkginst [ pkginst... ]]
```

The first option, `-C`, for pkgchk, or `-I`, for pkginfo, indicates the function to perform. The remaining options for this use of luupgrade, shown above, are described as follows:

- **n BE_name**  
Name of the BE on which packages will be checked or on whose packages information will be returned.

-0 "**pkgchk_options" or "pkginfo_options""  
Options passed directly to pkgchk (for -C) or pkginfo (for -I). See **pkgchk(1M)** or **pkginfo(1)** for a description of these options.

**pkginst [ pkginst...]**  
Zero or more packages to check or for which to have information returned. If you omit package names, luupgrade returns information on all of the packages on the BE. Separate multiple
package names with spaces.

With the -c option, `luupgrade` allows you to check that a local or remote medium, such as a DVD or CD, is a valid installation medium. The -c option returns useful information about the specified medium. The syntax for this use of `luupgrade` is as follows:

```
luupgrade -c [ -l error_log ] [ -o outfile ] -s path_to_medium
```

The first option, -c, indicates the function to perform—to check on an installation medium. The -s option, shown above, is described as follows:

```
-s path_to_medium      Path name to an installation medium such as a DVD or CD.
```

This section specifies the Solaris JumpStart keywords that can be used in a profile with `luupgrade`, using the -j option in conjunction with the -u (upgrade) or -f (flash) options. For -u, there are no required keywords. For -f, you must specify a value for install_type:

- flash_install for a full flash archive or flash_update for a differential flash archive. Also for the -f option with the -j option, you must specify the -a (archive location) option or specify the archive_location keyword in your profile.

The archive_location keyword is the only valid argument for the -J option.

The following optional keywords are sometimes used in profiles used with the -u and -f options:

- `cluster` Designates the software group to add to the system.
- `geo` Designates the regional locale or locales that you want to install on or add to a system. See the Solaris Installation Guide for a list of possible values.
- `isa_bits` Specifies whether 64-bit or 32-bit packages are to be installed. Valid values are 64 and 32.
- `locale` Designates the locale packages you want to install on or add to a system. See the Solaris Installation Guide for a list of possible values.
- `package` Specifies a package to be added to or deleted from a system.

The following keywords must not be used in a profile used with `luupgrade`:

- `boot_device`
- `dontuse`
- `fdisk`
- `filesys`
- `layout_constraint`
- `noreboot`
- `partitioning`
- `root_device`
- `usedisk`
See the Solaris Installation Guide for descriptions of all JumpStart profile keywords and instructions for creating a JumpStart profile.

**Examples**

**EXAMPLE 1**  Removing, then Adding Packages

The following example removes from then adds a set of packages to a boot environment.

```
# luupgrade -P -n second_disk SUNWabc SUNWdef SUNWghi
```

Now, to add the same packages:

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages 
SUNWabc SUNWdef SUNWghi
```

The following command adds the -O option to the preceding command. This option passes arguments directly to pkgadd.

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages 
-O "-r /net/testmachine/export/responses" SUNWabc SUNWdef SUNWghi
```

See pkgadd(1M) for a description of the options for that command.

**EXAMPLE 2**  Upgrading to a New OS from a Combined Image

The following example upgrades the operating environment on a boot environment. The source image is stored as a combined image on a remote disk or on a DVD.

```
# luupgrade -u -n second_disk -s /net/installmachine/export/solarisX/OS_image
```

Following the command above you could enter the command below to activate the upgraded BE.

```
# luactivate second_disk
```

Then, upon the next reboot, second_disk would become the current boot environment. See luactivate(1M).

**EXAMPLE 3**  Upgrading to a New OS from Multiple CDs

The following example is a variation on the preceding. The OS upgrade resides on two CDs. To begin the upgrade on a SPARC machine, you enter:

```
# luupgrade -u -n second_disk -s /cdrom/cdrom0/s0
```

On x86 machines, replace the s0 in the argument to -s with s2.

When the installer is finished with the contents of the first CD, insert the next CD in the drive and enter the following:
EXAMPLE 3  Upgrading to a New OS from Multiple CDs  (Continued)

# luupgrade -i -n second_disk -s /cdrom/cdrom0 \
-0 "-nodisplay -noconsole"

Note the use of -i rather than -u in the preceding. Were there additional CDs, you would enter the same command as the one immediately above. The -O options, above, are passed to installer(1M). If you omit these options, a graphical interface is invoked following the insertion and reading of the second CD. See installer(1M) for a description of the -O options.

Note that a multiple-CD upgrade is not complete until you have entered and completed luupgrade commands for all of the CDs in a set. Following installation of packages from a CD, you might receive a message such as:

WARNING: <num> packages must be installed on boot environment <disk_device>.

Such a message indicates the requirement that you install packages from one or more additional CDs, as in the example above. If you do not complete package installation, you will not be able to use luactivate to activate (designate for booting) the upgraded BE.

EXAMPLE 4  Upgrading Using a JumpStart Profile

The following example command uses the -D option to test the profile /home2/profiles/test.profile.

# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-j /home2/profiles/test.profile -D

Assuming the results of this command were acceptable, you could omit the -D in the preceding command to perform the upgrade.

EXAMPLE 5  Installing a New OS from a Solaris Flash Archive

The following example installs the operating environment on a boot environment, using a Solaris Flash archive. The file pointed to by -J is a JumpStart profile that specifies a flash installation.

# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-J "archive_location http://example.com/myflash.flar"

The following command differs from the preceding only in that -j replaces -J. You could append the -D option to either of these commands to test the profile prior to actually performing the flash installation.

# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \

luupgrade(1M)
EXAMPLE 5  Installing a New OS from a Solaris Flash Archive (Continued)

- j /net/example/flash_archives/flash_gordon

Either of the preceding commands works for a full or differential flash installation. Whether a flash installation is differential or full is determined by the value of the install_type keyword in the profile. See "JumpStart Profile Keywords," above.

EXAMPLE 6  Obtaining Information on Packages

The following example runs a pkgchk on the packages SUNWluu, SUNWlur, and SUNWlucfg, passing to pkgchk the -v option.

# luupgrade -C -n second_disk -O "-v" SUNWluu SUNWlur SUNWlucfg

The following command runs pkginfo on the same set of packages:

# luupgrade -I -n second_disk -O "-v" SUNWluu SUNWlur SUNWlucfg

For both commands, if the package names were omitted, luupgrade returns package information on all of the packages in the specified BE. See pkgchk(1M) and pkginfo(1) for a description of the options for those commands.

Exit Status  The following exit values are returned:

  0   Successful completion.

  >0   An error occurred.

Files  /etc/lutab  list of BEs on the system

/usr/share/lib/xml/dtd/lu_cli.dtd.<num>   Live Upgrade DTD (see -X option in “Options that Apply to All Uses,” above)

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWluu</td>
</tr>
</tbody>
</table>

See Also  installer(1M), luactivate(1M), lucancel(1M), lucompare(1M), lucreate(1M), lucurr(1M), ludelete(1M), ludesdesc(1M), lufslist(1M), lumake(1M), lumount(1M), lurename(1M), lustatus(1M), lutab(4), sysidcfg(4), attributes(5), live_upgrade(5), zones(5)

Warnings  For adding packages or patches (-p, -P, -t, or -T), luupgrade requires packages or patches that comply with the SVR4 Advanced Packaging Guidelines and the guidelines spelled out in Appendix C of the Oracle Solaris 10 08/11 Installation Guide: Basic Installations. This means that the package or patch is compliant with the pkgadd(1M) or patchadd(1M) -R option,
described in the man pages for those utilities. While nearly all Sun packages and patches
conform to these guidelines, Sun cannot guarantee the conformance of packages and patches
from third-party vendors. Some older Sun packages and patches might not be \-R compliant. If
you encounter such a package or patch, please report it to Sun. A non-conformant package
can cause the package- or patch-addition software in \texttt{luupgrade} to fail or, worse, alter the
current BE.

\textbf{Notes}  
For versions of the Solaris operating system prior to Solaris 10, Live Upgrade supports the
release it is distributed on and up to three marketing releases back. For example, if you
obtained Live Upgrade with Solaris 9 (including a Solaris 9 upgrade), that version of Live
Upgrade supports Solaris versions 2.6, Solaris 7, and Solaris 8, in addition to Solaris 9. No
version of Live Upgrade supports a Solaris version prior to Solaris 2.6.

Starting with version 10 of the Solaris operating system, Live Upgrade supports the release it is
distributed on and up to two marketing releases back. For example, if you obtained Live
Upgrade with Solaris 10 (including a Solaris 10 upgrade), that version of Live Upgrade
supports Solaris 8 and Solaris 9, in addition to Solaris 10.

Correct operation of Solaris Live Upgrade requires that a limited set of patch revisions be
installed for a given OS version. Before installing or running Live Upgrade, you are required to
install the limited set of patch revisions. Make sure you have the most recently updated patch
list by consulting \url{http://sunsolve.sun.com}. Search for the infodoc 72099 on the SunSolve
web site.
luxadm is an administrative command that manages the SENA, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices. luxadm performs a variety of control and query tasks depending on the command line arguments and options used.

The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.

Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure. The individual FC_AL devices may be specified by entering the WWN for the device or a port to the device.

Specify the device or controller by either a complete physical pathname or a complete logical pathname.

For SENA, a typical physical pathname for a device is:

```
/devices/sbus@1f,0/SUNW,socal@1,0/sf@0,0/ssd@w2200002037000f96,0:a,raw
```

For all SENA IBs (Interface Boards) and Sun Fire 880 SES device controllers on the system, a logical link to the physical paths is kept in the directory /dev/es. An example of a logical link is /dev/es/ses0.

The WWN may be used in place of the pathname to select an FC_AL device, SENA subsystem IB, or Sun Fire 880 internal storage subsystem. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:

```
2200002037000f96
```

See NOTES for more information on the WWN formats.

For a disk in a Sun Fire 880 internal storage subsystem, a typical physical pathname is:

```
/devices/pci@0,600000/SUNW,qlc@2/fp@0,0/ssd@w2100002037a6303c,0:a
```

and a typical logical pathname is:

```
/dev/rdsk/c2t8d0s2
```
For individual FC_AL devices, a typical physical pathname is:

/devices/sbus@3.0/SUNW,socal@d,10000/sf@0,0/ssd@w220002037049fc3,0:a,raw

and a typical logical pathname is:

/dev/rsk/c1t0d0s2

**Enclosure**  
For SENA, a device may be identified by its enclosure name and slot name:

- `box_name[,f|r]slot_number`
- `box_name[,r]slot_number`

`box_name` is the name of the SENA enclosure, as specified by the `enclosure_name` subcommand. When used without the optional `slot_number` parameter, the `box_name` identifies the SENA subsystem IB.

`f` or `r` specifies the front or rear slots in the SENA enclosure.

`slot_number` specifies the slot number of the device in the SENA enclosure, 0-6 or 0-10.

For a Sun Fire 880 internal storage subsystem, a device may also be identified by its enclosure name and slot name. However, there is only one set of disks:

- `box_name[,s]slot_number`

`box_name` is the name of the Sun Fire 880 enclosure, as specified by the `enclosure_name` subcommand. When used without the optional `slot_number` parameter, `box_name` identifies the Sun Fire 880 internal storage subsystem enclosure services device. Use `s` to specify the disk slot number in the Sun Fire 880 internal storage subsystem, 0-11.

See `disks(1M)` and `devlinks(1M)` for additional information on logical names for disks and subsystems.

**Options**  
The following options are supported by all subcommands:

- `-e` Expert mode. This option is not recommended for the novice user.
- `-v` Verbose mode.

Options that are specific to particular subcommands are described with the subcommand in the `USAGE` section.

**Operands**  
The following operands are supported:

- `enclosure` The `box_name` of the SENA or Sun Fire 880 internal storage subsystem.
- `fibre_channel_HBA_port` The path to the host controller port. A typical path is:
  
  /devices/pci@8,600000/pci@1/SUNW,qlc@4/fp@0,0:devctl
pathname

The logical or physical path of a SENAB, Sun Fire 880 internal storage subsystem, or disk device. pathname can also be the WWN of a SENAB, SENA disk, or individual FC_AL device.

Usage

Subcommands

\texttt{display} \texttt{enclosure[dev]...|pathname...} \\
\texttt{display -p} \texttt{pathname...} \\
\texttt{display -r} \texttt{enclosure[dev]...|pathname...} \\
\texttt{display -v} \texttt{enclosure[dev]...|pathname...}

Displays enclosure or device specific data.

Subsystem data consists of enclosure environmental sense information and status for all subsystem devices, including disks.

Disk data consists of inquiry, capacity, and configuration information.

\texttt{-p} \quad Displays performance information for the device or subsystem specified by \texttt{pathname}. This option only applies to subsystems that accumulate performance information.

\texttt{-r} \quad Displays error information for the FC_AL device specified by the pathname, or, if the path is a SENA, for all devices on the loop. The \texttt{-r} option only applies to SENA subsystems and individual FC_AL devices.

\texttt{-v} \quad Displays in verbose mode, including mode sense data.

\texttt{download [-s] [-f filename_path] enclosure...}

Download the prom image pointed to the SENA subsystem Interface Board unit or the Sun Fire 880 internal storage subsystem specified by the enclosure or pathname.

When the SENA's download is complete, the SENA will be reset and the downloaded code executed. If no
filename is specified, the default prom image will be used. The default prom image for the SENA is in the directory
/usr/lib/locale/C/LC_MESSAGES and is named ibfirmware.

When the Sun Fire 880 internal storage subsystem's download is complete, the subsystem resets and the downloaded
code begins execution. The default firmware image for the Sun Fire 880 internal storage subsystem is in:
/usr/platform/SUNW,Sun-Fire-880/lib/images/int_fcbpl_fw.

-s Save. The -s option is used to save the downloaded firmware in the FEPROM. If -s is not specified, the downloaded firmware will not be saved across power cycles.

The -s option does not apply to the Sun Fire 880 internal storage subsystem as it always stores downloaded firmware in the flash memory.

When using the -s option, the download subcommand modifies the FEPROM on the subsystem and should be used with caution.

enclosure_name new_name enclosure | pathname  Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (new_name) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA and the Sun Fire 880 internal storage subsystem.

failover primary | secondary pathname  Select which Sun Storage T3 storage array partner group controller accesses a given logical volume. If primary is specified, the logical volume is accessed through the primary controller. If
secondary is specified, the logical volume is accessed through the secondary controller specified by *pathname*.

**fcal_s_download** [-f *fcode-file*]

Download the fcode contained in the file *fcode-file* into all the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use **fcal_s_download only in single-user mode**. Using **fcal_s_download** to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

**-f fcode-file** When invoked without the -f option, the current version of the fcode in each FC100/S Sbus card is printed.

**fcode_download** -p

**fcode_download** -d *dir-name*

Locate the installed FC/S, FC100/S, FC100/P, or FC100/2P host bus adapter cards and download the FCode files in *dir-name* to the appropriate cards. The command determines the correct card for each type of file, and is interactive. User confirmation is required before downloading the FCode to each device.

Use **fcode_download** to load FCode only in single-user mode. Using **fcode_download** to update a host adapter while there is I/O activity through that adapter causes the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.
-d dir-name Download the FCode files contained in the directory dir-name to the appropriate adapter cards.

-p Prints the current version of FCode loaded on each card. No download is performed.

inquiry enclosure[,dev]... [pathname...]
Display the inquiry information for the selected device specified by the enclosure or pathname.

insert_device [enclosure,dev...]
Assist the user in the hot insertion of a new device or a chain of new devices. Refer to NOTES for limitations on hotplug operations. This subcommand applies only to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures or individual FC_AL drives can be inserted. For the SENA or the Sun Fire 880 internal storage subsystem, this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

led enclosure,dev... [pathname...]
Display the current state of the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.
led_blink enclosure,dev... | pathname...
Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

led_off enclosure,dev... | pathname...
Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

led_on pathname...
Requests the subsystem to enable (turn on) the LED associated with the disk specified by the pathname. This subcommand only applies to subsystems that support this functionality.

power_off [-F] enclosure[,dev]... | pathname...
When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode. This command does not apply to the Sun Fire 880 internal storage subsystem.

-F The force option only applies to the SENA. Instructs luxadm to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

Warning: Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal checks.

power_on enclosure[, dev]...
Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA. When this subcommand is addressed to a drive the drive is set to its normal start-up state. This command does not apply to the Sun Fire 880 internal storage subsystem.

probe [-p]
Finds and displays information about all attached SENA subsystems, Sun Fire 880 internal storage subsystems, and individual FC_AL devices, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

-p Includes the physical pathname in the display.
qlgc_s_download [-f fcode-file]
Download the FCode contained in the file fcode-file into all the FC100/P, FC100/2P PCI host adapter cards. This command is interactive and expects user confirmation before downloading the FCode to each device. Only use qlgc_s_download in single-user mode. Using qlgc_s_download to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

-f fcode-file When invoked without the -f option, the current version of the FCode in each FC100/P, FC100/2P PCI card is printed.

release pathname
Release a reservation held on the specified disk. The pathname should be the physical or logical pathname for the disk.

This subcommand is included for historical and diagnostic purposes only.

remove_device [-F] enclosure[dev]...|pathname...
Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. Refer to NOTES for limitations on hotplug operations. For the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL devices, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For Multi-Hosted disk, the steps taken are:

- Issue the luxadm remove_device command on the first host. When prompted to continue, wait.
- Issue the luxadm remove_device command on the secondary hosts. When prompted to continue, wait.
- Continue with the remove_device command on the first host. Remove the device when prompted to do so.
- Complete the luxadm remove_device command on the additional hosts.

-F Instructs luxadm to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, busy or reserved), to force the hotplugging operation.

Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.
reserve pathname
Reserve the specified disk for exclusive use by the issuing host. The pathname used should be the physical or logical pathname for the disk.

This subcommand is included for historical and diagnostic purposes only.

set_boot_dev [ -y ] pathname
Set the boot-device variable in the system PROM to the physical device name specified by pathname, which can be a block special device or the pathname of the directory on which the boot file system is mounted. The command normally runs interactively requesting confirmation for setting the default boot-device in the PROM. The -y option can be used to run it non-interactively, in which case no confirmation is requested or required.

start pathname
Spin up the specified disk(s) in a SENA.

stop pathname...
Spin down the specified disks in a SENA.

The following subcommands are for expert use only, and are applicable only to the SENA, Sun Fire 880 internal storage subsystem, and fiber channel loops. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.

If you specify a disk to an expert subcommand that operates on a bus, the subcommand operates on the bus to which the specified disk is attached.

- e bypass [ -ab ] enclosure.dev
- e bypass -f enclosure
Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the bypassed state for the port and device specified.

This subcommand supports the following options:

- a Bypass port a of the device specified.

- b Bypass port b of the device specified.

- e dump_map fibre_channel_HBA_port
Display WWN data for a target device or host bus adapter on the specified fibre channel port. If there are no target devices on the specified port, an error is returned.
-e enable [-ab] enclosure,dev
- e enable -f enclosure

Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the enabled state for the port and device specified.

This subcommand supports the following options:

- a   Enable port a of the device specified.
- b   Enable port b of the device specified.

-e forcelp enclosure[,dev] ...| pathname ...

Force the link to reinitialize, using the Loop Initialization Primitive (LIP) sequence. The enclosure or pathname can specify any device on the loop. Use the pathname to specify a specific path for multiple loop configurations.

This is an expert only command and should be used with caution. It will reset all ports on the loop.

-e rdls enclosure[,dev] ...| pathname ...

Read and display the link error status information for all available devices on the loop that contains the device specified by the enclosure or pathname.

See NOTES for limitations of these subcommands. They should only be used by users that are knowledgeable about the systems they are managing.

These commands do not apply to the Sun Fire 880 internal storage subsystem.

- e bus_getstate pathname       Get and display the state of the specified bus.
- e bus_quiesce pathname       Quiesce the specified bus.
- e bus_reset pathname         Reset the specified bus only.
- e bus_resetall pathname      Reset the specified bus and all devices.
- e bus_unquiesce pathname     Unquiesce the specified bus, the specified device.
- e dev_getstate pathname      Get and display the state of the specified device.
- e dev_reset pathname         Reset the specified device.
Examples

EXAMPLE 1  Displaying the SENAs and Individual FC_AL Devices on a System

The following example finds and displays all of the SENAs and individual FC_AL devices on a system:

example% luxadm probe

EXAMPLE 2  Displaying a SENA or Sun Fire 880 Internal Storage Subsystem

The following example displays a SENA or Sun Fire 880 internal storage subsystem:

example% luxadm display /dev/es/ses0

EXAMPLE 3  Displaying Two Subsystems

The following example displays two subsystems using the enclosure names:

example% luxadm display BOB system1

EXAMPLE 4  Displaying Information about the First Disk

The following example displays information about the first disk in the front of the enclosure named BOB. Use f to specify the front disks. Use r to specify the rear disks.

example% luxadm display BOB,f0

EXAMPLE 5  Displaying Information on a Sun Fire 880 Internal Storage Subsystem

The Sun Fire 880 internal storage subsystem has only one set of disks. In this case, use s to specify the slot:

example% luxadm display BOB,s0

EXAMPLE 6  Displaying Information about a SENA disk, an Enclosure, or an Individual FC_AL Drive

The following example displays information about a SENA disk, an enclosure, or an individual FC_AL drive with the port WWN of 2200002037001246:

example% luxadm display 2200002037001246

EXAMPLE 7  Using Unique Characters to Issue a Subcommand

The following example uses only as many characters as are required to uniquely identify a subcommand:

example% luxadm disp BOB
EXAMPLE 8  Displaying Error Information
The following example displays error information about the loop that the enclosure BOB is on:
example% luxadm display -r BOB

EXAMPLE 9  Downloading New Firmware into the Interface Board
The following example downloads new firmware into the Interface Board in the enclosure named BOB (using the default path for the file to download):
example% luxadm download -s BOB

EXAMPLE 10 Displaying Information from the SCSI Inquiry Command
The following example displays information from the SCSI inquiry command from all individual disks on the system, using only as many characters as necessary to uniquely identify the inquiry subcommand:
example% luxadm inq /dev/rdsk/c?t?d?s2

EXAMPLE 11 Hotplugging
The following example hotplugs a new drive into the first slot in the front of the enclosure named BOB:
example% luxadm insert_device BOB,f0

The following example hotplugs a new drive into the first slot in the Sun Fire 880 internal storage subsystem named SF880-1:
example% luxadm insert_device SF880-1,s0

EXAMPLE 12 Running an Expert Subcommand
The following example runs an expert subcommand. The subcommand forces a loop initialization on the loop that the enclosure BOB is on:
example% luxadm -e forcelip BOB

EXAMPLE 13 Using the Expert Mode Hot Plugging Subcommands
An example of using the expert mode hot plugging subcommands to hot remove a disk follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can’t be accessed by way of its second SCSI bus:
example# luxadm reserve /dev/rdsk/c1t8d0s2

EXAMPLE 14 Taking the Disk to be Removed Offline
The next two steps take the disk to be removed offline then quiesce the bus:
EXAMPLE 14  Taking the Disk to be Removed Offline  (Continued)

example# luxadm -e offline /dev/rdsk/c1t8d0s2
example# luxadm -e bus_quiesce /dev/rdsk/c1t8d0s2

EXAMPLE 15  Unquiescing the Bus

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then unreserving it:

example# luxadm -e bus_unquiesce /dev/rdsk/c1t8d0s2
example# luxadm -e online /dev/rdsk/c1t8d0s2
example# luxadm release /dev/rdsk/c1t8d0s2

Environment Variables  See environ(5) for a description of the LANG environment variable that affects the execution of luxadm.

Exit Status  The following exit values are returned:

0  Successful completion.

−1  An error occurred.

Files  usr/lib/firmware/fc_s/fc_s_fcode
       usr/lib/locale/C/LC_MESSAGES/ibfirmware

Attributes  See attributes(5) for descriptions of the following attributes:

SENA Array Installation and Service Manual (p/n 802-7573).

RAID Manager 6.1 Installation and Support Guide Answerbook

RAID Manager 6.1 User’s Guide Answerbook

Notes  See the SENA Array Installation and Service Manual for additional information on the SENA. Refer to Tutorial for SCSI use of IEEE Company_ID, R. Snively, for additional information regarding the IEEE extended WWN. See SEE ALSO. Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

luxadm: can’t acquire "PATHNAME": No such file or directory

will be displayed.
You must be careful not to quiesce a bus that contains the root or the /usr filesystems or any swap data. If you do quiesce such a bus a deadlock can result, requiring a system reboot.
m64config(1M)

Name  m64config, SUNWm64_config – configure the M64 Graphics Accelerator

Synopsis  /usr/sbin/m64config [-defaults] [-depth 8 | 24 | 32]
           [-dev device-filename] [-file machine | system]
           [-prconf] [-propt]
           [-res video-mode [now | try] [noconfirm | nocheck]]

/usr/sbin/m64config [-prconf] [-propt]
/usr/sbin/m64config [-help] [-res ?]

Description  m64config configures the M64 Graphics Accelerator and some of the X11 window system defaults for M64.

The first form of m64config stores the specified options in the OWconfig file. These options will be used to initialize the M64 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms which invoke only the -prconf, -propt, -help, and -res ? options do not update the OWconfig file. Additionally, for the third form all other options are ignored.

Options may be specified for only one M64 device at a time. Specifying options for multiple M64 devices requires multiple invocations of m64config.

Only M64-specific options can be specified through m64config. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the OpenWindows Desktop Reference Manual for details.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the m64config program, which is owned by the root user, always runs with setuid root permission.

Options  -defaults
          Resets all option values to their default values.

          -depth 8 | 24 | 32
          Sets the depth (bits per pixel) on the device. Possible values are 8, 24, or 32 (where 32 uses 24 bits per pixel). Log out of the current window system session and log back in for the change to take effect. 24 or 32 enables TrueColor graphics in the window system, at the expense of screen resolution.
The 32 setting enables simultaneous 8- and 24-bit color windows on m64 devices that support it. With setting 32, -propt shows depth 32 and -prconf shows depth 24. To check window depth, use the xwininfo utility. The xwininfo utility is usually shipped in the package containing frame buffer software (such as SUNWxwpflt).

The maximum resolution that is available with 24 bits per pixel depends on the amount of memory installed on the PGX card. For 2-MB PGX cards, the maximum available resolution is 800x600. For 4-MB cards, it is 1152x900. For 8-MB cards, it is 1920x1080. If there is not enough memory for the specified combination of resolution and depth, m64config displays an error message and exits.

-dev device-filename
Specifies the M64 special file. If not specified, m64config will try /dev/fbs/m640 through /dev/fbs/m648 until one is found.

-file machine| system
Specifies which OWconfig file to update. If machine, the machine-specific OWconfig file in the /etc/openwin directory tree is used. If system, the global OWconfig file in the /usr/openwin directory tree is used. If the file does not exist, it is created. This option has no effect unless other options are specified. The default is machine.

-help
Prints a list of the m64config command line options, along with a brief explanation of each.

-prconf
Prints the M64 hardware configuration. The following is a typical display using the -prconf option:

--- Hardware Configuration for /dev/fbs/m640 ---
ASIC: version 0x41004754
DAC: version 0x0
PROM: version 0x0
Card possible resolutions: 640x480x60, 800x600x75, 1024x768x60
1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76
1280x1024x60, 1152x900x66, 1152x900x76, 1280x1024x67
960x680x112S, 960x680x108S, 640x480x60i, 768x576x50i
1280x800x76, 1440x900x76, 1600x1000x66, 1600x1000x76
vga, svga, 1152, 1280, stereo, ntsc, pal
Monitor possible resolutions: 720x400x70, 720x400x85, 640x480x60
640x480x67, 640x480x72, 640x480x75, 800x600x56, 800x600x60
800x600x72, 800x600x75, 832x624x75, 1024x768x85, 1024x768x60
1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76,
1152x900x66, 1152x900x76, 1280x1024x67, 960x680x112S
vga, svga, 1152, 1280, stereo
Possible depths: 8, 24
Current resolution setting: 1280x1024x76
Current depth: 8
-propt
Prints the current values of all M64 options in the OWconfig file specified by the -file
option for the device specified by the -dev option. Prints the values of options as they will
be in the OWconfig file after the call to m64config completes. The following is a typical
display using the -propt option:

--- OpenWindows Configuration for /dev/fbs/m640 ---
OWconfig: machine
Video Mode: not set
Depth: 8

-res video-mode [ now | try [ noconfirm | nocheck ]]
Specifies the video mode used to drive the monitor connected to the specified M64 device.
Video modes are built-in. video-mode has the format of widthxheightxraters. width is the
screen width in pixels, height is the screen height in pixels, and rate is the vertical frequency
of the screen refresh. As a convenience, -res also accepts formats with @ preceding the
refresh rate instead of x. For example, 1280x1024@76.

A list of valid video modes is obtained by issuing the following command: m64config -res
'?'. Note that the ? must be quoted. Not all resolutions are supported by both the video
board and by the monitor. m64config will not permit you to set a resolution the board does
not support, and will request confirmation before setting a resolution the monitor does not
support.

Symbolic names
For convenience, some video modes have symbolic names defined for them. Instead of the
form widthxheightxraters, one of these names may be supplied as the argument to -res. The
meaning of the symbolic name none is that when the window system is run the screen
resolution will be the video mode that is currently programmed in the device.

<table>
<thead>
<tr>
<th>Name</th>
<th>Corresponding Video Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>svg  a</td>
<td>1024x768x60</td>
</tr>
<tr>
<td>1152</td>
<td>1152x900x76</td>
</tr>
<tr>
<td>1280</td>
<td>1280x1024x76</td>
</tr>
<tr>
<td>none</td>
<td>(video mode currently programmed in device)</td>
</tr>
</tbody>
</table>

The -res option also accepts additional sub-options immediately following the video
mode specification. Any or all of these may be present.

-nocheck If present, the normal error checking based on the monitor sense code will
be suspended. The video mode specified by the user will be accepted
regardless of whether it is appropriate for the currently attached monitor.
This option is useful if a different monitor is to be connected to the M64 device. *Use of this option implies noconfirm as well.*

**noconfirm**

Using the -res option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of m64config is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The noconfirm option instructs m64config to bypass this confirmation and to program the requested video mode anyway. This option is useful when m64config is being run from a shell script.

**now**

If present, not only will the video mode be updated in the OWconfig file, but the M64 device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

It is inadvisable to use this sub-option with m64config while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run m64config with the now sub-option, first bring the window system down. If the now sub-option is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and reentered again. Consequently, this usage is strongly discouraged.

**try**

If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing y within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than 'y' or carriage return is considered a no and the previous video mode will be restored and m64config will not change the video mode in the OWconfig file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with m64config while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run m64config with the try sub-option, the window system should be brought down first.

**Defaults**

For a given invocation of m64config command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if an M64 option has never been specified by m64config, a default value is used. The option defaults are as follows:
Option | Default
--- | ---
-dev | /dev/fbs/m640
-file | machine
-res | none

The default for the -res option of none means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default M64 video mode.

**Examples**

**EXAMPLE 1  Switching the Monitor Type**

The following example switches the monitor type to the maximum resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/sbin/m64config -res 1280x1024x76
```

**Files**

OpenWindows Desktop Reference Manual
Name  mail.local – store mail in a mailbox

Synopsis  /usr/lib/mail.local [-f sender] [-d] recipient

Description  mail.local reads the standard input up to an end-of-file and appends it to each user's mail file (mailbox). This program is intended to be used by sendmail(1M) as a mail delivery agent for local mail. It is not a user interface agent.

Messages are appended to the user's mail file in the /var/mail directory. The user must be a valid user name.

Each delivered mail message in the mailbox is preceded by a "Unix From line" with the following format:

From sender_address time_stamp

The sender_address is extracted from the SMTP envelope address (the envelope address is specified with the -f option).

A trailing blank line is also added to the end of each message.

The mail files are locked with a .lock file while mail is appended.

The mail files are created with mode 660, owner is set to recipient, and group is set to mail. If the "biff" service is returned by getservbyname(3SOCKET), the biff server is notified of delivered mail. This program also computes the Content-Length: header which will be used by the mailbox reader to mark the message boundary.

Options  The following options are supported:

- f sender  Specifies the "envelope from address" of the message. This flag is technically optional, but should be used.

- d  Specifies the recipient of the message. This flag is also optional and is supported here for backward compatibility. That is, mail.local recipient is the same as mail.local -d recipient.

- l  Turn on LMTP mode.

- r from  Specify the sender's name (for backward compatibility).

- 7  Do not advertise 8BITMIME support in LMTP mode.

- b  Return a permanent error instead of a temporary error if a mailbox exceeds quota.

Operands  The following operand is supported:

recipient  The recipient of the mail message.
TZ

Used to set the appropriate time zone on the timestamp.

The following exit values are returned:

0 Successful operation.

>0 An error occurred.

Files
/tmp/local.XXXXXX temporary files
/tmp/lochd.XXXXXX temporary files
/var/mail/user_name user's mail file

Name
makedbm – make a dbm file, or get a text file from a dbm file

Synopsis
makedbm [-b] [-l] [-s] [-E] [-i yp_input_file]
  [-o yp_output_name] [-d yp_domain_name]
  [-m yp_master_name] [-S delimiter]
  [-D number_of_delimiters] infile outfile

makedbm [-u dbmfilename]

Description
The makedbm utility takes the infile and converts it to a pair of files in ndbm format (see ndbm(3C)), namely outfile.pag and outfile.dir. Each line of the input file is converted to a single dbm record. All characters up to the first TAB or SPACE form the key, and the rest of the line is the data. If a line ends with \ (backslash), the data for that record is continued on to the next line. makedbm does not treat ‘#’ (pound-sign) as a special character.

Because makedbm is mainly used in generating dbm files for the NIS name service, it generates a special entry with the key yp_last_modified, which is the date of infile (or the current time, if infile is ‘−’). The entries that have keys with the prefix yp_ are interpreted by NIS server utilities.

Options
The following options are supported:

  -b
  Insert the YP_INTERDOMAIN into the output. This key causes ypserv(1M) to use DNS for hostname and address lookups for hosts not found in the maps.

  -d yp_domain_name
  Create a special entry with the key yp_domain_name.

  -D number_of_delimiters
  Specify number_of_delimiters to skip before forming the key.

  -E
  Delimiters are escaped.

  -i yp_input_file
  Create a special entry with the key yp_input_file.

  -l
  Lower case. Convert the keys of the given map to lower case, so that, for example, host name matches succeed independent of upper or lower case distinctions.

  -m yp_master_name
  Create a special entry with the key yp_master_name. If no master host name is specified, yp_master_name is set to the local host name.

  -o yp_output_name
  Create a special entry with the key yp_output_name.

  -s
  Secure map. Accept connections from secure NIS networks only.

  -S delimiter
  Specify the delimiter to use instead of the default delimiter for forming the key.

  -u dbmfilename
  Undo a dbm file. Prints out the file in text format, one entry per line, with a single space separating keys from values.
Operands  The following operands are supported:

infile  Input file for makedbm. If infile is ‘−’ (dash), the standard input is read.

outfile  One of two output files in ndbm format: outfile.pag and outfile.dir.

makemap(1M)

Name
makemap – create database maps for sendmail

Synopsis
       [-u] mctype mapname

Description
makemap creates the database maps used by the keyed map lookups in sendmail(1M). makemap reads from the standard input and outputs to the specified mapname.

In all cases, makemap reads lines from the standard input consisting of two words separated by whitespace. The first is the database key, the second is the value. The value may contain %n strings to indicate parameter substitution. Literal percents should be doubled (%%). Blank lines and lines beginning with # are ignored.

makemap handles three different database formats. Database format is selected using the mctype parameter. See OPERANDS.

Options
The following options are supported:

- c cachesize  Use the specified hash and B-Tree cache size (cachesize).
- C file       Use the specified sendmail configuration file (file) for looking up the TrustedUser option.
- d            Allow duplicate keys in the map. This is only allowed on B-Tree format maps. If two identical keys are read, both be inserted into the map.
- D commentchar Use the specified character to indicate a comment (which is ignored) instead of the default of '#'.
- e            Allow empty value (right hand side).
- f            Normally, all upper case letters in the key are folded to lower case. This flag disables that behavior. This is intended to mesh with the - f flag in the K line in sendmail.cf. The value is never case folded.
- l            List supported map types.
- N            Include the null byte that terminates strings in the map. This must match the - N flag in the K line in sendmail.cf
- o            Append to an old file. This allows you to augment an existing file.
- r            Allow replacement of existing keys. Normally makemap complains if you repeat a key, and does not do the insert.
- s            Ignore safety checks on maps being created. This includes checking for hard or symbolic links in world writable directories.
- t delim      Use the specified delimiter (delim) instead of whitespace.
Dump (unmap) the content of the database to standard output. Note that, if the -t option is also provided, the specified delimiter is used when the content is dumped instead of whitespace.

- v

Verbosely print what it is doing.

**Operands**

The following operands are supported:

- `mapname` File name of the database map being created.
- `maptype` Specifies the database format. The following `maptype` parameters are available:
  - `dbm` Specifies DBM format maps.
  - `btree` Specifies B-Tree format maps.
  - `hash` Specifies hash format maps.

editmap(1M), sendmail(1M), attributes(5)
The `makeuuid` command generates UUIDs (Universal Unique Identifiers) conforming to the OSF DCE specification for UUIDs. The specification states:

"A UUID is an identifier that is unique across both space and time, with respect to the space of all UUIDs. A UUID can be used for multiple purposes, from tagging objects with an extremely short lifetime, to reliably identifying very persistent objects across a network.

"The generation of UUIDs does not require a registration authority for each single identifier. Instead, it requires a unique value over space for each UUID generator. This spatially unique value is [normally] specified as an IEEE 802 address, which is usually already applied to network-connected systems."

The `makeuuid` command generates one or more UUIDs on the standard output.

**Options**

The `makeuuid` command supports the following options:

- `-e ether` Supplies an alternate address to be used in the generation of the UUIDs. Normally, the system's Ethernet address is acquired and used during the generation of a UUID. However, this requires root privileges to open and read the network devices. If this is not possible, you must supply an alternate Ethernet address.

- `-n count` Generate multiple UUIDs. This option generates the specified number of UUIDs, one per line. Using this form is more efficient than, and functionally equivalent to, calling the `makeuuid` command multiple times. This can be used, for example, when a large number of UUIDs need to be generated for a given application.

- `-R root` Use `root` as the root filesystem path when updating the shared state file (see FILES). The shared state file must be writable by the user running `makeuuid`, otherwise no UUIDs will be generated and the command will return in failure.

**Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

**Usage**

Normally, you run the `makeuuid` command with root privileges, as the Ethernet address and state files can be easily accessed and updated. If this is not possible, you must use the `-R` and `-e` options to specify an alternate root and Ethernet address to use when calculating the UUIDs.

**Examples**

**EXAMPLE 1** Generating Multiple UUIDs

The following command generates 3000 UUIDs:

```
example# makeuuid -n 3000
```
EXAMPLE 2  Invoking Without Root Privileges

If you cannot obtain root privileges, you must specify an alternate Ethernet address and state
file location:

See the caveat on the use of the -R option in the description of that option, above.

Exit Status  The following exit values are returned:

0   Successful completion.
1   Out of memory.
-1   Invalid Ethernet address given or access denied.

Files  /var/sadm/system/uuid_state  UUID state file. Use of time values is one way that UUID
generators, such as makeuuid, guarantee uniqueness. A
state file is a mechanism that allows makeuuid to
"remember" the last time value it used so it can
increment that value for use in a new UUID. See the
Internet Draft "UUIDs and GUIDs," dated February 4,
1998, for details on the state file mechanism.

masfcnv – SNMP configuration migration script

**Synopsis**

```
/usr/sfw/lib/sma_snmp/masfcnv [-cimnrs] [-l agentmaster]
[-p enabledisableerror] [-t noneadd]
[-u agentmastererror] [-y agentmastererror]
masfcnv [-V]
masfcnv [-?]`

**Description**

The *masfcnv* script is used to assist the system administrator in migrating an existing set of configuration files for the Sun SNMP Management Agent for Sun Fire and Netra Systems (MASF) to the Systems Management Agent (SMA).

The script accepts as input the currently installed set of MASF and SMA configuration files and outputs a new set of SMA configuration files. Existing SMA configuration files are backed up by appending `.bak` to the filename. The administrator can choose to output the new configuration to standard output, instead of replacing the current configuration, by specifying the `-n` option.

The migration script must be run as the superuser. Failure to do so causes the script to exit with an error message. Before running the script you should ensure that both the SMA and MASF agents are not running. If the agents are running they will be shut down by the script.

The migration script installs a new startup script for the MASF agent in `/etc/init.d`, as well as a backup of the old script. During migration, MASF will be configured as an AgentX subagent of SMA. All migration settings will be migrated to the SMA configuration file.

The migration script aborts if any unrecognized directives are found in either the MASF configuration files or the SMA configuration files. This can be overridden with the `-i` option. If this option is selected, the behavior is to retain unrecognized directives that were present in the SMA configuration, but remove those present in the MASF configuration.

The migration script then proceeds to migrate access control and trap configuration. As a side effect of running the migration script, the following directives might be expanded by the script into multiple directives with an equivalent interpretation:

- rwcommunity
- rocommunity
- rwuser
- rouser
- trapcommunity
- trapsink
- trap2sink
- informsink
Access Control Migration

Access control directives are expanded into the equivalent com2sec, group, access and view directives. Existing group names are renamed by prepending a prefix to avoid conflict with any which may already be defined in SMA.

When migrating SNMPv1 or v2c access control, a conflict can occur if both MASF and SMA configuration files have defined access permissions for the same community and source address. The default behavior is to abort with a message, unless a use of the -y option specifies otherwise. If -y agent is specified then the MASF configuration takes precedence. If -y master is specified then the SMA configuration is retained.

When migrating USM configuration (SNMPv3), a conflict can occur if both SMA and MASF configurations define a user with the same securityName. If this occurs, the behavior of the script is determined by the -u option. If -u agent is specified, the configuration of the user defined in the MASF configuration files is the one that is retained. Otherwise, if the -u master option is specified, the use defined in the SMA configuration files is retained.

By default, the migration script attempts to migrate USM users from MASF to SMA. The script determines whether there are any SNMPv3 users present in the SMA configuration and whether the default engineID has been overridden in the SMA configuration files. If neither of these conditions obtain, then the any usmUser statements containing localized authentication keys can be migrated to SMA, along with the MASF engineID. This results in the engineID of the SMA master agent changing.

If the script determines that there are existing SNMPv3 users or a manually configured engineID present in the SMA configuration, only those users defined in createUser statements are transferred. Those users that were defined in usmUser statements are transferred but will have their passwords reset to a random value. You should notify your users of their new password or reset the password yourself by editing the newly-generated configuration file.

Trap/Inform Migration

The migration script performs a check to determine whether a trap destination defined for MASF is already specified in an existing SMA trapsink, trap2sink or informsink directive. If this is the case, then the directive in the MASF configuration will be discarded to avoid duplicate traps/informs being received.

trapsink, trap2sink and informsink directives specified in the existing SMA configuration are considered valid destinations for MASF traps/informs and will receive them from the MASF subagent after migration.

If the -t none option was specified on the command line, the migration script carries over any remaining MASF trap/inform directives without modification.

If the -t add option was specified (the default), the migration script expands any trapsink, trap2sink, or informsink directives to use the TARGET-MIB and NOTIFICATION-MIB. The TARGET-MIB specifies targets using IP addresses, so it might be desirable to use the -t none option if, for example, the network allocates IP addresses to hostnames dynamically by means of DHCP.
The expanded directives define filters specific to the MASF agent so that traps from other subagents will not be received by migrated trap destinations. Existing filters present in the SMA configuration are, by default, not modified and might or might not receive MASF traps, depending upon the filters that were originally defined for them.

If the -l option is specified, any filters already defined in the TARGET-MIB and the NOTIFICATION-MIB for SMA are extended to include traps from MASF. In the event that a trap destination is already configured in the TARGET-MIB with the same target address and community as an existing MASF trap/inform sink, a conflict will arise.

If the -l option was specified and a conflict arises, the migration script uses the target SNMP parameters (that is, the SNMP version and choice of trap/inform) defined by the MASF trap/inform sink directive to send traps to this destination. Otherwise, if the -l master option was specified, the conflict will be resolved using the target SNMP parameters specified in the SMA configuration.

If the migration script encounters in the MASF configuration file any of the directives listed below and the directives are either not present or differ from the SMA configuration, the script will log a warning message.

- syslocation
- syscontact
- sysname
- sysservices
- agentgroup
- agentuser
- authtrapenable

If agent is specified, the existing SMA trap targets will be configured to receive traps that were previously sent to destinations for the Sun Fire SNMP agent. If master is specified, the targets will be configured to receive Sun Fire SNMP traps, but existing SNMP target parameters will be used.
-m
--no-usmuser

Do not transfer usm (v3) users.

-n
--dry-run

Run the migration without modifying any files. If an error arises, continue processing. This can be used to determine the likely migration issues.

-p enable|disable|error
--use-agent-port=enable|disable|error

 Indicates whether the port originally used by the Sun Fire SNMP agent should be used by the SMA agent after migration (if the two agents are using different ports). If enable is specified, then the port used by the Sun Fire SNMP agent will also be used by the SMA agent after migration. If disable is specified, the ports used by SMA will not be updated by the migration tool. If the error option is specified and the SMA agent is not already using the same ports as those used by the original Sun Fire SNMP agent, an error is reported and the migration process is terminated. If no option is specified the default behavior is equivalent to the error flag.

-r
--no-trap

Do not transfer trap destinations.

-s
--skip-user

If a user is found in the MASF configuration file that cannot be created in the new configuration because of a change in the engine ID, then output a message indicating that the user could not be migrated (needs to be manually recreated) and continue processing. If this option is not present, the migration tool will consider such a situation as an error and abort.

-t none|add
--trap-filter=none|add

If none is specified then the script will copy trap directives directly. The administrator might need to manually update the
configuration file to ensure traps are only delivered to their intended destinations. If add is specified, trap filters will be constructed so that traps originating from the original Sun Fire SNMP agent are delivered only to the destinations that originally received them. The default behavior is add.

```
-u agent|master|error
--select-user=agent|master|error
```

Specifies that if a user with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. Selecting a user from a particular will also cause the group declaration for that user to be taken from the same file. If agent is specified then the user will be taken from the configuration file for the Sun Fire SNMP Agent. If master is specified, the user will be taken from the SMA configuration. Otherwise, if error is given, the script will terminate. If this option is not present, the default behavior is equivalent to the error flag.

```
-V
--version
-y agent|master|error
--select-community=agent|master|error
```

Display the version of this script.

Examples

**EXAMPLE 1** Simplest Case

The command shown below is appropriate for a simple migration. The migration fails if there are any potential conflicts.

```
# masfcnv
```

**EXAMPLE 2** Migrating Such That MASF Settings Override

To migrate the MASF configuration such that it will always succeed, that MASF settings will override in the event of a conflict with SMA, and that access will still be provided on the original MASF port, enter:

```
# masfcnv -is -l agent -p enable -u agent -y agent
```
EXAMPLE 3  Dry Run, Retaining SMA Settings

To attempt a dry run and migrate the configuration such that any conflicts will be resolved by
retaining existing SMA settings, enter:

masfcnv -l master -u master -y master

Exit Status  0       Success.
non-zero       A problem occurred during migration.

Files  /etc/sma/snmp/snmpd.conf
       /var/sma_snmp/snmpd.conf          SMA configuration files
       /etc/opt/SUNWmasf/conf/snmpd.conf
       /var/opt/SUNWmasf/snmpd.dat       MASF configuration files
       /tmp/sma_migration.log            masfcnv log file

**Name**

mdlogd – Solaris Volume Manager daemon

**Synopsis**

`mdlogd`

**Description**

`mdlogd` implements a simple daemon that watches the system console looking for messages written by the Solaris Volume Manager. When a Solaris Volume Manager message is detected, `mdlogd` sends a generic SNMP trap.

To enable traps, you must configure `mdlogd` into the SNMP framework. See *Solaris Volume Manager Administration Guide*.

**Usage**

`mdlogd` implements the following SNMP MIB:

```plaintext
SOLARIS-VOLUME-MGR-MIB DEFINITIONS ::= BEGIN
  IMPORTS
    enterprises FROM RFC1155-SMI
    DisplayString FROM SNMPv2-TC;

  -- Sun Private MIB for Solaris Volume Manager

  sun OBJECT IDENTIFIER ::= { enterprises 42 }
sunSVM OBJECT IDENTIFIER ::= { sun 104 }

  -- this is actually just the string from /dev/log that
  -- matches the md: regular expressions.
  -- This is an interim SNMP trap generator to provide
  -- information until a more complete version is available.

  -- this definition is a formalization of the old
  -- Solaris DiskSuite mdlogd trap mib.

  svmOldTrapString OBJECT-TYPE
    SYNTAX DisplayString (SIZE (0..255))
    ACCESS read-only
    STATUS mandatory
    DESCRIPTION
      "This is the matched string that
       was obtained from /dev/log."
    ::= { sunSVM 1 }

  -- SVM Compatibility ( error trap )

  svmNotice TrapTRAP-TYPE
    ENTERPRISE sunSVM
    VARIABLES { svmOldTrapString }
    DESCRIPTION
      "SVM error log trap for NOTICE. This matches 'NOTICE: md:'"
```

*System Administration Commands - Part 1*
::= 1

svmWarningTrap TRAP-TYPE
ENTERPRISE sunSVM

Solaris Volume Manager Administration Guide
**mdmonitord(1M)**

**Name**  
mdmonitord – daemon to monitor metadevices

**Synopsis**  
/usr/sbin/mdmonitord [-t time_interval]

**Description**  
The `mdmonitord` utility is part of Solaris Volume Manager. It monitors and checks RAID1 (mirrors), RAID5 and hot spares.

There are two methods for checking:

- At fixed time intervals.
- When a RAID-1 (mirror), RAID-5, or hot spare fails. A failure generates an error event which triggers a check of these metadevices.

**Options**  
The following options are supported:

- `-t` Time interval in seconds. The default value is 0, which causes probes to occur only upon an error. If you want to run `mdmonitord` at a regular interval, a value of 1800 (seconds, every half hour) is recommended as a starting point.

**Exit Status**  
The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmdmu</td>
</tr>
</tbody>
</table>

`svs(1), metaclear(1M), metadata(1M), metahs(1M), metainit(1M), metaoffline(1M), metonline(1M), metaparam(1M), metarecover(1M), metarename(1M), metareplace(1M), metaroot(1M), metaset(1M), metassist(1M), metastat(1M), metastart(1M), metasync(1M), metattach(1M), svcadm(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), smf(5), md(7D)`

**Solaris Volume Manager Administration Guide**

**Notes**  
Since frequent probes can affect performance, it is recommended that the intervals between probes be limited.

The `mdmonitord` service is managed by the service management facility, `smf(5)`, under the service identifier:

svc:/system/mdmonitor

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
medstat(1M)

Name  medstat – check the status of mediator hosts for a given diskset

Synopsis  /usr/sbin/medstat [-q] -s setname

Description  If a specified diskset has been configured for mediators, medstat attempts to contact these hosts to see if they are accessible and returns the results of the communication.

Options  -q  This optional argument disables the printing of informative text. When used with -q, medstat still prints error messages and returns a result code.

-s setname  Specifies the name of a diskset on which medstat will work.

Examples  EXAMPLE 1  Checking diskset

This example checks the mediator hosts for the selected diskset.

# medstat -s relo-red

The name of the diskset is relo-red. The medstat command prints the status for each mediator host. Additionally, if the mediator quorum is met, either through a “golden” mediator host or because half+1 of the mediator hosts respond, the exit code is 0. If the quorum is not met, then the exit code is 1. If no mediator hosts have been configured for the named diskset, the exit code is 2. The status field will contain one of the following values: Unreachable, Bad, Fatal, or Ok, where Unreachable indicates an RPC/communication problem, Bad indicates an error in the mediator data, Fatal indicates any other error condition, and Ok indicates no error conditions.

Files  /etc/lvm/meddb  Contains the mediator data for a host that has been selected as a mediator host.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Sun Cluster documentation, Solaris Volume Manager Administration Guide
Notes  This command is designed for use in the high availability product.
Name  metaclear – delete active metadevices and hot spare pools

Synopsis  
/usr/sbin/metaclear -h
/usr/sbin/metaclear [-s setname] -a [-f]
/usr/sbin/metaclear component
/usr/sbin/metaclear [-s setname] [-f] metadevice...
    hot_spare_pool...
/usr/sbin/metaclear [-s setname] -r [-f] metadevice...
    hot_spare_pool...
/usr/sbin/metaclear [-s setname] -p component
/usr/sbin/metaclear [-s setname] -p metadevice

Description  The metaclear command deletes the specified metadevice or hot_spare_pool, or purges all soft partitions from the designated component. Once a metadevice or hot spare pool is deleted, it must be re-created using metainit before it can be used again.

Any metadevice currently in use (open) cannot be deleted.

Options  Root privileges are required for all of the following options except -h.

-a  Deletes all metadevices and configured hot spare pools in the set named by -s, or the local set by default.
-f  Deletes (forcibly) a metadevice that contains a subcomponent in an error state.
-h  Displays usage message.
-p  Deletes (purges) all soft partitions from the specified metadevice or component.
-r  Recursively deletes specified metadevices and hot spare pools, but does not delete metadevices on which others depend.
-s setname  Specifies the name of the diskset on which metaclear will work. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices and/or hot spare pools.

Operands  metadevice ...
    Specifies the name(s) of the metadevice(s) to be deleted.
component
    Specifies the c*d*t*s* name(s) of the components containing soft partitions to be deleted.
hot_spare_pool ... Specifies the name(s) of the hot spare pools to be deleted in the form hspnnn, where nnn is a number in the range 000-999.

Examples

**EXAMPLE 1**  Deleting Various Devices

The following example deletes a metadevice named d10.

```
# metaclear /dev/md/dsk/d10
```

The following example deletes all local metadevices and hot spare pools on the system.

```
# metaclear -a
```

The following example deletes a mirror, d20, with a submirror in an error state.

```
# metaclear -f d20
```

The following example deletes a hot spare pool, hsp001.

```
# metaclear hsp001
```

The following example deletes a soft partition, d23.

```
# metaclear d23
```

The following example purges all soft partitions on the slice c2t3d5s2 if those partitions are not being used by other metadevices or are not open.

```
# metaclear -p c2t3d5s2
```

The following example purges soft partitions from a metadevice.

```
# metaclear -p d2
d3: Soft Partition is cleared
d4: Soft Partition is cleared
d5: Soft Partition is cleared
```

**Exit Status**  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Solaris Volume Manager Administration Guide
**Name**
metadb – create and delete replicas of the metadevice state database

**Synopsis**
```
/sbin/metadb -h
/sbin/metadb [-s setname]
/sbin/metadb [-s setname] -a [-f] [-k system-file] mddbnn
/sbin/metadb [-s setname] -a [-f] [-k system-file] [-c number] [-l length] slice...
/sbin/metadb [-s setname] -d [-f] [-k system-file] mddbnn
/sbin/metadb [-s setname] -d [-f] [-k system-file] slice...
/sbin/metadb [-s setname] -i
/sbin/metadb [-s setname] -p [-k system-file]
    [mddb.cf-file]
```

**Description**
The `metadb` command creates and deletes replicas of the metadevice state database. State database replicas can be created on dedicated slices, or on slices that will later become part of a simple metadevice (concatenation or stripe) or RAID5 metadevice. Do not place state database replicas on fabric-attached storage, SANs, or other storage that is not directly attached to the system and available at the same point in the boot process as traditional SCSI or IDE drives. See NOTES.

The metadevice state database contains the configuration of all metadevices and hot spare pools in the system. Additionally, the metadevice state database keeps track of the current state of metadevices and hot spare pools, and their components. Solaris Volume Manager automatically updates the metadevice state database when a configuration or state change occurs. A submirror failure is an example of a state change. Creating a new metadevice is an example of a configuration change.

The metadevice state database is actually a collection of multiple, replicated database copies. Each copy, referred to as a replica, is subject to strict consistency checking to ensure correctness.

Replicated databases have an inherent problem in determining which database has valid and correct data. To solve this problem, Volume Manager uses a *majority consensus algorithm*. This algorithm requires that a majority of the database replicas be available before any of them are declared valid. This algorithm strongly encourages the presence of at least three initial replicas, which you create. A consensus can then be reached as long as at least two of the three replicas are available. If there is only one replica and the system crashes, it is possible that all metadevice configuration data can be lost.

The majority consensus algorithm is conservative in the sense that it will fail if a majority consensus cannot be reached, even if one replica actually does contain the most up-to-date data. This approach guarantees that stale data will not be accidentally used, regardless of the failure scenario. The majority consensus algorithm accounts for the following: the system will
stay running with exactly half or more replicas; the system will panic when less than half the replicas are available; the system will not reboot without one more than half the total replicas.

When used with no options, the `metadb` command gives a short form of the status of the metadevice state database. Use `metadb -i` for an explanation of the flags field in the output.

The initial state database is created using the `metadb` command with both the `-a` and `-f` options, followed by the slice where the replica is to reside. The `-a` option specifies that a replica (in this case, the initial) state database should be created. The `-f` option forces the creation to occur, even though a state database does not exist. (The `-a` and `-f` options should be used together only when no state databases exist.)

Additional replicas beyond those initially created can be added to the system. They contain the same information as the existing replicas, and help to prevent the loss of the configuration information. Loss of the configuration makes operation of the metadevices impossible. To create additional replicas, use the `metadb -a` command, followed by the name of the new slice(s) where the replicas will reside. All replicas that are located on the same slice must be created at the same time.

To delete all replicas that are located on the same slice, the `metadb -d` command is used, followed by the slice name.

When used with the `-i` option, `metadb` displays the status of the metadevice state databases. The status can change if a hardware failure occurs or when state databases have been added or deleted.

To fix a replica in an error state, delete the replica and add it back again.

The metadevice state database (`mddb`) also contains a list of the replica locations for this set (local or shared diskset).

The local set `mddb` can also contain host and drive information for each of the shared disksets of which this node is a member. Other than the diskset host and drive information stored in the local set `mddb`, the local and shared diskset `mddbs` are functionality identical.

The `mddbs` are written to during the resync of a mirror or during a component failure or configuration change. A configuration change or failure can also occur on a single replica (removal of a `mddb` or a failed disk) and this causes the other replicas to be updated with this failure information.

**Options**

Root privileges are required for all of the following options except `-h` and `-i`.

The following options can be used with the `metadb` command. Not all the options are compatible on the same command line. Refer to the `SYNOPSIS` to see the supported use of the options.
-a
Attach a new database device. The /kernel/drv/md.conf file is automatically updated with the new information and the /etc/lvm/mddb.cf file is updated as well. An alternate way to create replicas is by defining them in the /etc/lvm/md.tab file and specifying the assigned name at the command line in the form, mddbnn, where nn is a two-digit number given to the replica definitions. Refer to the md.tab(4) man page for instructions on setting up replicas in that file.

-c number
Specifies the number of replicas to be placed on each device. The default number of replicas is 1.

-d
Deletes all replicas that are located on the specified slice. The /kernel/drv/md.conf file is automatically updated with the new information and the /etc/lvm/mddb.cf file is updated as well.

-f
The -f option is used to create the initial state database. It is also used to force the deletion of replicas below the minimum of one. (The -a and -f options should be used together only when no state databases exist.)

-h
Displays a usage message.

-i
Inquire about the status of the replicas. The output of the -i option includes characters in front of the device name that represent the status of the state database. Explanations of the characters are displayed following the replica status and are as follows:

  d
  replica does not have an associated device ID.

  o
  replica active prior to last mddb configuration change

  u
  replica is up to date

  l
  locator for this replica was read successfully

  c
  replica's location was in /etc/lvm/mddb.cf

  p
  replica's location was patched in kernel

  m
  replica is master, this is replica selected as input
replica does not have device relocation information

tagged data is associated with the replica

replica has device write errors

replica is active, commits are occurring to this

replica had problem with master blocks

replica had problem with data blocks

replica had format problems

replica is too small to hold current database

replica had device read errors

tagged data associated with the replica is not valid

-k system-file
   Specifies the name of the kernel file where the replica information should be written. The default system-file is /kernel/drv/md.conf. This option is for use with the local diskset only.

-l length
   Specifies the size of each replica. The default length is 8192 blocks, which should be appropriate for most configurations. “Replica” sizes of less than 128 blocks are not recommended.

-p
   Specifies updating the system file (md.conf) in the current working directory with entries from the /etc/lvm/mddb.cf file. This option is normally used to update a newly built system before it is booted for the first time. If the system has been built on a system other than the one where it will run, the location of the mddb.cf on the local machine can be passed as an argument. The system file to be updated can be changed using the -k option. This option is for use with the local diskset only.
-s setname
Specifies the name of the disk on which the metadb command will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local database replicas.

slice
Specifies the logical name of the physical slice (partition), such as /dev/dsk/c0t0d0s3.

Examples

**EXAMPLE 1** Creating Initial State Database Replicas
The following example creates the initial state database replicas on a new system.

```
# metadb -a -f c0t0d0s7 c0t1d0s3 c1t0d0s7 c1t1d0s3
```

The -a and -f options force the creation of the initial database and replicas. You could then create metadevices with these same slices, making efficient use of the system.

**EXAMPLE 2** Adding Two Replicas on Two New Disks
This example shows how to add two replicas on two new disks that have been connected to a system currently running Volume Manager.

```
# metadb -a c0t2d0s3 c1t1d0s3
```

**EXAMPLE 3** Deleting Two Replicas
This example shows how to delete two replicas from the system. Assume that replicas have been set up on /dev/dsk/c0t2d0s3 and /dev/dsk/c1t1d0s3.

```
# metadb -d c0t2d0s3 c1t1d0s3
```

Although you can delete all replicas, you should never do so while metadevices still exist. Removing all replicas causes existing metadevices to become inoperable.

Files

/etc/lvm/mddb.cf
Contains the location of each copy of the metadevice state database.

/etc/lvm/md.tab
Workspace file for metadevice database configuration.

/kernel/drv/md.conf
Contains database replica information for all metadevices on a system. Also contains Solaris Volume Manager configuration information.

Exit Status
The following exit values are returned:

0
successful completion

>0
an error occurred
Attributes  See attributes(5) for descriptions of the following attributes:

Solaris Volume Manager Administration Guide

Notes  Replicas cannot be stored on fabric-attached storage, SANs, or other storage that is not directly attached to the system. Replicas must be on storage that is available at the same point in the boot process as traditional SCSI or IDE drives. A replica can be stored on a:

- Dedicated local disk partition
- Local partition that will be part of a volume
- Local partition that will be part of a UFS logging device
Name: metadevadm – update metadevice information

Synopsis: 

Description: The metadevadm command facilitates the administration of device ID entries in Solaris Volume Manager. Use this command when the pathname stored in the metadevice state database no longer correctly addresses the device or when a disk drive has had its device ID changed.

This command requires root privileges.

Options: The following options are supported.

- **-h**
  Provide a help display.

- **-l**
  Specify that metadevadm log to syslog(3C). metadevadm logs to the the DAEMON facility at the ERR level by default. See syslog.conf(4) for additional information on changing logging levels.

  Use this option anytime. It is most useful in startup scripts and less useful interactively.

- **-n**
  Emulate the effect of a command, without making any changes to the system.

- **-r**
  Recompute the pathname and disk specifier (including slice) associated with all devices in the metadevice state database if the device supports device IDs. If a device does not support device IDs or the device is not available, then no action is taken for that device.

  Use this option when the disk has been moved or readdressed.

  This option is run automatically at boot time to detect device ID changes and update the state database.

- **-s setname**
  Specify the name of the disk set on which metadevadm works. This option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on devices in the local disk set.

- **-u disk_specifier**
  Obtain the device ID associated with the disk_specifier (for example, c1t2d0) of a device and update the metadevice state database. If the device ID has not changed this option does nothing. Use this option when a disk drive has had its
device ID changed during a firmware upgrade or due to changing the controller of a storage subsystem.

-v
Execute in verbose mode. This option has no effect when used with -u. Verbose is the default.

Examples

**EXAMPLE 1**  Updating Device ID of Disk

The following example updates the device c2t3d0:

```
# metadevadm -u c2t3d0
```

Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id19280192391293123012012010012012091398
New device reloc information: id19380192391293123012012010012012091398

The following example is a variation of the preceding, using the full pathname.

```
# metadevadm -u /dev/dsk/c2t3d0
```

The following example uses the -n option, which means that the command is emulated, but does not take effect. Note that when the -v option is used with -u, -v has no effect (verbose is the default).

```
# metadevadm -u -v -n c2t3d0
```

Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id19280192391293123012012010012012091398
New device reloc information: id19380192391293123012012010012012091398

**EXAMPLE 2**  Recomputing Pathnames

In the following example, all device names are valid.

```
# metadevadm -r
```

Disk movement detected.
Updating device names in SLVM.

In the following example, once again device names are valid.

```
# metadevadm -r -v
```

Disk movement detected.
Updating device names in SLVM.
c0t0d0s0 changed to c0t0d1s0 from device relocation information
id12098123lkmsdklsdjaskfjadsdsfjads

In the following example, metadevadm detects an invalid device name.

```
# metadevadm -r
```

Invalid device relocation information detected in SLVM.
Please check status of following disk(s):
c3t0d0
The following exit values are returned:

0 Command was successful.
1 metadevadm encountered an error condition.
2 An invalid device ID was detected when using the -r option. This is for use in the rc2.d script. See init.d(4).

Attributes See attributes(5) for descriptions of the following attributes:

Solaris Volume Manager Administration Guide
## synopsis

```
/usr/sbin/metahs [-s setname] -a all component
/usr/sbin/metahs [-s setname] -a hot_spare_pool [component]
/usr/sbin/metahs [-s setname] -d hot_spare_pool [component]
/usr/sbin/metahs [-s setname] -d all component
/usr/sbin/metahs [-s setname] -e component
/usr/sbin/metahs [-s setname] -r hot_spare_pool component-old
/usr/sbin/metahs [-s setname] -r all component-old component-new
/usr/sbin/metahs [-s setname] -i [hot_spare_pool]...
```

## description

The `metahs` command manages existing hot spares and hot spare pools. It is used to add, delete, enable, and replace components (slices) in hot spare pools. Like the `metainit` command, the `metahs` command can also create an initial hot spare pool. The `metahs` command does not replace a component of a metadevice. This function is performed by the `metareplace` command.

Hot spares are always in one of three states: available, in-use, or broken. Available hot spares are running and ready to accept data, but are not currently being written to or read from. In-use hot spares are currently being written to and read from. Broken hot spares are out of service and should be repaired. The status of hot spares is displayed when `metahs` is invoked with the `-i` option.

Solaris Volume Manager supports storage devices and logical volumes, including hot spares, greater than 1 terabyte (TB) when Solaris 10 is running a 64-bit kernel.

If a system with large volumes or hot spares is rebooted under a 32-bit Solaris 10 kernel, the large volumes are visible through `metastat` output, but they cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to Solaris 10, Solaris Volume Manager will not start. All large volumes must be removed before Solaris Volume Manager runs under another version of the Solaris Operating Environment.

## options

Root privileges are required for any of the following options except `-i`.

The following options are supported:

- `-a all component`
  Add `component` to all hot spare pools. `all` is not case sensitive.

- `-a hot_spare_pool [component]`
  Add the `component` to the specified `hot_spare_pool`. `hot_spare_pool` is created if it does not already exist.
-d all component
  Delete component from all the hot spare pools. The component cannot be deleted if it is in the in-use state.

-d hot_spare_pool [component]
  Delete hot_spare_pool, if the hot_spare_pool is both empty and not referenced by a metadevice. If component is specified, it is deleted from the hot_spare_pool. Hot spares in the in-use state cannot be deleted.

-e component
  Enable component to be available for use as a hot spare. The component can be enabled if it is in the broken state and has been repaired.

-i [hot_spare_pool . . .]
  Display the status of the specified hot_spare_pool or for all hot spare pools if one is not specified.

-r all component-old component-new
  Replace component-old with component-new in all hot spare pools which have the component associated. Components cannot be replaced from any hot spare pool if the old hot spare is in the in-use state.

-r hot_spare_pool component-old component-new
  Replace component-old with component-new in the specified hot_spare_pool. Components cannot be replaced from a hot spare pool if the old hot spare is in the in-use state.

-s setname
  Specify the name of the diskset on which metahs works. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local hot spare pools.

Operands

The following operands are supported:

  component          The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s2.

  hot_spare_pool     Hot spare pools must be of the form hspnnn, where nnn is a number in the range 000-999.

Examples

EXAMPLE 1 Adding a Hot Spare to a Hot Spare Pool

The following example adds a hot spare /dev/dsk/c0t0d0s7 to a hot spare pool hsp003:

  # metahs -a hsp003 c0t0d0s7

When the hot spare is added to the pool, the existing order of the hot spares already in the pool is preserved. The new hot spare is added at the end of the list of hot spares in the hot spare pool specified.
**EXAMPLE 2**  Adding a Hot Spare to All Currently Defined Pools

This example adds a hot spare to the hot spare pools that are currently defined:

```
# metahs -a all c0t0d0s7
```

The keyword `all` in this example specifies adding the hot spare, `/dev/dsk/c0t0d0s7`, to all the hot spare pools.

**EXAMPLE 3**  Deleting a Hot Spare

This example deletes a hot spare, `/dev/dsk/c0t0d0s7`, from a hot spare pool, hsp003:

```
# metahs -d hsp003 c0t0d0s7
```

When you delete a hot spare, the position of the remaining hot spares in the pool changes to reflect the new order. For instance, if in this example `/dev/dsk/c0t0d0s7` were the second of three hot spares, after deletion the third hot spare would move to the second position.

**EXAMPLE 4**  Replacing a Hot Spare

This example replaces a hot spare that was previously defined:

```
# metahs -r hsp001 c0t1d0s0 c0t3d0s0
```

In this example, the hot spare `/dev/dsk/c0t1d0s0` is replaced by `/dev/dsk/c0t3d0s0`. The order of the hot spares does not change.

**Exit Status**  The following exit values are returned:

*Solaris Volume Manager Administration Guide*
**Warnings**  Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32-bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.
Name  metaimport - imports disk sets into existing Solaris Volume Manager configurations

Synopsis  metaimport -s setname [-n] [-v] [-f] [disks]...
          metaimport -r [disks]...
          metaimport -V
          metaimport -?

Description  The metaimport command allows the importing of disk sets, including replicated disk sets, into an existing Solaris Volume Manager configuration. Replicated disk sets are disk sets created using remote replication software.

The default Solaris Volume Manager configuration specifies a maximum number of disk sets that can be configured. The metaimport command fails if importing the disk set would result in exceeding the number of disk sets configured on the system. To increase the number of disk sets allowed on a system, see the Solaris Volume Manager Administration Guide.

Use metaset(1M) or metastat(1M) to view the configuration of the imported set.

You must run metaimport as root.

metaimport requires a functional Solaris Volume Manager configuration before it runs.

Options  The following options are supported:

-\( \text{-f} \)
  Force the import, even if a quorum of replicas from the imported disk set is not available. This option could result in corrupt configurations and should only be used when metaimport fails with the "Insufficient quorum detected; exiting" error. If only a partial disk set is available, this option might be necessary to successfully import. Some or all data could be corrupted or unavailable when importing a partial set or a set lacking a replica quorum.

-\( \text{-n} \)
  Does not actually perform the operation, but shows the output or errors that would have resulted from the operation, had it been run.

-\( \text{-r} \)
  Report on the non-configured disk sets found on the system. If no disk device or LUN is specified, metaimport reports on all non-configured disk sets attached to the system. When the name of one disk is specified, metaimport reports on the disk set (or virtual LUN) containing the specified disk. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks.
-s setname  Specify the disk set name to use when importing. The imported disk set will be called setname, without regard to the name it may have had on a different system.

-v  Verbose. Provides detailed information about the metadb replica location and status.

-V  Version information.

-?  Display a help message.

Examples  EXAMPLE 1  Importing a Disk Set

The following example creates a disk set called blue and identifies c1t5d0 as a disk containing a state database replica from the disk set being imported.

# metaimport -s blue c1t5d0

EXAMPLE 2  Reporting Disk Sets to Import

The following example scans all disks and LUNs attached to the system and configured as part of the system. It scans for disks that could be part of a disk set to be imported. Components that are already part of the Solaris Volume Manager configuration are ignored.

This use of metaimport provides suggested forms of the metaimport command to use to actually import the disk sets that have been found. You can specify a component on the command line to reduce the scope of the scan and generate results more quickly.

# metaimport -r

Exit Status  0  Successful completion.

>0  An error occurred.

Solaris Volume Manager Administration Guide
metainit – configure metadevices

/sbin/metainit -h
/sbin/metainit [generic options] concat/stripes numstripes
   width component... [-i interlace]
/sbin/metainit [width component... [ -i interlace]]
   [ -h hot_spare_pool]
/sbin/metainit [generic options] mirror -m submirror
   [read_options] [write_options] [pass_num]
/sbin/metainit [generic options] RAID -r component...
   [-i interlace] [ -h hot_spare_pool] [-k] [-o original_column_count]
/sbin/metainit [generic options] hot_spare_pool
   [hotspare...]
/sbin/metainit [generic options] metadevice-name
/sbin/metainit [generic options] -a
/sbin/metainit [generic options] softpart -p [-e]
   component [- A alignment] size
/sbin/metainit - r

The `metainit` command configures metadevices and hot spares according to the information specified on the command line. Alternatively, you can run `metainit` so that it uses configuration entries you specify in the `/etc/lvm/md.tab` file (see `md.tab(4)`). All metadevices must be set up by the `metainit` command before they can be used.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32–bit Solaris kernel, the large volumes are visible through `metastat` output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

If you edit the `/etc/lvm/md.tab` file to configure metadevices, specify one complete configuration entry per line. You then run the `metainit` command with either the `-a` option, to activate all metadevices you entered in the `/etc/lvm/md.tab` file, or with the metadevice name corresponding to a specific configuration entry.
metainit does not maintain the state of the volumes that would have been created when metainit is run with both the -a and -n flags. Any volumes in md.tab that have dependencies on other volumes in md.tab are reported as errors when metainit -a -n is run, although the operations might succeed when metainit -a is run. See md.tab(4).

Solaris Volume Manager never updates the /etc/lvm/md.tab file. Complete configuration information is stored in the metadevice state database, not md.tab. The only way information appears in md.tab is through editing it by hand.

When setting up a disk mirror, the first step is to use metainit create a one-on-one concatenation for the root slice. See EXAMPLES.

### Options

The following options are supported:

#### Generic Options

Root privileges are required for all of the following options except -h.

The following generic options are supported:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f</td>
<td>Forces the metainit command to continue even if one of the slices contains a mounted file system or is being used as swap, or if the stripe being created is smaller in size than the underlying soft partition. This option is required when configuring mirrors on root (/), swap, and /usr.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays usage message.</td>
</tr>
<tr>
<td>-n</td>
<td>Checks the syntax of your command line or md.tab entry without actually setting up the metadevice. If used with -a, all devices are checked but not initialized.</td>
</tr>
<tr>
<td>-r</td>
<td>Only used in a shell script at boot time. Sets up all metadevices that were configured before the system crashed or was shut down. The information about previously configured metadevices is stored in the metadevice state database (see metadb(1M)).</td>
</tr>
<tr>
<td>-s setname</td>
<td>Specifies the name of the diskset on which metainit works. Without the -s option, the metainit command operates on your local metadevices and/or hotspares.</td>
</tr>
</tbody>
</table>

#### Concat/Stripe Options

The following concat/stripe options are supported:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>concat/stripe</td>
<td>Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes being defined.</td>
</tr>
<tr>
<td>numstripes</td>
<td>Specifies the number of individual stripes in the metadevice. For a simple stripe, numstripes is always 1. For a concatenation, numstripes is equal to the number of slices. For a concatenation of stripes, numstripes varies according to the number of stripes.</td>
</tr>
<tr>
<td>width</td>
<td>Specifies the number of slices that make up a stripe. When width is greater than 1, the slices are striped.</td>
</tr>
</tbody>
</table>
**component**

The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s0`. For RAID level 5 metadevices, a minimum of three slices is necessary to enable striping of the parity information across slices.

**-i interlace**

Specifies the interlace size. This value tells Solaris Volume Manager how much data to place on a slice of a striped or RAID level 5 metadevice before moving on to the next slice. *interlace* is a specified value, followed by either 'k' for kilobytes, 'm' for megabytes, or 'b' for blocks. The characters can be either uppercase or lowercase. The *interlace* specified cannot be less than 16 blocks, or greater than 100 megabytes. If *interlace* is not specified, it defaults to 16 kilobytes.

**-h hot_spare_pool**

Specifies the *hot_spare_pool* to be associated with the metadevice. If you use the command line, the hot spare pool must have been previously created by the metainit command before it can be associated with a metadevice. The *hot_spare_pool* must be of the form *hspnnn*, where *nnn* is a number in the range 000-999. Use `/h hspnnn` when the concat/ stripe being created is to be used as a submirror.

**Mirror Options**

The following mirror options are supported:

**mirror -m submirror**

Specifies the metadevice name of the mirror. The -m indicates that the configuration is a mirror. *submirror* is a metadevice (stripes or concatenation) that makes up the initial one-way mirror. Solaris Volume Manager supports a maximum of four-way mirroring. When defining mirrors, first create the mirror with the metainit command as a one-way mirror. Then attach subsequent submirrors using the metattach command. This method ensures that Solaris Volume Manager properly syncs the mirrors. (The second and any subsequent submirrors are first created using the metainit command.)

**read_options**

The following read options for mirrors are supported:

**-g**

Enables the geometric read option, which results in faster performance on sequential reads.

**-r**

Directs all reads to the first submirror. This should only be used when the devices comprising the first submirror are substantially faster than those of the second mirror. This flag cannot be used with the -g flag.

If neither the -g nor -r flags are specified, reads are made in a round-robin order from all submirrors in the mirror. This enables load balancing across the submirrors.

**write_options**

The following write options for mirrors are supported:
-S Performs serial writes to mirrors. The first submirror write completes before the second is started. This can be useful if hardware is susceptible to partial sector failures. If -S is not specified, writes are replicated and dispatched to all mirrors simultaneously.

pass_num
A number in the range 0-9 at the end of an entry defining a mirror that determines the order in which that mirror is resynced during a reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the resync is skipped. 0 should be used only for mirrors mounted as read-only, or as swap.

RAID Level 5 Options
The following RAID level 5 options are available:

RAID -r
Specifies the name of the RAID level 5 metadevice. The -r specifies that the configuration is RAID level 5.

-k
For RAID level 5 metadevices, informs the driver that it is not to initialize (zero the disk blocks) due to existing data. Only use this option to recreate a previously created RAID level 5 device.

Use the -k option with extreme caution. This option sets the disk blocks to the OK state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the -k option, you might want to initialize the device and restore data from tape.

-o original_column_count
For RAID level 5 metadevices, used with the -k option to define the number of original slices in the event the originally defined metadevice was grown. This is necessary since the parity segments are not striped across concatenated devices.

Use the -o option with extreme caution. This option sets the disk blocks to the OK state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the -o option, you might want to initialize the device and restore data from tape.

Soft Partition Options
The following soft partition options are supported:

softpart -p [ -e ] component [ -A alignment ] size
The softpart argument specifies the name of the soft partition. The -p specifies that the configuration is a soft partition.

The -e specifies that the entire disk specified by component as c*t*d* should be repartitioned and reserved for soft partitions. The specified component is repartitioned such that slice 7 reserves space for system (state database replica) usage and slice 0 contains all remaining space on the disk. Slice 7 is a minimum of 4MB, but can be larger, depending on the disk geometry. The newly created soft partition is placed on slice 0 of the device.
The component argument specifies the disk ($c*t*d*$), slice ($c*t*d*s*$), or meta device ($d*$) from which to create the soft partition. The size argument determines the space to use for the soft partition and can be specified in K or k for kilobytes, M or m for megabytes, G or g for gigabytes, T or t for terabyte (one terabyte is the maximum size), and B or b for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted.

The -A alignment option sets the value of the soft partition extent alignment. This option used when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device. For example, a hardware device that does checksuming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When you use this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

The literal all, used instead of specifying size, specifies that the soft partition should occupy all available space on the device.

The following hot spare pool options are supported:

hot_spare_pool [ hotspare... ]

When used as arguments to the metainit command, hot_spare_pool defines the name for a hot spare pool, and hotspare... is the logical name for the physical slice(s) for availability in that pool. hot_spare_pool is a number of the form hspnnn, where nnn is a number in the range 000-999.

The following md.tab file options are supported:

metadevice-name

When the metainit command is run with a metadevice-name as its only argument, it searches the /etc/lvm/md.tab file to find that name and its corresponding entry. The order in which entries appear in the md.tab file is unimportant. For example, consider the following md.tab entry:

d0 2 1 c1t0d0s0 1 c2t1d0s0

When you run the command metainit d0, it configures metadevice d0 based on the configuration information found in the md.tab file.

-a

Activates all metadevices defined in the md.tab file.

metainit does not maintain the state of the volumes that would have been created when metainit is run with both the -a and -n flags. If a device d0 is created in the first line of the md.tab file, and a later line in md.tab assumes the existence of d0, the later line fails when metainit -an runs (even if it would succeed with metainit -a).
Creating a One-on-One Concatenation

The following command creates a one-on-one concatenation for the root slice. Such a command is the first step you take when setting up a mirror for the root slice (and any other slice that cannot be unmounted). The -f option is required it create a volume with an existing file system, such as root(/).

```
# metainit -f d1 1 1 c0t0d0s0
```

The preceding command makes d1 a one-on-one concatenation, using the root slice. You can then enter:

```
# metainit d0 -m d1
```

...to make a one-way mirror of the root slice.

Concatenation

All drives in the following examples have the same size of 525 Mbytes.

This example shows a metadevice, /dev/md/dsk/d7, consisting of a concatenation of four slices.

```
# metainit d7 4 1 c0t1d0s0 1 c0t2d0s0 1 c0t3d0s0 1 /dev/dsk/c0t4d0s0
```

The number 4 indicates there are four individual stripes in the concatenation. Each stripe is made of one slice, hence the number 1 appears in front of each slice. The first disk sector in all of these devices contains a disk label. To preserve the labels on devices /dev/dsk/c0t2d0s0, /dev/dsk/c0t3d0s0, and /dev/dsk/c0t4d0s0, the metadisk driver must skip at least the first sector of those disks when mapping accesses across the concatenation boundaries. Because skipping only the first sector would create an irregular disk geometry, the entire first cylinder of these disks is skipped. This allows higher level file system software to optimize block allocations correctly.

Stripe

This example shows a metadevice, /dev/md/dsk/d15, consisting of two slices.

```
# metainit d15 1 2 c0t1d0s0 c0t2d0s0 -i 32k
```

The number 1 indicates that one stripe is being created. Because the stripe is made of two slices, the number 2 follows next. The optional -i followed by 32k specifies the interlace size as 32 Kbytes. If the interlace size were not specified, the stripe would use the default value of 16 Kbytes.

Concatentation of Stripes

This example shows a metadevice, /dev/md/dsk/d75, consisting of a concatenation of two stripes of three disks.
EXAMPLE 4  Concatenation of Stripes  (Continued)

# metainit d75 2 3 c0t1d0s0 c0t2d0s0 \
  c0t3d0s0 -i 16k \
  3 clt1d0s0 clt2d0s0 clt3d0s0 -i 32k

On the first line, the -i followed by 16k specifies that the stripe interlace size is 16 Kbytes. The second set specifies the stripe interlace size as 32 Kbytes. If the second set did not specify 32 Kbytes, the set would use the default interlace value of 16 Kbytes. The blocks of each set of three disks are interlaced across three disks.

EXAMPLE 5  Mirroring

This example shows a two-way mirror, /dev/md/dsk/d50, consisting of two submirrors. This mirror does not contain any existing data.

# metainit d51 1 1 c0t1d0s0
# metainit d52 1 1 c0t2d0s0
# metainit d50 -m d51
# metattach d50 d52

In this example, two submirrors, d51 and d52, are created with the metainit command. These two submirrors are simple concatenations. Next, a one-way mirror, d50, is created using the -m option with d51. The second submirror is attached later using the metattach command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

EXAMPLE 6  Creating a metadevice in a diskset

This example shows a metadevice, /dev/md/dsk/d75, consisting of a concatenation of two stripes within a diskset called set1.

# metainit -s set1 d75 2 3 c2t1d0s0 c2t2d0s0 \
  c2t3d0s0 -i 32k
# metainit -s set1 d51 1 1 c2t1d0s0
# metainit -s set1 d52 1 1 c3t1d0s0
# metainit -s set1 d50 -m d51
# metattach -s set1 d50 d52

In this example, a diskset is created using the metaset command. Metadevices are then created within the diskset using the metainit command. The two submirrors, d51 and d52, are simple concatenations. Next, a one-way mirror, d50, is created using the -m option with d51. The second submirror is attached later using the metattach command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.
EXAMPLE 7  RAID Level 5
This example shows a RAID level 5 device, d80, consisting of three slices:

```
# metainit d80 -r c1t0d0s0 c1t1d0s0 c1t3d0s0 -i 20k
```

In this example, a RAID level 5 metadevice is defined using the -r option with an interlace size of 20 Kbytes. The data and parity segments are striped across the slices, c1t0d0s0, c1t2d0s0, and c1t3d0s0.

EXAMPLE 8  Soft Partition
The following example shows a soft partition device, d1, built on metadevice d100 and 100 Mbytes (indicated by 100M) in size:

```
# metainit d1 -p d100 100M
```

The preceding command creates a 100 Mbyte soft partition on the d100 metadevice. This metadevice could be a RAID level 5, stripe, concatenation, or mirror.

EXAMPLE 9  Soft Partition on Full Disk
The following example shows a soft partition device, d1, built on disk c3t4d0:

```
# metainit d1 -p -e c3t4d0 9G
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all 9 Gbytes of disk c3t4d0s0.

EXAMPLE 10  Soft Partition Taking All Available Space
The following example shows a soft partition device, d1, built on disk c3t4d0:

```
# metainit d1 -p -e c3t4d0 all
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all available disk space on slice c3t4d0s0.

EXAMPLE 11  HotSpare
This example shows a two-way mirror, /dev/md/dsk/d10, and a hot spare pool with three hot spare components. The mirror does not contain any existing data.

```
# metainit hsp001 c2t2d0s0 c3t2d0s0 c1t2d0s0
# metainit d41 1 1 c1t0d0s0 -h hsp001
# metainit d42 1 1 c3t0d0s0 -h hsp001
# metainit d40 -m d41
# metattach d40 d42
```

In this example, a hot spare pool, hsp001, is created with three slices from three different disks used as hot spares. Next, two submirrors are created, d41 and d42. These are simple
concatenations. The `metainit` command uses the `-h` option to associate the hot spare pool `hsp001` with each submirror. A one-way mirror is then defined using the `-m` option. The second submirror is attached using the `metattach` command.

**EXAMPLE 12** Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1 megabyte.

```
# metainit -s red d13 -p c1t3d0s4 -A 1m 4m
```

In this example the soft partition, `d13`, is created with an extent alignment of 1 megabyte. The `metainit` command uses the `-A` option with an alignment of `1m` to define the soft partition extent alignment.

**Files**

`/etc/lvm/md.tab`

Contains list of metadevice and hot spare configurations for batch-like creation.

**Warnings**

This section contains information on different types of warnings.

**Devices and Volumes Greater Than 1 TB**

Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32-bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

**Multi-Way Mirror**

Do not use the `metainit` command to create a multi-way mirror. Rather, create a one-way mirror with `metainit` then attach additional submirrors with `metattach`. When the `metattach` command is not used, no resync operations occur and data could become corrupted.

If you use `metainit` to create a mirror with multiple submirrors, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The submirrors may not have the same data.
Please see ERRORS in metainit(1M) for additional information.
```

**Truncation of Soft Partitions**

When creating stripes on top of soft partitions it is possible for the size of the new stripe to be less than the size of the underlying soft partition. If this occurs, `metainit` fails with an error indicating the actions required to overcome the failure.

If you use the `-f` option to override this behavior, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The stripe is truncating the size of the underlying device.
Please see ERRORS in metainit(1M) for additional information.
```
When mirroring data in Solaris Volume Manager, transfers from memory to the disks do not all occur at exactly the same time for all sides of the mirror. If the contents of buffers are changed while the data is in-flight to the disk (called write-on-write), then different data can end up being stored on each side of a mirror.

This problem can be addressed by making a private copy of the data for mirror writes, however, doing this copy is expensive. Another approach is to detect when memory has been modified across a write by looking at the dirty-bit associated with the memory page. Solaris Volume Manager uses this dirty-bit technique when it can. Unfortunately, this technique does not work for raw I/O or direct I/O. By default, Solaris Volume Manager is tuned for performance with the liability that mirrored data might be out of sync if an application does a "write-on-write" to buffers associated with raw I/O or direct I/O. Without mirroring, you were not guaranteed what data would actually end up on media, but multiple reads would return the same data. With mirroring, multiple reads can return different data. The following line can be added to `/etc/system` to cause a stable copy of the buffers to be used for all raw I/O and direct I/O write operations.

```
set md_mirror:md_mirror_wow_flg=0x20
```

Setting this flag degrades performance.

**Exit Status**

The following exit values are returned:

- 0          Successful completion.
- >0         An error occurred.

**Solaris Volume Manager Administration Guide**

**Limitations**

Recursive mirroring is not allowed; that is, a mirror cannot appear in the definition of another mirror.

Recursive logging is not allowed; that is, a trans metadevice cannot appear in the definition of another metadevice.

Stripes, concatenations, and RAID level 5 metadevices must consist of slices only.
Mirroring of RAID level 5 metadevices is not allowed.
Soft partitions can be built on raw devices, or on stripes, RAID level 5, or mirrors.
RAID level 5 or stripe metadevices can be built directly on soft partitions.

**Notes**  Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See `mount_ufs(1M)` for more information about UFS logging.
**Name**
metaoffline, metaonline – place submirrors offline and online

**Synopsis**
```
/usr/sbin/metaoffline  -h
/usr/sbin/metaoffline  [-s setname] [-f] mirror submirror
/usr/sbin/metaonline   -h
/usr/sbin/metaonline   [-s setname] mirror submirror
```

**Description**
The `metaoffline` command prevents Solaris Volume Manager from reading and writing to the submirror that has been taken offline. While the submirror is offline, all writes to the mirror will be kept track of (by region) and will be written when the submirror is brought back online. The `metaoffline` command can also be used to perform online backups: one submirror is taken offline and backed up while the mirror remains accessible. (However, if this is a two-way mirror, data redundancy is lost while one submirror is offline.) The `metaoffline` command differs from the `metadetach` command because it does not sever the logical association between the submirror and the mirror. To completely remove a submirror from a mirror, use the `metadetach` command.

A submirror that has been taken offline will only remain offline until the `metaonline` command is invoked or the system is rebooted.

When the `metaonline` command is used, reading from and writing to the submirror resumes. A resync is automatically invoked to resync the regions written while the submirror was offline. Writes are directed to the submirror during resync. Reads, however, will come from a different submirror. Once the resync operation completes, reads and writes are performed on that submirror. The `metaonline` command is only effective on a submirror of a mirror that has been taken offline.

The `metaoffline` and `metaonline` commands cannot be used on RAID 1 volumes in application-based recovery (ABR) mode.

A submirror that has been taken offline with the `metaoffline` command can only be mounted as read-only.

**Options**
Root privileges are required for all of the following options except `-h`.

- `-f`
  Forces offline of submirrors that have slices requiring maintenance.

- `-h`
  Displays usage message.

- `-s setname`
  Specifies the name of the diskset on which `metaoffline` and `metaonline` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.

- `mirror`
  Specifies the metadevice name of the mirror from which the submirror will be either taken offline or put online.
submirror  Specifies the metadevice name of the submirror to be either taken offline or put online.

Examples  EXAMPLE 1  Taking a Submirror Offline
This example takes one submirror, d9, offline from mirror d10.
# metaoffline d10 d9

Exit Status  The following exit values are returned:
0  Successful completion.
>0  An error occurred.

Solaris Volume Manager Administration Guide

Notes  The metaonline and metaoffline commands are not applicable to mirrors in application-based recovery (ABR) mode.
### metaparam(1M)

#### Name
metaparam – modify parameters of metadevices

#### Synopsis
/sbin/metaparam -h
/sbin/metaparam [-s setname] [concat/stripe or RAID5 options] concat/stripe RAID
/sbin/metaparam [-s setname] [mirror options] mirror

#### Description
The **metaparam** command is used to display or modify current parameters of metadevices.

If just the metadevice is specified as an argument to the **metaparam** command, the current settings are displayed.

The **metaparam** command enables most metadevice (volume) parameters to be changed. Only the interlace value cannot be changed by **metaparam**, because it is established when the metadevice is created and cannot be changed thereafter.

Root privileges are required for all of the options.

The following options are supported:

- **-h**
  Displays usage message.

- **-s setname**
  Specify the name of the diskset on which **metaparam** works. Using the **-s** option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

#### Concat/STRIPE Or RAID5 Options

- **-h hot_spare_pool | none**
  Specifies the hot spare pool to be used by a metadevice. If none is specified, the metadevice is disassociated with the hot spare pool assigned to it. If the metadevice is currently using a hot spare, then **metaparam** cannot replace the hot spare pool.

- **concat/stripe | RAID**
  Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes, or of the RAID5 metadevice.

#### Mirror Options

- **-r roundrobin | geometric | first**
  Modifies the read option for a mirror. The **-r** option must be followed by either **roundrobin**, **geometric**, or **first**. roundrobin, which is the default action under the **metainit** command, specifies reading the disks in a round-robin (load balancing) method. geometric allows for faster...
performance on sequential reads. first specifies reading only from the first submirror.

**-w parallel | serial**

Modifies the write option for a mirror. The -w option must be followed by either parallel or serial. parallel, the default action under the metainit command, specifies that all writes are parallel. serial specifies that all writes are serial.

**-p pass_number**

A number from 0-to-9 that specifies the order in which a mirror is resynced during reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the mirror resync is skipped. 0 should only be used for mirrors mounted as read-only, or as swap.

**mirror**

Specifies the metadevice name of the mirror.

**Examples**

**EXAMPLE 1**  Associating Hot Spare Pool with RAID5 Metadevice

This example associates a hot spare pool, hsp005, with a RAID5 metadevice, d80.

```
# metaparam -h hsp005 d80
```

**EXAMPLE 2**  Changing Read Option to Geometric

This example changes the read option on a mirror d50 from the default of roundrobin to geometric.

```
# metaparam -r geometric d50
```

**Exit Status**

The following exit values are returned:

- **0**: Successful completion.
- **>0**: An error occurred.

Solaris Volume Manager Administration Guide
metarecover(1M)

Name metarecover – recover soft partition information

Synopsis
/sbin/metarecover [-n] [-v] [-s setname] component -p
/sbin/metarecover [-n] [-v] [-s setname] component -p
 {-d}
/sbin/metarecover [-n] [-v] [-s setname] component -p
 {-m}

Description The metarecover command scans a specified component to look for soft partition configuration information and to regenerate the configuration.

Options The following options are supported:
-d Recover soft partitions in the metadevice state database from the extent headers on the device. Options -d and -m are mutually exclusive.
-m Regenerate the extent headers and reapply them to the underlying device based on the soft partitions listed in the metadevice state database. Options -d and -m are mutually exclusive.
-n Do not actually perform the operation. Show the output or errors that would have resulted from the operation, had it been run.
-p Regenerate soft partitions based on the metadevice state database or extent headers on the underlying device. If neither -d nor -m are specified, this option compares the soft partition information in the metadevice state database to the extent headers.
-s setname Specify the name of the diskset on which metarecover works. Using the s option causes the command to perform its function within the specified diskset. Without the -s option, the metarecover command operates on the metadevices and/or hot spare pools in the local diskset.

This option is required to recover former sps from a diskset component or raw-device. setname must be identical to the former setname in which the sps were created. The set numbers, however, seem irrelevant.

-v Verbose mode, displaying the changes being made.

Operands The following operand is supported:

component Specifies the c*t*d*s* number of the disk or slice containing the partitions, or the device name (for example, d10) of the metadevice containing the partitions.

component can be a slice name, component name, /dev/dsk path, or /dev/rdsk path.
Examples

**EXAMPLE 1**  Updating Metadevice State Database Based on Disk Extent Headers
A disk containing soft partitions is moved from one system to another. The system administrator would like to use the existing soft partitions. `metarecover` updates the metadevice state database based on the extent headers on the disk.

```bash
# metarecover -v c0t3d0s2 -p -d
```

**EXAMPLE 2**  Updating Metadevice State Database Based on Incomplete Soft Partition Creation
A system crashes in the middle of creating a new soft partition. The soft partition is in the creating state and the driver does not let that device be opened. `metarecover` rewrites the extent headers for the partially created soft partition and mark it as Okay.

```bash
# metarecover -v c0t3d0s2 -p -m
```

**EXAMPLE 3**  Updating Extent Headers Based on Metadevice State Database
Someone accidentally overwrote a portion of a disk leaving extent headers destroyed. `metarecover` rewrites the extent headers to ensure a valid soft partition configuration, though user data is not recovered.

```bash
# metarecover -v d5 -m
```

**EXAMPLE 4**  Validating Soft Partition Configuration
To validate the existing soft partition configuration, use `metarecover` with only the `-p` flag.

```bash
# metarecover c0t3d0s2 -p
```

**Exit Status**  The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.

*Solaris Volume Manager Administration Guide*
There are two ways to use metarename, one with and one without the -x option. The first method (without -x) renames an existing metadevice to a new name. This makes managing the metadevice namespace easier. The metadevice being renamed cannot be mounted or open, nor can the new name already exist. For example, to rename a metadevice that contains a mounted file system, you would first need to unmount the file system.

With the second way to use metarename, using the -x option, metarename switches (exchanges) the names of an existing layered metadevice and one of its subdevices. In Solaris Volume Manager terms, a layered metadevice can be either a mirror or a trans metadevice. The -x option enables you to switch the metadevice names of a mirror and one of its submirrors, or a trans metadevice and its master device.

metarename -x makes it easier to mirror or unmirror an existing stripe or concatenation, and to remove a trans device.

When used to mirror an existing stripe or concatenation, you must stop access to the device. For example, if the device contains a mounted file system, you must first unmount the file system before doing the rename.

You can also use the metarename -x command to untrans a trans metadevice from an existing device. This applies only to the master device. You cannot remove a logging device with metarename. Before you can rename a trans device, you must detach the logging device. Then you must stop access to the trans metadevice itself.

You cannot rename or switch metadevices that are in an error state or that have subcomponents in an error state, or metadevices actively using a hot spare replacement.

You can only switch metadevices that have a direct child/parent relationship. You could not, for example, directly exchange a stripe in a mirror that is a master device with the trans metadevice.

You must use the -f flag when switching members of a trans metadevice.

Only metadevices can be switched, not slices.

Options

The following options are supported:

- f
  Force the switching of trans metadevice members.

- h
  Display a help message.
- s setname
  Specifies the name of the diskset on which metarename will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on the local metadevices.

- x
  Exchange the metadevice names metadevice1 and metadevice2.

  metadevice1
  Specifies the metadevice to be renamed or switched.

  metadevice2
  Specifies the target metadevice name for the rename or switch operation.

Examples

EXAMPLE 1  Renaming a Metadevice
This example renames a metadevice named d10 to d100. Note that d100 must not exist for the rename to succeed.

  # metarename d10 d100

EXAMPLE 2  Creating a Two-Way Mirror
This example creates a two-way mirror from an existing stripe named d1 with a mounted file system, /home2.

  # metainit d2 1 1 c13d0s1
  # metainit -f d20 -m d1
  # umount /home2
  # metarename -x d20 d1
  # metattach d1 d2
  # mount /home2

First, a second concatenation d2, is created. (d1 already exists.) The metainit command creates a one-way mirror, d20, from d1. Next, you umount the file system and switch d1 for d20, making d1 the top-level device (mirror). You attach the second submirror, d2, to create a two-way mirror. Lastly, you remount the file system.

EXAMPLE 3  Mounting a Mirrored File System on Stripe
This example takes an existing mirror named d1 with a mounted file system, and ends up with the file system mounted on a stripe d1.

  # umount /fs2
  # metarename -x d1 d20
  # metadetach d20 d1
  # metaclear -r d20
  # mount /fs2

First, you unmount the file system, then switch the mirror d1 and its submirror d20. This makes the mirror into d20. Next, you detach d1 from d20, then delete the mirror d20 and its
EXAMPLE 3  Mounting a Mirrored File System on Stripe  (Continued)

other submirror. You then remount the file system.

EXAMPLE 4  Deleting a Trans Metadevice

This example deletes a trans metadevice named d10 while its mount point is /myhome. The master device, which is a stripe, is named d2. The logging device, also a stripe, is named d5.

```bash
# umount /myhome
# metadetach d10
# metarename -f -x d10 d2
# metaclear d2
# metaclear d5
# fsck /dev/md/dsk/d10
# mount /myhome
```

You umount the file system first, then detach the trans metadevice's logging device. The trans metadevice is switched with the master device, making the trans metadevice d2 and the underlying stripe d10. You clear the trans metadevice d2 and the logging device d5. d10 must be fsck'd, and then the file system is remounted.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Solaris Volume Manager Administration Guide

Limitations  Renaming and exchanging metadevice names can only be used for metadevices. A physical slice cannot be renamed to a metadevice, nor can a metadevice be exchanged with a physical slice name.

Metadevice names are strings of the pattern d<xyz> where xyz is a value between 0 and 8192. You cannot use logical names for metadevices.
Notes  Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging—they pass data directly through to the underlying device. See `mount.ufs(1M)` for more information about UFS logging.
The metareplace command is used to enable or replace components (slices) within a submirror or a RAID5 metadevice.

When you replace a component, the metareplace command automatically starts resyncing the new component with the rest of the metadevice. When the resync completes, the replaced component becomes readable and writable. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements.

Note that the new component must be large enough to replace the old component.

A component may be in one of several states. The Last Erred and the Maintenance states require action. Always replace components in the Maintenance state first, followed by a resync and validation of data. After components requiring maintenance are fixed, validated, and resynced, components in the Last Erred state should be replaced. To avoid data loss, it is always best to back up all data before replacing Last Erred devices.

Root privileges are required for all of the following options except -h.

- **-e**
  Transitions the state of component to the available state and resyncs the failed component. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements. This command is useful when a component fails due to human error (for example, accidentally turning off a disk), or because the component was physically replaced. In this case, the replacement component must be partitioned to match the disk being replaced before running the metareplace command.

- **-f**
  Forces the replacement of an errored component of a metadevice in which multiple components are in error. The component determined by the metastat display to be in the "Maintenance" state must be replaced first. This option may cause data to be fabricated since multiple components are in error.

- **-h**
  Display help message.
Specifies the name of the diskset on which `metareplace` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.

The metadevice name of the mirror.

The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s2`.

The physical slice that is being replaced.

The physical slice that is replacing `component-old`.

The metadevice name of the RAID5 device.

**Examples**

**EXAMPLE 1**  Recovering from Error Condition in RAID5 Metadevice

This example shows how to recover when a single component in a RAID5 metadevice is errored.

```
# metareplace d10 c3t0d0s2 c5t0d0s2
```

In this example, a RAID5 metadevice `d10` has an errored component, `c3t0d0s2`, replaced by a new component, `c5t0d0s2`.

**EXAMPLE 2**  Use of `-e` After Physical Disk Replacement

This example shows the use of the `-e` option after a physical disk in a submirror (a submirror of mirror `d11`, in this case) has been replaced.

```
# metareplace -e d11 c1t4d0s2
```

Note: The replacement disk must be partitioned to match the disk it is replacing before running the `metareplace` command.

**Exit Status**  The following exit values are returned:

- `0`  Successful completion.
- `>0`  An error occurred.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>

metareplace(1M)

metarename(1M), metaroot(1M), metaset(1M), metassist(1M), metastat(1M),
metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5),
md(7D)

Solaris Volume Manager Administration Guide
The `metaroot` command edits the `/etc/vfstab` and `/etc/system` files so that the system may be booted with the root file system (/) on an appropriate metadevice. The only metadevices that support the root file system are a stripe with only a single slice or a mirror on a single-slice stripe.

If necessary, the `metaroot` command can reset a system that has been configured to boot the root file system (/) on a metadevice so that it uses a physical slice.

### Options

Root privileges are required for all of the following options except `-h`.

The following options are supported:

- `-c mddb.cf-name` Use `mddb.cf-name` instead of the default `/etc/lvm/mddb.cf` file as a source of metadevice database locations.
- `-h` Display a usage message.
- `-k system-name` Edit a user-supplied `system-name` instead of the default `/etc/system` system configuration information file.
- `-m md.conf-name` Edit the configuration file specified by `md.conf-name` rather than the default, `/kernel/drv/md.conf`.
- `-n` Print what would be done without actually doing it.
- `-R root-path` When metaroot modifies system files, it accesses them in their relative location under `root-path`.

The `-R` option cannot be used in combination with the `-c`, `-k`, `-m`, or `-v` options.

#### Note

- The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See `zones(5)`.

- `-v vfstab-name` Edit `vfstab-name` instead of the default `/etc/vfstab` table of file system defaults.

### Operands

The following operands are supported:

- `device` Specifies either the metadevice or the conventional disk device (slice) used for the root file system (/).
Specifying Root File System on Metadevice

The following command edits /etc/system and /etc/vfstab to specify that the root file system is now on metadevice d0.

```
# metaroot d0
```

Specifying Root File System on SCSI Disk

The following command edits /etc/system and /etc/vfstab to specify that the root file system is now on the SCSI disk device /dev/dsk/c0t3d0s0.

```
# metaroot /dev/dsk/c0t3d0s0
```

/etc/system
System configuration information file. See system(4).

/etc/vfstab
File system defaults.

/etc/lvm/mddb.cf
Metadevice state database locations.

/kernel/drv/md.conf
Configuration file for the metadevice driver, md.

Exit Status
The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>

Solaris Volume Manager Administration Guide
The `metaset` command administers sets of disks in named disk sets. Named disk sets include any disk set that is not in the local set. While disk sets enable a high-availability configuration, Solaris Volume Manager itself does not actually provide a high-availability environment.

A single-owner disk set configuration manages storage on a SAN or fabric-attached storage, or provides namespace control and state database replica management for a specified set of disks.

In a shared disk set configuration, multiple hosts are physically connected to the same set of disks. When one host fails, another host has exclusive access to the disks. Each host can control a shared disk set, but only one host can control it at a time.

When you add a new disk to any disk set, Solaris Volume Manager checks the disk format. If necessary, it repartitions the disk to ensure that the disk has an appropriately configured reserved slice 7 (or slice 6 on an EFI labelled device) with adequate space for a state database replica. The precise size of slice 7 (or slice 6 on an EFI labelled device) depends on the disk geometry. For traditional disk sets, the slice is no less than 4 Mbytes, and probably closer to 6
Mbytes, depending on where the cylinder boundaries lie. For multi-owner disk sets, the slice is a minimum of 256 Mbytes. The minimal size for slice 7 might change in the future. This change is based on a variety of factors, including the size of the state database replica and information to be stored in the state database replica.

For use in disk sets, disks must have a dedicated slice (six or seven) that meets specific criteria:

- The slice must start at sector 0
- The slice must include enough space for disk label
- The state database replicas cannot be mounted
- The slice does not overlap with any other slices, including slice 2

If the existing partition table does not meet these criteria, or if the -L flag is specified, Solaris Volume Manager repartitions the disk. A small portion of each drive is reserved in slice 7 (or slice 6 on an EFI labelled device) for use by Solaris Volume Manager. The remainder of the space on each drive is placed into slice 0. Any existing data on the disks is lost by repartitioning.

After you add a drive to a disk set, it can be repartitioned as necessary, with the exception that slice 7 (or slice 6 on an EFI labelled device) is not altered in any way.

After a disk set is created and metadevices are set up within the set, the metadevice name is in the following form:

```
/dev/md/setname/{dsk,rdsk}/dnumber
```

where `setname` is the name of the disk set, and `number` is the number of the metadevice (0-127).

If you have disk sets that you upgraded from Solstice DiskSuite software, the default state database replica size on those sets is 1034 blocks, not the 8192 block size from Solaris Volume Manager. Also, slice 7 on the disks that were added under Solstice DiskSuite are correspondingly smaller than slice 7 on disks that were added under Solaris Volume Manager.

If disks you add to a disk set have acceptable slice 7s (that start at cylinder 0 and that have sufficient space for the state database replica), they are not reformatted.

Hot spare pools within local disk sets use standard Solaris Volume Manager naming conventions. Hot spare pools with shared disk sets use the following convention:

```
setname/hspnumber
```

where `setname` is the name of the disk set, and `number` is the number of the hot spare pool (0-999).
To create and work with a disk set in a multi-node environment, root must be a member of Group 14 on all hosts, or the / .rhosts file must contain an entry for all other host names. This is not required in a SunCluster 3.x environment.

Tagged data occurs when there are different versions of a disk set’s replicas. This tagged data consists of the set owner’s nodename, the hardware serial number of the owner and the time it was written out to the available replicas. The system administrator can use this information to determine which replica contains the correct data.

When a disk set is configured with an even number of storage enclosures and has replicas balanced across them evenly, it is possible that up to half of the replicas can be lost (for example, through a power failure of half of the storage enclosures). After the enclosure that went down is rebooted, half of the replicas are not recognized by SVM. When the set is retaken, the metaset command returns an error of “stale databases”, and all of the metadevices are in a read-only state.

Some of the replicas that are not recognized need to be deleted. The action of deleting the replicas also causes updates to the replicas that are not being deleted. In a dual hosted disk set environment, the second node can access the deleted replicas instead of the existing replicas when it takes the set. This leads to the possibility of getting the wrong replica record on a disk set take. An error message is displayed, and user intervention is required.

Use the -q to query the disk set and the -t, -u, and -y, options to select the tag and take the disk set. See OPTIONS.

SVM provides support for a low-end HA solution consisting of two hosts that share only two strings of drives. The hosts in this type of configuration, referred to as mediators or mediator hosts, run a special daemon, rpc.metamedd(1M). The mediator hosts take on additional responsibilities to ensure that data is available in the case of host or drive failures.

A mediator configuration can survive the failure of a single host or a single string of drives, without administrative intervention. If both a host and a string of drives fail (multiple failures), the integrity of the data cannot be guaranteed. At this point, administrative intervention is required to make the data accessible. See mediator(7D) for further details.

Use the -m option to add or delete a mediator host. See OPTIONS.

The following options are supported:

-a

Add drives or hosts to the named set. For a drive to be accepted into a set, the drive must not be in use within another metadevice or disk set, mounted on, or swapped on. When the drive is accepted into the set, it is repartitioned and the metadevice state database replica (for the set) can be placed on it. However, if a slice 7 (or slice 6 on an EFI labelled device), starts at cylinder 0, and is large enough to hold a state database replica, then the disk is not repartitioned. Also, a drive is not accepted if it cannot be found on all hosts specified as part of the set. This means that if a host within the specified set is unreachable due to network problems, or is administratively down, the add fails.
- a | - d | - n mediator_host_list
Add (- a) or delete (- d) mediator hosts to the specified disk set. A mediator_host_list is the
nodename(4) of the mediator host to be added and (for adding) up to two other aliases for
the mediator host. The nodename and aliases for each mediator host are separated only by
commas. Up to three mediator hosts can be specified for the named disk set. Specify only
the nodename of that host as the argument to - m to delete a mediator host.

In a single metaset command you can add or delete three mediator hosts. See EXAMPLES.

-A {enable | disable}
Specify auto-take status for a disk set. If auto-take is enabled for a set, the disk set is
automatically taken at boot, and file systems on volumes within the disk set can be
mounted through /etc/vfstab entries. Only a single host can be associated with an
auto-take set, so attempts to add a second host to an auto-take set or attempts to configure a
disk set with multiple hosts as auto-take fails with an error message. Disabling auto-take
status for a specific disk set causes the disk set to revert to normal behavior. That is, the disk
set is potentially shared (non-concurrently) among hosts, and unavailable for mounting
through /etc/vfstab.

-b
Insure that the replicas are distributed according to the replica layout algorithm. This can
be invoked at any time, and does nothing if the replicas are correctly distributed. In cases
where the user has used the metadb command to manually remove or add replicas, this
command can be used to insure that the distribution of replicas matches the replica layout
algorithm.

-C {take | release | purge}
Do not interact with the Cluster Framework when used in a Sun Cluster 3 environment. In
effect, this means do not modify the Cluster Configuration Repository. These options
should only be used to fix a broken disk set configuration. This option is not for use with a
multi-owner disk set.

take
Take ownership of the disk set but do not inform the Cluster Framework that the disk
set is available

release
Release ownership of the disk set without informing the Cluster Framework. This
option should only be used if the disk set ownership was taken with the corresponding
-C take option.

purge
Remove the disk set without informing the Cluster Framework that the disk set has been
purged
Delete drives or hosts from the named disk set. For a drive to be deleted, it must not be in use within the set. The last host cannot be deleted unless all of the drives within the set are deleted. Deleting the last host in a disk set destroys the disk set.

This option fails on a multi-owner disk set if attempting to withdraw the master node while other nodes are in the set.

Force one of three actions to occur: takes ownership of a disk set when used with `-t`; deletes the last disk drive from the disk set; or deletes the last host from the disk set. Deleting the last drive or host from a disk set requires the `-d` option.

When used to forcibly take ownership of the disk set, this causes the disk set to be grabbed whether or not another host owns the set. All of the disks within the set are taken over (reserved) and fail fast is enabled, causing the other host to panic if it had disk set ownership. The metadevice state database is read in by the host performing the take, and the shared metadevices contained in the set are accessible.

You can use this option to delete the last drive in the disk set, because this drive would implicitly contain the last state database replica.

You can use `-f` option to delete hosts from a set. When specified with a partial list of hosts, it can be used for one-host administration. One-host administration could be useful when a host is known to be non-functional, thus avoiding timeouts and failed commands. When specified with a complete list of hosts, the set is completely deleted. It is generally specified with a complete list of hosts to clean up after one-host administration has been performed.

Specify one or more host names to be added to or deleted from a disk set. Adding the first host creates the set. The last host cannot be deleted unless all of the drives within the set have been deleted. The host name is not accepted if all of the drives within the set cannot be found on the specified host. The host name is the same name found in `/etc/nodename`.

Join a host to the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

As a host boots and is brought online, it must go through three configuration levels to be able to use a multi-owner disk set:

1. It must be included in the cluster nodelist, which happens automatically in a cluster or single-node situation.
2. It must be added to the multi-owner disk set with the `-a -h` options documented elsewhere in this man page.
3. It must join the set. When the host is first added to the set, it is automatically joined.
On manual restarts, the administrator must manually issue

```
metaset -s multinodesetname -j
```

to join the host to the owner list. After the cluster reconfiguration, when the host reenters the cluster, the node is automatically joined to the set. The `metaset - j` command joins the host to all multi-owner sets that the host has been added to. In a single node situation, joining the node to the disk set starts any necessary resynchronizations.

`-L`
When adding a disk to a disk set, force the disk to be repartitioned using the standard Solaris Volume Manager algorithm. See DESCRIPTION.

`-l length`
Set the size (in blocks) for the metadevice state database replica. The length can only be set when adding a new drive; it cannot be changed on an existing drive. The default (and maximum) size is 8192 blocks, which should be appropriate for most configurations. Replica sizes of less than 128 blocks are not recommended.

`-M`
Specify that the disk set to be created or modified is a multi-owner disk set that supports multiple concurrent owners.

This option is required when creating a multi-owner disk set. Its use is optional on all other operations on a multi-owner disk set and has no effect. Existing disk sets cannot be converted to multi-owner sets.

`-o`
Return an exit status of 0 if the local host or the host specified with the `-h` option is the owner of the disk set.

`-P`
Purge the named disk set from the node on which the `metaset` command is run. The disk set must not be owned by the node that runs this command. If the node does own the disk set, the command fails.

If you need to delete a disk set but cannot take ownership of the set, use the `-P` option.

This option is not for use with a multi-owner disk set.

`-q`
Displays an enumerated list of tags pertaining to "tagged data" that can be encountered during a take of the ownership of a disk set.

This option is not for use with a multi-owner disk set.

`-r`
Release ownership of a disk set. All of the disks within the set are released. The metadevices set up within the set are no longer accessible.

This option is not for use with a multi-owner disk set.
-s setname
  Specify the name of a disk set on which `metaset` works. If no `setname` is specified, all disk sets are returned.

-t
  Take ownership of a disk set safely. If `metaset` finds that another host owns the set, this host is not be allowed to take ownership of the set. If the set is not owned by any other host, all the disks within the set are owned by the host on which `metaset` was executed. The metadevice state database is read in, and the shared metadevices contained in the set become accessible. The -t option takes a disk set that has stale databases. When the databases are stale, `metaset` exits with code 66, and prints a message. At that point, the only operations permitted are the addition and deletion of replicas. Once the addition or deletion of the replicas has been completed, the disk set should be released and retaken to gain full access to the data.

  This option is not for use with a multi-owner disk set.

-u tagnumber
  Once a tag has been selected, a subsequent take with -u `tagnumber` can be executed to select the data associated with the given `tagnumber`.

-w
  Withdraws a host from the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

  Instead of releasing a set, a host can issue
  ```
  metaset -s multinodesetname -w
  ```
  to withdraw from the owner list. A host automatically withdraws on a reboot, but can be manually withdrawn if it should not be able to use the set, but should be able to rejoin at a later time. A host that withdrew due to a reboot can still appear joined from other hosts in the set until a reconfiguration cycle occurs.

  `metaset` -w withdraws from ownership of all multi-owner sets of which the host is a member. This option fails if you attempt to withdraw the master node while other nodes are in the disk set owner list. This option cancels all resyncs running on the node. A cluster reconfiguration process that is removing a node from the cluster membership list effectively withdraws the host from the ownership list.

-y
  Execute a subsequent take. If the take operation encounters “tagged data,” the take operation exits with code 2. You can then run the `metaset` command with the -q option to see an enumerated list of tags.
Examples

EXAMPLE 1  Defining a Disk Set

This example defines a disk set.

```
# metaset -s relo-red -a -h red blue
```

The name of the disk set is relo-red. The names of the first and second hosts added to the set are red and blue, respectively. (The hostname is found in /etc/nodename.) Adding the first host creates the disk set. A disk set can be created with just one host, with the second added later. The last host cannot be deleted until all of the drives within the set have been deleted.

EXAMPLE 2  Adding Drives to a Disk Set

This example adds drives to a disk set.

```
# metaset -s relo-red -a c2t0d0 c2t1d0 c2t2d0 c2t3d0 c2t4d0 c2t5d0
```

The name of the previously created disk set is relo-red. The names of the drives are c2t0d0, c2t1d0, c2t2d0, c2t3d0, c2t4d0, and c2t5d0. There is no slice identifier ("sx") at the end of the drive names.

EXAMPLE 3  Adding Multiple Mediator Hosts

The following command adds three mediator hosts to the specified disk set.

```
# metaset -s mydiskset -a -m myhost1,alias1 myhost2,alias2 myhost3,alias3
```

EXAMPLE 4  Purging a Disk Set from the Node

The following command purges the disk set relo-red from the node:

```
# metaset -s relo-red -P
```

EXAMPLE 5  Querying a Disk Set for Tagged Data

The following command queries the disk set relo-red for a list of the tagged data:

```
# metaset -s relo-red -q
```

This command produces the following results:

```
The following tag(s) were found:
  1 - vha-1000c - Fri Sep 20 17:20:08 2002
  2 - vha-1000c - Mon Sep 23 11:01:27 2002
```

EXAMPLE 6  Selecting a tag and taking a Disk set

The following command selects a tag and takes the disk set relo-red:

```
# metaset -s relo-red -t -u 2
```
Defining a Multi-Owner Disk Set

The following command defines a multi-owner disk set:

```
# metaset -s blue -M -a -h hahost1 hahost2
```

The name of the disk set is `blue`. The names of the first and second hosts added to the set are `hahost1` and `hahost2`, respectively. The hostname is found in `/etc/nodename`. Adding the first host creates the multi-owner disk set. A disk set can be created with just one host, with additional hosts added later. The last host cannot be deleted until all of the drives within the set have been deleted.

**Files**

`/etc/lvm/md.tab` Contains list of metadevice configurations.

**Exit Status**

The following exit values are returned:

0 Successful completion.

$0 An error occurred.

**Attributes**

**Solaris Volume Manager Administration Guide**

**Notes**

Disk set administration, including the addition and deletion of hosts and drives, requires all hosts in the set to be accessible from the network.
**Name**

metassist – automated volume creation utility to support Solaris Volume Manager

**Synopsis**

metassist -V

metassist -?

metassist create [-v n] [-c] -F config_file

metassist create [-v n] [-c] [-d] -F request_file

metassist create [-v n] [-c | -d] -F request_file

[ -r redundancy] [ -a available [, available, ...]]

[ -u unavailable [, unavailable, ...]] -s setname

-S size

metassist create -?

**Description**

The metassist command provides assistance, through automation, with common Solaris Volume Manager tasks.

**SUBCOMMANDS**

The following subcommands are supported:

create

The create subcommand creates one or more Solaris Volume Manager volumes. You can specify this request on the command line or in a file specified on the command line.

If you create a volume using the command line, you can specify the characteristics of the volume in terms of the desired quality of service it will provide - its size, the number of redundant copies of the data it contains, the number of data paths by which it is accessible, and whether faulty components are replaced automatically. The diskset in which the volume will reside and the volume’s size must be specified on the command line in this form of the command.

If you create a volume using a request in a file, you can specify the characteristics of the volume in terms of the quality of service they provide, as on the command line. Alternatively, the file can specify the types and component parts of the volume, (for example, mirrors, stripes, concatenations, and their component slices). The file may also specify volumes partly in terms of their types and partly in terms of their component parts, and may specify the characteristics of more than one volume. All volumes specified in a file must reside in the same diskset, whose name must be specified in the file.

If you specify the -c or -d option on the command line, the command runs without creating an actual volume or volumes. Instead, it outputs either a Bourneshell command script (-c option) or a volume configuration (-d option). The command script, when run, creates the
specified volume or volumes. The volume configuration specifies the volume or volumes in complete detail, naming all their components.

The input file given on the command line can take one of the following forms:
- a volume request, which specifies a request for a volume with explicit attributes and components, or matching a given quality of service
- a volume configuration, produced by a previous execution of the command

Options
The following option is mandatory if you specify a volume request or volume configuration in a file:

-F config_file | request_file
Specify the volume request or volume configuration file to process. If config_file or request_file is -, it is read from standard input.

The -d option cannot be specified when inputfile is a volume configuration file.

The following options are mandatory if you specify a volume request on the command line:

-s set
Specify the disk set to use when creating volumes. All the volumes and hot spare pools are created in this disk set. If necessary, disks are moved into the diskset for use in the volumes and hot spare pools. If the diskset doesn’t exist the command creates it. This option is required. metassist works entirely within a named disk set. Use of the local, or unnamed disk set, is not allowed.

-S size
Specify the size of the volume to be created. The size argument consists of a numeric value (a decimal can be specified) followed by KB, MB, GB, or TB, indicating kilobytes, megabytes, gigabytes, or terabytes, respectively. Case is ignored when interpreting this option. This option is required.

The following options are optional command line parameters:

-a device1, device2, . . .
Explicitly specify the devices that can be used in the creation of this volume. Named devices may be controllers or disks. Only used when specifying a volume on the command line.

-c
Output the command script that would implement the specified or generated volume configuration. The command script is not run, and processing stops at this stage.

-d
Output the volume configuration that satisfies the specified or generated volume request. No command script is generated or executed, and processing stops at this stage.
Specify whether the volume should support automatic component replacement after a fault. If this option is specified, a mirror is created and its submirrors are associated with a hot spare.

-n name
Specify the name of the new volume. See `metainit(1M)` for naming guidelines.

-p n
Specify the number of required paths to the storage volume. The value of n cannot be greater than the number of different physical paths and logical paths to attached storage. Only used when specifying a volume on the command line.

-r n
Specify the redundancy level (0-4) of the data. The default is 0. Only used when specifying a volume on the command line. If redundancy is 0, a stripe is created. If redundancy is 1 or greater, a mirror with this number of submirrors is created. In this case, the volume can suffer a disk failure on \( n-1 \) copies without data loss. With the use of hot spares (see the -f option), a volume can suffer a disk failure on \( n+hsp-1 \) volumes without data loss, assuming non-concurrent failures.

-u device1, device2, . . .
Explicitly specify devices to exclude in the creation of this volume. Named devices can be controllers or disks. You can use this option alone, or to exclude some of the devices listed as available with the -a option. Only used when specifying a volume on the command line.

-v value
Specify the level of verbosity. Values from 0 to 2 are available, with higher numbers specifying more verbose output when the command is run. -v 0 indicates silent output, except for errors or other critical messages. The default level is 1.

-V
Display program version information.

-?
Display help information. This option can follow a subcommand for subcommand-specific help.

Examples

**EXAMPLE 1  Creating a Mirror**

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It places the volume in diskset `mirrorset`.

```
# metassist create -r 2 -a c1,c2 -s mirrorset -S 36G
```

**EXAMPLE 2  Creating a Mirror with Additional Fault Tolerance**

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It provides additional fault tolerance in the form of a hot spare. It places the volume in diskset `mirrorset`.

```
```
EXAMPLE 2  Creating a Mirror with Additional Fault Tolerance  (Continued)

# metassist create -f -r 2 -a c1,c2 -s mirrorset -S 36GB

EXAMPLE 3  Creating a Three-way Mirror and Excluding Devices

The following example creates a three-way, 180Gb mirror from storage devices on controller 1
or controller 2. It excludes the disks c1t2d0 and c2t2d1 from the volume. It places the volume
in diskset mirrorset.

metassist create -r 3 -a c1,c2 -u c1t2d0, c2t2d1 \
              -s mirrorset -S 180GB

EXAMPLE 4  Determining and Implementing a Configuration

The following example determines and implements a configuration satisfying the request
specified in a request file:

# metassist create -F request.xml

EXAMPLE 5  Determining a Configuration and Saving It in a volume-config File

The following example determines a configuration which satisfies the given request. It saves
the configuration in a volume-config file without implementing it:

# metassist create -d -F request.xml > volume-config

EXAMPLE 6  Determining a Configuration and Saving It in a Shell Script

The following example determines a configuration which satisfies the given request. It saves
the configuration in a shell script without implementing it:

# metassist create -c -F request.xml > setupvols.sh

EXAMPLE 7  Implementing the Given volume-config

The following example implements the given volume-config:

# metassist create -F config.xml

EXAMPLE 8  Converting the Given volume-config to a Shell Script

The following example converts the given volume-config to a shell script that you can run
later:

# metassist create -c -F config.xml > setupvols.sh

**Exit Status**  The following exit values are returned:

0  Successful completion.

>0  An error occurred.
Files
/usr/share/lib/xml/dtd/volume-request.dtd
/usr/share/lib/xml/dtd/volume-defaults.dtd
/usr/share/lib/xml/dtd/volume-config.dtd

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>

mdmonitor(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M),
metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M),
metarename(1M), metareplace(1M), metaroot(1M), metastat(1M),
metasync(1M), metattench(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4),
volume-config(4), volume-request(4), attributes(5), md(7D)

Notes
The quality of service arguments are mutually exclusive with the -F inputfile argument.

When specifying a request file or quality of service arguments on the command line, the
/etc/default/metassist.xml file is read for global and per-disk set defaults.

Characteristics of this file are specified in the DTD, in
/usr/share/lib/xml/dtd/volume-defaults.dtd.

Characteristics of the XML request file are specified in the DTD, in
/usr/share/lib/xml/dtd/volume-request.dtd.

Characteristics of the XML configuration file are specified in the DTD, in
/usr/share/lib/xml/dtd/volume-config.dtd.

This command must be run as root.

This command requires a functional Solaris Volume Manager configuration before it runs.
metastat(1M)

Name
metastat – display status for metadevice or hot spare pool

Synopsis
/usr/sbin/metastat -h
[-t] [metadevice...] [hot_spread_pool...]
component...

Description
The metastat command displays the current status for each metadevice (including stripes, concatenations, concatenations of stripes, mirrors, RAID5, soft partitions, and trans devices) or hot spare pool, or of specified metadevices, components, or hot spare pools.

It is helpful to run the metastat command after using the metattach command to view the status of the metadevice.

metastat displays the state of each Solaris Volume Manager RAID-1 volume on the system. The possible states include:

Okay
The device reports no errors.

Needs maintenance
A problem has been detected. This requires that the system administrator replace the failed physical device. Volumes displaying Needs maintenance have incurred no data loss, although additional failures could risk data loss. Take action as quickly as possible.

Last erred
A problem has been detected. Data loss is a possibility. This might occur if a component of a submirror fails and is not replaced by a hot spare, therefore going into Needs maintenance state. If the corresponding component also fails, it would go into Last erred state and, as there is no remaining valid data source, data loss could be a possibility.

Unavailable
A device cannot be accessed, but has not incurred errors. This might occur if a physical device has been removed with Solaris Dynamic Reconfiguration (DR) features, thus leaving the Solaris Volume Manager volume unavailable. It could also occur if an array or disk is powered off at system initialization, or if a >1TB volume is present when the system is booted in 32-bit mode.

After the storage has been made available, run the metastat command with the -i option to update the status of the metadevices. This clears the unavailable state for accessible devices.
See the Solaris Volume Manager Administration Guide for instructions on replacing disks and handling volumes in Needs maintenance or Last erred states.

**Options**

The following options are supported:

- `-a`
  Display all disk sets. Only metadevices in disk sets that are owned by the current host are displayed.

- `-B`
  Display the current status of all of the 64-bit metadevices and hot spares.

- `-c`
  Display concise output.
  
  There is one line of output for each metadevice. The output shows the basic structure and the error status, if any, for each metadevice.

  The `-c` output format is distinct from the `-p` output format. The `-p` option does not display metadevice status and is not intended as human-readable output.

- `-h`
  Display usage message.

- `-i`
  Check the status of RAID-1 (mirror) volumes, RAID-5 volumes, and hot spares. The inquiry checks each metadevice for accessibility, starting at the top level metadevice. When problems are discovered, the metadevice state databases are updated as if an error had occurred.

- `-p`
  Display the list of active metadevices and hot spare pools in the same format as `md.tab`. See `md.tab(4)`.

  The `-p` output is designed for snapshotting the configuration for later recovery or setup.

- `-q`
  Display the status for metadevices without the device relocation information.

- `-s setname`
  Specify the name of the disk set on which `metastat` works. Using the `-s` option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on metadevices and hot spare pools in the local disk set.

- `-t`
  Display the current status and timestamp for the specified metadevices and hot spare pools. The timestamp provides the date and time of the last state change.
The following operands are supported:

- **component**: Display the status of the component hosting a soft partition, including extents, starting blocks, and block count.
- **hot_spare_pool**: Display the status of the specified hot spare pool(s).
- **metadevice**: Display the status of the specified metadevice(s). If a trans metadevice is specified, the status of the master and log devices is also displayed. Trans metadevices have been replaced by UFS logging. See NOTES.

### Examples

**EXAMPLE 1**  Output Showing Mirror with Two Submirrors
The following example shows the partial output of the `metastat` command after creating a mirror, `d0`, consisting of two submirrors, `d70` and `d80`.

```bash
# metastat d0
d0: Mirror
  Submirror 0: d80
    State: Okay
  Submirror 1: d70
    State: Resyncing
    Resync in progress: 15 % done
    Pass: 1
    Read option: roundrobin (default)
    Write option: parallel (default)
    Size: 2006130 blocks

```

**EXAMPLE 2**  Soft Partition on Mirror with Submirror
The following example shows the partial output of the `metastat` command after creating a soft partition, `d3`, on concat `d2`, which is built on a soft partition.

```bash
# metastat
d2: Concat/Stripe
  Size: 204800 blocks
  Stripe 0:
    Device: d0
    Start Block: 0
    Dbase State: No
    Hot Spare: Okay

d0: Soft Partition
  Component: c0t3d0s0
  Status: Okay
  Size: 204800 blocks
  Extent: 0
    Start Block: 129
    Block count: 204800
```
EXAMPLE 2  Soft Partition on Mirror with Submirror  

(Continued)

d3: Soft Partition
Component: d2
Status: Okay
Size: 202752 blocks

<table>
<thead>
<tr>
<th>Extent</th>
<th>Start Block</th>
<th>Block count</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>129</td>
<td>202752</td>
</tr>
</tbody>
</table>

EXAMPLE 3  Trans Metadevice

The following example shows the output of the `metastat` command after creating a trans metadevice.

```
# metastat
d2: Concat/Stripe
  Size: 204800 blocks
  Stripe 0:
    Device    Start Block  Dbase State  Hot Spare
    d0        0           No        Okay

d0: Soft Partition
  Component: c0t3d0s0
  Status: Okay
  Size: 204800 blocks

<table>
<thead>
<tr>
<th>Extent</th>
<th>Start Block</th>
<th>Block count</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>129</td>
<td>204800</td>
</tr>
</tbody>
</table>

d3: Soft Partition
Component: d2
Status: Okay
Size: 202752 blocks

<table>
<thead>
<tr>
<th>Extent</th>
<th>Start Block</th>
<th>Block count</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>129</td>
<td>202752</td>
</tr>
</tbody>
</table>
```

EXAMPLE 4  Multi-owner disk set

The following example shows the output of the `metastat` command with a multi-owner disk set and application-based mirror resynchronization option. Application-based resynchronization is set automatically if needed.

```
# metastat -s oban
oban/d100: Mirror
  Submirror 0: oban/d10
    State: Okay
  Submirror 1: oban/d11
    State: Okay
Pass: 1
```
EXAMPLE 4 Multi-owner disk set (Continued)

Read option: roundrobin (default)
Write option: parallel (default)
Resync option: application based
Owner: None
Size: 1027216 blocks (501 MB)

oban/d10: Submirror of oban/d100
State: Okay
Size: 1027216 blocks (501 MB)
Stripe 0:
  Device  Start Block  Dbase  State  Reloc  Hot Spare
  c1t3d0s0  0  No  Okay

oban/d11: Submirror of oban/d100
State: Okay
Size: 1027216 blocks (501 MB)
Stripe 0:
  Device  Start Block  Dbase  State  Reloc  Hot Spare
  c1t4d0s0  0  No  Okay

Warnings metastat displays states as of the time the command is entered. It is unwise to use the output of the metastat -p command to create a md.tab(4) file for a number of reasons:

- The output of metastat -p might show hot spares being used.
- It might show mirrors with multiple submirrors. See metainit(1M) for instructions for creating multi-way mirrors using metainit and metattach.
- A slice may go into an error state after metastat -p is issued.

Exit Status The following exit values are returned:
0 Successful completion.
>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmdr</td>
</tr>
<tr>
<td>Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also mdmonitord(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M),
Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging--they pass data directly through to the underlying device. See `mount_ufs(1M)` for more information about UFS logging.
metasync -- handle metadevice resync during reboot

Synopsis
/usr/sbin/metasync -h
/usr/sbin/metasync [-s setname] [buffer_size] metadevice
/usr/sbin/metasync [-s setname] -r [buffer_size]
/usr/sbin/metasync -p metadevice

Description
The metasync command starts a resync operation on the specified metadevice. All components that need to be resynced are resynched. If the system crashes during a RAID5 initialization, or during a RAID5 resync, either an initialization or resync restarts when the system reboots.

Applications are free to access a metadevice at the same time that it is being resynced by metasync. Also, metasync performs the copy operations from inside the kernel, which makes the utility more efficient.

Use the -r option in boot scripts to resync all possible submirrors.

Options
The following options are supported:

- `h` Displays usage message.
- `p metadevice` Regenerates parity information for RAID5 metadevices.
- `s setname` Specifies the name of the diskset on which metasync will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.

- `r` Specifies that the metasync command handle special resync requirements during a system reboot. metasync -r should only be invoked from the svc:/system/mdmonitor service. The metasync command only resynchs those metadevices that need to be resynced. metasync schedules all the mirror resynchs according to their pass numbers.

To override the default buffer_size value used by the svc:/system/mdmonitor service, you can edit /etc/system to specify:

```
set md_mirror:md_resync_bufsz = 2048
```
so that resynchs occur as quickly as possible.

Operands

buffer_size
Specifies the size (number of 512-byte disk blocks) of the internal copy buffer for the mirror resync. The size defaults to 128 512-byte disk blocks (64 Kbytes). It can be no more than 2048 blocks. For best performance (quickest completion of the resync), 2048 blocks is the recommended...
Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Solaris Volume Manager Administration Guide

Notes  The metasync service is managed by the service management facility, smf(5), under the
service identifier:

svc:/system/mdmonitor

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be
performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.
metattach(1M)

**Name**
metattach, metadetach – attach or detach a metadevice

**Synopsis**
/usr/sbin/metattach [-h]
/usr/sbin/metattach [-s setname] mirror [metadevice]
/usr/sbin/metattach [-s setname] [-i interlace] concat/stripe component...
/usr/sbin/metattach [-s setname] RAID component...
/usr/sbin/metattach [-s setname] [-A alignment] softpart size | all
/usr/sbin/metadetach [-s setname] [-f] mirror submirror
/usr/sbin/metadetach [-s setname] [-f] trans

**Description**
metattach adds submirrors to a mirror, grows metadevices, or grows soft partitions. Growing metadevices can be done without interrupting service. To grow the size of a mirror or trans, the slices must be added to the submirrors or to the master devices.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32–bit Solaris kernel, the large volumes are visible through metastat output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

Solaris Volume Manager supports one-to-four-way mirrors. You can only attach a metadevice to a mirror if there are three or fewer submirrors beneath the mirror. Once a new metadevice is attached to a mirror, metattach automatically starts a resync operation to the new submirror.

metadetach detaches submirrors from mirrors and logging devices from trans metadevices.

When a submirror is detached from a mirror, it is no longer part of the mirror, thus reads and writes to and from that metadevice by way of the mirror are no longer performed through the mirror. Detaching the only existing submirror is not allowed. Detaching a submirror that has slices reported as needing maintenance (by metastat) is not allowed unless the -f (force) flag is used.

metadetach also detaches the logging device from a trans. This step is necessary before you can clear the trans volume. Trans metadevices have been replaced by UFS logging. Existing
trans devices are not logging. They pass data directly through to the underlying device. See
\texttt{mount_ufs(1M)} for more information about UFS logging.

Detaching the logging device from a busy trans device is not allowed unless the \texttt{-f (force)} flag
is used. Even so, the logging device is not actually detached until the trans is idle. The trans is
in the \texttt{Detaching} state (\texttt{metastat}) until the logging device is detached.

\textbf{Options}  
Root privileges are required for all of the following options except \texttt{-h}.

The following options are supported:

\texttt{-A alignment}  
Set the value of the soft partition extent alignment. Use this option when it is important
specify a starting offset for the soft partition. It preserves the data alignment between
the metadevice address space and the address space of the underlying physical device.

For example, a hardware device that does checksumming should not have its I/O requests
divided by Solaris Volume Manager. In this case, use a value from the hardware
configuration as the value for the alignment. When using this option in conjunction with a
software I/O load, the alignment value corresponds to the I/O load of the application. This
prevents I/O from being divided unnecessarily and affecting performance.

\texttt{-f}  
Force the detaching of metadevices that have components that need maintenance or are
busy. You can use this option only when a mirror is in a maintenance state that can be fixed
with \texttt{metareplace(1M)}. If the mirror is in a maintenance state that can only be fixed with
\texttt{metasync(1M)} (as shown by the output of \texttt{metastat(1M)}), \texttt{metadetach -f} has no effect,
because the mirrors must be resynchronized before one of them can be detached.

\texttt{-h}  
Display a usage message.

\texttt{-l interlace}  
Specify the interlace value for stripes, where \texttt{size} is a specified value followed by either \texttt{k}
for kilobytes, \texttt{m} for megabytes, or \texttt{b} for blocks. The units can be either uppercase or
lowercase. If \texttt{size} is not specified, the size defaults to the interlace size of the last stripe of the
metadevice. When an interlace size change is made on a stripe, it is carried forward on all
stripes that follow.

\texttt{-s setname}  
Specify the name of the diskset on which the \texttt{metattach} command or the \texttt{metadetach}
command works.. Using the \texttt{-s} option causes the command to perform its administrative
function within the specified diskset. Without this option, the command performs its
function on local metadevices.

\textbf{Operands}  
The following operands are supported:
component
The logical name for the physical slice (partition) on a disk drive, such as
/dev/dsk/c0t0d0s2, being added to the concatenation, stripe, concatenation of stripes, or
RAID5 metadevice.

concat/stripe
The metadevice name of the concatenation, stripe, or concatenation of stripes.

log
The metadevice name of the logging device to be attached to the trans metadevice.

metadevice
The metadevice name to be attached to the mirror as a submirror. This metadevice must
have been previously created by the metainit command.

mirror
The name of the mirror.

RAID
The metadevice name of the RAID5 metadevice.

size | all
The amount of space to add to the soft partition in K or k for kilobytes, M or m for megabytes,
G or g for gigabytes, T or t for terabytes, and B or b for blocks (sectors). All values represent
powers of 2, and upper and lower case options are equivalent. Only integer values are
permitted. The literal all specifies that the soft partition should grow to occupy all
available space on the underlying volume.

softpart
The metadevice name of the existing soft partition.

submirror
The metadevice name of the submirror to be detached from the mirror.

trans
The metadevice name of the trans metadevice (not the master or logging device).

Examples
EXAMPLE 1 Concatenating a New Slice to a Metadevice
This example concatenates a single new slice to an existing metadevice, d8. Afterwards, you
would use the growfs(1M) command to expand the file system.

# metattach d8 /dev/dsk/c0t1d0s2

EXAMPLE 2 Detaching Logging Device from Trans Metadevice
This example detaches the logging device from a trans metadevice d9. Notice that you do not
have to specify the logging device itself, as there can only be one.

# metadetach d9
EXAMPLE 3  Expanding a RAID5 Metadevice
This example expands a RAID5 metadevice, d45, by attaching another slice.

```
# metattach d45 /dev/dsk/c3t0d0s2
```

When you add additional slices to a RAID5 metadevice, the additional space is devoted to data. No new parity blocks are allocated. The data on the added slices is, however, included in the overall parity calculations, so it is protected against single-device failure.

EXAMPLE 4  Expanding a Soft Partition
The following example expands a soft partition, d42, attaching all space available on the underlying device.

```
# metattach d42 all
```

When you add additional space to a soft partition, the additional space is taken from any available space on the slice and might not be contiguous with the existing soft partition.

EXAMPLE 5  Adding Space to Two-Way Mirror
This example adds space to a two-way mirror by adding a slice to each submirror. Afterwards, you would use the `growfs(1M)` command to expand the file system.

```
# metattach d9 /dev/dsk/c0t2d0s5
# metattach d10 /dev/dsk/c0t3d0s5
```

This example tells the mirror to grow to the size of the underlying devices

```
# metattach d11
```

This example increases the size of the UFS on the device so the space can be used.

```
# growfs -M /export /dev/md/dsk/d11
```

EXAMPLE 6  Detaching a Submirror from a Mirror
This example detaches a submirror, d2, from a mirror, d4.

```
# metadetach d4 d2
```

EXAMPLE 7  Adding Four Slices to Metadevice
This example adds four slices to an existing metadevice, d9. Afterwards, you would use the `growfs(1M)` command to expand the file system.

```
# metattach d9 /dev/dsk/c0t1d0s2 /dev/dsk/c0t2d0s2 \ /dev/dsk/c0t3d0s2 /dev/dsk/c0t4d0s2
```

EXAMPLE 8  Setting the Value of the Soft PartitionExtent Alignment
This example shows how to set the alignment of the soft partition to 1mb when the soft partition is expanded.
EXAMPLE 8  Setting the Value of the Soft Partition Extent Alignment  

(Continued)

# metattach -s red -A 2m d13 lm

Exit Status  The following exit values are returned:

0       Successful completion.

>0      An error occurred.

Solaris Volume Manager Administration Guide

Warnings  This section provides information regarding warnings for devices greater than 1 TB and for multi-way mirrors.

Devices and Volumes Greater Than 1 TB  Do not create large (>1 TB) volumes if you expect to run the Solaris Operating System with a 32-bit kernel or if you expect to use a version of the Solaris Operating System prior to Solaris 9 4/03.

Multi-Way Mirrors  When a submirror is detached from its mirror, the data on the metadevice might not be the same as the data that existed on the mirror prior to running metadetach. In particular, if the -f option was needed, the metadevice and mirror probably do not contain the same data.

Notes  Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging. They pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.
The mib2c tool is designed to take a portion of the MIB tree (as defined by a MIB file) and generate the template C code necessary to implement the corresponding MIB module.

To implement a new MIB module, three files are necessary:

- MIB definition file
- C header file
- C implementation file

The mib2c tool uses the MIB definition file to produce the two C code files. Thus, mib2c generates a template that you can edit to add logic necessary to obtain information from the operating system or application to complete the module.

The operand mibnode is the top level MIB node for which you want to generate code. You must give mib2c a MIB node (for example, ifTable), not a MIB file, on the command line. This distinction is a common source of user error.

The mib2c tool accepts both SMIv1 and SMIv2 MIBs.

mib2c needs to be able to find and load a MIB file in order to generate C code for the MIB. To enable mib2c to find the MIB file, set the MIBS environment variable to include the MIB file you are using. An example of setting this environment variable is:

MIBS=+NET-SNMP-TUTORIAL-MIB

or

MIBS=ALL

The first example ensures that mib2c finds the NET-SNMP-TUTORIAL-MIB MIB, in addition to the default MIB modules. The default list of MIB modules is set when the suite is first configured and built. The list corresponds to the list of modules that the agent supports. The second example ensures that mib2c finds all MIBs in the search location for MIB files. The default search location for MIB files is DATADIR/snmp/mibs. This search location can be modified by the MIBDIRS environment variable.

Both the MIB files to be loaded and the MIB file search location can also be configured in the snmp.conf file. Please see snmp.conf(4) for more information.

The generated .c and .h files are created in the current working directory.

Options

The following options are supported:

- h Display a help message.
-c configfile  Use `configfile` when generating code. These files are searched for first in the current directory and then in the `DATADIR` directory, which is where the default `mib2c` configuration files are located. Running `mib2c` without the `-c configfile` option displays a description of the valid values for `configfile`, that is, the available configuration files, including new ones that you might have created.

For example:

```bash
% mib2c ifTable
```

...displays the contents of the `mib2.conf` file, which displays hints on choosing the best `configfile` option for the `mibnode`.

The following values are supported for `configfile`:

- `mib2c.scalar.conf`
- `mib2c.int_watch.conf`
- `mib2c.iterate.conf`
- `mib2c.create-dataset.conf`
- `mib2c.array-user.conf`
- `mib2c.column_defines.conf`
- `mib2c.column Enums.conf`

See EXAMPLES for commands you can use to generate code for scalar objects, tables, header files, and for SunOS 4.x code.

- `-f outname`  Places the output code into `outname.c` and `outname.h`. In most cases, `mib2c` places the output code into files with names that correspond to the group names for which it is generating code.

- `-i`  Do not run indent in the resulting code. Omitting this option results in indent error messages. These can safely be ignored. For example:

```bash
% /usr/sfw/bin/mib2c -c mib2c.scalar.conf ifTable
writing to ifTable.h
writing to ifTable.c
running indent on ifTable.h
indent: Command line: unknown parameter ".orig"
running indent on ifTable.c
indent: Command line: unknown parameter ".orig"
% ls
ifTable.c   ifTable.h
% rm i*
% /usr/sfw/bin/mib2c -c mib2c.scalar.conf -i ifTable
writing to ifTable.h
writing to ifTable.c
```

In the first invocation of `mib2c`, above, the indent errors are of no consequence.
- q       Run in "quiet" mode, which minimizes the status messages mib2c generates.
- S var=val  Preset a variable var in the mib2c.*.conf file to the value val. None of the existing mib2c configuration files (mib2c.*.conf) currently makes use of this feature. Consider this option available only for future use.

Examples

**EXAMPLE 1**  Generating Code for Scalar Objects

If you are writing code for some scalars, run:

```
% mib2c -c mib2c.scalar.conf  mibnode
```

If you want to magically "tie" integer variables to integer scalars, use:

```
% mib2c -c mib2c.int_watch.conf  mibnode
```

**EXAMPLE 2**  Generating Code for Tables

Consider the case where:

- You need to "iterate" over your table data to find the correct data for the SNMP row being accessed.
- Your table data is not kept within the agent (for example, it is in the kernel and not in the memory of the agent itself).

Under such conditions, use a command such as:

```
% mib2c -c mib2c.iterate.conf  mibnode
```

You can find a similar example in agent/mibgroup/mibII/vacm_context.c.

If your table data is kept in the agent (that is, it is not located in an external source) and is purely data-driven (that is, you do not need to perform any work when a set occurs), you can use a command such as the following:

```
% mib2c -c mib2c.create-dataset.conf  mibnode
```

See agent/mibgroup/examples/data_set.c for a similar example.

If your table data is kept in the agent (that is, it is not located in an external source) and you can keep your data sorted by the table index, but you do need to perform work when a set occurs, use a command such as the following:

```
% mib2c -c mib2c.array-user.conf  mibnode
```

**EXAMPLE 3**  Generating Header File Definitions

To generate just a header with a define for each column number in your table, enter a command such as:
EXAMPLE 3  Generating Header File Definitions  (Continued)

% mib2c -c mib2c.column_defines.conf mibnode

To generate only a header with a define for each enum for any column containing enums, enter:
% mib2c -c mib2c.column_enums.conf mibnode

EXAMPLE 4  Generating Code for the SunOS 4.X Line of Code

The following command generates code for SunOS 4.x:
% mib2c -c mib2c.old-api.conf mibnode

EXAMPLE 5  Generating Code for ucdDemoPublic

The command below generates C template code for the header and implementation files to implement UCD-DEMO-MIB::ucdDemoPublic.
% mib2c -c mib2c.scalar.conf ucdDemoPublic

writing to ucdDemoPublic.h
writing to ucdDemoPublic.c
running indent on ucdDemoPublic.h
running indent on ucdDemoPublic.c

The resulting ucdDemoPublic.c and ucdDemoPublic.h files are generated in the current working directory.

EXAMPLE 6  Generating Code for tcpConnTable

The command below generates C template code for the header and implementation files for the module to implement TCP-MIB::tcpConnTable.
% mib2c -c mib2c.iterate.conf tcpConnTable

writing to tcpConnTable.h
writing to tcpConnTable.c
running indent on tcpConnTable.h
running indent on tcpConnTable.c

The resulting tcpConnTable.c and tcpConnTable.h files are generated in the current working directory.

Exit Status  0  Successful completion.
1  A usage syntax error. A usage message is displayed.

The `mib2mof` utility reads input Management Information Base (MIB) files and produces one or more Managed Object Format (MOF) files. MOF files contain a Common Information Model (CIM) class declaration that represents the MIB for the Solaris Simple Network Management Protocol (SNMP) provider. The SNMP provider allows Web-Based Enterprise Management (WBEM) applications to access SNMP device information.

SNMP scalar variables map to properties in the CIM class. Qualifiers on each property convey the following MIB information for each scalar variable:

- syntax
- read/write access
- OID (Object IDentifier)
- description (optional)
- index (if the variable is within a group [sequence] that defines a row)

The syntax of an SNMP scalar variable is represented in a CIM class by the property's CIM datatype. All properties are marked with write access (true or false).

The following table shows how a Solaris SNMP datatype in a MIB maps to a Web-Based Enterprise Management (WBEM) CIM datatype and then to an SNMP datatype used by the WBEM SNMP API:

<table>
<thead>
<tr>
<th>SNMP SMI Datatype</th>
<th>SNMP CIM Ver. Datatype</th>
<th>SNMP API Object type</th>

The `mib2mof` utility includes its required `Solaris_SNMPmib_core.txt` file (containing core MIB definitions), installed in `/usr/sadm/mof`. The `mib2mof` utility looks first for `mib` core file in local directory. If this file is not found in the local directory, `mib2mof` looks in `/usr/sadm/mof`.

System Administration Commands - Part 2
A MOF file is generated for each SNMP group and table row sequence (that is, the columns in one row) found in the supplied MIBs. (This does not include the core MIB definitions contained in the Solaris_SNMPmib_core.txt file.)

There is no MOF file or property for an SNMP table - all table access is through the rows and columns of the table, and the SNMP variable for the table is marked as inaccessible in the MIB.

The MOF file created contains a CIM class that represents an SNMP group or row and a CIM class to represent a CIM association. The output file name (and CIM class) is of the format <SNMP_><MIB name><Group name>.mof.

**Options**  

The following options are supported:

- `-a` Generate MOF files for all of the input MIB files. If `-a` is not given, a MOF file is generated only for the last file of the input list.
- `-c` Do not use the default Solaris_SNMPmib_core.txt definitions file shipped with the Solaris SNMP Provider for WBEM. If this option is specified, you must specify another MIB_CORE definitions file as one of the input files.
- `-d directory` Generate output MOF files in the specified directory.
- `-h` Show how to invoke mib2mof and list its arguments.
- `-n` Parse the input MIB files without generating any output.
- `-q` Include the DESCRIPTION clause of SNMP OBJECT-TYPE as a qualifier in the generated MOF file.

**Operands**  

The following operands are supported:

`files` List of SNMP MIB files to be converted.

**Exit Status**  

The mib2mof utility terminates with exit status 0.

**Attributes**  

See attributes(5) for descriptions of the following attributes:

The mibiisa utility is an RFC 1157-compliant SNMP agent. It supports MIB-II as defined in RFC 1213, with Sun extensions under Sun’s enterprise number. The MIB (Management Information Base) is both readable and writable. The mibiisa utility supports all SNMP protocol operations including GET-REQUEST, GETNEXT-REQUEST, SET-REQUEST, GET-REPLY, and TRAP.

The SMA (Systems Management Agent) is the default SNMP agent in Solaris. MIB-II subagent mibiisa does not run by default. To enable mibiisa, rename the configuration file from /etc/snmp/conf/mibiisa.rsra to /etc/snmp/conf/mibiisa.rsra. SMA has the capability to handle any MIB-II requests. See netsnmp(5).

The mibiisa utility supports the coldStart, linkUp, linkDown, and authentication traps. The authentication trap may be disabled by a command-line switch, which itself may be overridden by a management station writing to a MIB variable in the standard SNMP MIB group.

The mibiisa utility supports four distinct views of the MIB. The view used for any request is determined by the community string contained in that request.

To enhance security, mibiisa supports an option to block all writes to the MIB. You can also limit the set of management stations from which the agent will accept requests in the configuration file used when starting the mibiisa. See the Security section for more information.

Unless overridden, mibiisa uses UDP port 161, the standard SNMP port. The mibiisa utility issues traps through the same port on which it receives SNMP requests.

The mibiisa utility must run with super-user privileges and is typically started at system startup via /etc/rc3.d. mibiisa may not be started using inetd(1M). When started, mibiisa detaches itself from the keyboard, disables all signals except SIGKILL, SIGILL, SIGUSR1, and SIGUSR2, and places itself in the background.

The following options are supported by mibiisa:

- **-a** Disable the generation of authentication traps. However, an SNMP manager may write a value into snmpEnableAuthenTraps to enable or disable authentication traps.

- **-c config-dir** Specify a directory where it expects snmpd.conf file, on startup. The default directory is /etc/snmp/conf.

- **-d debug-level** Debug. A value of 0 disables all debug and is the default. Levels 1 through 3 represent increasing levels of debug output. When mibiisa receives the
signal SIGUSR1, it resets the debug-level to 0. When mibiisa receives the signal SIGUSR2, it increments the debug-level by one.

Debug output is sent to the standard output in effect at the time mibiisa is started. No matter what debug level is in effect, certain significant events are logged in the system log.

-p port Define an alternative UDP port on which mibiisa listens for incoming requests. The default is UDP port 161.

-r Place the MIB into read-only mode.

-t cache-timer By default, information fetched from the kernel is considered to be valid for 45 seconds from the time it is retrieved. This cache lifetime may be altered with this parameter. You cannot set cache-timer to any value less than 1.

**Configuration File** The snmpd.conf file is used for configuration information. Each entry in the file consists of a keyword followed by a parameter string. The keyword must begin in the first position. Parameters are separated from the keyword and from one another by white space. Case in keywords is ignored. Each entry must be contained on a single line. All text following (and including) a pound sign (#) is ignored. Keywords currently supported are:

- `sysdescr` The value to be used to answer queries for sysDescr.
- `syscontact` The value to be used to answer queries for sysContact.
- `syslocation` The value to be used to answer queries for sysLocation.
- `trap` The parameter names one or more hosts to receive traps. Only five hosts may be listed.
- `system-group-read-community` The community name to get read access to the system group and Sun’s extended system group.
- `system-group-write-community` The community name to get write access to the system group and Sun’s extended system group.
- `read-community` The community name to get read access to the entire MIB.
- `write-community` The community name to get write access to the entire MIB (implies read access).
- `trap-community` The community name to be used in traps.
- `kernel-file` The name of the file to use for kernel symbols.
- `managers` The names of hosts that may send SNMP queries. Only five hosts may be listed on any one line. This keyword may be repeated for a total of 32 hosts.
The additional devices which are not built in SNMPD. The format is as follows: newdevice type speed name
where newdevice is the keyword, type is an integer which has to match your schema file, speed is the new device's speed, and name is this new device's name.

An example snmpd.conf file is shown below:

```plaintext
sysdescr Sun SNMP Agent, Sun Fire 4800, Company
       Property Number 123456
syscontact Cliff Claven
syslocation Room 1515, building 1
# system-group-read-community public
# system-group-write-community private
# read-community all_public
write-community all_private
# trap localhost
trap-community SNMP-trap
# kernel-file /vmunix
# managers lvs golden
managers swap
```

### Installation

The mibiisa utility and its configuration file, snmpd.conf, may be placed in any directory. However for Solaris 2.4 and subsequent releases, use /usr/lib/snmp for mibiisa itself and /etc/snmp/conf for the configuration file. You can modify the configuration file as appropriate. If you make any changes to snmpd.conf file keyword values, you must kill and restart mibiisa for the changes to take effect.

Your /etc/services file (or NIS equivalent) should contain the following entries:

<table>
<thead>
<tr>
<th>Service</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>snmp</td>
<td>161/udp</td>
<td># Simple Network Mgmt Protocol</td>
</tr>
<tr>
<td>snmp-trap</td>
<td>162/udp</td>
<td># SNMP trap (event) messages</td>
</tr>
</tbody>
</table>

The following is an example for Solaris 2.x and releases compatible with Solaris 2.x, such as Solaris 9:

```
# Start the SNMP agent
```
if [ -f /etc/snmp/conf/snmpd.conf -a -x
    /usr/lib/snmp/mibiisa ];
then
    /opt/SUNWconn/snm/agents/snmpd
    echo 'Starting SNMP-agent.'

Security  SNMP, as presently defined, offers relatively little security. The mibiisa utility accepts requests from other machines, which can have the effect of disabling the network capabilities of your computer. To limit the risk, the configuration file lets you specify a list of up to 32 manager stations from which mibiisa will accept requests. If you do not specify any such manager stations, mibiisa accepts requests from anywhere.

The mibiisa utility also allows you to mark the MIB as “read-only” by using the -r option.

mibiisa supports four different community strings. These strings, however, are visible in the configuration file and within the SNMP packets as they flow on the network.

The configuration file should be owned by, and readable only by super-user. In other words the mode should be:

```
−rw−−−−−−−−−−−−−−−−− 1 root 2090 Oct 17 15:04 /etc/snmp/conf/snmpd.conf
```

Managers can be restricted based on the community strings. This can be configured by creating an optional secondary configuration file /etc/snmp/conf/mibiisa.acl. To enable such a restriction, add the security line in the /etc/snmp/conf/mibiisa.rsfc file.

An example mibiisa.acl file is as follows:

```
acl = {
    {
        communities = public
        access = read-only
        managers = xyz
    },
    {
        communities = private
        access = read-write
        managers = abc,pqrs
    }
}
```

An example mibiisa.rsfc file is as follows:

```
resource = {
    {
        registration_file = "/etc/snmp/conf/mibiisa.reg"
        security = "/etc/snmp/conf/mibiisa.acl"
        policy = "spawn"
        type = "legacy"
    }
}
```
This section discusses some of the differences between the mibiisa MIB and the standard MIB-II (as defined in RFC 1213).

The following variables are read-only in the mibiisa MIB:

- sysName
- atIfIndex
- ipDefaultTTL

These variables are read-write in the standard MIB-II.

The mibiisa MIB Address Translation tables support limited write access: only atPhysAddress may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The mibiisa MIB IP Net to Media table supports limited write access: only ipNetToMediaPhysAddress and ipNetToMediaType may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The following variables are read-write in the mibiisa MIB; however, these variables have fixed values. Any new values “set” to them are accepted, but have no effect:

- ipRoutIfIndex
- ipRouteMetric1
- ipRouteMetric2
- ipRouteMetric3
- ipRouteMetric4
- ipRouteType
- ipRouteAge
- ipRouteMask
- ipRouteMetric5

The following mibiisa MIB variable reflects the actual state of the related table entry. “Sets” are accepted but have no effect:

- tcpConnState

The following mibiisa MIB variables are readable, but return a fixed value:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>icmpInDestUnreaches</td>
<td>Returns 1</td>
</tr>
<tr>
<td>icmpInTimeExcds</td>
<td>Returns 1</td>
</tr>
<tr>
<td>icmpInParmProbs</td>
<td>Returns 1</td>
</tr>
<tr>
<td>icmpInSrcQuenchs</td>
<td>Returns 1</td>
</tr>
</tbody>
</table>

```bash
command = "/usr/lib/snmp/mibiisa -r -p PORT"
```
<table>
<thead>
<tr>
<th>Metric</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>icmpInRedirects</td>
<td>Returns 1</td>
</tr>
<tr>

<tr>
<td>ipRoutingDiscards</td>
<td>Returns 0</td>
</tr>
</tbody>
</table>
The following variables return a fixed value of 0 for drivers not conforming to the GLD framework (see \texttt{gld(7D)}), including the old LAN drivers on SPARC machines:

\begin{center}
\begin{tabular}{ll}
\texttt{ifInOctets} & Returns 0 \\
\texttt{ifInNUcastPkts} & Returns 0 \\
\texttt{ifInDiscards} & Returns 0 \\
\texttt{ifOutOctets} & Returns 0 \\
\texttt{ifOutNUcastPkts} & Returns 0 \\
\texttt{ifOutDiscards} & Returns 0 \\
\end{tabular}
\end{center}

\textbf{Schema Attributes}

The following describes the attributes in the group and table definitions in the \texttt{/var/snmp/mib/sun.mib} file.

- \texttt{sysDescr} – A textual description of the entity. This value should include the full name and version identification of the system’s hardware type, software operating-system, and networking software. This value must only contain printable ASCII characters. (string[255])

- \texttt{sysObjectID} – The vendor’s authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining what type of equipment is being managed. For example, if vendor “Flintstones, Inc.” was assigned the subtree 1.3.6.1.4.1.4242, it could assign the identifier 1.3.6.1.4.1.4242.1.1 to its “Fred Router.” (objectid)

- \texttt{sysUpTime} – Time (in hundredths of a second) since the network management portion of the system was last reinitialized. (timeticks)

- \texttt{sysContact} – The textual identification of the contact person for this managed node, together with information on how to contact this person. (string[255])

- \texttt{sysName} – An administratively-assigned name for this managed node. By convention, this is the node’s fully-qualified domain name. (string[255])

- \texttt{sysLocation} – The physical location of this node (for example, “telephone closet, 3rd floor” (string[255]))

- \texttt{sysServices} – A value indicating the set of services that this entity primarily offers. (int) The value is a sum. This sum initially takes the value zero. Then, for each layer \texttt{L} in the range 1 through 7 for which this node performs transactions, \texttt{2} raised to \texttt{(L - 1)} is added to the sum. For example, a node that performs primarily routing functions would have a value of 4.
In contrast, a node that is a host offering application services would have a value of 72 \(2^{(4-1)} + 2^{(7-1)}\). Note that in the context of the Internet suite of protocols, values should be calculated accordingly:

<table>
<thead>
<tr>
<th>Layer</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>physical (such as repeaters)</td>
</tr>
<tr>
<td>2</td>
<td>datalink/subnetwork (such as bridges)</td>
</tr>
<tr>
<td>3</td>
<td>internet (such as IP gateways)</td>
</tr>
<tr>
<td>4</td>
<td>end-to-end (such as IP hosts)</td>
</tr>
<tr>
<td>7</td>
<td>applications (such as mail relays)</td>
</tr>
</tbody>
</table>

For systems including OSI protocols, Layers 5 and 6 may also be counted.

The `interfaces` group reports the number of interfaces handled by the agent.

- `ifNumber` – The number of network interfaces, regardless of their current state, present on this system. (int)
- `ifTable` – A table of interface entries. The number of entries is given by the value of `ifNumber`.
  - `ifIndex` – A unique value for each interface. Its value ranges between 1 and the value of `ifNumber`. The value for each interface must remain constant at least from one reinitialization of the entity's network management system to the next reinitialization. (int)
  - `ifDescr` – A textual string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface. (string[255])
  - `ifType` – The type of interface, distinguished according to the physical/link protocol(s) immediately below the network layer in the protocol stack. (enum)
  - `ifMtu` – The size of the largest datagram that can be sent/received on the interface, specified in octets. For interfaces used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. (int)
  - `ifSpeed` – An estimate of the interface's current bandwidth in bits-per-second. For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this object should contain the nominal bandwidth. (gauge)
  - `ifHysAddress` – The interface's address at the protocol layer immediately below the network layer in the protocol stack. For interfaces without such an address (for example, a serial line), this object should contain an octet string of zero length. (octet[128])
ifAdminStatus – The desired state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

ifOperStatus – The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

ifLastChange – The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, then this object contains a zero value. (timeticks)

ifInOctets – The total number of octets received on the interface, including framing characters. (counter) Returns a fixed value of 0.

ifInUcastPkts – The number of subnetwork-unicast packets delivered to a higher-layer protocol. (counter)

ifInNUcastPkts – The number of non-unicast (that is, subnetwork-broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. (counter) Returns a fixed value of 0.

ifInDiscards – The number of inbound packets chosen to be discarded, even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

ifInErrors – The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. (counter)

ifInUnknownProtos – The number of packets received via the interface that were discarded because of an unknown or unsupported protocol. (counter) Returns a fixed value of 0.

ifOutOctets – The total number of octets transmitted out of the interface, including framing characters. (counter) Returns a fixed value of 0.

ifOutUcastPkts – The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent. (counter)

ifOutNUcastPkts – The total number of packets that higher-level protocols requested be transmitted to a non-unicast (that is, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent. (counter) Returns a fixed value of 0.

ifOutDiscards – The number of outbound packets that were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

ifOutErrors – The number of outbound packets that could not be transmitted because of errors. (counter)
ifOutQLen — The length of the output packet queue (in packets). (gauge)

ifSpecific — A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an Ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

Table Address Translation tables contain the NetworkAddress to physical address equivalences. Some interfaces do not use translation tables for determining address equivalences (for example, DDN-X.25 has an algorithmic method). If all interfaces are of this type, then the Address Translation table is empty, that is, has zero entries.

IfIndex — The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

PhysAddress — The media-dependent physical address. (octet[128]) Setting this object to a null string (one of zero length) has the effect of invaliding the corresponding entry in the table object. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant PhysAddress object.

NetAddress — The NetworkAddress (that is, the IP address) corresponding to the media-dependent physical address. (netaddress)

table

The ip group reports statistics about the Internet Protocol (IP) group.

ipForwarding — The indication of whether this entity is acting as an IP gateway in respect to the forwarding of datagrams received by, but not addressed to, this entity. IP gateways forward datagrams. IP hosts do not—except those source-routed via the host. (enum)

Note that for some managed nodes, this object may take on only a subset of the values possible. Accordingly, it is appropriate for an agent to return a "badValue" response if a management station attempts to change this object to an inappropriate value.

ipDefaultTTL — The default value inserted into the Time-To-Live field of the IP header of datagrams originated at this entity, whenever a TTL value is not supplied by the transport layer protocol. (int)

ipInReceives — The total number of input datagrams received from interfaces, including those received in error. (counter)
**ipInHdrErrors** – The number of input datagrams discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, and so on. (counter)

**ipInAddrErrors** – The number of input datagrams discarded because the IP address in their IP header’s destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. (counter)

**ipForwDatagrams** – The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter will include only those packets that were Source-Routed via this entity, and the Source-Route option processing was successful. (counter)

**ipInUnknownProtos** – The number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. (counter)

**ipInDiscards** – The number of input IP datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. Note that this counter does not include any datagrams discarded while awaiting reassembly. (counter)

**ipInDelivers** – The total number of input datagrams successfully delivered to IP user-protocols (including ICMP). (counter)

**ipOutRequests** – The total number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any datagrams counted in ipForwDatagrams. (counter)

**ipOutDiscards** – The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include datagrams counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion. (counter)

**ipOutNoRoutes** – The number of IP datagrams discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in ipForwDatagrams which meet this “no-route” criterion. Note that this includes any datagrams that a host cannot route because all its default gateways are down. (counter)

**ipReasmTimeout** – The maximum number of seconds that received fragments are held while they are awaiting reassembly at this entity. (int)

**ipReasmReqds** – The number of IP fragments received that needed to be reassembled at this entity. (counter)
ipReasmOKs – The number of IP datagrams successfully reassembled. (counter)
ipReasmFails – The number of failures detected by the IP reassembly algorithm, for whatever reason: timed out, errors, and the like. Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. (counter)
ipFragOKs – The number of IP datagrams that have been successfully fragmented at this entity. (counter)
ipFragFails – The number of IP datagrams that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their “Don’t Fragment” flag was set. (counter)
ipFragCreates – The number of IP datagram fragments that have been generated as a result of fragmentation at this entity. (counter)
ipRoutingDiscards – The number of routing entries that were chosen to be discarded even though they were valid. One possible reason for discarding such an entry could be to free-up buffer space for other routing entries. (counter) Returns a fixed value of 0.

ipAddrTable

ipAddrTable is a table of addressing information relevant to this entity’s IP addresses.
ipAdEntAddr – The IP address to which this entry’s addressing information pertains. (netaddress)
ipAdEntIfIndex – The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)
ipAdEntNetMask – The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1, and all the hosts bits set to 0. (netaddress)
ipAdEntBcastAddr – The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the Internet standard all-ones broadcast address is used, the value will be 1. This value applies to both the subnet and network broadcasts address used by the entity on this (logical) interface. (int) Returns a fixed value of 1.
ipAdEntReasmMaxSize – The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface. (int) Returns a fixed value of 65535.

ipRouteTable

The ipRouteTable is this entity’s IP Routing table.
ipRouteDest – The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple routes to a single destination can appear in the table, but
access to such multiple entries is dependent on the table-access mechanisms defined by the network management protocol in use. (netaddress)

ipRouteIfIndex – The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

ipRouteMetric1 – The primary routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

ipRouteMetric2 – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

ipRouteMetric3 – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

ipRouteMetric4 – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

ipRouteNextHop – The IP address of the next hop of this route. (In the case of a route bound to an interface that is realized via a broadcast media, the value of this field is the agent’s IP address on that interface.) (netaddress)

ipRouteType – The type of route. Note that the values direct (3) and indirect (4) refer to the notion of direct and indirect routing in the IP architecture. (enum)

Setting this object to the value invalid (2) has the effect of invalidating the corresponding entry in the ipRouteTable object. That is, it effectively dissociates the destination identified with said entry from the route identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipRouteType object.

ipRouteProto – The routing mechanism through which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols. (enum)

ipRouteAge – The number of seconds since this route was last updated or otherwise determined to be correct. Note that no semantics of “too old” can be implied except through knowledge of the routing protocol by which the route was learned. (int) Returns a fixed value of 0.
ipRouteMask – Indicate the mask to be logical-ANDed with the destination address before being compared to the value in the ipRouteDest field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the ipRouteMask by determining whether the value of the correspondent ipRouteDest field belongs to a class-A, B, or C network, and then using one of:

<table>
<thead>
<tr>
<th>Mask</th>
<th>Network</th>
</tr>
</thead>
<tbody>
<tr>
<td>255.0.0.0</td>
<td>class-A</td>
</tr>
<tr>
<td>255.255.0.0</td>
<td>class-B</td>
</tr>
<tr>
<td>255.255.255.0</td>
<td>class-C</td>
</tr>
</tbody>
</table>

If the value of the ipRouteDest is 0.0.0.0 (a default route), then the mask value is also 0.0.0.0. It should be noted that all IP routing subsystems implicitly use this mechanism.

ipRouteMetric5 – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route’s ipRouteProto value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.

ipRouteInfo – A reference to MIB definitions specific to the particular routing protocol responsible for this route, as determined by the value specified in the route’s ipRouteProto value. If this information is not present, its value should be set to the OBJECT IDENTIFIER {0 0}, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

The ipNetToMediaTable is the IP Address Translation table used for mapping from IP addresses to physical addresses.

ipNetToMediaIfIndex – The interface on which this entry’s equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

ipNetToMediaPhysAddress – The media-dependent physical address. (octet[128])

ipNetToMediaNetAddress – The InetAddress corresponding to the media-dependent physical address. (netaddress)

ipNetToMediaType – The type of mapping. (enum) Returns a fixed value of (3)dynamic. Setting this object to the value invalid(2) has the effect of invalidating the corresponding entry in the ipNetToMediaTable. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipNetToMediaType object.
The `icmp` group reports statistics about the ICMP group.

`icmpInMsgs` – The total number of ICMP messages that the entity received. Note that this counter includes all those counted by `icmpInErrors`. (counter)

`icmpInErrors` – The number of ICMP messages that the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, and the like.). (counter)

`icmpInDestUnreachs` – The number of ICMP Destination Unreachable messages received. (counter)

`icmpInTimeExcds` – The number of ICMP Time Exceeded messages received. (counter)

`icmpInParmProbs` – The number of ICMP Parameter Problem messages received. (counter)

`icmpInSrcQuenchs` – The number of ICMP Source Quench messages received. (counter)

`icmpInRedirects` – The number of ICMP Redirect messages received. (counter)

`icmpInEchos` – The number of ICMP Echo (request) messages received. (counter)

`icmpInEchoReps` – The number of ICMP Echo Reply messages received. (counter)

`icmpInTimestamps` – The number of ICMP Timestamp (request) messages received. (counter)

`icmpInTimestampReps` – The number of ICMP Timestamp Reply messages received. (counter)

`icmpInAddrMasks` – The number of ICMP Address Mask Request messages received. (counter)

`icmpInAddrMaskReps` – The number of ICMP Address Mask Reply messages received. (counter)

`icmpOutMsgs` – The total number of ICMP messages that this entity attempted to send. Note that this counter includes all those counted by `icmpOutErrors`. (counter)

`icmpOutErrors` – The number of ICMP messages that this entity did not send due to problems discovered within ICMP, such as a lack of buffers. This value should not include errors discovered outside the ICMP layer, such as the inability of IP to route the resultant datagram. In some implementations there may be no types of errors that contribute to this counter's value. (counter)

`icmpOutDestUnreachs` – The number of ICMP Destination Unreachable messages sent. (counter)

`icmpOutTimeExcds` – The number of ICMP Time Exceeded messages sent. (counter)

`icmpOutParmProbs` – The number of ICMP Parameter Problem messages sent. (counter)
icmpOutSrcQuenchs – The number of ICMP Source Quench messages sent. (counter)

icmpOutRedirects – The number of ICMP Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. (counter)

icmpOutEchos – The number of ICMP Echo (request) messages sent. (counter)

icmpOutEchoReps – The number of ICMP Echo Reply messages sent. (counter)

icmpOutTimestamps – The number of ICMP Timestamp (request) messages sent. (counter)

icmpOutTimestampReps – The number of ICMP Timestamp Reply messages sent. (counter)

icmpOutAddrMasks – The number of ICMP Address Mask Request messages sent. (counter)

icmpOutAddrMaskReps – The number of ICMP Address Mask Reply messages sent. (counter)

tcp The tcp group reports statistics about the TCP group.

tcpRtoAlgorithm – The algorithm used to determine the timeout value used for retransmitting unacknowledged octets. (enum)

tcpRtoMin – The minimum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the LBOUND quantity described in RFC 793. (int)

tcpRtoMax – The maximum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the UBOUND quantity described in RFC 793. (int)

tcpMaxConn – The limit on the total number of TCP connections that the entity can support. In entities where the maximum number of connections is dynamic, this object should contain the value –1. (int)

tcpActiveOpens – The number of times that TCP connections have made a direct transition to the SYN-SENT state from the CLOSED state. (counter)

tcpPassiveOpens – The number of times that TCP connections have made a direct transition to the SYN-RCVD state from the LISTEN state. (counter)

tcpAttemptFails – The number of times that TCP connections have made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections have made a direct transition to the LISTEN state from the SYN-RCVD state. (counter)
tcpEstabResets – The number of times TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state. (counter)

tcpCurrEstab – The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. (gauge)

tcpInSegs – The total number of segments received, including those received in error. This count includes segments received on currently established connections. (counter)

tcpOutSegs – The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. (counter)

tcpRetransSegs – The total number of segments retransmitted - that is, the number of TCP segments transmitted containing one or more previously transmitted octets. (counter)

tcpInErrs – The total number of segments received in error (for example, bad TCP checksums). (counter)

tcpOutRsts – The number of TCP segments sent containing the RST flag. (counter)

tcpConnTable

The tcpConnTable is a table containing TCP connection-specific information.

tcpConnState – The state of this TCP connection. (enum)

The only value that may be set by a management station is deleteTCB(12). Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to set this object to any other value.

If a management station sets this object to the value deleteTCB(12), then this has the effect of deleting the TCB (as defined in RFC 793) of the corresponding connection on the managed node. This results in immediate termination of the connection.

As an implementation-specific option, an RST segment may be sent from the managed node to the other TCP endpoint. (Note, however, that RST segments are not sent reliably.)

tcpConnLocalAddress – The local IP address for this TCP connection. For a connection in the listen state that is willing to accept connections for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

tcpConnLocalPort – The local port number for this TCP connection. (int)

tcpConnRemAddress – The remote IP address for this TCP connection. (netaddress)

tcpConnRemPort – The remote port number for this TCP connection. (int)

udp

The udp group reports statistics about the UDP group.

udpInDatagrams – The total number of UDP datagrams delivered to UDP users. (counter)

Returns a fixed value of 0.
udpNoPorts - The total number of received UDP datagrams for which there was no application at the destination port. (counter) Returns a fixed value of 0.

udpInErrors - The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. (counter)

udpOutDatagrams - The total number of UDP datagrams sent from this entity. (counter) Returns a fixed value of 0.

The udpTable is a table containing UDP listener information.

udpLocalAddress - The local IP address for this UDP listener. For a UDP listener that is willing to accept datagrams for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

udpLocalPort - The local port number for this UDP listener. (int)

The snmp group reports statistics about the SNMP group.

snmpInPkts - The total number of Messages delivered to the SNMP entity from the transport service. (counter)

snmpOutPkts - The total number of SNMP Messages passed from the SNMP protocol entity to the transport service. (counter)

snmpInBadVersions - The total number of SNMP Messages delivered to the SNMP protocol entity that were for an unsupported SNMP version. (counter)

snmpInBadCommunityNames - The total number of SNMP Messages delivered to the SNMP protocol entity that used a SNMP community name not known to said entity. (counter)

snmpInBadCommunityUses - The total number of SNMP Messages delivered to the SNMP protocol entity, which represented an SNMP operation not allowed by the SNMP community named in the Message. (counter)

snmpInASNParseErrs - The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP Messages. (counter)

snmpInTooBigs - The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

snmpInNoSuchNames - The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “noSuchName.” (counter)

snmpInBadValues - The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)
snmpInReadOnlys — The total number valid SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “readOnly.” It should be noted that it is a protocol error to generate an SNMP PDU that contains the value “readOnly” in the error-status field. This object is provided as a means of detecting incorrect implementations of the SNMP. (counter)

snmpInGenErrs — The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

snmpInTotalReqVars — The total number of MIB objects successfully retrieved by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. (counter)

snmpInTotalSetVars — The total number of MIB objects successfully altered by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs. (counter)

snmpInGetRequests — The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInGetNexts — The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInSetRequests — The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInGetResponses — The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInTraps — The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpOutTooBigs — The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

snmpOutNoSuchNames — The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status is “noSuchName.” (counter)

snmpOutBadValues — The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)

snmpOutGenErrs — The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

snmpOutGetRequests — The total number of SNMP Get-Request PDUs which have been generated by the SNMP protocol entity. (counter)

snmpOutGetNexts — The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity. (counter)
snmpOutSetRequests – The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity. (counter)

snmpOutGetResponses – The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity. (counter)

snmpOutTraps – The total number of SNMP Trap PDUs generated by the SNMP protocol entity. (counter)

snmpEnableAuthenTraps – Indicates whether the SNMP agent process is permitted to generate authentication-failure traps. The value of this object overrides any configuration information. As such, it provides a means whereby all authentication-failure traps may be disabled. (enum)

Note that this object must be stored in non-volatile memory, so that it remains constant between reinitializations of the network management system.

The following are Sun-specific group and table definitions.

The sunSystem group reports general system information.

agentDescr – The SNMP agent's description of itself. (string[255])

hostID – The unique Sun hardware identifier. The value returned is four byte binary string. (octet[4])

motd – The first line of /etc/motd. (string[255])

unixTime – The UNIX system time. Measured in seconds since January 1, 1970 GMT. (counter)

The sunProcessTable table reports UNIX process table information.

psProcessID – The process identifier for this process. (int)

psParentProcessID – The process identifier of this process's parent. (int)

psProcessSize – The combined size of the data and stack segments (in kilobytes.) (int)

psProcessCpuTime – The CPU time (including both user and system time) consumed so far. (int)

psProcessState – The run-state of the process. (octet[4])

<table>
<thead>
<tr>
<th>R</th>
<th>Runnable</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>Stopped</td>
</tr>
<tr>
<td>P</td>
<td>In page wait</td>
</tr>
</tbody>
</table>
D Non-interruptable wait
S Sleeping (less than 20 seconds)
I Idle (more than 20 seconds)
Z Zombie

psProcessWaitChannel – Reason process is waiting. (octet[16])
psProcessTTY – Terminal, if any, controlling this process. (octet[16])
psProcessUserName – Name of the user associated with this process. (octet[16])
psProcessUserID – Numeric form of the name of the user associated with this process. (int)
psProcessName – Command name used to invoke this process. (octet[64])
psProcessStatus – Setting this variable will cause a signal of the set value to be sent to the process. (int)

sunHostPerf

rsUserProcessTime – Total number of timeticks used by user processes since the last system boot. (counter)
rsNiceModeTime – Total number of timeticks used by “nice” mode since the last system boot. (counter)
rsSystemProcessTime – Total number of timeticks used by system processes since the last system boot. (counter)
rsIdleModeTime – Total number of timeticks in idle mode since the last system boot. (counter)
rsDiskXfer1 – Total number of disk transfers since the last boot for the first of four configured disks. (counter)
rsDiskXfer2 – Total number of disk transfers since the last boot for the second of four configured disks. (counter)
rsDiskXfer3 – Total number of disk transfers since the last boot for the third of four configured disks. (counter)
rsDiskXfer4 – Total number of disk transfers since the last boot for the fourth of four configured disks. (counter)
rsVPagesIn – Number of pages read in from disk. (counter)
rsVPagesOut – Number of pages written to disk. (counter)
rsVSwapIn – Number of pages swapped in. (counter)
rsVSwapOut – Number of pages swapped out. (counter)
rsVIntr  – Number of device interrupts. (counter)
rsIfInPackets – Number of input packets. (counter)
rsIfOutPackets – Number of output packets. (counter)
rsIfInErrors – Number of input errors. (counter)
rsIfOutErrors – Number of output errors. (counter)
rsIfCollisions – Number of output collisions. (counter)

cannot parse response PDU  An error occurred parsing a response PDU.

request ID - response ID mismatch  The response ID does not match the request ID.

string contains non-displayable characters  A displayable string contains non-displayable characters.

cannot open schema file  An error occurred opening the proxy agent schema file.

cannot parse schema file  The proxy agent couldn't parse the proxy agent schema file.

cannot open host file  An error occurred opening the file associated with the `na.snmp.hostfile` keyword in `/etc/snmp/conf/snmpd.conf`

cannot parse host file  The proxy agent was unable to parse the file associated with the `na.snmp.hostfile` keyword in `/etc/snmp/conf/snmp.conf`.

attribute unavailable for set operations  The set could not be completed because the attribute was not available for set operations.

**Bugs** The `mibiisa` utility returns the wrong interface speed for the SBUS FDDI interface (for example, “bf0”).

The `mibiisa` utility does not return a MAC address for the SBUS FDDI interface (for example, “bf0”).

Process names retrieved from `mibiisa` contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as `mibiisa` is running. `mibiisa` does not save the changes to `/etc/snmp/conf/snmpd.conf`. 
Name: mipagent – Mobile IP agent

Synopsis: /usr/lib/inet/mipagent

Description: The `mipagent` utility implements the Mobile IP home agent and foreign agent functionality described in RFC 2002, IP Mobility Support. The term "mobility agent" is used to refer to the home agent and foreign agent functionality collectively. `mipagent` responds to Mobile IP registration and deregistration requests and router discovery solicitation messages from a mobile node. Besides responding to external messages, the `mipagent` utility also tasks on a periodic basis, such as aging the mobility bindings and visitor entries and sending agent advertisements. The mobility agent can also handle direct delivery style reverse tunneling as specified in RFC 2344, Reverse Tunneling for Mobile IP. Limited private address support for mobile nodes is also available. In addition, separate IPSec policies for registration requests, replies, and tunnel traffic can be configured to protect the datagrams associated with these between two mobility agents.

Run the `mipagent` daemon as root using the start-up script, which has the following syntax:

```
example# /etc/init.d/mipagent [start|stop]
```

`/etc/inet/mipagent.conf` must be present before you start-up the `mipagent` daemon. See `mipagent.conf(4)`. At start up, `mipagent` reads the configuration information from `/etc/inet/mipagent.conf`. The `mipagent` daemon records a continuous log of its activities by means of `syslog()`. See `syslog(3C)`. You can use the `LogVerbosity` parameter in `/etc/inet/mipagent.conf` to control the verbosity level of the log.

The `mipagent` daemon can be terminated either by the script:

```
example# /etc/init.d/mipagent stop
```

or by the `kill` command.

Periodically while running, or if terminated or shutdown, the `mipagent` daemon stores the following internal state information in `/var/inet/mipagent_state`:

- a list of the mobile nodes supported as home agents;
- their current care-of addresses; and
- the remaining registration lifetimes.

If the `mipagent` utility is terminated for maintenance and restarted, `mipagent_state` is used to recreate as much of the mobility agent's internal state as possible. This minimizes service disruption for mobile nodes that may be visiting other networks. If `mipagent_state` exists, it is read immediately after `mipagent.conf` when `mipagent` is restarted. The format of `mipagent_state` is undocumented since it is likely to change and programs other than `mipagent` should not use it for any purpose. A separate utility program `mipagent_stat` is provided for monitoring `mipagent`. 
The following exit values are returned:
0  The daemon started successfully.
-1  The daemon failed to start.

**Files**
- `/etc/inet/mipagent.conf`: Configuration file for Mobile IP mobility agent.
- `/var/inet/mipagent_state`: File where private state information from `mipagent` is stored.
- `/etc/init.d/mipagent [start|stop]`: `mipagent` start-up script.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmipu</td>
</tr>
</tbody>
</table>

**See Also**
- `mipagentstat(1M)`, `mipagentconfig(1M)`, `syslog(3C)`, `mipagent.conf(4)`, `attributes(5)`

**Diagnostics**
The `mipagent` utility exits with an error if the configuration file, `mipagent.conf`, cannot be read successfully. Upon receiving a SIGTERM or SIGINT signal, `mipagent` cleans its internal state, including any changes to the routing and ARP tables, and exits.

**Notes**
The foreign agent adds host-specific local routes to its routing table for visiting mobile nodes after they are successfully registered. If a visiting mobile node departs without sending a de-registration message through the foreign agent, these routing entries persist until the mobile node's previous registration expires. Any packets that arrive at the foreign agent for the departed mobile node during this time, for example because the foreign agent is also a router for the foreign network, will be lost. System administrators can configure foreign agents to accept only short registration lifetimes. This will automatically restrict the maximum duration for which a departed mobile node will be temporarily unreachable.

Home and foreign agents dynamically add and delete IPsec policies configured with a mobility agent peer. Those pertaining to the tunnel are only added when the tunnel is plumbed. At this time, IPsec tunnel policies must be identical in the forward and reverse direction. IPsec policies pertaining to permitting registration requests on the home agent are added to the IPsec policy file at init time as it must be ready to receive these at any time. Otherwise, IPsec policies pertaining to registration request and reply messages with a mobility agent peer are added as soon as they are needed, and are not removed until all mobile nodes are no longer registered with the mobility agent peer, at which point the tunnels are torn down.
mipagentconfig(1M)

Name  mipagentconfig – configure Mobility IP Agent

Synopsis  /sbin/mipagentconfig [-f configfile] command dest
           [parameters]...

Description  The mipagentconfig utility is used to configure the Mobility IP Agent. mipagentconfig
              allows the user to change settings. The mipagentconfig user can also add and delete mobility
              clients, Pools, and SPIs in the mobility agent configuration file.

Options  The following options are supported:

           -f configfile  Use the specified configuration file instead of the system default,
                          /etc/inet/mipagent.conf.

Operands  The command operand, as well as the parameters for each command are described below. See
           mipagent.conf(4) for the default values of the configuration operands that are described here.

           add  This command adds advertisement parameters, security parameters, SPIs, or
                addresses to the configuration file, based on the destination dest.

                add Address ipAddress attr_value
                Add the specified ipAddress with the specified SPI. To add an NAI address, you
                must specify the Pool.

                add adv device
                Enable home and foreign agent functionality on the specified interface.

                add adv device AdvLifetime seconds
                Add AdvLifetime to the specified device.

                add adv device RegLifetime seconds
                Add RegLifetime to the specified device.

                add adv device AdvFrequency seconds
                Add AdvFrequency to the specified device.

                add adv device AdvInitCount count
                Add initial unsolicited advertisement count. count should be a small integer.

                add adv device AdvLimitUnsolicited yes | no
                Enable limited or unlimited unsolicited advertisements for foreign agent.
                Accepted values are:

                yes  Limit unsolicited advertisement to AdvInitCount initial
                     advertisements.

                no   Do not limit unsolicited advertisement. The advertisement should take
                     place periodically at the frequency specified by AdvFrequency.

                add adv device HomeAgent yes | no
                Add the HomeAgent flag to the specified device.
add adv device ForeignAgent yes | no
   Add the ForeignAgent flag to the specified device.

add adv device PrefixLengthExt yes | no
   Add the PrefixLengthExt flag to the specified device.

add adv device NAIExt yes | no
   Add the NAIExt flag to the specified device.

add adv device Challenge yes | no
   Add the Challenge flag to the specified device.

add adv device ReverseTunnel no | neither fa ha yes | both
   Add the level of ReverseTunnel support that is indicated to the specified device. Possible values include:

   no          Do not support ReverseTunnel as either a foreign agent or a home agent on this device. Does not advertise reverse tunneling nor accept a registration requesting reverse tunnel support on this device.

   neither     Do not support ReverseTunnel as either a foreign agent or a home agent on this device. Do not advertise reverse tunneling or accept a registration that requests reverse tunnel support on this device.

   fa          When the foreign agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up to its home agent. If so, perform the necessary encapsulation of datagrams to the mobile node's home agent as described in RFC 3024. This means that a mobile node must see the agent advertising reverse tunnel support, so the reverse tunnel bit is advertised in the agent advertisement on this device.

   ha          When the home agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up from its care-of address. If so, perform the necessary decapsulation as described in RFC 3024. This does not mean the home agent is advertising support of reverse tunneling on this device. Mobile nodes are only interested in the advertisement flags if mobile nodes are going to use foreign agent services. Moreover, reverse tunnels by definition originate at the care-of address. HA support is therefore only of interest to the owner of the care-of address.

   yes        Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is
requesting that a reverse tunnel be set up. If so, apply RFC 3024 as appropriate, either as an encapsulating foreign agent, or as a decapsulating home agent, depending on how this mobility agent is servicing the specific mobile node. As a result, the mobility agent advertises reverse tunnel support on this device.

Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is requesting that a reverse tunnel be set up. If so, apply RFC 3024 as appropriate, either as an encapsulating foreign agent, or a decapsulating home agent, depending on how this mobility agent services the specific mobile node. As a result, the mobility agent advertises reverse tunnel support on this device.

**both**

Add the requirement that the ReverseTunnel flag be set in any registration request received on the indicated device. Possible values include:

- **no**
  - Reverse tunneling is not required by the mipagent on this device.
- **neither**
  - Reverse tunneling is not required by the mipagent on this device.
- **fa**
  - The ReverseTunnel flag is required to be set in registration requests received by the foreign agent on this device.
- **ha**
  - The ReverseTunnel flag is required to be set in registration requests received by the home agent on this device.
- **yes**
  - The ReverseTunnel flag is required to be set in all registration requests received by either home and or foreign agents on this device.
- **both**
  - The ReverseTunnel flag is required to be set in all registration requests received by either home and or foreign agents on this device.

**add Pool number start Addr length**

Add the specified Pool with the specified start addresses and length.

**add SPI number replay Key**

Add the specified SPI with the given replay type and key. The replay type can have a value of none or timestamps.

**add HA-FAAuth yes | no**

Add the HA-FAAuth flag.

**add MN-FAAuth yes | no**

Add the MN-FAAuth flag.
add MaxClockSkew seconds
   Add the MaxClockSkew.

add KeyDistribution type
   Add the KeyDistribution type. The only value for KeyDistribution that is supported at this time is file.

change
   Depending on the destination dest, this command will change advertisement parameters, security parameters, SPIs, or addresses in the configuration file. Any of the above destinations are valid.

delete
   Depending on the destination dest, this command will delete advertisement parameters, security parameters, SPIs, or addresses from the configuration file. Any destination discussed above is valid.

get
   Display all of the parameters associated with dest. Any destination discussed above is valid.

Examples

EXAMPLE 1
   Adding an SPI, a Pool, and a Mobile Node and Requiring Reverse Tunneling on a Device to the configfile

   The following example adds an SPI, a Pool, a mobile node, and requires reverse tunneling for the foreign agent in the configfile. First, the SPI of 250 is added. Then, a Pool of 200 addresses starting at 192.168.168.1 is added. joe@mobile.com is added with an SPI of 250 and using Pool 1. Finally, reverse tunneling is required for the foreign agent on device eri0.

   example# mipagentconfig add SPI 250 ReplayMethod none
   example# mipagentconfig add SPI 250 Key 00ff00ff00ff
   example# mipagentconfig add Pool 1 192.168.168.1 200
   example# mipagentconfig add Address joe@mobile.com 250 1
   example# mipagentconfig add adv eri0 reversetunnel fa
   example# mipagentconfig add adv eri0 reversetunnelrequired fa

EXAMPLE 2
   Adding Dynamic Interface Mobility Support on PPP Interfaces

   The following example adds dynamic interface mobility support on PPP interfaces. Note that in some shells the backslash (\) escape character is required to bypass the expansion of the asterix ("*") and pass the "*" character to mipagent config. The example also indicates that all the new PPP interfaces offer reverse tunnel service.

   example# mipagentconfig add adv sppp\* reversetunnel yes
   example# mipagentconfig add adv sppp\* AdvLimitUnsolicited yes
   example# mipagentconfig add adv sppp\* AdvInitCount 3
   example# mipagentconfig add adv sppp\* AdvFrequency 1

EXAMPLE 3
   Adding IPsec Policies to an Agent-Peer Entry

   The following example adds IPsec policies to an existing mobility agent entry, then displays the configuration for the mobility agent peer. The backslash (\) character denotes a line continuation for the formatting of this example.
EXAMPLE 3  Adding IPsec Policies to an Agent-Peer Entry  (Continued)

.example# mipagentconfig add Address 192.168.10.1 \
  IPsecRequest apply {auth_algs md5 sa shared}
.example# mipagentconfig add Address 192.168.10.1 \
  IPsecReply permit {auth_algs md5}
.example# mipagentconfig add Address 192.168.10.1 \
  IPsecTunnel permit {encr_auth_algs md5 encr_algs 3des}
.example# mipagentconfig get Address 192.168.10.1

<Address 192.168.10.1>
  Type = agent
  SPI = 137
  IPsecRequest = apply {auth_algs md5 sa shared}
  IPsecReply = permit {auth_algs md5}
  IPsecTunnel = \n    permit {encr_auth_algs md5 encr_algs 3des}

EXAMPLE 4  Modifying an SPI

To modify the SPI associated with joe, first, use the command get to verify the existing
settings, then change the SPI from 250 to 257.

.example# mipagentconfig get Address joe@mobile.com
Address: joe@mobile.com
SPI: 250
Pool: 1
.example# mipagentconfig change Address joe@mobile.com 257 1

EXAMPLE 5  Deleting a Pool

Use the following example to delete Pool 3:

.example# mipagentconfig delete Pool 3

EXAMPLE 6  Using the mipagentconfig command

Use the following example to delete Pool 3:

.example# mipagentconfig delete Pool 3

Exit Status  The following exit values are returned:

  0 successful completion
  non-zero  An error occurred

Files  /etc/inet/mipagent.conf  Configuration file for Mobile IP mobility agent

/etc/inet/mipagent.conf-sample  Sample configuration file for mobility agents
Sample configuration file for home agent functionality.

Sample configuration file for foreign agent functionality.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

**Name** mipagentstat – show Mobile IP Mobility Agent status

**Synopsis**
mipagentstat [-fhp]

**Description**
Use the `mipagentstat` utility to display the content of various Mobile-IP related data structures.

**Visitor Table (First Form)**
The visitor table display lists information for all mobile nodes registered with the foreign agent, one mobile node per line. This list consists of the mobile node’s home address or Network Access Identifier (NAI), home agent address, total registration lifetime and the number of seconds remaining before the registration expires.

The following command line shows the output from a foreign agent with two mobile nodes registered:

```bash
example# mipagentstat -f
```

<table>
<thead>
<tr>
<th>Mobile Node</th>
<th>Foreign Agent</th>
<th>Time Granted</th>
<th>Time Remaining</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="mailto:foobar@xyz.com">foobar@xyz.com</a></td>
<td><a href="mailto:fal@tuv.com">fal@tuv.com</a></td>
<td>600</td>
<td>125</td>
<td></td>
</tr>
<tr>
<td>10.1.5.23</td>
<td>123.2.5.12</td>
<td>1000</td>
<td>10</td>
<td>R</td>
</tr>
</tbody>
</table>

An “R” in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node foobar@xyz.com. A reverse tunnel is configured from mobile node 10.1.5.23.

**Binding Table (Second Form)**
The binding table display lists information for all mobile nodes registered with the home agent, one mobile node per line. This list consists of the mobile node’s home address or NAI, foreign agent address, total registration lifetime and the number of seconds remaining before the registration expires.

Use the following command line to show the output from a home agent with two active mobile nodes:

```bash
example# mipagentstat -h
```

<table>
<thead>
<tr>
<th>Mobile Node</th>
<th>Home Agent</th>
<th>Time Granted</th>
<th>Time Remaining</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="mailto:foobar@xyz.com">foobar@xyz.com</a></td>
<td><a href="mailto:ha1@xyz.com">ha1@xyz.com</a></td>
<td>600</td>
<td>125</td>
<td></td>
</tr>
<tr>
<td>10.1.5.23</td>
<td>10.1.5.1</td>
<td>1000</td>
<td>10</td>
<td>R</td>
</tr>
</tbody>
</table>

An “R” in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node foobar@xyz.com. A reverse tunnel is configured for mobile node 10.1.5.23.
The agent table display lists information for all current mobility agent-peers, that is all mobility agents with which mobile-nodes we are servicing are trying to obtain service.

Provided in this display are the IPsec protection mechanisms being used with registration requests, replies, and tunnels.

Use the following command line to show the output from a home agent with two (foreign) mobility agent peers:

```
example# mipagentstat -hp
```

<table>
<thead>
<tr>
<th>Foreign</th>
<th>Security Association(s)</th>
<th>Requests</th>
<th>Replies</th>
<th>FTunnel</th>
<th>RTunnel</th>
</tr>
</thead>
<tbody>
<tr>
<td>fa.eng.example.com</td>
<td>AH,ESP</td>
<td>AH</td>
<td>ESP</td>
<td>AH</td>
<td>ESP</td>
</tr>
<tr>
<td>fa.central.example.com</td>
<td>AH</td>
<td>AH</td>
<td>ESP</td>
<td>ESP</td>
<td></td>
</tr>
</tbody>
</table>

Use the following command line to show the output from a home agent with two (foreign) mobility agent peers:

```
example# mipagentstat -fp
```

<table>
<thead>
<tr>
<th>Home</th>
<th>Security Association(s)</th>
<th>Requests</th>
<th>Replies</th>
<th>FTunnel</th>
<th>RTunnel</th>
</tr>
</thead>
<tbody>
<tr>
<td>ha.eng.example.com</td>
<td>AH,ESP</td>
<td>AH</td>
<td>ESP</td>
<td>AH</td>
<td>ESP</td>
</tr>
<tr>
<td>ha.central.example.com</td>
<td>AH</td>
<td>AH</td>
<td>ESP</td>
<td>ESP</td>
<td></td>
</tr>
</tbody>
</table>

Use of the `-p` option without specifying the agent results in both displays described above, that is one display for each agent.

An AH in any column indicates the IPsec AH mechanism is in place for those datagrams.

An ESP in any column indicates the IPsec ESP mechanism is in place for those datagrams.

**Options**

The following options are supported:

- `-f` Display the list of active mobile nodes in the foreign agent's visitor's list.
- `-h` Display the list of active mobile nodes in the home agent's binding table.
- `-p` Display the list of mobility agent peers, and the IPsec protection mechanisms currently in use for registration and tunnel traffic.

**Exit Status**

The following exit values are returned:

- `0` Successful completion.
- `non-zero` An error occurred.
Attributes  See attributes(5) for descriptions of the following attributes:

mkbootmedia – create bootable Solaris ISO image

/usr/bin/mkbootmedia -v [-l label] media-root iso

The mkbootmedia utility takes media-root (the root of an on-disk Solaris install media) as input and creates a bootable Solaris ISO image in the file iso, using mkisofs(8). The file can then be burned onto a CD/DVD with utilities such as cdrw(1) or cdrecord(1). (Neither mkisofs(8) nor cdrecord(1) are SunOS man pages.)

Caution – The directory tree media-root must contain the file boot/grub/stage2_eltorito, which will be written to the media boot sectors. This file will be modified with some boot information, thus it must be writable. If necessary, first save a copy prior to running this utility.

Options The following options are supported:

- \label
  Sets label as the label/volume name of the ISO image.

- v
  Verbose. Multiple -v options increase verbosity.

Operands The following operands are supported:

media-root
  Top-level directory of an on-disk Solaris install media.

iso
  Name of the output file which will contain the resulting ISO image.

Examples

EXAMPLE 1  Creating an ISO Image and Burning a CD/DVD

The following commands create an ISO image from the content of s10u1 and burn the image to a CD/DVD.

# /usr/bin/mkbootmedia s10u1 s10u1.iso
# /usr/bin/cdrw -i s10u1.iso

mkisofs(8), (/usr/share/man/man8/mkisofs.8), in the SUNWfsman package (not a SunOS man page)
The `mkdevalloc` command writes to standard output a set of `device_allocate(4)` entries describing the system's framebuffer, audio and removable media devices.

The `mkdevalloc` command is used by the `init.d(4)` scripts to create or update the `/etc/security/device_allocate` file.

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevalloc` command checks for the following files under `/dev`:

- audio: `/dev/audio`, `/dev/audioctl`, `/dev/sound/...
- tape: `/dev/rst*`, `/dev/nrst*`, `/dev/rmt/...
- floppy: `/dev/diskette`, `/dev/fd*`, `/dev/rdiskette`, `/dev/rfd*
- removable disk: `/dev/sr*`, `/dev/nsr*`, `/dev/dsk/c0t?d0s?`, `/dev/rdsk/c0t?d0s?`
- framebuffer: `/dev/fb`

All entries set the `device-minimum` and `device-maximum` fields to the hex representations of `ADMIN_LOW` and `ADMIN_HIGH`, respectively. The `device-authorization` field is set to `solaris.device.allocate`, except for the framebuffer entry, where it is set to `*`. The `device-name`, `device-type` and `device-clean` fields are set to the following values:

```
device-name  device-type  device-clean
audio         audio        audio audio_clean_wrapper
tape          tape          tape tape_clean
floppy        floppy       floppy floppy_clean
removable disk disk         disk disk_clean
frame buffer  framebuffer  framebuffer fb /bin/true
```

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Obsolete</td>
</tr>
</tbody>
</table>

**See Also**

`allocate(1)`, `bsmconv(1M)`, `attributes(5)`

**Notes**

`mkdevalloc` might not be supported in a future release of the Solaris operating system.
The `mkdevmaps` command writes to standard output a set of `device_maps` entries describing the system's framebuffer, audio, and removable media devices.

The `mkdevmaps` command is used by the `init(4)` scripts to create or update the `/etc/security/device_maps` file.

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevmaps` command checks for the following files under `/dev`:

- **audio**  /dev/audio, /dev/audioctl, /dev/sound/...
- **tape**   /dev/rst*, /dev/nrst*, /dev/rmt/...
- **floppy** /dev/diskette, /dev/fd*, /dev/rdiskette, /dev/rfd*
- **removable disk** /dev/dsk/c0t?d0s?, /dev/rdsk/c0t?d0s?
- **frame buffer** /dev/fb

See also `allocate(1), bsmconv(1M), attributes(5)`

Notes `mkdevmaps` might not be supported in a future release of the Solaris operating system.
The `mkfifo` utility creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all.

If errors are encountered in creating one of the special files, `mkfifo` writes a diagnostic message to the standard error and continues with the remaining arguments, if any.

The `mkfifo` utility calls the library routine `mkfifo(3C)`, with the `path` argument passed as the `path` argument from the command line, and `mode` is set to the equivalent of `a=rw`, modified by the current value of the file mode creation mask `umask(1)`.

The following option is supported:

```
-m mode
```

Sets the file permission bits of the newly-created FIFO to the specified `mode` value. The `mode` option-argument will be the same as the `mode` operand defined for the `chmod(1)` command. In `<symbolic mode>` strings, the `op` characters `+` and `−` will be interpreted relative to an assumed initial mode of `a=rw`.

The following operand is supported:

```
file
```

A path name of the FIFO special file to be created.

See `largefile(5)` for the description of the behavior of `mkfifo` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

See `environ(5)` for descriptions of the following environment variables that affect the execution of `mkfifo`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

The following exit values are returned:

```
0    All the specified FIFO special files were created successfully.
>0   An error occurred.
```

See `attributes(5)` for descriptions of the following attributes:

mkfile(1M)

Name    mkfile – create a file

Synopsis  mkfile [-nv] size [g | k | b | m] filename...

Description  mkfile creates one or more files that are suitable for use as NFS-mounted swap areas, or as
local swap areas. When a root user executes mkfile(), the sticky bit is set and the file is padded
with zeros by default. When non-root users execute mkfile(), they must manually set the
sticky bit using chmod(1). The default size is in bytes, but it can be flagged as gigabytes,
kilobytes, blocks, or megabytes, with the g, k, b, or m suffixes, respectively.

Options  
- n  Create an empty filename. The size is noted, but disk blocks are not allocated until data
is written to them. Files created with this option cannot be swapped over local UFS
mounts.

- v  Verbose. Report the names and sizes of created files.

Exit Status  The following exit values are returned:

  0    Success.

  >0   An error occurred.

Usage  See largefile(5) for the description of the behavior of mkfile when encountering files
greater than or equal to 2 Gbyte (2^31 bytes).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

Name       mkfs – construct a file system

Synopsis    mkfs [-F FSType] [generic_options]
             [-o FSType-specific_options] raw_device_file
             [operands]

Description The mkfs utility constructs a file system on the raw_device_file by calling the specific mkfs module indicated by -F FSType.

Note: ufs file systems are normally created with the newfs(1M) command.

generic_options are independent of file system type. FSType-specific_options is a comma-separated list of keyword=value pairs (with no intervening spaces), which are FSType-specific. raw_device_file specifies the disk partition on which to write the file system. It is required and must be the first argument following the specific_options (if any). operands are FSType-specific. See the FSType-specific manual page of mkfs (for example, mkfs_ufs(1M)) for a detailed description.

Options    The following are the generic options for mkfs:

- F        Specify the FSType to be constructed. If -F is not specified, the FSType is determined from /etc/vfstab by matching the raw_device_file with a vfstab entry, or by consulting the /etc/default/fs file.

- V        Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from /etc/vfstab or /etc/default/fs. This option may be used to verify and validate the command line.

- m        Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system.

- o        Specify FSType-specific options. See the manual page for the mkfs module specific to the file system type.

Usage      See largefile(5) for the description of the behavior of mkfs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files      /etc/default/fs  Default file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

            LOCAL          The default partition for a command if no FSType is specified.

            /etc/vfstab    List of default parameters for each file system
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  mkfs_ufs(1M), newfs(1M), vfstab(4), attributes(5), largefile(5)

Manual pages for the FSType-specific modules of mkfs.

Notes  This command might not be supported for all FSTypes.

You can use lofiadm to create a file that appears to a mkfs command as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system (using mkfs_ufs(1M) and mkfs_pcfs(1M)) on a device created by lofiadm.
The `mkfs_pcfs` command constructs a File Allocation Table (FAT) on removable media (diskette, JAZ disk, ZIP disk, PCMCIA card), a hard disk, or a file (see NOTES). FATs are the standard MS-DOS and Windows file system format. Note that you can use `fdformat(1)` to construct a FAT file system only on a diskette or PCMCIA card.

`mkfs_pcfs` determines an appropriate FAT size for the medium, then it installs an initial boot sector and an empty FAT. A sector size of 512 bytes is used. `mkfs_pcfs` can also install the initial file in the file system (see the `pcfs`-specific `-o i` option). This first file can optionally be marked as read-only, system, and/or hidden.

If you want to construct a FAT with `mkfs_pcfs` on a medium that is not formatted, you must first perform a low-level format on the medium with `fdformat(1)` or `format(1M)`. Non-diskette media must also be partitioned with the `fdisk(1M)` utility. Note that all existing data on the diskette or disk partition, if any, is destroyed when a new FAT is constructed.

`generic_options` are supported by the generic `mkfs` command. See `mkfs(1M)` for a description of these options.

`raw_device_file` indicates the device on which to write unless the `-o N` option has been specified, or if the `-V` or `-m` generic options are passed from the generic `mkfs` module.

### Options

The following options are supported:

- ** `-o FSType_specific_options`**: Specify `pcfs` file system-specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

  - **`b=label`**: Label the media with volume label. The volume label is restricted to 11 uppercase characters.

  - **`B=filename`**: Install `filename` as the boot loader in the file system’s boot sector. If you don’t specify a boot loader, an MS-DOS boot loader is installed. The MS-DOS boot loader requires specific MS-DOS system files to make the diskette bootable. See `NOTES` for more information.

  - **`fat=n`**: The size of a FAT entry. Currently, 12, 16, and 32 are valid values. The default is 12 for diskettes, 16 for larger media.
Mark the first file installed as a hidden file. The -i option must also be specified.

Set the number of hidden sectors to \( n \). This is the number of sectors on the physical disk preceding the start of the volume (which is the boot sector itself). This defaults to 0 for diskettes or a computed value (based on the fdisk table) for disks. This option may be used only in conjunction with the nfdisk option.

Install \( filename \) as the initial file in the new file system. The initial file's contents are guaranteed to occupy consecutive clusters at the start of the files area. When creating bootable media, a boot program should be specified as the initial file.

Do not attempt to find an fdisk table on the medium. Instead rely on the size option for determining the partition size. By default, the created FAT is 16 bits and begins at the first sector of the device. This origination sector can be modified with the hidden option (-h).

The number of sectors per track on the disk. If not specified, the value is determined by using a dkio(7I) ioctl to get the disk geometry, or (for diskette) from the results of an FDIOGCHAR ioctl.

The number of tracks per cylinder on the disk. If not specified, the value is determined by using a dkio(7I) ioctl to get the disk geometry, or (for diskette) from the results of an FDIOGCHAR ioctl.

No execution mode. Print normal output, but do not actually write the file system to the medium. This is most useful when used in conjunction with the verbose option.

Mark the first file installed as read-only. The -i option must also be specified.

Set the number of reserved sectors to \( n \). This is the number of sectors in the volume,
preceding the start of the first FAT, including the boot sector. The value should always be at least 1, and the default value is exactly 1.

\[ s \]
Mark the first file installed as a system file. The -i option must also be specified.

\[ size=n \]
The number of sectors in the file system. If not specified, the value is determined from the size of the partition given in the fdisk table or (for diskette) by way of computation using the FDI06CHAR ioctl.

\[ spc=n \]
The size of the allocation unit for space within the file system, expressed as a number of sectors. The default value depends on the FAT entry size and the size of the file system.

\[ v \]
Verbose output. Describe, in detail, operations being performed.

**Files**

`raw_device_file` The device on which to build the FAT. The device name for a diskette must be specified as `/dev/rdiskette0` for the first diskette drive, or `/dev/rdiskette1` for a second diskette drive. For non-diskette media, a disk device name must be qualified with a suffix to indicate the proper partition. For example, in the name `/dev/rdsk/c0t0d0p0:c`, the :c suffix indicates that the first partition on the disk should receive the new FAT.

For a file, `raw_device_file` is the block device name returned by `lofiadm(1M)`.

**Examples**
The media in these examples must be formatted before running `mkfs` for pcfs. See DESCRIPTION for more details.

**EXAMPLE 1** Creating a FAT File System on a Diskette
The following command creates a FAT file system on a diskette:

```
mkfs -F pcfs /dev/rdiskette
```

**EXAMPLE 2** Creating a FAT File System on a Disk
The following command creates a FAT file system on the second fdisk partition of a disk attached to an x86 based system:

```
mkfs -F pcfs /dev/rdsk/c0d0p0:d
```
Creating a FAT File System on a ZIP Disk

The following command creates a FAT file system on a ZIP disk located on a SPARC based system:

```
mkfs -F pcfs /dev/rdsk/c0t4d0s2:c
```

Creating a FAT File System on a JAZ Disk

The following command creates a FAT file system on a JAZ disk located on a SPARC based system and overrides the sectors/track and tracks/cylinder values obtained from the device's controller:

```
mkfs -F pcfs -o nsect=32,ntrack=64 /dev/rdsk/c0t3d0s2:c
```

Attributes

fdformat(1), fdisk(1M), format(1M), lofiadm(1M), mkfs(1M), attributes(5), fd(7D), dkio(7I), fdio(7I)

Notes

The default MS-DOS boot loader, which is installed by default if -o B is not specified, requires specific MS-DOS system files to make the diskette bootable. These MS-DOS files are not installed when you format a diskette with mkfs for pcfs, which makes a diskette formatted this way not bootable. Trying to boot from it on an x86 based system will result in the following message:

```
Non-System disk or disk error
Replace and strike any key when ready
```

You must format a diskette with the DOS format command to install the specific MS-DOS system files required by the default boot loader.

You can use lofiadm to create a file that appears to a mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.
**Name**
mkfs_udfs – construct a udfs file system

**Synopsis**
mkfs -F udfs [generic_options] [-o specific_options] raw_device_file [size]

**Description**
This is the universal disk format file system (udfs) -specific module of the mkfs command. mkfs constructs a udfs file system with a root directory.

**Options**
See mkfs(1M) for the list of supported generic_options.

The following options are supported:

- `-o specific_options` Specify a udfs-specific option. Specify udfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

The following specific_options are available:

- `N` Print the file system parameters without actually creating the file system.
- `label=string` Specify the label to be written into the volume header structures. Specify string as the name of the label. If string is not specified, a default string is generated in the form of *NoLabel*.

**Operands**
The following operands are supported:

- `raw_device_file` Specify the disk partition on which to write.
- `size` Specify the number of 512-byte blocks in the file system.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWudf</td>
</tr>
</tbody>
</table>

**See Also**
fsck(1M), mkfs(1M), attributes(5)

**Diagnostics**

- not currently a valid file system
- The specified device does not contain a valid udfs file system.
- **Invalid size**: larger than the partition size
- Number of blocks given as parameter to create the file system is larger than the size of the device specified.
- is mounted can’t mkfs
Device is in use, cannot create file system when the device is in use.

**preposterous size**

Negative size parameter provided is invalid.

**sector size must be between 512, 8192 bytes**

Sector size given is not in the valid range.

**Volume integrity sequence descriptors too long**

**File set descriptor too long.**

Not enough space to create volume integrity sequence or file set descriptor.

**mkfs: argument out of range**

One of the arguments is out of range.

**mkfs: bad numeric arg**

One of the arguments is potentially a bad numeric.

**Notes** You can use `lofiadm` to create a file that appears to a `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use a `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`. 

mkfs_ufs – construct a UFS file system

Synopsis  

mkfs -F ufs [generic_options] [-o FSType_specific_options] raw_device_file
[size]

Description  

The UFS-specific module of mkfs builds a UFS file system with a root directory and a
lost+found directory (see fsck(1M)).

The UFS-specific mkfs is rarely run directly. Use the newfs(1M) command instead.

raw_device_file indicates the disk partition on which to create the new file system. If the -o N,
-V, or -m options are specified, the raw_device_file is not actually modified. size specifies the
number of disk sectors in the file system, where a disk sector is usually 512 bytes. This
argument must follow the raw_device_file argument and is required (even with -o N), unless
the -V or -m generic options are specified.

generic_options are supported by the generic mkfs command. See mkfs(1M) for a description
of these options.

Options  

The following generic options are supported:

- m    Print the command line that was used to create the existing file system.
- V    Print the current mkfs command line.

Options  

The following UFS-specific options are supported:

- o    Use one or more of the following values separated by commas (with no intervening
spaces) to specify UFS-specific options:

_{apc=n}  The number of alternate sectors per cylinder to reserve for bad block
replacement for SCSI devices only. The default is 0.

This option is not applicable for disks with EFI labels and is ignored.

_{bsize=n}  The logical block size of the file system in bytes, either 4096 or 8192.
The default is 8192. The sun4u architecture does not support the
4096 block size.

_{calcbinsb}  Sends to stdout a binary (machine-readable) version of the
superblock that would be used to create a file system with the
specified configuration parameters.

_{calcsb}  Sends to stdout a human-readable version of the superblock that
would be used to create a file system with the specified configuration
parameters.

_{cgsz=_{e}}  The number of cylinders per cylinder group, ranging from 16 to 256.
The default is calculated by dividing the number of sectors in the file
system by the number of sectors in a gigabyte. Then, the result is
multiplied by 32. The default value is always between 16 and 256.
The per-cylinder-group metadata must fit in a space no larger than what is available in one logical file system block. If too large a cgsize is requested, it is changed by the minimum amount necessary.

**fragsize=n**

The smallest amount of disk space in bytes that can be allocated to a file. **fragsize** must be a power of 2 divisor of **bsize**, where:

\[
\text{bsize} / \text{fragsize} \text{ is 1, 2, 4, or 8.}
\]

This means that if the logical block size is 4096, legal values for **fragsize** are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

For file systems greater than 1 terabyte or for file systems created with the **mtb=y** option, **fragsize** is forced to match block size (**bsize**).

**free=n**

The minimum percentage of free space to maintain in the file system between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system.

The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the **tunefs(1M)** command.

**gap=n**

Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.

**maxcontig=n**

The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

\[
\text{maxcontig} = \frac{\text{disk drive maximum transfer size}}{\text{disk block size}}
\]

If the disk drive's maximum transfer size cannot be determined, the default value for **maxcontig** is calculated from kernel parameters as follows:

If **maxphys** is less than **ufs_maxmaxphys**, which is typically 1 Mbyte, then **maxcontig** is set to **maxphys**. Otherwise, **maxcontig** is set to **ufs_maxmaxphys**.

You can set **maxcontig** to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.
You can subsequently change this parameter by using `tunefs(1M)`.

### mtb=y
Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets `fragsize` to be the same as `bsize`, and sets `nbpi` to 1 Mbyte, unless the `-i` option is used to make it even larger. If you explicitly set the `fragsize` or `nbpi` parameters to values that are incompatible with this option, the user-supplied value of `fragsize` or `nbpi` is ignored.

### N
Print out the file system parameters that would be used to create the file system without actually creating the file system.

### nbpi=n
The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default is 2048.

The number of inodes can increase if the file system is expanded with the `growfs` command.

### nrpos=n
The number of different rotational positions in which to divide a cylinder group. The default is 8.

This option is not applicable for disks with EFI labels and is ignored.

### nsect=n
The number of sectors per track on the disk. The default is 32.

### ntrack=n
The number of tracks per cylinder on the disk. The default is 16.

This option is not applicable for disks with EFI labels and is ignored.

### opt=s | t
The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is `time`.

This parameter can be subsequently changed with the `tunefs(1M)` command.

### rps=n
The rotational speed of the disk, in revolutions per second. The default is 60.

Note that you specify `rps` for `mkfs` and `rpm` for `newfs`.

This option is not applicable for disks with EFI labels and is ignored.
Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the -o option is omitted and the list follows the size operand. This is the way newfs passes the parameters to mkfs.

**Operands**
The following operands are supported:

`raw_device_file` The disk partition on which to write.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**
fsck(1M), mkfs(1M), newfs(1M), tunefs(1M), dir_ufs(4), attributes(5), ufs(7FS)

**Diagnostics**
The following error message typically occurs with very high density disks. On such disks, the file system structure cannot encode the proper disk layout information. However, such disks have enough onboard intelligence to make up for any layout deficiencies, so there is no actual impact on performance. The warning that performance might be impaired can be safely ignored.

Warning: insufficient space in super block for rotational layout tables with nsect sblock.fs_nsect
and ntrak sblock.fs_ntrak. (File system performance may be impaired.)

The following error message occurs when the disk geometry results in a situation where the last truncated cylinder group cannot contain the correct number of data blocks. Some disk space is wasted.

Warning: inode blocks/cyl group (grp) >= data blocks (num) in last cylinder

If there is only one cylinder group and if the above condition holds true, mkfs fails with the following error:

File system creation failed. There is only one cylinder group and that is not even big enough to hold the inodes.

The following error message occurs when the best calculated file system layout is unable to include the last few sectors in the last cylinder group. This is due to the interaction between how much space is used for various pieces of meta data and the total blocks available in a cylinder group. Modifying nbpi and cpg might reduce this number, but it is rarely worth the effort.

Warning: num sector(s) in last cylinder group unallocated

**Notes**
You can use lofiadm to create a file that appears to the mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use the mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.
Both the block and character devices, such as devices in /dev/dsk and /dev/rdsk, must be available prior to running the `mkfs` command.
**mknod (1M)**

**Name**  
mknod – make a special file

**Synopsis**  
mknod name b major minor  
mknod name c major minor  
mknod name p

**Description**  
mknod makes a directory entry for a special file.

**Options**  
The following options are supported:

- **b** Create a block-type special file.
- **c** Create a character-type special file.
- **p** Create a FIFO (named pipe).

**Operands**  
The following operands are supported:

- **major** The major device number.
- **minor** The minor device number; can be either decimal or octal. The assignment of major device numbers is specific to each system. You must be the super-user to use this form of the command.
- **name** A special file to be created.

**Usage**  
See `largefile(5)` for the description of the behavior of `mknod` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**  
`ftp(1), in.ftpd(1M), mknod(2), symlink(2), attributes(5), largefile(5)`

**Notes**  
If `mknod(2)` is used to create a device, the major and minor device numbers are always interpreted by the kernel running on that machine.

With the advent of physical device naming, it would be preferable to create a symbolic link to the physical name of the device (in the `/devices` subtree) rather than using `mknod`. 
Name  mkpwdict – maintain password-strength checking database

Synopsis  

/usr/sbin/mkpwdict [-s dict1,... ,dictN]
        [-d destination-path]

Description  The mkpwdict command adds words to the dictionary-lookup database used by pam_authtok_check(5) and passwd(1).

Files containing words to be added to the database can be specified on the command-line using the -s flag. These source files should have a single word per line, much like /usr/share/lib/dict/words.

If -s is omitted, mkpwdict will use the value of DICTIONLIST specified in /etc/default/passwd (see passwd(1)).

The database is created in the directory specified by the -d option. If this option is omitted, mkpwdict uses the value of DICTIONDBDIR specified in /etc/default/passwd (see passwd(1)). The default location is /var/passwd.

Options  The following options are supported:

- s  Specifies a comma-separated list of files containing words to be added to the dictionary-lookup database.
- d  Specifies the target location of the dictionary-database.

Files  

/etc/default/passwd  See passwd(1).
/var/passwd  default destination directory

</table>

See Also  passwd(1), attributes(5), pam_authtok_check(5)
modinfo (1M)

Name  modinfo – display information about loaded kernel modules

Synopsis /usr/sbin/modinfo [-c] [-w] [-i module-id]

Description The modinfo utility displays information about the loaded modules. The format of the information is as follows:

Id Loadaddr Size Info Rev Module Name

where Id is the module ID, Loadaddr is the starting text address in hexadecimal, Size is the size of text, data, and bss in hexadecimal bytes, Info is module specific information, Rev is the revision of the loadable modules system, and Module Name is the filename and description of the module.

The module specific information is the block and character major numbers for drivers, the system call number for system calls, and unspecified for other module types.

Options The following options are supported:

- c Display the number of instances of the module loaded and the module's current state.
- i module-id Display information about this module only.
- w Do not truncate module information at 80 characters.

Examples

EXAMPLE 1 Displaying the Status of a Module

The following example displays the status of module 2:

example% modinfo -i 2
Id Loadaddr Size Info Rev Module Name
2 ff08e000 1734 - 1 swageneric (root and swap configuration)

EXAMPLE 2 Displaying the Status of Kernel Modules

The following example displays the status of some kernel modules:

example% modinfo
Id Loadaddr Size Info Rev Module Name
2 ff08e000 1734 - 1 swageneric
4 ff07a000 3bc0 - 1 specs (filesystem for specs)
6 ff07db00 2918 - 1 TS (time sharing sched class)
7 ff0804d8 49c - 1 TS_DPTBL (Time sharing dispatch table)
8 ff04a000 24a30 2 1 ufs (filesystem for ufs)
9 ff080978 c640 226 1 rpcmod (RPC syscall)
9 ff080978 c640 - 1 rpcmod (rpc interface str mod)
10 ff08cfb0 2031c - 1 ip (IP Streams module)
10 ff08cfb0 2031c 2 1 ip (IP Streams device)
EXAMPLE 3  Using the -c Option

Using the modinfo command with the -c option displays the number of instances of the module loaded and the module's current state.

```bash
example% modinfo -c
```

See Also  modload(1M), modunload(1M), attributes(5)
modload(1M)

Name
modload – load a kernel module

Synopsis
modload [-p] [-e exec_file] filename

Description
The modload command loads the loadable module filename into the running system.

filename is an object file produced by ld -r. If filename is an absolute pathname then the file
specified by that absolute path is loaded. If filename does not begin with a slash (/), then the
path to load filename is relative to the current directory unless the -p option is specified.

The kernel's modpath variable can be set using the /etc/system file. The default value of the
kernel's modpath variable is set to the path where the operating system was loaded. Typically
this is /kernel/usr/kernel.

For example, the following command looks for ./drv/foo:

example# modload drv/foo

The following command looks for /kernel/drv/foo and then /usr/kernel/drv/foo:

example# modload -p drv/foo

Options
The following options are supported:

-e exec_file Specify the name of a shell script or executable image file that is executed after
the module is successfully loaded. The first argument passed is the module ID
(in decimal). The other argument is module specific. The module specific
information is: the block and character major numbers for drivers, the system
call number for system calls, or, for other module types, the index into the
appropriate kernel table. See modinfo(1M)

-p Use the kernel's internal modpath variable as the search path for the module.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

modldrvc9S), modlinkage(9S), modlstrmod(9S), module_info(9S)

Writing Device Drivers

Notes
Use add_drv(1M) to add device drivers, not modload. See Writing Device Drivers for
procedures on adding device drivers.
modunload -i module_id [-e exec_file]

modunload unloads a loadable module from the running system. The module_id is the ID of the module as shown by modinfo(1M). If ID is 0, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by modload(1M) are not affected.

The following options are supported:

- **-e exec_file** Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second argument is the driver major number. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the execsw table. For loadable filesystems, the second argument is the index into the vfs table. For loadable streams modules, the second argument is the index into the fmodsw table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply.

- **-i module_id** Specify the module to be unloaded.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also modinfo(1M), modload(1M), update_drv(1M), attributes(5)

Notes

The modunload command is often used on driver modules to force the system to reread the associated driver configuration file. While this works in the current Solaris release, it is not the supported way to reread the configuration file and is not guaranteed to work in future releases. The supported way for rereading driver configuration file is through the update_drv(1M) command.
**Name**  
`mofcomp` – compile MOF files into CIM classes

**Synopsis**  
```
/usr/sadm/bin/mofcomp [-c cimom_hostname ] [-h]
[-j filename] [-n namespace] [-o dirname]
[-x] file
```

**Description**  
The `mofcomp` utility is executed during installation to compile managed object format (MOF) files that describe the Common Information Model (CIM) and Solaris Schemas into the CIM Object Manager Repository, a central storage area for management data. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment.

The `mofcomp` utility must be run as root or as a user with write access to the namespace in which you are compiling.

MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU.

Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the `mofcomp` utility to compile MOF files at any time after installation.

**Options**  
The following options are supported:

- `-c cimom_hostname`  
Specify a remote system running the CIM Object Manager.

- `-C`  
Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.

- `-h`  
List the arguments to the `mofcomp` utility.

- `-I`  
Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.

- `-j filename`  
Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.

The contents of `filename` are:

```plaintext
PACKAGE=Java package name
IMPORTS=import1:...:importN
```
<EXCEPTIONS=exception1:...:exceptionN

PACKAGE is a valid Java package name to include in all generated Java source. IMPORTS is an optional colon separated list of valid Java classes to be imported in all generated Java source. EXCEPTIONS is an optional colon separated list of valid Java exceptions to be thrown by the methods in all generated Java source.

-n namespace
Requests that the compiler load the MOF file into the namespace specified as namespace. The default namespace (root\cimv2) is used unless this switch is used or a #pragma namespace ("namespace") statement appears in the MOF file. If both the -n namespace switch and the #pragma namespace construct are used, all namespaces are created, but the objects are created only in the #pragma namespaces.

-o dirame
Run compiler in standalone mode, without the CIM Object Manager. Specify dirame as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.

-p password
Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.

-Q
Run the compiler set with the qualifier types option, which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if the qualifier type already exists.

-u username
Specify user name for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.

-v
Run the compiler in verbose mode, which displays compiler messages.

-version
Display the version of the MOF compiler.

-x
Generate XML documents for the CIM classes defined in the input MOF file.
Operands The following operands are supported:
  file The pathname of the file to be compiled.

Exit Status The mofcomp utility exits with 0 upon success and a positive integer upon failure.

Files MOF files are installed in /usr/sadm/mof.

Attributes See attributes(5) for descriptions of the following attributes:

See Also init.wbem(1M), mofreg(1M), wbemadmin(1M), wbemlogviewer(1M), attributes(5), wbem(5)
Name  mofreg – register MOF classes with WBEM services

Synopsis  
/usr/sadm/bin/mofreg -r tag file  
/usr/sadm/bin/mofreg -s  
/usr/sadm/bin/mofreg -u tag [file]

Description  The mofreg command is used by package and patch install scripts, or by any applications that wish to register managed object format (MOF) classes with Sun The Web-Based Enterprise Management (WBEM) services.

The WBEM services daemon (Common Information Model or CIM object manager) processes at start up the files that are specified by mofreg commands. Files are processed in the order that the individual mofreg commands are executed.

As an alternative to using the mofreg command, MOFs can be registered or unregistered by manipulating directories in /var/sadm/wbem/logr. Instead of running the mofreg -r tag file version of the command you can create a directory named tag under /var/sadm/wbem/logr/preReg and copy file to the tag directory.

Similarly, instead of running the mofreg -u tag [file] command, you can create a directory named tag under /var/sadm/wbem/logr/preUnreg and copy the optional file to the tag directory.

The entries are processed in increasing order of last modification time of the tag directories. If you issue mofreg commands in rapid succession, the timestamps might be the same. If you have a situation where the timestamp order is critical, you can place appropriate sleeps between the successive registration or unregistration operations. As with the mofreg command, processing is done at next restart or by using the -s option.

This alternative mechanism is typically used in package install scripts which do not have access to /usr, and therefore do not have access to the mofreg command. This case arises when packages are installed for diskless clients.

Options  The following options are supported:

- -r tag file  
The file argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in .unreg.

#pragma namespace("__create")  
#pragma namespace("__delete")  
#pragma namespace("__modify")

These three pragmas are used to specify if the elements following the pragmas should be created, deleted, or modified by the CIM object manager. The __delete pragma can currently only be applied for a mofreg -u command.
The `tag` argument is a unique string that specifies the identity of the registry action. This tag can be set to the package name or the patch number if the `mofreg` script is being invoked through `packages/patches`, though any tag can be specified.

Errors and warnings that are encountered when the CIM object manager handles the `mofreg` script are logged. Processing of the `mofreg` script stops at the first error. Specific warnings include:

- **Element already defined** - the element already exists and cannot be created.
- **Element not found** - the element does not exist and cannot be modified.

The error conditions are:

- **Key modification** - A class cannot be modified if its keys are being changed.
- **Other mod compilation errors.**

`-s` Forces the CIM object manager to immediately process outstanding registry requests, instead of at the next restart. This currently requires Java.

`-u tag [file]` Undoes the operations performed during `mof registry`.

The `tag` argument must correspond to the value set during the original `mofreg` invocation. If no `mofreg` was done with the original `tag`, the command does not succeed.

If required, an `unreg` file can be specified. If no `unreg` file is specified, the CIM object manager automatically undoes the actions of the registry. Any class created by the registry process is removed and any classes modified by the registry revert to the old state.

The `mofreg` command does not take care of cases where packages and patches make conflicting changes to classes. This should be taken care of by the standard patch and package conflict resolution.

**Exit Status** The following exit values are returned:

0 Successful completion.
1 An error occurred. The reason for error is displayed.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

Monitor – SPARC System PROM Monitor

**Synopsis**

```
STOP-A
BREAK
```

- initial system power-on
- exit from a client program, e.g., the Operating System

**Description**

The CPU board of a workstation contains one or more EPROMs or EEPROMs. The program which executes from the PROMs is referred to as “the monitor”. Among other things, the monitor performs system initialization at power-on and provides a user interface.

The monitor of earlier workstations was known as the SunMON monitor and displayed the > for its prompt. See the SunMON MONITOR USAGE section for further details.

Existing workstations use a monitor which is known as the OpenBoot monitor. The OpenBoot monitor typically displays ok as its prompt, but it may also display the > prompt under certain circumstances.

If the ‘auto-boot?’ NVRAM parameter is set to ‘false’ when the workstation is powered on, the system does not attempt to boot and the monitor issues its prompt. If ‘auto-boot’ is set to ‘true’, the system initiates the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system’s keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Either a lower case a or an upper case A works for the keyboard abort sequence. If a console has been attached by way of one of the system’s serial ports then the abort sequence can be accomplished by sending a BREAK. See tip(1).

When the NVRAM ‘security-mode’ parameter has been turned on, or when the value of the ‘sunmon-compat?’ parameter is true, then the OpenBoot monitor displays the message: Type b (boot), c (continue), or n (new command mode)

and the > prompt appears.

**OpenBoot PROM Usage**

Some of the more useful commands that can be issued from OpenBoot’s ok prompt are described here. Refer to the OpenBoot 2.x Command Reference Manual book for a complete list of commands.

- **Help**
  - Help for various functional areas of the OpenBoot monitor can be obtained by typing `help`. The help listing provides a number of other key words which can then be used in the help command to provide further details.

- **NVRAM Parameters**
  - Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.

  See `eeprom(1M)` for a description of the parameters and information regarding setting the parameters from the OS level.
The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.

**printenv**  
Used to list the NVRAM parameters, along with their default values and current values.

**setenv pn pv**  
Used to set or modify a parameter. The *pn* represents the parameter name, and *pv* represents the parameter value.

**set-default pn**  
Used to set an individual parameter back to its default value.

**set-defaults**  
Used to reset all parameters to their default values. (Note that ‘set-defaults’ only affects parameters that have assigned default values.)

**Security Parameters**  
Newer OpenBoot monitors contain user interfaces that support the storage and listing of keys for later use by client programs.

**list-security-keys**  
Lists the names of keys currently stored on a machine.

**set-security-key keyname [keydata]**  
Stores key data *keydata* in a key named *keyname*. Actual key data can be up to 32 bytes in length. The maximum length of *keyname* is 64 bytes, which allows for the hex-formatted ASCII used to present the key data. If *keydata* is not present, *keyname* and its corresponding data is deleted.

**Hardware Checks and Diagnostics**  
The following commands are available for testing or checking the system’s hardware. If the ‘diag-switch?’ NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic is run, if present, sending its results messages to the system’s serial port A. Not all of the commands shown are available on all workstations.

**test-all**  
Run the diagnostic tests on each device which has provided a self-test.

**test floppy**  
Run diagnostics on the system’s floppy device.

**test /memory**  
Run the main memory tests. If the NVRAM parameter ‘diag-switch?’ is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the ‘selftest-#megs’ NVRAM parameter is tested.

**test net**  
Test the network connection for the on-board network controller.

**watch-net**  
Monitor the network attached to the on-board net controller.

**watch-net-all**  
Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots.

**watch-clock**  
Test the system’s clock function.
The following commands are available for displaying information about the system. Not all commands are available on all workstations.

**banner**
Display the power-on banner.

**.enet-addr**
Display the system's Ethernet address.

**.idprom**
Display the formatted contents of the IDPROM.

**module-info**
Display information about the system's processor(s).

**probe-scsi**
Identify the devices attached to the on-board SCSI controller.

**probe-scsi-all**
Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.

**show-disks**
Display a list of the device paths for installed SCSI disk controllers.

**show-displays**
Display a list of the device paths for installed display devices.

**show-nets**
Display a list of the device paths for installed Ethernet controllers.

**show-sbus**
Display list of installed SBus devices.

**show-tapes**
Display a list of the device paths for installed SCSI tape controllers.

**show-ttys**
Display a list of the device paths for tty devices.

**.traps**
Display a list of the SPARC trap types.

**.version**
Display the version and date of the OpenBoot PROM.

These commands must be typed from the keyboard, they do not work from a console which is attached by way of the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they've been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.

**Stop (L1)**
Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.

**Stop-A (L1-A)**
Abort the current operation and return to the monitor's default prompt.

**Stop-D (L1-D)**
Set the system's 'diag-switch?' NVRAM parameter to 'true', which places the system in diagnostic mode. POST diagnostics, if present, are run, and the messages are displayed by way of the system's serial port A.

**Stop-F (L1-F)**
Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the 'fexit' command to continue with system initialization.
Stop-N (L1-N) Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.

The following commands can be used while the monitor is displaying the ok prompt. Not all of these editing commands are available on all workstations.

CTRL-A Place the cursor at the start of line.
CTRL-B Move the cursor backward one character.
ESC-B Move the cursor backward one word.
CTRL-D Erase the character that the cursor is currently highlighting.
ESC-D Erase the portion of word from the cursor's present position to the end of the word.
CTRL-E Place the cursor at the end of line.
CTRL-F Move the cursor forward one character.
ESC-F Move the cursor forward one word.
CTRL-H Erase the character preceding the cursor (also use Delete or Back Space)
ESC-H Erase the portion of the word which precedes the cursor (use also CTRL-W)
CTRL-K Erase from the cursor's present position to the end of the line.
CTRL-L Show the command history list.
CTRL-N Recall the next command from the command history list
CTRL-P Recall a previous command from the command history list.
CTRL-Q Quote the next character (used to type a control character).
CTRL-R Retype the current line.
CTRL-U Erase from the cursor's present position to the beginning of the line.
CTRL-Y Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.

nvramrc The nvramrc is an area of the system's NVRAM where users may store Forth programs. The programs which are stored in the nvramrc are executed each time the system is reset, provided that the 'use-nvramrc?' NVRAM parameter has been set to 'true'. Refer to the OpenBoot 2.x Command Reference Manual book for information on how to edit and use the nvramrc.

Restricted Monitor The command 'old-mode' is used to move OpenBoot into a restricted monitor mode, causing the > prompt to be displayed. Only three commands are allowed while in the restricted monitor; the 'go' command (to resume a program which was interrupted with the
Stop-A command), the ‘n’ command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor’s boot commands approximate the older SunMON monitor’s boot command syntax. If a ‘security-mode’ has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the ‘sunmon-compat?’ NVRAM parameter is set to true. Not all workstations have the ‘sunmon-compat?’ parameter.

**SunMON Prom Usage**

The following commands are available systems with older SunMON-based PROM:

- `+|--` Increment or decrement the current address and display the contents of the new location.

- `^c source destination n`
  (caret-C) Copy, byte-by-byte, a block of length n from the source address to the destination address.

- `^i program`
  (caret-I) Display the compilation date and location of program.

- `^t virtual_address`
  (caret-T) Display the physical address to which virtual_address is mapped.

- `b [ ! ] [ device [ (c, u, p ) ] ] [ pathname ] [ arguments_list ]`

- `b[?]`
  Reset appropriate parts of the system and bootstrap a program. A ‘!’ (preceding the device argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). ‘b’ with no arguments causes a default boot, either from a disk, or from an Ethernet controller. ‘b?’ displays all boot devices and their devices.

**device**

- `le` Lance Ethernet
- `ie` Intel Ethernet
- `sd` SCSI disk, CDROM
- `st` SCSI 1/4” or 1/2” tape
- `fd` Diskette
- `id` IPI disk
- `mt` Tape Master 9-track 1/2” tape
- `xd` Xylogics 7053 disk
- `xt` Xylogics 1/2” tape
- `xy` Xylogics 440/450 disk
c A controller number (0 if only one controller),
u A unit number (0 if only one driver), and
p A partition.
pathname A pathname for a program such as /stand/diag.
arguments_list A list of up to seven arguments to pass to the program being booted.

c [virtual_address]
Resume execution of a program. When given, virtual_address is the address at which execution resumes. The default is the current PC. Registers are restored to the values shown by the d, and r commands.

d [window_number]
Display (dump) the state of the processor. The processor state is observable only after:
  ■ An unexpected trap was encountered.
  ■ A user program dropped into the monitor (by calling abortent).
  ■ The user manually entered the monitor by typing L1-A or BREAK.

The display consists of the following:
  ■ The special registers: PSR, PC, nPC, TBR, WIM, and Y
  ■ Eight global registers
  ■ 24 window registers (8 in, 8 local, and 8 out), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown.

window_number Display the indicated window_number, which can be any value between 0 and 6, inclusive. If no window is specified and the PSR’s current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are displayed. Otherwise, registers from window 0 are displayed.

e [virtual_address] [action] . . .
Open the 16-bit word at virtual_address (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of action.

f virtual_address1 virtual_address2 pattern [size ]
Fill the bytes, words, or long words from virtual_address1 (lower) to virtual_address2 (higher) with the constant, pattern. The size argument can take one of the following values:
  b byte format (the default)
  w word format
  l long word format
For example, the following command fills the address block from 0x1000 to 0x2000 with the word pattern, 0xABCD:

```
f 1000 2000 ABCD W
```

**g [vector ] [argument ]**

Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of `argument` is passed to the routine. If the `vector` or `virtual_address` argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor’s `g` command, set the variable `*romp->v_vector_cmd` to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied `vector` according to the format supplied in `argument`. This format can be one of:

- `%x` hexadecimal
- `%d` decimal

**g0**

Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

**g4**

(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

**h**

Display the help menu for monitor commands and their descriptions. To return to the monitor’s basic command level, press ESCAPE or `q` before pressing RETURN.

**i [cache_data_offset ] [action ] . . .**

Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the `a` command for a description of `action`.

**j [cache_tag_offset ] [action ] . . .**

Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the `a` command for a description of `action`.

**k [reset_level]**

Reset the system, where `reset_level` is:

- `0` Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.
- `1` Software reset.
Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.

**kb**
Display the system banner.

**l** `[virtual_address] [action] . . .
Open the long word (32 bit) at memory address virtual_address (default zero). The address is interpreted in the address space defined by the s command (below). See the a command for a description of action.

**m** `[virtual_address] [action] . . .
Open the segment map entry that maps virtual_address (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of action.

**ne**
Disable, enable, or invalidate the cache, respectively.

**o** `[virtual_address] [action] . . .
Open the byte location specified by virtual_address (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of action.

**p** `[virtual_address] [action] . . .
Open the page map entry that maps virtual_address (default zero) in the address space defined by the s command. See the a command for a description of action.

**q** `[eeprom_offset] [action] . . .
Open the EEPROM eeprom_offset (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the a command for a description of action.

**r** `[register_number]`
**r** `[register_type]`
**r** `[w window_number]`
Display and/or modify one or more of the IU or FPU registers. A hexadecimal register_number can be one of:

- `0x00−0x0F` window(0,i0)—window(0,i7), window(0,i0)—window(0,i7)
- `0x16−0x1F` window(1,i0)—window(1,i7), window(1,i0)—window(1,i7)
Register numbers can only be displayed after an unexpected trap, a user program has entered the monitor using the `abortent` function, or the user has entered the monitor by manually typing `L1-A` or `BREAK`.

If a `register_type` is given, the first register of the indicated type is displayed. `register_type` can be one of:

- `f` floating-point
- `g` global
- `s` special

If `w` and a `window_number` (0—6) are given, the first in-register within the indicated window is displayed. If `window_number` is omitted, the window that was active just prior to entering the monitor is used. If the PSR’s current window pointer is invalid, window 0 is used.

`s` Set or display the Address Space Identifier. With no argument, `s` displays the current Address Space Identifier. The `asi` value can be one of:

- `0x2` control space
- `0x3` segment table
- `0x4` Page table
- `0x8` user instruction
- `0x9` supervisor instruction
- `0xa` user data
- `0xb` supervisor data
- `0xc` flush segment
With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the u argument (uu...), set the I/O device to be the virtual_address of a UART device currently mapped.

**echo**
Can be either e to enable input to be echoed to the output device, or ne, to indicate that input is not echoed.

**port**
Assign the indicated port to be the current I/O device. port can be one of:
- a serial port A
- b serial port B
- k the workstation keyboard
- s the workstation screen

**baud_rate**
Any legal baud rate.

**options**
can be any combination of:
- i input
- o output
- u UART
- e echo input to output
- ne do not echo input
- r reset indicated serial port (a and b ports only)

If either a or b is supplied, and no options are given, the serial port is assigned for both input and output. If k is supplied with no options, it is assigned for input only. If s is supplied with no options, it is assigned for output only.

**virtual_address1 virtual_address2 [size]**
Display the contents of virtual_address1 (lower) virtual_address2 (higher) in the format specified by size:
- b byte format (the default)
Enter return to pause for viewing; enter another return character to resume the display. To
terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from
address 0x1000 to 0x2000 in word format:

```
v 1000 2000 w
```

`w`  [virtual_address] [argument]
Set the execution vector to a predetermined or default routine. Pass virtual_address and
argument to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the
monitor's `w` command, set the variable `*romp->v_vector_cmd` to be equal to the virtual
address of the desired routine. Predetermined routines need not necessarily return control
to the monitor.

The default routine, defined by the monitor, prints the user-supplied vector according to
the format supplied in argument. This format can be one of:

- `%x` hexadecimal
- `%d` decimal

`x`  Display a menu of extended tests. These diagnostics permit additional testing of such
things as the I/O port connectors, video memory, workstation memory and keyboard, and
boot device paths.

`y`  `c` context_number

`y`  `p|s` context_number virtual_address
Flush the indicated context, context page, or context segment.

`c`  flush context context_number

`p`  flush the page beginning at virtual_address within context context_number

`s`  flush the segment beginning at virtual_address within context context_number

*OpenBoot 2.x Command Reference Manual*
mount(1M)

**Name**
mount, umount – mount or unmount file systems and remote resources

**Synopsis**

```
mount [-p | -v]
mount [-F FSType] [generic_options] [-o specific_options]
    [-O] special | mount_point
mount [-F FSType] [generic_options] [-o specific_options]
    [-O] special mount_point
mount -a [-F FSType] [-V] [current_options]
    [-o specific_options] [mount_point]...
umount [-f] [-V] [-o specific_options] special | mount_point
umount -a [-f] [-V] [-o specific_options] [mount_point]...
```

**Description**

`mount` attaches a file system to the file system hierarchy at the `mount_point`, which is the pathname of a directory. If `mount_point` has any contents prior to the `mount` operation, these are hidden until the file system is unmounted.

`umount` unmounts a currently mounted file system, which may be specified either as a `mount_point` or as `special`, the device on which the file system resides.

The table of currently mounted file systems can be found by examining the mounted file system information file. This is provided by a file system that is usually mounted on `/etc/mnttab`. The mounted file system information is described in `mnttab(4)`. Mounting a file system adds an entry to the mount table; a `umount` removes an entry from the table.

When invoked with both the `special` and `mount_point` arguments and the `-F` option, `mount` validates all arguments except for `special` and invokes the appropriate `FSType`-specific `mount` module. If invoked with no arguments, `mount` lists all the mounted file systems recorded in the mount table, `/etc/mnttab`. If invoked with a partial argument list (with only one of `special` or `mount_point`, or with both `special` or `mount_point` specified but not `FSType`), `mount` will search `/etc/vfstab` for an entry that will supply the missing arguments. If no entry is found, and the special argument starts with “/”, the default local file system type specified in `/etc/default/fs` will be used. Otherwise the default remote file system type will be used. The default remote file system type is determined by the first entry in the `/etc/dfs/fstypes` file. After filling in missing arguments, `mount` will invoke the `FSType`-specific `mount` module.

Only a super-user can mount or unmount file systems using `mount` and `umount`. However, any user can use `mount` to list mounted file systems and resources.

**Options**

- `-F FSType`
  Used to specify the `FSType` on which to operate. The `FSType` must be specified or must be determinable from `/etc/vfstab`, or by consulting `/etc/default/fs` or `/etc/dfs/fstypes`.

- `-a [ mount_points...]`
  Perform mount or umount operations in parallel, when possible.
If mount points are not specified, `mount` will mount all file systems whose `/etc/vfstab` "mount at boot" field is "yes". If mount points are specified, then `/etc/vfstab` "mount at boot" field will be ignored.

If mount points are specified, `umount` will only `umount` those mount points. If none is specified, then `umount` will attempt to unmount all file systems in `/etc/mnttab`, with the exception of certain system required file systems: `/`, `/usr`, `/var`, `/var/adm`, `/var/run`, `/proc`, `/dev/fd` and `/tmp`.

- `f`
  Forcibly unmount a file system.

Without this option, `umount` does not allow a file system to be unmounted if a file on the file system is busy. Using this option can cause data loss for open files; programs which access files after the file system has been unmounted will get an error (EIO).

- `p`
  Print the list of mounted file systems in the `/etc/vfstab` format. Must be the only option specified. See BUGS.

- `v`
  Print the list of mounted file systems in verbose format. Must be the only option specified.

- `V`
  Echo the complete command line, but do not execute the command. `umount` generates a command line by using the options and arguments provided by the user and adding to them information derived from `/etc/mnttab`. This option should be used to verify and validate the command line.

**generic_options**

Options that are commonly supported by most FSType-specific command modules. The following options are available:

- `m`
  Mount the file system without making an entry in `/etc/mnttab`.

- `g`
  Globally mount the file system. On a clustered system, this globally mounts the file system on all nodes of the cluster. On a non-clustered system this has no effect.

- `o`
  Specify FSType-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the FSType-specific module of the command. (See `mount_ufs(1M)`.) When you use `-o` with a file system that has an entry in `/etc/vfstab`, any mount options entered for that file system in `/etc/vfstab` are ignored.

The following options are supported:
devices | nodevices
Allow or disallow the opening of device-special files. The default is devices.

If you use nosuid in conjunction with devices, the behavior is equivalent to that of nosuid.

exec | noexec
Allow or disallow executing programs in the file system. Allow or disallow mmap(2) with PROT_EXEC for files within the file system. The default is exec.

nbmand | nonbmand
Allow or disallow non-blocking mandatory locking semantics on this file system. Non-blocking mandatory locking is disallowed by default.

If the file system is mounted with the nbmand option, then applications can use the fcntl(2) interface to place non-blocking mandatory locks on files and the system enforces those semantics. If you enable this option, it can cause standards conformant applications to see unexpected errors.

Do not use the nbmand option with /, /var and /usr.

You should not use the remount option to change the nbmand disposition of the file system. The nbmand option is mutually exclusive of the global option. See -g.

ro | rw
Specify read-only or read-write. The default is rw.

setuid | nosetuid
Allow or disallow setuid or setgid execution. The default is setuid.

If you specify setuid in conjunction with nosuid, the behavior is the same as nosuid.

nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.

This option is highly recommended whenever the file system is shared by way of NFS with the root= option. Without it, NFS clients could add setuid programs to the server or create devices that could open security holes.

suid | nosuid
Allow or disallow setuid or setgid execution. The default is suid. This option also allows or disallows opening any device-special entries that appear within the filesystem.

nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.
This option is highly recommended whenever the file system is shared using NFS with the root=option, because, without it, NFS clients could add setuid programs to the server, or create devices that could open security holes.

**rstchown | norstchown**
Allow or disallow restricted chown. If the file system is mounted with rstchown, the owner of the file is prevented from changing the owner ID of the file. If the file system is mounted with norstchown, the user can permit ownership changes for files they own. Only the superuser or a user with appropriate privilege can arbitrarily change owner IDs.

**-O**
Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

**-r**
Mount the file system read-only.

**Usage** See **largefile(5)** for the description of the behavior of mount and umount when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

**Files**

/etc/mnttab
Table of mounted file systems.

/etc/default/fs
Default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

LOCAL:
The default partition for a command if no FSType is specified.

/etc/vfstab
List of default parameters for each file system.

Notes  If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Bugs  The mount -p output is incorrect for cachefs.
Name  
mountall, umountall – mount, unmount multiple file systems

Synopsis

mountall [-F FSType] [-l | -r] [file_system_table]

umountall [-k] [-s] [-F FSType] [-l | -r] [-n] [-Z]

umountall [-k] [-s] [-h host] [-n] [-Z]

Description

mountall is used to mount file systems specified in a file system table. The file system table must be in vfstab(4) format. If no file_system_table is specified, /etc/vfstab is used. If - is specified as file_system_table, mountall reads the file system table from the standard input. mountall mounts only those file systems with the mount at boot field set to yes in the file_system_table.

For each file system in the file system table, the following logic is executed: if there exists a file/usr/lib/fs/FSType/fsckall, where FSType is the type of the file system, save that file system in a list to be passed later, and all at once, as arguments to the /usr/lib/fs/FSType/fsckall script. The /usr/lib/fs/FSType/fsckall script checks all of the file systems in its argument list to determine whether they can be safely mounted. If no /usr/lib/fs/FSType/fsckall script exists for the FSType of the file system, the file system is individually checked using fsck(1M). If the file system does not appear mountable, it is fixed using fsck before the mount is attempted. File systems with a - entry in the fsckdev field are mounted without first being checked.

umountall causes all mounted file systems in the current zone except root, /usr, /var, /var/adm, /var/run, /proc, and /dev/fd to be unmounted. If the FSType is specified, mountall and umountall limit their actions to the FSType specified. There is no guarantee that umountall unmounts busy file systems, even if the -k option is specified.

Options

The following options are supported:

-F  Specify the FSType of the file system to be mounted or unmounted.

-h host  Unmount all file systems listed in /etc/mnttab that are remote-mounted from host.

-k  Use the fuser -k mount-point command. See the fuser(1M) for details. The -k option sends the SIGKILL signal to each process using the file. As this option spawns kills for each process, the kill messages might not show up immediately. There is no guarantee that umountall unmounts busy file systems, even if the -k option is specified.

-l  Limit the action to local file systems.

-n  List the actions that would be performed for the specified options, but do not actually execute these actions. Repeating the command without the -n option executes the listed actions, assuming that the /etc/mnttab file has not changed in the interval prior to repeating the command.

-r  Limit the action to remote file system types.
mountall(1M)

- s  Do not perform the umount operation in parallel.
- Z  Apply the action(s) only to the file systems mounted in non-global zones. By default, umountall unmounts only file systems mounted in the current zone. Option -Z is ignored if used in a non-global zone.

Files  /etc/mnttab
       Mounted file system table

/etc/vfstab
       Table of file system defaults

/usr/lib/fs/FSType/fsckall
       Script called by mountall to perform the file system check of all file systems of type FSType

See Also  fsck(1M), fuser(1M), mount(1M), mnttab(4), vfstab(4), attributes(5)

Diagnostics  No messages are printed if the file systems are mountable and clean.
            Error and warning messages come from fsck(1M) and mount(1M).

Notes  At this time, NFS is the only remote file system supported by the -l, -r, and -h options.
mount_cachefs(1M)

Name  
mount_cachefs – mount CacheFS file systems

Synopsis  
mount -F cachefs [generic_options] -o backfstype=file_system_type
          [specific_options]
          [-O] special mount_point

Description  
The CacheFS-specific version of the mount command mounts a cached file system; if
necessary, it NFS-mounts its back file system. It also provides a number of CacheFS-specific
options for controlling the caching process. For more information regarding back file systems,
refer to the System Administration Guide: Basic Administration.

mount_cachefs cannot be used with replicated NFS mounts. mount_cachefs creates a pass
through when used with an NFS version 4 mount. No caching is performed.

Options  
To mount a CacheFS file system, use the generic mount command with the -F option followed
by the argument cachefs.

See mount(1M) for a list of supported generic_options.

-o specific_options  
Specify CacheFS file system specific options in a comma-separated list
with no intervening spaces.

- acdirmax=n  
Specifies that cached attributes are
held for no more than $n$ seconds
after directory update. After $n$
seconds, all directory information is
purged from the cache. The default
value is 30 seconds.

- acdirmin=n  
Specifies that cached attributes are
held for at least $n$ seconds after
directory update. After $n$ seconds,
CacheFS checks to see if the
directory modification time on the
back file system has changed. If it
has, all information about the
directory is purged from the cache
and new data is retrieved from the
back file system. The default value is
30 seconds.

- acregmax=n  
Specifies that cached attributes are
held for no more than $n$ seconds
after file modification. After $n$
seconds, all file information is
purged from the cache. The default
value is 30 seconds.
acregmin=n

Specifies that cached attributes are held for at least $n$ seconds after file modification. After $n$ seconds, CacheFS checks to see if the file modification time on the back file system has changed. If it has, all information about the file is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds.

actimeo=n

Sets acregmin, acregmax, acdirmin, and acdirmax to $n$.

backfstype=file_system_type

The file system type of the back file system (can be nfs or hsfs).

backpath=path

Specifies where the back file system is already mounted. If this argument is not supplied, CacheFS determines a mount point for the back file system. The back file system must be read-only.

cachedir=directory

The name of the cache directory.

cacheid=ID

$ID$ is a string specifying a particular instance of a cache. If you do not specify a cache ID, CacheFS will construct one.

demandconst

Verifies cache consistency only when explicitly requested, rather than the periodic checking that is done by default. A consistency check is requested by using the -s option of the cfsadmin(1M) command. This option is useful for back file systems that change infrequently, for example, /usr/openwin. demandconst and noconst are mutually exclusive.

local-access

Causes the front file system to interpret the mode bits used for access checking instead of having the back file system verify access
permissions. Do not use this argument with secure NFS.

noconst

Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify noconst only when you know that the back file system will not be modified. Trying to perform cache consistency check using cfsadmin -s will result in error.

demandconst and noconst are mutually exclusive.

write-around | non-shared

Write modes for CacheFS. The write-around mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the non-shared mode when you are sure that no one else will be writing to the cached file system. In this mode, all writes are made to both the front and the back file system, and the file remains in the cache.

-O

Overlay mount. Allows the filesystem to be mounted over an existing mount point, making the underlying filesystem inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, mount will fail with the error: mount -F cachefs: mount failed Device busy.

Examples

**EXAMPLE 1** CacheFS-mounting a File System

The following example CacheFS-mounts the file system server1:/user2, which is already NFS-mounted on /usr/abc as /xyz.

```
example# mount -F cachefs -o backfstype=nfs,backpath=/usr/abc,
cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the /etc/mnttab file after the mount command is executed:

```
server1:/user2 /usr/abc nfs
/usr/abc /cached/xyz cachefs backfstype=nfs
```

Bugs  The output for the generic_option -p output is incorrect for cachefs.
**Name**  
mountd – server for NFS mount requests and NFS access checks

**Synopsis**  
/usr/lib/nfs/mountd [-v] [-r]

**Description**  
mountd is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file /etc/dfs/sharetab to determine which file systems are available for mounting by which remote machines. See `sharetab(4)`. nfsd running on the local server will contact mountd the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the remote procedure call from the client. See `share_nfs(1M)`.

The command also provides information as to what file systems are mounted by which clients. This information can be printed using the `showmount(1M)` command.

The mountd daemon is automatically invoked by `share(1M)`.

Only super user can run the mountd daemon.

**Options**  
The options shown below are supported for NVSv2/v3 clients. They are not supported for Solaris NFSv4 clients.

- `-r`  
  Reject mount requests from clients. Clients that have file systems mounted will not be affected.

- `-v`  
  Run the command in verbose mode. Each time mountd determines what access a client should get, it will log the result to the console, as well as how it got that result.

**Files**  
/etc/dfs/sharetab  
shared file system table

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnfssu</td>
</tr>
</tbody>
</table>

**See Also**  
nfsd(1M), share(1M), share_nfs(1M), showmount(1M), nfs(4), sharetab(4), attributes(5)

**Notes**  
Since mountd must be running for nfsd to function properly, mountd is automatically started by the `svc:/network/nfs/server` service. See `nfs(4)`.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.
mount_hsfs(1M)

Name  
mount_hsfs – mount hsfs file systems

Synopsis  
mount -F hsfs [generic_options]
   [-o FSType-specific_options] [-O] special | mount_point

Description  
mount attaches a High Sierra file system (hsfs) to the file system hierarchy at the mount_point, which is the pathname of a directory. If mount_point has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If mount is invoked with special or mount_point as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the FSType-specific_options; see mount(1M) for more details.

If the file system being mounted contains Rock Ridge extensions, by default they will be used, enabling support of features not normally available under High Sierra file systems such as symbolic links, and special files.

Options  
generic_options  
See mount(1M) for the list of supported options.

-o  Specify hsfs file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

   global | noglobal  If global is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If noglobal is specified, the mount will not be globally visible. The default behavior is noglobal.

   ro  Mount the file system read-only. This option is required.

   nrr  no Rock Ridge: if Rock Ridge extensions are present in the file system, ignore them; interpret it as a regular High Sierra file system.

   notraildot  File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file’s name for all file access operations, even if there is no extension present. Specifying notraildot makes it optional to specify the trailing dot to access a file whose name lacks an extension.
Exceptions: This option is effective only on file systems for which Rock Ridge extensions are not active, either because they are not present on the CD-ROM, or they are explicitly ignored via the `nrr` option. If Rock Ridge extensions are active, `hsfs` quietly ignores this option.

`nomapcase` File names on High Sierra cdroms with no Rock Ridge extensions present should be uppercase characters only. By default, `hsfs` maps file names read from a non-Rock Ridge disk to all lowercase characters. `nomapcase` turns off this mapping. The exceptions for `notraildot` discussed above apply to `nomapcase`.

`-0` Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error `device busy`.

**Files**

/etc/mnttab  table of mounted file systems
/etc/vfstab  list of default parameters for each file system

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**

`mount(1M), mountall(1M), mount(2), mnttab(4), vfstab(4), attributes(5)`

**Notes** If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.
mount_nfs – mount remote NFS resources

Synopsis

mount [-F nfs] [generic_options] [-o specific_options] [-O] resource

mount [-F nfs] [generic_options] [-o specific_options] [-O] mount_point

mount [-F nfs] [generic_options] [-o specific_options]

[-O] resource mount_point

The mount utility attaches a named resource to the file system hierarchy at the pathname location mount_point, which must already exist. If mount_point has any contents prior to the mount operation, the contents remain hidden until the resource is once again unmounted.

mount_nfs starts the lockd(1M) and statd(1M) daemons if they are not already running.

If the resource is listed in the /etc/vfstab file, the command line can specify either resource or mount_point, and mount consults /etc/vfstab for more information. If the -F option is omitted, mount takes the file system type from /etc/vfstab.

If the resource is not listed in the /etc/vfstab file, then the command line must specify both the resource and the mount_point.

host can be an IPv4 or IPv6 address string. As IPv6 addresses already contain colons, enclose host in a pair of square brackets when specifying an IPv6 address string. Otherwise the first occurrence of a colon can be interpreted as the separator between the host name and path, for example, [1080::8:800:200C:417A]:tmp/file. See inet(7P) and inet6(7P).

host:pathname
Where host is the name of the NFS server host, and pathname is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this is the case.

nfs://host[:port]/pathname
This is an NFS URL and follows the standard convention for NFS URLs as described in NFS URL Scheme, RFC 2224. See the discussion of URL's and the public option under NFS FILE SYSTEMS for a more detailed discussion.

host:pathname nfs://host[:port]/pathname
host:pathname is a comma-separated list of host:pathname.

See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.

hostlist pathname
hostlist is a comma-separated list of hosts.

See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.
The `mount` command maintains a table of mounted file systems in `/etc/mnttab`, described in `mnttab(4)`.

`mount_nfs` supports both NFSv3 and NFSv4 mounts. The default NFS version is NFSv4.

**Options**

See `mount(1M)` for the list of supported `generic_options`. See `share_nfs(1M)` for a description of server options.

- `-o specific_options`
  Set file system specific options according to a comma-separated list with no intervening spaces.

  - `acdirmax=n`
    Hold cached attributes for no more than `n` seconds after directory update. The default value is 60.

  - `acdirmin=n`
    Hold cached attributes for at least `n` seconds after directory update. The default value is 30.

  - `acregmax=n`
    Hold cached attributes for no more than `n` seconds after file modification. The default value is 60.

  - `acregmin=n`
    Hold cached attributes for at least `n` seconds after file modification. The default value is 3.

  - `actimeo=n`
    Set `min` and `max` times for regular files and directories to `n` seconds. See "File Attributes," below, for a description of the effect of setting this option to 0.

    See "Specifying Values for Attribute Cache Duration Options," below, for a description of how `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo` are parsed on a `mount` command line.

  - `bg | fg`
    If the first attempt fails, retry in the background, or, in the foreground. The default is `fg`.

  - `forcedirectio | noforcedirectio`
    If `forcedirectio` is specified, then for the duration of the mount, forced direct I/O is used. If the filesystem is mounted using `forcedirectio`, data is transferred directly between client and server, with no buffering on the client. If the filesystem is mounted using `noforcedirectio`, data is buffered on the client. `forcedirectio` is a performance option that is of benefit only in large sequential data transfers. The default behavior is `noforcedirectio`.

  - `grpid`
    By default, the GID associated with a newly created file obeys System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior can be
overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see open(2) and mkdir(2)). Files created on file systems that are mounted with the grp id option obeys BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

**hard | soft**
Continue to retry requests until the server responds (hard) or give up and return an error (soft). The default value is hard. Note that NFSv4 clients do not support soft mounts.

**intr | nointr**
Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is intr, which makes it possible for clients to interrupt applications that can be waiting for a remote mount.

**noac**
Suppress data and attribute caching. The data caching that is suppressed is the write-behind. The local page cache is still maintained, but data copied into it is immediately written to the server.

**nocto**
Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client’s local caches. This behavior ensures a file’s consistency across multiple NFS clients. When -octo is in effect, the client does not perform the flush on close and the request for validation, allowing the possibility of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system are made from only one client and only that client. Under such a condition, the effect of -octo can be a slight performance gain.

**port=n**
The server IP port number. The default is NFS_PORT. If the port option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a port number, then the port number in the option and in the URL must be the same.

**posix**
Request POSIX.1 semantics for the file system. Requires a mount Version 2 mountd(1M) on the server. See standards(5) for information regarding POSIX.

**proto=netid | rdma**
By default, the transport protocol that the NFS mount uses is the first available TCP transport supported both by the client and the server. If no TCP transport is found, then it attempts to use a UDP transport, as ordered in the /etc/net config file.
Use this option to override the default behavior.

proto is set to the value of netid or rdma. netid is the value of the network_id field entry in the /etc/netconfig file.

The UDP protocol is not supported for NFS Version 4. If you specify a UDP protocol with the proto option, NFS version 4 is not used.

public
The public option forces the use of the public file handle when connecting to the NFS server. The resource specified might not have an NFS URL. See the discussion of URLs and the public option under NFS FILE SYSTEMS for a more detailed discussion.

quota
Enable or prevent quota (1M) to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas are still checked for operations on this file system.

reMount
Remounts a read-only file system as read-write (using the rw option). This option cannot be used with other -o options, and this option works only on currently mounted read-only file systems.

retrans=n
Set the number of NFS retransmissions to n. The default value is 5. For connection-oriented transports, this option has no effect because it is assumed that the transport performs retransmissions on behalf of NFS.

retry=n
The number of times to retry the mount operation. The default for the mount command is 10000.

The default for the automounter is 0, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary server not responding errors.

rsize=n
Set the read buffer size to a maximum of n bytes. The default value is 1048576 when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and 32768 when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "Read" operations may not necessarily use the maximum buffer size. When using Version 2, the default value is 32768 for all transports.

sec=mode
Set the security mode for NFS transactions. If sec= is not specified, then the default action is to use AUTH_SYS over NFS Version 2 mounts, or to negotiate a mode over NFS Version 3 or Version 4 mounts.
NFS Version 3 mounts negotiate a security mode when the server returns an array of security modes. The client picks the first mode in the array that is supported on the client. In negotiations, an NFS Version 3 client is limited to the security flavors listed in `/etc/nfssec.conf`.

NFS Version 4 mounts negotiate a security mode when the server returns an array of security modes. The client attempts the mount with each security mode, in order, until one is successful.

Only one mode can be specified with the `sec=` option. See `nfssec(5)` for the available mode options.

```
secure
```
This option has been deprecated in favor of the `sec=dh` option.

```
timeo=n
```
Set the NFS timeout to `n` tenths of a second. The default value is 11 tenths of a second for connectionless transports, and 600 tenths of a second for connection-oriented transports. This value is ignored for connectionless transports. Such transports might implement their own timeouts, which are outside the control of NFS.

```
vers=NFS version number
```
By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. The default maximum for the client is Version 4. This can be changed by setting the `NFS_CLIENT_VERSMAX` parameter in `/etc/default/nfs` to a valid version (2, 3, or 4). If the NFS server does not support the client's default maximum, the next lowest version attempted until a matching version is found.

```
wsize=n
```
Set the write buffer size to a maximum of `n` bytes. The default value is 1048576 when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and 32768 when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "Write" operations may not necessarily use the maximum buffer size. When using Version 2, the default value is 32768 for all transports.

```
xattr|noxattr
```
Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See `fsattr(5)` for a description of extended attributes.

```
-O
```
Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error "device busy."
Nfs File Systems

Background versus Foreground

File systems mounted with the `bg` option indicate that `mount` is to retry in the background if the server's mount daemon (`mountd(1M)`) does not respond. `mount` retries the request up to the count specified in the `retry=n` option. (Note that the default value for `retry` differs between `mount` and `automount`. See the description of `retry`, above.) Once the file system is mounted, each NFS request made in the kernel waits `timeo=n` tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the `retrans=n` option, a file system mounted with the `soft` option returns an error on the request; one mounted with the `hard` option prints a warning message and continues to retry the request.

Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the `hard` option. Applications using `soft` mounted file systems can incur unexpected I/O errors, file corruption, and unexpected program core dumps. The `soft` option is not recommended.

Authenticated requests

The server can require authenticated NFS requests from the client. `sec=dh` authentication might be required. See `nfssec(5)`.

URLs and the public option

If the public option is specified, or if the resource includes an NFS URL, `mount` attempts to connect to the server using the public file handle lookup protocol. See `WebNFS Client Specification`, RFC 2054. If the server supports the public file handle, the attempt is successful; `mount` does not need to contact the server's `rpcbind(1M)` and the `mountd(1M)` daemons to get the port number of the mount server and the initial file handle of `pathname`, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports, such as `NFS_PORT`, then this enables NFS operations through the firewall. The public option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

<table>
<thead>
<tr>
<th>Resource Style</th>
<th>NFS URL</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>host:pathname</code></td>
<td><code>NFS URL</code></td>
</tr>
<tr>
<td>public option</td>
<td>Force public file handle and fail mount if not supported.</td>
</tr>
<tr>
<td>default</td>
<td>Use Native paths.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
A Native path is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A Canonical path is a path name that is interpreted according to the URL rules. See Uniform Resource Locators (URL), RFC 1738. See Examples for uses of Native and Canonical paths.

Replicated file systems and failover

The resource can list multiple read-only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. It is also recommended that they be created by a utility such as rdist(1). The file systems can be specified either with a comma-separated list of host/pathname entries and/or NFS URL entries, or with a comma-separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover uses the next alternate server to access files. If the read-only option is not chosen, replication is disabled. File access, for NFS Versions 2 and 3, is blocked on the original if NFS locks are active for that file.

File Attributes

To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting actimeo=n sets flush time to n seconds for both regular files and directories.

Setting actimeo=0 disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server though file data is still cached. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the noac option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application is written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (mmap(2)) are not written directly to this server.

The attribute cache duration options are acdirmax, acdirmin, acregmax, acregmin, and actimeo, as described under OPTIONS. A value specified for actimeo sets the values of all attribute cache duration options except for any of these options specified following actimeo on a mount command line. For example, consider the following command:

eexample# mount -o acdirmax=10,actimeo=1000 server:/path /localpath

Because actimeo is the last duration option in the command line, its value (1000) becomes the setting for all of the duration options, including acdirmax. Now consider:
EXAMPLE 1  Mounting an NFS File System
To mount an NFS file system:
example# mount serv:/usr/src /usr/src

EXAMPLE 2  Mounting An NFS File System Read-Only With No suid Privileges
To mount an NFS file system read-only with no suid privileges:
example# mount -r -o nosuid serv:/usr/src /usr/src

EXAMPLE 3  Mounting An NFS File System Over Version 2, with the UDP Transport
To mount an NFS file system over Version 2, with the UDP transport:
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src

EXAMPLE 4  Mounting an NFS File System Using An NFS URL
To mount an NFS file system using an NFS URL (a canonical path):
example# mount nfs://serv/usr/man /usr/man

EXAMPLE 5  Mounting An NFS File System Forcing Use Of The Public File Handle
To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7–bit ASCII escape sequence:
example# mount -o public nfs://serv/usr/%A0abc /mnt/test

EXAMPLE 6  Mounting an NFS File System Using a Native Path
To mount an NFS file system using a native path (where the server uses colons ("." as the component separator) and the public file handle:
example# mount -o public serv:C:doc:new /usr/doc

EXAMPLE 7  Mounting a Replicated Set of NFS File Systems with the Same Pathnames
To mount a replicated set of NFS file systems with the same pathnames:
example# mount serv-a,serv-b,serv-c:/usr/man /usr/man

EXAMPLE 8  Mounting a Replicated Set of NFS File Systems with Different Pathnames
To mount a replicated set of NFS file systems with different pathnames:
example# mount serv-x:/usr/man,serv-y:/var/man,nfs://serv-z/man /usr/man

Callaghan, Brent, NFS URL Scheme, RFC 2224, October 1997.

Notes

An NFS server should not attempt to mount its own file systems. See lofs(7FS).

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than being mounted on top of the symbolic link itself.

SunOS 4.x used the biod maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.x made biod obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (/) file system is mounted read-only by the kernel during the boot process, only the remount option (and options that can be used in conjunction with remount) affect the root (/) entry in the /etc/vfstab file.

mount_cachefs cannot be used with replicated NFS mounts or any NFS Version 4 mount.
mount_pcfs(1M)

Name
mount_pcfs – mount pcfs file systems

Synopsis
mount -F pcfs [generic_options]
       [-o FSType-specific_options] special | mount_point

mount -F pcfs [generic_options]
       [-o FSType-specific_options] special mount_point

Description
mount attaches an MS-DOS file system (pcfs) to the file system hierarchy at the mount_point, which is the pathname of a directory. If mount_point has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If mount is invoked with special or mount_point as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the FSType-specific_options; see mount(1M) for more details.

The special argument can be one of two special device file types:

- A floppy disk, such as /dev/diskette0 or /dev/diskette1.
- A DOS logical drive on a hard disk expressed as device-name:logical-drive, where device-name specifies the special block device-file for the whole disk and logical-drive is either a drive letter (c through z) or a drive number (1 through 24). Examples are /dev/dsk/c0t0d0p0:c and /dev/dsk/c0t0d0p0:1.

The special device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.

Options
generic_options
See mount(1M) for the list of supported options.

-o
Specify pcfs file system-specific options. The following options are supported:

foldcase | nofoldcase
Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of pcfs. The default is nofoldcase.

hidden | nohidden
Allow or disallow listing of files with hidden or system bits set. Option hidden is the default. When nohidden is effect, hidden and system files are neither visible nor accessible. Note that PCFS in previous releases of the Solaris operating system used the nohidden option as the default.

atime | noatime
Enable or disable write access timestamps on DOS-formatted media. Default for fixed disks is atime, while for removable media noatime is used. The latter default is so that writes to flash-based media ("memory sticks") can be minimized, to prolong lifetime.
Timestamps on DOS-formatted media are recorded in the local time of the recording system. This can cause confusion when accessing removable media in which the recording and receiving system use different time zones. Use this option to force media timestamps to be interpreted for a specific time zone. The `mount_pcfs` command converts the given time zone name into a numerical offset that is passed to the `pcfs` kernel module, using the same rules as described in `environ(5)` for the `TZ` environment variable. By default, the `timezone` value is taken from the `TZ` environment variable.

**Notes**

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.
mount_tmpfs – mount tmpfs filesystems

Synopsis mount [-F tmpfs] [-o specific_options] [-O] special mount_point

Description tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system.

mount attaches a tmpfs file system to the file system hierarchy at the pathname location mount_point, which must already exist. If mount_point has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying mount_point, provided that those attributes are determinable. If not, the root’s attributes are set to their default values.

The special argument is usually specified as swap but is in fact disregarded and assumed to be the virtual memory resources within the system.

Options -o specific_options Specify tmpfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

size=sz The sz argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.

xattr | noxattr Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.

-0 Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error device busy.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.
**Name**
mount_udfs – mount a udfs file system

**Synopsis**
```
mount -F udfs [generic_options] [-o specific_options] [-O] special mount_point
mount -F udfs [generic_options] [-o specific_options] [-O] special | mount_point
```

**Description**
The `mount` utility attaches a udfs file system to the file system hierarchy at the `mount_point`, which is the pathname of a directory. If `mount_point` has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If `mount` is invoked with either `special` or `mount_point` as the only arguments, `mount` searches `/etc/vfstab` to fill in the missing arguments, including the `specific_options`. See `mount(1M)`.

If `special` and `mount_point` are specified without any `specific_options`, the default is `rw`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

**Options**
See `mount(1M)` for the list of supported `generic_options`.

The following options are supported:

- `-o specific_options`
  Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following `specific_options` are available:

  - `m` Mount the file system without making an entry in `/etc/mnttab`.

  - `remount` Remount the file system as read-write. The option is used in conjunction with the `rw` option.

    A file system mounted read-only can be remounted as read-write. This option fails if the file system is not currently mounted.

- `-O`
  Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error `device busy`.

**Files**
- `/etc/mnttab` Table of mounted file systems
- `/etc/vfstab` List of default parameters for each file system

**Attributes**

</table>
See Also  fsck(1M), fsck_udfs(1M), mount(1M), mountall(1M), mount(2), mnttab(4), vfstab(4), attributes(5)

Diagnostics  not super user  The command is run by a non-root user. Run as root.
            no such device  The device name specified does not exist.
            not a directory  The specified mount point is not a directory.
            is not an udfs file system  The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.
            is already mounted  The specified device is already in use.
            not a block device  The device specified is not a block device. Use block device to mount.
            write-protected  The device is read-only.
            is corrupted. needs checking  The file system is in an inconsistent state. Run fsck.

Notes  Copy-protected files can be stored on DVD-ROM media using Universal Disk Format (UDF). Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.
Name  
mount_ufs – mount ufs file systems

Synopsis  
mount -F ufs [generic_options] [-o specific_options]  
[-O] special | mount_point

mount -F ufs [generic_options] [-o specific_options]  
[-O] special | mount_point

Description  
The mount utility attaches a ufs file system to the file system hierarchy at the mount_point,  
which is the pathname of a directory. If mount_point has any contents prior to the mount  
operation, these are hidden until the file system is unmounted.

The ufs file system supports direct mounting of files containing the file system as well as block  
devices. See mount(1M) and lofiadm(1M).

If mount is invoked with special or mount_point as the only arguments, mount will search  
/etc/vfstab to fill in the missing arguments, including the specific_options. See mount(1M).

If special and mount_point are specified without any specific_options, the default is rw.

If the directory on which a file system is to be mounted is a symbolic link, the file system is  
mounted on the directory to which the symbolic link refers, rather than on top of the symbolic  
link itself.

Options  
See mount(1M) for the list of supported generic_options.

The following options are supported:

-o specific_options  
Specify ufs file system specific options in a comma-separated list with no intervening  
spaces. If invalid options are specified, a warning message is printed and the invalid options  
are ignored. The following options are available:

dfratime | nodfratime  
By default, writing access time updates to the disk may be deferred (dfratime) for the  
file system until the disk is accessed for a reason other than updating access times.  
nodfratime disables this behavior.

If power management is enabled on the system, do not set nodfratime unless noatime is  
also set. If you set nodfratime without setting noatime, the disk is spun up every time a  
file within a file system on the disk is accessed - even if the file is not modified.

forcedirectio | noforcedirectio  
If forcedirectio is specified and supported by the file system, then for the duration of  
the mount, forced direct I/O will be used. If the filesystem is mounted using  
forcedirectio, data is transferred directly between user address space and the disk. If  
the filesystem is mounted using noforcedirectio, data is buffered in kernel address.
space when data is transferred between user address space and the disk. **forcedirectio**
is a performance option that is of benefit only in large sequential data transfers. The
default behavior is **noforcedirectio**.

**global | noglobal**

If **global** is specified and supported on the file system, and the system in question is part
of a cluster, the file system will be globally visible on all nodes of the cluster. If **noglobal**
is specified, the mount will not be globally visible. The default behavior is **noglobal**.

**intr | nointr**

Allow (do not allow) keyboard interrupts to kill a process that is waiting for an
operation on a locked file system. The default is **intr**.

**largefiles | nolargefiles**

If **nolargefiles** is specified and supported by the file system, then for the duration of
the mount it is guaranteed that all regular files in the file system have a size that will fit in
the smallest object of type off_t supported by the system performing the mount. The
mount will fail if there are any files in the file system not meeting this criterion. If
**largefiles** is specified, there is no such guarantee. The default behavior is **largefiles**.

If **nolargefiles** is specified, **mount** will fail for **ufs** if the file system to be mounted has
contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last
invocation of **fsck** on the file system. The large file need not be present in the file system
at the time of the mount for the mount to fail; it could have been created previously and
destroyed. Invoking **fsck** (see **fsck_ufs(1M)**) on the file system will reset the file system
state if no large files are present. After invoking **fsck**, a successful mount of the file
system with **nolargefiles** specified indicates the absence of large files in the file system;
an unsuccessful mount attempt indicates the presence of at least one large file.

**logging | nologging**

If **logging** is specified, then logging is enabled for the duration of the mounted file
system. Logging is the process of storing transactions (changes that make up a complete
UFS operation) in a log before the transactions are applied to the file system. Once a
transaction is stored, the transaction can be applied to the file system later. This prevents
file systems from becoming inconsistent, therefore reducing the possibility that **fsck**
might run. And, if **fsck** is bypassed, logging generally reduces the time required to
reboot a system.

The default behavior is **logging** for all UFS file systems.

The log is allocated from free blocks in the file system, and is sized approximately 1
Mbyte per 1 Gbyte of file system, up to a maximum of 256 Mbytes. The log size may be
larger (up to a maximum of 512 Mbytes) dependent upon the number of cylinder
groups present in the file system.

Logging is enabled on any UFS file system, including root (/), except under the
following conditions:
When logging is specifically disabled.

- If there is insufficient file system space for the log. In this case, the following message is displayed and file system is still mounted:

```
# mount /dev/dsk/c0t4d0s0 /mnt
/mnt: No space left on device
Could not enable logging for /mnt on /dev/dsk/c0t4d0s0.
```

The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the `lockfs -f` command.

- Mount the file system without making an entry in `/etc/mnttab`.

`noatime`

By default, the file system is mounted with normal access time (`atime`) recording. If `noatime` is specified, the file system will ignore access time updates on files, except when they coincide with updates to the `ctime` or `mtime`. See `stat(2)`. This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool).

`noatime` turns off access time recording regardless of `dfratime` or `nodfratime`.

The POSIX standard requires that access times be marked on files. `-noatime` ignores them unless the file is also modified.

`nosec`

By default, Access Control Lists (ACLs) are supported on a mounted UFS file system. Use this option to disallow the setting or any modification of an ACL on a file within a mounted UFS file system. See `getfacl(1)` for background on ACLs.

`onerror = action`

This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify `action` as `panic`, `lock`, or `umount`. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is `panic`.

`quota`

Quotas are turned on for the file system.

`remount`

Remounts a file system with a new set of options. All options not explicitly set with `remount revert` to their default values.

`rq`

Read-write with quotas turned on. Equivalent to `rw`, `quota`.

`xattr | noxattr`

Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See `fsattr(5)` for a description of extended attributes.
-O
  Overlay mount. Allow the file system to be mounted over an existing mount point, making
  the underlying file system inaccessible. If a mount is attempted on a pre-existing mount
  point without setting this flag, the mount will fail, producing the error "device busy".

Examples  EXAMPLE 1  Turning Off (and On) Logging
  The following command turns off logging on an already mounted file system. The subsequent
  command restores logging.

  # mount -F ufs -o remount,nologging /export
  # (absence of message indicates success)
  # mount -F ufs -o remount,logging /export

  In the preceding commands, the -F ufs option is not necessary.

Files  /etc/mnttab
  table of mounted file systems

  /etc/vfstab
  list of default parameters for each file system

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcs</td>
</tr>
</tbody>
</table>

See Also  getfacl(1), fsck(1M), fsck_ufs(1M), lofiadm(1M), mount(1M), mountall(1M), fcntl(2),
mount(2), stat(2), mnttab(4), vfstab(4), attributes(5), fsattr(5), largefile(5)

Notes  Since the root (/) file system is mounted read-only by the kernel during the boot process, only
the remount option (and options that can be used in conjunction with remount) affect the root
(/) entry in the /etc/vfstab file.
Name  mount_xmemfs – mount xmemfs file systems

Synopsis  mount -F xmemfs [generic_options] -o[largebsize,]size=sz
          [-O] special mount_point

Interface Level  xmemfs is obsolete. Users requiring large physical memory should migrate to 64-bit platform support.

Description  xmemfs is an extended memory file system which provides file system semantics to manage and access large amounts of physical memory which can exceed 4 GB in size.

 mount attaches a xmemfs file system to the file system hierarchy at the pathname location mount_point, which must already exist. If mount_point has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the xmemfs filesystem are inherited from the underlying mount_point, provided that those attributes are determinable. If not, the root’s attributes are set to their default values.

The special argument is not currently used by xmemfs but a placeholder, (such as xmem), needs to be specified nevertheless.

Options  See mount(1M) for the list of supported generic_options.

- specific_options  Specify xmemfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

The size=sz specific option is required.

The following options are available:

size=sz  The sz argument specifies the desired size of this particular xmemfs file system. If the sz argument has a k suffix, the number is interpreted as kilobytes. An m suffix is interpreted as megabytes and g is interpreted as gigabytes. A sz specified with no suffix is interpreted as bytes.

In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system or to the large page size if largebsize is specified.

This specific_option is required.

largebsize  If largebsize is specified, xmemfs uses the large memory page size as the file system block size. On IA32, the large memory page size with mmu36 which supports PAE (Physical Address Extension) is 2 MB. The large memory
page size without mmu36/PAE is 4 MB. If there is no large
page support, the file system block size is PAGESIZE.

-0 Overlay mount. Allow the file system to be mounted over an existing
mount point, making the underlying file system inaccessible. If a mount
is attempted on a pre-existing mount point without setting this flag, the
mount fails, producing the error device busy.

Files /etc/mnttab table of mounted file systems

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Interface Stability</td>
<td>Obsolete</td>
</tr>
</tbody>
</table>

See Also mount(1M), mount(2), mkdir(2), open(2), umount(2), mnttab(4), attributes(5), xmemfs(7FS)

Notes If the directory on which a file system is to be mounted is a symbolic link, the file system is
mounted on the directory to which the symbolic link refers, rather than on top of the symbolic
link itself.

The only file types allowed on xmemfs are directories and regular files. The execution of object
files resident in xmemfs is not supported. Execution is prevented by not allowing users to set
execute permissions on regular files.

Support for xmemfs may be removed in a future release of Solaris.
**Name**
mpathadm – multipath discovery and administration

**Synopsis**
mpathadm subcommand direct-object [options] [operand]

**Description**
The `mpathadm` command enables multipathing discovery and management. The `mpathadm` command is implemented as a set of subcommands, many with their own options, that are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS. The `mpathadm` subcommands operate on a `direct-object`. These are described in this section for each subcommand. The `direct-objects`, `initiator-port`, `target-port`, and `logical-unit` in the subcommands are consistent with SCSI standard definitions.

The `mpathadm` command supports the following subcommands, which are described in detail in subsections that follow.

- **list**
  Display a list of discovered instances for a given object.
- **show**
  Display information about a given object instance.
- **modify**
  Modify properties of an object.
- **enable**
  Enable an object.
- **disable**
  Disable an object.
- **failover**
  Cause target port group failover for a logical-unit.
- **override**
  Set a path to be used over other paths on a logical-unit.

The `mpathadm` subcommands operate on a `direct-object`. These are described in this section for each subcommand.

**list Subcommand**
The syntax for the `list` subcommand is:

```
# mpathadm list direct-object [operands...]
```

The `list` subcommand displays data for following direct-objects:

- **mpath-support [mpath-support-name, ...]**
  List the multipathing support that can be administered by this CLI. This presents itself in the form of a library name registered through the MPAPI framework. If no `mpath-support` name `mpath-support-name` is specified, all registered multipathing support libraries will be displayed.

- **initiator-port [initiator-port-name, ...]**
  List the initiator ports that are discovered on this system. If no `initiator-port-name` is specified, all discovered initiator ports are displayed.

- **{logical-unit | lu} [options] [logical-unit-name, ...]**
  List the information on multipath logical units. If no `logical-unit-name` is specified, all discovered logical-units will be displayed.
Options for list logical-unit are as follows:

- **-n, --name name**
  Return the logical unit name that is associated with the given name string. This name can be extracted from the output of the `mpathadm show lu` command.

- **-t, --target-port target-port-name**
  Return the list of logical units names that are associated with the given target-port-name.

**show Subcommand**

The syntax for the `show` subcommand is:

```
# mpathadm show direct-object [operands...]
```

The `show` subcommand displays detailed information for following the direct-objects:

- **mpath-support [mpath-support-name, ...]**
  Show the detailed information on the given `mpath-support-name` if the name exists. If the given `mpath-support-name` supports only a limited set of device products, the list of device products will be listed as part of the output.

- **initiator-port initiator-port-name[, initiator-port-name, ...]**
  Show the detailed information for the given `initiator-port-name`.

- **{logical-unit | lu} [logical-unit-name, ...]**
  Display the detailed information on multipath logical unit(s), including path and target port group information. Note that the name property in the logical unit information represents the identifier for this LUN, derived from the hardware, and used by this system. If the name is derived from SCSI Inquiry Vital Product Data (VPD) page 83h, the name type property represents an associated identifier type defined by the SCSI standards.

**modify Subcommand**

The syntax for the `modify` subcommand is:

```
# mpathadm modify direct-object [options] [operands...]
```

The `modify` subcommand modifies characteristics of the following direct-objects:

- **mpath-support [options] mpath-support-name, ...**
  Configuration management of an `mpath-support`. Options to modify `mpath-support` are as follows:

  - **Set autofallback:**
    Applicable only when `mpath-support` provides auto failback support.

  - **Set autoprobe:**
    Applicable only when `mpath-support` provides auto probing support.

  - **Change loadbalance type:**
    The loadbalance type is one of the
supported types listed in the show mpath-support output.

{logical-unit | lu} [options] logical-unit-name, ...

Configuration management of a logical unit. Options to modify logical-unit are as follows:

Set autofailback on|off
Set autoprobe on|off
Set loadbalance type

Applicable only when mpath-support provides auto failback support
Applicable only when mpath-support provides auto probing support.
Applicable only when load balance configuration is supported at the logical unit level.

enable Subcommand
The syntax for the enable subcommand is:

```
# mpathadm disable [options]
```

The enable subcommand supports the following direct-objects to be enabled:

```
path -i initiator-port-name -t target-port-name -l logical-unit-name
```

The path that consists of the specified initiator port, target port, and logical unit will be enabled.

disable Subcommand
The syntax for the disable subcommand is:

```
# mpathadm disable [options]
```

The disable subcommand supports the following direct-objects to be disabled:

```
path -i initiator-port-name -t target-port-name -l logical-unit-name
```

The path that consists of the specified initiator port, target port, and logical unit will be disabled.

failover Subcommand
The syntax for the failover subcommand is:

```
# mpathadm failover direct-object [operand]
```

The failover subcommand supports failover for the following direct-objects:

```
{logical-unit | lu} logical-unit-name
```

The target port group will failover when the given logical-unit is asymmetric and supports explicit
override Subcommand

The syntax for the override subcommand is:

```
# mpathadm override [options]
```

The `override` subcommand controls whether or not the following direct-objects override another:

```
path [-i initiator-port-name -t target-port-name] [-l logical-unit-name]
```

- Cause a path that consists of the specified initiator port, target port, and logical unit to override other paths on the logical unit. Once a path overrides other paths, the `mpath-support` uses only that path regardless of any other path selection configuration. The `-c` option cancels the setting. The path that consists of the specified initiator port, target port, and logical unit will be disabled.

Options for override path are as follows:

- `-i`, `-initiator-port` *initiator-port-name* Represent the initiator port element of a path. Options `-t` and `-l` must also be included.
- `-t`, `-target-port` *target-port-name* Represent the target port element of a path. Options `-i` and `-l` must also be included.
- `-l`, `-logical-unit` *logical-unit* Represent the logical unit element of a path. Options `-i` and `-t` must also be included.
- `-c`, `-cancel` Cancels overriding setting for the given logical unit. Option `-l` must also be included.

Options

The following options are supported:

- `-V`, `-version` Display the version information.
- `-?, `-help` Display context help. Can be used following an `mpathadm` command with no arguments, following a subcommand, or following a subcommand direct-object combination. Responds with help information appropriate for your entry. For example, if you enter:

```
# mpathadm add mpath-support-help
```

... `mpathadm` responds with a display of the options available for that combination of subcommand and direct-object.
**Examples**

**EXAMPLE 1**  Obtaining a List of Multipathing Support

The following command uses the `list` subcommand to list all currently registered `mpath-support` libraries.

```
# mpathadm list mpath-support
mpath-support: libmpscsi_vhci.so
```

**EXAMPLE 2**  Displaying the Properties of a Particular Multipathing Support

The following command uses the `show` subcommand to display the properties for a currently registered `mpath-support` library.

```
# mpathadm show mpath-support libmpscsi_vhci.so
mpath-support: libmpscsi_vhci.so
  Vendor: Sun Microsystems
  Driver Name: scsi_vhci
  Default Load Balance: round-robin
  Supported Load Balance Types:
    round-robin
    logical-block
  Allows To Activate Target Port Group Access: yes
  Allows Path Override: no
  Supported Auto Failback Config: 1
  Auto Failback: on
  Failback Polling Rate (current/max): 0/0
  Supported Auto Probing Config: 0
  Auto Probing: NA
  Probing Polling Rate (current/max): NA/NA
  Supported Devices:
    Vendor: SUN
    Product: T300
    Revision: 
    Supported Load Balance Types:
      round-robin
    Vendor: SUN
    Product: T4
    Revision: 
    Supported Load Balance Types:
      round-robin
```

**EXAMPLE 3**  Obtaining a List of Initiator Ports Discovered Through the `mpath-support` Libraries

The following command uses the `list initiator-port` subcommand to display a list of initiator ports discovered by the currently registered `mpath-support` libraries.

```
# mpathadm list initiator-port
Initiator-Port: iqn.1986-03.com.sun:01:080020b7ac2b.437a3b3e,400002a0000
Initiator-Port: 2000000173018713
Initiator-Port: 2000000173818713
```
EXAMPLE 4  Displaying the Properties of a Particular Initiator Port

The following command uses the show initiator-port subcommand to display the properties of a particular initiator port discovered using the list initiator-port subcommand in an example above.

```
# mpathadm show initiator-port 2000000173018713
initiator-port: 2000000173018713
  Transport Type: Fibre Channel
  OS device File: devices/pci@1f,4000/pci@2/SUNW,qlca@5/fp@0,0:fc
```

EXAMPLE 5  Displaying the Properties of a Particular Logical Unit

The following command uses the show logical-unit subcommand to display the properties of the logical unit with the specified name.

```
# mpathadm show lu /dev/rdsk/c4t60003bA27D212D004204AC2B000DAB00d0s2
Logical Unit: /dev/rdsk/c4t60003bA27D212D004204AC2B000DAB00d0s2
  mpath-support libmpscsi_vhci.so
  Vendor: SUN
  Product: T4
  Revision: 0301
  Name Type: SCSI Inquiry VPD Page 83 type 3
  Name: 6003ba27d212d004204ac2b000dab00
  Asymmetric: yes
  Current Load Balance: round-robin
  Logical Unit Group ID: NA
  Auto Failback: on
  Auto Probing: NA

Paths:
  Initiator Port Name: 2000000173018713
  Target Port Name: 20030003ba27d212
  Override Path: NA
  Path State: OK
  Disabled: no

  Initiator Port Name: 2000000173018713
  Target Port Name: 20030003ba27d095
  Override Path: NA
  Path State: OK
  Disabled: no

Target Port Group:
  ID: 2
  Explicit Failover: yes
  Access State: standby
  Target Ports:
    Name: 20030003ba27d212
```
EXAMPLE 5  Displaying the Properties of a Particular Logical Unit (Continued)

Relative ID: 0

ID: 5
Explicit Failover: yes
Access State: active
Target Ports
  Name: 20030003ba27d095
  Relative ID: 0

EXAMPLE 6  Enabling a Path

The following command uses the enable path subcommand to enable the path with the specified initiator port, target port, and logical unit.

```
# mpathadm enable path -i 2000000173018713 -t 20030003ba27d095 -l /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
```

EXAMPLE 7  Modifying mpath-support To Turn On autofailback

```
# mpathadm modify mpath-support -a on libmpscsi_vhci.so
```

See Also  mpathadm(1M), libMPAPI(3LIB), exec_attr(4), attributes(5)
mpstat command reports processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot. Each subsequent table summarizes activity for the preceding interval. All values are rates listed as events per second unless otherwise noted.

During execution of the kernel status command, the state of the kernel can change. If relevant, a state change message is included in the mpstat output, in one of the following forms:

<<processor 3 moved from pset: -1 to: 1>>
<<pset destroyed: 1>>
<<pset created: 1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>

The mpstat command reports the following information:

- **CPU or SET** Without the -a option, mpstat reports CPU statistics for a processor ID. With the -a option, mpstat reports SET statistics for a processor set ID.
- **minf** minor faults
- **mjf** major faults
- **xcal** inter-processor cross-calls
- **intr** interrupts
- **ithr** interrupts as threads (not counting clock interrupt)
- **csw** context switches
- **icsw** involuntary context switches
- **migr** thread migrations (to another processor)
- **smtx** spins on mutexes (lock not acquired on first try)
- **srw** spins on readers/writer locks (lock not acquired on first try)
- **syscl** system calls
- **usr** percent user time
- **sys** percent system time
- **wt** the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero.
- **idl** percent idle time
sze number of processors in the requested processor set
set processor set membership of each CPU

Options
The following options are supported:

- **a** Aggregate output by processor set. Sort the output by set. The default output is sorted by CPU number.
- **p** Report processor set membership of each CPU. Sort the output by set. The default output is sorted by CPU number.
- **P set** Display only those processors in the specified set.
- **q** Suppress messages related to state changes.

**interval** Report once each interval seconds.

**count** Only print count reports.

Examples

**EXAMPLE 1** Using `mpstat` to Generate User and System Operation Statistics

The following command generates processor statistics over a five-second interval in two reports. The command shows the processor set membership of each CPU. The default output is sorted by CPU number, aggregated by processor set, for user (usr) and system (sys) operations.

```
example% mpstat -ap 5 2
```

```
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
0  6  0  355  291  190  22  0  0  0  0  43  0  2  0  43  1
1  24 17  534  207  200  70  1  0  2  0  600  4  1  0  84  2
2  19  7  353  325  318  44  0  0  5  0  345  1  1  0  94  3
3  36  2  149  237  236  14  0  0  4  0  97  0  0  0  98  2
```

```
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
0  1  0  720  405  304  55  0  0  18  0  12  0  15  0  81  1
1  0  69 1955  230  200  313  33  4  41  9  7086  34  10  0  19  2

<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Invocation is evolving. Human readable output is unstable.
The sum of CPU utilization might vary slightly from 100 due to rounding errors in the production of a percentage figure.

The total time used for CPU processing is the sum of user and system operations. The \texttt{idl} value reports the time that the CPU is idle for any reason other than pending disk I/O operations.

Run the \texttt{iostat} command with the \texttt{-x} option to report I/O service times in \texttt{svc\_t} output. The \texttt{iostat} utility also reports the same \texttt{wt}, user (\texttt{us}), and system (\texttt{sy}) statistics. See \texttt{iostat(1M)} for more information.

When executing in a zone and if the pools facility is active, \texttt{mpstat(1M)} will only provide information for those processors which are a member of the processor set of the pool to which the zone is bound.
The `msgid` utility generates message IDs. A message ID is a numeric identifier that uniquely identifies a message. Although the probability of two distinct messages having the same ID is high, this can be greatly reduced with the appropriate priority or facility.level designator (see `syslogd(1M)`). Specifically, the message ID is a hash signature on the message’s unexpanded format string, generated by `STRLOG_MAKE_MSGID()` as defined in `<sys/strlog.h>`.

`syslogd(1M)` is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by `syslogd(1M)` includes the message ID. The message ID is intended to serve as a small, language-independent identifier.

**Examples**

**EXAMPLE 1** Using the `msgid` command to generate a message ID

The following example uses the `msgid` command to generate a message ID for the `echo` command.

```
example# echo hello | msgid 205790 hello
```

**EXAMPLE 2** Using the `msgid` command to generate a message catalog

The following example uses the `msgid` command to enumerate all of the messages in the binary `ufs`, to generate a message catalog.

```
example# strings /kernel/fs/ufs | msgid
```

mvdir(1M)

Name    mvdir – move a directory

Synopsis  /usr/sbin/mvdir dirname name

Description  mvdir moves directories within a file system. dirname must be a directory. If name does not exist, it will be created as a directory. If name does exist, and is a directory, dirname will be created as name/dirname. dirname and name may not be on the same path; that is, one may not be subordinate to the other. For example:

example% mvdir x/y x/z

is legal, but

example% mvdir x/y/x/z

is not.

Operands  dirname  The name of the directory that is to be moved to another directory in the filesystem.

ame  The name of the directory into which dirname is to be moved. If name does not exist, it will be created. It may not be on the same path as dirname.

Usage  See largefile(5) for the description of the behavior of mvdir when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status  0  Successful operation.

>0  Operation failed.

Attributes  See attributes(5) for descriptions of the following attributes:

named(1M)

Name
named, in.named – Internet domain name server

Synopsis
named [-fgsVv] [-c config-file] [-d debug-level] [-m flag]
[-n #cpus] [-p port] [-S #max-socks] [-t directory]
[-u user] [-x cache-file] [-4 | -6]

Description
The named utility is a Domain Name System (DNS) server, part of the BIND 9 distribution
from ISC. For more information on the DNS, see RFCs 1033, 1034, and 1035.

When invoked without arguments, named reads the default configuration file
/etc/named.conf, reads any initial data, and listens for queries.

in.named is a link to named.

Options
The following options are supported:

-4
  Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options -4
  and -6 are mutually exclusive.

-6
  Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options -4
  and -6 are mutually exclusive.

-c config-file
  Use config-file as the configuration file instead of the default /etc/named.conf. To ensure
  that reloading the configuration file continues to work after the server has changed its
  working directory due to a possible directory option in the configuration file, config-file
  should be an absolute pathname.

-d debug-level
  Set the daemon’s debug level to debug-level. Debugging traces from named become more
  verbose as the debug level increases.

-f
  Run the server in the foreground (that is, do not run as a daemon).

-g
  Run the server in the foreground and force all logging to stderr.

-m flag
  Turn on memory usage debugging flags. Possible flags are usage, trace, and record, size,
  and mctx. These correspond to the ISC_MEM_DEBUGxxxx flags described in <isc/mem.h>.

-n #cpus
  Create #cpus worker threads to take advantage of multiple CPUs. If not specified, named
  will try to determine the number of CPUs present and create one thread per CPU. If it is
  unable to determine the number of CPUs, a single worker thread will be created.

-p port
  Listen for queries on port port. If not specified, the default is port 53.
-S #max-socks
   Allow named to use up to #max-socks sockets.

   This option should be unnecessary for the vast majority of users. The use of this option could even be harmful, because the specified value might exceed the limitation of the underlying system API. It therefore should be set only when the default configuration causes exhaustion of file descriptors and the operational environment is known to support the specified number of sockets. Note also that the actual maximum number is normally a little smaller than the specified value because named reserves some file descriptors for its internal use.

-s
   Write memory usage statistics to stdout on exit.

   This option is mainly of interest to BIND 9 developers and might be removed or changed in a future release.

-t directory
   Change the root directory using chroot(2) to directory after processing the command line arguments, but before reading the configuration file.

   This option should be used in conjunction with the -u option, as chrooting a process running as root does not enhance security on most systems; the way chroot() is defined allows a process with root privileges to escape a chroot jail.

-u user
   Set the real user ID using setuid(2) to user after completing privileged operations, such as creating sockets that listen on privileged ports.

-V
   Report the version number and build options, and exit.

-v
   Report the version number and exit.

-x cache-file
   Load data from cache-file into the cache of the default view.

   Do not use this option. It is of interest only to BIND 9 developers and might be removed or changed in a future release.

This section describes additional attributes of named.

When starting named from the service management facility, smf(5), named configuration is read from the service configuration repository. Use svccprop(1) to list the properties and svccfg(1M) to make changes.

The following application configuration properties are available to administrators:
options/server
Specifies the server executable to be used instead of the default server, /usr/sbin/named.

options/configuration_file
Specifies the configuration file to be used instead of the default, /etc/named.conf. A directory option might be specified in the configuration file. To ensure that reloading the configuration file continues to work in such a situation, configuration_file should be specified as an absolute pathname. This pathname should not include the chroot_dir pathname. This property is the equivalent of the -c option.

options/ip_interfaces
Specifies over which IP transport, IPv4 or IPv6, BIND will transmit. Possible values are IPv4 or IPv6. Any other setting assumes all, the default. This property is the equivalent of command line option -4 or -6

options/listen_on_port
Specifies the default UDP and TCP port to be used for listening to DNS requests. This property is the equivalent of the command line option -p port.

options/debug_level
Specifies the default debug level. The default is 0, which means no debugging. The higher the number the more verbose debug information becomes. Equivalent of the command line option -d debug_level.

options/threads
Specifies the number of CPU worker threads to create. The default of 0 causes named to try and determine the number of CPUs present and create one thread per CPU. Equivalent of command line option -n #cpus.

options/chroot_dir
Specifies the directory to be used as the root directory after processing SMF properties and the command line arguments but before reading the configuration file. Use this property when using a chroot(2) environment. Synonymous to command line option -t pathname.

When using chroot(2), named is unable to disable itself when receiving rndc(1M) stop or halt commands. Instead, you must use the svcadm(1M) disable command.

In the event of a configuration error originating in one of the above SMF application options, named displays a message providing information about the error and the parameters that need correcting. The process then exits with exit code SMF_EXIT_ERR_CONFIG.

At startup, in the event of an error other than a configuration error, named exits with exit code SMF_EXIT_ERR_FATAL. Both of this code and SMF_EXIT_ERR_CONFIG cause the start method, smf_method(5), to place the service in the maintenance state, which can be observed with the svcs(1) command svcs -x.

In addition to the properties listed above, the following property can be used to invoke named as a user other than root:
**start/user**

Specifies the identity of the user that is invoking named. See `smf_method(5)` and `chroot(2)`. Note that the user must have `solaris.smf.manage.bind` authorization. Without this role the named will be unable to manage its SMF FMRI and named will automatically be restarted by the SMF after an `rndc(1M)` stop or halt command. See EXAMPLES for a sequence of commands that establishes the correct authorization.

**Signals**

In routine operation, signals should not be used to control the nameserver; `rndc(1M)` should be used instead.

**SIGHUP**

Force a reload of the server.

**SIGINT, SIGTERM**

Shut down the server.

The result of sending any other signals to the server is undefined.

**Configuration**

The named configuration file is too complex to describe in detail here. A list of configuration options is provided in the `named.conf` man page shipped with the BIND 9 distribution. A complete description is provided in the `BIND 9 Administrator Reference Manual`.

**Examples**

**Example 1** Configuring named to Transmit Only over IPv4 Networks

The following command sequence configures named such that it will transmit only over IPv4 networks.

```
# svcfg -s svc:network/dns/server:default setprop \ 
> options/ip_interfaces=IPv4
# svcadm refresh svc:network/dns/server:default
```

**Example 2** Listing Current Configuration File and Setting an Alternative File

The following sequence of commands lists the current named configuration file and sets an alternative file.

```
# svcprop -p options/configuration_file dns/server:default /etc/named.conf
# svcfg -s dns/server:default setprop \ 
> options/configuration_file=/var/named/named.conf
# svcadm refresh dns/server:default
# svcprop -p options/configuration_file dns/server:default /var/named/named.conf
```

**Example 3** Establishing Appropriate Authorization for named

To have named start with the `solaris.smf.manage.bind` authorization, perform the steps shown below.

Add the user `dnsadmin` to the `solaris.smf.manage.bind` role:
EXAMPLE 3  Establishing Appropriate Authorization for named  (Continued)

# usermod -A solaris.smf.manage.bind dnsadmin
Observe effect of command:
# tail -1 /etc/user_attr
dnsadmin:::type=normal;auths=solaris.smf.manage.bind

Modify the service properties:

# svccfg
svc:/> select svc:/network/dns/server:default
svc:/network/dns/server:default> setprop start/user = dnsadmin
svc:/network/dns/server:default> setprop start/group = dnsadmin
svc:/network/dns/server:default> exit
# svcadm refresh svc:/network/dns/server:default
# svcadm restart svc:/network/dns/server:default

Because only root has write access to create the default process-ID file, /var/run/named/named.pid, named must be configured to use an alternative path for the user dnsadmin. Here is an example of how to accomplish this:

# mkdir /var/named/tmp
# chown dnsadmin /var/named/tmp

Shown below is what you must add to named.conf to make use of the directory created above.

# head /etc/named.conf
options {
  directory "/var/named";
  pid-file "/var/named/tmp/named.pid";
};

Files  
/etc/named.conf
default configuration file

/var/run/named/named.pid
default process-ID file

The named.conf man page shipped with the BIND 9 distribution
**Name**
named-checkconf – named configuration file syntax checking tool

**Synopsis**
```
named-checkconf [-hjvz] [-t directory] filename
```

**Description**
The `named-checkconf` utility checks the syntax, but not the semantics, of a specified configuration file.

**Options**
The following options are supported:

- `-h`
  Display the usage summary and exit.

- `-j`
  When loading a zonefile, read the journal if it exists.

- `-t directory`
  Change the root directory to `directory` so that include directives in the configuration file are processed as if run by a named configuration whose root directory has been similarly changed.

- `-v`
  Print the version of the `named-checkconf` program and exit.

- `-z`
  Perform a test load of the master zones found in `named.conf`.

**Operands**
The following operands are supported:

- `filename`
  The name of the configuration file to be checked. If not specified, it defaults to `/etc/named.conf`.

**Exit Status**

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No errors were detected.</td>
</tr>
<tr>
<td>1</td>
<td>An error was detected.</td>
</tr>
</tbody>

`named(1M), named-checkzone(1M), attributes(5)`

See the BIND 9 Administrator’s Reference Manual. As of the date of publication of this man page, this document is available at `https://www.isc.org/software/bind/documentation`.
named-checkzone utility checks the syntax and integrity of a zone file. It performs the same checks as named(1M) does when loading a zone. The named-checkzone utility is useful for checking zone files before configuring them into a name server.

named-compilezone is similar to named-checkzone, differing in that it always dumps the zone contents to a specified file in a specified format. Additionally, it applies stricter check levels by default, since the dump output will be used as an actual zone file loaded by named(1M). Unless manually specified otherwise, the check levels must be at least as strict as those specified in the named configuration file.

Options For either or both utilities, the following options are supported:

- `-c class`
  Specify the class of the zone. If not specified, “IN” is assumed.

- `-D`
  Dump zone file in canonical format.

- `-d`
  Enable debugging.

- `-F format`
  Specify the format of the output file specified. Possible formats are text (default) and raw. For named-checkzone, this does not cause any effects unless it dumps the zone contents.

- `-f format`
  Specify the format of the zone file. Possible formats are text (default) and raw.

- `-h`
  Display usage message for named-checkzone.

- `-i mode`
  Perform post-load zone integrity checks. Possible modes are full (default), full-sibling, local, local-sibling, and none.

  Mode full checks that MX records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode local checks only MX records that refer to in-zone hostnames.
Mode full checks that SRV records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode local checks only SRV records that refer to in-zone hostnames.

Mode full checks that delegation NS records refer to A or AAAA record (both in-zone and out-of-zone hostnames). It also checks that glue address records in the zone match those advertised by the child. Mode local checks only NS records that refer to in-zone hostnames or check that some required glue exists, that is, when the nameserver is in a child zone.

Mode full-sibling and local-sibling disable sibling glue checks, but are otherwise the same as full and local, respectively.

Mode none disables the checks.

-k mode
Perform "check-name" checks with the specified failure mode. Possible modes are fail (default for named-compilezone), warn (default for named-checkzone) and ignore.

-j
Read the journal, if it exists, when loading the zone file.

-M mode
Check if an MX record refers to a CNAME. Possible modes are fail, warn (default) and ignore.

-m mode
Specify whether MX records should be checked to see if they are addresses. Possible modes are fail, warn (default) and ignore.

-n mode
Specify whether NS records should be checked to see if they are addresses. Possible modes are fail (default for named-compilezone), warn (default for named-checkzone) and ignore.

-o filename
Write zone output to filename. If filename is - (a hyphen), then write to standard out. The hyphen mandatory for named-compilezone

-q
Run in quiet mode, reporting only the exit status.

-S mode
Check if a SRV record refers to a CNAME. Possible modes are fail, warn (default) and ignore.

-s style
Specify the style of the dumped zone file. Possible styles are full (default) and relative. The full format is most suitable for processing automatically by a separate script. The relative format is more human-readable and is thus suitable for editing by hand. For
named-checkzone

The command named-checkzone checks the zone file named in the file.

Operands

The following operands are supported:

filename

The name of the zone file.

zonename

The domain name of the zone being checked.

Exit Status

0

No errors were detected.

1

An error was detected.

See the BIND 9 Administrator’s Reference Manual. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.
**Name**
ncaconfd – Solaris Network Cache and Accelerator (NCA) configuration daemon

**Synopsis**
/usr/lib/inet/ncaconfd [-a] interface1 [interface2 ...]

**Description**
Use the ncaconfd utility to set up NCA on a system. At boot time, the ncakmod initialization script reads in nca.if(4) to determine on which interface(s) NCA should run. ncaconfd then sets up the interface.

ncaconfd also operates as a daemon if the nca_active key is set to enabled in ncakmod.conf(4) file. In this case, ncaconfd will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connections.

**Options**
The following options are supported:
- `-a` Enable active connections.
- `-l` Enable logging.

**Files**
/etc/nca/ncakmod.conf

**Attributes**

ncheck(1M)

Name  ncheck – generate a list of path names versus i-numbers

Synopsis  ncheck [-F FSType] [-V] [generic_options]
           [-o FSType-specific_options] [special] ...

Description  ncheck with no options generates a path-name versus i-number list of all files on special. If special is not specified on the command line the list is generated for all specials in /etc/vfstab which have a numeric fsckpass. special is the raw device on which the file system exists.

Options  -F  Specify the FSType on which to operate. The FSType should either be specified here or be determinable from /etc/vfstab by finding an entry in the table that has a numeric fsckpass field and an fsckdev that matches special.

-V  Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.

generic_options  Options that are commonly supported by most FSType-specific command modules. The following options are available:

- i  i-list  Limit the report to the files on the i-list that follows. The i-list must be separated by commas with no intervening spaces.

- a  Print the names “.” and “..” which are ordinarily suppressed.

- s  Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy.

-o  Specify FSType-specific_options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the FSType-specific module of the command.

Usage  See largefile(5) for the description of the behavior of ncheck when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Files  /etc/vfstab  list of default parameters for each file system

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  vfstab(4), attributes(5), largefile(5) Manual pages for the FSType-specific modules of ncheck
Notes  This command may not be supported for all FSTypes.
ncheck_ufs(1M)

Name  ncheck_ufs  --  generate pathnames versus i-numbers for ufs file systems

Synopsis  ncheck -F ufs  [generic_options]  [-o m]  [special]...

Description  ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on special. Names of directory files are followed by ‘/’.

Options  See ncheck(1M) for the list of generic_options supported.

- o  Specify ufs file system specific options. The available option is:

 m  Print mode information.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  ff(1M), ncheck(1M), attributes(5)

Diagnostics  When the file system structure is improper, ‘??’ denotes the “parent” of a parentless file and a pathname beginning with ‘.’. ‘.’ denotes a loop.
**Name**  
`ndd` – get and set driver configuration parameters

**Synopsis**  
`ndd [-set] driver parameter [value]`

**Description**  
`ndd` gets and sets selected configuration parameters in some kernel drivers. Currently, `ndd` only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using `ndd`. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only.

If the `-set` option is omitted, `ndd` queries the named `driver`, retrieves the value associated with the specified `parameter`, and prints it. If the `-set` option is given, `ndd` passes `value`, which must be specified, down to the named `driver` which assigns it to the named `parameter`.

By convention, drivers that support `ndd` also support a special read-only `parameter` named `` which can be used to list the parameters supported by the driver.

**Examples**  
**EXAMPLE 1  Getting Parameters Supported By The TCP Driver**
To see which parameters are supported by the TCP driver, use the following command:
```bash
example% ndd /dev/tcp \?
```

The parameter name `` may need to be escaped with a backslash to prevent its being interpreted as a shell meta character.

The following command sets the value of the parameter `ip_forwarding` in the dual stack IP driver to zero. This disables IPv4 packet forwarding.
```bash
example% ndd -set /dev/ip ip_forwarding 0
```

Similarly, in order to disable IPv6 packet forwarding, the value of parameter `ip6_forwarding` can be set to zero.
```bash
example% ndd -set /dev/ip ip6_forwarding 0
```

To view the current IPv4 forwarding table, use the following command:
```bash
example% ndd /dev/ip ipv4_ire_status
```

To view the current IPv6 forwarding table, use the following command:
```bash
example% ndd /dev/ip ipv6_ire_status
```

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
nca
ioctl
attributes
arp
ip
ip6
tcp
udp

The parameters supported by each driver may change from release to release. Like programs that read /dev/kmem, user programs or shell scripts that execute ndd should be prepared for parameter names to change.

The ioctl() command that ndd uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The meanings of many ndd parameters make sense only if you understand how the driver is implemented.

See Also  nca(1), ioctl(2), attributes(5), arp(7P), ip(7P), ip6(7P), tcp(7P), udp(7P)

Notes
The `netservices` command uses the Solaris service management facility, `smf(5)`, to control services that accept over the network from remote clients.

When `netservices` is invoked with the `limited` command-line argument, all network services except the secure shell daemon, `sshd(1M)`, are either disabled or constrained to respond to local requests only.

Invoking `netservices` with the `open` command-line argument enables a large set of network services, as in previous releases of Solaris.

To customize the configuration set enabled by `netservices`, use `svcadm(1M)` to enable or disable individual services. Use `svccfg(1M)` to set properties that determine whether a service accepts input from remote clients. See the man pages for individual services for the names of service instances and their properties.

Note that the `netservices` command has an interface stability of Obsolete.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

The `netstat` command displays the contents of certain network-related data structures in various formats, depending on the options you select.

The `netstat` command has the several forms shown in the SYNOPSIS section, above, listed as follows:

- The first form of the command (with no required arguments) displays a list of active sockets for each protocol.
- The second, third, and fourth forms (-g, -p, and -s options) display information from various network data structures.
- The fifth form (-m option) displays STREAMS memory statistics.
- The sixth form (-i option) shows the state of the interfaces.
- The seventh form (-r option) displays the routing table.
- The eighth form (-M option) displays the multicast routing table.
- The ninth form (-D option) displays the state of DHCP on one or all interfaces.

These forms are described in greater detail below.

With no arguments (the first form), `netstat` displays connected sockets for `PF_INET`, `PF_INET6`, and `PF_UNIX`, unless modified otherwise by the -f option.

### Options

- **-a**
  
  Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.
-f address_family
Limit all displays to those of the specified address_family. The value of address_family can be one of the following:

inet For the AF_INET address family showing IPv4 information.
inet6 For the AF_INET6 address family showing IPv6 information.
unix For the AF_UNIX address family.

-f filter
With -r only, limit the display of routes to those matching the specified filter. A filter rule consists of a keyword:value pair. The known keywords and the value syntax are:

af:{inet/inet6/unix/number} Selects an address family. This is identical to -f address_family and both syntaxes are supported.

{inif|outif}:{name|ifIndex|any|none} Selects an input or output interface. You can specify the interface by name (such as hme0) or by ifIndex number (for example, 2). If any is used, the filter matches all routes having a specified interface (anything other than null). If none is used, the filter matches all routes having a null interface. Note that you can view the index number (ifIndex) for an interface with the -a option of ifconfig(1M).

{src|dst}:{ip-address[/mask]|any|none} Selects a source or destination IP address. If specified with a mask length, then any routes with matching or longer (more specific) masks are selected. If any is used, then all but addresses but 0 are selected. If none is used, then address 0 is selected.

flags:[+ -]?[ABDGHLMSU]+ Selects routes tagged with the specified flags. By default, the flags as specified must be set in order to match. With a leading +, the flags specified must be set but others are ignored. With a leading -, the flags specified must not be set and others are permitted.

You can specify multiple instances of -f to specify multiple filters. For example:

% netstat -nr -f outif:hme0 -f outif:hme1 -f dst:10.0.0.0/8

The preceding command displays routes within network 10.0.0.0/8, with mask length 8 or greater, and an output interface of either hme0 or hme1, and excludes all other routes.
-g  Show the multicast group memberships for all interfaces. If the -v option is included, source-specific membership information is also displayed. See DISPLAYS, below.

-i  Show the state of the interfaces that are used for IP traffic. Normally this shows statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See ifconfig(1M).

-m  Show the STREAMS memory statistics.

-n  Show network addresses as numbers. netstat normally displays addresses as symbols. This option may be used with any of the display formats.

-p  Show the net to media tables. See DISPLAYS, below.

-r  Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the -a option, all routes will be displayed, including cache.

-s  Show per-protocol statistics. When used with the -M option, show multicast routing statistics instead. When used with the -a option, per-interface statistics will be displayed, when available, in addition to statistics global to the system. See DISPLAYS, below.

-v Verbose. Show additional information for the sockets, STREAMS memory statistics, routing table, and multicast group memberships.

-I interface  Show the state of a particular interface. interface can be any valid interface such as hme0 or eri0. Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the -a option, information for the logical interfaces is also reported.

-M  Show the multicast routing tables. When used with the -s option, show multicast routing statistics instead.

-P protocol  Limit display of statistics or state of all sockets to those applicable to protocol. The protocol can be one of ip, ipv6, icmp, icmpv6, icmp, igmpv6, igmp, udp, tcp, rawip. rawip can also be specified as raw. The command accepts protocol options only as all lowercase.

-D  Show the status of DHCP configured interfaces.
This modifier displays extended security attributes for sockets and routing table entries. The -R modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

With -r only, this option displays the routing entries' gateway security attributes. See route(1M) for more information on security attributes.

When displaying socket information using the first form of the command, this option displays additional information for Multi-Level Port (MLP) sockets. This includes:

- The label for the peer if the socket is connected.
- The following flags can be appended to the socket’s “State” output:
  - P The socket is a MLP on zone-private IP addresses.
  - S The socket is a MLP on IP addresses shared between zones.

Operands

interval Display statistics accumulated since last display every interval seconds, repeating forever, unless count is specified. When invoked with interval, the first row of netstat output shows statistics accumulated since last reboot.

The following options support interval: -1, -m, -s and -Ms. Some values are configuration parameters and are just redisplayed at each interval.

count Display interface statistics the number of times specified by count, at the interval specified by interval.

Displays

Active Sockets (First Form) The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol.

The symbolic format normally used to display socket addresses is either:

hostname:port when the name of the host is specified, or

network:port if a socket address specifies a network but no specific host.

The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the hosts or networks database.
If the network or hostname for an address is not known, or if the \(-n\) option is specified, the numerical network address is shown. Unspecified, or “wildcard”, addresses and ports appear as an asterisk (*). For more information regarding the Internet naming conventions, refer to \texttt{inet(7P)} and \texttt{inet6(7P)}.

For SCTP sockets, because an endpoint can be represented by multiple addresses, the verbose option (-v) displays the list of all the local and remote addresses.

TCP Sockets

The possible state values for TCP sockets are as follows:

- **BOUND**: Bound, ready to connect or listen.
- **CLOSED**: Closed. The socket is not being used.
- **CLOSING**: Closed, then remote shutdown; awaiting acknowledgment.
- **CLOSE_WAIT**: Remote shutdown; waiting for the socket to close.
- **ESTABLISHED**: Connection has been established.
- **FIN_WAIT_1**: Socket closed; shutting down connection.
- **FIN_WAIT_2**: Socket closed; waiting for shutdown from remote.
- **IDLE**: Idle, opened but not bound.
- **LAST_ACK**: Remote shutdown, then closed; awaiting acknowledgment.
- **LISTEN**: Listening for incoming connections.
- **SYN_RECEIVED**: Initial synchronization of the connection under way.
- **SYN_SENT**: Actively trying to establish connection.
- **TIME_WAIT**: Wait after close for remote shutdown retransmission.

SCTP Sockets

The possible state values for SCTP sockets are as follows:

- **CLOSED**: Closed. The socket is not being used.
- **LISTEN**: Listening for incoming associations.
- **ESTABLISHED**: Association has been established.
- **COOKIE_WAIT**: INIT has been sent to the peer, awaiting acknowledgment.
- **COOKIE_ECHOED**: State cookie from the INIT-ACK has been sent to the peer, awaiting acknowledgement.
- **SHUTDOWN_PENDING**: SHUTDOWN has been received from the upper layer, awaiting acknowledgement of all outstanding DATA from the peer.
SHUTDOWN_SENT
All outstanding data has been acknowledged in the SHUTDOWN_SENT state. SHUTDOWN has been sent to the peer, awaiting acknowledgement.

SHUTDOWN_RECEIVED
SHUTDOWN has been received from the peer, awaiting acknowledgement of all outstanding DATA.

SHUTDOWN_ACK_SENT
All outstanding data has been acknowledged in the SHUTDOWN_RECEIVED state. SHUTDOWN_ACK has been sent to the peer.

The form of the display depends upon which of the -g, -m, -p, or -s options you select.

- g  Displays the list of multicast group membership.
- m  Displays the memory usage, for example, STREAMS mblk.
- p  Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See arp(1M). For IPv6, the neighbor cache is displayed.
- s  Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for ipForwarding are:
forwarding(1)     Acting as a gateway.
not-forwarding(2)  Not acting as a gateway.

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the -a option is specified with the -s option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

For the second, third, and fourth forms of the command, you must specify at least -g, -p, or -s. You can specify any combination of these options. You can also specify -m (the fifth form) with any set of the -g, -p, and -s options. If you specify more than one of these options, netstat displays the information for each one of them.

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the -I option, it displays information for only the specified interface.

The list consists of the interface name, mtu (maximum transmission unit, or maximum packet size)(see ifconfig(1M)), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.
If the -a option is specified with either the -i option or the -I option, then the output includes names of the physical interface(s), counts for input packets and output packets for each logical interface, plus additional information.

If the -n option is specified, the list displays the IP address instead of the interface name.

If an optional interval is specified, the output will be continually displayed in interval seconds until interrupted by the user or until count is reached. See OPERANDS.

The physical interface is specified using the -I option. When used with the interval operand, output for the -I option has the following format:

<table>
<thead>
<tr>
<th>input packets</th>
<th>eri0 packets</th>
<th>output packets</th>
<th>colls</th>
<th>input packets</th>
<th>(Total) packets</th>
<th>err</th>
<th>packets</th>
<th>colls</th>
</tr>
</thead>
<tbody>
<tr>
<td>227681</td>
<td>0</td>
<td>659471</td>
<td>1</td>
<td>502</td>
<td>261331</td>
<td>0</td>
<td>99597</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>8</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>10</td>
<td>0</td>
<td>2</td>
<td>0</td>
<td>0</td>
<td>10</td>
<td>0</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

If the input interface is not specified, the first interface of address family inet or inet6 will be displayed.

The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The flags column shows the status of the route. These flags are as follows:

- **U**: Indicates route is up.
- **G**: Route is to a gateway.
- **H**: Route is to a host and not a network.
- **M**: Redundant route established with the -multirt option.
- **S**: Route was established using the -setsrc option.
- **D**: Route was created dynamically by a redirect.

If the -a option is specified, there will be routing entries with the following flags:

- **A**: Combined routing and address resolution entries.
- **B**: Broadcast addresses.
- **L**: Local addresses for the host.

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The use column displays the number of packets sent using a combined routing and address resolution (A) or a broadcast (B) route. For a local (L) route, this count is the number of packets...
received, and for all other routes it is the number of times the routing entry has been used to
create a new combined route and address resolution entry.

The interface entry indicates the network interface utilized for the route.

The multicast routing table consists of the virtual interface table and the actual routing table.

The DHCP interface information consists of the interface name, its current state, lease
information, packet counts, and a list of flags.

The states correlate with the specifications set forth in RFC 2131.

Lease information includes:
- when the lease began;
- when lease renewal will begin; and
- when the lease will expire.

The flags currently defined include:

BOOTP The interface has a lease obtained through BOOTP (IPv4 only).
BUSY The interface is busy with a DHCP transaction.
PRIMARY The interface is the primary interface. See dhcpinfo(1) and ifconfig(1M).
FAILED The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received,
and the number of lease offers declined by the DHCP client. All three counters are initialized
to zero and then incremented while obtaining a lease. The counters are reset when the period
of lease renewal begins for the interface. Thus, the counters represent either the number
of packets sent, received, and declined while obtaining the current lease, or the number
of packets sent, received, and declined while attempting to obtain a future lease.

Files /etc/default/inet_type DEFAULT_IP setting

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

protocols(4), services(4), attributes(5), dhcp(5), kstat(7D), inet(7P), inet6(7P)

Droms, R., RFC 2131, Dynamic Host Configuration Protocol, Network Working Group, March
1997.

Notes When displaying interface information, netstat honors the DEFAULT_IP setting in /etc/default/inet_type. If it is set to IP_VERSION4, then netstat will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However, you can override the DEFAULT_IP setting in /etc/default/inet_type on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the inet6 address family or one of the IPv6 protocols, it will override the DEFAULT_IP setting.

If you need to examine network status information following a kernel crash, use the mdb(1) utility on the savecore(1M) output.

The netstat utility obtains TCP statistics from the system by opening /dev/tcp and issuing queries. Because of this, netstat might display an extra, unused connection in IDLE state when reporting connection status.

Previous versions of netstat had undocumented methods for reporting kernel statistics published using the kstat(7D) facility. This functionality has been removed. Use kstat(1M) instead.

netstat restricts its output to information that is relevant to the zone in which netstat runs. (This is true for both shared-IP and exclusive-IP zones.)
netstrategy – return network configuration information

/sbin/netstrategy

The `netstrategy` command determines the network configuration strategy in use on a system and returns information in a form that is easily consumable by a script. The command returns three tokens:

`<root filesystem type> <primary interface> <network config strategy>`

These tokens are described as follows:

- `<root filesystem type>`
  Type of filesystem that contains the bootable kernel, as would be specified in the `fstype` column of the `mnttab(4)`.

- `<primary interface>`
  Name of the primary network interface. For a diskless machine, this is the interface used to load the kernel.

- `<network config strategy>`
  The means by which a system obtains its IP address for booting. This can be one of `rarp`, `dhcp`, or `none`.

The `netstrategy` command is not intended for use on a command line.

Options
The `netstrategy` command has no options.

Exit Status
- `0` Success.
- `!=0` An error occurred.

newaliases – rebuild the database for the mail aliases file

**Synopsis**

`newaliases`

**Description**

`newaliases` rebuilds the random access data base for the mail aliases file `/etc/mail/aliases`

`newaliases` accepts all the flags that `sendmail(1M)` accepts. However, most of these flags have no effect, except for the `-C` option and three of the Processing Options that can be set from a configuration file with the `-o` option:

- `-C/path/to/alt/config/file` Use alternate configuration file.
- `-oAfile` Specify possible alias files.
- `-oLN` Set the default log level to `n`. Defaults to 9.
- `-on` Validate the RHS of aliases when rebuilding the `aliases(4)` database.

`newaliases` runs in verbose mode (`-v` option) automatically.

**Examples**

**Example 1** Running the `newaliases` Command

The following command runs `newaliases` on an alias file different from the `/etc/mail/aliases` default in `sendmail(1M)`:

```bash
example% newaliases -oA/path/to/alternate/alias/file
```

**Exit Status**

`newaliases` returns an exit status describing what it did. The codes are defined in `/usr/include/sysexits.h`.

- `EX_OK` Successful completion on all addresses.
- `EX_NOUSER` User name not recognized.
- `EX_UNAVAILABLE` Catch all. Necessary resources were not available.
- `EX_SYNTAX` Syntax error in address.
- `EX_SOFTWARE` Internal software error, including bad arguments.
- `EX_OSERR` Temporary operating system error, such as “cannot fork”.
- `EX_NOHOST` Host name not recognized.
- `EX_TEMPFAIL` Message could not be sent immediately, but was queued.

**Files**

- `/etc/aliases` Symbolic link to `/etc/mail/aliases`
- `/etc/mail/aliases.pag` Berkeley Database file maintained by `newaliases`
- `/etc/mail/aliases.dir` ndbm files maintained by `newaliases`

newfs(1M)

Name  newfs – construct a UFS file system

Synopsis  

Description  

newfs is a "friendly" front-end to the mkfs(1M) program for making UFS file systems on disk partitions. newfs calculates the appropriate parameters to use and calls mkfs.

If run interactively (that is, standard input is a tty), newfs prompts for confirmation before making the file system.

If the -N option is not specified and the inodes of the device are not randomized, newfs calls fsirand(1M).

You must be super-user or have appropriate write privileges to use this command, except when creating a UFS file system on a diskette. See EXAMPLES.

Creating a Multiterabyte UFS File System

Keep the following limitations in mind when creating a multiterabyte UFS file system:

■ nbpi is set to 1 Mbyte unless you specifically set it higher. You cannot set nbpi lower than 1 Mbyte on a multiterabyte UFS file system.

■ fragsize is set equal to bsize.

Options  

The following options are supported:

-N  Print out the file system parameters that would be used to create the file system without actually creating the file system. fsirand(1M) is not called here.

-S  Sends to stdout a human-readable version of the superblock that would be used to create a filesystem with the specified configuration parameters.

-B  Sends to stdout a binary (machine-readable) version of the superblock that would be used to create a filesystem with the specified configuration parameters.

-T  Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets fragsize to be the same as bsize, and sets nbpi to 1 Mbyte, unless the -i option is used to make it even larger. If you use the -f or -i options to specify a fragsize or nbpi that is incompatible with this option, the user-supplied value of fragsize or nbpi is ignored.

-v  Verbose. newfs prints out its actions, including the parameters passed to mkfs.

mkfs-options  Options that override the default parameters are:

-a apc  The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is 0.
-b bsize

This option is not applicable for disks with EFI labels and is ignored.

The logical block size of the file system in bytes, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size.

-c cgsz

The number of cylinders per cylinder group, ranging from 16 to 256. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by 32. The default value is always between 16 and 256.

mkfs can override this value. See mkfs_ufs(1M) for details.

This option is not applicable for disks with EFI labels and is ignored.

-C maxcontig

The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

\[
\text{maxcontig} = \frac{\text{disk drive maximum transfer size}}{\text{disk block size}}
\]

If the disk drive’s maximum transfer size cannot be determined, the default value for maxcontig is calculated from kernel parameters as follows:

If maxphys is less than ufs_maxmaxphys, which is typically 1 Mbyte, then maxcontig is set to maxphys. Otherwise, maxcontig is set to ufs_maxmaxphys.

You can set maxcontig to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.

You can subsequently change this parameter by using tunefs(1M).

-d gap

Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.

-f fragsize

The smallest amount of disk space in bytes that can be allocated to a file. fragsize must be a power of 2 divisor of bsize, where:
bsize / fragsize is 1, 2, 4, or 8.

This means that if the logical block size is 4096, legal values for fragsize are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

For file systems greater than 1 terabyte or for file systems created with the -T option, fragsize is forced to match block size (bsize).

-i nbpi

The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default for nbpi is as follows:

<table>
<thead>
<tr>
<th>Disk size</th>
<th>Density</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 1 GB</td>
<td>2048</td>
</tr>
<tr>
<td>Less than 2 GB</td>
<td>4096</td>
</tr>
<tr>
<td>Less than 3 GB</td>
<td>6144</td>
</tr>
<tr>
<td>3 GB to 1 Tbyte</td>
<td>8192</td>
</tr>
<tr>
<td>Greater than 1 Tbyte</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of inodes can increase if the file system is expanded with the growths command.

-m free

The minimum percentage of free space to maintain in the file system, between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system.

The default is \((64 \text{ Mbytes/partition size}) \times 100\), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the tunefs(1M) command.
newfs(1M)

The following operands are supported:

- **raw-device**  The name of a raw special device residing in the /dev directory (for example, /dev/rdsk/c0t0d0s6) on which to create the file system.

**Usage**  See largefile(5) for the description of the behavior of newfs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

**Examples**  

**EXAMPLE 1**  Displaying the Parameters for the Raw Special Device

The following example verbosely displays the parameters for the raw special device, c0t0d0s6. It does not actually create a new file system:

```bash
example# newfs -Nv /dev/rdsk/c0t0d0s6
mkfs -F ufs -o N /dev/rdsk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60
2048 t 0 -1 8 /dev/rdsk/c0t0d0s6: 1112940 sectors in
1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl
groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups
(for fsck -b #) at:
```

- **n nrpos**  The number of different rotational positions in which to divide a cylinder group. The default is 8.

This option is not applicable for disks with EFI labels and is ignored.

- **o space | time**  The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is time.

This parameter can subsequently be changed with the tunefs(1M) command.

- **r rpm**  The rotational speed of the disk in revolutions per minute. The default is driver- or device-specific.

Note that you specify rpm for newfs and rps for mkfs.

This option is not applicable for disks with EFI labels and is ignored.

- **s size**  The size of the file system in sectors. The default is to use the entire partition.

- **t ntrack**  The number of tracks per cylinder on the disk. The default is taken from the disk label.

This option is not applicable for disks with EFI labels and is ignored.
EXAMPLE 1  Displaying the Parameters for the Raw Special Device

(Continued)

32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, ...

EXAMPLE 2  Creating a UFS File System

The following example creates a UFS file system on a diskette that is managed by Volume Manager.

eexample% newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /vol/dev/aliases/floppy0: (y/n)? y
/vol/dev/aliases/floppy0: 2880 sectors in 80 cylinders of 2 tracks,
18 sectors 1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 640, 1184, 1792, 2336, ...

EXAMPLE 3  Creating a UFS File System That Will Eventually Be Grown to a Multiterabyte UFS File System

The following example creates a UFS file system that will eventually be grown to a multiterabyte UFS file system.

This command creates a 800-Gbyte file system on the volume, /dev/md/rdsk/d99.

# newfs -T /dev/md/rdsk/d99
newfs: construct a new file system /dev/md/rdsk/d99: (y/n)? y
/dev/md/rdsk/d99: 1677754368 sectors in 45512 cylinders of
144 tracks, 256 sectors
819216.0MB in 1821 cyl groups (25 c/g, 450.00MB/g, 448 i/g)...

Then, if you increase the volume size for this file system, you can use the growfs command to expand the file system. The file system is grown to 1.2 terabytes in this example:

# growfs -v /dev/md/rdsk/d99
/usr/lib/fs/ufs/mkfs -G /dev/md/rdsk/d99 2516631552 /dev/md/rdsk/d99:
2516631552 sectors in 68268 cylinders of 144 tracks, 256 sectors
1228824.0MB in 2731 cyl groups (25 c/g, 450.00MB/g, 448 i/g)...

Exit Status  The following exit values are returned:

0  The operation was successful.

1, 10  Usage error or internal error. A message is output to STDERR explaining the error.

Other exit values may be returned by mkfs(1M), which is called by newfs.

Attributes  See attributes(5) for descriptions of the following attributes:
### See Also

- `fsck(1M)`, `fsck_ufs(1M)`, `fsirand(1M)`, `mkfs(1M)`, `mkfs_ufs(1M)`, `tunefs(1M)`, `attributes(5)`, `largefile(5)`, `ufs(7FS)`

### Diagnostics

- **newfs: No such file or directory**
  
  The device specified does not exist, or a disk partition was not specified.

- **special: cannot open**
  
  You must write access to the device to use this command.
newkey(1M)

Name  newkey – create a new Diffie-Hellman key pair in the public key database

Synopsis  

newkey -h hostname [-s nisplus | nis | files | ldap]
newkey -u username [-s nisplus | nis | files | ldap]

Description  

newkey establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service.

newkey prompts for a password for the given username or hostname and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the /etc/publickey file, the NIS publickey map, or the NIS+ cred.org_dir table.

newkey consults the publickey entry in the name service switch configuration file (see nsswitch.conf(4)) to determine which naming service is used to store the secure RPC keys. If the publickey entry specifies a unique name service, newkey will add the key in the specified name service. However, if there are multiple name services listed, newkey cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the -s option.

In the case of NIS, newkey should be run by the superuser on the master NIS server for that domain. In the case of NIS+, newkey should be run by the superuser on a machine which has permission to update the cred.org_dir table of the new user/host domain.

In the case of NIS+, nisaddcred(1M) should be used to add new keys. newkey cannot be used to create keys other than 192-bit Diffie-Hellman.

In the case of LDAP, newkey should be run by the superuser on a machine that also recognizes the directory manager’s bind distinguished name (DN) and password to perform an LDAP update for the host.

Options  

- h hostname  Create a new public/secret key pair for the privileged user at the given hostname. Prompts for a password for the given hostname.

- u username  Create a new public/secret key pair for the given username. Prompts for a password for the given username.

- s nisplus
- s nis
- s files
- s ldap  Update the database in the specified source: nisplus (for NIS+), nis (for NIS), files, or ldap (LDAP). Other sources may be available in the future.

Attributes  See attributes(5) for descriptions of the following attributes:

**Notes**  
NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit [http://www.sun.com/directory/nisplus/transition.html](http://www.sun.com/directory/nisplus/transition.html).
nfs4cbd - NFS Version 4 callback daemon

**Synopsis**
/usr/lib/nfs/nfs4cbd

**Description**
The `nfs4cbd` daemon manages communication endpoints for the NFS Version 4 protocol callback program. `nfs4cbd` runs on the NFS Version 4 client and creates a listener port for each transport over which callbacks can be sent.

The `nfs4cbd` daemon is provided for the exclusive use of the NFS version 4 client.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnfs3cu</td>
</tr>
</tbody>
</table>

**See Also**
`svis(1), mount_nfs(1M), svcadm(1M), attributes(5), smf(5)`

**Notes**
The `nfs4cbd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/cbd
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M)` and `automountd(1M)` on the first NFSv4 mount, unless its application/auto_enable property is set to false.

This daemon might not exist in a future release of Solaris.
Name  nfsd – NFS daemon

Description  nfsd is the daemon that handles client file system requests. Only users with \{PRIV_SYS_NFS\} and sufficient privileges to write to /var/run can run this daemon.

The nfsd daemon is automatically invoked using \texttt{share(1M)} with the -a option.

By default, nfsd starts over the TCP and UDP transports for versions 2 and 3. By default, it starts over the TCP for version 4. You can change this with the -p option.

A previously invoked nfsd daemon started with or without options must be stopped before invoking another nfsd command.

Administrators wanting to change startup parameters for nfsd should, as root, make changes in the /etc/default/nfs file. See \texttt{nfs(4)}.

Options  The following options are supported:

- -a  Start a NFS daemon over all available connectionless and connection-oriented transports, including UDP and TCP. Equivalent of setting the NFSD_PROTOCOL parameter to ALL in the nfs file.

- -c #_conn  This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited. Equivalent of the NFSD_MAX_CONNECTIONS parameter in the nfs file.

- -l  Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries. Equivalent of the NFSD_LISTEN_BACKLOG parameter in the nfs file.

- -p protocol  Start a NFS daemon over the specified protocol. Equivalent of the NFSD_PROTOCOL parameter in the nfs file.

- -t device  Start a NFS daemon for the transport specified by the given device. Equivalent of the NFSDDEVICE parameter in the nfs file.

Operands  The following operands are supported:

- nservers  This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to nservers threads created as needed in the kernel. nservers should be based on the load expected on this server. 16 is the usual number of nservers. If nservers is not specified, the maximum number of concurrent NFS requests will default to 1. Equivalent of the NFSD SERVERS parameter in the nfs file.
If the `NFS_PORTMON` variable is set in `/etc/system`, then clients are required to use privileged ports (ports < 1PORT_RESERVED) to get NFS services. This variable is equal to zero by default. This variable has been moved from the “nfs” module to the “nfssrv” module. To set the variable, edit the `/etc/system` file and add this entry:

```
set nfssrv:nfs_portmon = 1
```

**Exit Status**

- **0** Daemon started successfully.
- **1**Daemon failed to start.

**Files**

- `.nfsXXX` Client machine pointer to an open-but-unlinked file.
- `/etc/default/nfs` Contains startup parameters for `nfsd`.
- `/etc/system` System configuration information file.
- `/var/nfs/v4_state` Directories used by the server to manage client state information. These directories should not be removed.
- `/var/nfs/v4_oldstate`

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnfsui</td>
</tr>
</tbody>
</table>

**See Also**

- `ps(1)`, `svcs(1)`, `mountd(1M)`, `share(1M)`, `svcadm(1M)`, `nfs(4)`, `sharetab(4)`, `system(4)`, `attributes(5)`, `smf(5)`

*System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*

**Notes**

Manually starting and restarting `nfsd` is not recommended. If it is necessary to do so, use `svcadm` to enable or disable the nfs service (`svc:/network/nfs/server`). If it is disabled, it will be enabled by `share_nfs(1M)`, unless its `application/auto_enable` property is set to `false`. See the *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*, and `svcadm(1M)` for more information.

The `nfsd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If `nfsd` is killed with SIGTERM, it will not be restarted by the service management facility. Instead, `nfsd` can be restarted by other signals, such as SIGINT.
nfslogd(1M)

**Name**

nfslogd – nfs logging daemon

**Synopsis**

/usr/lib/nfs/nfslogd

**Description**

The nfslogd daemon provides operational logging to the Solaris NFS server. It is the nfslogd daemon's job to generate the activity log by analyzing the RPC operations processed by the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the `share_nfs(1M)` command.

NFS server logging is not supported on Solaris machines that are using NFS Version 4.

Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPD daemon. The log format can be extended to include directory modification operations, such as `mkdir`, `rmdir`, and `remove`. The extended format is not compatible with the Washington University FTPD daemon format. See `nfslog.conf(4)` for details.

The NFS server logging mechanism is divided into two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the `/etc/nfs/nfslog.conf` file. Refer to `nfslog.conf(4)` for more information. The second phase involves the nfslogd user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The nfslogd daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the `IDLE_TIME` parameter in `/etc/default/nfslogd`. The work buffers are intended for internal consumption of the nfslogd daemon.

NFS operations use file handles as arguments instead of path names. For this reason the nfslogd daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client.

Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the `fhtable` parameter in the `/etc/nfs/nfslog.conf` file. This database is intended for the internal use of the nfslogd daemon.

In order to keep the size of the file handle mapping database manageable, nfslogd prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The `PRUNE_TIMEOUT` configurable parameter in...
/etc/default/nfslogd specifies the interval length between successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the PRUNE_TIMEOUT as high as INT_MAX.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the PRUNE_TIMEOUT and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the nfslogd daemon. These parameters are found in /etc/default/nfslogd and are described below:

- **UMASK**
  Sets the file mode for the log files, work buffer files and file handle mapping database.

- **MIN_PROCESSING_SIZE**
  Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of MIN_PROCESSING_SIZE must be between 1 and ulimit.

- **IDLE_TIME**
  Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. IDLE_TIME also determines how often the configuration file will be reread. The value of IDLE_TIME must be between 1 and INT_MAX.

- **MAX_LOGS_PRESERVE**
  The nfslogd periodically cycles its logs. MAX_LOGS_PRESERVE specifies the maximum number of log files to save. When MAX_LOGS_PRESERVE is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with filename.0. The oldest file will have the highest numbered extension up to the value configured for MAX_LOGS_PRESERVE. The value of MAX_LOGS_PRESERVE must be between 1 and INT_MAX.

- **CYCLE_FREQUENCY**
  Specifies how often, in hours, the log files are cycled. CYCLE_FREQUENCY is used to insure that the log files do not get too large. The value of CYCLE_FREQUENCY must be between 1 and INT_MAX.

- **MAPPING_UPDATE_INTERVAL**
  Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the atime of a record each time that record is accessed, it is only updated if it has aged based on this
parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and INT_MAX.

**PRUNE_TIMEOUT**

Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than PRUNE_TIMEOUT then the record can be pruned from the database. The default value for PRUNE_TIMEOUT is 168 hours (7 days). The value of PRUNE_TIMEOUT must be between 1 and INT_MAX.

**Exit Status**

The following exit values are returned:

- **0**  Daemon started successfully.
- **1**  Daemon failed to start.

**Files**

/etc/nfs/nfslogtab
/etc/nfs/nfslog.conf
/etc/default/nfslogd

share_nfs(1M), nfslog.conf(4), attributes(5)
nfsmapid (1M)

Name  nfsmapid – NFS user and group id mapping daemon

Synopsis  /usr/lib/nfs/nfsmapid

Description  The nfsmapid daemon maps to and from NFS version 4 owner and owner_group identification attributes and local UID and GID numbers used by both the NFS version 4 client and server.

nfsmapid uses the passwd and group entries in the /etc/nsswitch.conf file to direct how it performs the mappings.

The nfsmapid daemon has no external, customer-accessible interfaces. You can, however, administratively configure nfsmapid in one of the following ways:

- Specify the NFSMAPID_DOMAIN parameter in nfs(4)
- Specify the _nfsv4idmapdomain DNS resource record.

Please refer to the System Administration Guide: Network Services for further details.

Files  /var/run/nfs4_domain Contains the domain name currently used by NFSv4.

Attributes  See attributes(5) for descriptions of the following attributes:

See Also  svs(1), automountd(1M), groupdel(1M), groupmod(1M), mount_nfs(1M), passmgmt(1M), svcadm(1M), share_nfs(1M), userdel(1M), usermod(1M), nfs(4), attributes(5), smf(5)

System Administration Guide: Network Services

Notes  The nfsmapid service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nfs/mapid

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If it is disabled, it will be enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M), unless its application/auto_enable property is set to false.

nfsmapid caches a user's UID and GID. If a user subsequently changes a UID or GID, using one of the utilities listed below, the nfsmapid cache becomes stale. At this point, any NFS operation that gets or sets attributes will result in the exchange of this stale information. To resolve this situation, restart nfsmapid, as follows:

# svcadm restart svc:/network/nfs/mapid:default
The utilities that allow you to change UID and GID are:

- `usermod(1M)`
- `userdel(1M)`
- `groupmod(1M)`
- `groupdel(1M)`
- `passmgmt(1M)`

The `nfsmapid` daemon might not exist in a future release of Solaris.
nfsstat(1M)

**Name**
nfsstat – NFS statistics

**Synopsis**
nfsstat [-cnrsza] [-v version] [interval [count]]
nfsstat -m [pathname]...

**Description**
nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is as follows:

nfsstat -csnra

The default displays everything, but reinitializes nothing.

**Options**

- **-a**
  Display NFS_ACL information.

- **-c**
  Display client information. Only the client side NFS, RPC, and NFS_ACL information is printed. Can be combined with the -n, -r, and -a options to print client side NFS, RPC, and NFS_ACL information only.

- **-m [pathname]...**
  Display statistics for each NFS mounted file system. If pathname is not specified, displays statistics for all NFS mounted file systems. If pathname is specified, displays statistics for the NFS mounted file systems indicated by pathname.

  This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. The dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission.

  If you specify the -m option, this is the only option that nfsstat uses. If you specify other options with -m, you receive an error message alerting that the -m flag cannot be combined with other options.

- **-n**
  Display NFS information. NFS information for both the client and server side are printed. Can be combined with the -c and -s options to print client or server NFS information only.

- **-r**
  Display RPC information.

- **-s**
  Display server information.

- **-v version**
  Specify which NFS version for which to print statistics. When followed by the optional version argument, (2|3|4), specifies statistics for that version. By default, prints statistics for all versions.
Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.

**Operands**
The following operands are supported:

- `count` Display only count reports
- `interval` Report once each interval seconds.
- `pathname` Specify the pathname of a file in an NFS mounted file system for which statistics are to be displayed.

**Displays**
The server RPC display includes the following fields:

- `calls` The total number of RPC calls received.
- `badcalls` The total number of calls rejected by the RPC layer (the sum of `bdlen` and `xdrcall` as defined below).
- `nullrecv` The number of times an RPC call was not available when it was thought to be received.
- `bdlen` The number of RPC calls with a length shorter than a minimum-sized RPC call.
- `xdrcall` The number of RPC calls whose header could not be XDR decoded.
- `dupchecks` The number of RPC calls that looked up in the duplicate request cache.
- `dupreqs` The number of RPC calls that were found to be duplicates.

The server NFS display shows the number of NFS calls received (`calls`) and rejected (`badcalls`), and the counts and percentages for the various calls that were made.

The server NFS_ACL display shows the counts and percentages for the various calls that were made.

The client RPC display includes the following fields:

- `calls` The total number of RPC calls made.
- `badcalls` The total number of calls rejected by the RPC layer.
- `badxids` The number of times a reply from a server was received which did not correspond to any outstanding call.
- `timeouts` The number of times a call timed out while waiting for a reply from the server.
- `newcreds` The number of times authentication information had to be refreshed.
- `badverfs` The number of times the call failed due to a bad verifier in the response.
The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.

The number of times the call failed due to a failure to make a connection to the server.

The number of times the call failed due to a failure to allocate memory.

The number of times the call was interrupted by a signal before completing.

The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.

The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (clgets), the number of times the CLIENT handle cache had no unused entries (cltoomany), as well as a count of the various calls and their respective percentages.

The client NFS_ACL display shows the counts and percentages for the various calls that were made.

The -m option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See mount_nfs(1M).

The following mount flags are set by mount options:

- **sec** has one of the following values:
  - none: No authentication.
  - sys: UNIX-style authentication (UID, GID).
  - short: Short hand UNIX-style authentication.
  - krb5: kerberos v5–style authentication.
  - krb5i: kerberos v5–style authentication with integrity.
  - krb5p: kerberos v5–style authentication with privacy.

- **hard**: Hard mount.
- **soft**: Soft mount.
- **intr**: Intermits allowed on hard mount.
- **nointr**: No interrupts allowed on hard mount.
noac  Client is not caching attributes.
resize  Read buffer size in bytes.
wsiz e Write buffer size in bytes.
retrans  NFS retransmissions.
timeo  Initial NFS timeout, in tenths of a second.
nocto  No close-to-open consistency.
llock  Local locking being used (no lock manager).
grpid  System V group id inheritance.
rpctimesync  RPC time sync.

The following mount flags are internal to the system:

printed  "Not responding” message printed.
down  Server is down.
dynamic  Dynamic transfer size adjustment.
link  Server supports links.
symlink  Server supports symbolic links.
readdir  Use readdir instead of readdirplus.

The following flags relate to additional mount information:

vers  NFS version.
proto  Protocol.

The -m option also provides attribute cache timeout values. The following fields in -m output provide timeout values for attribute cache:

acregmin  Minimum seconds to hold cached file attributes.
acregmax  Maximum seconds to hold cached file attributes.
acdirmin  Minimum seconds to hold cached directory attributes.
acdirmax  Maximum seconds to hold cached directory attributes.

The following fields in -m output provide failover information:

noresponse  How many times servers have failed to respond.
failover  How many times a new server has been selected.
remap  How many times files have been re-evaluated to the new server.
currserver  Which server is currently providing NFS service. See the System Administration Guide: IP Services for additional details.

The fields in -m output shown below provide information on dynamic retransmissions. These items are displayed only where dynamic retransmission is in use.

srtt  The value for the smoothed round-trip time, in milliseconds.
dev  Estimated deviation, in milliseconds.
cur  Current backed-off retransmission value, in milliseconds.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Oracle Solaris 10 08/11 Installation Guide: Basic Installations
System Administration Guide: IP Services
The `nisaddcred` command is used to create security credentials for NIS+ principals. NIS+ credentials serve two purposes. The first is to provide authentication information to various services; the second is to map the authentication service name into a NIS+ principal name.

When the `nisaddcred` command is run, these credentials get created and stored in a table named `cred.org_dir` in the default NIS+ domain. If `domain_name` is specified, the entries are stored in the `cred.org_dir` of the specified domain. The specified domain must either be the one to which you belong, or one in which you are authenticated and authorized to create credentials, that is, a subdomain. Note that the credentials of normal users must be stored in the same domain as their passwords.

It is simpler to add credentials using `nisclient(1M)`, because it obtains the required information itself. `nispopulate(1M)` is used for “bulk” updates and can also be used to add credentials for entries in the `hosts` and the `passwd` NIS+ tables.

NIS+ principal names are used in specifying clients that have access rights to NIS+ objects. For more details, refer to the “Principal Names” subsection of the NIS+(1) manual page. See `nischmod(1), nischown(1), nis_objects(3NSL), and nis_groups(3NSL)`. Various other services can also implement access control based on these principal names.

The `cred.org_dir` table is organized as follows:

<table>
<thead>
<tr>
<th>cname</th>
<th>auth_type</th>
<th>auth_name</th>
<th>public_data</th>
<th>private_data</th>
</tr>
</thead>
<tbody>
<tr>
<td>user1.foo.com.</td>
<td>LOCAL</td>
<td>2990</td>
<td>10,102,44</td>
<td></td>
</tr>
<tr>
<td>user1.foo.com.</td>
<td>DES</td>
<td><a href="mailto:unix.2990@foo.com">unix.2990@foo.com</a></td>
<td>098...819</td>
<td>3b8...ab2</td>
</tr>
<tr>
<td>user1.foo.com.</td>
<td>DHmmm-n</td>
<td><a href="mailto:unix.2990@foo.com">unix.2990@foo.com</a></td>
<td>248...428</td>
<td>a42...f32</td>
</tr>
</tbody>
</table>

The `cname` column contains a canonical representation of the NIS+ principal name. By convention, this name is the login name of a user, or the host name of a machine, followed by a dot (‘.’) followed by the fully qualified “home” domain of that principal. For users, the home domain is defined to be the domain where their DES credentials are kept. For hosts, their home domain is defined to be the domain name returned by the `domainname(1M)` command executed on that host.

There are two basic types of `auth_type` entries in the `cred.org_dir` table, those with authentication type LOCAL, and those with authentication type DES, `auth_type`, specified on the command line in upper or lower case, should be either local or des.
However, the cred.org_dir table may also be used to hold data for other values of auth_type. Currently, this is limited to the mechanisms listed on the nisauthconf(1M) man page, for which the nisaddcred auth_type argument is the same as the name of the mechanism. These mechanisms use a modified form of Secure RPC, and they are similar to the DES authentication type.

If the auth_type is des, and other authentication mechanisms are configured with nisauthconf(1M), then credential entries are added or updated for each mechanism configured. To only add or update 1992-bit Diffie Hellman credentials, that is, those with the auth_type of DES, use dh192-0 on the command line. If there are no authentication mechanisms configured, using des on the command line will only add or update 192-bit Diffie Hellman credentials.

Entries of type LOCAL are used by the NIS+ service to determine the correspondence between fully qualified NIS+ principal names and users identified by UIDs in the domain containing the cred.org_dir table. This correspondence is required when associating requests made using the AUTH_SYS RPC authentication flavor (see rpc_clnt_auth(3NSL)) to a NIS+ principal name. It is also required for mapping a UID in one domain to its fully qualified NIS+ principal name whose home domain may be elsewhere. The principal's credentials for any authentication flavor may then be sought for within the cred.org_dir table in the principal's home domain (extracted from the principal name). The same NIS+ principal may have LOCAL credential entries in more than one domain. Only users, and not machines, have LOCAL credentials. In their home domain, users of NIS+ should have both types of credentials.

The auth_name associated with the LOCAL type entry is a UID that is valid for the principal in the domain containing the cred.org_dir table. This may differ from that in the principal's home domain. The public information stored in public_data for this type contains a list of GIDs for groups in which the user is a member. The GIDs also apply to the domain in which the table resides. There is no private data associated with this type. Neither a UID nor a principal name should appear more than once among the LOCAL entries in any one cred.org_dir table.

The DES auth_type is used for Secure RPC authentication (see secure_rpc(3NSL)).

The authentication name associated with the DES auth_type is a Secure RPC netname. A Secure RPC netname has the form unix.id@domain.com, where domain must be the same as the domain of the principal. For principals that are users the id must be the UID of the principal in the principal's home domain. For principals that are hosts, the id is the host's name. In Secure RPC, processes running under effective UID 0 (root) are identified with the host principal. Unlike LOCAL, there cannot be more than one DES credential entry for one NIS+ principal in the NIS+ namespace.

The public information in an entry of authentication type DES is the public key for the principal. The private information in this entry is the private key of the principal encrypted by the principal's network password.
User clients of NIS+ should have credentials of both types in their home domain. In addition, a principal must have a LOCAL entry in the cred.org_dir table of each domain from which the principal wishes to make authenticated requests. A client of NIS+ that makes a request from a domain in which it does not have a LOCAL entry will be unable to acquire DES credentials. A NIS+ service running at security level 2 or higher will consider such users unauthenticated and assign them the name nobody for determining access rights.

This command can only be run by those NIS+ principals who are authorized to add or delete the entries in the cred table.

If credentials are being added for the caller itself, nisaddcred automatically performs a keylogin for the caller.

You can list the cred entries for a particular principal with nismatch(1).

The cred.org_dir NIS+ table replaces the maps publickeybyname and netidbyname used in NIS (YP).

**Options**

The following options are supported:

- **-p principal**

  The name principal specifies the name of the principal as defined by the naming rules for that specific mechanism. For example, LOCAL credential names are supplied with this option by including a string specifying a UID. For DES credentials, the name should be a Secure RPC netname of the form unix.id@domain.com, as described earlier. If the -p option is not specified, the auth_name field is constructed from the effective UID of the current process and the name of the local domain.

- **-P nis_principal**

  Use the NIS+ principal name nis_principal. This option should be used when creating LOCAL or DES credentials for users whose home domain is different than the local machine’s default domain.

  Whenever the -P option is not specified, nisaddcred constructs a principal name for the entry as follows. When it is not creating an entry of type LOCAL, nisaddcred calls nis_local_principal, which looks for an existing LOCAL entry for the effective UID of the current process in the cred.org_dir table and uses the associated principal name for the new entry. When creating an entry of authentication type LOCAL, nisaddcred constructs a default NIS+ principal name by taking the login name of the effective UID for its own process, and appending to it a dot (‘.’) followed by the local machine’s default domain. If the caller is a superuser, the machine name is used instead of the login name.

- **-l login_password**

  Use the login_password specified as the password to encrypt the secret key for the credential entry. This overrides the prompting for a password from the shell. This option is intended for administration
scripts only. Prompting guarantees not only that no one can see your password on the command line using `ps(1)` but it also checks to make sure you have not made any mistakes. `login_password` does not really have to be the user's password but if it is, it simplifies logging in.

```
-r [nis_principal]
```

Remove all credentials associated with the principal `nis_principal` from the `cred.org_dir` table. This option can be used when removing a client or user from the system. If `nis_principal` is not specified the default is to remove credentials for the current user. If `domain_name` is not specified, the operation is executed in the default NIS+ domain.

Examples

**EXAMPLE 1**  Adding the LOCAL and DES Credentials

The following examples illustrate how to add the LOCAL and DES credentials for some user, `user1`, with a UID of `2990`, who is an NIS+ user principal in the `some.domain.com` NIS+ domain:

```bash
example% nisaddcred -p 2990 -P user1.some.domain.com. local
```

Note that credentials are always added in the `cred.org_dir` table in the domain where `nisaddcred` is run, unless `domain_name` is specified as the last parameter on the command line. If credentials are being added from the domain server for its clients, then `domain_name` should be specified. The caller should have adequate permissions to create entries in the `cred.org_dir` table.

The system administrator can add a DES credential for the same user, using the following example:

```bash
example% nisaddcred -p unix.2990@some.domain.com -P user1.some.domain.com. des
```

Please note that DES credentials can be added only after the LOCAL credentials have been added. Also, if the system is configured to use more than one authentication mechanism, credentials will be made for each mechanism configured. See `nisauthconf(1M)`.

Note that the secure RPC netname does not end with a dot (`.`) while the NIS+ principal name, specified with the `-P` option, does. This command should be executed from a machine in the same domain as is the user.

The following example shows how to add a machine's DES credentials in the same domain:

```bash
example% nisaddcred -p unix.foo@some.domain.com -P foo.some.domain.com. des
```

Please note that no LOCAL credentials are needed in this case.

The following example illustrates how to add a NIS+ workstation's principal DES credential:

```bash
example% nisaddcred -p unix.host1@sub.some.domain.com \   -P newhost.sub.some.domain.com. des sub.some.domain.com.
```
EXAMPLE 1  Adding the LOCAL and DES Credentials  (Continued)

This format is particularly useful if you are running this command from a server which is in a higher domain than sub.some.domain.com. Without the last option for domain name, nisaddcred would fail because it would attempt to use the default domain of some.domain.com.

The following example illustrates adding DES credentials without being prompted for the root login password:

```
example% nisaddcred -p unix.2990@some.domain.com \
    -P user1.some.domain.com. -l login_password des
```

The following example shows how to add a credential for a user using a specific authentication mechanism that was previously configured with nisauthconf(1M). See nisauthconf(1M) for a list of the valid values of auth_type:

```
example% nisaddcred -p unix.2990@some.domain.com \
    -P user1.some.domain.com dh640-0
```

The password should be the same for all the credentials that belong to the user. Otherwise, only the credentials encrypted with the user's password will be used at login, and the user will have to run chkey(1) using the -p option.

The following example shows how to add a DES credential when other authentication mechanisms are configured on the system:

```
example% nisaddcred -p unix.2990@some.domain.com \
    -P user1.some.domain.com dh192-0
```

Exit Status  The following exit values are returned:

0  Successful operation.
1  Operation failed.

Notes  NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
nisaddent – create NIS+ tables from corresponding /etc files or NIS maps

Synopsis
   [nisdomain]
/usr/lib/nis/nisaddent [-D defaults] [-Paprmv] -f file
   [-t table] type [nisdomain]
/usr/lib/nis/nisaddent [-D defaults] [-Parmv] [-t table] -y ypdomain
   [-Y map] type [nisdomain]
/usr/lib/nis/nisaddent -d [-AMoq] [-t table] type
   [nisdomain]

Description
nisaddent creates entries in NIS+ tables from their corresponding /etc files and NIS maps. This operation is customized for each of the standard tables that are used in the administration of Solaris systems. The type argument specifies the type of the data being processed. Legal values for this type are one of aliases, bootparams, ethers, group, hosts, ipnodes, netid, netmasks, networks, passwd, protocols, publickey, rpc, services, shadow, or timezone for the standard tables, or key-value for a generic two-column (key, value) table. For a site specific table, which is not of key-value type, one can use nistbladm(1) to administer it.

The NIS+ tables should have already been created by nistbladm(1), nissetup(1M), or nisserver(1M).

It is easier to use nispopulate(1M) instead of nisaddent to populate the system tables.

By default, nisaddent reads from the standard input and adds this data to the NIS+ table associated with the type specified on the command line. An alternate NIS+ table may be specified with the -t option. For type key-value, a table specification is required.

Note that the data type can be different than the table name (-t). For example, the automounter tables have key-value as the table type.

Although, there is a shadow data type, there is no corresponding shadow table. Both the shadow and the passwd data is stored in the passwd table itself.

Files may be processed using the -f option, and NIS version 2 (YP) maps may be processed using the -y option. The merge option is not available when reading data from standard input.

When a ypdomain is specified, the nisaddent command takes its input from the dbm files for the appropriate NIS map (mail.aliases, bootparams, ethers.byaddr, group.byname, hosts.byaddr, hosts.byname, ipnodes.byaddr, ipnodes.byname, netid.byname, netmasks.byaddr, networks.byname, passwd.byname, protocols.byname, publickey.byname, rpc.bynumber, services.byname, or timezone.byname). An alternate NIS map may be specified with the -Y option. For type key-value, a map specification is required. The map must be in the /var/yp/ypdomain directory on the local machine. Note that ypdomain is case sensitive. ypxfr(1M) can be used to get the NIS maps.
If a nisdomain is specified, nisaddent operates on the NIS+ table in that NIS+ domain, otherwise the default domain is used.

In terms of performance, loading up the tables is fastest when done through the dbm files (-y).

To accommodate other credential entries used by other authentication mechanisms stored in the cred.org_dir table, the publickey dump output has been modified to include a special algorithm type field. This format is incompatible with older versions of nisaddent. To produce dumps that can be read by older versions of nisaddent, or to load dumps created by such older versions, use the -o option.

**Options**

The following options are supported:

- **-a** Add the file or map to the NIS+ table without deleting any existing entries. This option is the default. Note that this mode only propagates additions and modifications, not deletions.

- **-A** All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned.

- **-d** Dump the NIS+ table to the standard output in the appropriate format for the given type. For tables of type key-value, use niscat(1) instead. To dump the cred table, dump the publickey and the netid types.

- **-D defaults** This option specifies a different set of defaults to be used during this operation. The defaults string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

  - **ttl=time** This token sets the default time to live for objects that are created by this command. The value time is specified in the format as defined by the nischttl(1) command. The default is 12 hours.

  - **owner=ownername** This token specifies that the NIS+ principal ownername should own the created object. The default for this value is the principal who is executing the command.

  - **group=groupname** This token specifies that the group groupname should be the group owner for the object that is created. The default is NULL.

  - **access=rights** This token specifies the set of access rights that are to be granted for the given object. The value rights is specified in the format as defined by the nischmod(1) command. The default is

    

```bash
    - - - - rmcdr - - - r - - -
```
-f file
Specify that file should be used as the source of input (instead of the standard input).

-m
Merge the file or map with the NIS+ table. This is the most efficient way to bring an NIS+ table up to date with a file or NIS map when there are only a small number of changes. This option adds entries that are not already in the database, modifies entries that already exist (if changed), and deletes any entries that are not in the source. Use the -m option whenever the database is large and replicated, and the map being loaded differs only in a few entries. This option reduces the number of update messages that have to be sent to the replicas. Also see the -r option.

-M
Master server only. This option specifies that lookups should be sent to the master server. This guarantees that the most up-to-date information is seen at the possible expense that the master server may be busy, or that it may be made busy by this operation.

-o
Use strictly conforming publickey files. Dumps will not add the algorithm type field used by additional authentication mechanisms that might be configured using nisauthconf(1M). 192-bit keys that are dumped using this option can be read by previous versions of nisaddent. However, the algorithm field will be lost and assumed to be "0" when read. Use the -o option when reading publickey files from previous versions of nisaddent to avoid warnings about the missing algorithm field.

-p
Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid (the actual password appears in a shadow file).

-P
Follow concatenation path. This option specifies that lookups should follow the concatenation path of a table if the initial search is unsuccessful.

-q
Dump tables in "quick" mode. The default method for dumping tables processes each entry individually. For some tables, for example, hosts, multiple entries must be combined into a single line, so extra requests to the server must be made. In "quick" mode, all of the entries for a table are retrieved in one call to the server, so the table can be dumped more quickly. However, for large tables, there is a chance that the process will run out of virtual memory and the table will not be dumped.

-r
Replace the file or map in the existing NIS+ table by first deleting any existing entries, and then add the entries from the source (/etc files, or NIS+ maps). This option has the same effect as the -m option. The use of this option is strongly discouraged due to its adverse impact on performance, unless there are a large number of changes.
-t table Specify that table should be the NIS+ table for this operation. This should be a relative name as compared to your default domain or the domainname if it has been specified.

-v Verbose.

-y yppdomain Use the dbm files for the appropriate NIS map, from the NIS domain yppdomain, as the source of input. The files are expected to be on the local machine in the /var/yp/yppdomain directory. If the machine is not an NIS server, use ypxfr(1M) to get a copy of the dbm files for the appropriate map.

-Y map Use the dbm files for map as the source of input.

Examples
EXAMPLE 1 Using nisaddent
This example adds the contents of /etc/passwd to the passwd.org_dir table:

example% cat /etc/passwd | nisaddent passwd

The next example adds the shadow information. Note that the table type here is “shadow”, not “passwd”, even though the actual information is stored in the passwd table:

example% cat /etc/shadow | nisaddent shadow

This example replaces the hosts.org_dir table with the contents of /etc/hosts (in verbose mode):

example% nisaddent -rv -f /etc/hosts hosts

This example merges the passwd map from yppdomain with the passwd.org_dir.nisdomain table (in verbose mode). The example assumes that the /var/yp/myypdomain directory contains the yppasswd map.

example% nisaddent -mv -y myypdomain passwd nisdomain

This example merges the auto.master map from myypdomain with the auto_master.org_dir table:

example% nisaddent -m -y myypdomain -Y auto.master \ 
   -t auto_master.org_dir key-value

This example dumps the hosts.org_dir table:

example% nisaddent -d hosts

This example dumps the ipnodes.org_dir table:

example% nisaddent -d ipnodes

Environment Variables
NIS_DEFAULTS This variable contains a default string that will override the NIS+ standard defaults. If the -D switch is used, those values will then override both the NIS_DEFAULTS variable and the standard defaults. To avoid security
accidents, the access rights in the NIS_DEFAULTS variable are ignored for the passwd table (but access rights specified with -D are used).

**NIS_PATH**

If this variable is set, and neither the nisdomain nor the table are fully qualified, each directory specified in NIS_PATH will be searched until the table is found (see nisdefaults(1)).

**Exit Status**

The following exit values are returned:

- 0  Successful operation.
- 1  Failure caused by an error other than parsing.
- 2  A parsing error occurred on an entry. A parsing error does not cause termination; the invalid entries are simply skipped.

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>

**Notes**

NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
nisauthconf controls which authentication flavors NIS+ should use when communicating with other NIS+ clients and servers. If the command is not executed, then NIS+ will default to the AUTH_DES authentication flavor when running security level 2. See rpc.nisd(1M).

nisauthconf takes a list of authentication mechanism's in order of preference. An authentication mechanism may use one or more authentication flavors listed below. If des is the only specified mechanism, then NIS+ only use AUTH_DES with other NIS+ clients and servers. If des is the first mechanism, then other authentication mechanism's after des will be ignored by NIS+, except for nisaddcred(1M). After changing the mechanism configuration, the keyserv(1M) daemon must be restarted. Note that doing so will remove encryption keys stored by the running keyserv process. This means that a reboot usually is the safest option when the mechanism configuration has been changed.

The following mechanisms are available:

<table>
<thead>
<tr>
<th>Authentication mechanism</th>
<th>Authentication Flavor</th>
</tr>
</thead>
<tbody>
<tr>
<td>des</td>
<td>AUTH_DES</td>
</tr>
<tr>
<td>dh640-0</td>
<td>RPCSEC_GSS using 640-bit Diffie-Hellman keys</td>
</tr>
<tr>
<td>dh1024-0</td>
<td>RPCSEC_GSS using 1024-bit Diffie-Hellman keys</td>
</tr>
</tbody>
</table>

If no mechanisms are specified, then a list of currently configured mechanisms is printed.

**Options**

- **-v** Displays a verbose table listing the currently configured authentication mechanisms.

**Examples**

**EXAMPLE 1** Configuring a System with only RPCSEC_GSS Authentication Flavor

To configure a system to use only the RPCSEC_GSS authentication flavor with 640-bit Diffie-Hellman keys, execute the following as root:

```
example# /usr/lib/nis/nisauthconf dh640-0
```

**EXAMPLE 2** Configuring a System with both RPCSEC_GSS and AUTH_DES Authentication Flavors

To configure a system to use both RPCSEC_GSS (with 640-bit Diffie-Hellman keys) and AUTH_DES authentication flavors:

```
example# /usr/lib/nis/nisauthconf dh640-0 des
```

**EXAMPLE 3** Transitioning to Other Authentication Flavors

The following example can be used while adding credentials for a new mechanism before NIS+ is authenticating with the new mechanism:
EXAMPLE 3  Transitioning to Other Authentication Flavors  (Continued)

example# /usr/lib/nis/nisauthconf des dh640-0

Note that except for nisaddcred(1M), NIS+ will not use mechanisms that follow 'des.'

Exit Status  The following exit values are returned:

0    Successful completion.
1    An error occurred.

Files  /etc/rpcsec/nisplussec.conf  NIS+ authentication configuration file. This file may change or be removed in future versions of Solaris.

Attributes  See attributes(5) for descriptions of the following attributes:

Notes  A NIS+ client of a server that is configured for either dh640-0 or dh1024-0 must run Solaris 7 or later, even if the server is also configured with des.

NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
**nisbackup(1M)**

<table>
<thead>
<tr>
<th>Name</th>
<th>nisbackup – backup NIS+ directories</th>
</tr>
</thead>
</table>
| Synopsis | nisbackup [-v] backup-dir directory...  
|        | nisbackup [-v] -a backup-dir          |
| Description | nisbackup backs up a NIS+ directory object on a NIS+ master server. Updates to the NIS+ database will be temporarily disabled while nisbackup is running. The backup-dir is a UNIX directory that must exist prior to running nisbackup. The nisbackup command can be used to backup an individual NIS+ directory object or all (-a) of the NIS+ directory objects served by a master server. The NIS+ directory objects being backed up will be placed into subdirectories under the backup-dir directory. These subdirectories are named according to the NIS+ directory object they contain. nisbackup operates on individual NIS+ directory objects (for example, org_dir.wiz.com). This allows an administrator to selectively backup specific directories. |
|        | The rpc.nisd(1M) process must be running on the master server with a stable NIS+ database for nisbackup to complete. nisbackup will not attempt to correct any corruption in the NIS+ database, so it is important that backups be done regularly as part of the NIS+ administration. |
|        | The first synopsis is used to backup a single NIS+ directory object or a list of NIS+ directory objects. The objects can be partially qualified or fully qualified. The machine on which the command is executing must be the master for the NIS+ directory objects specified. |
|        | The second synopsis will backup all of the NIS+ directory objects that are served by this master. The -a option is the recommended method of backing up a master server, since it will backup all NIS+ directory objects that are served by this master. If this server is a master server for more than one domain, the backup will include NIS+ directories that belong to all of the domains served. Individual NIS+ directory objects can be selected for restoring from a backup-dir created with the -a option. See nisrestore(1M). |
|        | The -a option only includes directory objects for which this server is the master. It is possible, but not recommended, to configure a master server as a replica for other domains. The objects belonging to those replicated domains will not be backed up with the -a option. The backup of replicated objects must be run on the master server for those objects. |
|        | Do not use the same backup-dir to backup different master servers. Each master server must have its own backup-dir. |
|        | nisbackup will set the rpc.nisd(1M) to read only mode, which will disable updates to the NIS+ database. This is neccessary to ensure the consistency of the backup. For this reason, nisbackup should not be run while large numbers of updates are being applied to the NIS+ database. Update utilities such as nisaddent(1M) should not be run simultaneously with nisbackup. |
Options  
- a  creates a backup of all NIS+ directory objects for which this server is a master.
- v  verbose option. Additional output will be produced and sent to syslog(3C) upon execution of the command (see syslog.conf(4)).

Operands  
backup-dir  the directory into which the subdirectories containing the backed up objects are placed. This must be created prior to running nisbackup.
directory  the NIS+ directory object(s) being backed up.

Examples  
**EXAMPLE 1**  backup of the org_dir NIS+ directory object of the domain foo.com on a master server to a directory named /backup
To backup the org_dir NIS+ directory object of the domain foo.com on a master server to a directory named /backup:

```
master_server# nisbackup /backup org_dir.foo.com.
```

**EXAMPLE 2**  backup of the entire NIS+ domain foo.com to a directory named /backup
To backup the entire NIS+ domain foo.com to a directory named /backup:

```
master_server# nisbackup /backup foo.com.  
          ctx_dir.foo.com.
```

**EXAMPLE 3**  backup of an entire NIS+ database to a backup directory named /backup
To backup an entire NIS+ database to a backup directory named /backup:

```
master_server# nisbackup -a /backup
```

Exit Status  
0  Successful completion.
1  An error occurred.

Files  
/backup-dir/backup_list  this ascii file contains a list of all the objects contained in this backup-dir directory.
/backup-dir/directory-object  a subdirectory that is created in the backup-dir that contains the NIS+ directory-object backup.
/backup-dir/directory-object/data  a subdirectory that contains the data files that are part of the NIS+ directory-object backup.
/backup-dir/directory-object/last upd  this data file contains timestamp information about the directory-object.
/backup-dir/directory-object/data.dict  a NIS+ data dictionary for all of the objects contained in the NIS+ directory-object backup.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>

Notes  NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
nis_cachemgr – NIS+ utility to cache location information about NIS+ servers

Synopsis  
/usr/sbin/nis_cachemgr [-i] [-v]

Description  
The nis_cachemgr daemon maintains a cache of NIS+ directory objects and active servers for domains. It is responsible for locating servers for a domain on behalf of client processes. This improves performance because only one process has to search for servers. The cache contains location information necessary to contact the NIS+ servers. This includes transport addresses, information needed to authenticate the server, and a time to live field which gives a hint on how long the directory object can be cached. The cache helps to improve the performance of the clients that are traversing the NIS+ name space. nis_cachemgr should be running on all the machines that are using NIS+. However, it is not required that the nis_cachemgr program be running in order for NIS+ requests to be serviced.

The cache maintained by this program is shared by all the processes that access NIS+ on a machine. The cache is maintained in a file that is memory mapped by all the processes. See mmap(2). On start up, nis_cachemgr initializes the cache from the cold start file and preserves unexpired entries that already exist in the cache file. See nisinit(1M). Thus, the cache survives machine reboots.

The nis_cachemgr program is normally started from a system startup script. nisshowcache(1M) can be used to look at the cached objects and active servers.

The nisprefadm(1M) command can be used to control which NIS+ servers the nis_cachemgr program will try to select.

The nis_cachemgr program makes NIS+ requests under the NIS+ principal name of the host on which it runs. Before running nis_cachemgr, security credentials for the host should be added to the cred.org_dir table in the host’s domain using nisaddcred(1M). Credentials of type DES will be needed if the NIS+ service is operating at security level 2 (see rpc.nisd(1M)). See the Diagnostics section, below. Additionally, a ”keylogin -r ” should be done on the machine.

svc:/network/rpc/keyserv:default is required for NIS+ operation. See NOTES.

Options  
- i  Force nis_cachemgr to ignore the previous cache file and reinitialize the cache from just the cold start file. By default, the cache manager initializes itself from both the cold start file and the old cache file, thereby maintaining the entries in the cache across machine reboots.

- v  This flag sets verbose mode. In this mode, the nis_cachemgr program logs not only errors and warnings, but also additional status messages. The additional messages are logged using syslog(3C) with a priority of LOG_INFO.

Files  
/var/nis/NIS_SHARED_DIRCACHE  the shared cache file
/var/nis/NIS_COLD_START  the coldstart file
Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

Diagnostics

The nis_cachemgr daemon logs error messages and warnings using syslog(3C). Error messages are logged to the DAEMON facility with a priority of LOG_ERR. Warning messages are logged with a priority of LOG_WARNING. Additional status messages can be obtained using the -v option.

Notes

NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The nis_cachemgr service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/nisplus:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
nisclient(1M)

**Name**
nisclient – initialize NIS+ credentials for NIS+ principals

**Synopsis**
/usr/lib/nis/nisclient -c [-x] [-o] [-v]
   [-l <network_password>] [-d <NIS+_domain>] client_name...

   /usr/lib/nis/nisclient -i [-x] [-v] -h <NIS+_server_host>
   [-a <NIS+_server_addr] [-k <key_domain>] [-d <NIS+_domain>] [-S 0 | 2]

   /usr/lib/nis/nisclient -u [-x] [-v]
   /usr/lib/nis/nisclient -r [-x]

**Description**
The nisclient shell script can be used to:

- create NIS+ credentials for hosts and users
- initialize NIS+ hosts and users
- restore the network service environment

NIS+ credentials are used to provide authentication information of NIS+ clients to NIS+ service.

Use the first synopsis (-c option) to create individual NIS+ credentials for hosts or users. You must be logged in as a NIS+ principal in the domain for which you are creating the new credentials. You must also have write permission to the local "cred" table. The client_name argument accepts any valid host or user name in the NIS+ domain (for example, the client_name must exist in the hosts or passwd table). nisclient verifies each client_name against both the host and passwd tables, then adds the proper NIS+ credentials for hosts or users. Note that if you are creating NIS+ credentials outside of your local domain, the host or user must exist in the host or passwd tables in both the local and remote domains.

By default, nisclient will not overwrite existing entries in the credential table for the hosts and users specified. To overwrite, use the -o option. After the credentials have been created, nisclient will print the command that must be executed on the client machine to initialize the host or the user. The -c option requires a network password for the client which is used to encrypt the secret key for the client. You can either specify it on the command line with the -l option or the script will prompt you for it. You can change this network password later with passwd(1) or chkey(1).

nisclient -c is not intended to be used to create NIS+ credentials for all users and hosts which are defined in the passwd and hosts tables. To define credentials for all users and hosts, use nispopulate(1M).

Use the second synopsis (-i option) to initialize a NIS+ client machine. The -i option can be used to convert machines to use NIS+ or to change the machine’s domainname. You must be logged in as super-user on the machine that is to become a NIS+ client. Your administrator must have already created the NIS+ credential for this host by using nisclient -c or nispopulate -C. You will need the network password your administrator created. nisclient will prompt you for the network password to decrypt your secret key and then for this
machine's root login password to generate a new set of secret/public keys. If the NIS+
credential was created by your administrator using nisclient -c, then you can simply use the
initialization command that was printed by the nisclient script to initialize this host instead
of typing it manually.

To initialize an unauthenticated NIS+ client machine, use the -i option with -S 0. With these
options, the nisclient -i option will not ask for any passwords.

During the client initialization process, files that are being modified are backed up as
files.no_nisplus. The files that are usually modified during a client initialization are:
/etc/defaultdomain, /etc/nsswitch.conf, /etc/inet/hosts, and, if it exists,
/var/nis/NIS_COLD_START. Notice that a file will not be saved if a backup file already exists.

The -i option does not set up a NIS+ client to resolve hostnames using DNS. Please refer to
the DNS documentation for information on setting up DNS. (See resolv.conf(4)).

It is not necessary to initialize either NIS+ root master servers or machines that were installed
as NIS+ clients using suninstall(1M).

Use the third synopsis (-u option) to initialize a NIS+ user. You must be logged in as the user
on a NIS+ client machine in the domain where your NIS+ credentials have been created. Your
administrator should have already created the NIS+ credential for your username using
nisclient -c or nispopulate(1M). You will need the network password your administrator
used to create the NIS+ credential for your username. nisclient will prompt you for this
network password to decrypt your secret key and then for your login password to generate a
new set of secret/public keys.

Use the fourth synopsis (-r option) to restore the network service environment to whatever
you were using before nisclient -i was executed. You must be logged in as super-user on the
machine that is to be restored. The restore will only work if the machine was initialized with
nisclient -i because it uses the backup files created by the -i option.

Reboot the machine after initializing a machine or restoring the network service.

Options The following options are supported:

- **-a <NIS+_server_addr>**
  Specifies the IP address for the NIS+ server. This option is used
  only with the -i option.

- **-c**
  Adds DES credentials for NIS+ principals.

- **-d <NIS+_domain>**
  Specifies the NIS+ domain where the credential should be created
  when used in conjunction with the -c option. It specifies the
  name for the new NIS+ domain when used in conjunction with
  the -i option. The default is your current domain name.

- **-h <NIS+_server_host>**
  Specifies the NIS+ server's hostname. This option is used only
  with the -i option.
-i
  Initializes a NIS+ client machine.

-\<network_password\>
  Specifies the network password for the clients. This option is used
  only with the -c option. If this option is not specified, the script
  will prompt you for the network password.

-k <key_domain>
  This option specifies the domain where root's credentials are
  stored. If a domain is not specified, then the system default
  domain is assumed.

-o
  Overwrites existing credential entries. The default is not to
  overwrite. This is used only with the -c option.

-r
  Restores the network service environment.

-S 0|2
  Specifies the authentication level for the NIS+ client. Level 0 is for
  unauthenticated clients and level 2 is for authenticated (DES)
  clients. The default is to set up with level 2 authentication. This
  is used only with the -i option. nisclient always uses level 2
  authentication (DES) for both -c and -u options. There is no need
  to run nisclient with -u and -c for level 0 authentication. To
  configure authentication mechanisms other than DES at security
  level 2, use nisauthconf(1M) before running nisclient.

-u
  Initializes a NIS+ user.

-v
  Runs the script in verbose mode.

-x
  Turns the “echo” mode on. The script just prints the commands
  that it would have executed. Notice that the commands are not
  actually executed. The default is off.

**Examples**

**EXAMPLE 1** Adding the DES Credential in the Local Domain
To add the DES credential for host sunws and user fred in the local domain:

```
example% /usr/lib/nis/nisclient -c sunws fred
```

**EXAMPLE 2** Adding the DES Credential in a Specified Domain
To add the DES credential for host sunws and user fred in domain xyz.example.com:

```
example% /usr/lib/nis/nisclient -c -d xyz.example.com. sunws fred
```

**EXAMPLE 3** Initializing the Host in a Specific Domain
To initialize host sunws as a NIS+ client in domain xyz.example.com, where
nisplus_server is a server for the domain xyz.example.com:

```
example# /usr/lib/nis/nisclient -i -h nisplus_server -d xyz.example.com
```
### EXAMPLE 3  Initializing the Host in a Specific Domain  (Continued)

The script will prompt you for the IP address of nisplus_server if the server is not found in the /etc/hosts file. The -d option is needed only if your current domain name is different from the new domain name.

### EXAMPLE 4  Initializing the Host as an Unauthenticated Client in a Specific Domain

To initialize host sunws as an unauthenticated NIS+ client in domain xyz.example.com, where nisplus_server is a server for the domain xyz.example.com:

```
example# /usr/lib/nis/nisclient -i -S 0 \
  -h nisplus_server -d xyz.example.com. -a 172.16.44.1
```

### EXAMPLE 5  Initializing the User as a NIS+ principal

To initialize user fred as a NIS+ principal, log in as user fred on a NIS+ client machine.

```
example% /usr/lib/nis/nisclient -u
```

nisinit - NIS+ client and server initialization utility

Synopsis

nisinit -r

nisinit -p Y | D | N parent_domain host...

nisinit -c [-k <key_domain>] -H host | -B | -C coldstart

Description

nisinit initializes a machine to be a NIS+ client or an NIS+ root master server. It may be easier to use nisclient(1M) or nisserver(1M) to accomplish this same task.

Options

- r

Initialize the machine to be a NIS+ root server. This option creates the file /var/nis/data/root.object and initialize it to contain information about this machine. It uses the sysinfo(2) system call to retrieve the name of the default domain.

To initialize the machine as an NIS+ root server, it is advisable to use the “-r” option of nisserver(1M), instead of using “nisinit -r”.

- p Y | D | N parent_domain host...

This option is used on a root server to initialize a /var/nis/data/parent.object to make this domain a part of the namespace above it. Only root servers can have parent objects. A parent object describes the namespace “above” the NIS+ root. If this is an isolated domain, this option should not be used. The argument to this option tells the command what type of name server is serving the domain above the NIS+ domain. When clients attempt to resolve a name that is outside of the NIS+ namespace, this object is returned with the error NIS_FOREIGNNS indicating that a name space boundary has been reached. It is up to the client to continue the name resolution process.

The parameter parent_domain is the name of the parent domain in a syntax that is native to that type of domain. The list of host names that follow the domain parameter are the names of hosts that serve the parent domain. If there is more than one server for a parent domain, the first host specified should be the master server for that domain.

Y Specifies that the parent directory is a NIS version 2 domain.
D specifies that the parent directory is a DNS domain.

N specifies that the parent directory is another NIS+ domain. This option is useful for connecting a pre-existing NIS+ subtree into the global namespace.

Note that in the current implementation, the NIS+ clients do not take advantage of the -p feature. Also, since the parent object is currently not replicated on root replica servers, it is recommended that this option not be used.

-c initializes the machine to be a NIS+ client. There are three initialization options available: initialize by coldstart, initialize by hostname, and initialize by broadcast. The most secure mechanism is to initialize from a trusted coldstart file. The second option is to initialize using a hostname that you specify as a trusted host. The third method is to initialize by broadcast and it is the least secure method.

-C coldstart causes the file coldstart to be used as a prototype coldstart file when initializing a NIS+ client. This coldstart file can be copied from a machine that is already a client of the NIS+ namespace. For maximum security, an administrator can encrypt and encode (with uuencode(1C)) the coldstart file and mail it to an administrator bringing up a new machine. The new administrator would then decode (with uudecode), decrypt, and then use this file with the nisinit command to initialize the machine as an NIS+ client. If the coldstart file is from another client in the same domain, the nisinit command may be safely skipped and the file copied into
the /var/nis directory as /var/nis/NIS_COLD_START.

-H hostname  Specifies that the host hostname should be contacted as a trusted NIS+ server. The nisinit command will iterate over each transport in the NETPATH environment variable and attempt to contact `rpcbind(1M)` on that machine. This hostname must be reachable from the client without the name service running. For IP networks this means that there must be an entry in /etc/hosts for this host when nisinit is invoked.

-B  Specifies that the nisinit command should use an IP broadcast to locate a NIS+ server on the local subnet. Any machine that is running the NIS+ service may answer. No guarantees are made that the server that answers is a server of the organization's namespace. If this option is used, it is advisable to check with your system administrator that the server and domain served are valid. The binding information can be dumped to the standard output using the `nisshowcache(1M)` command.

Note that `nisinit -c` will just enable navigation of the NIS+ name space from this client. To make NIS+ your name service, modify the file `/etc/nsswitch.conf` to reflect that. See `nsswitch.conf(4)` for more details.

-k <key_domain>  This option specifies the domain where root's credentials are stored. If it is not specified, then the system default domain is assumed. This domain name is used to create the
nisinit returns 0 on success and 1 on failure.

**Examples**

**EXAMPLE 1** Initializing the Machine as an NIS+ Client using the Host freddy as a Trusted Server
This example initializes the machine as an NIS+ client using the host freddy as a trusted server.

```
example# nisinit -cH freddy
```

**EXAMPLE 2** Setting up a Client using a Trusted Coldstart File
This example sets up a client using a trusted coldstart file.

```
example# nisinit -cC /tmp/colddata
```

**EXAMPLE 3** Setting up a Client Using an IP Broadcast
This example sets up a client using an IP broadcast.

```
example# nisinit -cB
```

**EXAMPLE 4** Setting up a Root Server
This example sets up a root server.

```
example# nisinit -r
```

**Environment Variables**

- **NETPATH**
  This environment variable may be set to the transports to try when contacting the NIS+ server (see `netconfig(4)`). The client library will only attempt to contact the server using connection oriented transports.

**Files**

- **/var/nis/NIS_COLD_START**
  This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machine's default domain.

- **/var/nis/data/root.object**
  This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the `nis_modify()` interface.

- **/var/nis/data/parent.object**
  This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.

- **/etc/hosts**
  Internet host table.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

**Notes**

NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
nisldapmaptest(1M)

Name  nisldapmaptest – test NIS+ and LDAP mapping configuration files

Synopsis nisldapmaptest [-s | -r | -d] [-l | -t object] [-v] [-i]
               [-o] [-m conffile] [-x attr=val...] [ col=val]

Description Use the nisldapmaptest utility to test NIS+ to LDAP mapping configuration files. See NIS+LDAPmapping(4). The nisldapmaptest utility uses much of the same internal interface as the rpc.nisd(1M) does to read, add, modify, or delete LDAP data, as specified by the column name and value operand pairs. nisldapmaptest does not read or modify any of the rpc.nisd(1M) database files.

See Notes for details on important differences between the ways that nisldapmaptest and rpc.nisd(1M) operate on LDAP data.

Options The nisldapmaptest utility supports the following options:

- d  Delete data in LDAP.
- i  Ignore failures when obtaining information from the NIS+ server. This enables nisldapmaptest to work to some extent, even if the NIS+ server is unreachable, or if the system is not a NIS+ client. However, NIS+ lookups are still attempted, so there may be NIS+ error messages.

In this mode, nisldapmaptest also tries to guess things such as NIS+ object types and derives table column information from the mapping rules in the configuration files. Avoid using the -i option to add, modify, or delete, until you have determined that the nisldapmaptest’s guesses are adequate for your needs.

- l  Parse the configuration file into internal data structures, and then print out the configuration per those structures. Note that the printed data is not in configuration file format.

Either -l or -t must be specified. If both are present, -l is ignored.

- m conffile Specify the name of the NIS+LDAPmapping(4) configuration file. The default directory is /var/nis, and the default mapping file is NIS+LDAPmapping.

- o  For NIS+ tables, work on the NIS+ object itself, specified by means of the -t option, not on the table entries.

- r  Replace or add data in LDAP.
- s  Search for data in LDAP. This is the default.

- t object Specify the NIS+ object on which to operate. If the object name is not fully qualified, that is, it does not end in a dot, the value of the nisplusLDAPbaseDomain attribute is appended.

- v  Set the verbose flag. This flag produces extra diagnostic information.
-x attr=val... Specify mapping attribute and value pairs to override those obtained by means of the configuration file. Although any attributes defined on NIS+LDAPmapping(4) or rpc.nisd(4) can be specified, the ones that control rpc.nisd(1M) operation have no effect on nisldapmaptest.

Operands The following operands are supported:

col=val... NIS+ column and value pairs used to specify which entries should be looked up, added, modified, or deleted. For additions and modifications, use col=val to specify the new values.

Examples

EXAMPLE 1 Searching for a User
Use the following example to search for the user xyzzy in the LDAP container specified for the passwd.org_dir table.

example% nisldapmaptest -t passwd.org_dir name=xyzzy

EXAMPLE 2 Listing Table Entries
Use the following example to list all entries in the container specified for the services.org_dir table.

example% nisldapmaptest -t services.org_dir

EXAMPLE 3 Listing an Object
Use the following example to list the services.org_dir object itself, as it is stored in LDAP.

example% nisldapmaptest -o -t services.org_dir

EXAMPLE 4 Modifying a Table Entry
Use the following example to modify the membership list of the group grp, in the container specified for the group.org_dir table, to be mem1, mem2, and mem3.

example% nisldapmaptest -r -t group.org_dir name=grp \ members=mem1,mem2,mem3

EXAMPLE 5 Deleting a Table Entry
Use the following example to delete the host called bad from the container specified for the hosts.org_dir table.

example% nisldapmaptest -d -t hosts.org_dir name=bad

Exit Status The following exit values are returned:

0 The requested operation was successful.
!= 0 An error occurred.
### Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

</tr>
</tbody>
</table>

### See Also

rpc.nisd(1M), NIS+LDAPmapping(4), rpc.nisd(4), attributes(5)

### Notes

There are several differences between the ways that nisldapmaptest and rpc.nisd operate:

1. nisldapmaptest obtains information about NIS+ by means of the NIS+ API calls, while rpc.nisd looks in its internal database. Thus, if the NIS+ server is not available, nisldapmaptest may be unable to determine NIS+ object types or table column information.

2. While nisldapmaptest can add, modify, or delete LDAP data, it does not modify any NIS+ data.

3. When operating on table entries, if nisldapmaptest is unable to obtain the entry from NIS+, it composes LDAP operations using only the supplied col=val operands. Depending on the mapping used, this can result in extra LDAP operations, for example, attempting to obtain a DN for add, modify, or delete.

4. The default value for nisplusLDAPbaseDomain is the system domain name per sysinfo(2) in nisldapmaptest, but the internal notion of the domain it serves in rpc.nisd. While the two usually are the same, this is not necessarily always the case.

5. When more than one NIS+ entry maps to a single LDAP entry, nisldapmaptest may be unable to perform a complete update, unless you make sure that the col=val specification picks up all relevant NIS+ entries. For example, if you have the services.org_dir NIS+ entries:

<table>
<thead>
<tr>
<th>cname</th>
<th>name</th>
<th>proto</th>
<th>port</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>x</td>
<td>tcp</td>
<td>12345</td>
</tr>
<tr>
<td>x</td>
<td>y</td>
<td>tcp</td>
<td>12345</td>
</tr>
<tr>
<td>x</td>
<td>z</td>
<td>tcp</td>
<td>12345</td>
</tr>
</tbody>
</table>

then specifying cname=x will pick up all three entries and create or modify the corresponding LDAP entry to have three CN values: x, y, and z. However, specifying name=x will match just the first NIS+ entry, and create or modify the LDAP entry to have just one CN: x.
nislog(1M)

**Name**

nislog – display the contents of the NIS+ transaction log

**Synopsis**

/usr/sbin/nislog [-h num | -t num] [-v] [directory]...

**Description**

nislog displays the contents of the NIS+ server transaction log on the standard output. This command can be used to track changes in the namespace. The /var/nis/trans.log file contains the transaction log maintained by the NIS+ server. When updates occur, they are logged to this file and then propagated to replicas as log transactions. When the log is checkpointed, updates that have been propagated to the replicas are removed.

The nislog command can only be run on an NIS+ server by superuser. It displays the log entries for that server only.

If directory is not specified, the entire log is searched. Otherwise, only those logs entries that correspond to the specified directories are displayed.

**Options**

- **-h num**  
  Display num transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.

- **-t num**  
  Display num transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.

- **-v**  
  Verbose mode.

**Files**

/var/nis/trans.log  transaction log

**Attributes**

**Notes**

NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
nisping(1M)

Name
nisping – send ping to NIS+ servers

Synopsis
/usr/lib/nis/nisping [-uf] [-H hostname] [-r directory]
/usr/lib/nis/nisping -C [-a] [-H hostname] [directory]

Description
In the first Synopsis line, the nisping command sends a “ping” to all replicas of an NIS+ directory. Once a replica receives a ping, it will check with the master server for the directory to get updates. Prior to pinging the replicas, this command attempts to determine the last update “seen” by a replica and the last update logged by the master. If these two timestamps are the same, the ping is not sent. The -f (force) option will override this feature.

Under normal circumstances, NIS+ replica servers get the new information from the master NIS+ server within a short time. Therefore, there should not be any need to use nisping.

In the second Synopsis line, the nisping -C command sends a checkpoint request to the servers. If no directory is specified, the home domain, as returned by nisdefaults(1), is checkpointed. If all directories, served by a given server, have to be checkpointed, then use the -a option.

On receiving a checkpoint request, the servers would commit all the updates for the given directory from the table log files to the database files. This command, if sent to the master server, will also send updates to the replicas if they are out of date. This option is needed because the database log files for NIS+ are not automatically checkpointed. nisping should be used at frequent intervals (such as once a day) to checkpoint the NIS+ database log files. This command can be added to the crontab(1) file. If the database log files are not checkpointed, their sizes will continue to grow.

If the server specified by the -H option does not serve the directory, then no ping is sent.

Per-server and per-directory access restrictions may apply; see nisopaccess(1). nisping uses NIS_CPTIME and NIS_PING (resync (ping) of replicas), or NIS_CHECKPOINT (for checkpoint). Since the NIS_PING operation does not return a status, the nisping command is typically unable to indicate success or failure for resyncs.

Options
- a Checkpoint all directories on the server.
- C Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.
- H hostname Only the host hostname is sent the ping, checked for an update time, or checkpointed.
- f Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.
- r This option can be used to update or get status about the root object from the root servers, especially when new root replicas are added or deleted from the list.
If used without -u option, -r will send a ping request to the servers serving the root domain. When the replicas receive a ping, they will update their root object if needed.

The -r option can be used with all other options except with the -C option; the root object need not be checkpointed.

- u Display the time of the last update; no servers are sent a ping.

Return Values

-1 No servers were contacted, or the server specified by the -H switch could not be contacted.

0 Success.

1 Some, but not all, servers were successfully contacted.

Examples

**EXAMPLE 1 Using nisping**

This example pings all replicas of the default domain:

example% nisping

Note that this example will not ping the org_dir and groups_dir subdirectories within this domain.

This example pings the server example which is a replica of the org_dir.foo.com. directory:

example% nisping -H example org_dir.foo.com.

This example checkpoints all servers of the org_dir.bar.com. directory.

example% nisping -C org_dir.bar.com.

Environment Variables

**NIS_PATH** If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found.

Attributes

nispopulate – populate the NIS+ tables in a NIS+ domain

Synopsis
[-S 0 | 2] [-l <network_passwd>]
[-d <NIS+ domain>] -h <NIS_server_host>
[-a <NIS_server_addr>] -y <NIS_domain>
[table] ...

[-p <directory_path>] [-l <network_passwd>]
[-d <NIS+ domain>] [-s <directory_path>]
[table] ...

/usr/lib/nis/nispopulate -C [-x] [-f] [-v]
[-d <NIS+ domain>] [-s <directory_path>]
[hosts | passwd]

Description
The nispopulate shell script can be used to populate NIS+ tables in a specified domain from their corresponding files or NIS maps. nispopulate assumes that the tables have been created either through nisserver(1M) or nissetup(1M).

The table argument accepts standard names that are used in the administration of Solaris systems and non-standard key-value type tables. See nisaddent(1M) for more information on key-value type tables. If the table argument is not specified, nispopulate will automatically populate each of the standard tables. These standard (default) tables are: auto_master, auto_home, ethers, group, hosts, ipnodes, networks, passwd, protocols, services, rpc, netmasks, bootparams, netgroup, aliases and shadow. Note that the shadow table is only used when populating from files. The non-standard tables that nispopulate accepts are those of key-value type. These tables must first be created manually with the nistbladm(1) command.

Use the first synopsis (-Y) to populate NIS+ tables from NIS maps. nispopulate uses ypxfr(1M) to transfer the NIS maps from the NIS servers to the /var/yp/<NIS_domain> directory on the local machine. Then, it uses these files as the input source. Note that <NIS_domain> is case sensitive. Make sure there is enough disk space for that directory.

Use the second synopsis (-F) to populate NIS+ tables from local files. nispopulate will use those files that match the table name as input sources in the current working directory or in the specified directory.

Note that when populating the hosts, ipnodes, and passwd tables, nispopulate will automatically create the NIS+ credentials for all users and hosts (ipnodes) that are defined in the hosts, ipnodes, and passwd tables, respectively. A network passwd is required to create these credentials. This network password is used to encrypt the secret key for the new users and hosts. This password can be specified using the -l option or it will use the default password, nisplus. nispopulate will not overwrite any existing credential entries in the credential table. Use nisclient(1M) to overwrite the entries in the cred table. It creates both LOCAL and DES credentials for users, and only DES credentials for hosts. To disable automatic credential creation, specify the “-S 0” option.
The third synopsis (-C) is used to populate NIS+ credential table with level 2 authentication (DES) from the hosts, ipnodes and passwd tables of the specified domain. The valid table arguments for this operation are hosts, ipnodes and passwd. If this argument is not specified then it will use hosts, ipnodes and passwd as the input source. If other authentication mechanisms are configured using nisauthconf(1M), the NIS+ credential table will be loaded with credentials for those mechanisms.

If nispopulate was earlier used with " -S 0" option, then no credentials were added for the hosts or the users. If later the site decides to add credentials for all users and hosts, then this (-C) option can be used to add credentials.

Options
- `a <NIS_server_addr>` Specifies the IP address for the NIS server. This option is only used with the -Y option.
- `-C` Populate the NIS+ credential table from hosts, ipnodes, and passwd tables using DES authentication (security level 2). If other authentication mechanisms are configured using nisauthconf(1M), the NIS+ credential table will be populated with credentials for those mechanisms.
- `-d <NIS+_domain.>` Specifies the NIS+ domain. The default is the local domain.
- `-F` Populates NIS+ tables from files.
- `-f` Forces the script to populate the NIS+ tables without prompting for confirmation.
- `-h <NIS_server_host>` Specifies the NIS server hostname from where the NIS maps are copied from. This is only used with the -Y option. This hostname must be present in the NIS+ hosts or ipnodes table, or in the /etc/hosts file. If the hostname is not defined, the script will prompt you for its IP address, or you can use the -a option to specify the address manually.
- `-l <network_passwd>` Specifies the network password for populating the NIS+ credential table. This is only used when you are populating the hosts, ipnodes, and passwd tables. The default passwd is "nisplus".
- `-n` Does not overwrite local NIS maps in /var/yp/<NISdomain> directory if they already exist. The default is to overwrite the existing NIS maps in the local /var/yp/<NISdomain> directory. This is only used with the -Y option.
- `-p <directory_path>` Specifies the directory where the files are stored. This is only used with the -F option. The default is the current working directory.
- `-S 0|2` Specifies the authentication level for the NIS+ clients. Level 0 is for unauthenticated clients and no credentials will be created for users and hosts in the specified domain. Level 2 is for authenticated clients.
(DES) clients and DES credentials will be created for users and hosts in the specified domain. The default is to set up with level 2 authentication (DES). There is no need to run nispopulate with -C for level 0 authentication. Also, if other authentication mechanisms are configured with nisauthconf(1M), credentials for those mechanisms will also be populated for the NIS+ clients.

-\textbf{u}\ \textit{updates the NIS+ tables (ie., adds, deletes, modifies) from either files or NIS maps. This option should be used to bring an NIS+ table up to date when there are only a small number of changes. The default is to add to the NIS+ tables without deleting any existing entries. Also, see the }\textbf{-n}\textit{ option for updating NIS+ tables from existing maps in the }\texttt{/var/yp}\textit{ directory.}

-\textbf{v}\ \textit{Runs the script in verbose mode.}

-\textbf{x}\ \textit{Turns the “echo” mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.}

-\textbf{Y}\ \textit{Populate the NIS+ tables from NIS maps.}

-\textbf{y }\texttt{<NIS\_domain>}\ \textit{Specifies the NIS domain to copy the NIS maps from. This is only used with the }\textbf{-Y}\textit{ option. The default domainname is the same as the local domainname.}

**Examples**

**EXAMPLE 1** \textbf{Using nispopulate}

To populate all the NIS+ standard tables in the domain \texttt{xyz.sun.com} from NIS maps of the \texttt{yp.sun.COM} domain as input source where host \texttt{yp\_host} is a YP server of \texttt{yp.sun.COM}:

\begin{verbatim}
\end{verbatim}

To update all of the NIS+ standard tables from the same NIS domain and hosts shown above:

\begin{verbatim}
nis_server# /usr/lib/nis/nispopulate -Y -u -y yp.sun.COM -h yp_host \\
-d xyz.sun.com.
\end{verbatim}

To populate the hosts table in domain \texttt{xyz.sun.com} from the hosts file in the \texttt{/var/nis/files} directory and using \texttt{somepasswd} as the network password for key encryption:

\begin{verbatim}
nis_server# /usr/lib/nis/nispopulate -F -p \\
/var/nis/files -l somepasswd hosts
\end{verbatim}

To populate the passwd table in domain \texttt{xyz.sun.com} from the passwd file in the \texttt{/var/nis/files} directory without automatically creating the NIS+ credentials:
EXAMPLE 1 Using nispopulate (Continued)

nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files \
-d xys.sun.com. -S 0 passwd

To populate the credential table in domain xyz.sun.com. for all users defined in the passwd table.

nis_server# /usr/lib/nis/nispopulate -C -d xys.sun.com. passwd

To create and populate a non-standard key-value type NIS+ table, private, from the file /var/nis/files/private: (nispopulate assumes that the private.org_dir key-value type table has already been created).

nis_server# /usr/bin/nistbladm -D access=og=rmcd,nw=r \ 
-c private key=$,nogw= value=,nogw= private.org.dir
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files private

nispopulate normally creates temporary files in the directory /tmp. You may specify another directory by setting the environment variable TMPDIR to your chosen directory. If TMPDIR is not a valid directory, then nispopulate will use /tmp).

Environment Variables

Files

/etc/inet/hosts local database associating names of nodes with IP addresses
/var/yp NIS (YP) domain directory
/var/nis NIS+ domain directory
/tmp

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
nisprefadm(1M)

Name  nisprefadm – NIS+ utility to set server preferences for NIS+ clients

Synopsis
/usr/bin/nisprefadm -a {-L | -G} [-o opt-string]
    [-d domain] [-C client] server...
/usr/bin/nisprefadm -m {-L | -G} [-o opt-string]
    [-d domain] [-C client] oldserver=newserver...
/usr/bin/nisprefadm -r {-L | -G} [-o opt-string]
    [-d domain] [-C client] server...
/usr/bin/nisprefadm -u {-L | -G} [-o opt-string]
    [-d domain] [-C client] server...
/usr/bin/nisprefadm -l {-L | -G} [-d domain] [-C client]
/usr/bin/nisprefadm -F

Description  nisprefadm defines which servers are to be preferred by NIS+ clients. This information is used by nis_cachemgr(1M) to control the order in which it selects which server to use for a particular domain. On a client system, the cache manager first looks for a local preferred server list in /var/nis. If it doesn’t find one, it looks for an entry with its host name in the NIS+ table. Finally, if it doesn’t find it there, it looks for an entry for its subnet. By default, nis_cachemgr puts all servers that are on the same subnet as the client system (that is, local servers) are on the preferred server list. In some cases this default preferred server list is inadequate. For example, if all of the servers for a domain are remote, but some are closer than others, the cache manager should try to select the closer one. Because the cache manager has no reliable way to determine the distance to remote servers, nisprefadm is used to provide this information.

The preferred server information is stored either globally in a NIS+ table (with the -G option) or locally in a file, /var/nis/client_info (with the -L option). It is preferable to store the information globally so that it can be used by all clients on a subnet. The nis_cachemgr process on a client machine reloads the preferred server information periodically, depending on the machine’s setup. If the local file is used, the information is reloaded every 12 hours. If the global table is used, the information is reloaded based on the TTL value of the client information table. This TTL value can be changed using nischttl(1). If you want your changes to take effect immediately, use the nisprefadm -F command. When changing local information (-L), nisprefadm automatically forces nis_cachemgr to reload the information.

The cache manager assigns weights to all of the servers on the preferred list. By default, local servers (that is, servers on the same subnet) are given a weight of 0. Other servers are given the weight, “infinite”. This can be changed by using the nisprefadm command and giving a weight in parentheses after the server name. When selecting a server for a domain, the cache manager first tries to contact the servers with the lowest weight. If it doesn’t get a response, it tries the servers with the next lowest weight, and so on. If it fails to get a response from any of the preferred servers, it tries to contact the non-preferred servers.

1594  man pages section 1M: System Administration Commands • Last Revised 12 Dec 2001
The use of weights gives fine control over the server selection process, but care must be given to avoid assigning too many different weights. For example, if weights 0, 1, 2, and 3 are used, but all of the servers with weight 0, 1, and 2, are unavailable, then there will be a noticeable delay in selecting a server. This is because the cache manager waits 5 seconds for a response at each weight level before moving on to the next one. As a general rule, one or two weight levels provides a good balance of server selection control and performance.

When specifying a server name, it is not necessary to fully qualify the name. When the cache manager tries to access a domain, it compares the list of servers for the domain with the list of preferred servers. It will find a match if a preferred server name is a prefix of the name of a server for the domain. If a domain is served by two servers with the same prefix, the preferred server name must include enough of the domain name to distinguish the two.

The `nis_cachemgr(1M)` process automatically adds local servers (same subnet as the client) to the preferred server list with a weight of 0. Thus, it is not necessary to specify them, though it does no harm.

If you specify a weight for a server, you probably should quote the parentheses to avoid having the shell interpret them. The following command illustrates this:

```
example% nisprefadm -G -a -C client1 "srv1(2)"
```

In general, `nis_cachemgr` does a fairly good job of selecting servers on its own. Therefore, the use of `nisprefadm` is not usually necessary. Some situations in which it is recommended are:

- **No local servers, many remote servers**
  
  In this case, `nis_cachemgr` needs to choose one of the remote servers. Because it doesn’t have information on which is closest, it sends a ping to all of them and then selects the one that responds fastest. This may not always select the best server. If some of the servers are closer to the client than the others, they should be listed as preferred servers so that `nis_cachemgr` will try them first. This reduces the amount of network traffic for selecting a server.

- **Very remote servers**
  
  In some networks there are NIS+ servers that are only reachable through very slow network connections. It is usually best to avoid unnecessary traffic over that connection. If the `pref_type=pref_only` option is set along with preferred servers, then only the preferred servers are contacted for domains they serve. The non-preferred servers are not tried at all; even if all of the preferred servers are unavailable. For domains that are not served by any of the preferred servers, the `pref_only` option is ignored.
**Options**

In the SYNOPSIS, when several options are surrounded by braces (that is, by `{` and `}`) one of the options must be specified.

- **-a** Add the specified servers to the preferred server list.

- **-C client** Store the preferred server information with the key, *client*. The *client* can be either a hostname or a subnet number. When a hostname is specified, the preferred server information applies to that host only. When a subnet is specified, the preferred server information applies to all clients on that subnet. The cache manager searches for host specific entries first. It only searches for subnet entries if no host entry is found. If this option is not specified, then the hostname of the machine on which the command is run is used.

- **-d domain** Specify the *domain* to which the command is to apply.

- **-F** Tells *nis_cachemgr*(1M) to refresh its preferred server information. The program periodically does this anyway, but this option forces it to do the refresh immediately. When updating the local information, *nis_cachemgr* automatically refreshes the preferred server information.

  This option must be executed as root.

- **-l** List the current preferred server information.

- **-L | -G** Store the preferred server information locally in the file, */var/nis/client_info* (the -L option), or globally in a NIS+ table *client.info.org-dir.domain* (the -G option). If the information is stored locally, then it only applies to the system on which the command is run. If it is stored globally then it can apply to all systems on a subnet (depending on the value of the -C option).

  The -L option must be run as root.

- **-m** Modify the preferred server list. The server specified by *oldserver* is replaced by *newserver*. This is typically used to change the weight for a server.

- **-o** Specify additional options to control server selection. Currently the only valid option is *pref_type*, which can have a value of either *all* (the default) or *pref_only*. If the value is *all*, then the cache manager tries to contact non-preferred servers if all of the preferred servers fail to respond. If *pref_only* is specified, then it won't try non-preferred servers. The only exception to this is when a domain is not served by any of the preferred servers. In this case, the cache manager ignores the option. This is to avoid requiring that preferred servers be defined for every domain.

- **-r** Remove the specified servers from the preferred server list.

- **-u** Clear the list of preferred servers and then add the specified servers to the preferred server list.
-x  Remove the preferred server information completely.

**Return Values**  
nisprefadm returns the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>On success.</td>
</tr>
<tr>
<td>1</td>
<td>On failure.</td>
</tr>
</tbody>
</table>

**Examples**

**EXAMPLE 1 Using nisprefadm**

This command sets the preferred server list for the system on which it is run:

```bash
example% nisprefadm -L -a srv1 srv2
```

The information is stored in a file, /var/nis/client_info, so it will only affect this one system.

The following command has the same effect, but the information is stored in a NIS+ table in the default domain.

```bash
example% nisprefadm -G -a srv1 srv2
```

As a system administrator, you might want to set the preferred server information for a client system other than the one you are running the command on. The following command sets the preferred server information for a client system named `client1`:

```bash
example% nisprefadm -G -a -C client1 srv1 srv2
```

It is common for all client systems on a subnet to use the same set of preferred servers. The following command sets a preferred server list that applies to all clients on subnet, 192.85.18.0:

```bash
example% nisprefadm -G -a -C 192.85.18.0 srv1 srv2
```

nischtltl(1), nis_cachemgr(1M), attributes(5)

**Notes**

NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit [http://www.sun.com/directory/nisplus/transition.html](http://www.sun.com/directory/nisplus/transition.html).
nisrestore(1M)

**Name**  
nisrestore – restore NIS+ directory backup

**Synopsis**  
nisrestore [-fv]  backup-dir directory...

nisrestore [-fv]  -a backup-dir

nisrestore  -t  backup-dir

**Description**  
nisrestore restores an existing backup of a NIS+ directory object that was created using nisbackup(1M). The backup-dir is the UNIX directory that contains the NIS+ backup on the server being restored. The nisrestore command can be used to restore a NIS+ directory object or a complete NIS+ database. It also can be used as an “out of band” fast replication for a new replica server being initialized. The rpc.nisd(1M) daemon must be stopped before running nisrestore.

The first synopsis is used to restore a single directory object or a specified list of directory objects. The directory can be partially qualified or fully qualified. The server being restored will be verified against the list of servers serving the directory. If this server is not configured to serve this object, nisrestore will exit with an error. The -f option will override this check and force the operation.

The second synopsis will restore all of the directory objects contained in the backup-dir. Again, the server will be validated against the serving list for each of the directory objects in the backup-dir. If one of the objects in the backup-dir are not served by this server, nisrestore will exit with an error. The -f option will override this check and force the operation.

The -a option will attempt to restore all NIS+ objects contained in the backup-dir. If any of these objects are not served by the server, nisrestore will exit with an error. If the backup-dir contains objects that are not served by the server, nisrestore must be executed without the -a option and the specific directory objects listed.

The -f option will disable verification of the server being configured to serve the objects being restored. This option should be used with care, as data could be inadvertently restored to a server that doesn’t serve the restored data. This option is required in the case of restoring a single server domain (master server only) or if the other NIS+ servers are unavailable for NIS+ lookups.

The combination of options -f and -a should be used with caution, as no validation of the server serving the restored objects will be done.

New replicas can be quickly added to a namespace with the nisrestore command. The steps are as follows.

Configure the new replica on the master server (see nissserver(1M)):

```
master# nissserver  -R  -h  replica
```

Temporarily stop the rpc.nisd server process on the new replica server:

```
replica# svcadm  disable  -t  network/rpc/nisplus:default
```
Create a backup of the NIS+ database on the master, which will include the new replica information. See `nisbackup(1M)`. The /backup will need to be exported to the new replica. See `share_nfs(1M)`.

```
master# nisbackup -a /backup
```

Restore the backup of the NIS+ database on the new replica. Use the -f option if `nisrestore` is unable to lookup the NIS+ objects being restored. The backup should be available through nfs or similar means. See `share_nfs(1M)`.

```
replica# nisrestore -f -a //nfs-mnt/backup
```

Restart the `rpc.nisd(1M)` process on the new replica, and the server will immediately be available for service:

```
replica# svcadm enable network/rpc/nisplus:default
```

### Options

The following options are supported:

- `-a` Restores all directory objects included in the `backup-dir` partition.
- `-f` Forces the restoration of a directory without the validation of the server in the directory object's serving list.
- `-t` Lists all directory objects contained in `backup-dir`.
- `-v` Verbose option. Additional output will be produced upon execution of the command.

### Operands

The following options are supported:

- `backup-dir` The UNIX directory that contains the data files for the NIS+ directory objects to be restored.
- `directory` The NIS+ directory object(s) to be restored. This can be a fully or partially qualified name.

### Examples

**EXAMPLE 1** Restoring the Directory Object on a Replica Server from a Local UFS Partition

To restore the `org_dir` directory object of the domain `foo.com` on a replica server from a local ufs partition named `/var/backup`:

```
replica_server# nisrestore /var/backup org_dir.foo.com.
```

**EXAMPLE 2** Forcing the Restore of a Backed up NIS+ Namespace to a Replica Server From the Backup Partition

To force the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named `/var/backup`:

```
replica_server# nisrestore -f -a /var/backup
```
EXAMPLE 3  Restoring the Subdomain on a Master Server From a Backup that Includes Other Directory Objects

To restore the subdomain sub.foo.com on a master server, from a backup that includes other directory objects:

    master_server# nisrestore /var/backup sub.foo.com. \ 

Exit Status  0  Successful completion.

1  An error occurred.

Files  

/backup-dir/backup_list  This ASCII file contains a list of all the objects contained in this backup-dir directory. This information can be displayed with the -t option.

/backup-dir/directory-object  A subdirectory that is created in the backup-dir which contains the directory-object backup.

/backup-dir/directory-object/data  A subdirectory that contains the data files that are part of the directory-object backup.

/backup-dir/directory-object/last.upd  This data file contains timestamp information about the directory-object.

/backup-dir/directory-object/data.dict  A NIS+ data dictionary for all of the objects contained in this directory-object backup.

</table>

See Also  nisrestore(1M), NIS+(1), nisdefaults(1), nisbackup(1M), nisserver(1M), rpc.nisd(1M), share_nfs(1M), svcadm(1M), nisfiles(4), attributes(5), smf(5)

Notes  NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The NIS+ service is managed by the service management facility, smf(5), under the service identifier:

    svc:/network/rpc/nisplus:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svc(1) command.
nisserver – set up NIS+ servers

**Synopsis**

```
/usr/lib/nis/nisserver -r [-x] [-f] [-v] [-Y]
    [-d NIS+_domain] [-g NIS+_groupname]
    [-l network_passwd]

    [-g NIS+_groupname]
    [-h NIS+_server_host]

/usr/lib/nis/nisserver -R [-x] [-f] [-v] [-Y]
    [-d NIS+_domain] [-h NIS+_server_host]
```

**Description**

The `nisserver` shell script can be used to set up a root master, non-root master, and replica NIS+ server with level 2 security (DES). If other authentication mechanisms are configured with `nisauthconf(1M)`, `nisserver` will set up a NIS+ server using those mechanisms. `nisauthconf(1M)` should be used before `nisserver`.

When setting up a new domain, this script creates the NIS+ directories (including `groups_dir` and `org_dir`) and system table objects for the domain specified. It does not populate the tables. `nispopulate(1M)` must be used to populate the tables.

**Options**

- `-d NIS+_domain` specifies the name for the NIS+ domain. The default is your local domain.
- `-f` forces the NIS+ server setup without prompting for confirmation.
- `-g NIS+_groupname` specifies the NIS+ group name for the new domain. This option is not valid with `-R` option. The default group is `admin.<domain>`.
- `-h NIS+_server_host` specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, `hostx.xyz.sun.com`) to specify a host outside of your local domain. This option is only used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname.
- `-l network_password` specifies the network password with which to create the credentials for the root master server. This option is only used for master root server setup (-r option). If this option is not specified, the script prompts you for the login password.
- `-M` sets up the specified host as a master server. Make sure that `rpc.nisd(1M)` is running on the new master server before this command is executed.
- `-R` sets up the specified host as a replica server. Make sure that `rpc.nisd` is running on the new replica server.
Sets up the server as a root master server. Use the -R option to set up a root replica server.

- v
Run the script in verbose mode.

- x
Turns the echo mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.

- Y
Sets up a NIS+ server with NIS-compatibility mode. The default is to set up the server without NIS-compatibility mode.

Usage
Use the first synopsis of the command (-r) to set up a root master server. To run the command, you must be logged in as super-user on the server machine.

Use the second synopsis of the command (-M) to set up a non-root master server for the specified domain. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are setting up. The new non-root master server machine must already be an NIS+ client (see nisclient(1M)) and have the rpc.nisd(1M) daemon running.

Use the third synopsis of the command (-R) to set up a replica server for both root and non-root domains. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are replicating. The new non-root replica server machine must already be an NIS+ client and have the rpc.nisd daemon running.

Examples

EXAMPLE 1 Setting up Servers

To set up a root master server for domain sun.com:

root_server# /usr/lib/nis/nisserver -r -d sun.com.

For the following examples make sure that the new servers are NIS+ clients and that rpc.nisd is running on these hosts before executing nisserver. To set up a replica server for the sun.com domain on host sunreplica:

root_server# /usr/lib/nis/nisserver -R -d sun.com. -h sunrep

To set up a non-root master server for domain xyz.sun.com on host sunxyz with the NIS+ groupname as admin-mgr.xyz.sun.com:

root_server# /usr/lib/nis/nisserver -M -d xyz.sun.com. -h sunxyz
 -g admin-mgr.xyz.sun.com.

To set up a non-root replica server for domain xyz.sun.com on host sunabc:

sunxyz# /usr/lib/nis/nisserver -R -d xyz.sun.com. -h sunabc

## Description

nissetup is a shell script that sets up a NIS+ domain to service clients that wish to store system administration information in a domain named *domain*. This domain should already exist prior to executing this command. See `nismkdir(1)` and `nisinit(1M)`.

A NIS+ domain consists of a NIS+ directory and its subdirectories: `org_dir` and `groups_dir`. `org_dir` stores system administration information and `groups_dir` stores information for group access control.

nissetup creates the subdirectories `org_dir` and `groups_dir` in *domain*. Both subdirectories will be replicated on the same servers as the parent domain. After the subdirectories are created, nissetup creates the default tables that NIS+ serves. These are `auto_master`, `auto_home`, `bootparams`, `cred`, `ethers`, `group`, `hosts`, `mail_aliases`, `netmasks`, `networks`, `passwd`, `protocols`, `rpc`, `services`, and `timezone`. The nissetup script uses the `nistbladm(1)` command to create these tables. The script can be easily customized to add site specific tables that are created at setup time.

This command is normally executed just once per domain.

While this command creates the default tables, it does not initialize them with data. This is accomplished with the `nisaddent(1M)` command.

It is easier to use the `nisserver(1M)` script to create subdirectories and the default tables.

### Options

- `-Y` Specify that the domain will be served as both a NIS+ domain as well as an NIS domain using the backward compatibility flag. This will set up the domain to be less secure by making all the system tables readable by unauthenticated clients as well.

nisshowcache – NIS+ utility to print out the contents of the shared cache file

Synopsis  
/usr/lib/nis/nisshowcache [-v]

Description  
nisshowcache prints out the contents of the per-machine NIS+ directory cache that is shared by all processes accessing NIS+ on the machine. By default, nisshowcache only prints out the directory names in the cache along with the list of active servers. The shared cache is maintained by nis_cachemgr(1M).

Options  
-v  Verbose mode. Print out the contents of each directory object, including the information on the server name and its universal addresses.

Files  
/var/nis/NIS_SHARED_DIRCACHE

Attributes

<table>
<thead>
<tr>
<th><strong>Name</strong></th>
<th>nisstat – report NIS+ server statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Synopsis</strong></td>
<td>/usr/lib/nis/nisstat [-H host] [directory]</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>The <code>nisstat</code> command queries a NIS+ server for various statistics about its operations. These statistics may vary between implementations and from release to release. Not all statistics are available from all servers. If you request a statistic from a server that does not support that statistic, it is never a fatal error. The message “unknown statistic” is returned. By default, statistics are fetched from the server(s) of the NIS+ directory for the default domain. If <code>directory</code> is specified, servers for that directory are queried. Supported statistics for this release are as follows:</td>
</tr>
<tr>
<td><strong>root server</strong></td>
<td>This reports whether the server is a root server.</td>
</tr>
<tr>
<td><strong>NIS compat mode</strong></td>
<td>This reports whether the server is running in NIS compat mode.</td>
</tr>
<tr>
<td><strong>DNS forwarding in NIS mode</strong></td>
<td>This reports whether the server in NIS compat mode will forward host lookup calls to DNS.</td>
</tr>
<tr>
<td><strong>security level</strong></td>
<td>This reports the security level of this server.</td>
</tr>
<tr>
<td><strong>serves directories</strong></td>
<td>This lists the directories served by this server.</td>
</tr>
<tr>
<td><strong>Operations</strong></td>
<td>This statistic returns results in the form: <code>OP=opname; C=calls; E=errors; T=micros</code> Where <code>opname</code> is replaced by the RPC procedure name or operation, <code>calls</code> is the number of calls to this procedure that have been made since the server started running, <code>errors</code> is the number of errors that have occurred while processing a call, and <code>micros</code> is the average time in microseconds to complete the last 16 calls.</td>
</tr>
<tr>
<td><strong>Directory Cache</strong></td>
<td>This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td>
</tr>
<tr>
<td><strong>Group Cache</strong></td>
<td>This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td>
</tr>
<tr>
<td><strong>Static Storage</strong></td>
<td>This statistic reports the number of bytes the server has allocated for its static storage buffers.</td>
</tr>
<tr>
<td><strong>Dynamic Storage</strong></td>
<td>This statistic reports the amount of heap the server process is currently using.</td>
</tr>
<tr>
<td><strong>Uptime</strong></td>
<td>This statistic reports the time since the service has been running.</td>
</tr>
</tbody>
</table>
Per-server and per-directory access restrictions may apply. See `nisopaccess(1)`. `nisstat` uses `NIS_STATUS`.

**Options**

- `-H host`
  Normally all servers for the directory are queried. With this option, only the machine named `host` is queried. If the named machine does not serve the directory, no statistics are returned.

**Environment Variables**

- `NIS_PATH`
  If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found. See `nisdefaults(1)`.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

**See Also**

`nisdefaults(1), nisopaccess(1), attributes(5)`

**Notes**

NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit [http://www.sun.com/directory/nisplus/transition.html](http://www.sun.com/directory/nisplus/transition.html).
nisupdkeys(1M)

**Name**
nisupdkeys – update the public keys in a NIS+ directory object

**Synopsis**
```
/usr/lib/nis/nisupdkeys [-a | -C] [-H host] [directory]
/usr/lib/nis/nisupdkeys -s [-a | -C] -H host
```

**Description**
This command updates the public keys in an NIS+ directory object. When the public key(s)
for a NIS+ server are changed, nisupdkeys reads a directory object and attempts to get the
public key data for each server of that directory. These keys are placed in the directory object
and the object is then modified to reflect the new keys. If `directory` is present, the directory
object for that directory is updated. Otherwise the directory object for the default domain is
updated. The new key must be propagated to all directory objects that reference that server.

On the other hand, `nisupdkeys -s` gets a list of all the directories served by `host` and updates
those directory objects. This assumes that the caller has adequate permission to change all the
associated directory objects. The list of directories being served by a given server can also be
obtained by `nisstat(1M)`. Before you do this operation, make sure that the new
address/public key has been propagated to all replicas. If multiple authentication mechanisms
are configured using `nisauthconf(1M)`, then the keys for those mechanisms will also be
updated or cleared.

The user executing this command must have modify access to the directory object for it to succeed. The existing directory object can be displayed with the `niscat(1)` command using the `-o` option.

This command does not update the directory objects stored in the NIS_COLD_START file on the
NIS+ clients.

If a server is also the root master server, then `nisupdkeys -s` cannot be used to update the root
directory.

**Options**
- **-a**
  Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server’s new address is resolved using `getipnodebyname(3SOCKET)` on this machine. The `/etc/nsswitch.conf` file must point to the correct source for `ipnodes` and `hosts` for this resolution to work.

- **-C**
  Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.

- **-H host**
  Limit key changes only to the server named `host`. If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.

- **-s**
  Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to change all the associated directory objects. If the NIS+ principal making this call does not have adequate permissions to update the directory objects, those particular updates will fail and the caller will...
be notified. If the rpc.nisd on host cannot return the list of servers it serves, the command will print an error message. The caller would then have to invoke nisupdkeys multiple times (as in the first synopsis), once per NIS+ directory that it serves.

**Examples**

**EXAMPLE 1 Using nisupdkeys**

The following example updates the keys for servers of the foo.bar. domain.

```
example% nisupdkeys foo.bar.
```

This example updates the key(s) for host fred that serves the foo.bar. domain.

```
example% nisupdkeys -H fred foo.bar.
```

This example clears the public key(s) for host wilma in the foo.bar. directory.

```
example% nisupdkeys -CH wilma foo.bar.
```

This example updates the public key(s) in all directory objects that are served by the host wilma.

```
example% nisupdkeys -s -H wilma
```

**Attributes**

nlsadmin(1M)

**Name**
nlsadmin – network listener service administration

**Synopsis**
/usr/sbin/nlsadmin -x
/usr/sbin/nlsadmin [options] net_spec
/usr/sbin/nlsadmin [options] -N port_monitor_tag
/usr/sbin/nlsadmin -V
/usr/sbin/nlsadmin -c cmd | -o streamname [-p modules]
       [-A address | -D] [-R prognum : versnum]

**Description**
nlsadmin is the administrative command for the network listener process(es) on a machine. Each network has at least one instance of the network listener process associated with it; each instance (and thus, each network) is configured separately. The listener process "listens" to the network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any network (more precisely, with any connection-oriented transport provider) that conforms to the transport provider specification.

nlsadmin can establish a listener process for a given network, configure the specific attributes of that listener, and start and kill the listener process for that network. nlsadmin can also report on the listener processes on a machine, either individually (per network) or collectively.

net_spec represents a particular listener process. Specifically, net_spec is the relative path name of the entry under /dev for a given network (that is, a transport provider). address is a transport address on which to listen and is interpreted using a syntax that allows for a variety of address formats. By default, address is interpreted as the symbolic ASCII representation of the transport address. An address preceded by "\x" will let you enter an address in hexadecimal notation. Note that address must appear as a single word to the shell, thus it must be quoted if it contains any blanks.

Changes to the list of services provided by the listener or the addresses of those services are put into effect immediately.

**Options**
nlsadmin may be used with the following combinations of options and arguments:

- **-x**
  Report the status of all of the listener processes installed on this machine.

- **net_spec**
  Print the status of the listener process for net_spec.

- **-q net_spec**
  Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit code will be 1; the exit code will be greater than 1 in case of error.
\textbf{-v net\_spec}\hspace{1em}Print a verbose report on the servers associated with net\_spec, giving the service code, status, command, and comment for each. It also specifies the uid the server will run as and the list of modules to be pushed, if any, before the server is started.

\textbf{-z service\_code net\_spec}\hspace{1em}Print a report on the server associated with net\_spec that has service code service\_code, giving the same information as in the -v option.

\textbf{-q -z service\_code net\_spec}\hspace{1em}Query the status of the service with service code service\_code on network net\_spec, and exits with a status of 0 if that service is enabled, 1 if that service is disabled, and greater than 1 in case of error.

\textbf{-l address net\_spec}\hspace{1em}Change or set the transport address on which the listener listens (the general listener service). This address can be used by remote processes to access the servers available through this listener (see the -a option, below).

If address is just a dash ("-"), \texttt{nlsadmin} reports the address currently configured, instead of changing it.

A change of address takes effect immediately.

\textbf{-t address net\_spec}\hspace{1em}Change or set the address on which the listener listens for requests for terminal service but is otherwise similar to the -l option above. A terminal service address should not be defined unless the appropriate remote login software is available; if such software is available, it must be configured as service code 1 (see the -a option, below).

\textbf{-i net\_spec}\hspace{1em}Initialize an instance of the listener for the network specified by net\_spec; that is, create and initialize the files required by the listener as well as starting that instance of the listener.

Note that a particular instance of the listener should be initialized only once. The listener must be initialized before assigning addresses or services.

\textbf{-a service\_code}\hspace{1em}[ -p modules ] [ -w name ] -c cmd -y comment net\_spec

Add a new service to the list of services available through the indicated listener. service\_code is the code for the service, cmd is the command to be invoked in response to that service code, comprised of the full path name of the server and its arguments, and comment is a brief (free-form) description of the service for use in various reports. Note that cmd must appear as a single word to the shell; if arguments are required,
the `cmd` and its arguments must be enclosed in quotation marks. The `comment` must also appear as a single word to the shell. When a service is added, it is initially enabled (see the `-e` and `-d` options, below).

Service codes are alphanumeric strings, and are administered by AT&T. The numeric service codes 0 through 100 are reserved for internal use by the listener. Service code 0 is assigned to the nilps server, which is the service invoked on the general listening address. In particular, code 1 is assigned to the remote login service, which is the service automatically invoked for connections to the terminal login address.

If the `-p` option is specified, then `modules` will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order they are specified. `modules` should be a comma-separated list of modules, with no white space included.

If the `-w` option is specified, then `name` is interpreted as the user name from `/etc/passwd` that the listener should look up. From the user name, the listener obtains the user ID, the group ID(s), and the home directory for use by the server. If `-w` is not specified, the default is to use the user name `listen`.

A service must explicitly be added to the listener for each network on which that service is to be available. This operation will normally be performed only when the service is installed on a machine, or when populating the list of services for a new network.

```
-r service_code net_spec
-e service_code net_spec
-d service_code net_spec
```

- Remove the entry for the `service_code` from that listener's list of services. This is normally done only in conjunction with the de-installation of a service from a machine.
- Enable or disable (respectively) the service indicated by `service_code` for the specified network. The service must previously have been added to the listener for that network (see the `-a` option, above). Disabling a service will cause subsequent service requests for that service to be denied, but the processes from any prior service requests that are still running will continue unaffected.
-s net_spec
- k net_spec

Start and kill (respectively) the listener process for the indicated network. These operations are normally performed as part of the system startup and shutdown procedures. Before a listener can be started for a particular network, it must first have been initialized (see the -i option, above). When a listener is killed, processes that are still running as a result of prior service requests will continue unaffected.

Under the Service Access Facility, it is possible to have multiple instances of the listener on a single net_spec. In any of the above commands, the option -N port_monitor_tag may be used in place of the net_spec argument. This argument specifies the tag by which an instance of the listener is identified by the Service Access Facility. If the -N option is not specified (that is, the net_spec is specified in the invocation), then it will be assumed that the last component of the net_spec represents the tag of the listener for which the operation is destined. In other words, it is assumed that there is at least one listener on a designated net_spec, and that its tag is identical to the last component of the net_spec. This listener may be thought of as the primary, or default, listener for a particular net_spec.

nlsadmin is also used in conjunction with the Service Access Facility commands. In that capacity, the following combinations of options can be used:

- V

Write the current version number of the listener's administrative file to the standard output. It is used as part of the sacadm command line when sacadm adds a port monitor to the system.

- c cmd | - o streamname [ - p modules ] [ - A address ] [ - D ] [ - R prognum : versnum ]

Format the port monitor-specific information to be used as an argument to pmadm(1M)

The - c option specifies the full path name of the server and its arguments. cmd must appear as a single word to the shell, and its arguments must therefore be surrounded by quotes.

The - o option specifies the full path name of a FIFO or named stream through which a standing server is actually receiving the connection.

If the - p option is specified, then modules will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order in which they are specified. modules must be a comma-separated list, with no white space included.

If the - A option is specified, then address will be interpreted as the server's private address. The listener will monitor this address on behalf of the service and will dispatch all calls arriving on this address directly to the designated service. This option may not be used in conjunction with the - D option.
If the -D option is specified, then the service is assigned a private address dynamically, that is, the listener will have the transport provider select the address each time the listener begins listening on behalf of this service. For RPC services, this option will be often be used in conjunction with the -R option to register the dynamically assigned address with the rpcbinder. This option may not be used in conjunction with the -A option.

When the -R option is specified, the service is an RPC service whose address, program number, and version number should be registered with the rpcbinder for this transport provider. This registration is performed each time the listener begins listening on behalf of the service. prognum and versnum are the program number and version number, respectively, of the RPC service.

nlsadmin may be invoked by any user to generate reports; all operations that affect a listener's status or configuration may only be run by a super-user.

The options specific to the Service Access Facility may not be used together with any other options.

**Errors** If successful, nlsadmin exits with a status of 0. If nlsadmin fails for any reason, it exits with a status greater than or equal to 2. See -q option for a return status of 1.

**Notes** Dynamically assigned addresses are not displayed in reports as statically assigned addresses are.
nscd – name service cache daemon

/usr/sbin/nscd [-f configuration-file] [-g] [-e cachename, yes | no] [-i cachename]

The nscd daemon is a process that provides a cache for most name service requests. The default configuration-file /etc/nscd.conf determines the behavior of the cache daemon. See nscd.conf(4).

nscd provides caching for the passwd(4), group(4), hosts(4), ipnodes(4), exec_attr(4), prof_attr(4), user_attr(4), ethers(4), rpc(4), protocols(4), networks(4), bootparams(4), audit_user(4), auth_attr(4), services(4), netmasks(4), printers(4), project(4) databases through standard libc interfaces, such as gethostbyname(3NSL), getipnodebyname(3SOCKET), gethostbyaddr(3NSL), and others. Each cache has a separate time-to-live for its data; modifying the local database (/etc/hosts, /etc/resolv.conf, and so forth) causes that cache to become invalidated upon the next call to nscd. The shadow file is specifically not cached. getspnam(3C) calls remain uncached as a result.

nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently.

When running with per-user lookups enabled (see nscd.conf(4)), nscd forks one and only one child process (that is, a per-user nscd) on behalf of the user making the request. The per-user nscd will use the credentials of the user to open a per-user connection to the name repository configured for the per-user style of lookups. The lookup will be performed in the child process. The results are cached in the process and are available only to the same user. The caches are managed exactly the same as the main nscd daemon manages its own caches. Subsequent requests from the user will be handled by the per-user nscd until it terminates. The per-user nscd uses a configurable inactivity time-to-live (TTL) value and terminates itself after the inactivity TTL expires.

The maximum number of per-user nscds that can be created by the main nscd is configurable (see nscd.conf(4)). After the maximum number of them are created, the main nscd will use an LRU algorithm to terminate less active child nscds as needed.

The main nscd daemon creates, monitors, and manages all the child nscds. It creates a user’s own nscd upon receiving the user’s first per-user lookup. When the nscd daemon is started, if per-user lookups are enabled, it checks to ensure all conditions are met before getting ready to create a per-user nscd. When the daemon is stopped, it terminates all the per-user nscds under its control.

Per-user nscds use the same configuration as the main nscd. They read and use the same default configuration file or the one specified with the -f command line option. Once the configuration is read, the per-user nscd will use it for its entire lifetime.
Several of the options described below require a `cachename` specification. Supported values for `cachename` are: `passwd`, `group`, `hosts`, `ipnodes`, `exec_attr`, `prof_attr`, `user_attr`, `ethers`, `rpc`, `protocols`, `networks`, `bootparams`, `audit_user`, `auth_attr`, `services`, `netmasks`, `printers`, and `project`.

- `configuration-file`
  Causes `nscd` to read its configuration data from the specified file.

- `g`
  Prints current configuration and statistics to standard output. This is the only option executable by non-root users.

- `e cachename, yes|no`
  Enables or disables the specified cache.

- `i cachename`
  Invalidates the specified cache.

**Examples**

**EXAMPLE 1** Stopping and restarting the `nscd` daemon.
```
example# svcadm disable system/name-service-cache
example# svcadm enable system/name-service-cache
```

**Files** `/etc/nscd.conf` Determines the behavior of the cache daemon

**Attributes**

`svecs(1), svcadm(1M), getspnam(3C), gethostbyname(3NSL), getipnodebyname(3SOCKET), audit_user(4), auth_attr(4), bootparams(4), ethers(4), exec_attr(4), group(4), hosts(4), netmasks(4), networks(4), nscd.conf(4), nsswitch.conf(4), passwd(4), printers(4), prof_attr(4), project(4), protocols(4), rpc(4), services(4), user_attr(4), attributes(5)`

**Notes**
The output from the `-g` option to `nscd` is subject to change. Do not rely upon it as a programming interface.

The `nscd` service is managed by the service management facility, `smf(5)`, under the service identifier:
```
svc:/system/name-service-cache
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
nslookup – query Internet name servers interactively

nslookup [-option] [name | -] [server]

The nslookup utility is a program to query Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to query name servers for information about various hosts and domains or to print a list of hosts in a domain. Non-interactive mode is used to print just the name and requested information for a host or domain.

Parameters

Interactive mode is entered in the following cases:

1. No arguments are given (the default name server is used).
2. The first argument is a hyphen (-) and the second argument is the host name or Internet address of a name server.

Non-interactive mode is used when the name or Internet address of the host to be looked up is given as the first argument. The optional second argument specifies the host name or address of a name server.

Options can also be specified on the command line if they precede the arguments and are prefixed with a hyphen. For example, to change the default query type to host information, and the initial timeout to 10 seconds, type:

```
nslookup -query=hinfo -timeout=10
```

Interactive Commands

host [server]

Look up information for host using the current default server or using server, if specified. If host is an Internet address and the query type is A or PTR, the name of the host is returned. If host is a name and does not have a trailing period, the search list is used to qualify the name. To look up a host not in the current domain, append a period to the name.

server domain

 Change the default server to domain; \server uses the initial server to look up information about domain, while \server uses the current default server. If an authoritative answer can't be found, the names of servers that might have the answer are returned.

exit
   Exits the program.
set keyword[=value]
   This command is used to change state information that affects the lookups. Valid keywords are:
   all
      Prints the current values of the frequently used options to set. Information about the current default server and host is also printed.
   class=value
      Change the query class to one of:
      IN
         the Internet class
      CH
         the Chaos class
      HS
         the Hesiod class
      ANY
         wildcard
      The class specifies the protocol group of the information.
      (Default = IN; abbreviation = cl)
[no]debug
   Turn on or off the display of the full response packet and any intermediate response packets when searching.
   (Default = nodebug; abbreviation = [no]deb)
[no]d2
   Turn debugging mode on or off. This displays more about what nslookup is doing.
   (Default = nod2)
domain=name
   Sets the search list to name.
If the lookup request contains at least one period but doesn't end with a trailing period, append the domain names in the domain search list to the request until an answer is received.

(Default = search)

port=value
Change the default TCP/UDP name server port to value.

(Default = 53; abbreviation = po)

querytype=value
type=value
Change the top of the information query.

(Default = A; abbreviations = q, ty)

[no]recursion
Tell the nameserver to query other servers if it does not have the information. (Default = recursion; abbreviation = [no]rec)

retry=number
Set the number of retries to number.

timeout=number
Change the initial timeout interval for waiting for a reply to number seconds.

[no]vc
Always use a virtual circuit when sending requests to the server.

(Default = novc)

[no]fail
Try the next nameserver if a nameserver responds with SERVFAIL or a referral (nofail) or terminate query (fail) on such a response.

(Default = nofail)

Files
/etc/resolv.conf
 resolver configuration file

page, this document is available at https://www.isc.org/software/bind/documentation.

Notes  
BIND 9 nslookup is deprecated and not as full featured as its BIND 8 version. For more
features and functionality refer to dig(1M).

nslookup and dig(1M) now report "Not Implemented" as NOTIMP rather than NOTIMPL. This
will have impact on scripts that are looking for NOTIMPL.
nsupdate – Dynamic DNS update utility

**Synopsis**

```
nsupdate [-dv] [-y keyname:secret | -k keyfile] [-t timeout]
         [-u udptimeout] [-r udpretries] [filename]
```

**Description**
The `nsupdate` utility submits Dynamic DNS Update requests as defined in RFC 2136 to a nameserver. This utility allows resource records to be added or removed from a zone without manually editing the zone file. A single update request can contain requests to add or remove more than one resource record.

Zones that are under dynamic control with `nsupdate` or a DHCP server should not be edited by hand. Manual edits could conflict with dynamic updates and cause data to be lost.

The resource records that are dynamically added or removed with `nsupdate` must be in the same zone. Requests are sent to the zone’s master servers identified by the `MNAME` field of the zone’s SOA record.

Transaction signatures can be used to authenticate the Dynamic DNS updates using the TSIG resource record type described in RFC 2845. The signatures rely on a shared secret that should only be known to `nsupdate` and the nameserver. Currently, the only supported encryption algorithm for TSIG is HMAC-MD5, which is defined in RFC 2104. Once other algorithms are defined for TSIG, applications will need to ensure that they select the appropriate algorithm as well as the key when authenticating each other. For instance, suitable key and server statements would be added to `/etc/named.conf` so that the name server can associate the appropriate secret key and algorithm with the IP address of the client application that will be using TSIG authentication. The `nsupdate` utility does not read `/etc/named.conf`.

The `nsupdate` utility uses the `-y` or `-k` option to provide the shared secret needed to generate a TSIG record for authenticating Dynamic DNS update requests. These options are mutually exclusive. See OPTIONS.

**Options**
The following options are supported:

- `-d` Operate in debug mode. This provides tracing information about the update requests that are made and the replies received from the name server.

- `-k keyfile` Read the shared secret from the file `keyfile`, whose name is of the form `K{name}.+157.++{random}.private`. For historical reasons, the file `K{name}.+157.++{random}.key` must also be present.

- `-r udpretries` Set the number of UDP retries. The default is 3 seconds. If `udpretries` is set to zero, only one update request is made.

- `-t timeout` Set `timeout` interval in seconds before update is aborted. The default is 300 seconds. A setting of zero disables the timeout.

- `-u udptimeout` Set interval in seconds between UDP retries, the default is 3 seconds. A setting of zero causes the interval to be calculated based on the timeout (`-t`) and the number of UDP retries (`-r`).
Use a TCP connection. Using a TCP connection could be preferable when a batch of update requests is made. By default, nsupdate uses UDP to send update requests to the name server.

-usecret

Generate a signature from keyname:secret, where keyname is the name of the key and secret is the base64 encoded shared secret.

Use of the -y option is discouraged because the shared secret is supplied as a command line argument in clear text and could be visible in the output from `ps(1)` or in a history file maintained by the user's shell.

Input Format

The `nsupdate` utility reads input from `filename` or the standard input. Each command is supplied on exactly one line of input. Some commands are for administrative purposes. The others are either update instructions or prerequisite checks on the contents of the zone. These checks set conditions that some name or set of resource records (RRset) either exists or is absent from the zone. These conditions must be met if the entire update request is to succeed. Updates will be rejected if the tests for the prerequisite conditions fail.

Every update request consists of zero or more prerequisites and zero or more updates. This condition allows a suitably authenticated update request to proceed if some specified resource records are present or missing from the zone. A blank input line (or the `send` command) causes the accumulated commands to be sent as one Dynamic DNS update request to the name server.

The command formats and their meaning are as follows:

```
server servername [ port ]
```

Send all dynamic update requests to the name server servername. When no server statement is provided, nsupdate sends updates to the master server of the correct zone. The MNAME field of that zone's SOA record identifies the master server for that zone. The port argument is the port number on servername where the dynamic update requests get sent. If no port number is specified, the default DNS port number of 53 is used.

```
local address [ port ]
```

Send all dynamic update requests using the local address. When no local statement is provided, nsupdate sends updates using an address and port chosen by the system. The port argument can also be used to make requests come from a specific port. If no port number is specified, the system assigns one.

```
zone zonename
```

Specify that all updates are to be made to the zone zonename. If no zone statement is provided, nsupdate attempts to determine the correct zone to update based on the rest of the input.

```
class classname
```

Specify the default class. If no class is specified the default class is IN.
key name secret
Specify that all updates are to be TSIG signed using the name secret pair. The key command overrides any key specified on the command line with -y or -k.

prereq nxdomain domain-name
Require that no resource record of any type exists with the name domain-name.

prereq yxdomain domain-name
Require that domain-name exists (has at least one resource record, of any type).

prereq nxrrset domain-name [ class ] type
Require that no resource record exists of the specified type, class and domain-name. If class is omitted, IN (internet) is assumed.

prereq yxrrset domain-name [ class ] type
Require that a resource record of the specified type, class and domain-name must exist. If class is omitted, IN (internet) is assumed.

prereq yxrrset domain-name [ class ] type data...
The data from each set of prerequisites of this form sharing a common type, class, and domain-name are combined to form a set of RRs. This set of RRs must exactly match the set of RRs existing in the zone at the given type, class, and domain-name. The data are written in the standard text representation of the resource record's RDATA.

update delete domain-name [ ttl ] [ class ] [ type [ data... ] ]
Delete any resource records named domain-name. If type and data are provided, only matching resource records are removed. The internet class is assumed if class is not supplied. The ttl is ignored, and is only provided for compatibility.

update add domain-name ttl [ class ] type data...
Add a new resource record with the specified ttl, class and data.

show
Display the current message, containing all of the prerequisites and updates specified since the last send.

send
Sends the current message. This is equivalent to entering a blank line.

Lines beginning with a semicolon are comments and are ignored.

Examples

EXAMPLE 1
Insert and delete resource records from the zone.
The examples below show how nsupdate could be used to insert and delete resource records from the example.com zone. Notice that the input in each example contains a trailing blank line so that a group of commands are sent as one dynamic update request to the master name server for example.com.

# nsupdate
> update delete oldhost.example.com A
EXAMPLE 1  Insert and delete resource records from the zone.  (Continued)

> update add newhost.example.com 86400 A 172.16.1.1
> send

Any A records for oldhost.example.com are deleted. An A record for newhost.example.com
with IP address 172.16.1.1 is added. The newly-added record has a 1 day TTL (86400 seconds).

# nsupdate
> prereq nxdomain nickname.example.com
> update add nickname.example.com 86400 CNAME somehost.example.com
> send

The prerequisite condition gets the name server to check that there are no resource records of
any type for nickname.example.com. If there are, the update request fails. If this name does
not exist, a CNAME for it is added. This action ensures that when the CNAME is added, it cannot
conflict with the long-standing rule in RFC 1034 that a name must not exist as any other
record type if it exists as a CNAME. (The rule has been updated for DNSSEC in RFC 2535 to
allow CNAMEs to have SIG, KEY, and NXT records.)

Files  /etc/resolv.conf  used to identify default name server
K{name}.+157.+{random}.key  base-64 encoding of HMAC-MD5 key created by
dnssec-keygen(1M).
K{name}.+157.+{random}.private  base-64 encoding of HMAC-MD5 key created by
dnssec-keygen(1M)

Bugs  The TSIG key is redundantly stored in two separate files. This is a consequence of nsupdate
using the DST library for its cryptographic operations and could change in future releases.

    RFC 2136, RFC 3007, RFC 2104, RFC 2845, RFC 1034, RFC 2535, RFC 2931

Notes  Source for BIND9 is available in the SUNWbind9S package.
The `ntpdate` utility sets the local date and time. To determine the correct time, it polls the Network Time Protocol (NTP) servers on the hosts given as arguments. This utility must be run as root on the local host. It obtains a number of samples from each of the servers and applies the standard NTP clock filter and selection algorithms to select the best of these.

The reliability and precision of `ntpdate` improve dramatically with a greater number of servers. While a single server may be used, better performance and greater resistance to inaccuracy on the part of any one server can be obtained by providing at least three or four servers, if not more.

The `ntpdate` utility makes time adjustments in one of two ways. If it determines that your clock is off by more than 0.5 seconds it simply steps the time by calling `gettimeofday(3C)`. If the error is less than 0.5 seconds, by default, it slews the clock’s time with the offset, by way of a call to `adjtime(2)`. The latter technique is less disruptive and more accurate when the offset is small; it works quite well when `ntpdate` is run by `cron` every hour or two. The adjustment made in the latter case is actually 50% larger than the measured offset. This adjustment tends to keep a badly drifting clock more accurate, at some expense to stability. This tradeoff is usually advantageous. At boot time, however, it is usually better to step the time. This can be forced in all cases by specifying the `-b` option on the command line.

The `ntpdate` utility declines to set the date if an NTP server daemon like `xntpd(1M)` is running on the same host. It can be run on a regular basis from `cron(1M)` as an alternative to running a daemon. Doing so once every one to two hours results in precise enough timekeeping to avoid stepping the clock.

### Options

The following options are supported:

- `-a key#` Authenticate transactions, using the key number, `key#`.
- `-b` Step the time by calling `gettimeofday(3C)`.
- `-B` Force the time to always be slewed using the `adjtime(2)` system call, even if the measured offset is greater than ±128 ms. The default is to step the time using `settimeofday(3C)` if the offset is greater than ±128 ms. If this option is used and the offset is much greater than ±128 ms, it can take a long time (hours) to slew the clock to the correct value. During this time the host should not be used to synchronize clients.
- `-d` Display what will be done without actually doing it. Information useful for general debugging is also printed.
Specify an authentication processing delay, authdelay in seconds. See xntpd(1M) for details. This number is usually small enough to be negligible for purposes of ntpdate. However, specifying a value may improve timekeeping on very slow CPU’s.

- k keyfile Read keys from the file keyfile instead of the default file, /etc/inet/ntp.keys. keyfile should be in the format described in xntpd(1M).

- m Join multicast group specified in server and synchronize to multicast NTP packets. The standard NTP group is 224.0.1.1.

- o version Force the program to poll as a version 1 or version 2 implementation. By default ntpdate claims to be an NTP version 3 implementation in its outgoing packets. However, some older software declines to respond to version 3 queries. This option can be used in these cases.

- p samples Set the number of samples ntpdate acquires from each server. samples can be between 1 and 8 inclusive. The default is 4.

- q Query only. Do not set the clock.

- s Log actions by way of the syslog(3C) facility rather than to the standard output — a useful option when running the program from cron(1M).

- t timeout Set the time ntpdate spends, waiting for a response. timeout is rounded to a multiple of 0.2 seconds. The default is 1 second, a value suitable for polling across a LAN.

- u Use an unprivileged port to send the packets from. This option is useful when you are behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. The -d option always uses unprivileged ports.

- v Be verbose. This option causes ntpdate’s version identification string to be logged.

- w Wait until able to synchronize with a server. When the -w option is used together with -m, ntpdate waits until able to join the group and synchronize.

**Files** /etc/inet/ntp.keys Contains the encryption keys used by ntpdate.

</table>
The technique of compensating for clock oscillator errors to improve accuracy is inadequate. However, to further improve accuracy would require the program to save state from previous runs.
ntpq(1M)

**Name**
ntpq – standard Network Time Protocol query program

**Synopsis**
/usr/sbin/ntpq [-inp] [-c command] [host] [...]

**Description**
ntpq queries NTP servers which implement the recommended NTP mode 6 control message format, about current state. It can also request changes in that state. The program can be run in interactive mode; or it can be controlled using command line arguments. Requests to read and write arbitrary variables can be assembled, with raw and pretty-printed output options available. By sending multiple queries to the server, ntpq can also obtain and print a list of peers in a common format.

If one or more request options are included on the command line, ntpq sends each of the requests to NTP servers running on each of the hosts given as command line arguments. By default, ntpq sends its requests to localhost, if hosts are not included on the command line. If no request options are given, ntpq attempts to read commands from the standard input and execute them on the NTP server running on the first host given on the command line. Again, ntpq defaults to localhost if no other host is specified.

ntpq uses NTP mode 6 packets to communicate with an NTP server. Thus, it can be used to query any compatible server on the network that permits queries. Since NTP is a UDP protocol, this communication will be somewhat unreliable, especially over large distances.

ntpq makes one attempt to retransmit requests; requests timeout if the remote host is not heard from within a suitable period.

**Options**
Command line options are described below. Specifying a command line option other than -i or -n causes the specified query (queries) to be sent, immediately to the indicated host(s).
Otherwise, ntpq attempts to read interactive format commands from standard input.

- **-c**
Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.

- **-i**
Operate in interactive mode; write prompts to standard output and read commands from standard input.

- **-n**
Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.

- **-p**
Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers' interactive command. See USAGE below.

**Usage**
Interactive format commands consist of a keyword followed by up to four arguments. Only enough characters of the full keyword to uniquely identify the command need be typed. Normally, the output of a command is sent to standard output; but this output may be written to a file by appending a '>'; followed by a file name, to the command line.

**Interactive Commands**
A number of interactive format commands are executed entirely within the ntpq program itself. They do not result in NTP mode 6 requests being sent to a server. If no request options are included on the command line, and if the standard input is a terminal device, ntpq prompts for these commands. The interactive commands are described below:
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

<tr>
<td>timeout milliseconds</td>
<td>Specifies a time out period for responses to server queries. The default is about 5000 milliseconds. Since <code>ntpq</code> retries each query once after a time out, the total waiting time for a timeout is twice the timeout value that is set.</td>
</tr>
<tr>
<td>delay milliseconds</td>
<td>Specifies a time interval to be added to timestamps included in requests which require authentication. This command is used to enable (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Currently, the server does not require time stamps in authenticated requests. Thus, this command may be obsolete.</td>
</tr>
<tr>
<td>hosthostname</td>
<td>Set the name of the host to which future queries are to be sent. Hostname may be either a host name or a numeric address.</td>
</tr>
<tr>
<td>keyid #</td>
<td>Specify of a key number to be used to authenticate configuration requests. This number must correspond to a key number the server has been configured to use for this purpose.</td>
</tr>
<tr>
<td>passwd</td>
<td>Allow the user to specify a password at the command line. This will be used to authenticate configuration requests. If an authenticating key has been specified (see <code>keyid</code> above), this password must correspond to this key. <code>ntpq</code> does not echo the password as it is typed.</td>
</tr>
<tr>
<td>hostnames yes</td>
<td>no</td>
</tr>
<tr>
<td>raw</td>
<td>Print all output from query commands exactly as it is received from the remote server. The only formatting/filtering done on the data is to transform non-ASCII data into printable form.</td>
</tr>
</tbody>
</table>
| cooked             | Causes output from query commands to be “cooked”. The values of variables recognized by the server are reformatted,
so that they can be more easily read. Variables which ntpq thinks should have a decodable value, but do not, are marked with a trailing '?'.

**ntpversion[1 | 2 | 3]**

Sets the NTP version number which ntpq claims in packets (defaults is 3). Note that mode 6 control messages (and modes, for that matter) did not exist in NTP version 1. There appear to be no servers left which demand version 1.

**authenticate[yes | no]**

The command authenticate yes instructs ntpq to send authentication with all requests it makes. Normally ntpq does not authenticate requests unless they are write requests. Authenticated requests cause some servers to handle requests slightly differently, and can occasionally cause a slowed response if you turn authentication on before doing a peer display.

```
addvars variable_name[=value] [. . . ]
rmvars variable_name [. . . ]
clearvars
```

The data carried by NTP mode 6 messages consists of a list of items of the form

```
variable_name=value
```

where the "=value" is ignored, and can be omitted, in requests to the server to read variables. ntpq maintains an internal list in which data to be included in control messages can be assembled, and sent. This is accomplished with the readlist and writelist commands described below. The addvars command allows variables and their optional values to be added to the list. If more than one variable is to be added, the list should be comma-separated, and it should not contain white space. The rmvars command can be used to remove individual variables from the list; the clearlist command removes all variables from the list.

**debug[more | less | off]**

Turns internal query program debugging on and off.

**quit**

Exit ntpq.

---

**Control Message Commands**

Each peer known to an NTP server has a 16 bit integer *association identifier* assigned to it. NTP control messages which carry peer variables must identify the peer that the values correspond to, by including its association ID. An association ID of 0 is special. It indicates the variables are system variables, whose names are drawn from a separate name space.
Control message commands send one or more NTP mode 6 messages to the server, and cause the data returned to be printed in some format. Most commands currently implemented send a single message and expect a single response. The current exceptions are the peers mreadlist and mreadvar commands. The peers command sends a preprogrammed series of messages to obtain the data it needs. The mreadlist and mreadvar commands, iterate over a range of associations.

Control message commands are described below:

associations
Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in columns. The first of these is an index that numbers the associations from 1, for internal use. The second column contains the actual association identifier returned by the server and the third the status word for the peer. This is followed by a number of columns containing data decoded from the status word. Note that the data returned by the associations command is cached internally in ntpq. The index is then of use when dealing with “dumb” servers which use association identifiers that are hard for humans to type. For any subsequent commands which require an association identifier as an argument, the identifier can be specified by using the form, &index. Here index is taken from the previous list.

lassociations
Obtains and prints a list of association identifiers and peer statuses for all associations for which the server is maintaining state. This command differs from the associations command only for servers which retain state for out-of-spec client associations. Such associations are normally omitted from the display when the associations command is used, but are included in the output of lassociations.

passociations
Prints association data concerning in-spec peers from the internally cached list of associations. This command performs identically to the associations command except that it displays the internally stored data rather than making a new query.

\passociations
Print data for all associations, including out-of-spec client associations, from the internally cached list of associations. This command differs from passociations only when dealing with servers which retain state for out-of-spec client associations.

pstatusassocID
Sends a read status request to the server for the given association. The names and values of the peer variables returned will be printed. Note that the status word from the header is displayed preceding the variables, both in hexadecimal and in pigeon English.

readvar [ assoc ] [ variable_name[=value] [ , . . . ] ]
Requests that the values of the specified variables be returned by the server by sending a read variables request. If the association ID is omitted or is given as zero the variables are system variables, otherwise they are peer variables and the values returned will be those of
the corresponding peer. Omitting the variable list will send a request with no data which should induce the server to return a default display.

\texttt{rv [assocID] [variable\_name=value] [\ldots]}

An easy-to-type short form for the \texttt{readvar} command.

\texttt{writevar assocID variable\_name=value [\ldots]}

Like the \texttt{readvar} request, except the specified variables are written instead of read.

\texttt{readlist [assocID]}

Requests that the values of the variables in the internal variable list be returned by the server. If the association ID is omitted or is 0 the variables are assumed to be system variables. Otherwise they are treated as peer variables. If the internal variable list is empty a request is sent without data, which should induce the remote server to return a default display.

\texttt{rl [assocID]}

An easy-to-type short form of the \texttt{readlist} command.

\texttt{writelist [assocID]}

Like the \texttt{readlist} request, except the internal list variables are written instead of read.

\texttt{mreadvar assocID assocID [variable\_name=value] [\ldots]}

Like the \texttt{readvar} command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent associations command.

\texttt{mr\_\_readvar} assocID assocID [variable\_name=value] [\ldots]}

An easy-to-type short form of the \texttt{mreadvar} command.

\texttt{mreadlist assocID assocID}

Like the \texttt{readlist} command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent associations command.

\texttt{mrl assocID assocID}

An easy-to-type short form of the \texttt{mreadlist} command.

\texttt{clockvar [assocID] [variable\_name=value] [\ldots]}

Requests that a list of the server’s clock variables be sent. Servers which have a radio clock or other external synchronization respond positively to this. If the association identifier is omitted or zero the request is for the variables of the “system clock”. This request generally gets a positive response from all servers with a clock. Some servers may treat clocks as pseudo-peers and, hence, can possibly have more than one clock connected at once. For these servers, referencing the appropriate peer association ID shows the variables of a particular clock. Omitting the variable list causes the server to return a default variable display.

\texttt{cv [assocID] [variable\_name=value] [\ldots]}

An easy-to-type short form of the \texttt{clockvar} command.
peers
Obtains a list of in-spec peers of the server, along with a summary of each peer’s state. Summary information includes:
- The address of the remote peer
- The reference ID (0.0.0.0 if the ref ID is unknown)
- The stratum of the remote peer
- The type of the peer (local, unicast, multicast or broadcast) when the last packet was received
- The polling interval in seconds
- The reachability register, in octal
- The current estimated delay offset and dispersion of the peer, all in milliseconds.

The character in the left margin indicates the fate of this peer in the clock selection process. The codes mean:

SPACE   Discarded due to high stratum and/or failed sanity checks.
x       Designated falsticker by the intersection algorithm.
.       Culled from the end of the candidate list.
−       Discarded by the clustering algorithm.
+       Included in the final selection set.
#       Selected for synchronization; but distance exceeds maximum.
*       Selected for synchronization.
o       Selected for synchronization, pps signal in use.

Since the peers command depends on the ability to parse the values in the responses it gets, it may fail to work from time to time with servers which poorly control the data formats.

The contents of the host field may be given in one of four forms. It may be a host name, an IP address, a reference clock implementation name with its parameter or, REFCLK(implementation number, parameter). On “hostnames no” only IP–addresses will be displayed.

\peers
Like peers, except a summary of all associations for which the server is maintaining state is printed. This can produce a much longer list of peers from inadequate servers.

opeers
An old form of the peers command with the reference ID replaced by the local interface address.

Bugs

The peers command is non-atomic. It may occasionally result in spurious error messages about invalid associations occurring and terminating the command.

The timeout value is a fixed constant. As a result, it often waits a long time to timeout, since the fixed value assumes sort of a worst case. The program should improve the time out estimate as it sends queries to a particular host; but it does not.
ntptrace - trace a chain of NTP hosts back to their master time source

Synopsis
/usr/sbin/ntptrace [-vdn] [-r retries] [-t timeout] [server]

Description
ntptrace determines where a given Network Time Protocol (NTP) server gets its time from, and follows the chain of NTP servers back to their master time source. If given no arguments, it starts with localhost.

Options
The following options are supported:
- d  Turns on some debugging output.
- n  Turns off the printing of hostnames; instead, host IP addresses are given. This may be necessary if a nameserver is down.
- r retries  Sets the number of retransmission attempts for each host.
- t timeout  Sets the retransmission timeout (in seconds); default = 2.
- v  Prints verbose information about the NTP servers.

Examples
Example 1  Sample Output From the ntptrace Command
The following example shows the output from the ntptrace command:

% ntptrace

  localhost: stratum 4, offset 0.0019529, synch distance 0.144135
  server2.bozo.com: stratum 2, offset 0.0124263, synch distance 0.115784
  usndh.edu: stratum 1, offset 0.0019298, synch distance 0.011993, refid 'WWVB'

On each line, the fields are (left to right):
- The server’s host name
- The server’s stratum
- The time offset between that server and the local host (as measured by ntptrace; this is why it is not always zero for localhost)
- The host’s synchronization distance
- The reference clock ID (only for stratum-1 servers)

All times are given in seconds. Synchronization distance is a measure of the goodness of the clock's time.

**Bugs**  This program makes no attempt to improve accuracy by doing multiple samples.
obpsym (1M)

**Name**

obpsym – Kernel Symbolic Debugging for OpenBoot Firmware

**Synopsis**

```bash
modload -p misc/obpsym
```

**Description**

obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric *addresses* to kernel symbol names for display purposes, and to convert kernel symbol names to numeric *literals* allowing symbolic names to be used as input arguments to user interface commands.

Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware’s user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands `ctrace` and `dis` typically display symbolic names and offsets in the form `modname:symbolname + offset`. User interface Commands such as `dis` can be given a kernel symbolic name such as `ufs:ufs_mount` instead of a numeric address.

Placing the command

```bash
forceload: misc/obpsym
```

into the `system(4)` file forces the kernel module `misc/obpsym` to be loaded and activates the kernel callbacks during the kernel startup sequence.

obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware’s `ctrace` command to display symbolic names in the stack backtrace after a watchdog reset.

**Kernel Symbolic Name Syntax**

The syntax for a kernel symbolic name is:

```
[ module-name : ] symbol-name
```

Where `module-name` is the name of the kernel module that the symbol `symbol-name` appears in. A NULL module name is taken as "all modules, in no particular order" by obpsym. The module name `unix` is equivalent to a NULL module name, so that conflicts with words defined in the firmware’s vocabulary can be avoided.

Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal *vocabulary* before checking if the word is a *literal*. Thus, kernel symbols, such as `reset` may be given as `unix:reset` to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.

**Files**

- `/etc/system` system configuration information file
- `/platform/platform-name/kernel/misc/obpsym`

OpenBoot 2.x Command Reference Manual

Warnings

Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of "last resort".

If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

Notes

platform-name can be found using the -i option of uname(1)

obpsym is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the obpsym symbol callback support can be added to the firmware, if the firmware doesn’t include support for the symbol callbacks. On these systems, obpsym may complain that it requires that "you must use ramforth to use this module".

See the OpenBoot 2.x Command Reference Manual for details on how to use the ramforth command, how to place the command into nvrarc, and how to set use-nvrarc? to true. On systems with version 1.x OpenBoot firmware, nvrarc doesn’t exist, and the ramforth command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

0 0 set-symbol-lookup
ocferv – OCF server

cferv [-D] [-p path]

The OCF server, ocfserv, is a per-host daemon that acts as the central point of communications with all smartcards connected to the host. Applications that need to use a smartcard can do so by using the APIs in libsmartcard.so or smartcard.jar. The internal implementation of these APIs communicates with ocfserv to perform the requested function.

inetd(1M) automatically starts the ocfserv command when it is needed. Once started, ocfserv runs forever. If ocfserv is killed or crashes, it restarts automatically if necessary.

Because ocfserv is run automatically, there really is not a reason to run it manually. You must have root privileges to execute this utility.

The following options are supported:
- D Run ocfserv in debug mode.
- p path Specify property file name.

The following exit values are returned:
0 Successful completion.
>0 An error occurred.

/etc/smartcard/opencard.properties File where server stores properties

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWocf</td>
</tr>
</tbody>
</table>

The ocfserv service is managed by the service management facility, smf(5), under the service identifier:
svc:/network/rpc/ocfserv

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svc(1) command.
**Name**  oplhp - Hot plug daemon for SPARC Enterprise Server line

**Synopsis**  /usr/platform/SUNW,SPARC-Enterprise/lib/sparcv9/lib/oplhpd

**Description**  The hot plug daemon for SPARC Enterprise Servers is a daemon process that runs on the SUNW,SPARC-Enterprise family of servers. The daemon is started by the service management facility (see `smf(5)`) and communicates with the service processor when hot plug PCI cassettes change their dynamic reconfiguration state.

The service FMRI for `oplhp` is:

```
svc:/platform/sun4u/oplhpd:default
```

A domain supports only one running `oplhp` process at a time.

**Errors**  OPLHPD uses `syslog(3C)` to report status and error messages. All of the messages are logged with the LOG_DAEMON facility.

Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_DEBUG priority. The default entries in the `/etc/syslog.conf` file log all of the OPLHPD error messages to the `/var/adm/messages` log.

Name
parse_dynamic_clustertoc – parse clustertoc file based on dynamic entries

Synopsis
cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc
cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc

Description
This script parses the clustertoc file before the suninstall(1M) process is run.
parse_dynamic_clustertoc is called by a modified sysconfig script on the install CD. When
parse_dynamic_clustertoc runs, it reads the clustertoc and when it encounters
SUNW_CSRMBRIFF lines, it either checks the platform using the script’s builtin function, or calls
an external script. The script exits with a 0 if the cluster entry is included, otherwise it will be
ignored. If the cluster entry is to be included, the SUNW_CSRMBRIFF = (test test_arg) cluster line
is converted to SUNW_CSRMEMBER = cluster.

Examples
EXAMPLE 1 Checking For an SX Framebuffer

The following is an example of a simple external test to check for an SX Framebuffer. The
entry in the clustertoc file is shown and following that is the script that must be placed in the
install.d/dynamic_test directory.
SUNW_CSRMBRIFF = (smcc.dctoc sx) SUNW_Csx
#!/bin/sh
#
# Likewise, this file is expected to live under $TESTDIR.
#
case "$1"
in
  sx) prtconf -p | grep 'SUNW,sx' 1> /dev/null;;
esac

Name  passmgmt – password files management

Synopsis  passmgmt -a options name
            passmgmt -m options name
            passmgmt -d name

Description  The passmgmt command updates information in the password files. This command works with both /etc/passwd and /etc/shadow.

passmgmt -a adds an entry for user name to the password files. This command does not create any directory for the new user and the new login remains locked (with the string *LK* in the password field) until the passwd(1) command is executed to set the password.

passmgmt -m modifies the entry for user name in the password files. The name field in the /etc/shadow entry and all the fields (except the password field) in the /etc/passwd entry can be modified by this command. Only fields entered on the command line will be modified.

passmgmt -d deletes the entry for user name from the password files. It will not remove any files that the user owns on the system; they must be removed manually.

passmgmt can be used only by the super-user.

Options  -c comment  A short description of the login, enclosed in quotes. It is limited to a maximum of 128 characters and defaults to an empty field.

    -e expire  Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

    -f inactive  The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

    Changing the password reactivates an account for the inactivity period.

    -g gid  GID of name. This number must range from 0 to the maximum non-negative value for the system. The default is 1.

    -h homedir  Home directory of name. It is limited to a maximum of 256 characters and defaults to /usr/name.

    -K key=value  Set a key=value pair. See user_attr(4), auth_attr(4), and prof_attr(4). The valid key=value pairs are defined in user_attr(4), but the "type" key is subject to the usermod(1M) and rolemod(1M) restrictions. Multiple key=value pairs may be added with multiple -K options.
-k skel_dir A directory that contains skeleton information (such as .profile) that can be copied into a new user's home directory. This directory must already exist. The system provides the /etc/skel directory that can be used for this purpose.

-\ logname This option changes the name to logname. It is used only with the -m option. The total size of each login entry is limited to a maximum of 511 bytes in each of the password files.

-o This option allows a UID to be non-unique. It is used only with the -u option.

-s shell Login shell for name. It should be the full pathname of the program that will be executed when the user logs in. The maximum size of shell is 256 characters. The default is for this field to be empty and to be interpreted as /usr/bin/sh.

-u uid UID of the name. This number must range from 0 to the maximum non-negative value for the system. It defaults to the next available UID greater than 99. Without the -o option, it enforces the uniqueness of a UID.

**Exit Status** The passmgmt command exits with one of the following values:

0 Success.
1 Permission denied.
2 Invalid command syntax. Usage message of the passmgmt command is displayed.
3 Invalid argument provided to option.
4 UID in use.
5 Inconsistent password files (for example, name is in the /etc/passwd file and not in the /etc/shadow file, or vice versa).
6 Unexpected failure. Password files unchanged.
7 Unexpected failure. Password file(s) missing.
8 Password file(s) busy. Try again later.
9 name does not exist (if -m or -d is specified), already exists (if -a is specified), or logname already exists (if -m -l is specified).

**Files** /etc/passwd
/etc/shadow
/etc/opasswd
/etc/oshadow
Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

</tr>
</tbody>
</table>

See Also passwd(1), roleadd(1M), roledel(1M), rolemod(1M), useradd(1M), userdel(1M), usermod(1M), auth_attr(4), passwd(4), prof_attr(4), shadow(4), user_attr(4), attributes(5)

Notes Do not use a colon (:) or RETURN as part of an argument. It is interpreted as a field separator in the password file.

This command only modifies password definitions in the local /etc/passwd and /etc/shadow files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, passmgmt cannot change information supplied by the network nameservice.

In a future release, passmgmt might be removed. In its place, use the current useradd/userdel/usermod and roleadd/roledel/rolemod commands, which provide the same functionality.
patchadd – apply a patch package to a system running the Solaris operating system

**Synopsis**

```bash
patchadd [-dun] [-G] [-B backout_dir] [-k keystore]
     [-P passwd] [-t] [-x proxy] {patch} |
     {-M patch_location [patch_list]} [-C net_install_image]
     [-R client_root_path] [-S service]
```

```bash
patchadd -p
     [-C net_install_image] [-R client_root_path] [-S service]
```

**Description**

`patchadd` applies a patch package to a system running the Solaris 2.x operating environment or later Solaris environments (such as Solaris 10) that are compatible with Solaris 2.x. This patch installation utility cannot be used to apply Solaris 1 patches. `patchadd` must be run as root.

The `patchadd` command has the following forms:

- The first form of `patchadd` installs one or more patches to a system, client, service, or to the miniroot of a Net Install Image.
- The second form of `patchadd` displays installed patches on the client, service, or to the miniroot of a Net Install Image.

Starting with version 10 of the Solaris operating system, `patchadd` performs validity and dependency checking among a collection of patches that you specify with the `-M source specifier. See the description of `-M` under OPERANDS, below.

With respect to `zones(5)`, when invoked in the global zone, by default, `patchadd` patches all appropriate packages in all zones. Patching behavior on system with zones installed varies according to the following factors:

- use of the `-G` option (described below)
- setting of the `SUNW_PKG_ALLZONES` variable in the `pkginfo` file (see `pkginfo(4)``
- type of zone, global or local (non-global) in `patchadd` which is invoked

The interaction of the factors above is specified in “Interaction of `-G` and `pkginfo` Variable in Zones,” below.

When you add patches to packages on a Solaris system with zones installed, you will see numerous zones-related messages, the frequency and content of which depend on whether you invoke `patchadd` in a global or local zone, the setting of `SUNW_PKG_ALLZONES`, and the use of the `-G` option.

Note that if you apply a patch that modifies objects in the boot archive, you will need to run the `bootadm` command shown below. This is true whether the patch is installed individually or as part of a cluster, using `install_cluster` and specifying an alternate root.

```bash
# bootadm update_archive -R /altroot
```

If you do not enter the preceding command, you will need to boot twice to build a clean boot archive.
The patch, -M, -C, -R, and -S arguments shown in the SYNOPSIS are described under OPERANDS, following OPTIONS.

Options  The following options are supported:

- B backout_dir
  Saves backout data to a directory other than the package database. Specify backout_dir as an absolute path name.

- d
  Does not back up the files to be patched. The patch cannot be removed.

- G
  Add patch(es) to packages in the current zone only. When used in the global zone, the patch is added to packages in the global zone only and is not propagated to packages in any existing or yet-to-be-created non-global zone. When used in a non-global zone, the patch is added to packages in the non-global zone only. See "Interaction of -G and pkginfo Variable in Zones," below.

- k keystore
  Use keystore as the location to get trusted certificate authority certificates when verifying digital signatures found in each patch. If no keystore is specified, then the default keystore locations are searched for valid trusted certificates. See KEY STORE LOCATIONS in pkgadd(1M) for more information.

- n
  Tells patchadd to ignore the signature and not to validate it. This should be used only when the content of the patch is known and trusted, and is primarily included to allow patchadd to apply a patch on systems without the ability to verify the patch signature, such as Solaris 8.

- p
  In the second form, displays a list of the patches currently applied.

- P passwd
  Password to use to decrypt the keystore specified with -k, if required. See PASS PHRASE ARGUMENTS in pkgadd(1M) for more information about the format of this option's argument.

- t
  Maintains the patchadd return codes from the Solaris release prior to Solaris 10. On a system with zones(5) installed, a return code of 0 indicates success. Any other return code indicates failure.

- u
  Turns off validation against other required or incompatible patches. Use extreme caution when using this option. Its use can precipitate unanticipated bad consequences.
-x proxy
Specify a HTTP[S] proxy to use when downloading packages. The format of proxy is
<host>:<port>, where <host> is the hostname of the HTTP[S] proxy, and <port> is the port number
associated with the proxy. This switch overrides all other methods of specifying a proxy.
See ENVIRONMENT VARIABLES in pkgadd(1M) for more information on alternate
methods of specifying a default proxy.

Operands
The following operands are supported:

Sources
- patchadd must be supplied a source for retrieving the patch. Specify sources using the syntax
shown below.

patch
The absolute path name to patch_id or a URI pointing to a signed patch.
/var/sadm/spool/patch/104945-02 is an example of a patch.
https://syrinx.eng:8887/patches/104945-02 is an example of a URI pointing to a
signed patch.

-M patch_location[patch_list]
Specifies the patches to be installed by directory location or URL and, optionally, the name
of a file containing a patch list.

When using a directory as the patch_location, specify that directory as an absolute path
name. Specify a URL as the server and path name that contains the spooled patches. The
optional patch_list is the name of the file at a specified location containing the patches to be
installed.

-M patch_location patch_id[patch_id...]
Specifies the patches to be installed by directory location or URL, and patch number.

To use the directory location or URL and the patch number, specify patch_location as the
absolute path name of the directory that contains spooled patches. Specify a URL as the
server and path name that contains the spooled patches. Specify patch_id as the patch
number of a given patch. 104945-02 is an example of a patch_id. 104945-02 is also an
example of a patchid in 104945-02.jar.

Note that patchadd does not require a list of patches. Among a collection of patches—residing
in a directory, specified in a list, or entered on a command line—patchadd performs validity
and dependency checking. Specifically, the command does the following:

- Determines whether a patch is applicable for a system. For example, if the package to be
  patched is not installed, patchadd does not attempt to add the patch.
- Establishes dependencies among valid patches and orders the installation of patches
  accordingly.

With the “Zones Parallel Patching” feature, patches can be applied to zones in parallel. After a
patch is installed successfully in the global zone, the patch installation software will start a
number of processes whose task is to apply patches to zones. The number of processes to be started would be determined by the `num_proc` parameter in the configuration file `/etc/patch/pdo.conf`.

The number of processes to be started is determined in the following order:

1. The value of the `num_proc` parameter. Setting this to 1 retains the current behavior of the patch system.
2. The number of online CPUs in the system.

The upper bound is the number of configured Solaris zones.

Most users will find the easiest way to specify a source for `patchadd` is to specify only a `patch_location` containing a set of patches.

Destinations

By default, `patchadd` applies a patch to the specified destination. If no destination is specified, then the current system (the one with its root filesystem mounted at `/`) is assumed to be the destination for the patch. You can specify a destination in the following ways:

- `-C net_install_image`
  Patches the files located on the miniroot on a Net Install Image created by `setup_install_server`. Specify `net_install_image` as the absolute path name to a Solaris 8 or compatible version boot directory. See EXAMPLES.

  You should use the `-C` option only to install patches that are recommended for installation to the miniroot. Patches that are recommended for installation to the miniroot usually include install-related patches such as package commands, and Sun install and patch installation tools. If you apply too many patches to the miniroot it can grow too large to fit into memory during a net installation of Solaris. Use the `-B` option and the `-C` option together so the miniroot does not get too large. See `-B`, above.

  Note that in the current release and in certain versions of Solaris 10, the miniroot is compressed. To determine whether the miniroot is compressed on your system, look for a file called `sparc.miniroot` or `x86.miniroot` under `/boot`, on the boot medium. Before you can patch a compressed miniroot, you must perform certains steps. See "Patching a Compressed Miniroot" below.

- `-R client_root_path`
  Locates all patch files generated by `patchadd` under the directory `client_root_path`. `client_root_path` is the directory that contains the bootable root of a client from the server's perspective. Specify `client_root_path` as the absolute path name to the beginning of the directory tree under which all patch files generated by `patchadd` are to be located. `-R` cannot be specified with the `-S` option. See NOTES.

  **Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.  

-S service
  Specifies an alternate service (for example, Solaris_8). This service is part of the server
  and client model, and can only be used from the server’s console. Servers can contain
  shared /usr file systems that are created by smosservice(1M). These service areas can then
  be made available to the clients they serve. -S cannot be specified with the -R option. See
  NOTES.

The Solaris operating system uses a compressed miniroot. The compressed miniroot was
adopted first in Solaris for x86 and then in Solaris for SPARC over the course of Solaris 10
update releases. See below for an easy way to determine whether your Solaris system uses a
compressed miniroot.

To patch a system with a compressed miniroot (full or partial), you must unpack and then
repack the miniroot before and after running patchadd with the -C destination specifier. Use
the procedure shown below and accompanying example commands.

1. Unpack the compressed miniroot:

   # /boot/solaris/bin/root_archive unpackmedia \
   /export/home/altuser/testdir /export/home/altuser/mr

2. Run patchadd with -C to patch the miniroot:

   # patchadd -C /export/home/altuser/mr \
   /var/sadm/spool/104945-02

3. Repack the miniroot:

   # /boot/solaris/bin/root_archive packmedia \
   /export/home/altuser/testdir /export/home/altuser/mr

At this point, you can use setup_install_server(1M) to install the patched miniroot on an
install server. See root_archive(1M) for a description of that command.

To determine whether a Solaris image uses a compressed miniroot, check for the presence of
either an x86.miniroot or sparc.miniroot file under /boot on the boot medium.

The following list specifies the interaction between the -G option and the SUNW_PKG_ALLZONES
variable (see pkginfo(4)) when adding a patch in global and local (non-global) zones.

- global zone, -G specified
  If any packages have SUNW_PKG_ALLZONES set to true: Error; nothing changes.

  If no packages have SUNW_PKG_ALLZONES set to true: Apply patch to package(s) in global
  zone only.

- global zone, -G not specified
  If any packages have SUNW_PKG_ALLZONES set to true: Apply patch to appropriate
  package(s) in all zones.

  If no packages have SUNW_PKG_ALLZONES set to true: Apply patch to appropriate package(s)
  in all zones.
local zone, -G specified or not specified
  If any packages have SUNW_PKG_ALLZONES set to true: Error; nothing changes.
  If no packages have SUNW_PKG_ALLZONES set to true: Apply patch package(s) in local zone only.

**Keystore Locations**
See the section KEystore LOCATIONS in the `pkgadd(1M)` man page for details.

**Keystore And Certificate Formats**
See the section KEYSTORE AND CERTIFICATE FORMATS in the `pkgadd(1M)` man page for details.

**Examples**
The examples in this section are all relative to the `/usr/sbin` directory.

**EXAMPLE 1** Installing a Patch to a Standalone Machine
The following example installs a patch to a standalone machine:

```
example# patchadd /var/sadm/spool/104945-02
```

**EXAMPLE 2** Installing a Patch to a Client From the Server's Console
The following example installs a patch to a client from the server's console:

```
example# patchadd -R /export/root/client1 /var/sadm/spool/104945-02
```

**EXAMPLE 3** Installing a Patch to a Service From the Server's Console
The following example installs a patch to a service from the server's console:

```
example# patchadd -S Solaris_8 /var/sadm/spool/104945-02
```

**EXAMPLE 4** Installing Multiple Patches in a Single Invocation
The following example installs multiple patches in a single `patchadd` invocation:

```
example# patchadd -M /var/sadm/spool 104945-02 104946-02 102345-02
```

**EXAMPLE 5** Installing Multiple Patches Specifying List of Patches to Install
The following example installs multiple patches specifying a file with the list of patches to install:

```
example# patchadd -M /var/sadm/spool patchlist
```

**EXAMPLE 6** Installing Multiple Patches to a Client and Saving the Backout Data
The following example installs multiple patches to a client and saves the backout data to a directory other than the default:

```
example# patchadd -M /var/sadm/spool -R /export/root/client1 \
    -B /export/backoutrepository 104945-02 104946-02 102345-02
```

**EXAMPLE 7** Installing a Patch to a Solaris 8 or Compatible Version Net Install Image
The following example installs a patch to a Solaris 8 or compatible version Net Install Image:
EXAMPLE 7  Installing a Patch to a Solaris 8 or Compatible Version Net Install Image  (Continued)

example# patchadd -C /export/Solaris_8/Tools/Boot \
/var/sadm/spool/104945-02

EXAMPLE 8  Installing a Patch to a Compressed Miniroot
The following example installs a patch to a compressed miniroot, such as one finds on a
Solaris x86 machine that supports GRUB–style booting. This example assumes that
/export/Solaris_11/Tools/Boot contains the unpacked miniroot. After applying the patch,
the miniroot needs to be repacked

example# patchadd -C /export/Solaris_11/Tools/Boot \
/var/sadm/spool/104945-02

See “Patching a Compressed Miniroot,” above, for information on Solaris versions that use a
compressed miniroot.

EXAMPLE 9  Installing a Patch to an Uncompressed Miniroot
The following example installs a patch to a miniroot on a Solaris machine that does not have a
compressed miniroot.

example# patchadd -C /export/Solaris_9/Tools/Boot \
/var/sadm/spool/104945-02

See “Patching a Compressed Miniroot,” above, for information on Solaris versions that use a
compressed miniroot.

EXAMPLE 10  Displaying the Patches Installed on a Client
The following example displays the patches installed on a client:

example# patchadd -R /export/root/client1 -p

Note the caveat on the use of the -R option in the description of that option, above.

EXAMPLE 11  Installing a Digitally Signed Set of Patches
The following example installs multiple patches, some of which have been signed, using the
supplied keystore, password, and HTTP proxy.

example# patchadd -k /etc/mycerts -P pass:abcd -x webcache.eng:8080 \
-M http://www.sun.com/solaris/patches/latest 101223-02 102323-02

Files  One configuration file of note:

/etc/patch/pdo.conf  Patch configuration file. Can be used to configure "Zones Parallel
                    Patching" feature.
Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWswmt, SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>

Diagnostics  The following messages might help in determining some of the most common problems
associated with installing a patch.

Patch Installation errors  Message

The prepatch script exited with return code retcode.  
patchadd is terminating.

Explanation and Recommended Action
The prepatch script supplied with the patch exited with a return code other than 0. Run
a script trace of the prepatch script and find out why the prepatch had a bad return code.
Add the -x option to the first line of the prepatch script to fix the problem and run
patchadd again.

Message

The signature on patch patch_id was unable to be verified.  
patchadd is terminating.

Explanation and Recommended Action
The digital signature on a patch was unable to be verified given the keystore in use and
the signature on the patch. Check the keystore to make sure it has the requisite trust
anchor(s) required to validate the signature on the package and that the package has not
been tampered with.

Message

The postpatch script exited with return code retcode.  
Back out patch.
Explanation and Recommended Action
The postpatch script provided with the patch exited with an error code other than 0.
This script is mostly used to cleanup files (that is, when a package is known to have
ownership or permission problems) attributes that do not correspond to the patch
package's objects. After the user has noted all validation errors and taken the
appropriate action for each one, the user should re-run patchadd using the -u
(unconditional) option. This time, the patch installation will ignore validation errors
and install the patch anyway.

Message
Insufficient space in /var/sadm/patch to save old files.
(For 2.4 systems and previous)

Explanation and Recommended Action
There is insufficient space in the /var/sadm/patch directory to save old files. The user
has three options for handling this problem: Use the -B option while invoking
patchadd. This option will direct patchadd to: save the backout data to the user
specified file system, generate additional disk space by deleting unneeded files, or
override the saving of the old files by using the -d (do not save) option when running
patchadd.

If the user elects not to save the old versions of the files to be patched, patchrm cannot be
used. One way to regain space on a system is to remove the save area for previously
applied patches. Once the user has decided that it is unlikely that a patch will be backed
out, the user can remove the files that were saved by patchadd. The following
commands should be executed to remove the saved files for patch patch_id:

cd /var/sadm/patch/patch_id
rm -r save/*
rmdir .oldfiles saved

After these commands have been executed, patch patch_id can no longer be backed out.

Message
Insufficient space in /var/sadm/pkg/PKG/save to save old files.
(For 2.5 systems and later)

Explanation and Recommended Action
There is insufficient space in the /var/sadm/pkg/PKG/save directory to save old files.
The user has three options for handling this problem: (1) Use the -B option while
invoking patchadd. This option will direct patchadd to save the backout data to the user
specified file system. (See synopsis above.) (2) Generate additional disk space by deleting
unneeded files, or (3) override the saving of the old files by using the -d (do not save)
option when running patchadd. However, if the user elects not to save the old versions
of the files to be patched, patchrm cannot be used. One way to regain space on a system
is to remove the save area for previously applied patches. Once the user has decided that
it is unlikely that a patch will be backed out, the user can remove the files that were saved by patchadd. The following commands should be executed to remove the saved files for patch `patch_id`:

```bash
cd /var/sadm/pkg/pkgabbrev/save
rm -r patch_id
```

After these commands have been executed, patch `patch_id` can no longer be backed out.

Message

Save of old files failed.
(For 2.4 systems and previous)

Explanation and Recommended Action

Before applying the patch, the patch installation script uses `cpio` to save the old versions of the files to be patched. This error message means that the `cpio` failed. The output of the `cpio` would have been preceded this message. The user should take the appropriate action to correct the `cpio` failure. A common reason for failure will be insufficient disk space to save the old versions of the files. The user has two options for handling insufficient disk space: (1) generate additional disk space by deleting unneeded files, or (2) override the saving of the old files by using the `-d` option when running `patchadd`. However if the user elects not to save the old versions of the files to be patched, the patch cannot be backed out.

Message

`Pkgadd of pkgname package failed with error code code.`
See `/tmp/log.patch_id` for reason for failure.

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will backout the patch to leave the system in its pre-patched state. See the log file for the reason for failure. Correct the problem and reapply the patch.

Message

`Pkgadd of pkgname package failed with error code code.`
Will not backout patch...patch re-installation.

Warning: The system may be in an unstable state!
See `/tmp/log.patch_id` for reason for failure.

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will not backout the patch. You may manually backout the patch using `patchrm`, then re-apply the entire patch. Look in the log file for the reason `pkgadd` failed. Correct the problem and re-apply the patch.
Message

patchadd is unable to find the INST_RELEASE file. This file must be present for patchadd to function correctly.

Explanation and Recommended Action

The INST_RELEASE file is missing from the system. This file is created during either initial installation or during an update.

Message

A previous installation of patch $patch_id$ was invoked that saved files that were to be patched. Since files were saved, you must run this instance of patchadd without the -d option.

Explanation and Recommended Action

If a patch was previously installed without using the -d option, then the re-installation attempt must also be invoked without the -d option. Execute patchadd without the -d option.

Message

A previous installation of patch $patch_id$ was invoked with the -d option. (i.e. Do not save files that would be patched) Therefore, this invocation of patchadd must also be run with the -d option.

Explanation and Recommended Action

If a patch was previously installed using the -d option, then the re-installation attempt must also be invoked with the -d option. Execute patchadd with the -d option.

Message

Illegal character found during parsing. Read the man page for pdo config file.

Explanation and Recommended Action

The /etc/patch/pdo.conf follows a specific layout. Each entry in this file should conform to this layout. See pdo.conf(4).

Diagnostic Reference

The patch installation messages listed below are not necessarily considered errors, as indicated in the explanations given. These messages are, however, recorded in the patch installation log for diagnostic reference.

Message

Package not patched:
PKG=SUNxxxx
Original package not installed
Explaination and Recommended Action
One of the components of the patch would have patched a package that is not installed on your system. This is not necessarily an error. A patch may fix a related bug for several packages.

For example, suppose a patch fixes a bug in both the online-backup and fddi packages. If you had online-backup installed but didn't have fddi installed, you would get the message:

```
Package not patched:
PKG=SUNWbf
Original package not installed
```

This message only indicates an error if you thought the package was installed on your system. If this is the case, take the necessary action to install the package, backout the patch (if it installed other packages) and re-install the patch.

Message

```
Package not patched:
PKG=SUNxxx
ARCH=xxxxxxx
VERSION=xxxxxxx
Architecture mismatch
```

Explanations and Recommended Action

One of the components of the patch would have patched a package for an architecture different from your system. This is not necessarily an error. Any patch to one of the architecture-specific packages might contain one element for each of the possible architectures. For example, assume you are running on a sun4u. If you were to install a patch to package SUNWcar, you would see the following (or similar) messages:

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4c
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4u
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4e
VERSION=11.5.0,REV=2.0.18
```

Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4
VERSION=11.5.0,REV=2.0.18
Architecture mismatch

These messages indicate an error condition only if patchadd does not correctly recognize your architecture.

Message
Package not patched:
PKG=SUNxxxx
ARCH=xxxx
VERSION=xxxxxxx
Version mismatch

Explanation and Recommended Action
The version of software to which the patch is applied is not installed on your system. For example, if you were running Solaris 8, and you tried to install a patch against Solaris 9, you would see the following (or similar) message:

Package not patched:
PKG=SUNWcsu
ARCH=sparc
VERSION=10.0.2
Version mismatch

This message does not necessarily indicate an error. If the version mismatch was for a package you needed patched, either get the correct patch version or install the correct package version. Then backout the patch (if necessary) and reapply.

Message
Re-installing Patch.

Explanation and Recommended Action
The patch has already been applied, but there is at least one package in the patch that could be added. For example, if you applied a patch that had both Openwindows and Answerbook components, but your system did not have Answerbook installed, the Answerbook parts of the patch would not have been applied. If, at a later time, you pkgadd Answerbook, you could re-apply the patch, and the Answerbook components of the patch would be applied to the system.

Message
patchadd Interrupted.
patchadd is terminating.

Explanation and Recommended Action
patchadd was interrupted during execution (usually through pressing CTRL-c). patchadd will clean up its working files and exit.
Message

patchadd Interrupted.
Backing out Patch...

Explanation and Recommended Action

patchadd was interrupted during execution (usually through pressing CTRL-c).
patchadd will clean up its working files, backout the patch, and exit.

Message

Warning: Cannot open configuration file %s for reading. Using
default serial patching behavior

Explanation and Recommended Action

The /etc/patch/pdo.conf file is missing from the system. This file is typically created
during an initial install or update or by applying the patch for the “Zones Parallel
Patching” feature. If the file is not present, the default, one-at-time behavior of adding or
removing patches from a zoned system would ensue.

Notes

To successfully install a patch to a client or server, patchadd must be issued twice, once with
the -R option and once with the -S option. This guarantees that the patch is installed to both
the /usr and root partitions. This is necessary if there are both /usr and root packages in the
patch.

pkgadd is invoked by patchadd and executes the installation scripts in the pkg/install
directory. The checkinstall script is executed with its ownership set to user install, if there
is no user install then pkgadd executes the checkinstall script as noaccess. The SVR4 ABI
states that the checkinstall shall only be used as an information gathering script. If the
permissions for the checkinstall script are changed to something other than the initial
settings, pkgadd may not be able to open the file for reading, thus causing the patch
installation to abort with the following error:

pkgadd: ERROR: checkinstall script did not complete successfully.

The permission for the checkinstall script should not be changed. Contents of log file for a
successful installation: patchadd redirects pkgadd’s output to the patch installation log file.
For a successful installation, pkgadd will produce the following message that gets inserted into
the log file:

This appears to be an attempt to install the same architecture
and version of a package which is already installed. This
installation will attempt to overwrite this package.
This message does not indicate a failure, it represents the
correct behavior by pkgadd when a patch installs correctly.

This message does not indicate a failure, it represents the correct behavior by pkgadd when a
patch installs correctly.
On client server machines the patch package is not applied to existing clients or to the client root template space. Therefore, when appropriate, all client machines will need the patch applied directly using this same patchadd method on the client. See instructions above for applying patches to a client. A bug affecting a package utility (for example, pkgadd, pkgrm, pkgchk) could affect the reliability of patchadd or patchrm, which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

Solaris 2.5.1 Sparc Platform Edition:
104578

Solaris 2.5.1 Intel Platform Edition:
104579

Solaris 2.6 Sparc Platform Edition:
106292

Solaris 2.6 Intel Platform Edition:
106293

**Warnings**

Certain patches are classified as “deferred activation” patches (sometimes with initial capitals, as “Deferred Activation” patches). Under conditions indicated below, such patches require special treatment. A patch’s README file specifies whether that patch is of the deferred activation variety. (Search on “Deferred Activation” in the README file.)

If you are installing or removing a patch that uses deferred activation patching, you must check on the following:

- On a system running zones, all non-global zones must be in a halted state for adding or removing a patch.
- Deferred activation patching requires the loopback file system (lofs) in order to complete safely. Systems running Sun Cluster 3.1 or Sun Cluster 3.2 are likely to have lofs turned off because of restrictions on HA-NFS functionality when lofs is enabled. Therefore, before a deferred activation patch is installed or removed, you must re-enable the loopback file system by commenting out the following line in the /etc/system file:

  ```
  exclude:lofs
  ```

  Then, reboot your system and install or remove the patch. After you have completed the patch operation, uncomment the line cited above, then reboot to resume normal operation.
patchrm(1M)

Name
patchrm – remove a Solaris patch package and restore previously saved files

Synopsis
patchrm [ -f ] [ -G ] [ -B backout_dir ]
   [ -C net_install_image | -R client_root_path | -S service ]
   [ -t ] patch_id

Description
patchrm removes a patch package and restores previously saved files to a system running the Solaris 2.x operating environment or later Solaris environments (such as Solaris 8) that are compatible with Solaris 2.x. patchrm cannot be used with Solaris 1 patches. patchrm must be run as root.

With respect to zones(5), when invoked in the global zone, by default, patchrm patches all appropriate packages in all zones. Patch removal behavior in a zones environment varies according to the following factors:

- use of the -G option (described below)
- setting of the SUNW_PKG_ALLZONES variable in the pkginfo file (see pkginfo(4)).
- type of zone, global or local (non-global) in patchrm which is invoked

The interaction of the factors above is specified in “Interaction of -G and pkginfo Variable in Zones,” below.

When you remove patches from packages on a Solaris system with zones installed, you will see numerous zones-related messages, the frequency and content of which depend on whether you invoke patchrm in a global or local zone, the setting of SUNW_PKG_ALLZONES, and the use of the -G option.

With the “Zones Parallel Patching” feature, patches can be removed from zones in parallel. Using this feature, patches are removed from all zones first and, once they are removed from all zones, removed from the global zone. For this removal to occur, the patch removal software starts a number of processes whose task is to remove patches from zones. The number of processes to be started would be determined by the num_proc parameter in the configuration file /etc/patch/pdo.conf.

The number of processes to be started is determined in the following order:

1. The value of the num_proc parameter. Setting this to 1 retains the current behavior of the patch system.
2. The number of online CPUs in the system.

The upper bound is the number of configured Solaris zones.

Options
The following options are supported:

- B backout_dir
  Removes a patch whose backout data has been saved to a directory other than the package database. This option is only needed if the original backout directory, supplied to the patchadd command at installation time, has been moved. Specify backout_dir as an absolute path name.
-C net_install_image
Removes the patched files located on the mini root on a Net Install Image created by
setup_install_server. Specify net_install_image as the absolute path name to a Solaris
2.6 or compatible version boot directory. See EXAMPLES.

-f
Forces the patch removal regardless of whether the patch was superseded by another patch.

-G
Remove patch(es) to packages in the current zone only. When used in the global zone, the
patch is removed from packages in the global zone only and is not removed from packages
in any existing non-global zone. When used in a non-global zone, the patch is removed
from packages in the non-global zone only. See “Interaction of -G and pkginfo Variable in
Zones”, below.

-R client_root_path
Locates all patch files generated by patchrm under the directory client_root_path.
client_root_path is the directory that contains the bootable root of a client from the server’s
perspective. Specify client_root_path as the absolute path name to the beginning of the
directory tree under which all patch files generated from patchrm will be located. -R cannot
be specified with the -S option.

Note – The root file system of any non-global zones must not be referenced with the -R
option. Doing so might damage the global zone’s file system, might compromise the
security of the global zone, and might damage the non-global zone’s file system. See
zones(5).

-S service
Specifies an alternate service (for example, Solaris_2.3). This service is part of the server
and client model, and can only be used from the server’s console. Servers can contain
shared /usr file systems that are created by smosservice(1M). These service areas can then
be made available to the clients they serve. -S cannot be specified with the -R option.

-t
Maintains the patchrm return codes from the Solaris release prior to Solaris 10. On a
system with zones(5) installed, a return code of 0 indicates success. Any other return code
indicates failure.

The following list specifies the interaction between the -G option and the SUNW_PKG_ALLZONES
variable (see pkginfo(4)) when removing a patch in global and local (non-global) zones.
global zone, -G specified
If any packages have SUNW_PKG_ALLZONES set to true: Error; nothing changes.

If no packages have SUNW_PKG_ALLZONES set to true: Remove patch from package(s) in
global zone only.
If any packages have SUNW_PKG_ALLZONES set to true: Remove patch from appropriate package(s) in all zones.

If no packages have SUNW_PKG_ALLZONES set to true: Remove patch from appropriate package(s) in all zones.

If any packages have SUNW_PKG_ALLZONES set to true: Error; nothing changes.

If no packages have SUNW_PKG_ALLZONES set to true: Remove patch from package(s) in local zone only.

Operands

The following operands are supported:

\textit{patch\_id}

The patch number of a given patch. 104945-02 is an example of a \textit{patch\_id}.

Examples

The examples in this section assume that patch 104945-02 has been installed to the system prior to removal. All of the examples are relative to the /usr/sbin directory.

\textbf{EXAMPLE 1}  Removing a Patch From a Stand-alone System

The following example removes a patch from a standalone system:

example# patchrm 104945-02

\textbf{EXAMPLE 2}  Removing a Patch From a Client's System From the Server's Console

The following example removes a patch from a client's system from the server's console:

example# patchrm -R /export/root/client1 104945-02

Note the caveat on the use of the -R option in the description of that option, above.

\textbf{EXAMPLE 3}  Removing a Patch From a Server's Service Area

The following example removes a patch from a server's service area:

example# patchrm -S Solaris_2.3 104945-02

\textbf{EXAMPLE 4}  Removing a Patch From a Net Install Image

The following example removes a patch from a Net Install Image:

example# patchrm -C /export/Solaris_2.6/Tools/Boot 104945-02

Files

One configuration file of note:

\texttt{/etc/patch/pdo.conf}  Patch configuration file. Can be used to configure "Zones Parallel Patching" feature.
Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWswmt, SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  cpio(1), pkginfo(1), patchadd(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M), showrev(1M), pdo.conf(4), pkginfo(4), attributes(5), zones(5)

Diagnostics  The following messages may help in determining some of the most common problems associated with backing out a patch.

Message

  prebackout patch exited with return code code.  
  patchrm exiting.

  Explanation and Recommended Action
  The prebackout script supplied with the patch exited with a return code other than 0. Generate a script trace of the prebackout script to determine why the prebackout script failed. Add the -x option to the first line of the prepatch script to fix the problem and run patchrm again.

Message

  postbackout patch exited with return code code.  
  patchrm exiting.

  Explanation and Recommended Action
  The postbackout script supplied with the patch exited with a return code other than 0. Look at the postbackout script to determine why it failed. Add the -x option to the first line of the prepatch script to fix the problem, and, if necessary, re-execute the postbackout script only.

Message

  Only one service may be defined.  

  Explanation and Recommended Action
  You have attempted to specify more than one service from which to backout a patch. Different services must have their patches backed out with different invocations of patchrm.
Message

The `-S` and `-R` arguments are mutually exclusive.

Explanation and Recommended Action
You have specified both a non-native service and a `client_root_path` from which to backout a patch. These two arguments are mutually exclusive. If backing out a patch from a non-native `usr` partition, the `-S` option should be used. If backing out a patch from a client's root partition (either native or non-native), the `-R` option should be used.

Message

The `service` service cannot be found on this system

Explanation and Recommended Action
You have specified a non-native service from which to backout a patch, but the specified service is not installed on your system. Correctly specify the service when backing out the patch.

Message

Only one `client_root_path` may be defined.

Explanation and Recommended Action
You have specified more than one `client_root_path` using the `-R` option. The `-R` option may be used only once per invocation of `patchrm`.

Message

The `dir` directory cannot be found on this system.

Explanation and Recommended Action
You have specified a directory using the `-R` option which is either not mounted, or does not exist on your system. Verify the directory name and re-backout the patch.

Message

Patch `patch_id` has not been successfully installed to this system.

Explanation and Recommended Action
You have attempted to backout a patch that is not installed on this system. If you must restore previous versions of patched files, you may have to restore the original files from the initial installation CD.

Message

Patch `patch_id` has not been successfully applied to this system.
Will remove directory `dir`.

Explanation and Recommended Action
You have attempted to back out a patch that is not applied to this system. While the patch has not been applied, a residual `/var/sadm/patch/patch_id` (perhaps from an unsuccessful `patchadd`) directory still exists. The patch cannot be backed out. If you
must restore old versions of the patched files, you may have to restore them from the initial installation CD.

Message
This patch was obsoleted by patch patch_id.
Patches must be backed out in the reverse order in which they were installed. Patch backout aborted.

Explanation and Recommended Action
You are attempting to backout patches out of order. Patches should never be backed-out out of sequence. This could undermine the integrity of the more current patch.

Message
Patch patch_id is required to be installed by an already installed patch_id.
It cannot be backed out until the required patch is backed out first.

Explanation and Recommended Action
Backout the patch that is required to be installed then backout the desired patch.

Message
The installation of patch patch_id was interrupted.

Explanation and Recommended Action
A previous installation was interrupted. The interrupted patch needs to be installed before backing out the desired patch.

Message
Patch patch_id was installed without backing up the original files. It cannot be backed out.

Explanation and Recommended Action
Either the -d option of patchadd was set when the patch was applied, or the save area of the patch was deleted to regain space. As a result, the original files are not saved and patchrm cannot be used. The original files can only be recovered from the original installation CD.

Message
pkgadd of pkgname package failed return code code.
See /var/sadm/patch/patch_id/log for reason for failure.

Explanation and Recommended Action
The installation of one of patch packages failed. See the log file for the reason for failure. Correct the problem and run the backout script again.

Message
Restore of old files failed.
Explanation and Recommended Action
The backout script uses the cpio command to restore the previous versions of the files that were patched. The output of the cpio command should have preceded this message. The user should take the appropriate action to correct the cpio failure. This is for Solaris 2.4 or previous versions.

Message
Illegal character found during parsing. Read the man page for pdo config file.

Explanation and Recommended Action
The /etc/patch/pdo.conf follows a specific layout. Each entry in this file should conform to this layout. See pdo.conf(4).

Message
Warning: Cannot open configuration file %s for reading. Using default serial patching behavior

Explanation and Recommended Action
The /etc/patch/pdo.conf file is missing from the system. This file is typically created during an initial install or update or by applying the patch for the “Zones Parallel Patching” feature. If the file is not present, the default, one-at-time behavior of adding or removing patches from a zoned system would ensue.

Notes
On client server machines the patch package is not removed from existing clients or from client root template space. Therefore, when appropriate, all client machines will need the patch removed directly using this same patchrm method on the client. A bug affecting a package utility (for example, pkgadd, pkgrm, pkgchk) could affect the reliability of patchadd or patchrm which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

Solaris 2.1:
  patch 100901

Solaris 2.2:
  101122

Solaris 2.3:
  10133

Solaris 2.4 Sparc Platform Edition:
  102039

Solaris 2.4 Intel Platform Edition:
  102041

Solaris 2.5.1 Sparc Platform Edition:
  104578
Solaris 2.5.1 Intel Platform Edition:
104579

Solaris 2.6 Sparc Platform Edition:
106292

Solaris 2.6 Intel Platform Edition:
106293

**Warnings**

Certain patches are classified as "deferred activation" patches (sometimes with initial capitals, as "Deferred Activation" patches). Under conditions indicated below, such patches require special treatment. A patch's README file specifies whether that patch is of the deferred activation variety. (Search on "Deferred Activation" in the README file.)

If you are installing or removing a patch that uses deferred activation patching, you must check on the following:

- On a system running zones, all non-global zones must be in a halted state for adding or removing a patch.
- Deferred activation patching requires the loopback file system (lofs) in order to complete safely. Systems running Sun Cluster 3.1 or Sun Cluster 3.2 are likely to have lofs turned off because of restrictions on HA-NFS functionality when lofs is enabled. Therefore, before a deferred activation patch is installed or removed, you must re-enable the loopback file system by commenting out the following line in the /etc/system file:

```
exclude:lofs
```

Then, reboot your system and install or remove the patch. After you have completed the patch operation, uncomment the line cited above, then reboot to resume normal operation.
pbind(1M)

Name   pbind – control and query bindings of processes or LWPs

Synopsis   pbind -b processor_id pid [/lwpid]...
   pbind [-q] [pid [/lwpid]]...
   pbind -Q [processor_id]...
   pbind -u pid [/lwpid]...
   pbind -U [processor_id]...

Description   pbind controls and queries bindings of processes and LWPs (lightweight processes) to processors. pbind can also remove processor bindings that were previously established.

When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free to execute other LWPs as well.

Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

Superusers may bind or unbind any process or LWP, while other users can bind or unbind any process or LWP for which they have permission to signal, that is, any process that has the same effective user ID as the user.

Options   The following options are supported:
   
   -b processor_id
       Binds all or a subset of the LWPs of the specified processes to the processor processor_id. Specify processor_id as the processor ID of the processor to be controlled or queried. processor_id must be present and on-line. Use the psrinfo command to determine whether or not processor_id is present and on-line. See psrinfo(1M).

   -q
       Displays the bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs will be displayed. The bindings of a subset of LWPs can be displayed by appending “/lwpids” to the process IDs. Multiple LWPs may be selected using “,” and “,” delimiters. See EXAMPLES.

   -Q
       Displays the LWPs bound to the specified list of processors, or all LWPs with processor bindings. For processes composed of multiple LWPs, the bindings of individual LWPs will be displayed.

   -u
       Removes the bindings of all or a subset of the LWPs of the specified processes, allowing them to be executed on any on-line processor.
Removes the bindings of all LWP IDs bound to the specified list of processors, or to any processor if no argument is specified.

**Operands**
The following operands are supported:

- **pid**
  The process ID of the process to be controlled or queried.

- **lwpid**
  The set of LWP IDs of the specified process to be controlled or queried. The syntax for selecting LWP IDs is as follows:
  - 2,3,4-8: LWP IDs 2, 3, and 4 through 8
  - -4: LWPs whose IDs are 4 or below
  - 4-: LWPs whose IDs are 4 or above

- **processor_id**
  The processor ID of the processor to be controlled or queried.

**Examples**

**EXAMPLE 1  Binding Processes**
The following example binds processes 204 and 223 to processor 2:

```
example% pbind -b 2 204 223
process id 204: was 2, now 2
process id 223: was 3, now 2
```

**EXAMPLE 2  Unbinding a Process**
The following example unbinds process 204:

```
example% pbind -u 204
```

**EXAMPLE 3  Querying Bindings**
The following example queries bindings. It demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
process id 1: 0
process id 149: 3
process id 101: not bound
```

**EXAMPLE 4  Querying LWP Bindings**
The following example queries bindings of LWPs. It demonstrates that LWP 1 of process 149 is bound to CPU3, and LWP 2 of process 149 is not bound.

```
example% pbind -q 149/1-2
lwp id 149/1: 3
lwp id 149/2: not bound
```
EXAMPLE 5  Querying LWP Bindings for Processor 2:
The following example queries all LWPs bound to processor 2:

    example% pbind -Q 2
    lwp id 149/4: 2
    lwp id 149/5: 2

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

Exit Status  The following exit values are returned:

    0  Successful completion.

    >0  An error occurred.

See Also  psradm(1M), psrinfo(1M), psrset(1M), processor_bind(2), processor_info(2),
          sysconf(3C), attributes(5)

Diagnostics  pbind: cannot query pid 31: No such process
              The process specified did not exist or has exited.

              pbind: cannot bind pid 31: Not owner
              The user does not have permission to bind the process.

              pbind: cannot bind pid 31: Invalid argument
              The specified processor is not on-line.
**Name**

pcitool – interrupt routing tool

**Synopsis**

```
/usr/sbin/pcitool -h
```

```
x86:
/usr/sbin/pcitool pci@unit-address -i cpu#,ino# | all [-r [-c] | -w cpu# [-g] | [-v] [-q]
```

```
SPARC:
/usr/sbin/pcitool pci@unit-address | nia@unit-address -i ino# | all [-r [-c] | -w cpu# [-g] | [-v] [-q]
```

```
/usr/sbin/pcitool pci@unit-address -m msi# | all [-r [-c] | -w cpu# [-g] | [-v] [-q]
```

**Description**

PCItool is a low-level tool that provides a facility for getting and setting interrupt routing information.

**Interrupt Routing**

The `pcitool -i` command displays device and CPU routing information for INOs on a given nexus, and allows rerouting of a given INO or INO group to a specific CPU.

On SPARC platforms, the INO is mapped to an interrupt mondo, where as one or more MSI/Xs are mapped to an INO. So, INO and MSI/Xs are individually retargetable. Use the `-i` option to retrieve or reroute a given INO; use the `-m` option for MSI/Xs.

Specifying `cpu#` is available on the x86 platform. In combination with `ino#`, this identifies an exclusive vector. The `cpu#` argument is not supported on the SPARC platform.

**Required Privileges**

A user must have all privileges in order to access interrupt information. A regular user can access interrupt information following an `su(1M)` to root or if he is granted the "Maintenance and Repair" rights profile in the `user_attr` file. See `user_attr(4)` and `rbac(5)`.

**Options**

The following options are supported:

- `-h`
  Display command usage.

- `-q`
  No errors are displayed as messages. However, pcitool still returns Unix error codes.

- `-r [-c]`
  Display device and CPU routing information for INOs on a given nexus. The device path and instance number of each device for each displayed INO is displayed. On some platforms, interrupts dedicated to the root complex are indicated by the string "(Internal)" appended to their pathnames.

  With `-c`, dump interrupt controller information.

  If neither `-r` nor `-w` are provided on the command line, `-r` is assumed. See Examples.
-V
  Verbose output.

-w cpu# [-g]
  Route the given INO or MSI/X to the given CPU. Display the new and original routing information. The INO or MSI/X must be specified.

  On some platforms (such as x86) multiple MSI interrupts of a single function need to be rerouted together. Use -g to do this. The -g option works only on supported platforms and only for groups of MSI interrupts. (A “group” of 1 is accepted.) When -g is used, the vector provided must be the lowest-numbered vector of the group. The size of the group is determined internally. See Examples.

Examples

**EXAMPLE 1**  Displaying All INOs

The command for showing all INOs on /pci@0,0 is:

```
# pcitool /pci@0,0 -i all
```

**EXAMPLE 2**  Displaying Output for Specific INO

The command for showing INO 0x0,0x21 on the root nexus /pci@0,0 differs slightly between x86 and SPARC platforms.

On an x86 platform:

```
# pcitool /pci@0,0 -i 0,21
0x0,0x21: mpt 0 /pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 21
0x0,0x21: mpt 0 /pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

Output shown above is an example and might vary from your output.

**EXAMPLE 3**  Displaying Output for Specific MSI

The command for showing MSI 0x1 on the root nexus /pci@0,0, along with sample output, is shown below.

```
# pcitool /pci@0,0 -m 0x1
0x0,0x1: pcieb 0 /pci@7b,0/pci10de,5d@e
```

**EXAMPLE 4**  Rerouting an INO from One CPU to Another

Successful rerouting INO 21 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:
EXAMPLE 4  Rerouting an INO from One CPU to Another  (Continued)

```bash
# pcitool /pci@0,0 -i 0,21 -w 1
0x0,0x21 -> 0x1,0x20
```

On a SPARC platform:

```bash
# pcitool /pci@0,0 -i 21 -w 1
0x0,0x21 -> 0x1,0x20
```

EXAMPLE 5  Rerouting an MSI from One CPU to Another

Successful rerouting MSI 1 from CPU 1 to CPU 0 produces the output shown below.

```bash
# pcitool /pci@0,0 -m 1 -w 0
0x1,0x1 -> 0x0,0x1
```

EXAMPLE 6  Rerouting a Group of INOs

Successful rerouting of a group of INOs starting at 24 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:

```bash
# pcitool /pci@0,0 -i 3,24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

On a SPARC platform:

```bash
# pcitool /pci@0,0 -i 24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

**Exit Status**

- **0**
  - No error.
- **EINVAL**
  - Out-of-range, misaligned, or otherwise invalid argument has been passed in.
- **ETIME**
  - Timeout waiting for pending interrupt to settle before changing interrupts to a new CPU.
- **EIO**
  - An I/O error occurred.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

**Notes**  All values are entered in hex.

Not all commands are applicable to all platforms.
**Name**  pcmcia – PCMCIA user daemon

**Synopsis**  
/usr/lib/pmcia

**Description**  The PCMCIA user daemon provides user-level services for the PCMCIA nexus driver and PCMCIA card client drivers. There are no user-configurable options for this daemon.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpcmci</td>
</tr>
</tbody>
</table>

**See Also**  pcmcia(7D), attributes(5)

**Diagnostics**  pcmcia: can’t open /dev/pem: No such file or directory
The user daemon could not communicate with the PCMCIA event management driver.
After you create a profile, you can use the `pfinstall` command to test the profile and see if it does what you want before using it to install or upgrade a system. `pfinstall` enables you to test a profile against:

- The system’s disk configuration where `pfinstall` is being run.
- Other disks by using a disk configuration file that represents a structure of a disk. See `NOTES` on how to create a disk configuration file.

To successfully and accurately test a profile for a particular Solaris release, you must test a profile within the Solaris environment of the same release. For example, if you want to test a profile for Solaris 2.10, you have to run the `pfinstall` command on a system running Solaris 2.10.

So, on a system running Solaris 2.10, you can test Solaris 2.10 initial installation profiles. However, if you want to test a Solaris 2.10 upgrade profile on a system running a previous version of Solaris, or if you don’t have a Solaris 2.10 system installed yet to test Solaris 2.10 initial installation profiles, you have to boot a system from a Solaris 2.10 CD image and temporarily create a Solaris 2.10 install environment. Then, you can run `pfinstall` in the Solaris 2.10 install environment to test your profiles.

To create a temporary Solaris operating system install environment, boot a system from a Solaris CD image (just as you would to install), answer any system identification questions, choose the Solaris Interactive Installation program, and exit out of the first screen that is presented. Then, from the shell, you can execute the `pfinstall` command.

### Options

The following options are supported:

- `-c CDpath` The path to the Solaris installation image. This is required if the image is not mounted on `/cdrom`. (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than `/cdrom`.) When testing a profile on an x86 machine, the miniroot needs to be unpacked before using `-c` option. See EXAMPLES, below, for the procedure to unpack the miniroot.

- `-d disk_config` `pfinstall` uses a disk configuration file, `disk_config`, to test the profile. See `NOTES` on how to create a disk configuration file. You must specify either this option or the `-D` option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (`install_type upgrade`). You must always test an upgrade profile against a system’s disk configuration (`-D` option).

- `-D` `pfinstall` uses the system’s disk configuration to test the profile. You must specify either this option or the `-d` option to test the profile (see WARNINGS).
Operands

The following operands are supported:

  profile      The file name of the profile to test. If profile is not in the directory where pfinstall is being run, you must specify the path.

Examples

EXAMPLE 1  Testing an Upgrade Profile

The following example tests an upgrade profile, upgrade.prof, on a system with a previous version of the Solaris software installed.

1. Boot the system to be upgraded from the Solaris image chosen for the upgrade, just as you would to install. The image can be located in the system’s local CD-ROM or on an install server.
2. Answer the system configuration questions, if prompted.
3. If you are presented with a choice of installation options, choose the Solaris Interactive Installation program.
4. Exit from the first screen of the Solaris Interactive Installation program.
   After the Solaris Interactive Installation program exits, a shell prompt is displayed.
5. Create a temporary mount point:

        example# mkdir /tmp/mnt

6. Mount the directory that contains the profile(s) you want to test.
   If you want to mount a remote NFS file system (for systems on the network), enter:

        example# mount -F nfs server_name:path /tmp/mnt

   If you want to mount a UFS-formatted diskette, enter:

        example# mount -F ufs /dev/diskette /tmp/mnt

   If you want to mount a PCFS-formatted diskette, enter:

        example# mount -F pcfs /dev/diskette /tmp/mnt

7. Change directory to /tmp/mnt where the profile resides:

        example# cd /tmp/mnt

8. Test the upgrade.prof profile:

        example# /usr/sbin/install.d/pfinstall -D upgrade.prof

EXAMPLE 2  Testing the basic.prof Profile on an x86 Machine (Includes Unpacking miniroot)

The following example tests the basic.prof profile against the disk configuration on a Solaris 8 system where pfinstall is being run. The path to the Solaris CD image is specified because Volume Management is being used.

        example# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/s0 basic.prof
**EXAMPLE 2**  Testing the `basic.prof` Profile on an x86 Machine (Includes Unpacking miniroot)

(Continued)

When testing a profile on an x86 machine, before using `pfinstall` with `-c` option, use the following procedure to unpack the miniroot:

1. Uncompress the miniroot archive into a temporary file. The miniroot archive is under `/cdrom/cdrom0/s0`.

   ```
   # /usr/bin/gzcat /cdrom/cdrom0/boot/x86.miniroot > \n   /tmp/x86_miniroot_gz
   ```

2. Create the miniroot device using `lofiadm(1M)`:

   ```
   /usr/sbin/lofiadm -a /tmp/x86_miniroot_gz
   /dev/lofi/1
   ```

3. Mount the miniroot under miniroot directory using the `lofi` device returned by `lofiadm` in the previous step:

   ```
   # /usr/sbin/mount -F ufs /dev/lofi/1 \n   /cdrom/cdrom0/Solaris_10/Tools/Boot
   ```

4. Now run `pfinstall` with `-D` option:

   ```
   # /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/ jumpstart.profile
   ```

5. After `pfinstall` testing is completed, unmount the `lofi` device:

   ```
   # /usr/sbin/umount /dev/lofi/1
   ```

6. Delete the `lofi` device:

   ```
   # /usr/sbin/lofiadm -d /tmp/x86_miniroot_gz
   ```

**EXAMPLE 3**  Testing the `basic.prof` Profile Against Disk Config File

The following example tests the `basic.prof` profile against the `535_test` disk configuration file. This example uses a Solaris CD image located in the `/export/install` directory, and `pfinstall` is being run on a Solaris 2.6 system.

```
example# /usr/sbin/install.d/pfinstall -d 535_test \n   -c /export/install basic.prof
```

**Exit Status**  
0  Successful (system rebooted).  
1  Successful (system not rebooted).  
2  An error occurred.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:
If the `-d` or `-D` option is not specified, `pfinstall` may perform an actual installation on the system by using the specified profile, and the data on the system may be overwritten.

You have to test a profile on a system with the same platform type for which the profile was created.

**SPARC**

To create a disk configuration file (`-d` option) for a SPARC based system:

1. Locate a SPARC based system with a disk that you want to test.
2. Create a disk configuration file by redirecting the output of the `prtvtoc(1M)` command to a file.
   ```
   example# prtvtoc /dev/rdsk/c0t3d0s2 > 535_disk
   ```
3. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.
   ```
   example# cat 535_disk 1G_disk > mult_disks
   ```

**x86**

To create a disk configuration file (`-d` option) for an x86 based system:

1. Locate an x86 based system with a disk that you want to test.
2. Create part of the disk configuration file by saving the output of the `fdisk(1M)` command to a file:
   ```
   example# fdisk -R -W 535_disk /dev/rdsk/c0t3d0p0
   ```
3. Append the output of the `prtvtoc(1M)` command to the disk configuration file.
   ```
   example# prtvtoc /dev/rdsk/c0t3d0s2 >> 535_disk
   ```
4. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.
   ```
   example# cat 535_disk 1G_disk > mult_disks
   ```

To test a profile with a specific system memory size, set `SYS_MEMSIZE` to the specific memory size (in Mbytes) before running `pfinstall`:

```
example# SYS_MEMSIZE=memory_size
example# export SYS_MEMSIZE
```
The pginfo displays information about the Processor Group (PG) hierarchy, its contents, and its characteristics. A PG is a set of CPUs that are grouped together by a common characteristic.

PGs are used by the operating system to represent the CPUs that share performance relevant hardware such as the execution pipelines, caches, and so forth. These PGs are organized into a hierarchy that models the processor topology of the machine. In this hierarchy, each CPU (strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each successive ancestor of the leaf PG shares progressively less hardware with the CPU until the root PG is reached. The root PG contains all of the CPUs in the system and represents the group of CPUs sharing the least hardware with each other. (See EXAMPLES below for an example of PG hierarchy.)

If a machine does not have any performance-relevant hardware sharing relationships, then pginfo displays only a root PG that contains all of the CPUs in the system.

By default, pginfo displays information about each PG in the system, including its PG ID, sharing relationship, and online and offline CPUs. It displays the PGs in depth first order by default and uses indentation to help show how the PGs are related to each other (see EXAMPLES below).

You can specify options to:

- Display the PG hierarchy graphically
- List the PG sharing relationships that exist on the running system
- Give current PG utilization information, specifying PGs of interest by PG ID, CPU ID, or sharing relationship
- Specify that only CPU or PG IDs be displayed

In addition, there is a -p option to show which PGs contain the CPUs that correspond to the CPUs with a common physical relationship such as system, chip, and core. These physical relationships describe the physical characteristics of the CPUs and might or might not encapsulate performance-relevant processor sharing relationships.

If the system configuration repeatedly changes when pginfo is obtaining a snapshot of system data, pginfo displays an error message and terminates with exit status 1.
Options

The following options are supported:

- `c processor_id`
  Interpret arguments as processor IDs and display only information about PGs that contain the specified processors.

  When used with the `-T` option, this option limits the PG hierarchy displayed to include only the lineage of each of the specified CPUs. This option cannot be used when specifying PGs of interest by PG ID.

- `c`
  Display only CPU IDs for all CPUs belonging to the PGs. This option cannot be used at the same time as the `-I` option.

- `h`
  Display short help message and exit with exit status 0.

- `I`
  Display only PG IDs for the PGs. This option cannot be used at the same time as the `-C` option.

- `p`
  Display the physical relationship that corresponds to a PGs. If a PG has the same CPUs as the whole system, a processor core, or a chip, `system`, `core`, or `chip` will be displayed, as appropriate, after the sharing relationship of the PG in square brackets (“[ ]”).

- `r string1,string2,...`
  Display only information about PGs with a sharing relationship name that matches any of the specified strings.

  Each specified string can be a whole relationship name or a portion of one or more relationship names and the string matching is case-insensitive. The possible relationship names are in the list of sharing relationships that the `-s` option displays.

  You can specify multiple `-r` options, which results in matching all PGs with a relationship name that contain any of the specified strings. When used with the `-T` option, this option limits the PG hierarchy displayed to include only the lineage of each of the PGs with the specified relationship.

- `R string1,string2,...`
  Display only information about PGs with a sharing relationship name other than the one(s) specified.

  String matching is the same as described above for the `-r` option. Multiple `-R` options can be entered.

- `s`
  Display all sharing relationships supported on the running system for the specified PGs. The `-v` option can be used with this option to get the list of PGs for each sharing relationship.
In the resulting hierarchy, the lineage of each CPU (hardware strand) is arranged from the
PGs that share the most hardware in common with the CPU to the PGs that share the least
with the CPU. If any CPUs, PGs, or relationships of interest are specified, the resulting PG
hierarchy is limited to the lineages of the PGs with the specified CPUs, PGs, or
relationships in the PG hierarchy.

-v
Verb mode. Display additional information about PGs. When used without -s, -C, or -I,
it is equivalent to giving the -T and -p options together at the same time. When used with
the -s option, it gives the list of PGs for each sharing relationship.

Operands
The following operands can be given on the command line by specifying one or more of their
corresponding IDs or the keyword all. Multiple IDs can be specified as a space-separated list
(for example, 1 3), a range of numbers (for example, 5-8), or both (for example, 1 3 5-8
13-16). PGs and CPUs cannot be specified at the same time.

pg
PGs of interest can be specified on the command line by PG ID.

processor_id
When the -c option is entered, CPUs of interest can be specified on the
command line by CPU ID.

If an invalid PG or CPU is specified, the pginfo command displays a message on standard
error showing the invalid ID and continues processing other PGs or CPUs specified on the
command line. When none of the specified PGs or CPUs are valid, pginfo exits with an exit
status of 2.

Examples
In the examples below, the system contains one UltraSPARC T1 processor chip with 8 cores
and 32 strands.

EXAMPLE 1 Displaying Information About Every PG

The following command, using no arguments, displays information about every PG.

$ pginfo
PG RELATIONSHIP CPUs
0 System 0-31
3 Data_Pipe_to_memory 0-31
2 Floating_Point_Unit 0-31
1 Integer_Pipeline 0-3
4 Integer_Pipeline 4-7
5 Integer_Pipeline 8-11
6 Integer_Pipeline 12-15
7 Integer_Pipeline 16-19
8 Integer_Pipeline 20-23
9 Integer_Pipeline 24-27
10 Integer_Pipeline 28-31
EXAMPLE 2  Displaying Information About All Sharing Relationships

The following command displays information about all sharing relationships.

$ pginfo -s -v

RELATIONSHIP          PGs
----------------------- -------
System                  0
Data_Pipe_to_memory    3
Floating_Point_Unit    2
Integer_Pipeline       1  4-10

EXAMPLE 3  Displaying PG Hierarchy

The following command displays general information about all PGs in the system. The output shows which PGs belong to chips and cores.

$ pginfo -p -T

0 (System) CPUs: 0-31
  |-- 3 (Data_Pipe_to_memory [system,chip]) CPUs: 0-31
   |   |-- 2 (Floating_Point_Unit [system,chip]) CPUs: 0-31
   |       |   |-- 1 (Integer_Pipeline [core]) CPUs: 0-3
   |       |   |-- 4 (Integer_Pipeline [core]) CPUs: 4-7
   |       |   |-- 5 (Integer_Pipeline [core]) CPUs: 8-11
   |       |   |-- 6 (Integer_Pipeline [core]) CPUs: 12-15
   |       |   |-- 7 (Integer_Pipeline [core]) CPUs: 16-19
   |       |   |-- 8 (Integer_Pipeline [core]) CPUs: 20-23
   |       |   |-- 9 (Integer_Pipeline [core]) CPUs: 24-27
   |       '   |-- 10 (Integer_Pipeline [core]) CPUs: 28-31

EXAMPLE 4  Displaying List with Specific Criterion

The following command displays a list of CPUs sharing integer pipeline with CPU 0. This example also demonstrates the use of -r option to filter PGs by sharing relationship name.

$ pginfo -r integer_pipeline -C -c 0

0 1 2 3

EXAMPLE 5  Using Option to Exclude by Specific Criterion

The following command lists all PGs other than the ones that have Integer_Pipeline as their relationship.

$ pginfo -R Integer_Pipeline

PG RELATIONSHIP       CPUs
0 System               0-31
3 Data_Pipe_to_memory 0-31
2 Floating_Point_Unit  0-31
Exit Status

0

Successful completion.

1

An error occurred.

2

Invalid syntax.

Name  
pgstat – report utilization statistics for Processor Groups

Synopsis  
[-r string] [-R string] [-P pg ...] [-c processor_id ...]
[interval [count]]

pgstat -h

Description  
The pgstat displays utilization statistics about Processor Groups (PGs). A PG is a set of CPUs
that are grouped together by a common characteristic.

PGs are used by the operating system to represent CPUs that share performance relevant
hardware, such as execution pipelines, caches, and so forth. These PGs are organized into a
hierarchy that models the processor topology of the machine. In this hierarchy, each CPU
(strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each
successive ancestor of the leaf PG shares progressively less hardware with the CPU until the
root PG is reached. The root PG contains all of the CPUs in the system and represents the
group of CPUs sharing the least hardware with each other. (See “Examples” below for an
example of PG hierarchy).

If a machine does not have any performance-relevant hardware sharing relationships, then
pgstat displays only a root PG that contains all of the CPUs in the system.

By default, pgstat does the following:

■ Measures the hardware and software utilization of all PGs in the PG hierarchy over a one
second interval.

■ Displays the utilization of the PGs in depth first order using indentation to help show how
the PGs relate to each other.

■ Displays the ID, sharing relationship, hardware load, software load, and online CPUs for
each PG at the end of each interval.

The interval and count can be given as arguments to specify the number of seconds in the
sampling interval and number of times to measure and display the utilization for the specified
PGs.

You can specify options to further tailor the output, organize the output a certain way, and
specify PGs of interest (see “Options” below for details).

A hyphen (“-”) is displayed when the utilization for a given PG is not supported and a
question mark (?) is displayed when the utilization is not available. On systems where the
CPU hardware performance counters are needed to measure the hardware utilization, the
hardware utilization might be unavailable because the counters are being used by a
 CPC(3CPC) consumer such as attributes(5), cputrack(1), dtrace(1M), or another
application that uses libcpc(3LIB).
Options

The following options are supported:

- **A**
  Display summary of utilization data when `pgstat` is run over multiple intervals.

- **c processor_id...**
  Display utilization about PGs that contain the specified CPUs. The CPUs can be specified as a comma separated list of CPU IDs. A hyphen (“-”) can be used to specify contiguous ranges of CPU IDs (for example, 0-3).

- **C**
  Display utilization of each CPU in each PG.

- **h**
  Display short help message and exit with exit status 0.

- **p**
  Display the physical relationship that corresponds to a PG. If a PG has the same CPUs as the whole system, a processor core, or a chip, system core, or chip, as appropriate, is displayed after the sharing relationship of the PG in square brackets (“[ ]”).

- **P pg,...**
  Display utilization for specified PGs. Multiple PGs can be specified as a comma-separated list of PG IDs. A hyphen (“-”) can be used to specify a contiguous range of PG IDs (for example, 0-3).

- **r string1,string2,...**
  Display utilization only for PGs with a sharing relationship name that matches any of the specified strings. The string can be a whole relationship name or a portion of one or more relationship names. The string matching is case-insensitive.

  Multiple - **r** options can be entered, which results in matching all PGs with a relationship name that matches any of the specified strings.

- **R string1,string2,...**
  Display information only about PGs with a sharing relationship name other than the one(s) specified.

  String matching is the same as described above for the - **r** option. Multiple - **R** options can be entered.

- **s key**
  Sort output lines by the specified key in descending order. The specified key can be one of the following:

  - **pg**
    Sort by PG ID.

  - **hwLoad**
    Sort by hardware utilization.
swload
   Sort by software utilization.

user
   Sort by user time.

sys
   Sort by system time.

idle
   Sort by idle time.

depth
   Sort by descending PG tree from root to leaves, depth-first (default).

breadth
   Sort by descending PG tree from root to leaves, breadth-first.

-S key
   Sort output lines by the specified key in ascending order. Possible key values are the same as for the -s option.

-t number
   Show the top number of PGs for the specified integer number.

-T u | d
   Display timestamp for each sampling interval in Unix time (see time(2)) or the standard date format used by date(1).

-v
   Display extra information about each PG including hardware utilization and capacity and software user, system, and idle times.

Output Headings

pgstat displays the column headings, which are listed below, along with the meanings of those headings.

PG
   Processor Group ID.

RELATIONSHIP
   Sharing relationship for PG.

HW
   Hardware load in percent (calculated as UTIL/CAP for interval).

UTIL
   Hardware utilization of PG’s shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.
CAP
Approximate maximum possible utilization for PG's shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.

SW
Software load in percent (calculated as (USR + SYS) / (USR + SYS + IDLE))

USR
Percentage of time that software threads ran in user mode on CPUs in PG during interval.

SYS
Percentage of time that software threads ran in system mode on CPUs in PG during interval.

IDLE
Percentage of time that no software threads ran on CPUs in PG during interval.

CPUS
CPU IDs for CPUs in PG.

Examples
In the following examples, the system contains one UltraSPARC T1 processor chip with 8 cores and 32 strands.

EXAMPLE 1 Displaying Utilization for Specified Period

The following command displays utilization for all PGs over the last two seconds.

```
$ pgstat 1 2
```

```
PG RELATIONSHIP HW SW CPUS
 0 System - 0.4% 0-31

Name  pgxconfig, GFXconfig, TSIgfxp_config – configure the PGX32 (Raptor GFX) Graphics Accelerator

Synopsis  /usr/sbin/pgxconfig [-dev device-filename]
          [-res video-mode [try | noconfirm | nocheck]]
          [-file machine | system] [-depth 8 | 24]
          [-24only true | false] [-cached pixmap true | false]
          [-defaults]

/usr/sbin/pgxconfig [-propt] [-prconf]
/usr/sbin/pgxconfig [-help] [-res ?]
/usr/sbin/pgxconfig [-i]

Description  The pgxconfig utility configures the PGX32 (Raptor GFX) Graphics Accelerator and some of the X11 window system defaults for PGX32 (Raptor GFX). A previous version of this utility was named GFXconfig.

The first form of pgxconfig shown in the synopsis above stores the specified options in the OWconfig file. These options are used to initialize the PGX32 (Raptor GFX) device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second, third, and fourth forms, which invoke only the -prconf, -propt, -help, and -res ? options, do not update the OWconfig file. For the third form all other options are ignored.

The -i option starts pgxconfig in interactive mode.

Options may be specified for only one PGX32 (Raptor GFX) device at a time.

Only PGX32 (Raptor GFX)-specific options can be specified through pgxconfig. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the Xsun(1) manual page available with the SUNWxwman package.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /usr/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /etc/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root.

Options  The following options are supported:

- cached pixmap true | false  When set to false, it forces the PGX32 (Raptor GFX) device to use 24-bit only when running OpenWindows. The default value is true.
Certain applications make use of a cached pixmap when writing to the display device. Such a technique can cause garbled output and can cause the X server to crash. If you experience such behavior, try setting the \texttt{-cached pixmap} option to \texttt{false}.

- \texttt{defaults} \\
  Reset all option values to their default values.

- \texttt{depth 8|24} \\
  Sets the screen depth to 8 or 24 bits per pixel. 24 bits per pixel enables TrueColor graphics in the window system.

- \texttt{dev device-filename} \\
  Specify the PGX32 (Raptor GFX) special file. The default is \texttt{/dev/fbs/gfxp0}, or \texttt{/dev/fbs/raptor0} if applicable.

- \texttt{file machine|system} \\
  Specifies which OWconfig file to update. If \texttt{machine} is specified, the machine-specific OWconfig file in the \texttt{/etc/openwin} directory tree is updated. If \texttt{system} is specified, the global OWconfig file in the \texttt{/usr/openwin} directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is \texttt{machine}.

- \texttt{help} \\
  Print a list of the pgxconfig command line options, along with a brief explanation of each.

- \texttt{i} \\
  Start pgxconfig in interactive mode.

- \texttt{prconf} \\
  Print the PGX32 (Raptor GFX) hardware configuration. This following is a typical display:

--- Hardware Configuration for /dev/fbs/gfxp0 ---
DAC: version 0x0

Current depth: 8

-propt

Print the current values of all PGX32 (Raptor GFX) options in the OWconfig file specified by the -file option for the device specified by the -dev option. Print the values of options as they would be in the OWconfig file after the call to pgxconfig would have completed. The following is a typical display:

--- OpenWindows Configuration for /dev/fbs/gfxp0 ---
OWconfig: machine
Video Mode: not set
Depth: 8+24

-res video-mode[try|noconfirm|nocheck]

Specify the built-in video mode used to drive the monitor connected to the specified PGX32 (Raptor GFX) device.

The format for video-mode can be one of the following:

widthxheightxrate The width is the screen width in pixels, height is the screen height in pixels, and rate is the vertical frequency of the screen refresh. As a convenience, -res
also accepts formats with @ prepended to the refresh rate rather than x. For example: 1280x1024@76. The list can be obtained by running pgxconfig with the -res ? option (the third form shown in the command synopsis above). Note that not all resolutions are supported by both the video board and by the monitor. The pgxconfig utility will not permit you to set a resolution not supported by the board unless the noconfirm or nocheck option is specified. It will also request confirmation before setting a resolution not supported by the monitor if the nocheck option is not specified.

Symbolic names
For convenience, the video modes listed below have symbolic names defined. Rather than the form widthxheightxrate, the symbolic name may be supplied as the argument to
- res. If the symbolic name is none, the screen resolution will be the video mode that is currently programmed in the device when the window system is run.

    svga  1024x768x60
    1152  1152x900x76
    1280  1280x1024x76
    vga   640x480x60
    none  default console resolution

The -res option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

noconfirm Using the -res option, the user could put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this occurring, the default behavior of pgxconfig is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The noconfirm option instructs pgxconfig to bypass this confirmation and to
program the requested video mode anyway. This option is useful when pgxconfig is being run from a shell script.

nocheck
If present, normal error checking based on the monitor sense code is suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the PGX32 (Raptor GFX) device). Use of this option implies noconfirm as well.

try
This option allows the user to test the specified resolution before committing it. It displays a pattern on the screen with the specified resolution. If the test pattern appears correctly, the user may answer "y" to the query. The other permissible answer is "n".

This sub-option should not be used with pgxconfig while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run pgxconfig with the try sub-option, the window system should be brought down first.
-res ?     Print the list of possible resolutions supported by the PGX32 and the monitor.

-24only    Force the PGX32 (Raptor GFX) device to use 24 bit only when running Openwindows.

**Defaults**

For a given invocation of `pgxconfig`, if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value, except for `-depth` and `-24only`.

A default value is used if a PGX32 (Raptor GFX) option has not been specified with `pgxconfig` when the window system is run. The option defaults are as follows:

- **-dev**  /dev/fbs/gfxp0
- **-file** system
- **-res** none

The default of none for the `-res` option indicates that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

**Examples**

**EXAMPLE 1**  Switching the Resolution on the Monitor Type

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example# /usr/sbin/pgxconfig -res 1280x1024x76
```

**Files**

- `/dev/fbs/gfxp0` device special file
- `/usr/openwin/server/etc/OWconfig` system configuration file
- `/etc/openwin/server/etc/OWconfig` machine configuration file

**See Also**  *PGX32 Installation Manual*
The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. The daemon is started in both single-user and multi-user boot mode.

Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the `libpicltree(3PICLTREE)` interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.

The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is `picl`, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are `name` and `_class`, where `name` contains the name of the node, and the `_class` contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is `/` and the name of the root node of the sub-tree containing platform device nodes is `platform`.

The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them.

Plug-in modules are located in one of the following plug-in directories depending on the platform-specific nature of the data that they collect and publish:

```
/usr/platform/uname -i/lib/picl/plugins
/usr/platform/uname -m/lib/picl/plugins
```

A plug-in module can specify its dependency on another plug-in module using the `-l` or `-R` linker option. The plug-ins are loaded by the daemon using `dlopen(3C)` according to the specified dependencies. Each plug-in module must define a `.init` section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See `picld_plugin_register(3PICLTREE)` for additional information on plug-in registration.

The plug-in modules use the `libpicltree(3PICLTREE)` interface to publish nodes and properties in the PICL tree so that clients can access them.

When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.
An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the `libpicl(3PICL)` interface to send requests to `picld` for accessing the PICL tree.

**Exit Status**  
`picld` does not return an exit status.

**Files**  
/var/run/picld_door  
PICL daemon door

/usr/lib/picl/picld  
PICL daemon

**Notes**  
The `picld` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/picl
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
Name ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts

Synopsis /usr/sbin/ping host [timeout]

/usr/sbin/ping -s [-l | -U] [-ad

-traffic_class] [-g gateway [-g gateway...]] [-F flow_label]
host [data_size] [npackets]

Description The utility ping utilizes the ICMP (ICMP6 in IPv6) protocol's ECHO_REQUEST datagram to elicit an ICMP (ICMP6) ECHO_RESPONSE from the specified host or network gateway. If host responds, ping will print:

host is alive

on the standard output and exit. Otherwise, after timeout seconds, it will write:

no answer from host

The default value of timeout is 20 seconds.

When you specify the s flag, sends one datagram per second (adjust with -I) and prints one line of output for every ECHO_RESPONSE that it receives. ping produces no output if there is no response. In this second form, ping computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default data_size is 56 bytes, or you can specify a size with the data_size command-line argument. If you specify the optional npackets, ping sends ping requests until it either sends npackets requests or receives npackets replies.

When using ping for fault isolation, first ping the local host to verify that the local network interface is running.

Options The following options are supported:

- A addr_family Specify the address family of the target host. addr_family can be either inet or inet6. Address family determines which protocol to use. For an argument of inet, IPv4 is used. For inet6, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, ping will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family inet or inet6 to override the default behavior. If the argument specified is inet, ping will use the IPv4 address associated with the host name. If none
exists, `ping` will state that the host is unknown and exit. It does not try to determine if an IPv6 address exists in the name service database.

If the specified argument is `inet6`, `ping` uses the IPv6 address that is associated with the host name. If none exists, `ping` states that the host is unknown and exits.

`-F flow_label` Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

`-I interval` Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the `-s` option.

`-L` Turn off loopback of multicast packets. Normally, members are in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.

`-P tos` Set the type of service (`tos`) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path can route the probe packet differently, depending upon the value of `tos` that is set in the probe packet. This option is valid only on IPv4.

`-R` Record route. Sets the IPv4 record route option, which stores the route of the packet inside the IPv4 header. The contents of the record route are only printed if the `-v` and `-s` options are given. They are only set on return packets if the target host preserves the record route option across echos, or the `-l` option is given. This option is valid only on IPv4.

`-U` Send UDP packets instead of ICMP (ICMP6) packets. `ping` sends UDP packets to consecutive ports expecting to receive back ICMP (ICMP6) `PORT_UNREACHABLE` from the target host.

`-a all_addresses` ping all addresses, both IPv4 and IPv6, of the multihomed destination. The output appears as if `ping` has been run once for each IP address of the destination. If this option is used together with `-A`, `ping` probes only the addresses that are of the specified address family. When used with the `-s` option and `npackets` is not specified, `ping` continuously probes the destination addresses in a round robin fashion. If `npackets` is
ping sends \textit{npackets} number of probes to each IP address of the destination and then exits.

\texttt{-c traffic\_class} Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path can route the probe packet differently, depending upon the value of \texttt{traffic\_class} set in the probe packet. This option is valid only on IPv6.

\texttt{-d} Set the \texttt{SO\_DEBUG} socket option.

\texttt{-g gateway} Specify a loose source route gateway so that the probe packet goes through the specified host along the path to the target host. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6.

\texttt{-i interface\_address} Specify the outgoing interface address to use for multicast packets for IPv4 and both multicast and unicast packets for IPv6. The default interface address for multicast packets is determined from the (unicast) routing tables. \texttt{interface\_address} can be a literal IP address, for example, 10.123.100.99, or an interface name, for example, \texttt{eri0}, or an interface index, for example 2.

\texttt{-l} Use to send the probe packet to the given host and back again using loose source routing. Usually specified with the \texttt{-R} option. If any gateways are specified using \texttt{-g}, they are visited twice, both to and from the destination. This option is ignored if the \texttt{-U} option is used.

\texttt{-n} Show network addresses as numbers. \textsc{ping} normally does a reverse name lookup on the IP addresses it extracts from the packets received. The \texttt{-n} option blocks the reverse lookup, so \textsc{ping} prints IP addresses instead of host names.

\texttt{-p port} Set the base UDP \texttt{port} number used in probes. This option is used with the \texttt{-U} option. The default base \texttt{port} number is 33434. The \textsc{ping} utility starts setting the destination port number of UDP packets to this base and increments it by one at each probe.

\texttt{-r} Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This option can be used to \textsc{ping} a local host through an interface that has been dropped by the router daemon. See \texttt{in\_routed(1M)}. 

\textit{ping(1M)}
Send one datagram per second and collect statistics.

Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets can be set with the `ndd` module, `/dev/icmp`, using the `icmp_ipv4_ttl` variable for IPv4 and the `icmp_ipv6_hoplimit` variable for IPv6. The default time to live (hop limit) for multicast is one hop. See EXAMPLES. For further information, see `ndd(1M)`.

Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.

**Operands**

- `host` The network host

**Examples**

**EXAMPLE 1 Using ping With IPv6**

This example shows `ping` sending probe packets to all the IPv6 addresses of the host `xyz`, one at a time. It sends an ICMP6 ECHO_REQUEST every second until the user interrupts it.

```
istanbul% ping -s -A inet6 -a xyz
PING xyz: 56 data bytes
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=0.479 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=0.843 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=0.516 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=4.94 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=0.485 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=2.20 ms
^C
```

```
----xyz PING Statistics----
6 packets transmitted, 6 packets received, 0% packet loss
round-trip (ms) min/avg/stddev = 0.479/1.58/4.94/1.8
```

**EXAMPLE 2 Using ndd to Set the icmp_ipv6_hoplimit**

This example shows the `ndd` module, `/dev/icmp`, used to set the `icmp_ipv6_hoplimit`.

```
# ndd -set /dev/icmp icmp_ipv6_hoplimit 100
```

**Exit Status**

The following exit values are returned:

- `0` Successful operation; the machine is alive.

- non-zero An error has occurred. Either a malformed argument has been specified, or the machine was not alive.

pkg2du–convertdriverpackages
to DriverUpdateformat

The /usr/bin/pkg2du utility takes one or more packages as input and converts them to Driver Update (DU) format. If the -d option is specified, the resulting DU directory tree is placed in the directory dir. If the -o option is specified, a Solaris ISO image of the DU directory tree is written in the file iso. The ISO image can be burned onto CD/DVD using cdrw(1) or cdrecord(1) (not a SunOS man page) and used during Solaris installation.

At least one of the -d and -o options must be specified. If both are specified, then both an ISO image and a directory tree are generated.

The following options are supported:

- d dir
  Directory where the DU directory should be created.

- o iso
  Create a Solaris ISO image of the DU directory.

- f
  If dir/DU or iso exists, remove it without asking first.

- l label
  Label/volume name of the ISO image (if -o option is specified).

- r release
  Solaris release number to use. It takes the form of the return from uname - r command, for example, 5.10. If unspecified, the release number of the currently running Solaris is used.

- v
  Verbose. Multiple - v options increase verbosity.

The following operands are supported:

pkg [pkg...]
One or more packages to be converted to DU format.

The following commands create a DU CD/DVD containing packages SUNWfoo and SUNWbar.

# /usr/bin/pkg2du -r 5.10 -o my.iso SUNWfoo SUNWbar
# /usr/bin/cdrw -i my.iso

pkgadd – transfer software packages to the system

Synopsis

```
pkgadd [-nv] [-a admin] [-G] [-x proxy]
        [-M] -R root_path] [-r response] [-k keystore]
        [-P passwd] [-V fs_file]
        [-d device | -d datastream pkginst | all]
        [pkginst | -Y category [,category]...]
```

```
pkgadd -s [-d device | -d datastream pkginst | all]
        [pkginst | -Y category [,category]...]
```

Description

pkgadd transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the `-d device` source specifier, pkgadd looks in the default spool directory (`/var/spool/pkg`) for the package. Used with the `-s` option, it writes the package to a spool directory instead of installing it.

The `pkgadd` utility requires an amount of temporary space the size of the package that is being installed. `pkgadd` determines which temporary directory to use by checking for the existence of the `$TMPDIR` environment variable. If `$TMPDIR` is not defined, `pkgadd` uses `P_tmpdir` from `stdio.h`. `P_tmpdir` has a default of `/var/tmp/`.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of `pkgadd`. These packages require user interaction throughout the installation and not just at the very beginning, or require that their request scripts be run as the root user.

To install these older packages (released prior to Solaris 2.4), set the following environment variable: `NONABI_SCRIPTS=TRUE`

As long as this environment variable is set, `pkgadd` permits keyboard interaction throughout the installation and package request scripts are run as root.

If you have package request scripts that require running as user `root` (instead of `noaccess` [the default] or user `install`), use the `-r script_alt` parameter in the `admin(4)` file to make an appropriate selection. See `admin(4)`.

Note that, in Solaris 8 and Solaris 9, the default user when running a request script was either `root` or `nobody`, depending on the operating system's patch level. In the current release, the default user is `noaccess`.

When running `pkgadd` in the global zone (see `zones(5)`), a package that contains a request script (see `pkgask(1M)`) is added only to the global zone. The package is not propagated to any current or yet-to-be-installed non-global zone. This behavior mimics the effect of the `-G` option, described below.

Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd`, `pkgtrans(1)` and other package commands can process a datastream of up to 4 GB.

The `-d`, `-y`, and `pkginst` arguments shown in the SYNOPSIS are described under OPERANDS, following OPTIONS.
Options  The supported options are described as follows. The `-d` device source specifier is described under OPERANDS, below.

- `a admin`  
  Define an installation administration file, `admin`, to be used in place of the default administration file. The token `none` overrides the use of any `admin` file, and thus forces interaction with the user. Unless a full path name is given, `pkgadd` first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, `pkgadd` looks in the `/var/sadm/install/admin` directory for the administration file.

- `G`  
  Add package(s) in the current zone only. When used in the global zone, the package is added to the global zone only and is not propagated to any existing or yet-to-be-created non-global zone. When used in a non-global zone, the package(s) are added to the non-global zone only.

  This option causes package installation to fail if, in the `pkginfo` file for a package, `SUNW_PKG_ALLZONES` is set to true. See `pkginfo(4)`.

- `k` keystore  
  Use `keystore` as the location from which to get trusted certificate authority certificates when verifying digital signatures found in packages. If no keystore is specified, then the default keystore locations are searched for valid trusted certificates. See KEYSTORE LOCATIONS for more information.

- `M`  
  Instruct `pkgadd` not to use the `$root_path/etc/vfstab` file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

- `n`  
  Installation occurs in non-interactive mode. Suppress output of the list of installed files. The default mode is interactive.

- `P passwd`  
  Password to use to decrypt keystore specified with `-k`, if required. See PASS PHRASE ARGUMENTS for more information about the format of this option's argument.

- `r` response  
  Identify a file or directory which contains output from a previous `pkgask(1M)` session. This file supplies the interaction responses that would be requested by the package in interactive mode. `response` must be a full pathname.

- `R root_path`  
  Define the full path name of a directory to use as the `root_path`. All files, including package system information files, are relocated to a directory tree starting in the specified `root_path`. The `root_path` may be specified when installing to a client from a server (for example, `/export/root/client1`).
**Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See `zones(5)`.

- **s spool**
  Write the package into the directory `spool` instead of installing it.

- **v**
  Trace all of the scripts that get executed by `pkgadd`, located in the `pkginst/install` directory. This option is used for debugging the procedural and non-procedural scripts.

- **v fs_file**
  Specify an alternative `fs_file` to map the client’s file systems. For example, used in situations where the `$root_path/etc/vfstab` file is non-existent or unreliable.

- **x proxy**
  Specify a HTTP[S] proxy to use when downloading packages. The format of proxy is `host:port`, where `host` is the hostname of the HTTP[S] proxy, and `port` is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See `ENVIRONMENT VARIABLES` for more information on alternate methods of specifying a default proxy.

When executed without options or operands, `pkgadd` uses `/var/spool/pkg` (the default spool directory).

**Operands**

The following operands are supported:

**Sources**

By default, `pkgadd` looks in the `/var/spool/pkg` directory when searching for instances of a package to install or spool. Optionally, the source for the package instances to be installed or spooled can be specified using:

- **d device**
- **d datastream pkgnames,... | all**
  Install or copy a package from `device`. `device` can be any of the following:
  - A full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, `/var/tmp` or `/floppy/floppy_name`).
  - A device alias (for example, `/floppy/floppy0`).
  - A datastream created by `pkgtrans` (see `pkgtrans(1)`).
  - A URL pointing to a datastream created by `pkgtrans`. The supported Universal Resource Identifiers (URIs) are `http:` and `https:`.

The second form of the `-d` specifier, above, indicates the syntax you use when specifying a datastream. In this case you must specify either a comma-separated list of package names or the keyword `all`. 
Instances  By default, pkgadd searches the specified source, and presents an interactive menu allowing the user to select which package instances found on the source are to be installed. As an alternative, the package instances to be installed can be specified using:

\textit{pkginst}

The package instance or list of instances to be installed. The token a\textbackslash\ may be used to refer to all packages available on the source medium. The format \textit{pkginst}.\* can be used to indicate all instances of a package.

The asterisk character (\*) is a special character to some shells and may need to be escaped. In the C-Shell, the asterisk must be surrounded by single quotes (\') or preceded by a backslash (\).\par

\textit{-Y category[,category...]}  Install packages based on the value of the \texttt{CATEGORY} parameter stored in the package's \texttt{pkginfo(4)} file. All packages on the source medium whose \texttt{CATEGORY} matches one of the specified categories will be selected for installation or spooling.

Keystore Locations  Package and patch tools such as pkgadd or pacadd use a set of trusted certificates to perform signature validation on any signatures found within the packages or patches. If there are no signatures included in the packages or patches then signature validation is skipped. The certificates can come from a variety of locations. If \texttt{-k keystore} is specified, and \texttt{keystore} is a directory, then \texttt{keystore} is assumed to be the base directory of the certificates to be used. If \texttt{keystore} is a file, then the file itself is assumed to have all required keys and certificates. When \texttt{-k} is not specified, then \texttt{/var/sadm/security} is used as the base directory.

Within the specified base directory, the store locations to be searched are different based on the application doing the searching and the type of store being searched for. The following directories are searched in the specified order:

1. \texttt{<store_dir>/<app_name>/<store_type>}
2. \texttt{<store_dir>/<store_type>}

Where \texttt{<store_dir>} is the directory specified by \texttt{-k}, \texttt{<app_name>} is the name of the application doing the searching, and \texttt{<store_type>} is one of \texttt{keystore} (for private keys), \texttt{certstore} (for untrusted public key certificates), or \texttt{truststore} (for trusted certificate authority certificates).

For example, when pkgadd is run with \texttt{-k/export/certs}, then the following locations are successively searched to find the trust store:

1. \texttt{/export/certs/pkgadd/truststore}
2. \texttt{/export/certs/truststore}

This searching order enables administrators to have a single location for most applications, and special certificate locations for certain applications.
The packaging and patching utilities, such as **pkgtrans** and **patchadd**, require access to a set of keys and certificates in order to sign, and optionally verify, packages and patches.

The keystore files found by following the search pattern specified in **KEYSTORE LOCATIONS** must each be a self-contained PKCS#12-format file.

When signing a package with **pkgtrans**, if a **certstore** has more than one public key certificate, then each public key must have a **friendlyName** attribute in order to be identifiable and selectable with the `-a` option when signing packages or patches. In addition, the public key certificate selected with `-a` and found in the **certstore** must have an associated private key in the keystore.

Several browsers and utilities can be used to export and import certificates and keys into a PKCS#12 keystore. For example, a trusted certificate can be exported from Mozilla, and then imported into a PKCS#12 keystore for use with **pkgadd** with the OpenSSL Toolkit.

**pkgtrans** and **pkgadd** accept password arguments, typically using `-p` to specify the password. These allow the password to be obtained from a variety of sources. Both of these options take a single argument whose format is described below. If no password argument is given and a password is required then the user is prompted to enter one: this will typically be read from the current terminal with echoing turned off.

**Pass Phrase Arguments**

**pass**: `password`
  The actual password is `password`. Because the password is visible to utilities such as `ps` this form should only be used where security is not important.

**env**: `var`
  Obtain the password from the environment variable `var`. Because the environment of other processes is visible on certain platforms this option should be used with caution.

**file**: `pathname`
  The first line contained within `pathname` is the password. `pathname` need not refer to a regular file: it could, for example, refer to a device or named pipe. For example, to read the password from standard input, use `file:` `stdin`.

**console**
  Read the password from `/dev/tty`.

**Examples**

**EXAMPLE 1** Installing a Package from a Solaris DVD

The following example installs a package from a Solaris DVD. You are prompted for the name of the package you want to install.

```
example# pkgadd -d /cdrom/cdrom0/s0/Solaris_10/Product
```

**EXAMPLE 2** Installing a Set of Packages from a Datastream

The example command shown below installs all of the packages in the datastream specified by the `-d` source specifier. Prior to this command, this datastream must have been created with the **pkgtrans**(1) command.
EXAMPLE 2  Installing a Set of Packages from a Datastream  (Continued)

example# pkgadd -d /var/tmp/datastream all

The keyword all specifies that all of the packages found in the designated datastream will be installed.

Exit Status

0
  Successful completion
1
  Fatal error.
2
  Warning.
3
  Interruption.
4
  Administration.
5
  Administration. Interaction is required. Do not use pkgadd -n.
10
  Reboot after installation of all packages.
20
  Reboot after installation of this package.

Environment Variables

HTTPPROXY
  Specifies an HTTP proxy host. Overrides administration file setting, and http_proxy environment variable.

HTTPPROXYPORT
  Specifies the port to use when contacting the host specified by HTTPPROXY. Ignored if HTTPPROXY is not set.

http_proxy
  URL format for specifying proxy host and port. Overrides administration file setting.

Files

/var/sadm/install/logs/
  Location where pkgadd logs an instance of software installation.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpkgcmdsu</td>
</tr>
</tbody>
</table>
When transferring a package to a spool directory, the -r, -n, and -a options cannot be used.

The -r option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of pkgadd. In this situation, each package would need a response file. If you create response files with the same name as the package (for example, pkinst1 and pkinst2), then name the directory in which these files reside after the -r.

The -n option causes the installation to halt if any interaction is needed to complete it.

If the default admin file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See admin(4) for details.

If a package stream is specified with -d, and a digital signature is found in that stream, the default behavior is to attempt to validate the certificate and signature found. This behavior can be overridden with admin file settings. See admin(4) for more information.
pkgadm(1M)

Name
pkgadm – manage packaging and patching system

Synopsis
pkgadm addcert [-ty] [-a app] [-k keystore] [-e keyfile]
[-f format] [-n name] [-P passarg]
[-p import_passarg] [-R rootpath] certfile
pkgadm removecert [-a app] [-k keystore] [-n name]
[-P passarg] [-R rootpath]
pkgadm listcert [-a app] [-f format] [-k keystore] [-n name]
[-P passarg] [-o outfile] [-R rootpath]
 pkgadm dbstatus [-R rootpath]
 pkgadm sync [-R rootpath] [-q]
 pkgadm -V
 pkgadm -? 

Description
The pkgadm utility is used for managing the packaging and patching system. It has several subcommands that perform various operations relating to packaging. The pkgadm command includes subcommands for managing certificates and keys used.

Managing Keys and Certificates
pkgadm maintains the packaging-system-wide keystore in /var/sadm/security, and individual user’s certificates in ~/.pkg/security. The following subcommands operate on the package keystore database:

addcert
Add (import) a certificate into the database, with optional trust. Once added, trusted certificates can be used to verify signed packages and patches. Non-trusted user certificates and their associated keys can be used to sign packages and patches. Added user certificates are not used to build certificate chains during certificate verification.

removecert
Removes a user certificate/private key pair, or a trusted certificate authority certificate from the keystore. Once removed, the certificate and keys cannot be used.

listcert
Print details of one or more certificates in the keystore.

sync
Writes the contents file and rolls the contents log file. With use of the -q option, forces the contents file server to quit.

Internal Install Database
The Solaris operating system relies upon enhanced System V revision 4 (SVr4) packages as the basis for its software installation and revision management. The package maintenance software stores information about installed packages in an internal database. The pkgadm subcommand dbstatus is used to determine how the package internal database is implemented. The dbstatus command returns a string that indicates the type of internal database in use. In
the current implementation, the `dbstatus` command always returns the string `text`, which indicates that the `contents(4)` package database is in use. Future releases of Solaris might supply alternative database implementations.

**Options** The following options are supported:

- `-a app`
  If this option is used, then the command only affects the keystore associated with a particular application. Otherwise, the global keystore is affected.

- `-e keyfile`
  When adding a non-trusted certificate/key combination, this option can be used to specify the file that contains the private key. If this option is not used, the private key must be in the same file as the certificate being added.

- `-f format`
  When adding certificates, this specifies the format to expect certificates and private keys in. Possible values when adding are:
  - `pem` Certificate and any private key uses PEM encoding.
  - `der` Certificate and any private key uses DER encoding.

  When printing certificates, this specifies the output format used when printing. Acceptable values for `format` are:
  - `pem` Output each certificate using PEM encoding.
  - `der` Output each certificate using DER encoding.
  - `text` Output each certificate in human-readable format.

- `-k keystore`
  Overrides the default location used when accessing the keystore.

- `-n name`
  Identifies the entity in the store on which you want to operate. When adding a user certificate, or removing certificates, this name is required. The name is associated with the certificate/key combination, and when adding, can be used later to reference the entity. When printing certificates, if no alias is supplied, then all keystore entities are printed.

- `-o outfile`
  Output the result of the command to `outfile`. Only used when examining (printing) certificates from the key store. Standard out is the default.
-P passarg
Password retrieval method to use to decrypt keystore specified with -k, if required. See PASS PHRASE ARGUMENTS in pkgadd(1M) for more information about the format of this option's argument. console is the default.

-p import_passarg
This option's argument is identical to -P, but is used for supplying the password used to decrypt the certificate and/or private key being added. console is the default.

-q
(Applies to sync subcommand.) Shuts down the contents file cache daemon.

-R rootpath
Defines the full name of a directory to use as the root (/) path. The default user location of the certificate operations is ${HOME}/.pkg. If the -R option is supplied, the certificates and keys will be stored under <altroot>/var/sadm/security. Note that this operation fails if the user does not have sufficient permissions to access this directory. The listcert command requires read permission, while addcert and removecert require both read and write permission.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-t
Indicates the certificate being added is a trusted CA certificate. The details of the certificate (including the Subject Name, Validity Dates, and Fingerprints) are printed and the user is asked to verify the data. This verification step can be skipped with -y. When importing a trusted certificate, a private key should not be supplied, and will be rejected if supplied. Once a certificate is trusted, it can be used as a trust anchor when verifying future untrusted certificates.

-V
Print version associated with packaging tools.

-y
When adding a trusted certificate, the details of the certificate (Subject name, Issuer name, Validity dates, Fingerprints) are shown to the user and the user is asked to verify the correctness before proceeding. With -y, this additional verification step is skipped.

-?
Print help message.

Operands
The following operand is supported:

certfile
File containing the certificate and optional private key, used when adding a trust anchor or certificate/key combination. Certificates must be encoded using PEM or binary DER.
**Keystore Aliases**

All keystore entries (user cert/key and trusted certificate entries) are accessed via unique aliases. Aliases are case-sensitive.

An alias is specified when you add an entity to a keystore using the `addcert` or `trustcert` subcommand. If an alias is not supplied for a trust anchor, the trust anchor’s Common Name is used as the alias. An alias is required when adding a signing certificate or chain certificate. Subsequent `pkgcert` or other package tool commands must use this same alias to refer to the entity.

**Keystore Passwords**

See the `pkgadd(1M)` man page for a description of the passwords supplied to the `pkgadm` utility.

**Examples**

**EXAMPLE 1** Adding a Trust Anchor

The following example adds a well-known and trusted certificate to be used when verifying signatures on packages.

`example% pkgadm addcert -t /tmp/certfile.pem`

**EXAMPLE 2** Adding a Signing Certificate

The following example adds a signing certificate and associated private key, each of which is in a separate file, which can then be used to sign packages.

`example% pkgadm addcert -a pkgtrans -e /tmp/keyfile.pem /tmp/certfile.pem`

**EXAMPLE 3** Printing Certificates

The following example prints all certificates in the root keystore.

`example% pkgadm listcert`

**Exit Status**

0  
successful completion

non-zero  
fatal error

**Attributes**

The service for `pkgadm` is managed by the service management facility, `smf(5)`, under the service identifier:
```
svc:/system/pkgserv
```
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
pkgask – stores answers to a request script

Synopsis

pkgask [-d device] [-R root_path] -r response pkginst...

Description

pkgask allows the administrator to store answers to an interactive package (one with a request script, that is, a user-created file that must be named request). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.

Options

The following options are supported:

- d device
  Run the request script for a package on device. device can be a directory pathname or the identifiers for tape, floppy disk or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The default device is the installation spool directory.

- R root_path
  Define the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path.

  Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

- r response
  Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the pkgadd(1M) command.

Operands

The following operands are supported:

pkginst
  Specify the package instance, or list of instances for which request scripts will be created. The token all may be used to refer to all packages available on the source medium.

Exit Status

  0     Successful completion.

  >0    An error occurred.

pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), installf(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M), removef(1M), admin(4), attributes(5)
The `-r` option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.
pkgchk – check package installation accuracy

Synopsis

pkgchk [-l | -acfnvx] [-i file | -] [-p path... | -P partial-path... | -R root_path] [-m pkgmap [-e envfile]] | pkginst... | -Y category,...] pkgchk -d device [-l | -fv] [-i file | -] [-M] [-p path...] [-V fs_file] [pkginst... | -Y category[,category...]]

Description

pkgchk checks the accuracy of installed files or, by using the -l option, displays information about package files. pkgchk checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem.

The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated pkgmap. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked.

The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.

Options

The following options are supported:

-a
Audit the file attributes only and do not check file contents. Default is to check both.

-c
Audit the file contents only and do not check file attributes. Default is to check both.

-d device
Specify the device on which a spooled package resides. device can be a directory path name or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp or /dev/diskette).

-e envfile
Request that the package information file named as envfile be used to resolve parameters noted in the specified pkgmap file.

-f
Correct file attributes if possible. If used with the -x option, this option removes hidden files. When pkgchk is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the -d option calls out an uninstalled package, the -f option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the pkgmap file except that setuid, setgid, and sticky bits will not be set in the mode.
-1 file

Read a list of path names from file or from stdin (-) and compare this list against the installation software database or the indicated pkgmap file. Path names that are not contained in file or stdin are not checked.

-1

List information on the selected files that make up a package. This option is not compatible with the -a, -c, -f, -g, and -v options.

-n pkgmap

Check the package against the package map file, pkgmap.

-M

Instruct pkgchk not to use the $root_path/etc/vfstab file for determining the client’s mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-n

Do not check volatile or editable files’ contents. This should be used for most post-installation checking.

-p path

Check the accuracy only of the path name or path names listed. path can be one or more path names separated by commas (or by whitespace, if the list is quoted).

To specify a path that includes a comma, you must use the -i option, described above. See EXAMPLES.

-P partial-path

Check the accuracy of only the partial path name or path names listed. partial-path can be one or more partial path names separated by commas (or by whitespace, if the list is quoted). This option can be used instead of -p and is not compatible with the other option. This option matches any path name that contains the string contained in the partial path. See the note about paths that contain commas in the description of -p.

-q

Quiet mode. Do not give messages about missing files.

-R root_path

Define the full name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path. The root_path may be specified when installing to a client from a server (for example, /export/root/client1).

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).
-v
  Verbose mode. Files are listed as processed.

-V fs_file
  Specify an alternative fs_file to map the client's file systems. For example, used in situations where the $root_path/etc/vfstab file is non-existent or unreliable.

-x
  Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated pkgmap file.

-Y category
  Check packages based on the value of the CATEGORY parameter stored in the installed or spooled package's pkginfo file.

Operands

pkginst
  The package instance or instances to be checked. The format pkginst.* can be used to check all instances of a package. The default is to display all information about all installed packages.

  The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, an asterisk must be surrounded by single quotes (' ') or preceded by a backslash (\);

partial-path
  A portion of a path, such as a file or directory name.

Examples

EXAMPLE 1  Using pkgchk for Displaying Package Installation Information
  The following example displays package installation information for /usr/bin/ls:
  example% pkgchk -l -p /usr/bin/ls

EXAMPLE 2  Checking on Java Font Properties
  The following example displays package installation information for all Java font properties installed on the system.
  example% pkgchk -l -P font.properties

EXAMPLE 3  Specifying a Path That Contains a Comma
  Assume you want to specify the path:
  /platform/SUNW,Netra-T12/lib

  List this path in a file. Here is one way in which you can do that:
  example% echo "/platform/SUNW,Netra-T12/lib" > /tmp/p

  You can then enter:
EXAMPLE 3  Specifying a Path That Contains a Comma  

```
example% pkgchk -i /tmp/p -l
Pathname: /platform/SUNW,Netra-T12/lib
Type: directory
Expected mode: 0755
Expected owner: root
Expected group: bin
Referenced by the following packages:
    SUNWcar
Current status: installed

See Also  pkginfo(1), pkgtrans(1), pkgadd(1M), pkgask(1M), pkgrm(1M), pkginfo(4), attributes(5), largefile(5)

Application Packaging Developer's Guide

Notes  Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1) and other package commands can process a datastream of up to 4 GB.
The `pkgcond` command allows you to determine the type of target being operated on (global zone, non-global zone, diskless client, and so forth) and the capabilities available for that type of client (can add a driver, path is writable, and so forth). The `pkgcond` command is intended to be invoked from package and patch scripts, but can also be used in situations that mimic the context of these scripts. See `NOTES` for further guidance.

`pkgcond` has one mandatory argument, a condition. The command tests whether the condition is true for the specified path. The condition can be one of the following:

- `can_add_driver [path]`
- `can_remove_driver [path]`
- `can_update_driver [path]`
- `is_alternative_root [path]`
- `is_boot_environment [path]`
- `is_diskless_client [path]`
- `is_global_zone [path]`
- `is_mounted_miniroot [path]`
- `is_netinstall_image [path]`
- `is_nonlocal_zone [path]`
- `is_path_writable path`
- `is_running_system [path]`
- `is_sparse_root_nonglobal_zone [path]`
- `is_what [path]`
- `is_whole_root_nonglobal_zone [path]`

The `path` argument usually denotes the root of the global zone or non-global zone, or alternate root. If `path` is optional and not specified, the default is `/`.

The behavior of the `is_what` condition is somewhat special, because it displays results of all other conditions to standard output.

**Options**

The following options are supported:

- `-n`
  Negate return status (0 becomes 1 and 1 becomes 0). It negates results in the case of `is_what` condition.

- `-v`
  Verbose mode. Displays detailed data about intermediate checks performed.

**Examples**

**EXAMPLE 1** Listing All Available Information

The following command lists all available information about the current running system, in a user-friendly way.

```
example# pkgcond -n is_what
```
EXAMPLE 2  Determining if Target is an Alternate Root

The following command determines whether an alternate boot environment exists under
/altroot_mount.

example# pkgcond is_alternative_root /altroot_mount

Exit Status  0
  Condition is true unless -n was specified.
  1  Condition is false unless -n was specified.
  2  Command line usage error.
  3  Command failed to perform the test due to a fatal error.

Attributes  See attributes(5) for descriptions of the following attributes:

</tbody>
</table>

See Also  pkgtrans(1), pkgadd(1M), pkgask(1M), pkgchk(1M), pkgrm(1M), pkginfo(4), attributes(5)

Notes  Supported usage of pkgcond is subject to the following constraints:

1. Do not use pkgcond outside of the Solaris marketing release in which it is provided (for
   example, do not use Solaris 10 pkgcond against a Solaris 9 target).

2. Restrict use of the optional path argument according to the following rules:
   - The command pkgcond condition $ROOTDIR can be used in patch level scripts.
   - The command pkgcond condition $PKG_INSTALL_ROOT can be used in package level
     scripts.
   - A command of the form pkgcond condition without the optional path argument can be
     used in any context.

Use of pkgcond with an arbitrary path argument is not recommended or supported, as the
results returned might not be accurate.
pkgrm(1M)

Name  pkgrm – remove a package from the system

Synopsis  pkgrm [-nv] [-a admin] [-A | -M] [-R root_path]
         [-V fs_file]
         [pkginst... | -Y category[,category...]]

pkgrm -s spool
         [pkginst... | -Y category[,category...]]

Description  pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the admin file.

The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the -n option.

The -s option can be used to specify the directory from which spooled packages should be removed.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning.

To remove these older packages (released prior to Solaris 2.4), set the following environment variable: NONABI_SCRIPTS=TRUE pkgrm permits keyboard interaction throughout the removal as long as this environment variable is set.

Options  The following options are supported:

   -a admin
         Use the installation administration file, admin, in place of the default admin file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the /var/sadm/install/admin directory for the administration file.

   -A
         Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system.

   -M
         Instruct pkgrm not to use the $root_path/etc/vfstab file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

   -n
         Non-interactive mode. If there is a need for interaction, the command will exit.
Use of this option requires that at least one package instance be named upon invocation of the command. Certain conditions must exist for a package to be removed non-interactively or a non-restrictive admin file needs to be used.

-R root_path
Defines the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-s spool
Remove the specified package(s) from the directory spool. The default directory for spooled packages is /var/sadm/pkg.

-v
Trace all of the scripts that get executed by pkgrm, located in the pkginst/install directory. This option is used for debugging the procedural and non-procedural scripts.

-V fs_file
Specify an alternative fs_file to map the client's file systems. Used in situations where the $root_path/etc/vfstab file is non-existent or unreliable.

-Y category
Remove packages based on the value of the CATEGORY parameter stored in the installed or spooled package's pkginfo(4) file. No package with the CATEGORY value of system can removed from the file system with this option.

Operands
The following operand is supported:

pkginst
Specifies the package to be removed. The format pkginst.* can be used to remove all instances of a package.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes ('') or preceded by a backslash (\).

Examples
EXAMPLE 1 Removing All Instances of SUNWjunk from client1
The following example removes all instances of SUNWjunk from client1:

example% pkgrm -R /export/root/client1 SUNWjunk*

Note the caveat on the use of the -R option in the description of that option, above.
Exit Status  The following exit values are returned:

0  Successful completion.
1  Fatal error.
2  Warning.
3  Interruption.
4  Administration.
10  Reboot after removal of all packages.
20  Reboot after removal of this package.

Application Packaging Developer’s Guide

Notes  Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1) and other package commands can process a datastream of up to 4 GB.
plockstat(1M)

Name plockstat – report user-level lock statistics

Synopsis plockstat [-vACHV] [-n count] [-s depth] [-e secs]
[-x arg [=val]] command [arg]...
plockstat [-vACHV] [-n count] [-s depth] [-e secs]
[-x arg [=val]] -p pid

Description The plockstat utility gathers and displays user-level locking statistics. By default, plockstat monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.

plockstat gathers data until the specified command completes or the process specified with the -p option completes.

plockstat relies on DTrace to instrument a running process or a command it invokes to trace events of interest. This imposes a small but measurable performance overhead on the processes being observed. Users must have the dtrace_proc privilege and have permission to observe a particular process with plockstat. Refer to the Solaris Dynamic Tracing Guide for more information about DTrace security features.

Options The following options are supported:

-A Watch all lock events. This option is equivalent to -CH.
-C Watch contention events.
-H Watch hold events.
-e secs Exit after the number of seconds specified have elapsed.
-n count Display only the specified number of entries for each output category.
-s depth Record a stack trace rather than just the calling function.
-p pid Specify a process ID from which plockstat is to gather data.
-v Print out a message to indicate that tracing has started.
-x arg [=val] Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the Solaris Dynamic Tracing Guide. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).
-V Print the DTrace commands used to gather the data. The output can then be used directly with the dtrace(1M) command.

Operands The following operands are supported:

arg A string to be passed as an argument to command.
command The name of a utility to be invoked.
count A positive integer value.

pid A process identifier for a process to be monitored.

secs Duration specified as a positive integer number of seconds.

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

*Solaris Dynamic Tracing Guide*
pmadm is the administrative command for the lower level of the Service Access Facility hierarchy, that is, for service administration. A port may have only one service associated with it although the same service may be available through more than one port. In order to uniquely identify an instance of a service, the pmadm command must identify both the port monitor or port monitors through which the service is available (-p or -t) and the service (-s). See Options.

pmadm performs the following functions:

- adds or removes a service
- enables or disables a service
- installs or replaces a per-service configuration script
- prints requested service information

Any user on the system may invoke pmadm to request service status (-l or -L) or to print per-service configuration scripts (-g without the -z option). pmadm with other options may be executed only by a privileged user.

Options

The following options are supported:

- **-a**
  Add a service. pmadm adds an entry for the new service to the port monitor’s administrative file. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add services.

- **-d**
  Disable a service. Add x to the flag field in the entry for the service svctag in the port monitor’s administrative file. This is the entry used by port monitor pmtag. See the -f option, below, for a description of the flags available.
- e  Enable a service. Remove x from the flag field in the entry for the service svctag in the port monitor administrative file. This is the entry used by port monitor pmtag. See the - f option, below, for a description of the flags available.

- f xu  The - f option specifies one or both of the following two flags which are then included in the flag field of the entry for the new service in the port monitor's administrative file. If the - f option is not included, no flags are set and the default conditions prevail. By default, a new service is enabled and no utmpx entry is created for it. An - f option without a following argument is illegal.

  x  Do not enable the service svctag available through port monitor pmtag.

  u  Create a utmpx entry for service svctag available through port monitor pmtag.

- g  Print, install, or replace a per-service configuration script. The - g option with a - p option and a - s option prints the per-service configuration script for service svctag available through port monitor pmtag. The - g option with a - p option, a - s option, and a - z option installs the per-service configuration script contained in the file script as the per-service configuration script for service svctag available through port monitor pmtag. The - g option with a - s option, a - t option, and a - z option installs the file script as the per-service configuration script for service svctag available through any port monitor of type type. Other combinations of options with - g are invalid.

- i id  id is the identity that is to be assigned to service svctag when it is started. id must be an entry in /etc/passwd.

- l  The - l option requests service information. Used by itself and with the options described below, it provides a filter for extracting information in several different groupings.

  - l  By itself, the - l option lists all services on the system.

  - l - p pmtag  Lists all services available through port monitor pmtag.

  - l - s svctag  Lists all services with tag svctag.

  - l - p pmtag - ssvctag  Lists service svctag.

  - l - t type  Lists all services available through port monitors of type type.

  - l - t type - ssvctag  Lists all services with tag svctag available through a port monitor of type type.
Other combinations of options with -l are invalid.

-\(L\) The -\(L\) option is identical to the -\(l\) option except that output is printed in a condensed format.

-\(m\) \(pmspecific\) \(pmspecific\) is the port monitor-specific portion of the port monitor administrative file entry for the service.

-\(p\) \(pmtag\) Specifies the tag associated with the port monitor through which a service (specified as -\(s\) \(svctag\)) is available.

-\(r\) Remove a service. When \(pmadm\) removes a service, the entry for the service is removed from the port monitor's administrative file.

-\(s\) \(svctag\) Specifies the service tag associated with a given service. The service tag is assigned by the system administrator and is part of the entry for the service in the port monitor's administrative file.

-\(t\) \(type\) Specifies the port monitor type.

-\(v\) \(ver\) Specifies the version number of the port monitor administrative file. The version number may be given as

\[-v \ 'pmspec' \ -V\]

where \(pmspec\) is the special administrative command for port monitor \(pmtag\). This special command is \(ttyadm\) for \(ttymon\) and \(nlsadm\) for \(listen\). The version stamp of the port monitor is known by the command and is returned when \(pmspec\) is invoked with a -\(V\) option.

-\(y\) \(comment\) Associate \(comment\) with the service entry in the port monitor administrative file.

-\(z\) \(script\) Used with the -\(g\) option to specify the name of the file that contains the per-service configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (-\(g\) alone). Then the copy is edited. Finally, the copy is put in place over the existing script (-\(g\) with -\(z\)).

Options that request information write the requested information to the standard output. A request for information using the -\(l\) option prints column headers and aligns the information under the appropriate headings. In this format, a missing field is indicated by a hyphen. A request for information in the condensed format using the -\(L\) option prints the information in colon-separated fields; missing fields are indicated by two successive colons. \# is the comment character.
**Examples**

**EXAMPLE 1**  Adding a Service to a Port Monitor with the Tag pmtag

The following command adds a service to a port monitor with tag pmtag and gives the service the tag svctag. The port monitor-specific information is generated by specpm. The service defined by svctag will be invoked with identity root.

```
pmadm -a -p pmtag -s svctag -i root -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

**EXAMPLE 2**  Adding a Service with Service Tag svctag

The following command adds a service with service tag svctag, identity guest, and port monitor-specific information generated by specpm to all port monitors of type type:

```
pmadm -a -s svctag -i guest -t type -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

**EXAMPLE 3**  Removing a Service

The following command removes the service svctag from port monitor pmtag:

```
pmadm -r -p pmtag -s svctag
```

**EXAMPLE 4**  Enabling a Service

The following command enables the service svctag available through port monitor pmtag:

```
pmadm -e -p pmtag -s svctag
```

**EXAMPLE 5**  Disabling a Service

The following command disables the service svctag available through port monitor pmtag:

```
pmadm -d -p pmtag -s svctag
```

**EXAMPLE 6**  Listing Status Information

The following command lists status information for all services:

```
pmadm -l
```

**EXAMPLE 7**  Listing Status Information

The following command lists status information for all services available through the port monitor with tag ports:

```
pmadm -l -p ports
```

**EXAMPLE 8**  Listing Status Information in Condensed Format

The following command lists the status information for all services available through the port monitor with tag ports in condensed format:

```
pmadm -L -p ports
```
EXAMPLE 9  Listing Status Information for All Services
List status information for all services available through port monitors of type listen:
   pmadm -l -t listen

EXAMPLE 10  Printing the per-service Configuration
The following command prints the per-service configuration script associated with the service
svctag available through port monitor pmtag:
   pmadm -g -p pmtag -s svctag

Exit Status  The following exit values are returned:
   0       Successful operation.
   >0      Operation failed.

Files       /etc/saf/pmtag/_config
          /etc/saf/pmtag/svctag
          /var/saf/pmtag/*

pmconfig – Configure the Power Management system

Synopsis
/usr/sbin/pmconfig [-r]

Description
The pmconfig utility sets the Power Management and suspend-resume configuration. User has permission to change Power Management configuration using pmconfig only if he is allowed to do so according to PMCHANGEPERM keyword of /etc/default/power. User has permission to change the suspend-resume configuration using pmconfig only if he is allowed to do so according to the CPRCHANGEPERM keyword of /etc/default/power. See FILES section below for a description of the PMCHANGEPERM and CPRCHANGEPERM keywords of /etc/default/power.

Based on user permissions, pmconfig first resets the Power Management and/or suspend-resume state back to its default and then reads the new Power Management and/or suspend-resume configuration from /etc/power.conf and issues the commands to activate the new configuration. The pmconfig utility is run at system boot. This utility can also be run from the command line after manual changes have been made to the /etc/power.conf file. For editing changes made to the /etc/power.conf file to take effect, users must run pmconfig.

The preferred interface for changing Power Management and suspend-resume configuration is dtpower(1M).

Options
The following options are supported:

- -r  Reset Power Management and suspend-resume state to default and exit. User must have both Power Management and suspend-resume configuration permission for this option.

Exit Status
The following exit values are returned:

0  Upon successful completion
>0  An error occurred

Files
/etc/power.conf System Power Management configuration file
/etc/default/power File that controls permissions for system’s Power Management and suspend-resume features. The PMCHANGEPERM keyboard controls the Power Management configuration permissions, while the CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.

Allowed values are:

all  Any user can change the configuration.
-  No one except super-user can change the configuration.

pmconfig(1M)
<user1, user2,...> A user in this user list or a super-user can change the configuration. The user list is a space and/or comma (,) separated list. You must enclose the list in < and > characters.

console-owner A user who owns the system console device node or a super-user can change the configuration.

The default values are PMCHANGEPERM=console-owner and CPRCHANGEPERM=console-owner.

</tr>
</tbody>
</table>

See Also svcs(1), powerd(1M), power.conf(4), svcadm(1M), attributes(5), smf(5), cpr(7), pm(7D)

Using Power Management

Notes The pmconfig service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/power:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Diagnostics If the program cannot open the configuration file, it prints an error message to standard error. If the program encounters a syntax error in the configuration file, it prints an error message and the line number of the error in the configuration file. It then skips the rest of the information on that line and processes the next line. Any configuration information already processed on the line containing the error is used. If user does not have permission to change Power Management and/or suspend-resume configuration, and configuration file has entries for which user doesn't have permission, it process the entries for which user has permissions and prints error on rest.
The `pntadm` command is used to manage the Dynamic Host Configuration Protocol (DHCP) network tables. It is used to add and remove networks under DHCP management, and add, delete, or modify IP address records within network tables, or to view tables. For a description of the format of DHCP network tables, see `dhcp_network(4)`.

If the networks you want to add are subnetted, you need to update the `netmasks(4)` table.

One of the following options (function flags) must be specified with the `pntadm` command: `-A`, `-B`, `-C`, `-D`, `-L`, `-M`, `-P`, or `-R`.

The following options are supported:

- `-A name_IP_address` Add a client entry with hostname or client IP address, `name_IP_address`, to the named DHCP network table.

  The following sub-options are optional:

  - `-c comment` Comment text. The default is `NULL`.
  - `-e mm/dd/yyyy` Absolute lease. The default is `0`.
  - `-f num | keywords` Flag value. The default is `00`.
  - `-i [-a] client_ID` `-m [-y] macro` `-s server` `-r resource` `-p path` `-u uninterpreted` network

- `-B [-v] [batchfile]` Batch mode.

- `-C [-r resource] [-p path] [-u uninterpreted] network`

- `-D name_IP_address [-y] [-r resource] [-p path] [-u uninterpreted] network`

- `-R [-r resource] [-p path] [-u uninterpreted] network`

- `-L [-r resource] [-p path] [-u uninterpreted] network`

- `-B [-v] [batchfile]`
The flag (-f) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DYNAMIC</td>
<td>00</td>
<td>Server manager's assignment.</td>
</tr>
<tr>
<td>PERMANENT</td>
<td>01</td>
<td>Lease on entry is permanent.</td>
</tr>
<tr>
<td>MANUAL</td>
<td>02</td>
<td>Administrator managed assignment.</td>
</tr>
<tr>
<td>UNUSABLE</td>
<td>04</td>
<td>Entry is not valid.</td>
</tr>
<tr>
<td>BOOTP</td>
<td>08</td>
<td>Entry reserved for BOOTP clients.</td>
</tr>
</tbody>
</table>

For a more detailed description of the flag values, see `dhcp_network(4)`.

- `-h client_hostname`  
  Client hostname. The default is NULL.

  When the `-h` option is used in this mode, the `client_hostname` is added to the hosts table within the resource used for storing host names (files, NIS+ or DNS). The command will fail if this `client_hostname` is already present in the hosts table.

- `-i client_ID [-a]`  
  Client identifier [-a]. The default is 00.

  The `-i` option modified with `-a` specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

- `-m macro [-y]`  
  Macro name. Default is UNKNOWN.

  The `-m` option modified with `-y` verifies the existence of the named macro in the dhcp.tab table before adding the entry.

- `-s server`  
  Server IP or name. Default is system name (uname -n).
-B Activate batch mode. pntadm will read from the specified file or from standard input a series of pntadm commands and execute them within the same process. Processing many pntadm commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using pntadm in scripts.

The following sub-option is optional:

- v Display commands to standard output as they are processed.

-C Create the DHCP network table for the network specified by network. See Operands. For details, see dhcp_network(4) and networks(4).

-D name_IP_address Delete the specified client entry with hostname or client IP address, name_IP_address, in the named DHCP network table. (See dhcp_network(4).)

The following sub-option is optional:

- y Remove associated host table entry. The -y option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.

-L List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of 0 is returned.

-M name_IP_address Modify the specified client entry with hostname or client IP address, name_IP_address, in the named DHCP network table. See dhcp_network(4). The default for the sub-options is what they currently are set to.

The following sub-options are optional.

- c comment New comment text.

-e mm/dd/yy New absolute lease expiration date. Time defaults to 12:00 AM of the day specified.

-f num | keyboard New flag value, see explanation following the description of the -A option.

-h host_name New client hostname.
The -h option allows you to change the current hostname associated with the IP address or to add a new hostname to the hosts table if an entry associated with this IP address does not exist.

- i client_ID
  New client identifier [- a].

- n macro [- y]
  Macro name defined in dhcp.tab.

- n new_client_IP_address
  New IP address.

- s server
  New server IP or name.

For more detailed description of the sub-options and flag values, see dhcp_network(4).

-P
Display the named DHCP network table.

The following sub-options are optional:

- v  Display lease time in full verbose format and resolve IP addresses for the clients and server to hostnames.

- x  Display lease time in raw format.

These flag codes are used with the - P sub-options:

<table>
<thead>
<tr>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-v</td>
<td>DYNAMIC</td>
</tr>
<tr>
<td>-x</td>
<td>PERMANENT</td>
</tr>
<tr>
<td></td>
<td>MANUAL</td>
</tr>
<tr>
<td></td>
<td>UNUSABLE</td>
</tr>
<tr>
<td></td>
<td>BOOTP</td>
</tr>
</tbody>
</table>

See dhcp_network(4) for information on these sub-options and associated flag codes.

-p path
Override the dhcpsvc.conf(4) configuration value for data store resource path, path. See dhcpsvc.conf(4)

-R
Remove the named DHCP network table. See dhcp_network(4).

-r data_store_resource
Override the /etc/inet/dhcpsvc.conf configuration value for RESOURCE= with the data_store_resource specified. See the
dhcpsvc.conf(4) man page for more details on resource type, and the Solaris DHCP Service Developer’s Guide for more information about adding support for other data stores.

-u uninterpreted
Data which will be ignored by pntadm, but passed to the currently configured public module to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a particular data store.

Operands
The following operand is supported:

network 
The network address or network name which corresponds to the dhcp network table. See dhcp_network(4).

Examples
EXAMPLE 1 Creating a Table for the 10.0.0.0 DHCP Network
The following command creates a table for the 10.0.0.0 (subnetted to class C) DHCP network table. Note that if you have an alias for this network in your networks(4) table, you can use that value rather than the dotted Internet Address notation.

example# pntadm -C 10.0.0.0

EXAMPLE 2 Adding an Entry to the 10.0.0.0 Table
The following command adds an entry to the 10.0.0.0 table in the files resource in the /var/mydhcp directory:

example# pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0

EXAMPLE 3 Modifying the 10.0.0.1 Entry of the 10.0.0.0 Table
The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the macro name to Green, setting the flags field to MANUAL and PERMANENT:

example# pntadm -M 10.0.0.1 -m Green -f 'PERMANENT+MANUAL' 10.0.0.0

EXAMPLE 4 Changing the 10.0.0.1 Entry to 10.0.0.2
The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the hosts(4) table called myclient:

example# pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0

EXAMPLE 5 Setting the Client ID as ASCII
The following command sets the client ID as ASCII aruba.foo.com for the myclient entry:

example# pntadm -M myclient -i ‘aruba.foo.com’ -a 10.0.0.0
pntadm(1M)

EXAMPLE 6  Deleting the myclient Entry from the 10.0.0.0 Table
The following command deletes the myclient (10.0.0.2) entry from the 10.0.0.0 table:

```
example# pntadm -D myclient 10.0.0.0
```

EXAMPLE 7  Removing the Named DHCP Network Table
The following command removes the named DHCP network table in the NIS+ directory specified:

```
example# pntadm -r SUNWnisplus -p Test.Nis.Plus. -R 10.0.0.0
```

EXAMPLE 8  Listing the Configured DHCP Network Tables
The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

EXAMPLE 9  Executing pntadm Commands in Batch Mode
The following command runs a series of pntadm commands contained in a batch file:

```
example# pntadm -B addclients
0  Successful completion.
1  Object already exists.
2  Object does not exist.
3  Non-critical error.
4  Critical error.
```

Exit Status
0  Successful completion.
1  Object already exists.
2  Object does not exist.
3  Non-critical error.
4  Critical error.

Files
/etc/inet/dhcpsvc.conf
/etc/inet/hosts

pooladm(1M)

**Name**
pooladm – activate and deactivate the resource pools facility

**Synopsis**

```
/usr/sbin/pooladm [-n] [-s] [-c] [filename] | -x
/usr/sbin/pooladm [-d | -e]
```

**Description**
The `pooladm` command provides administrative operations on pools and sets. `pooladm` reads the specified filename and attempts to activate the pool configuration contained in it.

Before updating the current pool run-time configuration, `pooladm` validates the configuration for correctness.

Without options, `pooladm` prints out the current running pools configuration.

**Options**
The following options are supported:

- `-c` Instantiate the configuration at the given location. If a filename is not specified, it defaults to `/etc/pooladm.conf`.
- `-d` Disable the pools facility so that pools can no longer be manipulated.
- `-e` Enable the pools facility so that pools can be manipulated.
- `-n` Validate the configuration without actually updating the current active configuration. Checks that there are no syntactic errors and that the configuration can be instantiated on the current system. No validation of application specific properties is performed.
- `-s` Update the specified location with the details of the current dynamic configuration.
  
  This option requires update permission for the configuration that you are going to update. If you use this option with the `-c` option, the dynamic configuration is updated before the static location.
- `-x` Remove the currently active pool configuration. Destroy all defined resources, and return all formerly partitioned components to their default resources.

**Operands**
The following operands are supported:

```
filename
```

Use the configuration contained within this file.

**Examples**

**EXAMPLE 1** Instantiating a Configuration

The following command instantiates the configuration contained at `/home/admin/newconfig`:

```
example# /usr/sbin/pooladm -c /home/admin/newconfig
```

**EXAMPLE 2** Validating the Configuration Without Instantiating It

The following command attempts to instantiate the configuration contained at `/home/admin/newconfig`. It displays any error conditions that it encounters, but does not actually modify the active configuration.
Validating the Configuration Without Instantiating It  (Continued)
example# /usr/sbin/pooladm -n -c /home/admin/newconfig

Removing the Current Configuration
The following command removes the current pool configuration:
example# /usr/sbin/pooladm -x

Enabling the Pools Facility
The following command enables the pool facility:
example# /usr/sbin/pooladm -e

Enabling the Pools Facility Using SMF
The following command enables the pool facility through use of the Service Management Facility. See smf(5).
example# /usr/sbin/svcadm enable svc:/system/pools:default

Saving the Active Configuration to a Specified Location
The following command saves the active configuration to /tmp/state.backup:
example# /usr/sbin/pooladm -s /tmp/state.backup

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpool</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The invocation is Evolving. The output is Unstable.

See Also  poolcfg(1M), poolbind(1M), psrset(1M), svcadm(1M), pset_destroy(2), libpool(3LIB), attributes(5), smf(5)

Notes  Resource bindings that are not presented in the form of a binding to a partitionable resource, such as the scheduling class, are not necessarily modified in a pooladm -x operation.
The pools facility is not active by default when Solaris starts. `pooladm -e` explicitly activates the pools facility. The behavior of certain APIs related to processor partitioning and process binding are modified when pools is active. See `libpool(3LIB)`.

You cannot enable the pools facility on a system where processor sets have been created. Use the `psrset(1M)` command or `pset_destroy(2)` to destroy processor sets manually before you enable the pools facility.

Because the Resource Pools facility is an `smf(5)` service, it can also be enabled and disabled using the standard SMF interfaces.
**Name**
poolbind – bind processes, tasks, or projects or query binding of processes to resource pools

**Synopsis**
/usr/sbin/poolbind -p poolname [-i idtype] id...
/usr/sbin/poolbind -q pid...
/usr/sbin/poolbind -Q pid...

**Description**
The `poolbind` command allows an authorized user to bind zones, projects, tasks, and processes to pools. It can also allow a user to query a process to determine which pool the process is bound to.

**Options**
The following options are supported:

```
-i idtype
```
This option, together with the `idlist` arguments, specifies one or more processes to which the poolbind command is to apply. The interpretation of `idlist` depends on the value of `idtype`. The valid `idtype` arguments and corresponding interpretations of `idlist` are as follows:

```
pid
```
`idlist` is a list of process IDs. Binds the specified processes to the specified pool. This is the default behavior if no `idtype` is specified.

```
taskid
```
`idlist` is a list of task IDs. Bind all processes within the list of task IDs to the specified pool.

```
projid
```
`idlist` is a list of project IDs. Bind all processes within the list of projects to the specified pool. Each project ID can be specified as either a project name or a numerical project ID. See `project(4)`.

```
zeoneid
```
`idlist` is a list of zone IDs. Bind all processes within the list of zones to the specified pool. Each zone ID can be specified as either a zone name or a numerical zone ID. See `zones(5)`.

```
-p poolname
```
Specifies the name of a pool to which the specified zone, project, tasks, or processes are to be bound.

```
-q pid...
```
Queries the pool bindings for a given list of process IDs. If the collection of resources associated with the process does not correspond to any currently existing pool, or if there are multiple pools with the set of resources that the process is bound to, the query fails for that particular process ID.

```
-Q pid...
```
Queries the resource bindings for a given list of process IDs. The resource bindings are each reported on a separate line.
Examples

**EXAMPLE 1**  Binding All Processes

The following command binds all processes in projects 5 and 7 to the pool `web_app`:

```
example# /usr/sbin/poolbind -p web_app -i projid 5 7
```

**EXAMPLE 2**  Binding the Running Shell

The following command binds the running shell to the pool `web_app`:

```
example# /usr/sbin/poolbind -p web_app $$
```

**EXAMPLE 3**  Querying the Pool Bindings

The following command queries the bindings to verify that the shell is bound to the given pool:

```
example# /usr/sbin/poolbind -q $$
```

**EXAMPLE 4**  Querying the Resource Bindings

The following command queries the bindings to verify that the shell is bound to the given resources:

```
example# /usr/sbin/poolbind -o $$
```

Exit Status

The following exit values are returned:

- **0**  Successful completion.
- **1**  Requested operation could not be completed.
- **2**  Invalid command line options were specified.

*System Administration Guide: Oracle Solaris Containers-Resource Management and Oracle Solaris Zones*
poolcfg – create and modify resource pool configuration files

/usr/sbin/poolcfg -c command [-d | [filename]]
/usr/sbin/poolcfg -f command_file [-d | [filename]]
/usr/sbin/poolcfg -h

The poolcfg utility provides configuration operations on pools and sets. These operations are performed upon an existing configuration and take the form of modifications to the specified configuration file. If you use the -d option, the modifications occur to the kernel state. Actual activation of the resulting configuration is achieved by way of the pooladm(1M) utility.

Pools configuration files are structured files that must have been constructed using poolcfg itself or libpool(3LIB) directly.

An invocation of poolcfg with the pool dynamic location and write permission will hang if the dynamic location has already been opened for writing.

The configurations which are created by this utility can be used by pooladm to instantiate the configuration upon a target host.

The following options are supported:

- **c command** Specify command as an editing command. See USAGE.
- **d** Operate directly on the kernel state. No filename is allowed.
- **f command_file** Take the commands from command_file. command_file consists of editing commands, one per line.
- **h** Display extended information about the syntax of editing commands.

A script consists of editing commands, one per line, of the following:

- **info [entity-name]** Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, poolcfg -c 'info' afile is an equivalent invocation to poolcfg -c 'info system name' afile.

- **create entity-name [property-list]** Make an entity of the specified type and name.

- **destroy entity-name** Remove the specified entity.

- **modify entity-name [property-list]** Change the listed properties on the named entity.

- **associate pool-name [resource-list]** Connect one or more resources to a pool, or replace one or more existing connections.
transfer to [resourcetype] name[component-list]
Transfer one or more discrete components to a resource.

transfer [quantity] from [resourcetype] [src] to [tgt]
Transfer a resource quantity from src to tgt.

transfer [quantity] to [resourcetype] [tgt] from [src]
Transfer a resource quantity to tgt from src.

discover
Create a system entity, with one pool entity and resources to match current system configuration. All discovered resources of each resource type are recorded in the file, with the single pool referring to the default resource for each resource type.

This command is a NO-OP when poolcfg operates directly on the kernel. See the -d option.

You should avoid use of this command. The preferred method for creating a configuration is to export the dynamic configuration using pooladm(1M) with the -s option.

rename entity-name to new-name
Change the name of an entity on the system to its new name.

Property Lists
The property list is specified by:
( proptype name = value [ ; proptype name = value ]* )
where the last definition in the sequence for a given proptype, name pair is the one that holds. For property deletion, use ~ proptype name.

Resource Lists
A resource list is specified by:
( resourcetype name [ ; resourcetype name ]* )
where the last specification in the sequence for a resource is the one that holds. There is no deletion syntax for resource lists.

Component Lists
A component list is specified by:
( componenttype name [ ; componenttype name ]* )
where the last specification in the sequence for a component is the one that holds. There is no deletion syntax for component lists.

Recognized Entities
  system    Machine level entity
  pool      Named collection of resource associations

Resource Types
  pset      Processor set resource
**Property Types**

- **boolean**: Takes one of two values, true or false.
- **int**: A 64-bit signed integer value.
- **uint**: A 64-bit unsigned integer value.
- **string**: Strings are delimited by quotes ("), and support the character escape sequences defined in `formats(5)`.
- **float**: Scientific notation is not supported.

**Examples**

**EXAMPLE 1** Writing a `pool.cfg` Script

The following `pool.cfg` script creates a pool named Accounting, and a processor set, `small-1`. The processor set is created first, then the pool is created and associated with the set.

```
create pset small-1 ( uint pset.min = 1 ; uint pset.max = 4)
create pool Accounting
associate pool Accounting ( pset small-1 )
```

**EXAMPLE 2** Reporting on `pool_0`

The following command reports on `pool_0` to standard output in human readable form:

```
# poolcfg -c 'info pool pool_0' /etc/pooladm.conf
```

**EXAMPLE 3** Destroying `pool_0` and Its Associations

The following command destroys `pool_0` and associations, but not the formerly associated resources:

```
# poolcfg -c 'destroy pool pool_0' /etc/pooladm.conf
```

**EXAMPLE 4** Displaying the Current Configuration

The following command displays the current configuration:

```
$ poolcfg -c 'info' /etc/pooladm.conf
```

```
system example_system
    int system.version 1
    boolean system.bind-default true
    string system.comment Discovered by libpool

pool pool_default
    boolean pool.default true
    boolean pool.active true
    int pool.importance 5
    string pool.comment
    string pool.scheduler FSS
    pset pset_default

pset pset_default
```
EXAMPLE 4  Displaying the Current Configuration  (Continued)

```
int pset.sys_id -1
string pset.units population
boolean pset.default true
uint pset.max 4294967295
uint pset.min 1
string pset.comment
boolean pset.escapable false
uint pset.load 0
uint pset.size 2

cpu
  int cpu.sys_id 0
  string cpu.comment

cpu
  int cpu.sys_id 2
  string cpu.comment
```

EXAMPLE 5  Moving cpu with ID 2 to Processor Set pset1 in the Kernel

The following command moves cpu with ID 2 to processor set pset1 in the kernel:

```
# poolcfg -dc 'transfer to pset pset1 ( cpu 2 )'
```

EXAMPLE 6  Moving 2 cpus from Processor Set pset1 to Processor Set pset2 in the Kernel

The following command moves 2 cpus from processor set pset1 to processor set pset2 in the kernel:

```
# poolcfg -dc 'transfer 2 from pset pset1 to pset2'
```

poold (1M)

Name  poold – automated resource pools partitioning daemon

Synopsis  poold [-l level]

Description  poold provides automated resource partitioning facilities. Normally, poold is active on the
system whenever the pools facility is active. poold starts and stops when the
pool_set_status(3POOL) function activates or deactivates the pools facility. poold starts
when you activate pools and stops when you deactivate pools. If you manually stop poold by
using a utility such as kill(1), you can invoke it manually.

poold’s configuration details are held in a libpool(3LIB) configuration and you can access all
customizable behavior from this configuration.

poold periodically examines the load on the system and decides whether intervention is
required to maintain optimal system performance with respect to resource consumption.
poold also responds to externally initiated (with respect to poold) changes of either resource
configuration or objectives.

If intervention is required, poold attempts to reallocate the available resources to ensure that
performance objectives are satisfied. If it is not possible for poold to meet performance
objectives with the available resources, then a message is written to the log. poold allocates
scarce resources according to the objectives configured by the administrator. The system
administrator must determine which resource pools are most deserving of scarce resource and
indicate this through the importance of resource pools and objectives.

Options  The following options are supported:

-  Specify the verbosity level for logging information.

    -l level

    Specify level as ALERT, CRIT, ERR, WARNING, NOTICE, INFO, and DEBUG. If
    level is not supplied, then the default logging level is INFO.

    ALERT  A condition that should be corrected immediately,
            such as a corrupted system database.

    CRIT   Critical conditions, such as hard device errors.

    ERR    Errors.

    WARNING  Warning messages.

    NOTICE Conditions that are not error conditions, but that
            may require special handling.

    INFO   Informational messages.

    DEBUG  Messages that contain information normally used only when debugging a program.

When invoked manually, with the -l option, all log output is directed to standard error.
Examples

EXAMPLE 1  Modifying the Default Logging Level

The following command modifies the default logging level to ERR:

```
# /usr/lib/pool/poold -l ERR
```

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWpool</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The invocation is Evolving. The output is Unstable.

See Also

pooladm(1M), poolbind(1M), poolcfg(1M), poolstat(1M), pool_set_status(3POOL), libpool(3LIB), attributes(5)

**poolstat** utility iteratively examines all active pools on the system. It reports statistics based on the selected output mode. `poolstat` provides options to examine only specified pools and report resource set-specific statistics.

Without options, `poolstat` examines all pools, reports basic statistics for their resource sets, and exits.

**DISPLAY FORMATS**

In default output format, `poolstat` outputs a header line and a line for each pool. The line begins with the pool ID and its name, followed by a column of statistical data for the processor set attached to the pool.

The columns are defined as follows:

- **id**: Pool ID.
- **pool**: Pool name.
- **rid**: Resource set id.
- **rset**: Resource set name.
- **type**: Resource set type.
- **min**: Minimum resource set size.
- **max**: Maximum resource set size.
- **size**: Current resource set size.
- **used**: The measure of how much of the resource set is currently in use. This is calculated as the percentage utilization of the resource set multiplied by its size. If resource set has been reconfigured during last sampling interval, this value might be not reported (-).
- **load**: The absolute representation of the load that is put on the resource set. For the definition of this property see `libpool(3LIB)`.

**Options**

The following options are supported:

- **-o format**: Report statistics according to the format specification given in `format`. See DISPLAY FORMATS.

  The `-o` option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

  You can specify multiple `-o` options. The format specification is interpreted as the whitespace separated concatenation of all the format option arguments.
The -o option must be used in conjunction with the -r option.

-p pool-list
Report only pools whose names are in the given list. If the -r option is also used, this option selects only resource sets which belong to pools in the given list. Statistics for pools or resource sets are reported in the same order in which pool names are listed on the pool-list. Pool can be specified by name or by ID.

The -p option accepts lists as arguments. Items in a pool-list can only be separated by spaces.

-r rset-list
Report resource set statistics. If the rset-list argument is "all", then all possible resource set types are selected.

The -r option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

The following resource set types are supported:
all All resource set types
pset Processor set

Operands
The following operands are supported:

count The number of times that the statistics are repeated. By default, poolstat reports statistics only once.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

interval The sampling interval in seconds.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

Examples

EXAMPLE 1 Using poolstat

The following example shows the default output from the poolstat utility:

% poolstat

id pool pset
0 pool_default 4 3.6 6.2
1 pool_admin 4 3.3 8.4

EXAMPLE 2 Reporting Resource Set Statistics

The following example reports resource set statistics.

% poolstat -r pset
EXAMPLE 2  Reporting Resource Set Statistics  (Continued)

<table>
<thead>
<tr>
<th>id</th>
<th>pool</th>
<th>type</th>
<th>rid</th>
<th>rset</th>
<th>min</th>
<th>max</th>
<th>size</th>
<th>used</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>pool_default</td>
<td>pset</td>
<td>-1</td>
<td>pset_default</td>
<td>1</td>
<td>65K</td>
<td>2</td>
<td>1.2</td>
<td>8.3</td>
</tr>
<tr>
<td>1</td>
<td>pool_admin</td>
<td>pset</td>
<td>1</td>
<td>pset_admin</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0.4</td>
<td>5.2</td>
</tr>
<tr>
<td>2</td>
<td>pool_other</td>
<td>pset</td>
<td>-1</td>
<td>pset_default</td>
<td>1</td>
<td>65K</td>
<td>2</td>
<td>1.2</td>
<td>8.3</td>
</tr>
</tbody>
</table>

Resource sets attached to multiple pools, as pset_default in the example above, are listed multiple times, once for each pool.

EXAMPLE 3  Restricting the Output to the List of Pools

The following example restricts the output to the list of pools

```
% poolstat -p pool_default
```

```
pool      size   used  load
0  pool_default  8   5.3  10.3
```

```
% poolstat -p 'pool_admin pool_default'
pool      size   used  load
1  pool_admin   6   4.3   5.3
0  pool_default 2   1.9   2.0
```

```
% poolstat -r all -p 'pool_admin pool_default'

<table>
<thead>
<tr>
<th>id</th>
<th>pool</th>
<th>type</th>
<th>rid</th>
<th>rset</th>
<th>min</th>
<th>max</th>
<th>size</th>
<th>used</th>
<th>load</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>pool_admin</td>
<td>pset</td>
<td>1</td>
<td>pset_admin</td>
<td>1</td>
<td>1</td>
<td>0.9</td>
<td>2.3</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>pool_default</td>
<td>pset</td>
<td>-1</td>
<td>pset_default</td>
<td>1</td>
<td>65K</td>
<td>2</td>
<td>2.0</td>
<td>2.0</td>
</tr>
</tbody>
</table>
```

EXAMPLE 4  Customizing Output

The following example customizes output:

```
% poolstat -r -o pool,rset,size,load
```

```
pool      rset  size  load
pool_default  pset_default  4   4.5
pool_admin   pset_admin     4   2.1
```

Exit Status  The following exit values are returned:

0  Successful completion.
1  An error occurred.
2  Invalid command line options were specified.

</tr>
</tbody>
</table>

See Also  libpool(3LIB), attributes(5)

Notes  The system ids associated with resources can change after the system reboots or the resource configuration is altered.
ports(1M)

Name
ports – creates /dev entries and inittab entries for serial lines

Synopsis
/usr/sbin/ports [-r rootdir]

Description
devfsadm(1M) is now the preferred command for /dev and /devices and should be used
instead of ports.

The ports command creates symbolic links in the /dev/term and /dev/cua directories to the
serial-port character device files in /devices and adds new entries in /etc/inittab for
non-system ports found. System-board ports are given single lower-case letters for names
(such as a and b) while other ports are named numerically.

ports searches the kernel device tree to find the serial devices attached to the system. It also
checks /dev/term and /dev/cua to see what symbolic links to serial devices already exist.
ports then performs the following:

1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the
   system but do not have /dev/term and /dev/cua entries. The numbers or letters assigned
   are the lowest-unused numbers or letters.

2. Removes dangling links: links from /dev/term and /dev/cua pointing to
   no-longer-existing ports.

4. Invokes sacadm(1M) to make new port monitor entries for the new devices. This is not
done automatically for on-board ports; on workstations these ports are often not used for
dial-in sessions, so a port-monitor for one of these ports must be created explicitly.

If the configuration has not changed, ports exits without doing anything.

Notice to Driver Writers
ports considers devices with a node type of DDI_NT_SERIAL, DDI_NT_SERIAL_MB,
DDI_NT_SERIAL_DO, or DDI_NT_SERIAL_MB_DO to be serial port devices. Devices with one of
these node types must create minor device names that obey the following conventions when
calling ddi_create_minor_node(9F).

- The minor name for non-system port devices (DDI_NT_SERIAL) consists of an ASCII
  numeric string, where the first port on the device is named 0, the second named 1, the third
  named 2, up to the number of ports provided by the device.

- The minor name for non-system dialout devices (DDI_NT_SERIAL_DO) is the ASCII
  numeric port name, concatenated with , cu. For example, the minor name for the first
dialout port on the serial board is 0, cu.

- The minor name for system-board port devices (DDI_NT_SERIAL_MB) consists of a string
  containing a single ASCII lowercase character, where the first port on the device is named
  a, the second is named b, the third is named c, for all ports on the device (or up through
  port z).

- The minor name for system-board dialout devices (DDI_NT_SERIAL_MB_DO) consists of the
  lowercase character port name, concatenated with , cu. For example, the minor name for
  the first dialout port on the on-board serial device is a , cu.
To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling `ddi_create_minor_node(9F)`. 

**Options**

The following options are supported:

- `-r rootdir` Causes ports to presume that the `/dev/term`, `/dev/cua`, and `/devices` directories are found under `rootdir`, not directly under `/`. If this argument is specified, `sacadm(1M)` is not invoked, since it would update terminal administration files under `/etc` without regard to the `rootdir`. 

**Examples**

**EXAMPLE 1** Creating the Serial and Dialout Minor Device Nodes

The following example creates the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function:

```c
/*
 * Create the minor number by combining the instance number
 * with the port number.
 */
#define XKNUMPORTS 8
#define XKMINORNUM(i, p) ((i) << 4 | (p))
#define XKMINORNUM_DO(i, p) ((i) << 4 | (p) | 0x80)

int xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, portnum;
    char name[8];
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);
    for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
        /*
         * create the serial port device
         */
        sprintf(name, "%d", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

        /*
         * create the dialout device
         */
        sprintf(name, "%d,cu", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
    }
}
```
EXEMPLARY 2. Installing the xkserial Port Driver on a Sun Fire 4800

The following example installs the xkserial port driver on a Sun Fire 4800 (with the driver controlling the fictional XKSerial 8 port serial board), with these special files in /devices:

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/xkserial@f,800000/
crw-r----- 1 root sys 32, 16 Aug 29 00:02 xkserial@2000:0
```

```
crw-r----- 1 root sys 32, 144 Aug 29 00:02 xkserial@2000:0,cu
```

```
crw-r----- 1 root sys 32, 17 Aug 29 00:02 xkserial@2000:1
```

```
crw-r----- 1 root sys 32, 145 Aug 29 00:02 xkserial@2000:1,cu
```

```
crw-r----- 1 root sys 32, 18 Aug 29 00:02 xkserial@2000:2
```

```
crw-r----- 1 root sys 32, 146 Aug 29 00:02 xkserial@2000:2,cu
```

```
crw-r----- 1 root sys 32, 19 Aug 29 00:02 xkserial@2000:3
```

```
crw-r----- 1 root sys 32, 147 Aug 29 00:02 xkserial@2000:3,cu
```

```
crw-r----- 1 root sys 32, 20 Aug 29 00:02 xkserial@2000:4
```

```
crw-r----- 1 root sys 32, 148 Aug 29 00:02 xkserial@2000:4,cu
```

```
crw-r----- 1 root sys 32, 21 Aug 29 00:02 xkserial@2000:5
```

```
crw-r----- 1 root sys 32, 149 Aug 29 00:02 xkserial@2000:5,cu
```

```
crw-r----- 1 root sys 32, 22 Aug 29 00:02 xkserial@2000:6
```

```
crw-r----- 1 root sys 32, 150 Aug 29 00:02 xkserial@2000:6,cu
```

```
crw-r----- 1 root sys 32, 23 Aug 29 00:02 xkserial@2000:7
```

```
crw-r----- 1 root sys 32, 151 Aug 29 00:02 xkserial@2000:7,cu
```

/dev/term contains symbolic links to the serial port device nodes in /devices

```
# ls -l /dev/term
/dev/term/0 -> ../../devices/[....]/xkserial@2000:0
/dev/term/1 -> ../../devices/[....]/xkserial@2000:1
/dev/term/2 -> ../../devices/[....]/xkserial@2000:2
/dev/term/3 -> ../../devices/[....]/xkserial@2000:3
/dev/term/4 -> ../../devices/[....]/xkserial@2000:4
/dev/term/5 -> ../../devices/[....]/xkserial@2000:5
/dev/term/6 -> ../../devices/[....]/xkserial@2000:6
/dev/term/7 -> ../../devices/[....]/xkserial@2000:7
```

and /dev/cua contain symbolic links to the dialout port device nodes in /devices

```
# ls -l /dev/cua
/dev/cua/0 -> ../../devices/[....]/xkserial@2000:0,cu
/dev/cua/1 -> ../../devices/[....]/xkserial@2000:1,cu
/dev/cua/2 -> ../../devices/[....]/xkserial@2000:2,cu
/dev/cua/3 -> ../../devices/[....]/xkserial@2000:3,cu
/dev/cua/4 -> ../../devices/[....]/xkserial@2000:4,cu
/dev/cua/5 -> ../../devices/[....]/xkserial@2000:5,cu
/dev/cua/6 -> ../../devices/[....]/xkserial@2000:6,cu
/dev/cua/7 -> ../../devices/[....]/xkserial@2000:7,cu
```
Files  /dev/term/n   Logical serial port devices

Writing Device Drivers
powerd(1M)

Name  powerd – power manager daemon

Synopsis  /usr/lib/power/powerd [-n]

Description  The powerd daemon is started by pmconfig(1M) to monitor system activity and perform an automatic shutdown using the suspend-resume feature. When the system is suspended, complete current state is saved on the disk before power is removed. On reboot, the system automatically starts a resume operation and the system is restored to the same state it was in immediately prior to suspend.

Immediately prior to system shutdown, the daemon notifies syslogd(1M) of the shutdown, which broadcasts a notification.

Options  The following option is supported:

- `n`  No broadcast mode. The daemon silently shuts down the system without notifying syslogd(1M).

Files  /etc/power.conf  Power Management configuration information file

Using Power Management
Name  ppdmgr – utility for managing PPD files

Synopsis  

```
ppdmgr -a ppd_filename_path [-L label] [-R ppd_repository_name] [-w]
ppdmgr -r [-L label] [-R ppd_repository_name]
ppdmgr -u [-L label] [-R ppd_repository_name]
```

Description  The PPD File Manager adds PPD files to the print system’s PPD file repositories. When changes in the PPD file repositories are made by the utility, they are reflected in the Solaris Print Manager (see `printmgr(1M)` GUI printer driver field when adding or modifying local attached or network attached printers.

Multiple PPD file repositories may be available. PPD files that are supplied with the system are available in the “system” repository. PPD files that are supplied by third party vendors may be available in the “vendor” repository. PPD files that are supplied by system administrators may be available in the “admin” repository, and PPD files that are added using this utility are available in the “user” repository. When this utility is used to update or rebuild printer information reflected in the `printmgr(1M)`, the special reserved repository name “all” can be used to specify all of the available PPD file repositories.

PPD files are grouped under a user-provided “label” within the print system’s PPD file repository to allow easier selection of a printer driver through the `printmgr` GUI. The special reserved label name “all” can be used to specify all of the available labels in a PPD file repository. The results are undefined if a label name contains characters that are not in the portable filename character set or if a label name starts with a hyphen (-). A label name may not contain a semi-colon (;).

Options  The following subcommand are supported:

```
-a ppd_file_path
```

Adds a copy of `ppd_file_path` to the system under the specified label in the specified repository, where `ppd_file_path` is the full path and file name to the PPD file. The utility accepts a valid PPD file with either a .ppd or .ppd.gz (gzipped) extension.

```
-L label
```

Specifies a label to group PPD files under. When specified with the -a option, the default label is “user”. When specified with the -r or -u option, the default label is “all”. The following are reserved labels:

- `caches`  may never be specified
- `ppdcache`  may never be specified
- `manufaliases`  may never be specified
- `all`  applies the specified action to all labels in a repository, and may only be specified with the -r or -u option.
- `SUNW*`  anything starting with SUNW is reserved and should not be specified with the -a option.
-R repository_name
   Specifies the name of a PPD file repository representing one of the PPD file installation locations. Possible repository names include: "user", "admin", "vendor", "system", and "all".

   The repository name "all" signifies all of the possible repository names. The default repository name is "user". Only the "user" or "admin" repository may be specified with the -a option.

-r
   Rebuilds the cache information for the specified label in the specified repository.

-u
   Updates the cache information for the specified label in the specified repository.

-w
   Write the full path of the added PPD file. This option is only valid with the -a option. Otherwise, this option is ignored.

Examples

Example 1  Adding a copy of a PPD file to the repository

   The following commands add a copy of a PPD file to the "user" repository under the "user" label:

   # ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd

   or

   # ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd -L user

   The following command adds a copy of a PPD file to the "user" repository under the "Photo" label and write the full path of the added copy to standard output:

   # ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd -L "Photo" -w

Example 2  Updating the cache for the PPD files

   The following commands update the cache for the PPD files under the "all" labels in the "user" repository:

   # ppdmgr -u

   or

   # ppdmgr -u -R user -L all

   The following command updates the cache for the PPD files under the "photo" label in the "user" repository:

   # ppdmgr -u -R user -L Photo
EXAMPLE 3  Rebuilding the cache for the PPD files

The following command rebuilds the cache for the PPD files under the "Photo" label in the "user" repository:

```
# ppdmgr -r -R user -L Photo
```

Exit Status  The following exit values are returned:

- 0    Successful completion.
- >0   An error occurred.

The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols.

The encapsulation scheme is provided by driver code in the kernel. pppd provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or "IPCP") and IPv6 (IPV6CP).

The following sections discuss the pppd options:

Options

Options are taken from files and the command line. pppd reads options from the files 
/etc/ppp/options, $HOME/.ppprc and /etc/ppp/options.ttyname (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the options.ttyname file is read.) To form the name of the options.ttyname file, the initial /dev/ is removed from the terminal name, and any remaining forward slash characters (/) are replaced with dots. For example, with serial device /dev/cua/a, option file /etc/ppp/options.cua.a is read.

An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes ("`). A backslash (\) quotes the succeeding character. A hash (#) starts a comment, which continues until the end of the line. There is no restriction on using the file or call options within an options file.

Frequently Used Options

- **<tty_name>**
  Communicate over the named device. The string /dev/ is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.

- **<speed>**
  Set the baud rate to <speed> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.

- **asyncmap <map>**
  Set the async character map to <map>. The map describes which control characters cannot be successfully received over the serial line. pppd asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0 (00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or ^_. If multiple asyncmap options are given, the values are ORed together. If no asyncmap option is given, pppd attempts to negotiate a value of 0. If the
peer agrees, this disables escaping of the standard control characters. Use the \texttt{default -asyncmap} option to disable negotiation and escape all control characters.

**auth**

Require the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the \texttt{auth} or the \texttt{noauth} option is not specified, \texttt{pppd} allows the peer to use only those IP addresses to which the system does not already have a route.

**call name**

Read options from the file \texttt{/etc/ppp/peers/name}. This file may contain privileged options, including \texttt{noauth}, even if \texttt{pppd} is not being run by root. The \texttt{name} string may not begin with a slash ("/"") or include consecutive periods ("..") as a pathname component.

**callback number**

Request a callback to the given telephone number using Microsoft CBCP.

**connect script**

Use the executable or shell command specified by \texttt{script} to set up the serial line. This script would typically use the \texttt{chat(1M)} program to dial the modem and start the remote PPP session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.

**crtscs**

Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the \texttt{crtscs}, \texttt{nocrtscs}, \texttt{cdtrcst}, \texttt{nocdtrcst} or \texttt{nocdtrcst} option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line.

**defaultroute**

Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the PPP connection is broken. This option is privileged if the \texttt{nodefaultroute} option is specified.

**disconnect script**

Run the executable or shell command specified by \texttt{script} after \texttt{pppd} terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. \texttt{disconnect} is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.

**escape xx,yy,...**

Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its \texttt{async} control
character map. The characters to be escaped are specified as a list of hex
numbers separated by commas. Note that almost any character can be
specified for the escape option, unlike the asyncmap option which
allows only control characters to be specified. Characters that cannot
be escaped are those containing hex values 0x20 through 0x3f and
0x5e.

file name  Read options from file name. If this option is used on the command
line or in $HOME/.ppprc, the file must be readable by the user invoking
pppd. See Options Files for a list of files that pppd always reads,
regardless of the use of this option.

init script  Run the executable or shell command specified by script to initialize
the serial line. This script would typically use the chat(1M) program to
configure the modem to enable auto-answer. A value for this option
from a privileged source cannot be overridden by a non-privileged
user.

lock  Directs pppd to create a UUCP-style lock file for the serial device to
ensure exclusive access to the device.

mru n  Set the Maximum Receive Unit (MRU) value to n. pppd asks the peer to
send packets of no more than n bytes. Minimum MRU value is 128.
Default MRU value is 1500. A value of 296 is recommended for slow
links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU
must be at least 1280.

mtu n  Set the Maximum Transmit Unit (MTU) value to n. Unless the peer
requests a smaller value via MRU negotiation, pppd requests the kernel
networking code to send data packets of no more than n bytes through
the PPP network interface. For IPv6, MTU must be at least 1280.

passive  Enables the "passive" option in the LCP. With this option, pppd
attempts to initiate a connection; if no reply is received from the peer,
pppd waits passively for a valid LCP packet instead of exiting, as it
would without this option.

Options  <local_IP_address>::<remote_IP_address>
Set the local and/or remote interface IP addresses. Either one may be omitted, but the colon
is required. The IP addresses are specified with a host name or in decimal dot notation, for
example: :10.1.2.3. The default local address is the first IP address of the system unless
the nodefault option is provided. The remote address is obtained from the peer if not
specified in any option. Thus, in simple cases, this option is not required. If a local and/or
remote IP address is specified with this option, pppd will not accept a different value from
the peer in the IPCP negotiation unless the ipcp-accept-local and/or
ipcp-accept-remote options are given, respectively.
allow-fcs fcs-type
Set allowable FCS type(s) for data sent to the peer. The fcs-type is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.

allow-ip address(es)
Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed in the same manner as each element of the list of allowed IP addresses is parsed in the secrets files. See the Authentication section for more details.

bsdcomp nr, nt
Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of nr bits, and agree to compress packets sent to the peer with a maximum code size of nt bits. If nt is not specified, it defaults to the value given for nr. Values in the range 9 to 15 may be used for nr and nt; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for nr or nt disables compression in the corresponding direction. Use nobsdcomp or bsdcomp 0 to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

cdtrcts
Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the crtscts, nocrtscts, cdtrcts or nocdtrcts option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.

chap-interval n
If this option is given, pppd will rechallenge the peer every n seconds.

chap-max-challenge n
Set the maximum number of CHAP challenge transmissions to n (default 10).

chap-restart n
Set the CHAP restart interval (retransmission timeout for challenges) to n seconds. The default is 3.

connect-delay n
Wait for up to n milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, pppd begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the connect or pty option is used.

datarate n
Set maximum data rate to n (in bytes per second) when using the pty, notty, record, or socket options.
debug
Enables connection debugging facilities. If this option is given, pppd logs the contents of all control packets sent or received in a readable form. The packets are logged through syslog with facility daemon and level debug. This information can be directed to a file by configuring /etc/syslog.conf appropriately.

default-asyncmap
Disable asyncmap negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

default-fcs
Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

default-mru
Disable MRU [Maximum Receive Unit] negotiation. With this option, pppd uses the default MRU value of 1500 bytes for the transmit and receive directions.

deflate \textit{nr}, \textit{nt}, e
Request that the peer compress packets that it sends, using the deflate scheme, with a maximum window size of \(2^{*nr}\) bytes, and agree to compress packets sent to the peer with a maximum window size of \(2^{*nt}\) bytes and effort level of \(e\) (1 to 9). If \(nt\) is not specified, it defaults to the value given for \(nr\). If \(e\) is not specified, it defaults to 6. Values in the range 9 to 15 may be used for \(nr\) and \(nt\); larger values provide better compression but consume more kernel memory for compression dictionaries. (Value 8 is not permitted due to a zlib bug.) Alternatively, a value of 0 for \(nr\) or \(nt\) disables compression in the corresponding direction. Use no deflate or deflate 0 to disable deflate compression entirely. (Note: pppd requests deflate compression in preference to BSD-Compress if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

demand
Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. pppd initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, pppd connects to the peer and performs negotiation, authentication and other actions. When completed, pppd passes data packets across the link. The demand option implies the persist option. If this behavior is not desired, use the nopersist option after the demand option. The idle and holdoff options can be used in conjunction with the demand option.

domain \(d\)
Append the domain name \(d\) to the local host name for authentication purposes. For example, if gethostname() returns the name porsche, but the fully qualified domain name is porsche.Quotron.COM, you could specify domain Quotron.COM. With this configuration, pppd uses the name porsche.Quotron.COM for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.
endpoint endpoint-value  
Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation). The *endpoint-value* consists of a class identifier and a class-dependent value. The class identifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If present, the class-dependent value is separated from the identifier by a colon (":") or period ("."). This value may be a standard dotted-decimal IP address for class "IP," an optionally colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an arbitrary string of bytes specified in hex with optional colon or dot separators between bytes. Although this option is available, this implementation does not support multilink.

fcs fcs-type  
Set FCS type(s) desired for data sent by the peer. The *fcs-type* is a comma-separated list of crc16, crc32, null, or integers. By default, an FCS Alternatives option is not specified, and the medium-dependent FCS type is used. If this option is specified and the peer sends an LCP Configure-Nak, only the listed types are used. If none are in common, the FCS Alternatives option is omitted from the next LCP Configure-Request to drop back to the default.

hide-password  
When logging the contents of PAP packets, this option causes *pppd* to exclude the password string from the log. This is the default.

holdoff n  
Specifies how many seconds to wait before re-initiating the link after it terminates. This option is effective only if the persist or demand option is used. The holdoff period is not applied if the link is terminated because it was idle.

ident string  
Set the LCP Identification string. The default value is a version string similar to that displayed by the *--version* option.

idle n  
Specifies that *pppd* must disconnect if the link is idle for *n* seconds. The link is idle when no data packets (i.e. IP packets) are being sent or received. Do not use this option with the persist option but without the demand option.

ipcp-accept-local  
With this option, *pppd* accepts the peer's idea of the local IP address, even if the local IP address is specified in an option.

ipcp-accept-remote  
With this option, *pppd* accepts the peer's idea of its remote IP address, even if the remote IP address is specified in an option.

ipcp-max-configure n  
Set the maximum number of IPCP Configure-Request transmissions to *n* (default 10).
ipcp-max-failure n
Set the maximum number of IPCP Configure-NAKs sent before sending Configure-Rejects instead to n (default 10).

ipcp-max-terminate n
Set the maximum number of IPCP terminate-request transmissions to n (default 3).

ipcp-restart n
Set the IPCP restart interval (retransmission timeout) to n seconds (default 3).

ipparam string
Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the string supplied is given as the sixth parameter to those scripts. See the Scripts section.

ipv6 <local_interface_identifier>, <remote_interface_identifier>
Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: ::dead:beef). If the ipv6cp-use-ipaddr option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The ipv6cp-use-persistent option can be used instead of the ipv6 <local>, <remote> option.

ipv6cp-accept-local
Accept peer's interface identifier for the local link identifier.

ipv6cp-max-configure n
Set the maximum number of IPv6CP Configure-Request transmissions to n (default 10).

ipv6cp-max-failure n
Set the maximum number of IPv6CP Configure-NAKs sent before sending Configure-Rejects instead to n (default 10).

ipv6cp-max-terminate n
Set the maximum number of IPv6CP terminate-request transmissions to n (default 3).

ipv6cp-restart n
Set the IPv6CP restart interval (retransmission timeout) to n seconds (default 3).

ipv6cp-use-ipaddr
If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with ipcp-accept-local if the local IPv6 identifier is unspecified or with ipcp-accept-remote if the remote IPv6 identifier is unspecified.)

ipv6cp-use-persistent
Use uniquely-available persistent value for link local address.

ekdebug n
Enable debugging code in the kernel-level PPP driver. Argument n is the sum of the following values: 1 to enable general debug messages, 2 to request that contents of received
packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by `syslogd(1M)` to a file directed in the `/etc/syslog.conf` configuration file. Do not use the `kdebug` option to debug failed links. Use the debug option instead.

**lcp-echo-failure**

If this option is given, pppd presumes the peer to be dead if n LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, pppd terminates the connection. This option requires a non-zero value for the `lcp-echo-interval` parameter. This option enables pppd to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.

**lcp-echo-interval**

If this option is given, pppd sends an LCP Echo-Request frame to the peer every n seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the `lcp-echo-failure` option to detect that the peer is no longer connected.

**lcp-max-configure**

Set the maximum number of LCP Configure-Request transmissions to n (default 10).

**lcp-max-failure**

Set the maximum number of LCP Configure-NAKs sent before starting to send Configure-Rejects instead to n (default 10).

**lcp-max-terminate**

Set the maximum number of LCP Terminate-Request transmissions to n (default 3).

**lcp-restart**

Set the LCP restart interval (retransmission timeout) to n seconds (default 3).

**linkname**

Sets the logical name of the link to name. pppd creates a file named `ppp-name.pid` in `/var/run` containing its process ID. This is useful in determining which instance of pppd is responsible for the link to a given peer system. This is a privileged option.

**local**

Do not use modem control lines. With this option, pppd ignores the state of the CD (Carrier Detect) signal from the modem and does not change the state of the DTR (Data Terminal Ready) signal.

**logfile**

Append log messages to the file `filename` (and send the log messages to syslog). The file is opened in append mode with the privileges of the user who invoked pppd.
login
Use the system password database for authenticating the peer using PAP, and record the user in the system wtmp file. Note that the peer must have an entry in the /etc/ppp/pap-secrets file and the system password database to be allowed access.

maxconnect n
Terminate the connection after it has been available for network traffic for n seconds (that is, n seconds after the first network control protocol starts). An LCP Time-Remaining message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are remaining.

maxfail n
Terminate after n consecutive failed connection attempts. A value of 0 means no limit. The default value is 10.

modem
Use the modem control lines. This option is the default. With this option, pppd waits for the CD (Carrier Detect) signal from the modem to be asserted when opening the serial device (unless a connect script is specified), and drops the DTR (Data Terminal Ready) signal briefly when the connection is terminated and before executing the connect script.

ms-dns <addr>
If pppd is acting as a server for Microsoft Windows clients, this option allows pppd to supply one or two DNS (Domain Name Server) addresses to the clients. The first instance of this option specifies the primary DNS address; the second instance (if given) specifies the secondary DNS address. If the first instance specifies a name that resolves to multiple IP addresses, then the first two addresses are used. (This option is present in some older versions of pppd under the name dns-addr.)

ms-lanman
If pppd connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication, this option selects the LAN Manager password style instead of Microsoft NT.

ms-wins <addr>
If pppd acts as a server for Microsoft Windows or Samba clients, this option allows pppd to supply one or two WINS (Windows Internet Name Services) server addresses to the clients. The first instance of this option specifies the primary WINS address; the second instance (if given) specifies the secondary WINS address. As with ms-dns, if the name specified resolves to multiple IP addresses, then the first two will be taken as primary and secondary.

name name
Set the name of the local system for authentication purposes to name. This is a privileged option. With this option, pppd uses lines in the secrets files that have name as the second field to look for a secret to use in authenticating the peer. In addition, unless overridden with the user option, name is used as the name to send to the peer when authenticating the local system. (Note that pppd does not append the domain name to name.)
no-acm-test
Disable use of asyncmap (ACCM) checking using LCP Echo-Request messages. If the lcp-echo-failure is used on an asynchronous line, pppd includes all control characters in the first $n$ LCP Echo-Request messages. If the asyncmap is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

noaccomp
Disable HDLC Address/Control compression in both directions (send and receive).

noauth
Do not require the peer to authenticate itself. This option is privileged.

nobsdcomp
Disables BSD-Compress compression; pppd will not request or agree to compress packets using the BSD-Compress scheme. This option is not necessary if noccp is specified.

noccp
Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from pppd for CCP negotiation. If CCP is disabled, then BSD and deflate compression do not need to be separately disabled.

crtstc
Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the crtscts, noctstc, cdtrcts or nocdtrcts options are not given, the hardware flow control setting for the serial port is left unchanged.

nocdtrcts
This option is a synonym for noctstc. Either option will disable both forms of hardware flow control.

nodefaultroute
Disable the default route option. You can prevent non-root users from creating default routes with pppd by placing this option in the /etc/ppp/options file.

nodeflate
Disables deflate compression; pppd will not request or agree to compress packets using the deflate scheme. This option is not necessary if noccp is specified.

nodeflatedraft
Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression. This option is not necessary if noccp is specified.

nodetach
Do not detach from the controlling terminal. Without this option, pppd forks to become a background process if a serial device other than the terminal on the standard input is specified.

noendpoint
Do not send or accept the Multilink Endpoint Discriminator option.
noident
Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, pppd sends LCP Code-Reject in response to received LCP Identification messages.)

noip
Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from pppd for IPCP negotiation.

noipv6
Disable IPv6CP negotiation and IPv6 communication. IPv6 is not enabled by default.

noipdefault
Disables the default behavior when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

nolog
Do not send log messages to a file or file descriptor. This option cancels the logfd and logfile options. nologfd acts as an alias for this option.

nomagic
Disable magic number negotiation. With this option, pppd cannot detect a looped-back line. Use this option only if the peer has bugs. Do not use this option to work around the “Serial line is looped back” error message.

nopam
This privileged option disables use of pluggable authentication modules. If this option is specified, pppd reverts to standard authentication mechanisms. The default is not to use PAM.

nopcomp
Disable protocol field compression negotiation in the receive and the transmit direction.

nopersist
Exit once a connection has been made and terminated. This is the default unless the persist or demand option is specified.

noplink
Cause pppd to use I_LINK instead of I_PLINK. This is the default. When I_LINK is used, the system cleans up terminated interfaces (even when SIGKILL is used) but does not allow ifconfig(1M) to unplug PPP streams or insert or remove modules dynamically. Use the plink option if ifconfig(1M) modinsert, modremove or unplumb support is needed.

nopredictor1
Do not accept or agree to Predictor-1 compression. (This option is accepted for compatibility. The implementation does not support Predictor-1 compression.)
noproxyarp
   Disable the proxyarp option. If you want to prevent users from creating proxy ARP entries with pppd, place this option in the /etc/ppp/options file.

notty
   Normally, pppd requires a terminal device. With this option, pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. pppd creates a child process to act as a character shunt to transfer characters between the pseudo-tty master and its standard input and output. Thus, pppd transmits characters on its standard output and receives characters on its standard input even if they are not terminal devices. This option increases the latency and CPU overhead of transferring data over the ppp interface as all of the characters sent and received must flow through the character shunt process. An explicit device name may not be given if this option is used.

novj
   Disable Van Jacobson style TCP/IP header compression in both the transmit and the receive direction.

novjccomp
   Disable the connection-ID compression option in Van Jacobson style TCP/IP header compression. With this option, pppd does not omit the connection-ID byte from Van Jacobson compressed TCP/IP headers, nor does it ask the peer to do so. This option is unnecessary if novj is specified.

pam
   This privileged option enables use of PAM. If this is specified, pppd uses the pam(3PAM) framework for user authentication with a service name of "ppp" if the login option and PAP authentication are used. The default is not to use PAM.

papcrypt
   Indicates that pppd should not accept a password which, before encryption, is identical to the secret from the /etc/ppp/pap-secrets file. Use this option if the secrets in the pap-secrets file are in crypt(3C) format.

pap-max-authreq n
   Set the maximum number of PAP authenticate-request transmissions to n (default 10).

pap-restart n
   Set the PAP restart interval (retransmission timeout) to n seconds (default 3).

pap-timeout n
   Set the maximum time that pppd waits for the peer to authenticate itself with PAP to n seconds (0= no limit). The default is 30 seconds.

password string
   Password string for authentication to the peer.

persist
   Do not exit after a connection is terminated; instead try to reopen the connection.
plink
  Cause pppd to use _PLINK instead of _LINK. The default is to use _LINK, which cleans up terminated interface (even if SIGKILL is used), but does not allow `ifconfig(1M)` to unplug PPP streams or insert or remove modules dynamically. Use this option if `ifconfig(1M)` modinsert/modremove/unplug support is needed. See also the plumbed option.

plugin filename
  Load the shared library object file filename as a plugin. This is a privileged option. Unless the filename specifies an explicit path, `/etc/ppp/plugins` and `/usr/lib/inet/ppp` will be searched for the object to load in that order.

plumbed
  This option indicates that pppd should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older aspppd implementation and may be helpful when pppd is used with external applications that use `ifconfig(1M)`.

pppmux timer
  Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to timer microseconds.

privgroup group-name
  Allows members of group group-name to use privileged options. This is a privileged option. Because there is no guarantee that members of group-name cannot use pppd to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of group-name in the root or sys group.

proxyarp
  Add an entry to the system’s Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

pty script
  Specifies that the command script, and not a specific terminal device is used for serial communication. pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. script runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the record option is used in conjunction with the pty option, the child process will have pipes on its standard input and output.)

receive-all
  With this option, pppd accepts all control characters from the peer, including those marked in the receive asyncmap. Without this option, pppd discards those characters as specified in RFC 1662. This option should be used only if the peer has bugs, as is often found with dial-back implementations.
record filename
Directs pppd to record all characters sent and received to a file named filename. filename is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the pppdmp(1M) program. This option is generally used when debugging the kernel portion of pppd (especially CCP compression algorithms) and not for debugging link configuration problems. See the debug option.

remotename name
Set the assumed name of the remote system for authentication purposes to name. Microsoft WindowsNT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

refuse-chap
With this option, pppd will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

refuse-mschap
Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-mschapv2
Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-pap
With this option, pppd will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

require-chap
Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

require-mschap
Require the peer to authenticate itself using MS-CHAPv1 authentication.

require-mschapv2
Require the peer to authenticate itself using MS-CHAPv2 authentication.

require-pap
Require the peer to authenticate itself using PAP authentication.

show-password
When logging contents of PAP packets, this option causes pppd to show the password string in the log message.
silent
With this option, pppd will not transmit LCP packets to initiate a connection until a valid LCP packet is received from the peer. This is like the “passive” option with older versions of pppd and is retained for compatibility, but the current passive option is preferred.

small-accm-test
When checking the asyncmap (ACCM) setting, pppd uses all 256 possible values by default. See no-accm-test. This option restricts the test so that only the 32 values affected by standard ACCM negotiation are tested. This option is useful on very slow links.

socket host:port
Connect to given host and port using TCP and run PPP over this connection.

sync
Use synchronous HDLC serial encoding instead of asynchronous. The device used by pppd with this option must have sync support. Currently supports zs, se, and hsi drivers.

unit n
Set PPP interface unit number to n, if possible.

updetach
With this option, pppd detaches from its controlling terminal after establishing the PPP connection. When this is specified, messages sent to stderr by the connect script, usually chat(1M), and debugging messages from the debug option are directed to pppd’s standard output.

usehostname
Enforce the use of the hostname with domain name appended, if given, as the name of the local system for authentication purposes. This overrides the name option. Because the name option is privileged, this option is normally not needed.

usepeerdns
Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are passed to the /etc/ppp/ip-up script in the environment variables DNS1 and DNS2. In addition, pppd creates an /etc/ppp/resolv.conf file containing one or two nameserver lines with the address(es) supplied by the peer.

user name
Sets the name used for authenticating the local system to the peer to name.

vj-max-slots n
Sets the number of connection slots to be used by the Van Jacobson TCP/IP header compression and decompression code to n, which must be between 2 and 16 (inclusive).

welcome script
Run the executable or shell command specified by script before initiating PPP negotiation, after the connect script, if any, has completed. A value for this option from a privileged source cannot be overridden by a non-privileged user.
Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

The following options are obsolete:

+ua name
Read a PAP user name and password from the file name. This file must have two lines for name and password. Name and password are sent to the peer when the peer requests PAP authentication.

+ipv6
Enable IPv6 and IPv6CP without specifying interface identifiers.

--version
Show version number and exit.

--help
Show brief help message and exit.

The following sections discuss miscellaneous features of pppd:

pppd allows system administrators to provide legitimate users with PPP access to a server machine without fear of compromising the security of the server or the network it runs on. Access control is provided by restricting IP addresses the peer may use based on its authenticated identity (if any), and through restrictions on options a non-privileged user may use. Options that permit potentially insecure configurations are privileged. Privileged options are accepted only in files that are under the control of the system administrator or when pppd is being run by root.

By default, pppd allows an unauthenticated peer to use a given IP address only if the system does not already have a route to that IP address. For example, a system with a permanent connection to the wider Internet will normally have a default route, meaning all peers must authenticate themselves to set up a connection. On such a system, the auth option is the default. Conversely, a system with a PPP link that comprises the only connection to the Internet probably does not possess a default route, so the peer can use virtually any IP address without authenticating itself.

Security-sensitive options are privileged and cannot be accessed by a non-privileged user running pppd, either on the command line, in the user’s $HOME/.ppprc file, or in an options file read using the file option. Privileged options may be used in /etc/ppp/options file or in an options file read using the call option. If pppd is run by the root user, privileged options can be used without restriction. If the /etc/ppp/options file does not exist, then only root may invoke pppd. The /etc/ppp/options file must be created (but may be empty) to allow ordinary non-root users to access pppd.

When opening the device, pppd uses the invoking user’s user ID or the root UID (that is, 0), depending if the device name was specified by the user or the system administrator. If the device name comes from a privileged source, that is, /etc/ppp/options or an options file read using the call option, pppd uses full root privileges when opening the device. Thus, by creating an appropriate file under /etc/ppp/peers, the system administrator can allow users
to establish a PPP connection via a device that they would not normally have access to. Otherwise pppd uses the invoking user’s real UID when opening the device.

Authentication

During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the “client” and the second becomes the “server.” Authentication names can (but are not required to) correspond to the peer’s Internet hostnames.

pppd supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, pppd authenticates if requested and does not require authentication from the peer. However, pppd does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the `/etc/ppp/pap-secrets` (for PAP), and `/etc/ppp/chap-secrets` (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that contain the client and server names followed by the secret. Often, these three fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign (“@”) is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP Addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen (“-”). To allow any address, use “*”. An address starting with an exclamation point (“!”) indicates that the specified address is not acceptable. An address may be followed by “/” and a number n to indicate a whole subnet (all addresses that have the same value in the most significant n bits).
In this form, the address may be followed by a plus sign ("+") to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, pppd chooses a secret with the peer’s name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the domain option is used. The default can be overridden with the name option unless the usehostname option is used.

When authenticating to the peer, pppd first determines the name it will use to identify itself to the peer. This name is specified with the user option. If the user option is not used, the name defaults to the host name of the local system. pppd then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer’s name in the second field. pppd will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, pppd must determine the peer’s name from the options specified by the user. The user can specify the peer’s name directly with the remotename option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer’s name. If that fails, pppd uses the null string as the peer’s name.

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted using crypt() and checked against the secret again. If the papcrypt option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted crypt(3C) form.

If the login option is specified, the username and password are also checked against the system password database. This allows you to set up the pap-secrets file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the login option, the secret in /etc/ppp/pap-secrets would be "", which matches any password supplied by the peer. This makes having the same secret in two places unnecessary. When login is used, the pam option enables access control through pam(3PAM).

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, pppd closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To allow hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the pap-secrets file specifying the empty string for the client name and secret.

Additional pppd options for a given peer may be specified by placing them at the end of the secrets entry, separated by two dashes (---). For example

```
peername servername secret ip-address -- novj
```
When IPCP negotiation is complete, pppd informs the kernel of the local and remote IP addresses for the PPP interface and creates a host route to the remote end of the link that enables peers to exchange IP packets. Communication with other machines generally requires further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In most cases the default route and/or proxyarp options are sufficient for this, but further intervention may be necessary. If further intervention is required, use the /etc/ppp/ip-up script or a routing protocol daemon.

To add a default route through the remote host, use the default route option. This option is typically used for "client" systems; that is, end-nodes that use the PPP link for access to the general Internet.

In some cases it is desirable to use proxy ARP, for example on a server machine connected to a LAN, to allow other hosts to communicate with the remote host. proxyarp instructs pppd to look for a network interface on the same subnet as the remote host. That is, an interface supporting broadcast and ARP that is not a point-to-point or loopback interface and that is currently up. If found, pppd creates a permanent, published ARP entry with the IP address of the remote host and the hardware address of the network interface.

When the demand option is used, the interface IP addresses are already set at the time when IPCP comes up. If pppd cannot negotiate the same addresses it used to configure the interface, it changes the interface IP addresses to the negotiated addresses. This may disrupt existing connections. Using demand dialing with peers that perform dynamic IP address assignment is not recommended.

pppd invokes scripts at various stages during processing that are used to perform site-specific ancillary processing. These scripts may be shell scripts or executable programs. pppd does not wait for the scripts to finish. The scripts are executed as root (with the real and effective user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform other tasks. Be sure that the contents of these scripts do not compromise your system’s security. pppd runs the scripts with standard input, output and error redirected to /dev/null, and with an environment that is empty except for some environment variables that give information about the link. The pppd environment variables are:

- **DEVICE**: Name of the serial tty device.
- **IFNAME**: Name of the network interface.
- **IPLOCAL**: IP address for the link's local end. This is set only when IPCP has started.
- **IPREMOTE**: IP address for the link's remote end. This is set only when IPCP has started.
- **PEERNAME**: Authenticated name of the peer. This is set only if the peer authenticates itself.
- **SPEED**: Baud rate of the tty device.
- **ORIG_UID**: Real user-id of user who invoked pppd.
PPPLOGNAME  Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

CONNECT_TIME  Number of seconds between the start of PPP negotiation and connection termination.

BYTES_SENT  Number of bytes sent at the level of the serial port during the connection.

BYTES_RCVD  Number of bytes received at the level of the serial port during the connection.

LINKNAME  Logical name of the link, set with the linkname option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

/etc/ppp/auth-up  Program or script executed after the remote system successfully authenticates itself. It is executed with five command-line arguments: interface-name peer-name user-name tty-device speed. Note that this script is not executed if the peer does not authenticate itself, for example, when the noauth option is used.

/etc/ppp/auth-down  Program or script executed when the link goes down if /etc/ppp/auth-up was previously executed. It is executed in the same manner with the same parameters as /etc/ppp/auth-up.

/etc/ppp/ip-up  A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with six command-line arguments: interface-name tty-device speed local-IP-address remote-IP-address ipparam.

/etc/ppp/ip-down  A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the /etc/ppp/ip-up script. It is invoked in the same manner and with the same parameters as the ip-up script.

/etc/ppp/ipv6-up  Similar to /etc/ppp/ip-up, except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with six command-line arguments: interface-name tty-device speed local-link-local-address remote-link-local-address ipparam.

/etc/ppp/ipv6-down  Similar to /etc/ppp/ip-down, but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the ipv6-up script.

Examples  Example 1  Using the auth Option

The following examples assume that the /etc/ppp/options file contains the auth option.
EXAMPLE 1  Using the auth Option  (Continued)

pppd is commonly used to dial out to an ISP. You can do this using the "pppd call isp" command where the /etc/ppp/peers/isp file is set up to contain a line similar to the following:
cua/a 19200 ctscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth

For this example, chat(1M) is used to dial the ISP's modem and process any login sequence required. The /etc/ppp/chat-isp file is used by chat and could contain the following:

```
ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
** "at"
OK "at6f6d26c1"
OK "atdt2468135"
"name: "^Umyuserid"
"word: "^Qmypassword"
"ispts "^Q"uppc"
"--^Uppc--"
```

See the chat(1M) man page for details of chat scripts.

EXAMPLE 2  Using pppd with proxyarp

pppd can also provide a dial-in ppp service for users. If the users already have login accounts, the simplest way to set up the ppp service is to let the users log in to their accounts and run pppd as shown in the following example:

```
example% pppd proxyarp
```

EXAMPLE 3  Providing a User with Access to PPP Facilities

To provide a user with access to the PPP facilities, allocate an IP address for the user's machine, create an entry in /etc/ppp/pap-secrets or /etc/ppp/chap-secrets. This enables the user's machine to authenticate itself. For example, to enable user "Joe" using machine "joespc" to dial in to machine "server" and use the IP address "joespc.my.net," add the following entry to the /etc/ppp/pap-secrets or /etc/ppp/chap-secrets files:

```
joespc server "joe's secret" joespc.my.net
```

Alternatively, you can create another username, for example "ppp," whose login shell is /usr/bin/pppd and whose home directory is /etc/ppp. If you run pppd this way, add the options to the /etc/ppp/.ppprc file.
EXAMPLE 3 Providing a User with Access to PPP Facilities (Continued)

If your serial connection is complex, it may be useful to escape such control characters as XON (\^Q) and XOFF (\^S), using asyncmap a0000. If the path includes a telnet, escape \^] (asyncmap 200a0000). If the path includes a rlogin command, add escape ff option to the options, because rlogin removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

Exit Status The pppd exit status indicates errors or specifies why a link was terminated. Exit status values are:

0 pppd has detached or the connection was successfully established and terminated at the peer’s request.
1 An immediately fatal error occurred. For example, an essential system call failed.
2 An error was detected in the options given. For example, two mutually exclusive options were used, or /etc/ppp/options is missing and the user is not root.
3 pppd is not setuid-root and the invoking user is not root.
4 The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.
5 pppd terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.
6 The serial port could not be locked.
7 The serial port could not be opened.
8 The connect script failed and returned a non-zero exit status.
9 The command specified as the argument to the pty option could not be run.
10 The PPP negotiation failed because no network protocols were able to run.
11 The peer system failed or refused to authenticate itself.
12 The link was established successfully, but terminated because it was idle.
13 The link was established successfully, but terminated because the connect time limit was reached.
14 Callback was negotiated and an incoming call should arrive shortly.
15 The link was terminated because the peer is not responding to echo requests.
16 The link was terminated by the modem hanging up.
17 The PPP negotiation failed because serial loopback was detected.
18 The init script failed because a non-zero exit status was returned.
19 Authentication to the peer failed.
Files

/var/run/spppn.pid Process-ID for pppd process on PPP interface unit n.
/var/run/ppp-name.pid Process-ID for pppd process for logical link name (see the linkname option).
/etc/ppp/pap-secrets Usernames, passwords and IP addresses for PAP authentication. This file should be owned by root and not readable or writable by any other user, otherwise pppd will log a warning.
/etc/ppp/chap-secrets Names, secrets and IP addresses for all forms of CHAP authentication. The /etc/ppp/pap-secrets file should be owned by root should not readable or writable by any other user, otherwise pppd will log a warning.
/etc/ppp/options System default options for pppd, read before user default options or command-line options.
$HOME/.ppprc User default options, read before /etc/ppp/options.
/etc/ppp/options.ttyname System default options for the serial port in use; read after $HOME/.ppprc. The ttyname component of this filename is formed when the initial /dev/ is stripped from the port name (if present), and slashes (if any) are converted to dots.
/etc/ppp/peers Directory with options files that may contain privileged options, even if pppd was invoked by a user other than root. The system administrator can create options files in this directory to permit non-privileged users to dial out without requiring the peer to authenticate, but only to certain trusted peers.

**Notes** These signals affect `pppd` behavior:

- **SIGINT, SIGTERM** Terminate the link, restore the serial device settings and exit.
- **SIGHUP** Terminate the link, restore the serial device settings and close the serial device. If the `persist` or `demand` option is specified, `pppd` attempts to reopen the serial device and start another connection after the holdoff period. Otherwise `pppd` exits. If received during the holdoff period, `SIGHUP` causes `pppd` to end the holdoff period immediately.
- **SIGUSR1** Toggles the state of the debug option and prints link status information to the log.
- **SIGUSR2** Causes `pppd` to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.)

**Diagnostics** Messages are sent to the syslog daemon using facility `LOG_DAEMON`. To see error and debug messages, edit the `/etc/syslog.conf` file to direct the messages to the desired output device or file, or use the `updatetime` or `logfile` options.

The debug option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a `SIGUSR1` signal, which acts as a toggle to the `pppd` process.
### Name
`pppoec` – PPPoE chat utility

### Synopsis

```bash
pppoec [-omillisecs] [-smillisecs] [-v] device
       [service [ [except]server... [only]]]
pppoec [-omillisecs] [-v] -i [device]
```

### Description

The `pppoec` utility implements the client-side negotiation of PPPoE. It is intended to be used with the `pppd(1M)` `connect` option, in the same manner as the `chat(1M)` utility is used for asynchronous dial-up PPP.

When given with the `-i` flag, `pppoec` sends out a broadcast query on the given interface named by the `device` parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output.

Otherwise, when given without the `-i` flag, `pppoec` does the full PPPoE client-side negotiation. The `device` parameter is the intended Ethernet interface, and must already be plumbed with `sppptun(1M)`. The optional `service` parameter specifies a particular `service` desired; other offered services will be ignored. The optional `server` parameter specifies a specific server desired. You can specify `server` as an Ethernet address in the usual x:x:x:x:x:x format (with `*` in any of the six byte positions interpreted to mean “any”), or as a symbolic name resolved through `/etc/ethers` (or NIS), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword `except` before this string. This parameter can be specified more than once, and the first match is taken.

If you specify the `server` parameter, then the selected servers become “preferred.” If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword `only`.

### Options

The following options are supported:

- `-i` Sends out broadcast query over interface specified by `device`.
- `-o` Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (-i) mode.
- `-s` Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).
- `-v` Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.

You normally do not need to adjust the parameters set with `-o` and `-s`. They are provided for coping with unusually slow servers.

### Operands

The following operands are supported:

- `device` plumbed Ethernet interface
preferred server or, if you specify only, the specified server

desired service; other available services are ignored

**Examples**

**EXAMPLE 1** Connecting to Any Service on hme0

The following command enables you to connect to any PPPoE service on hme0:

```
# /usr/bin/pppd sppptun plugin pppoe.so \
connect "/usr/lib/inet/pppoe hme0" debug
```

Often, a command such as the preceding is specified in an /etc/ppp/peers file instead. For example, enter the following in /etc/ppp/peers/myisp:

```
sppptun plugin pppoe.so \
connect "/usr/lib/inet/pppoe hme0" debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the /etc/ppp/peers files are considered privileged by pppd, you need not be root to invoke the preceding command.

**EXAMPLE 2** Connecting to a Particular Service

A more complex example: on hme0, connect to only the internet service offered by PPPoE servers with access concentrator name isp, but not to any Ethernet addresses starting with 40:0:1a.

```
# /usr/lib/inet/pppoe hme0 internet except 40:0:1a:*::* isp only
```

Note that the except 40:0:1a:*::* filter must come before isp, because the filters are first-match.

**Exit Status**

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Files**

```
/usr/lib/inet/pppoe  executable command
/dev/sppptun       Solaris PPP tunneling device driver.
/etc/ppp/connect-errors usual location of error output (see DIAGNOSTICS, below)
```

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

Diagnostics  Error messages are written to standard error, which is normally redirected by pppd to /etc/ppp/connect-errors. The errors can also be redirected to pppd's standard output by using the upndetach option.

If you specify the -v, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the upndetach or nodetach pppd option is helpful when using verbose mode.
The `pppoed` daemon implements the server-side negotiation of PPPoE. When a client requests service from this daemon, a copy of `pppd(1M)` is invoked to handle the actual PPP communication.

At startup, options are read from the command line and the `/etc/ppp/pppoe` file. After these options have been read, options in the per-device `/etc/ppp/pppoe .device` files are read, using the device names specified on the command line or in `/etc/ppp/pppoe`. Device names are not permitted in the per-device files. It is not an error if any of these files are absent; missing files are ignored.

Options are reread in the same order on SIGHUP. Except for the possibility of short delays due to the processing time, SIGHUP does not interfere with any client operations. Current status, including options read, is dumped to `/tmp/pppoed .pid` on SIGINT.

The options are used to set up a list of services to be offered to PPPoE clients on the broadcast domains (Ethernet subnets) specified by the named devices. Option parsing is always in one of two modes, either global mode or service mode. The initial mode at the beginning of each file (and the command line) is global mode. Options specified in global mode serve as default values for subsequently defined services. Service mode is entered by the `service name` option. In this mode, the named option is defined. Options that appear in this mode override any global mode definitions for the current service.

The option parsing follows standard shell tokenizing rules, using whitespace to delimit tokens, quotes to enclose strings that can contain whitespace, and escape sequences for special characters. Environment variables are substituted using familiar `$VAR` and `${VAR}` syntax and set using `NEWVAR=string`. Variables are both usable in subsequent options and provided to the `pppd(1M)` processes spawned for each client, but they are interpreted as they are encountered during option processing. Thus, all set variables are seen by all processes spawned; position in the configuration files has no effect on this.

The `pppoed` daemon supports the following options:

- **client [except] client-list**

  This option restricts the clients that may receive the service. If the `except` keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.

  This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it matches an option with `except` specified, then access is denied. Otherwise, it is granted. The `client` list within a service is prepended to any list specified in the global context.
If no client options are given or if all options are specified with except, then all clients are permitted by default. If any client options without except are specified, then no clients are permitted by default.

The client-list is a comma-separated list of client identifiers. The match is made if any client on the list matches; thus, these are logically "ORed" together. Each client identifier can be either a symbolic name (resolved through /etc/ethers or NIS, as defined by /etc/nsswitch.conf) or a hexadecimal Ethernet address in the format \texttt{x:x:x:x:x:x}. In the latter case, any byte of the address can be "\texttt{*}" which matches any value in that position. For example, \texttt{40:0:1a:*:*:*} matches Ethernet adapters from the manufacturer assigned block \texttt{40:0:1a}.

**debug**

Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to \texttt{syslog(3C)} using facility \texttt{daemon} (see the log option below). When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option also sets the daemon's default (non-service-related) detail level.

**device device-list**

Specify the devices on which the service is available. The device-list is a comma-separated list of logical device names (without the leading /dev/), such as hme0. This option is ignored if encountered in the per-device /etc/ppp/pppoe.device files.

**extra string**

Specifies extra options to \texttt{pppd(1M)}. It defaults to "plugin pppoe.so directtty" and usually does not need to be overridden.

**file path**

Suspends parsing of the current file, returns to global mode, and reads options from path. This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

The global mode options specified in files read by this command use the options set in the current file's global mode; this condition extends to any file included by those files. All files read are parsed as though the command line had specified this option, and thus inherit the command line's global modes.
This option can be used to revert to global mode at any point in an option file by specifying file /dev/null.

</tbody>
</table>
/etc/ppp/pppoe file, this option causes pppoe to ignore all wildcard service requests. This is the default.

**Examples**

**EXAMPLE 1** Configuring for Particular Services

In the /etc/ppp/pppoe file:

```
  service internet
device $DEV
      pppd "proxyarp 192.168.1.1:"
  service debugging
      device hme0,$DEV
      pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```
  example% /usr/lib/inet/pppoe DEV=eri0
```

The lines in /etc/ppp/pppoe and the preceding command result in offering services "internet" and "debugging" (and responding to wildcard queries) on interface eri0, and offering only service "debugging" on interface hme0.

**Signals**

The pppoe daemon responds to the following signals:

- **SIGHUP** Causes pppoe to reparse the original command line and all configuration files, and close and reopen any log files.
- **SIGINT** Causes a snapshot of the state of the pppoe daemon to be written to /tmp/pppoe.pid (where pid is the decimal process ID of the daemon).

**Files**

- `/usr/lib/inet/pppoe` executable command
- `/dev/sppptun` Solaris PPP tunneling device driver
- `/etc/ppp/pppoe` main configuration option file
- `/etc/ppp/pppoe.device` per-device configuration option file
- `/etc/ppp/pppoe-errors` location of output from pppd’s stderr
- `/etc/ppp/pppoe.if` list of Ethernet interfaces to be plumbed at boot time
- `/tmp/pppoe.pid` ASCII text file containing dumped pppoe state information

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>

<tbody>
<tr>
<td>Availability</td>
<td>SUNWpppdt</td>
</tr>
</tbody>
</table>
Because `pppd` is installed setuid root, this daemon need not be run as root. However, if it is not run as root, the user and group options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the `sppptun(1M)` utility before services can be offered.

The daemon operator runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use `pkill -HUP pppoed` after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661’s default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.

See Also  `pppd(1M), pppoec(1M), sppptun(1M), sppptun(7M)`

Network Working Group. February 1999

**Name**
pppstats – print PPP statistics

**Synopsis**
pppstats [-a] [-v] [-r] [-z] [-c <count>] [-w <secs>] [interface]

**Description**
The pppstats utility reports PPP-related statistics at regular intervals for the specified PPP interface. If the interface is unspecified, pppstats defaults to sppp0. The display is split horizontally into input and output sections containing columns of statistics describing the properties and volume of packets received and transmitted by the interface.

**Options**
The pppstats options are:

- **-a**
  Display absolute values rather than deltas. With this option, all reports show statistics for the time elapsed since the link was initiated. Without this option, the second and subsequent reports show statistics for the time since the last report.

- **-c count**
  Repeat the display count times. If this option is not specified, the default repeat count is 1 if the -w option is not specified, otherwise infinity.

- **-r**
  Display additional statistics summarizing the compression ratio achieved by the packet compression algorithm in use.

- **-v**
  Display additional statistics relating to the performance of the Van Jacobson TCP header compression algorithm.

- **-w wait**
  Pause wait seconds between each display. If this option is not specified, the default interval is five seconds.

- **-z**
  Instead of the standard display, show statistics indicating the performance of the packet compression algorithm in use.

**Extended Description**
The following fields are printed on the input side when the -z option is not used:

- **IN**
  Total number of bytes received by this interface.

- **PACK**
  Total number of packets received by this interface.

- **VJCOMP**
  Number of header-compressed TCP packets received by this interface.

- **VJUNC**
  Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.

- **VJERR**
  Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.

- **VJTOSS**
  Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.

- **NON-VJ**
  Total number of non-TCP packets received by this interface. Only reported when the -v option is specified.
RATIO  Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the -r option is specified.

UBYTE  Total number of bytes received, after decompression of compressed packets. Only reported when the -r option is specified.

The following fields are printed on the output side:

OUT  Total number of bytes transmitted from this interface.

PACK  Total number of packets transmitted from this interface.

VJCOMP  Number of TCP packets transmitted from this interface with VJ-compressed TCP headers.

VJUNC  Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the -r option is specified.

NON-VJ  Total number of non-TCP packets transmitted from this interface. Not reported when the -r option is specified.

VJSRCH  Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

VJMISS  Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

RATIO  Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the -r option is specified.

UBYTE  Total number of bytes to be transmitted before packet compression is applied. Only reported when the -r option is specified.

When the -z option is specified, pppstats displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:

COMPRESSED BYTE  Number of bytes of compressed packets received.

COMPRESSED PACK  Number of compressed packets received.

INCOMPRESSIBLE BYTE  Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received.

INCOMPRESSIBLE PACK  Number of incompressible packets received.

COMP RATIO  Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets).
The fields displayed on the output side are:

- **COMPRESSED BYTE**: Number of bytes of compressed packets transmitted.
- **COMPRESSED PACK**: Number of compressed packets transmitted.
- **INCOMPRESSIBLE BYTE**: Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form.
- **INCOMPRESSIBLE PACK**: Number of incompressible packets transmitted.
- **COMP RATIO**: Recent compression ratio for outgoing packets.

Name  pprosetup – setup program for Patch Manager

Synopsis  /usr/sbin/pprosetup [-a admin-email-addr] [-b backout-dir] 
[-c config-name] [-C] [-d patch-dir] 
[ [-D ] -M day-of-month | -W day-of-week ] [-s hh:mm] ] 
[-h] [-H] [-i {none | patch-property-list}] [-L] 
[-p {none | standard}] [-p patch-source-url] 
[-q sequester-dir] [-u user-name] 
[-U proxy-user-name] [-x {host:port}]

Description  Note – This command is deprecated. Use the smpatch set, smpatch unset, and smpatch get commands instead. See the smpatch(1M) man page.

Use the pprosetup command, as superuser, to configure your patch management environment by doing the following:

- Scheduling the patch operations
- Setting a patch policy
- Specifying patch directories
- Specifying the hardware on the system
- Specifying alternate configurations

Scheduling the Patch Operations
Schedule the automatic synchronization of patches with Sun's patch base. This scheduling makes the pprosvc command run in automatic mode. This mode is set up by using the cront interface. Use the -C, -D, -M, -s, and -W options to perform the scheduling tasks.

If you do not want to schedule patch operations, you can run the pprosvc and smpatch commands in manual mode, which means running the tool from the command line.

Note that midnight is represented as 00:00.

Note – The smpatch command does not directly support this mechanism for scheduling patch operations. You can set up a schedule by using cront to run smpatch in local mode. See the smpatch(1M) man page.

Setting a Patch Policy
Patches are classified as being standard or nonstandard. A standard patch can be applied by pprosvc in automatic mode. Such a patch is associated with the standard patch property. A nonstandard patch is one that has one of the following characteristics:

- A patch that is associated with the rebootafter, rebootimmediate, reconfigafter, reconfigimmediate, or singleuser properties. This nonstandard patch can be applied by running the pprosvc command or the smpatch command in manual mode.
- A patch that is associated with the interactive property. Such a patch cannot be applied by using the smpatch command.

Use pprosetup to schedule patch operations to run in automatic mode. Patches are applied based on the policy, which you can set by running pprosetup.

Use pprosetup -p to specify the types of patches to apply in automatic mode. You can set a policy to apply no patches (none) or standard patches (standard).
Use `pprosetup -i` to specify the types of patches to apply in manual mode. Such patches might include those that require a reboot and those that must be applied while the system is in single-user mode. Specify the types of patches that can be applied by using the following command:

```
# pprosetup -i patch-property-list
```

`patch-property-list` is a colon-separated list of one or more of the following patch properties:

- **interactive**: A patch that cannot be applied by running the usual patch management tools (`pprosvc`, `smpatch`, or `patchadd`). Before this patch is applied, the user must perform special actions. Such actions might include checking the serial number of a disk drive, stopping a critical daemon, or reading the patch’s README file.

- **rebootafter**: The effects of this patch are not visible until after the system is rebooted.

- **rebootimmediate**: When this patch is applied, the system becomes unstable until the system is rebooted. An unstable system is one in which the behavior is unpredictable and data might be lost.

- **reconfigafter**: The effects of this patch are not visible until after a reconfiguration reboot (`boot -r`). See the `boot(1M)` man page.

- **reconfigimmediate**: When this patch is applied, the system becomes unstable until the system gets a reconfiguration reboot (`boot -r`). An unstable system is one in which the behavior is unpredictable and data might be lost.

- **singleuser**: Do not apply this patch while the system is in multiuser mode. You must apply this patch on a quiet system with no network traffic and with extremely restricted I/O activity.

- **standard**: This patch can be applied while the system is in multiuser mode. The effects of the patch are visible as soon as it is applied unless the application being patched is running while the patch is applied. In this case, the effects of the patch are visible after the affected application is restarted.

**Note** – The `smpatch` command only supports the patch policy for manual mode.

### Specifying Patch Directories

Use the following options to specify the directories in which to store patch-related data:

- Use the `-b` option to specify the directory in which to store backout data. During a patch backout operation, the data is retrieved from this directory to restore the system to its state prior to applying the patch.

- Use the `-d` option to specify the download directory in which to store patches that are downloaded from the Sun patch server. This directory is also the location from which patches are applied.
Use the `-q` option to specify the directory in which to store patches that cannot be applied automatically. Such patches are called *sequestered patches*.

**Note** – The sequester directory is not used by the `smpatch` command.

### Specifying the Hardware on the System

Use the `-H` option to run a program that helps you determine the hardware that is attached to the host system, such as firmware, disk array systems, and tape storage systems.

Use this option to select the hardware that applies to this system. Select the sequence number of the specific hardware. A confirmation page lists the selections.

Save the specified hardware configuration information to a file. Then, the system responds by performing the appropriate actions.

**Note** – The `smpatch` command does not support this feature for specifying hardware on your system.

### Specifying Alternate Configurations

The `pprosetup` command uses a configuration file to specify the collection of patches with which to perform patch operations. By default, all of the patches from the Sun patch server are available for patch operations.

The `-c` option enables you to specify an alternate configuration.

Sun currently provides one alternate configuration, which is called the `recommended` configuration. This configuration includes only those patches that have been declared significant. Such patches include security patches and patches that address known performance and availability problems.

You can use the `-c recommended` option when you schedule patch operations. For example, the following command schedules monthly patch operations that use the `recommended` configuration:

```bash
# pprosetup -c recommended -M 15 -s 23:30
```

To cancel a schedule that uses the `recommended` configuration, type:

```bash
# pprosetup -c recommended -C
```

You are permitted to modify the `recommended` configuration by using the `-c` option. See EXAMPLES.

**Note** – The `smpatch` command does not support this feature for specifying alternate configurations.

### Options

The following options are supported:

- `-a admin-email-addr` Is the email address of the patch administrator. Email notification is sent to describe the patches downloaded, the
patches applied, and any error events that occurred when running the pprosvc -i -n command.

**Note** – This option does not affect the smpatch command.

**-b backout-dir**
Stores backout data in the specified directory.

The backout data is used whenever you use the patchrm command to remove a patch that has already been applied to your system. The data is used to restore a system to the state it was in before you applied a particular patch. Since backout data might be quite large, store the data in a large partition that holds large transitory data. Such a partition might be /var.

If you do not specify the -b option, the backout data is stored in the default locations used by patchadd. These locations are the save directories of the packages that were modified by the patch. For example, if a patch modifies the SUNWcsr package, the backout data for that package is stored in the /var/sadm/pkg/SUNWcsr/save directory.

To specify the backout directory, use the smpatch set command to set the patchpro.backout.directory parameter.

**Note** – The root file system of any non-global zones must not be referenced with the -b option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

**-C**
Clears the existing patch service schedule.

**Note** – This feature is not supported by the smpatch command.

**-c config-name**
Uses the config-name configuration for patch operations. When this option is included in any pprosetup command, the entire command applies to the specified configuration.

**Note** – This feature is not supported by the smpatch command.

**-d patch-dir**
Is the directory in which to download the patches that are appropriate for this host system. This directory is also the
location from which patches are applied. By default, the
download directory is `/var/sadm/spool`.

**Note** – To specify the download directory, use the `smpatch set` command to set the `patchpro.download.directory` parameter.

-D

Schedules the automatic analysis, download, and optional application of patches on a daily basis. This option is equivalent to executing the `pprosvc -i -n` command on a daily basis. See the `crontab(1)` man page.

The policy defined by the -p option determines whether no patches (`pprosetup -p none`) are applied or whether standard patches (`pprosetup -p standard`) are applied. By default, no patches are applied.

This option is mutually exclusive with the -M option and the -W option.

**Note** – This feature is not supported by the `smpatch` command.

-h

Displays information about command-line options.

-H

Establishes a dialog with the user to determine what hardware is attached to the host system.

**Note** – This feature is not supported by the `smpatch` command.

-1 [none | patch-property-list]

 Specifies the policy for applying patches in manual mode.

No patches are applied when `none` is specified.

`patch-property-list` is a colon-separated list of one or more of the following patch properties: `interactive`, `rebootafter`, `rebootimmediate`, `reconfigafter`, `reconfigimmediate`, `singleuser`, and `standard`. See Setting a Patch Policy.

**Note** – To specify the patch policy, use the `smpatch set` command to set the `patchpro.install.types` parameter.

-L

Displays the configuration parameter settings of your patch management environment.

This option is mutually exclusive with the other options.
Note – To view the configuration parameter settings, use the `smpatch get` command.

-M day-of-month
Schedules the automatic analysis, download, and optional application of patches on a monthly basis.

The policy defined by the -p option determines whether no patches (`pprosetup -p none`) are applied or whether standard patches (`pprosetup -p standard`) are applied. By default, no patches are applied.

day-of-month is a numerical value from 1-28, which represents the day of the month. Note that the values 29, 30, and 31 are invalid. See the `crontab(1)` man page.

This option is mutually exclusive with the -D option and the -W option.

Note – This feature is not supported by the `smpatch` command.

-p [none | standard]
Specifies the policy for applying patches in automatic mode.

No patches are applied when none, the default, is specified.

When standard is specified, only standard patches are applied.

Note – This feature is not supported by the `smpatch` command.

-P patch-source-url
Is the URL that points to the collection of patches. The default is the Sun patch server, which has the following URL:

https://updateserver.sun.com/solaris/

Note – To specify the URL that points to the collection of patches, use the `smpatch set` command to set the `patchpro.patch.source` parameter.

-q sequester-dir
Is the directory in which patches are moved if they cannot be automatically applied. By default, the sequester directory is `/var/sadm/spool/patchproSequester`.

Note – The sequester directory is not used by the `smpatch` command.
Optionally sets the time of day to perform patch operations, which by default, is midnight local time.

`hh` is a value from 00-23, which specifies the hour. `mm` is a value from 00-59, which specifies the minute.

Use this option with the `-D`, `-M`, and `-W` options.

**Note** – This feature is not supported by the `smpatch` command.

**-u user-name**

Is the user name with which to obtain contract patches from Sun.

Store the corresponding SunSpectrum user’s password in the `/lib/.sunsolvepw` file. If PatchPro is installed in the default location, this file is in the `/opt/SUNWppro` directory.

Keep the password safe by setting the owner, group, and permissions to `root`, `sys`, and `0600`, respectively.

**Note** – This file method of supplying passwords is no longer supported.

**Note** – To specify this user, use the `smpatch set` command to set the `patchpro.sun.user` parameter. Also, specify this user’s password by setting the `patchpro.sun.passwd` parameter.

**-U proxy-user-name**

Is the user name required for authentication of the web proxy, if applicable.

Store the corresponding user’s password in the `/lib/.proxypw` file. If PatchPro is installed in the default location, this file is in the `/opt/SUNWppro` directory.

Keep the password safe by setting the owner, group, and permissions to `root`, `sys`, and `0600`, respectively.

**Note** – This file method of supplying passwords is no longer supported.

**Note** – To specify this user, use the `smpatch set` command to set the `patchpro.proxy.user` parameter. Also, specify this user’s password by setting the `patchpro.proxy.passwd` parameter.
-W day-of-week

Schedules the automatic analysis, download, and optional application of patches on a weekly basis.

day-of-week is a numerical value from 0-6, which represents the day of the week. 0 represents Sunday. See the crontab(1) man page.

The policy defined by the -p option determines whether no patches (pprosetup -p none) are applied or whether standard patches (pprosetup -p standard) are applied. By default, no patches are applied.

This option is mutually exclusive with the -D option and the -M option.

Note – This feature is not supported by the smpatch command.

-x [host:port]

Specifies the web proxy. If your system is behind a firewall, use this option to specify your web proxy. Get the name of the web proxy and its port from your system administrator or network administrator.

Note – To specify the web proxy host name and port, use the smpatch set command to set the patchpro.proxy.host and patchpro.proxy.port parameters, respectively.

**Examples**

**EXAMPLE 1**  Scheduling Daily Patch Operations in Automatic Mode

```
# pprosetup -D
```

Schedules smpatch update to run in automatic mode daily at midnight local time.

**EXAMPLE 2**  Scheduling Weekly Patch Operations in Automatic Mode

```
# pprosetup -W 0 -s 00:45
```

Schedules smpatch update to run in automatic mode every Sunday at 12:45 a.m. local time.

**EXAMPLE 3**  Scheduling Monthly Patch Operations in Automatic Mode

```
# pprosetup -M 15 -s 02:30
```

Schedules smpatch update to run in automatic mode on the 15th day of every month at 2:30 a.m. local time.
EXAMPLE 4  Canceling Scheduled Jobs

# pprosetup -C

Cancels the scheduled jobs that use the default configuration.

EXAMPLE 5  Specifying the Patch Policy for Manual Mode

# pprosetup -i standard:singleuser:reconfigafter:rebootafter

Specifies the policy for applying patches in manual mode. This policy permits you to apply the following types of patches to your system in manual mode:

- Standard patches
- Patches that must be applied in single-user mode
- Patches that require that the system undergo a reconfiguration reboot after they have been applied
- Patches that require that the system undergo a reboot after they have been applied

EXAMPLE 6  Specifying the Patch Policy for Automatic Mode

# pprosetup -p none

Specifies that no patches are automatically applied.

# pprosetup -p standard

Specifies that only standard patches can be downloaded and applied.

EXAMPLE 7  Specifying an Alternate Download Directory

# pprosetup -d /export/home/patches

Specifies that patches are downloaded to the /export/home/patches directory.

EXAMPLE 8  Specifying an Alternate Sequester Directory

# pprosetup -q /export/home/patches/sequester

Specifies that sequestered patches are stored in the /export/home/patches/sequester directory.

EXAMPLE 9  Identifying the Hardware on Your System

# pprosetup -H

Enables a patch analysis to determine whether your system needs specific patches based on your hardware configuration. This command only helps you identify hardware products from Sun Network Storage.
**EXAMPLE 10**  Configuring Your System to Obtain Contract Patches

```
# pprosetup -u myuser
# echo mypasswd > /opt/SUNWppro/lib/.sunsolvepw
```

Enables your contract user, myuser, to obtain the contract patches.

Ensure that the contract user's password is safe by setting the owner, group, and permissions of the `.sunsolvepw` file to root, sys, and `0600`, respectively.

**EXAMPLE 11**  Specifying a Web Proxy

```
# pprosetup -x webaccess.corp.net.com:8080
```

Specifies the host name, webaccess.corp.net.com, and port, `8080`, of the web proxy to use.

**EXAMPLE 12**  Scheduling Daily Patch Operations to Use the recommended Configuration

```
# pprosetup -c recommended -D -s 23:00
```

Schedules a daily patch analysis that uses the recommended configuration. You can use the alternate configuration in conjunction with or in place of a full analysis.

```
# pprosetup -c recommended -C
```

 Cancels this job that uses the recommended configuration.

**EXAMPLE 13**  Modifying the recommended Configuration

```
# pprosetup -c recommended -a recommended@local
```

Modifies the recommended configuration to send email notifications to the `recommended@local` email alias about each scheduled analysis that uses the recommended cluster. Any scheduled operation that uses the recommended configuration will send notification to the alias you specify.

**EXAMPLE 14**  Creating a New Configuration

```
# pprosetup -c export -d /export/patches
```

 Creates a new configuration named `export` that downloads patches to the `/export/patches` directory. After executing this command, you can schedule patch operations or manually run patch operations that use the `export` configuration by running the `pprosetup` or `pprosvc` commands, respectively.

```
# pprosvc -c export -d
```

Downloads patches to the download directory specified by the `export` configuration.

See Also  
`crontab(1), boot(1M), patchadd(1M), patchrm(1M), pprosvc(1M), smpatch(1M), attributes(5)`
Name  
pprosvc – automation service program for Patch Manager

Synopsis  
/usr/sbin/pprosvc [-c config-name]
           [-d [-p patch-id [, patch-id]...]] [-h]
           [-i [-n] [-p patch-id [, patch-id]...]] [-l]

Description  
Note – This command is deprecated. Use the smpatch analyze, smpatch download, and
         smpatch update commands instead. See the smpatch(1M) man page.

         Use the pprosvc command to analyze a system to determine the list of appropriate patches,
download the patches, and apply them. This command invokes patch operations in response
         to a user request or at a scheduled time. You must run this command as superuser.

         The pprosvc command enables you to do the following:
         ▪ Analyze the host system for appropriate patches based on an established configuration
         ▪ Generate the list of appropriate patches
         ▪ Download the patches to your host system from the Sun patch server
         ▪ Apply the patches based on a patch policy

         Use the pprosvc -i command to analyze a system, download the appropriate patches, and
         apply them. If analysis determines that patches are needed, the pprosvc command downloads
         them and applies them.

         Specify other options to automate a subset of the patch management tasks. If you specify the
         -d option, your system is analyzed and the appropriate patches are downloaded to your
         system. If you specify the -l option, your system is analyzed and the appropriate patches are
         listed.

         The list of patches that is generated by the analysis is based on all of the available patches from
         the Sun patch server. No explicit information about your host system or its network
         configuration is transmitted to Sun. Only a request for the Sun patch set is transmitted. The
         patch set is scanned for patches that are appropriate for this host system, the results are
         displayed, and those patches are optionally downloaded.

         The -d, -i, and -l options are mutually exclusive.

         Use the -p option to specify the patches on which to operate. You can use the -p option with
         the -d and -i options.

Options  
The following options are supported:

   -c config-name  Uses an alternate configuration for the current patch operation.
   Use the pprosetup command to create new configurations.

   A configuration named recommended is included. For more
   information, see “Specifying Alternate Configurations” in the
   pprosetup(1M) man page.
Note – This feature is not supported by the smpatch command.

-d
Downloads the patches that are appropriate for this host system. The patches are downloaded to the designated download directory.

This option generates a list of appropriate patches, as does the -l option. However, instead of just displaying the list of patches, the -d option displays and downloads the patches from the Sun patch server. The patches are downloaded using a secure connection, and all patches are authenticated using digital signature technology. Only patches that are signed with a Sun digital signature are stored in your download directory.

Note – Specifying this option is equivalent to running the smpatch download command.

-h
Displays information about the command-line options.

-i
Applies the patches based on the patch policy. This option analyzes your system to generate a list of appropriate patches. If analysis determines that patches are needed, the patches are downloaded and applied. If no patches are permitted to be applied in automatic mode (by running pprosetup -p none), this option is identical to specifying the -d option.

If only standard patches are permitted to be applied in automatic mode (by running pprosetup -p standard), all standard patches are applied.

Note – Specifying this option is equivalent to running the smpatch update command.

-l
Generates a list of the patches that are appropriate for this host system.

Note – Specifying this option is equivalent to running the smpatch analyze command.

-n
Runs pprosvc in automatic mode. The command that the cron job specifies is pprosvc -i -n. To schedule patch operations to run in automatic mode, see the pprosetup(1M) man page.

In automatic mode, the patch administrator (specified by the -a option) receives email notifications that describe the patches you downloaded and applied, and any error events that occurred.
Do not use this option on the command line.

Standard patches do not require any special actions on the part of the user. Such patches can be applied by using the patchadd command (see the `patchadd(1M)` man page) and do not need the host system to reboot for the patch to take effect.

All nonstandard patches are moved to the sequester directory if you use the `-n` option to run in automatic mode. If you run in manual mode, however, nonstandard patches that have properties that match the policy specified by `pprosetup -i` are applied. The rest of the nonstandard patches are moved to the sequester directory. You can apply patches from this directory at a later time. Patches, whether standard or nonstandard, that depend on sequestered patches are not applied under any circumstances. Such patches are placed in the sequester directory.

For any patch that is placed in the sequester directory, refer to the patch’s README file to determine how to apply it to your system.

**Note** – This feature is not supported by the `smpatch` command.

```
-p [patch-id,patch-id,...]  Designates the specific patches on which to operate. Use this option with the `-d` option or the `-i` option. The list of patch IDs must be separated by commas.
```

The specified patches are adjusted to use the current versions based on the patch baseline. Patches that are required by the specified patches are added to the complete list of patches to be applied.

**Note** – Specifying this option is equivalent to specifying the `-i` option to the `smpatch analyze`, `smpatch download`, and `smpatch update` commands.

**Examples**  

**EXAMPLE 1**  Applying Specific Patches in Manual Mode
```
# pprosvc -i -p 102893-01,106895-09,106527-05
```
Applies patches 102893-01, 106895-09, and 106527-05 to the local system in manual mode.

**EXAMPLE 2**  Analyzing a System and Downloading Appropriate Patches
```
# pprosvc -i
```
EXAMPLE 2  Analyzing a System and Downloading Appropriate Patches  (Continued)

Performs an analysis of the current system and downloads the appropriate patches based on all the patches from the Sun patch server. The resulting list of patches can be very long.

EXAMPLE 3  Applying Patches From the Recommended Configuration

   # pprosvc -c recommended -i

Uses the recommended configuration to perform an analysis of the current system and downloads the appropriate patches. Standard patches and those needed from the recommended configuration are applied to the system based on the established patch policy. For information about setting the patch policy for manual mode, see the description of the -i option on the pprosetup(1M) man page.

praudit (1M)

Name
praudit – print contents of an audit trail file

Synopsis
praudit [-lrsx] [ -ddel ] [filename]...

Description
praudit reads the listed filenames (or standard input, if no filename is specified) and interprets the data as audit trail records as defined in audit.log(4). By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.

Options
The following options are supported:

- ddel
  Use del as the field delimiter instead of the default delimiter, which is the comma. If del has special meaning for the shell, it must be quoted. The maximum size of a delimiter is three characters. The delimiter is not meaningful and is not used when the -x option is specified.

- l
  Print one line per record.

- r
  Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option is useful when naming services are offline. The -r option and the -s option are exclusive. If both are used, a format usage error message is output.

- s
  Display records in their short form. Numeric fields' ASCII equivalents are looked up by means of the sources specified in the /etc/nsswitch.conf file (see nsswitch.conf(4)). All numeric fields are converted to ASCII and then displayed. The short ASCII representations for the record type and event fields are used. This option and the -r option are exclusive. If both are used, a format usage error message is output.

- x
  Print records in XML form. Tags are included in the output to identify tokens and fields within tokens. Output begins with a valid XML prolog, which includes identification of the DTD which can be used to parse the XML.

Files
/etc/security/audit_event
  Audit event definition and class mappings.

/etc/security/audit_class
  Audit class definitions.

/usr/share/lib/xml/dtd
  Directory containing the versioned DTD file referenced in XML output, for example, adt_record.dtd.1

/usr/share/lib/xml/style
  Directory containing the versioned XSL file referenced in XML output, for example, adt_record.xsl.1.
Attributes   See attributes(5) for descriptions of the following attributes:

Notes   This functionality is available only if the Solaris Auditing feature has been enabled. See bsmconv(1M) for more information.
printmgr – Solaris Print Manager is a graphical user interface for managing printers in a network

Synopsis
/usr/sadm/admin/bin/printmgr

Description
Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer access. This tool can be used in the following name service environments: LDAP, NIS, NIS+, and files. You must be logged in as superuser to use this tool.

Using Solaris Printer Manager is the preferred method for managing printer access because Solaris Print Manager centralizes printer information when it is used in a name service environment.

Adding printer information to a name service makes access to printers available to all systems on the network and generally makes printer administration easier because all the information about printers is centralized.

Solaris Print Manager may be run on a remote system with the display sent to the local system. See the System Administration Guide: Printing for instructions on setting the DISPLAY environment variable.

Using Solaris Print Manager to perform printer-related tasks automatically updates the appropriate printer databases. Solaris Print Manager also includes a command-line console that displays the lp command line for the add, modify, and delete printer operations. Errors and warnings may also be displayed when Printer Manager operations are performed.

Help is available by clicking the Help button.

Usage
Solaris Print Manager enables you to do the following tasks:

Select a Name Service
Select a name service for retrieving or changing printer information.

Add Access to a Printer
Add printer access on a printer client using Solaris Print Manager.

Add an Attached Printer
After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing.

Add a Network Printer
After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing.

Modify Printer Properties
After adding access to a printer or adding an attached or network printer, you can modify certain printer attributes.

Delete a Printer
Delete access to a printer from the print client or delete a printer from the print server or from the name service environment.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

System Administration Guide: Printing for information on LDAP server replication.

Although users can use the LDAP command line utilities ldapadd(1) and ldapmodify(1) to update printer entries in the directory, the preferred method is to use lpset. Otherwise, if the lpadd and lpmodify utilities are used, the administrator must ensure that the printer-name attribute value is unique within the ou=printers container on the LDAP server. If the value is not unique, the result of modifications done using lpset or the Solaris Print Manager, printmgr may be unpredictable.
**privatepw(1M)**

**Synopsis**

privatepw [-c] [-f ftpgroups] [-g real_group_name] accessgroup

privatepw -d [-f ftpgroups] accessgroup

privatepw -l [-f ftpgroups]

privatepw -V

**Description**

The `privatepw` utility is an administrative tool to add, delete and list enhanced access group information in the `ftpgroups` file. See `ftpgroups(4)`.

When `privatepw` is used without options, the help usage message is displayed. The `privatepw` utility prompts for a password when adding an enhanced access group entry or modifying an existing one.

**Options**

The following options are supported by the `privatepw` utility:

- `-c`  
  Create a new `ftpgroups` file for the specified `accessgroup`.

- `-d`  
  Delete information about the specified `accessgroup` from the `ftpgroups` file.

- `-f ftpgroups`  
  Use the specified `ftpgroups` file for all updates.

- `-g group`  
  Set the real system group to the `group` specified. `group` is a valid group name returned by `getgrnam(3C)`. If the real system group is not supplied with the `-g` option when adding an enhanced access group entry, the `privatepw` utility prompts for it.

- `-l`  
  List the contents of the `ftpgroups` file.

- `-V`  
  Display program copyright and version information, then terminate.

**Operands**

The following operands are supported:

- `accessgroup`  
  The name of the enhanced access group to create or update. It consists of an arbitrary string of alphanumeric and punctuation characters. See `ftpgroups(4)`.

**Exit Status**

The following exit values are returned:

- `0`  
  Successful completion.

- `>0`  
  An error occurred.

**Files**

/etc/ftpd/ftpgroups

/etc/group

The \texttt{prodreg} utility browses, unregisters, and uninstalls components in the Solaris Product Registry.

Some installers make use of the \texttt{libwsreg(3LIB)} interface to register information. The Solaris Product Registry contains information about this installed software.

The database associated with the Solaris Product Registry is relative to the root of the installed file system. Normally, this is the root of the file system (/). Sometimes, an alternate root, with a different Solaris Product Registry install database is used, as during live upgrade installation. See \texttt{live\_upgrade(5)}.

The Registry database informs installers about installed software. The Registry and the \texttt{prodreg} utility do not directly perform installation or deinstallation. \texttt{prodreg} supports installers which are executed externally and launched by the \texttt{prodreg} utility or other means.

Depending on the subcommand, the \texttt{prodreg} command offers equivalent functions from the command line or a GUI viewer. Two versions of the GUI viewer are available. The default is the Java Swing GUI. The other version, the Java awt GUI is provided for environments without Java Swing support.

The only feature which exists in the CLI which is not present in the GUI is the \texttt{unregister} subcommand. It is possible for the product registry to become corrupted, if for example, some software is removed manually instead of by means of an uninstaller program. These entries can confuse installers which are run subsequently. The \texttt{unregister} subcommand allows stale entries to be removed, even forcefully. Care should be exercised when unregistering software with the recursive or force options so that valid entries in the registry are not removed by mistake.

The \texttt{prodreg} command, whether it launches the GUI or the command line interface browser, displays the contents of the registry at that time only. If software is installed or uninstalled subsequent to or concurrent with launching either \texttt{prodreg} viewer, the view can be inconsistent with the Solaris Product Registry.

\textbf{Subcommands} You can specify options to the \texttt{prodreg} command without specifying a subcommand. If the subcommand is omitted, the \texttt{swing} subcommand is assumed.

The following subcommands are supported:
\begin{verbatim}
awt  Launch the Java awt GUI.

The awt subcommand has the following format:
awt [-R alt_root | -help]
\end{verbatim}
browse Display the Solaris Product Registry using a command line interface. The text output of this command displays identifying information of any component in the product registry tree, including its ancestors and children. If you repeatedly invoke this subcommand, you can interactively browse the product registry.

The database components are related as a tree. Components may have one or more children. Except for the root, components have one parent. This subcommand displays the ancestors and children for a given component in the Solaris Product Registry database.

Each time the `prodreg browse` subcommand is executed, one component in the Registry is shown, along with its ancestry to the root of the Registry, as well as the component’s children. To browse in the `prodreg` GUI, a user selects a node to expand and clicks on it. The analogous activity using the command line interface is to browse on children of nodes successively, which effectively expands a view into the registry.

Start by browsing the root of the Registry with `prodreg browse`. Select components to expand the scope of the browsing activity. Use browse numbers as a convenience during this interactive browsing, but not in scripts. Browse numbers can change from one session to the next or on different systems. This is because browse numbers are generated as they are first used, by a given user on a particular system.

The browse subcommand has the following format:

```
browse [-R alt_root] [-u uuid [-i instance | -p location]]
browse [-R alt_root] -n bnum [-i instance | -p location]
browse [-R alt_root] -m name
browse --help
```

This following information is output for each component:

- **BROWSE #** This is the browse number associated with each component. This number can be used as an argument to either the `prodreg browse` or `info` subcommands as a convenience.
- **+/-.** The + indicates a component in the tree with children who are not shown. - indicates a component with children of which at least one child is being shown. The . indicates a component which has no children. This field is
arranged so that each space (reading left to right) depicts a successive generation.

**UUID**
This is the component's unique identifier.

**#**
This is the instance number of the component. Software components can be installed multiple times. The software registry assigns a unique instance to each one.

**NAME**
Each component in the Solaris Product Registry database has a localized name which is displayed in this field. It is possible that this name may not be unique in the registry since there could be another component that has the same name.

The `browse` subcommand provides four distinct options for viewing the registry database. If multiple instances are associated with the same component, then the output of the subcommand is the ambiguous list. The request must be made unambiguous. The instance or location operands can be used to disambiguate the `browse` subcommand when used with the `-u` or `-n` options.

- If no operand information is given, the root of the registry tree is displayed, as well as its children. This is the starting point for interactive browsing of the entire registry database.
- If the browse number is given, the component associated is output.
- If the `uuid` is given, the component associated with it is output.
- If the name is given, the component associated with it is output.

**info**
Display attributes for any component in the Solaris Product Registry by supplying identifying information for the component.

Components in the product registry are associated with attributes. These attributes are composed of a `name` and a single `value` string.

This subcommand outputs attribute information associated with components in the Solaris Product Registry. Individual components in the product registry are specified as for the `browse` subcommand, except that either the `uuid`, `name` or `bnum` must be specified.
If a component requested is ambiguous as it has more than one instance or the name is assigned to more than one component in the registry, the list of possibilities is output, not the attribute information.

The default output of this subcommand is a complete list of each attributes, each on a new line. The attribute name is followed by a colon (:) and a SPACE. The attribute value follows, after which a RETURN is appended. Other options include can be specified using -a and -d.

The info subcommand has the following format:

```bash
info --help
info [-R alt_root] -u uuid [-i instance | -p location]
info [-R alt_root] -n bnum [-i instance | -p location]
info [-R alt_root] -m name [-a attr | -d]
```

help | --help | -?

Display help text.

The help subcommand has the following format:

```bash
help | --help | -?
```

swing

Launch the Java Swing GUI. If the Java Swing GUI is not available, this subcommand fails.

The swing subcommand has the following format:

```bash
swing [-R alt_root] --help
```

version | --version | -V

Outputs a current version string.

The version subcommand has the following format:

```bash
version | --version | -V
```

unregister

Remove a component from the Solaris Product Registry. The component corresponding to the uuid specified with the -u option must be a single instance. If it is not, the subcommand fails and returns the list of instances with the associated uuid. The subcommand must be reissued using either -p or -i to uniquely determine which component instance to unregister.

The unregister subcommand fails if there are components in the registry which depend on the component which is to be unregistered.
The unregister subcommand fails if the user does not have write access to the registry. See `wsreg can access registry` (3WSREG). The unregister subcommand fails if the user attempts to unregister a system component, instead of a component registered with the Solaris Product Registry. System components include those which include the attribute PKG and certain special Registry nodes including the following:

<table>
<thead>
<tr>
<th>UUID</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>System Registry</td>
</tr>
<tr>
<td>801ee8dd-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>Solaris System Software</td>
</tr>
<tr>
<td>8f64eabf-1dd2-11b2-a3f1-0800209a5b6b</td>
<td>Unclassified Software</td>
</tr>
<tr>
<td>b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>System Software Localizations</td>
</tr>
<tr>
<td>blc436d1-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>Additional System Software</td>
</tr>
<tr>
<td>a8dca84f-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>Software Localizations</td>
</tr>
</tbody>
</table>

Before the unregister subcommand with the `-f` option is used, you should carefully review what components depend upon the component which is to be unregistered. The `-r` option is even more dangerous, since all children and software components depending upon the component are also deregistered. You can obtain the list of dependent components for a component with UUID `uuid` using:

```
prodreg info -u uuid -a "Dependent Components"
```

You can obtain a list of required components using:

```
prodreg info -u <uuid> -a "Required Components"
```

The output lists the name, UUID and instance of the component.

The unregister subcommand has the following format:

```
unregister [-R alt_root] [-fr] -u uuid [-p location | -i instance]
unregister --help
```

Launch an uninstaller program.

Each component in the registry can have an uninstaller associated with it. This subcommand executes this associated installer, if there is one, for a component in the registry given by the `-u` option. If there is no uninstaller associated with the component, the subcommand fails. If the component given by the `-u` option is not unique (as there is more than one instance of the component installed), the subcommand outputs a list of all instances. The subcommand must then be reissued using `-i` or `-p`
to disambiguate the uuid given with the -u option. Finally, if the component to uninstall is depended upon by other components, the command fails.

The command may also launch an uninstaller with a -x option. No checks for whether this uninstalls a component upon which other components depend in this case.

The uninstall command is not executed if the user does not have write access to the registry. See wsreg_can_access_registry(3WSREG).

The uninstall command has the following format:

```
uninstall [-R alt_root] [-f] -u uuid -p location
uninstall [-R alt_root] -i instance[arguments ...]
uninstall --help
```

**Options**

The `awt` subcommand supports the following options:

- `-help` Display help text, do not launch the viewer.
- `-R alt_root` Use the specified alternate root to locate the database to display with the GUI viewer.

See OPERANDS for information regarding specification of `alt_root`.

**Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

The `browse` subcommand supports the following options:

- `-help` Display help text, do not execute the browse subcommand.
- `-i instance` Output the specified component instance.
- `-n name` Output the component instances associated with the name.
- `-n bnum` Output the component instances associated with the browse number.
- `-p location` Output the component instance installed in the specified location. The install location for a component can be obtained using the `info` subcommand.
- `-R alt_root` Use the specified alternate root to locate the database.
Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-u uuid

Output the component instances associated with the uuid.

The info subcommand supports the following options:

-a attr
Output only the attribute whose name is given by the operand 'attr', instead of all attributes of the specified component.

-d
Output only the attribute whose name is isDamaged, instead of all attributes of the specified component. If the value is set to true, this attribute indicates that the component in the registry

-\help
Output help text, do not execute the browse subcommand.

-i instance
The instance operand distinguishes among multiple instances of components with the same uuid or browse number.

-m name
The name operand indicates one or more components in the registry.

-n bnum
Output the attributes of the component instance associated with the browse number bnum. If there is more than one instance, the command must be disambiguated using the -i or -p options.

-p location
The install location indicated distinguishes among multiple instances of components with the same uuid or browse number.

-R alt_root
Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-u uuid
Output the attributes of the component instance associated with the uuid. If there is more than one instance, the subcommand must be disambiguated using the -i or -p options.

The swing subcommand supports the following options:

-\help
Output help text, do not execute the install subcommand.

-R alt_root
Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global...
zone’s file system. See zones(5).

The uninstall subcommand supports the following options:

- **-f**  
  Force the uninstall. A forced subcommand uninstalls all instances of a component, even if there are multiple ambiguous instances of the uuid operand.

- **--help**  
  Output help text, do not execute the unregister subcommand.

- **-i instance**  
  Disambiguate the uuid operand.

- **-p location**  
  Disambiguate the uuid operand. location corresponds to the where the software component was installed.

- **-R alt_root**  
  Use the specified alternate root to locate the database.

**Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

- **-u uuid**  
  Unregister the uuid component. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the -i or -p option.

The unregister subcommand supports the following options:

- **-f**  
  Force the unregistration. A forced subcommand unregisters a component even if there are other components which are dependent on this component.

- **--help**  
  Output help text, do not execute the unregister subcommand.

- **-i instance**  
  Disambiguate the uuid operand.

- **-p location**  
  Disambiguate the uuid operand. The location corresponds to the where the software component was installed.

- **-r**  
  Causes a recursive deregistration of a component as well as that component’s children and dependencies.

- **-R alt_root**  
  Use the specified alternate root to locate the database.

**Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

- **-u uuid**  
  Unregister component uuid of the component to unregister. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the -i or -p option.
Operands The following operands are supported:

- **alt_root**: Pathname to a file indicating an alternate root. The Solaris Product Registry database is located relative to the alternate root. If database relative to this location does not exist, it is created.

  **Note** – The root file system of any non-global zones must not be referenced by **alt_root**. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

- **attr**: Name of an attribute. This operand is used only with the info subcommand. If attr is associated with a component, the attribute name and value is displayed.

- **bnum**: The browse number.

  Each component in the Solaris Product Registry is associated with a browse number. This number is generated for the convenience of an interactive user. The browse number can change if the system is rebooted or reinstalled. Do not store or use the browse number except to facilitate the browse and info subcommands. Browse numbers are always output by the prodreg browse subcommand. Only these values can be used as input values to the browse or info subcommand.

- **instance**: Software can be installed in more than one location. The Solaris Product Registry associates a unique instance number for each. The browse subcommand shows the instance number associated with each component in the registry. The instance operand is used to distinguish between installed, and possibly different, copies of software, when such exist.

- **location**: A path to a specific file or directory in the file system. This operand indicates the installed location of registered software. For instance, if software is installed relative to /usr/local the value of this operand would be /usr/local. The install location is used to installer or to indicate the location of an installer or to disambiguate which instance is intended, of a software component which can have multiple instances.

- **name**: Each software component in the Solaris Product Registry is associated with a name. This name is output by the browse subcommand. Some subcommands allow the user to input the software by name as an operand as a convenience. These names might not be unique. If the user supplies an ambiguous name, for which more than one components exist, the subcommand outputs a list of possible choices. The name can be localized; depending on the language setting the name can differ.

- **uuid**: Each software component in the Solaris Product Registry is associated with a unique identifier. This identifier is a handle which accesses an entry in the registry database. The uuid corresponds to the component irrespective of how many
instances of the component have been installed, and what the localized name of the component is.

**Examples**

**EXAMPLE 1** Using the *prodreg* Command to Browse

Browsing is performed by means of the *prodreg* browse subcommand. Using these requests iteratively, one can peruse the tree, much as one would using a GUI by expanding components which are collections of other components. Browsing using browse numbers for convenience should be done only during this iterative browsing process, since the numbers are generated as a result of the browsing operation.

Evoking the *browse* subcommand without any arguments browses from the top of the registry. The output varies depending on the software installed on a particular system.

```
$ prodreg browse
BROWSE # +/-/. UUID # NAME
-------- ------ ------------------------------- = = = = =
 1   -     root 1  System Registry
 2   +     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b 1 Solaris 10 System Software
 3   +     8f64eabf-1dd2-11b2-a3f1-0800209a5b6b 1 Unclassified Software
```

The output of this command lists the browse number, UUID, instance number and name of the root component and its children. The ancestors of a component, each parent up to the root, are also shown. The +/-/. column indicates whether the component in the tree is an expanded parent (-), a child with children (+) or a child without children (.).

**EXAMPLE 2** Requesting Information About the Components in a Tree

The UUID, name and browse number fields can be used to request browsing information about components in the tree. The next example shows how a component can be browsed by UUID.

```
$ prodreg browse -u a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b
BROWSE # +/-/. UUID # NAME
-------- ------ ------------------------------- = = = = =
 1   -     root 1  System Registry
 2   -     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b 1 Solaris 10 System Software
 3   +     b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b 1 System Software Localizations
 4   +     SUNWCall 1 Entire
```
EXAMPLE 2  Requesting Information About the Components in a Tree (Continued) Distribution

EXAMPLE 3  Browsing a Node by Name
The following example shows how a node can be browsed by name.

$ prodreg browse -m "System Software Localizations"

<table>
<thead>
<tr>
<th>Browse</th>
<th>+/-.</th>
<th>UUID</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-</td>
<td>root</td>
<td>System Registry</td>
</tr>
<tr>
<td>2</td>
<td>-</td>
<td>a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>Solaris 10 System Software</td>
</tr>
<tr>
<td>3</td>
<td>b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>System Software Localizations</td>
<td></td>
</tr>
<tr>
<td>316</td>
<td>.</td>
<td>SUNWceuow</td>
<td>Central Europe OW Support</td>
</tr>
<tr>
<td>317</td>
<td>.</td>
<td>SUNWcsfw</td>
<td>Simplified Chinese freeware message</td>
</tr>
<tr>
<td>318</td>
<td>.</td>
<td>SUNWceuox</td>
<td>Central Europe 64-bit OS Support</td>
</tr>
</tbody>
</table>

EXAMPLE 4  Browsing Iteratively
Additional output has been omitted. As a convenience, the browse number can be used for iterative browsing. This number should not be stored, as it differs depending on which system the prodreg command is run on, which user is running the command, and the login session in which the command is run.

$ prodreg browse -n 3

<table>
<thead>
<tr>
<th>Browse</th>
<th>+/-.</th>
<th>UUID</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-</td>
<td>root</td>
<td>System Registry</td>
</tr>
<tr>
<td>2</td>
<td>-</td>
<td>a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>Solaris 10 System Software</td>
</tr>
<tr>
<td>5</td>
<td>-</td>
<td>SUNWCall</td>
<td>Entire Software</td>
</tr>
</tbody>
</table>
EXAMPLE 4  Browsing Iteratively  (Continued)

6  .  SUNWrsmo  Distribution  1  RSMPI
   Operations
   Registration
   Module

7  +  SUNWCjvx  1  JavaVM
   (64-bit)

8  .  SUNWrsrx  1  Remote
   Shared
   Memory
   (64-bit)

9  +  SUNWCacc  1  System
   Accounting

EXAMPLE 5  Browsing Using an Ambiguous Value

If the requested value is ambiguous, the list of ambiguous instances are displayed. In the following example, there are two distinct software components with the same name.

$ ./prodreg browse -m JavaVM
The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

BROWSE # +/-/. UUID # NAME
======== ======================================== = ===========
12 .  org.spybeam.javavm 1  JavaVM
51 .  SUNWCjv 1  JavaVM

Issue one of the following requests again:

$ prodreg browse -u SUNWCjv

 or

$ prodreg browse -u org.spybeam.javavm

EXAMPLE 6  Browsing Multiple Installations of Software

Another possible ambiguous response arises when a particular software component is installed multiple times. In the example below Example software is registered three times.

$ prodreg browse -m Example
The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

BROWSE # +/-/. UUID # NAME
======== ======================================== = ===========
**EXAMPLE 6**  Browsing Multiple Installations of Software  (Continued)

```
<table>
<thead>
<tr>
<th>BROWSE</th>
<th>+/-/</th>
<th>UUID</th>
<th>#</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 .</td>
<td></td>
<td>org.spybeam.example</td>
<td>2</td>
<td>Example</td>
</tr>
<tr>
<td>7 .</td>
<td></td>
<td>org.spybeam.example</td>
<td>3</td>
<td>Example</td>
</tr>
<tr>
<td>7 .</td>
<td></td>
<td>org.spybeam.example</td>
<td>1</td>
<td>Example</td>
</tr>
</tbody>
</table>
```

The component requested could not be found.

**EXAMPLE 7**  Browsing Using a Particular Instance

The request can be repeated specifying a particular instance to disambiguate it. It is also possible to disambiguate a request with the `-p` option, followed by the install location. In this case, to browse the first instance of the Example software, one would use the command:

```
$ prodreg browse -u org.spybeam.example -i 1
```

**EXAMPLE 8**  Using the `info` Subcommand

The install location, as well as other attributes of a component can be obtained with the `info` subcommand. The `info` subcommand accepts the same disambiguating options and returns all the attributes of a component, each on a single line.

```
$ prodreg info -m Example
```

The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

```
BROWSE # +/-/ UUID # NAME
================= ========= =========== ===========
7 . org.spybeam.example 2 Example
7 . org.spybeam.example 3 Example
7 . org.spybeam.example 1 Example
```

The component requested could not be found.

This variation of the `info` subcommand outputs all information associated with instance 1 of the `Example` component. The output from this variation is not displayed.

```
$ prodreg info -u org.spybeam.example -i 1
```

**EXAMPLE 9**  Obtaining Information on the Install Location

You can use the `info` subcommand to obtain the install location and other attributes of a component. The `info` subcommand accepts the same disambiguating options as the `browse` subcommand. It returns all the attributes of a component, each on a single line. You can also request a single attribute.

The following command outputs the value of the install location attribute:

```
$ prodreg info -n 23 -a Location
```
EXAMPLE 10  Identifying and Unregistering Damaged Software

Removing installed software without using the associated uninstaller can damage the software in the registry. A damaged component indicates that certain software is installed, when in fact it is not present. A component can be damaged by removing files or packages directly, without running the associated uninstaller. The general rule to follow is: If software has been installed by an installer program, it should be uninstalled using the supplied uninstaller program.

This example shows how to identify and repair damaged software components so that software can be reinstalled.

Browsing for Examplesoft, produces the following:

```
$ prodreg browse -m Examplesoft
BROWSE # +/-/. UUID # NAME
======== ===== ==================================== = ============
1 - root 1 System Registry
2 + a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b 1 Solaris 10 System Software
3 + 8f64eabf-1dd2-11b2-a3f1-0800209a5b6b 1 Unclassified Software

233 . 90209809-9785-b89e-c821-0472985982be 1 Example Doc
234 . EXSOzzt 1
235 . EXSOblob 1 Example Data
```

The Examplesoft child EXSOzzt, representing a package component of registered software does not display its name. This is likely to be because the software Examplesoft is damaged. Verify this with the following command:

```
$ prodreg info -u 95842091-725a-8501-ef29-0472985982be -i 1 -d
isDamaged=TRUE
```

Since Damaged is TRUE, some part of Examplesoft is damaged. The following command lists the packages which make up Examplesoft:

```
$ prodreg info -u 95842091-725a-8501-ef29-0472985982be -i 1 -a PKGS pkgs:
EXSOzzt EXSOblob
```

Use the pkginfo command to verify if EXSO is installed:

```
$ pkginfo EXSOzzt
ERROR: information for "EXSOzzt" was not found
```
EXAMPLE 10  Identifying and Unregistering Damaged Software  (Continued)

$ pkginfo EXSOblob
application EXSOblob Example Data

The output of these commands shows that the package EXSOzzt has been removed, probably with the pkgrm command. The Examplesoft software will probably not function. To repair the software, one should run the uninstaller registered with Examplesoft. You probably need to run the uninstaller with root permissions, as it unregisters the software and runs pkgrm commands. Both of these operations require root permissions.

# prodreg uninstall -u 95842091-725a-8501-ef29-0472985982be -i 1
The install program requested could not be found.

Something is wrong, or else you would be able to access uninstall program to uninstall the software. One possibility is that the uninstaller program has been removed manually. It is possible to determine where the uninstaller is located by requesting the uninstallprogram attribute:

$ prodreg info -m ExampleSoft -a uninstallprogram
uninstallprogram: /usr/bin/java -mx64m -classpath
/var/sadm/prod/org.example.ExampleSoft/987573587 uninstall_ExampleSoft

Check to see if there is an uninstaller in the registered location.

# ls /var/sadm/prod/org.example.ExampleSoft/987573587
/var/sadm/prod/org.example.ExampleSoft/987573587:
No such file or directory

Since there is no uninstaller at the desired location, you have two options. One is to load the uninstaller from backup storage and run it manually. Use the command line stored in the registry:

# /usr/bin/java -mmx64m -classpath \
   /var/sadm/prod/org.example.ExampleSoft/987573587 \
   uninstall_ExampleSoft

If there is no other possibility, manually unregister the software.

# prodreg unregister -u 95842091-725a-8501-ef29-0472985982be -i 1
This does not remove the remaining package EXSOblob. You must do this manually.

# pkgrm EXSOblob

EXAMPLE 11  Removing Multiple Components
Component A has children B and C, and C has children D and E, and the you wish to remove all of the components at once. This is useful if the whole hierarchy has to be reinstalled and the uninstaller has been lost or cannot be run.
EXAMPLE 11  Removing Multiple Components  (Continued)

$ prodreg browse -u UUID-of-C

<table>
<thead>
<tr>
<th>BROWSE #</th>
<th>+/-/.</th>
<th>UUID</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-</td>
<td>root</td>
<td>System Registry</td>
</tr>
<tr>
<td>2</td>
<td>+</td>
<td>a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b</td>
<td>Solaris 10 System Software</td>
</tr>
<tr>
<td>3</td>
<td>+</td>
<td>8f64eabf-1dd2-11b2-a3f1-0800209a5b6b</td>
<td>Unclassified Software</td>
</tr>
</tbody>
</table>

# prodreg uninstall -u UUID-of-A -i 1

The `uninstall` subcommand can fail various ways, for example if the java classes have been removed, if the user has insufficient permissions or if Java software is not present on the system. The recursive unregistration subcommand is very powerful and dangerous. Not only does it unregister every child of a component, it also unregisters every component which depends upon the component to unregister. It is a good idea to view all information about the component to determine if any components will be unintentionally unregistered with UUID-of-A.

$ prodreg info -u UUID-of-A

Title: Example A Software
Version: 5.8.0.2001.11.02
Location: /usr
Vendor: Example Vendor
uninstallprogram: /usr/bin/java -mx64m -classpath /var/sadm/prod/org.example.ExampleA/90820965 uninstall_ExampleA
vendorurl: http://www.example.org
description: Example A Software has many uses
Supported Languages: en

Child Components:
<table>
<thead>
<tr>
<th>Name</th>
<th>UUID</th>
<th>#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example B</td>
<td>UUID-of-B</td>
<td>1</td>
</tr>
<tr>
<td>Example C</td>
<td>UUID-of-C</td>
<td>1</td>
</tr>
</tbody>
</table>

Required Components:
<table>
<thead>
<tr>
<th>Name</th>
<th>UUID</th>
<th>#</th>
</tr>
</thead>
</table>
EXAMPLE 11  Removing Multiple Components  (Continued)

Example B  UUID-of-B  1
Example C  UUID-of-C  1

No software depends on Example A, or else an additional field, Dependent Components would be shown. To further ensure that there are no surprises, one should examine the dependent components and children of UUID-of-B and UUID-of-C, all the components which depend on UUID-of-B, UUID-of-C and their children, and so on.

If you examine the browse tree, you know the entire list of descendents of UUID-of-A. You can also examine the dependent component attributes of all of Example A’s descendents.

$ prodreg info -u UUID-of-B -i 1 -a "Dependent Components"
Dependent Components:
Name  UUID  #
Example A  UUID-of-A  1

$ prodreg info -u UUID-of-C -i 1 -a "Dependent Components"
Dependent Components:
Name  UUID  #
Example A  UUID-of-A  1

$ prodreg info -u UUID-of-D -i 1 -a "Dependent Components"
Dependent Components:
Name  UUID  #
Example C  UUID-of-C  1

$ prodreg info -u UUID-of-E -i 1 -a "Dependent Components"
Dependent Components:
Name  UUID  #
Example C  UUID-of-C  1

A recursive unregistration of Example A only results in unregistering Example A and its descendents, as intended.

# prodreg unregister -r -u UUID-of-A -i 1

EXAMPLE 12  Reinstalling a Damaged Component

In this example, there is a component, Software ZZZ which is depended upon by other software. Software ZZZ has been damaged and you need to reinstall it. The reinstallation is impossible until Software ZZZ is unregistered.
EXAMPLE 12 Reinstalling a Damaged Component  (Continued)

First, you check what depends upon Software ZZZ:

$ prodreg info -m "Software ZZZ" -a "Dependent Components"

Dependent Components:

<table>
<thead>
<tr>
<th>Name</th>
<th>UUID</th>
<th>#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Software Foobar</td>
<td>d9723500-9823-1432-810c-0100e09832ff</td>
<td>1</td>
</tr>
</tbody>
</table>

Normally, you would have to uninstall Software Foobar before unregistering Software ZZZ, since Software Foobar depends on Software ZZZ. You decide that it is impossible or unreasonable to reinstall Software Foobar. Performing a recursive unregister of Software ZZZ is not an option as it would unregister Software Foobar as well. Instead you can do a forced unregister of Software ZZZ. The UUID of Software ZZZ is 90843fb1-9874-3a20-9b88-984b32098432.

# prodreg unregister -f -u 90843fb1-9874-3a20-9b88-984b32098432 -i 1

You can then reinstall Software ZZZ:

# /usr/bin/java -cp /usr/installers/org.example.softwarezzz

Bugs The registry can become out of date because of software being manually removed, or removed using pkg rm(1M) directly. To avoid damaging the registry, use uninstall programs to remove software which was initially installed using an install program.

Environment Variables The following environment variable affects the execution of prodreg:

PKG_INSTALL_ROOT If present, defines the full path name of a directory to use as the system’s PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of / is used.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWwsr2, SUNWwsrv</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>
The prodreg GUI and command line interface view both the Solaris Product Registry and the package database. Both look like components in the registry, but some of these cannot be unregistered or uninstalled. Packages do not have an associated uninstaller, so they cannot be uninstalled using the prodreg uninstall subcommand. Solaris packages cannot be unregistered using the prodreg unregister subcommand. Packages are removed using the pkgrm(1M) command, after which time the packages do not appear in the GUI or CLI prodreg viewer.

It is preferable to remove software using the uninstaller associated with the software installed than to remove individual packages using pkgrm(1M), since the uninstaller software takes care of comprehensive removal of all resources associated with the installed software, including unregistering information in Registry and removing the appropriate packages.

The prodreg uninstall subcommand launches an external program. The command line conventions of these programs have to be used to indicate the alternate root for the product registry. Another possibility is to use the PKG_INSTALL_ROOT environment variable for this purpose as the install program is executed in the same environment as prodreg. Uninstall programs are frequently java classes which require Java to be installed. If Java software has been removed or is missing from a Solaris distribution, it is impossible to run java based uninstallers.

Only the prodreg unregister and uninstall subcommands can only be run with root permissions. This is because they modify the product registry in the case of unregister, and remove packages in the case of uninstall. The other operations merely read the registry and can be run with any user permissions. The prodreg uninstall subcommand might require root permissions as well, as installers can execute commands such as pkgadd(1M) or pkgrm(1M) which require root permissions to run.

Attributes associated with components are documented in various places - primarily in the Application Packaging Developer's Guide. The attributes associated with the Solaris Product Registry itself are described in the following glossary:

- **Dependent Components**: List of components upon which the component depends.
- **Location**: The location relative to which software was installed.
- **pkgs**: List of packages which correspond to the component. These packages are added with pkgadd after the component is registered. They are removed with pkgrm before the component is unregistered.
- **Required Components**: List of components on which the component depends.
- **Source**: Media from which the install was done.

**See Also**

</tr>
</tbody>
</table>

The Registry can contain components which do not correspond to software actually installed on the system. This can be detected several ways. The easiest is to check using the `info` subcommand if a component is damaged. Another way is to determine where software was installed using the `info` subcommand, and verify it is still there.
Name  projadd – administer a new project on the system

Synopsis  projadd [-n] [-f filename] [-p projid [-o]] [-c comment]
          [-U user [,user]...] [-G group [,group]...] [-K name [=value [,value]...]]

Description  projadd adds a new project entry to the /etc/project file. If the files backend is being used
              for the project database, the new project is available for use immediately upon the completion
              of the projadd command.

Options  The following options are supported:

- c comment  Add a project comment. Comments are stored in the project’s
             entry in the /etc/project file. Generally, comments contain a
             short description of the project and are used as the field for the
             project’s full name.

             Specify comment as a text string. comment cannot contain a
             colon (:) or NEWLINE.

- f filename  Specify the project file to modify. If no filename is specified, the
             system project file, /etc/project, is modified.

- G group[.group...]  Specify a group list for the project.

- K name[=value[,value...]  Specify an attribute list for the project. Multiple -K options can
             be specified to set values on multiple keys, such as:

             -K key1=value1 -K "key2=(value2a) , (value2b)"

             Resource control attributes use parentheses to specify values for a
             key. Because many user shells interpret parentheses as special
             characters, it is best to enclose an argument to -K that contains
             parentheses with double quotes, as shown above and in
             EXAMPLES, below. See resource_controls(5) for a
             description of the resource controls you can specify for a
             project.

- n  Syntax check. Check the format of the existing system project
             file and modifications only. The contents of the existing project
             file, such as user names, group names, and resources that are
             specified in the project attributes are not checked.

- o  This option allows the project ID specified by the -p option to
             be non-unique within the project file.

- p projid  Set the project ID of the new project.

             Specify projid as a non-negative decimal integer below UID_MAX
             as defined in limits.h. projid defaults to the next available
unique number above the highest number currently assigned. For example, if \texttt{projids 100, 105,} and \texttt{200} are assigned, the next default \texttt{projid} is \texttt{201}. \texttt{projids} between \texttt{0-99} are reserved by SunOS.

\texttt{-U user[,user...] Specify a user list for the project.}

**Operands**

The following operands are supported:

\texttt{project The name of the project to create. The \textit{project} operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline \texttt{(_)}, and hyphen \texttt{(-)}. The period \texttt{(.)} is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. An error message is displayed if these restrictions are not met.}

**Examples**

**EXAMPLE 1 Adding a Project**

The following command creates the project \texttt{salesaudit} and sets the resource controls specified as arguments to the \texttt{-K} option.

\begin{verbatim}
projadd -p 111 -G sales,finance -c "Auditing Project" \
   -K "rcap.max-rss=10GB" \
   -K "process.max-file-size=(priv,50MB,deny)" \
   -K "task.max-lwps=(priv,100,deny)" salesaudit
\end{verbatim}

This command would produce the following entry in \texttt{/etc/project}:

\begin{verbatim}
salesaudit:111:Auditing Project::sales,finance: \
     process.max-file-size=(priv,52428800,deny); \
     rcap.max-rss=1873418240; task.max-lwps=(priv,100,deny)
\end{verbatim}

Note that the preceding would appear as one line in \texttt{/etc/project}.

Comparing the \texttt{projadd} command and resulting output in \texttt{/etc/project}, note the effect of the scaling factor in the resource cap (\texttt{rcap.max-rss=10GB}) and the resource control (\texttt{process.max-file-size=(priv,50MB,deny)}). Modifiers, such as \texttt{B}, \texttt{KB}, and \texttt{MB}, and scaling factors are specified in \texttt{resource_controllers(5)}.

**Exit Status**

The following exit values are returned:

\begin{center}
\begin{tabular}{ll}
0 & Successful completion. \\
2 & The command syntax was invalid. A usage message for \texttt{projadd} is displayed. \\
3 & An invalid argument was provided to an option. \\
4 & The \texttt{projid} given with the \texttt{-p} option is already in use. \\
5 & The project files contain an error. See \texttt{project(4)}. \\
6 & The project to be added, group, user, or resource does not exist.
\end{tabular}
\end{center}
9 The project is already in use.
10 Cannot update the /etc/project file.

Files /etc/project System project file

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
<tr>

</table>

Invocation is evolving. Human readable output is unstable.

See Also projects(1), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), projdel(1M), projmod(1M), useradd(1M), userdel(1M), usermod(1M), project(4), attributes(5), resource_controls(5)

Notes In case of an error, projadd prints an error message and exits with a non-zero status.

projadd adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, projadd cannot change information supplied by the network name service.
Name  projdel – delete a project from the system

Synopsis  projdel [-f filename] project

Description  The projdel utility deletes a project from the system and makes the appropriate changes to the system file.

Options  The following options are supported:

  -f filename   Specify the project file to modify. If no filename is specified, the system project file, /etc/project, is modified.

Operands  The following operands are supported:

  project     The name of the project to be deleted.

Exit Status  The following exit values are returned:

  0   Successful completion.
  2   The command syntax was invalid. A usage message for projdel is displayed.
  3   An invalid argument was provided to an option.
  4   The projid given with the -p option is already in use.
  5   The project files contain an error. See project(4).
  6   The project to be modified, group, user, or resource does not exist.
  9   The project is already in use.
 10   Cannot update the /etc/project file.

Files  /etc/project  System project file

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
<tr>
<td>Interface stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Invocation is evolving. Human readable output is unstable.

In case of an error, `projdel` prints an error message and exits with a non-zero status.

**Notes**  
`projdel` deletes a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local `/etc/project` file with additional entries, `projdel` cannot change information supplied by the network name service.
**Name**
projmod – modify a project's information on the system

**Synopsis**
projmod [-n] [-A| -f filename | -] 
projmod [-n] [-A| -f filename | -] [-p projid [ -o] 
[ -c comment ] [-a | -s | -r] [-U user [,user] ... ] 
[ -G group [,group] ... ] 
[ [-K name [=value [,value]...]]... ] 
[ -l new_projectname] project

**Description**
The `projmod` utility modifies a project's definition on the system. `projmod` changes the definition of the specified project and makes the appropriate project-related system file and file system changes.

**Options**
The following options are supported:

- **-A**
  Apply the project's resource controls, as defined in the system's project database, to the project if it is active.

- **-a**
  Specify that the users, groups, attributes, or attribute values specified by the `-U`, `-G` or `-K` options should be added to the project, rather than replacing the existing member or attribute list.

- **-c comment**
  Specify `comment` as a text string. Generally, `comment` contains a short description of the project. This information is stored in the project's `/etc/project` entry.

- **-f filename**
  Specify the project file to modify. If no `filename` is specified, the system project file, `/etc/project`, is modified.

- **-G group [,group...]**
  Specify a replacement list of member groups of the project. When used in conjunction with the `-a` or `-r` options, this option specifies a list of groups to be added or removed from the project.

- **-K name[=value [,value]...]**
  Specify a replacement list of project attributes for the project. When used in conjunction with the `-a`, `-r`, or `-s` options, this option specifies a list of attribute values to be added, removed, or replaced in the project. Attributes must be delimited by semicolons (;). Multiple `-K` options can be specified to set, add, remove, or substitute values on multiple keys, such as:

  `-K key1=value1 -K *key2=(value2a), (value2b)*`

  Resource control attributes use parentheses to specify values for a key. Because many user shells interpret parentheses as special characters, it is best to enclose an argument to `-K` that
contains parentheses with double quotes, as shown above and in EXAMPLES, below. See
resource_controls(5) for a description of the resource controls you can specify for a
project.

-l new_projectname
Specify the new project name for the project. The new_projectname argument is a string
consisting of characters from the set of alphabetic characters, numeric characters, period
(,), underline (_), and hyphen (-). The first character should be alphabetic. An error
message is written if these restrictions are not met. The project name must also be unique
within the project file.

-n
Syntax check. Check the format of the existing system project file and modifications only.
The contents of the existing project file, such as user names, group names, and resources
that are specified in the project attributes are not checked.

-o
This option allows the project ID specified by the -p option to be non-unique within the
project file.

-p projid
Specify a new project ID for the project. It must be a non-negative decimal integer less than
MAXUID as defined in param.h. This value must be unique within the project file if the -o
option is not specified.

-r
Specify that the users, groups, attributes, or attribute values specified by the -U, -G or -K
options should be removed from the project, rather than replacing the existing member or
attribute list.

-s
Specify that the list of attributes specified by the -K option should have their values
replaced. If the attributes do not exist, they are added as if the a option was used. This
option has no effect the -U or -G options.

-U user [,user...]
Specify a replacement list of member users of the project. When used in conjunction with
the -a or -r options, this option specifies a list of users to be added or removed from the
project.

Operands
The following operands are supported:

project
An existing project name to be modified or displayed.

(none)
If no operand is given, the project file is validated without
modifying any project.
**Examples**

**Example 1** Using the -K Option for Addition of an Attribute Value

Consider the following `project(4)` entry:

```
salesaudit:111:Auditing Project::sales,finance: \
    process.max-file-size=(priv,52428800,deny); \
    task.max-lwps=(priv,100,deny)
```

The preceding would appear as one line in `/etc/project`. For this and the following examples, the focus is on the attributes field in the `project` entry. That is, the last field, the field following the last semicolon.

The attributes field for the project `salesaudit` lists the following resource control:

```
task.max-lwps=(priv,100,deny)
```

The following `projmod` command adds an action clause to the preceding entry:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

**Example 2** Using the -K Option for the Substitution of an Attribute Value

Assume an attributes field in a `project(4)` entry for the project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command substitutes the action clause specified in the command for the action clauses in the preceding entry:

```
# projmod -s -K "task.max-lwps=(priv,500,signal=SIGSTOP)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,500,signal=SIGSTOP)
```

**Example 3** Using the -K Option for Removal of an Attribute Value

Assume an attributes field in a `project(4)` entry for a project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command removes the first action clause from the preceding entry:

```
# projmod -r -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:
EXAMPLE 3  Using the -K Option for Removal of an Attribute Value  (Continued)

```
task.max-lwps=(priv,1000,signal=KILL)
```

EXAMPLE 4  Specifying Multiple Attribute Values

Suppose you want to achieve the following resource controls for the project salesaudit:

```
task.max-lwps=(priv,100,deny)
process.max-file-size=(priv,50MB,deny)
```

The following projmod command adds these resource controls for salesaudit:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" \ 
-K "process.max-file-size=(priv,50MB,deny)" salesaudit
```

...with the resulting attributes field in the entry for salesaudit:

```
task.max-lwps=(priv,100,deny);process.max-file-size=(priv,52428800,deny)
```

In this example, note the effect of the use of the modifier and scaling factor for the resource control process.max-file-size. The specification in projmod:

```
"process.max-file-size=(priv,50MB,deny)"
```

...becomes, in /etc/project:

```
process.max-file-size=(priv,52428800,deny)
```

That is, 50MB is expanded to 52428800. The modifiers, such as MB, and scaling factors you can use for resource controls are specified in resource_controls(5).

EXAMPLE 5  Binding a Pool to a Project

The following command sets the project.pool attribute for the project sales.

```
# projmod -a -K project.pool=salespool sales
```

Exit Status  In case of an error, projmod prints an error message and exits with one of the following values:

The following exit values are returned:

0  Successful completion.
2  The command syntax was invalid. A usage message for projmod is displayed.
3  An invalid argument was provided to an option.
4  The projid given with the -p option is already in use.
5  The project files contain an error. See project(4).
6  The project to be modified, group, user, or resource does not exist.
The project is already in use.

Cannot update the /etc/project file.

Files
- /etc/group: System file containing group definitions
- /etc/project: System project file
- /etc/passwd: System password file
- /etc/shadow: System file containing users' encrypted passwords and related information

Invocation is committed. Human readable output is uncommitted.

See Also
- groupadd(1M), groupdel(1M), groupmod(1M), projadd(1M), projdel(1M), useradd(1M), userdel(1M), usermod(1M), passwd(4), project(4), attributes(5), resource_controls(5)

Notes
The `projmod` utility modifies project definitions only in the local /etc/project file. If a network name service such as NIS or LDAP is being used to supplement the local files with additional entries, `projmod` cannot change information supplied by the network name service. However `projmod` verifies the uniqueness of project name and project ID against the external name service.
**Name**
`prstat` – report active process statistics

**Synopsis**
```
```

**Description**
The `prstat` utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. `prstat` provides options to examine only processes matching specified PIDs, UIDs, zone IDs, CPU IDs, and processor set IDs.

The `-j`, `-k`, `-C`, `-p`, `-P`, `-u`, `-U`, and `-z` options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

If you do not specify an option, `prstat` examines all processes and reports statistics sorted by CPU usage.

**Options**
The following options are supported:

- `-a`
  Report information about processes and users. In this mode `prstat` displays separate reports about processes and users at the same time.

- `-c`
  Print new reports below previous reports instead of overprinting them.

- `-C psrsetlist`
  Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by `psrset(1M)`. The load averages displayed are the sum of the load averages of the specified processor sets (see `pset_getloadavg(3C)`). Processes with one or more LWPs bound to processor sets in the given list are reported even when the `-L` option is not used.

- `-h lgrplist`
  Report only processes or lwps whose home lgroup is in the given list of lgroups. No processes or lwps will be listed for invalid lgroups.

- `-H`
  Report information about home lgroup. In this mode, `prstat` adds an extra column showing process or lwps home lgroup with the header LGRP.

- `-j projlist`
  Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See `project(4)`.

- `-J`
  Report information about processes and projects. In this mode `prstat` displays separate reports about processes and projects at the same time.
-k tasklist
  Report only processes or lwps whose task ID is in tasklist.

-L
  Report statistics for each light-weight process (LWP). By default, prstat reports only the number of LWPs for each process.

-m
  Report microstate process accounting information. In addition to all fields listed in -v mode, this mode also includes the percentage of time the process has spent processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).

-n ntop,[nbottom]
  Restrict number of output lines. The ntop argument determines how many lines of process or lwp statistics are reported, and the nbottom argument determines how many lines of user, task, or projects statistics are reported if the -a, -t, -T, -J, or -Z options are specified. By default, prstat displays as many lines of output that fit in a window or terminal. When you specify the -c option or direct the output to a file, the default values for ntop and nbottom are 15 and 5.

-p pidlist
  Report only processes whose process ID is in the given list.

-P cpulist
  Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by psrinfo(1M).

-R
  Put prstat in the real time scheduling class. When this option is used, prstat is given priority over time-sharing and interactive processes. This option is available only for superuser.

-s key
  Sort output lines (that is, processes, lwps, or users) by key in descending order. Only one key can be used as an argument.

There are five possible key values:

  cpu
    Sort by process CPU usage. This is the default.

  pri
    Sort by process priority.

  rss
    Sort by resident set size.

  size
    Sort by size of process image.
time
Sort by process execution time.

-S key
Sort output lines by key in ascending order. Possible key values are the same as for the -s option. See -s.

-t
Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images, total resident set size, total cpu time, and percentages of recent cpu time and system memory.

-T
Report information about processes and tasks. In this mode prstat displays separate reports about processes and tasks at the same time.

-u euidlist
Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-U uiddlist
Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-v
Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received. Statistics that are not reported are marked with the - sign.

-z zoneidlist
Report only processes or LWPs whose zone ID is in the given list. Each zone ID can be specified as either a zone name or a numerical zone ID. See zones(5).

-Z
Report information about processes and zones. In this mode, prstat displays separate reports about processes and zones at the same time.

Output The following list defines the column headings and the meanings of a prstat report:

PID
The process ID of the process.

USERNAME
The real user (login) name or real user ID.

SWAP
The sum of swap reservations of the associated processes for each user, project, task, or zone. This counts shared memory only once for each user, project, task, or zone. Swap is
reserved when anonymous memory is allocated or files are mapped private. The value of
swap is expressed in kilobytes (K), megabytes (M), or gigabytes (G).

RSS
The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G).
The RSS value is an estimate provided by proc(4) that might underestimate the actual
resident set size. Users who want to get more accurate usage information for capacity
planning should use the -x option to pmap(1) instead.

STATE
The state of the process:

   cpuN
       Process is running on CPU N.

   sleep
       Sleeping: process is waiting for an event to complete.

   wait
       Waiting: process is waiting for CPU usage to drop to the CPU-caps enforced limits. See
       the description of CPU-caps in resource_controls(5).

   run
       Runnable: process in on run queue.

   zombie
       Zombie state: process terminated and parent not waiting.

   stop
       Process is stopped.

PRI
The priority of the process. Larger numbers mean higher priority.

NICE
Nice value used in priority computation. Only processes in certain scheduling classes have
a nice value.

TIME
The cumulative execution time for the process.

CPU
The percentage of recent CPU time used by the process. If executing in a non-global zone
and the pools facility is active, the percentage will be that of the processors in the processor
set in use by the pool to which the zone is bound.

PROCESS
The name of the process (name of executed file).

LWPID
The lwp ID of the lwp being reported.
NLWP
   The number of lwp in the process.

With the some options, in addition to a number of the column headings shown above, there are:

NPROC
   Number of processes in a specified collection.

MEMORY
   Percentage of memory used by a specified collection of processes.

The following columns are displayed when the -v or -m option is specified

USR
   The percentage of time the process has spent in user mode.

SYS
   The percentage of time the process has spent in system mode.

TRP
   The percentage of time the process has spent in processing system traps.

TFL
   The percentage of time the process has spent processing text page faults.

DFL
   The percentage of time the process has spent processing data page faults.

LCK
   The percentage of time the process has spent waiting for user locks.

SLP
   The percentage of time the process has spent sleeping.

LAT
   The percentage of time the process has spent waiting for CPU.

VCX
   The number of voluntary context switches.

ICX
   The number of involuntary context switches.

SCL
   The number of system calls.

SIG
   The number of signals received.

Under the -L option, one line is printed for each lwp in the process and some reporting fields show the values for the lwp, not the process.
The following column is displayed when the -H option is specified:

**LGRP**  
The home *group* of the process or lwp.

**Operands**  
The following operands are supported:

- **count**  
  Specifies the number of times that the statistics are repeated. By default, `prstat` reports statistics until a termination signal is received.

- **interval**  
  Specifies the sampling interval in seconds; the default interval is 5 seconds.

**Examples**  
**EXAMPLE 1**  
Reporting the Five Most Active Super-User Processes

The following command reports the five most active super-user processes running on CPU1 and CPU2:

```
example% prstat -u root -n 5 -P 1,2 1 1
```

<table>

</tr>
</tbody>
</table>

**TOTAL:** 71, load averages: 0.02, 0.04, 0.08

**Exit Status**  
The following exit values are returned:

- **0**  
  Successful completion.

- **1**  
  An error occurred.
Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also proc(1), ps(1), psinfo(1M), psrset(1M), sar(1M), pset_getloadavg(3C), proc(4), project(4), attributes(5), resource_controls(5), zones(5)

Notes The snapshot of system usage displayed by prstat is true only for a split-second, and it may not be accurate by the time it is displayed. When the -m option is specified, prstat tries to turn on microstate accounting for each process; the original state is restored when prstat exits. See proc(4) for additional information about the microstate accounting facility.

The total memory size reported in the SWAP and RSS columns for groups of processes can sometimes overestimate the actual amount of memory used by processes with shared memory segments.
**Name**  
prtconf – print system configuration

**Synopsis**  
```
/usr/sbin/prtconf [-V] | [-F] | [-x] | [-bpv]  
| [-acDPv] [dev_path]
```

**Description**  
The **prtconf** command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.

If a device path is specified on the command line for those command options that can take a device path, **prtconf** will only display information for that device node.

**Options**  
The following options are supported:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-a</code></td>
<td>Display all the ancestors device nodes, up to the root node of the device tree, for the device specified on the command line.</td>
</tr>
<tr>
<td><code>-b</code></td>
<td>Display the firmware device tree root properties for the purpose of platform identification. These properties are “name”, “compatible”, “banner-name” and “model”.</td>
</tr>
<tr>
<td><code>-c</code></td>
<td>Display the device subtree rooted at the device node specified on the command line, that is, display all the children of the device node specified on the command line.</td>
</tr>
<tr>
<td><code>-d</code></td>
<td>For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral.</td>
</tr>
<tr>
<td><code>-F</code></td>
<td>A SPARC-only option. Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, <strong>prtconf</strong> returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SUNW, Ultra-30 is ffb, the command returns: <code>/SUNW, ffb@1e, 0: ffb0</code>. This option could be used to create a symlink for <code>/dev/fb</code> to the actual console device.</td>
</tr>
<tr>
<td><code>-p</code></td>
<td>Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on x86 platforms. The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later.</td>
</tr>
<tr>
<td><code>-P</code></td>
<td>Includes information about pseudo devices. By default, information regarding pseudo devices is omitted.</td>
</tr>
<tr>
<td><code>-V</code></td>
<td>Specifies verbose mode.</td>
</tr>
<tr>
<td></td>
<td>Displays platform-dependent PROM (on SPARC platforms) or booting system (on x86 platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent.</td>
</tr>
</tbody>
</table>
-x  Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel.

This flag overrides all other flags and must be used by itself.

**Operands**  The following operands are supported:

*dev_path*  The path to a target device minor node, device nexus node, or device link for which device node configuration information is displayed

**Exit Status**  The following exit values are returned:

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No error occurred.</td>
</tr>
<tr>
<td>non-zero</td>
<td>With the -F option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the -x option, a non-zero return value means that the firmware is not 64–bit ready. In all other cases, a non-zero return value means that an error occurred.</td>
</tr>
</tbody>
</table>

Sun Hardware Platform Guide

SPARC Only  openprom(7D)

**Notes**  The output of the prtconf command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The *driver not attached* message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.
On x86 platforms, the use of `prtconf -vp` provides a subset of information from `prtconf -v`.

The value of integer properties from `prtconf -vp` might require byte swapping for correct interpretation.
**Synopsis**

/prtdiag [-v] [-l]

**Description**

`/usr/sbin/prtdiag` displays system configuration and diagnostic information on Sun4u and Sun4v systems.

The diagnostic information lists any failed field replaceable units (FRUs) in the system.

The interface, output, and location in the directory hierarchy for /usr/sbin/prtdiag are uncommitted and subject to change in future releases.

`/usr/sbin/prtdiag` does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the `/var/opt/SUNWssp/adm/${SUNW_HOSTNAME}/messages` file on the system service processor (SSP) to obtain such information for this server.

**Options**

The following options are supported:

- `-l` - Log output. If failures or errors exist in the system, output this information to `/var/log/syslogd(1M)` only.
- `-v` - Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.

**Exit Status**

The following exit values are returned:

- 0 - No failures or errors are detected in the system.
- 1 - Failures or errors are detected in the system.
- 2 - An internal /usr/sbin/prtdiag error occurred, for example, out of memory.

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWkvm</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Unstable*</td>
</tr>
</tbody>
</table>

*The output is unstable.

**See Also**

`modinfo(1M), prtconf(1M), prsrinfo(1M), sysdef(1M), syslogd(1M), attributes(5), openprom(7D)`
Not all diagnostic and system information is available on every Solaris platform, and therefore cannot be displayed by `prtdiag`. On those platforms, further information can be obtained from the System Controller.
Name  prtdscp  – display DSCP IP addresses

Synopsis  prtdscp [-v ]
          prtdscp [-v ] -h
          prtdscp [-v ] -d
          prtdscp [-v ] -s

Description  prtdscp displays the IP addresses associated with a Domain to Service Processor Communications Protocol (DSCP) link. If no arguments are specified, prtdscp displays the IP addresses on both ends of the DSCP link. The IP address of either the Service Processor or domain side can be displayed separately by the use of the -s or -d options, respectively.

Options  The following options are supported:
          -v  Verbose mode. Print additional details about the program's internal progress to stderr.
          -h  Help. Print a brief synopsis of the program's usage and exit. All other command line arguments are ignored.
          -d  Display only the local domain's IP address.
          -s  Display only the remote Service Processor's IP address.

Examples  EXAMPLE 1  Displaying both addresses
          The following example displays both the local domain's IP address and the remote SP's IP address:
          
          # prtdscp
          Domain Address: 192.168.103.2
          SP Address: 192.168.103.1

          EXAMPLE 2  Displaying the local IP address
          The following example displays the local domain's IP address:
          
          # prtdscp -d
          192.168.103.2

          EXAMPLE 3  Displaying the remote IP address
          The following example display the remote SP's IP address:
          
          # prtdscp -s
          192.168.103.1

Name  prtfru – print FRUID-specific information about the FRUs on a system or domain

Synopsis  /usr/sbin/prtfru [-d] | [-clx] [container]

Description  The prtfru utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well.

prtfru without any arguments will print the FRU hierarchy and all of the FRUID container data. prtfru prints to stdout which may be redirected to a file.

Options  The following options are supported:

- c    Prints only the containers and their data. This option does not print the FRU tree hierarchy.
- d    Prints a DTD for the current registry to stdout.
- l    Prints only the FRU tree hierarchy. This option does not print the container data.
- x    Prints in XML format with a system identifier (SYSTEM) of prtfrureg.dtd.

Options -c and -l can be used together to obtain a list of the containers.

Operands  The following operand is supported:

container    The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the -l option.

Exit Status  The following exit values are returned:

0       All information was found and printed successfully.
>0      An error has occurred.

prtpicl (1M)

Name prtpicl – print PICL tree

Synopsis /usr/sbin/prtpicl [-c picl_class] [-v]

Description The prtpicl command prints the PICL tree maintained by the PICL daemon. The output of prtpicl includes the name and PICL class of the nodes.

Options The following options are supported:
- `c picl_class` Print only the nodes of the named PICL class.
- `v` Print in verbose mode. In verbose mode, prtpicl prints a list of properties and values for each node. Verbose mode is disabled by default.

Exit Status The following exit values are returned:
- 0 Successful completion.
- non-zero An error occurred.

prtvtoc – report information about a disk geometry and partitioning

Synopsis

```
prtvtoc [-fhs] [-t vfstab] [-m mnttab] device
```

Description

The `prtvtoc` command allows the contents of the label to be viewed. The command can be used only by the super-user.

The `device` name can be the file name of a raw device in the form of `/dev/rdsk/c?t?d?s2` or can be the file name of a block device in the form of `/dev/dsk/c?t?d?s2`.

Options

The following options are supported:

- `-f`
  Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions.

- `-h`
  Omit the headers from the normal output.

- `-m mnttab`
  Use `mnttab` as the list of mounted filesystems, in place of `/etc/mnttab`.

- `-s`
  Omit all headers but the column header from the normal output.

- `-t vfstab`
  Use `vfstab` as the list of filesystem defaults, in place of `/etc/vfstab`.

Examples

**EXAMPLE 1** Using the `prtvtoc` Command

The following example uses the `prtvtoc` command on a 424-megabyte hard disk:

```
example# prtvtoc /dev/rdsk/c0t3d0s2
* /dev/rdsk/c0t3d0s2 partition map
*
* Dimension:
*   512 bytes/sector
*   80 sectors/track
*   9 tracks/cylinder
*   720 sectors/cylinder

<table>
<thead>
<tr>
<th>Name</th>
<th>psradm – change processor operational status</th>
</tr>
</thead>
</table>
| Synopsis     | psradm -f | -i | -n | -s [-v] [-F] processor_id  
|              | psradm -a -f | -i | -n | -s [-v] [-F] |
| Description  | The psradm utility changes the operational status of processors. The legal states for the processor are on-line, off-line, spare, faulted, and no-intr. |

An on-line processor processes LWPs (lightweight processes) and can be interrupted by I/O devices in the system.

An off-line processor does not process any LWPs. Usually, an off-line processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it might not be possible to disable interrupts for an off-line processor. Thus, the actual effect of being off-line might vary from machine to machine.

A spare processor does not process any LWPs. A spare processor can be brought on-line, off-line or to no-intr by a privileged user of the system or by the kernel in response to changes in the system state.

A faulted processor is identified by the kernel, which monitors the behavior of processors over time. A privileged user can set the state of a faulted processor to be on-line, off-line, spare or no-intr, but must use the force option to do so.

A no-intr processor processes LWPs but is not interruptible by I/O devices.

A processor can not be taken off-line or made spare if there are LWPs that are bound to the processor unless the additional -F option is used. The -F option removes processor bindings of such LWPs before changing the processor’s operational status. On some architectures, it might not be possible to take certain processors off-line or spare if, for example, the system depends on some resource provided by the processor.

At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an off-line or spare processor can be interruptible, it is possible to have an operational system with one processor no-intr and all other processors off-line or spare but with one or more accepting interrupts.

If any of the specified processors are powered off, psradm might power on one or more processors.

Only users with the PRIV_SYS_RES_CONFIG privilege can use the psradm utility.

<table>
<thead>
<tr>
<th>Options</th>
<th>The following options are supported:</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a</td>
<td>Perform the action on all processors, or as many as possible.</td>
</tr>
<tr>
<td>-f</td>
<td>Take the specified processors off-line.</td>
</tr>
</tbody>
</table>
-F  Force the transition to the additional specified state. Required if one or more of the specified processors was in the faulted state. Set the specified processors to faulted, if no other transition option was specified. Forced transitions can only be made to faulted, spare, or off-line states. Administrators are encouraged to use the -Q option for pbind(1M) to find out which threads will be affected by forced a processor state transition.

-i  Set the specified processors no-intr.
-n  Bring the specified processors on-line.
-s  Make the specified processors spare.
-v  Output a message giving the results of each attempted operation.

Operands

The following operands are supported:

processor_id  The processor ID of the processor to be on-line or off-line, spare, or no-intr.

Specify processor_id as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) processor_ids (for example, 1-3 5 7-8 9).

Examples

EXAMPLE 1  Setting Processors to off-line

The following example sets processors 2 and 3 off-line:

% psradm -f 2 3

EXAMPLE 2  Setting Processors to no-intr

The following example sets processors 1 and 2 no-intr:

% psradm -i 1 2

EXAMPLE 3  Setting Processors to spare

The following example sets processors 1 and 2 spare, even if either of the processors was in the faulted state:

% psradm -F -s 1 2

EXAMPLE 4  Setting All Processors on-line

% psradm -a -n
EXAMPLE 5  Forcing Processors to offline

The following example sets processors 1 and 2 offline, and revokes the processor bindings from the processes bound to them:

% psradm -F -f 1 2

Exit Status  The following exit values are returned:

0       Successful completion.

>0      An error occurred.

Files   /etc/wtmpx  Records logging processor status changes

See Also  pbind(1M), psrinfo(1M), psrset(1M), p_online(2), processor_bind(2), attributes(5)

Diagnostics  psradm: processor 4: Invalid argument
               The specified processor does not exist in the configuration.

psradm: processor 3: Device busy
               The specified processor could not be taken offline because it either has LWPs bound to it, is the last online processor in the system, or is needed by the system because it provides some essential service.

psradm: processor 3: Device busy
               The specified processor could not be set no-intr because it is the last interruptible processor in the system, or it is the only processor in the system that can service interrupts needed by the system.

psradm: processor 3: Device busy
               The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

psradm: processor 0: Not owner
               The user does not have permission to change processor status.

psradm: processor 2: Operation not supported
               The specified processor is powered off, and the platform does not support power on of individual processors.
Name  psrinfo – displays information about processors

Synopsis  psrinfo [-p] [-v] [processor_id]...
          psrinfo [-p] -s processor_id

Description  psrinfo displays information about processors. Each physical processor may support multiple virtual processors. Each virtual processor is an entity with its own interrupt ID, capable of executing independent threads.

Without the processor_id operand, psrinfo displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by no-intr), spare, off-line, faulted or powered off, and when that status last changed. Use the processor_id operand to display information about a specific processor. See OPERANDS.

Options  The following options are supported:

- s processor_id  Silent mode. Displays 1 if the specified processor is fully on-line. Displays 0 if the specified processor is non-interruptible, spare, off-line, faulted or powered off.

    Use silent mode when using psrinfo in shell scripts.

- p  Display the number of physical processors in a system.

    When combined with the - v option, reports additional information about each physical processor.

- v  Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown.

    When combined with the - p option, reports additional information about each physical processor.

Operands  The following operands are supported:

processor_id  The processor ID of the processor about which information is to be displayed.

    Specify processor_id as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) processor_ids (for example, 1-3 5 7-8 9).
Examples

**EXAMPLE 1**  Displaying Information About All Configured Processors in Verbose Mode

The following example displays information about all configured processors in verbose mode.

```
psrinfo -v
```

**EXAMPLE 2**  Determining If a Processor is On-line

The following example uses `psrinfo` in a shell script to determine if a processor is on-line.

```
if [ ""psrinfo -s 3 2> /dev/null"" =eq 1 ]
then
  echo "processor 3 is up"
fi
```

**EXAMPLE 3**  Displaying Information About the Physical Processors in the System

With no additional arguments, the `-p` option displays a single integer: the number of physical processors in the system:

```
> psrinfo -p
8
```

`psrinfo` also accepts command line arguments (processor IDs):

```
> psrinfo -p 0 512  # IDs 0 and 512 exist on the same physical processor
1
> psrinfo -p 0 1    # IDs 0 and 1 exist on different physical processors
2
```

In this example, virtual processors 0 and 512 exist on the same physical processor. Virtual processors 0 and 1 do not. This is specific to this example and is not a general rule.

**Exit Status**  The following exit values are returned:

- 0   Successful completion.
- >0   An error occurred.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

**Diagnostics**  
- `psrinfo: processor 9: Invalid argument`  The specified processor does not exist.
psrset – creation and management of processor sets

Synopsis

psrset -a [-F] processor_set_id processor_id...
psrset -b processor_set_id pid [/lwpid]...
psrset -c [-F] [processor_id]...
psrset -d processor_set_id...
psrset -e processor_set_id command [argument(s)]
psrset -f processor_set_id
psrset [-i] [processor_set_id]...
psrset -n processor_set_id
psrset -p [processor_id]...
psrset [-q] [pid] [/lwpid]...
psrset -o [processor_set_id]...
psrset -r [-F] processor_id...
psrset -u pid [/lwpid]...
psrset -U [processor_set_id]...

Description

The psrset utility controls the management of processor sets. Processor sets allow the binding of processes or LWP s to groups of processors, rather than just a single processor. Processes assigned to processor sets can run only LWP s that have been bound to that processor set.

This command cannot be used to modify processor disposition when pools are enabled. Use pooladm(1M) and poolcfg(1M) to modify processor set configuration through the resource pools facility.

Options

The following options are supported:

- **-a**
  Assign the specified processors to the specified processor set. With the additional -F option, all LWP s bound to the specified processors will be unbound prior to changing processor sets.

  This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

- **-b**
  Bind all or a subset of the LWP s of the specified processes to the specified processor set.

  LWP s bound to a processor set are restricted to run only on the processors in that set. Processes can only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.
Bindigns are inherited, so new LWPs and processes created by a bound LWP have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-c Create a new processor set and displays the new processor set ID. With the additional -F option, all LWPs bound to the specified processors will be unbound prior to assigning them to the processor set being created.

If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors are idle until LWPs are bound to the processor set. This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

Only a limited number of processor sets can be active (created and not destroyed) at a given time. This limit is always be greater than the number of processors in the system. If the -c option is used when the maximum number of processor sets is already active, the command fails.

The following format is used for the first line of output of the -c option when the LC_MESSAGES locale category specifies the “C” locale. In other locales, the strings created, processor, and set can be replaced with more appropriate strings corresponding to the locale.

"created processor set %d\n" processor set ID

-d Remove the specified processor set, releasing all processors and processes associated with it.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-e Execute a command (with optional arguments) in the specified processor set.

The command process and any child processes are executed only by processors in the processor set.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-f Disables interrupts for all processors within the specified processor set. See psradm(1M).

If some processors in the set cannot have their interrupts disabled, the other processors still have their interrupts disabled, and the command reports an error and return non-zero exit status.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.
Forces the specified processor set operation by unbinding all threads bound to the specified processor. Only the -a or the -r option can be used in combination with this option. Administrators are encouraged to use the -o option for `pbind(1M)` to find out which threads will be affected by such operation.

Display a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the `psrset` command is not given an option.

Enable interrupts for all processors within the specified processor set. See `psradm(1M)`.

Display the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.

Display the processor set bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs is displayed. The bindings of a subset of LWPs can be displayed by appending "/lwpids" to the process IDs. Multiple LWPs may be selected using "," and "," delimiters. See EXAMPLES.

Display the LWPs bound to the specified list of processor sets, or all LWPs with processor set bindings.

Remove a list of processors from their current processor sets. Processors that are removed return to the general pool of processors.

Processors with LWPs bound to them using `pbind(1M)` can be assigned to or removed from processor sets using the -F option.

Remove the processor set bindings of a subset or all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through `pbind`.

Users with the PRIV_SYS_RES_CONFIG privilege can unbind any process or LWP from any active processor set. Other users can unbind processes and LWPs from processor sets that do not have the PSET_NOESCAPE attribute set. In addition, the user must have permission to control the affected processes; the real or effective user ID of the user must match the real or saved user ID of the target processes.

Removes the bindings of all LWPs bound to the specified list of processor sets, or to any processor set if no argument is specified.
Operands  The following operands are supported:

**pid**  Specify **pid** as a process ID.

**lwpid**  The set of LWPIDs of the specified process to be controlled or queried. The syntax for selecting LWP IDs is as follows:
- **2,3,4-8**  LWP IDs 2, 3, and 4 through 8
- **-4**  LWPs whose IDs are 4 or below
- **4-**  LWPs whose IDs are 4 or above

**processor_id**  Specify **processor_id** as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) **processor_ids** (for example, 1-3 5 7-8 9).

**processor_set_id**  Specify **processor_set_id** as a processor set ID.

Exit Status  The following exit values are returned:

- **0**  Successful completion.
- **non-0**  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE_TYPE</th>
<th>ATTRIBUTE_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcstu</td>
</tr>
<tr>
<td>Stability Level</td>
<td>Stable</td>
</tr>
</tbody>
</table>

See Also  bbind(1M), pooladm(1M), poolcfg(1M), psradm(1M), psrinfo(1M), processor_bind(2), processor_info(2), pset_bind(2), pset_create(2), pset_info(2), sysconf(3C), libpool(3LIB), attributes(5), privileges(5)

Diagnostics  The following output indicates that the specified process did not exist or has exited:

```
psrset: cannot query pid 31: No such process
```

The following output indicates that the user does not have permission to bind the process:

```
psrset: cannot bind pid 31: Not owner
```

The following output indicates that the user does not have permission to assign the processor:

```
psrset: cannot assign processor 4: Not owner
```

The following output indicates that the specified processor is not on-line, or the specified processor does not exist.

```
psrset: cannot assign processor 8: Invalid argument
```
The following output indicates that an LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor:

```
psrset: cannot bind pid 67: Device busy
```

The following output indicates that the specified processor could not be added to the processor set. This can be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set:

```
psrset: cannot assign processor 7: Device busy
```

The following output indicates that the specified processor set does not exist:

```
psrset: cannot execute in processor set 8: Invalid argument
```

The following output indicates that the maximum number of processor sets allowed in the system is already active:

```
psrset: cannot create processor set: Not enough space
```

The following output indicates that the pools facility is active.

```
psrset: cannot assign processor 7: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: could not create processor set: Operation not supported
psrset: could not remove processor set 1: Operation not supported
psrset: cannot exec in processor set 1: Operation not supported
psrset: cannot remove processor 7: Operation not supported
psrset: cannot unbind pid 31: Operation not supported
```
**Synopsis**

```bash
putdev -a alias [attribute=value [ ... ]]
putdev -m device attribute=value [attribute = value [ ... ]]
putdev -d device [attribute [ ... ]]
```

**Description**

`putdev` adds a new device to the device table, modifies an existing device description or removes a device entry from the table. The first synopsis is used to add a device. The second synopsis is used to modify existing entries by adding or changing attributes. If a specified attribute is not defined, this option adds that attribute to the device definition. If a specified attribute is already defined, it modifies the attribute definition. The third synopsis is used to delete either an entire device entry or, if the attribute argument is used, to delete an attribute assignment for a device.

**Options**

The following options are supported:

- `-a`  
  Add a device to the device table using the specified attributes. The device must be referenced by its alias.

- `-d`  
  Remove a device from the device table, when executed without the `attributes` argument. Used with the `attribute` argument, it deletes the given attribute specification for `device` from the table.

- `-m`  
  Modify a device entry in the device table. If an entry already exists, it adds any specified attributes that are not defined. It also modifies any attributes which already have a value with the value specified by this command.

**Operands**

The following operands are supported:

- `alias`  
  Designates the alias of the device to be added.

- `attribute`  
  Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under `DEVICE ATTRIBUTES` except `alias`. This prevents an accidental modification or deletion of a device's alias from the table.

- `device`  
  Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.

- `value`  
  Designates the value to be assigned to a device's attribute.

**Device Attributes**

The following list shows the standard device attributes, used by applications such as `ufsdump(1M)` and `ufrestore(1M)`, which can be defined for a device. You are not limited to this list, you can define any attribute you like.

- `alias`  
  The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore (_), dollar sign ($), hyphen (−), and period ( ).
bdevice  The pathname to the block special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the cdevice field, if any. (It is the administrator’s responsibility to ensure that these major/minor numbers are unique in the database.)

capacity  The capacity of the device or of the typical volume, if removable.

cdevice  The pathname to the character special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the bdevice field, if any. (It is the administrator’s responsibility to ensure that these major/minor numbers are unique in the database.)

cyl  Used by the command specified in the mkfscmd attribute.

desc  A description of any instance of a volume associated with this device (such as floppy diskette).

dpartlist  The list of disk partitions associated with this device. Used only if type=disk. The list should contain device aliases, each of which must have type=dpart.

dparttype  The type of disk partition represented by this device. Used only if type=dpart. It should be either fs (for file system) or dp (for data partition).

erasecmd  The command string that, when executed, erases the device.

fmtcmd  The command string that, when executed, formats the device.

fsname  The file system name on the file system administered on this partition, as supplied to the /usr/sbin/labelit command. This attribute is specified only if type=dpart and dparttype=fs.

gap  Used by the command specified in the mkfscmd attribute.

mkfscmd  The command string that, when executed, places a file system on a previously formatted device.

mountpt  The default mount point to use for the device. Used only if the device is mountable. For disk partitions where type=dpart and dparttype=fs, this attribute should specify the location where the partition is normally mounted.

nblocks  The number of blocks in the file system administered on this partition. Used only if type=dpart and dparttype=fs.

ninodes  The number of inodes in the file system administered on this partition. Used only if type=dpart and dparttype=fs.

norewind  The name of the character special device node that allows access to the serial device without rewinding when the device is closed.
putdev(1M)

pathname  Defines the pathname to an i-node describing the device (used for non-block or character device pathnames, such as directories).

type  A token that represents inherent qualities of the device. Standard types include: 9-track, ctape, disk, directory, diskette, dpart, and qtape.

volname  The volume name on the file system administered on this partition, as supplied to the /usr/sbin/labelit command. Used only if type=dpart and dparttype=fs.

volume  A text string used to describe any instance of a volume associated with this device. This attribute should not be defined for devices which are not removable.

Exit Status  The following exit values are returned:

0  Successful completion.

1  Command syntax was incorrect, an invalid option was used, or an internal error occurred.

2  The device table could not be opened for reading, or a new device table could not be created.

3  If executed with the -a option, indicates that an entry in the device table with the alias alias already exits. If executed with the -m or -d options, indicates that no entry exists for device device.

4  Indicates that -d was requested and one or more of the specified attributes were not defined for the device.

System Administration Guide: Basic Administration
putdgrp(1M)

**Name**
putdgrp – edits device group table

**Synopsis**
putdgrp [-d] dgroup [device]...

**Description**
putdgrp modifies the device group table. It performs two kinds of modification. It can modify the table by creating a new device group or removing a device group. It can also change group definitions by adding or removing a device from the group definition.

When the command is invoked with only a `dgroup` specification, the command adds the specified group name to the device group table if it does not already exist. If the `-d` option is also used with only the `dgroup` specification, the command deletes the group from the table.

When the command is invoked with both a `dgroup` and a `device` specification, it adds the given device name(s) to the group definition. When invoked with both arguments and the `-d` option, the command deletes the device name(s) from the group definition.

When the command is invoked with both a `dgroup` and a `device` specification and the device group does not exist, it creates the group and adds the specified devices to that new group.

**Options**
The following options are supported:

- `-d` Delete the group or, if used with `device`, delete the device from a group definition.

**Operands**
The following operands are supported:

- `dgroup` Specify a device group name.
- `device` Specify the pathname or alias of the device that is to be added to, or deleted from, the device group.

**Exit Status**
The following exit values are returned:

- `0` Successful completion.
- `1` Command syntax was incorrect, an invalid option was used, or an internal error occurred.
- `2` Device group table could not be opened for reading or a new device group table could not be created.
- `3` If executed with the `-d` option, indicates that an entry in the device group table for the device group `dgroup` does not exist and so cannot be deleted. Otherwise, indicates that the device group `dgroup` already exists and cannot be added.
- `4` If executed with the `-d` option, indicates that the device group `dgroup` does not have as members one or more of the specified devices. Otherwise, indicates that the device group `dgroup` already has one or more of the specified devices as members.
putdgrp(1M)

Examples

EXAMPLE 1 Adding a new device group.
The following example adds a new device group:
example# putdgrp floppies

EXAMPLE 2 Adding a device to a device group.
The following example adds a device to a device group:
example# putdgrp floppies diskette2

EXAMPLE 3 Deleting a device group.
The following example deletes a device group:
example# putdgrp -d floppies

EXAMPLE 4 Deleting a device from a device group.
The following example deletes a device from a device group:
example# putdgrp -d floppies diskette2

pwck(1M)

Name  pwck, grpck – password/group file checkers

Synopsis  
   /usr/sbin/pwck [filename]
   /usr/sbin/grpck [filename]

Description  pwck scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is /etc/passwd.

   grpck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than NGROUPS_MAX groups, and that all login names appear in the password file. The default group file is /etc/group.

   All messages regarding inconsistent entries are placed on the stderr stream.

Files  
   /etc/group
   /etc/passwd

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  getpwent(3C), group(4), passwd(4), attributes(5)

Diagnostics  Group entries in /etc/group with no login names are flagged.

   Group file ‘filename’ is empty
   The /etc/passwd or /etc/group file is an empty file.
   cannot open file filename: No such file or directory
   The /etc/passwd or /etc/group file does not exist.

Notes  If no filename argument is given, grpck checks the local group file, /etc/group, and also makes sure that all login names encountered in the checked group file are known to the system getpwent(3C) routine. This means that the login names may be supplied by a network name service.
Name  pwconv – installs and updates /etc/shadow with information from /etc/passwd

Synopsis  pwconv

Description  The pwconv command creates and updates /etc/shadow with information from /etc/passwd.

pwconv relies on a special value of ‘x’ in the password field of /etc/passwd. This value of ‘x’ indicates that the password for the user is already in /etc/shadow and should not be modified.

If the /etc/shadow file does not exist, this command will create /etc/shadow with information from /etc/passwd. The command populates /etc/shadow with the user’s login name, password, and password aging information. If password aging information does not exist in /etc/passwd for a given user, none will be added to /etc/shadow. However, the last changed information will always be updated.

If the /etc/shadow file does exist, the following tasks will be performed:

- Entries that are in the /etc/passwd file and not in the /etc/shadow file will be added to the /etc/shadow file.
- Entries that are in the /etc/shadow file and not in the /etc/passwd file will be removed from /etc/shadow.
- Password attributes (for example, password and aging information) that exist in an /etc/passwd entry will be moved to the corresponding entry in /etc/shadow.

The pwconv command can only be used by the super-user.

Files  /etc/opasswd

/etc/oshadow

/etc/passwd

/etc/shadow

<td>$UNWcsu</td>
</tr>
</tbody>
</table>

See Also  passwd(1), passmgmt(1M), usermod(1M), passwd(4), attributes(5)

Diagnostics  pwconv exits with one of the following values:

0 SUCCESS.
1 Permission denied.
2 Invalid command syntax.
3  Unexpected failure. Conversion not done.
4  Unexpected failure. Password file(s) missing.
5  Password file(s) busy. Try again later.
6  Bad entry in /etc/shadow file.
Name          quot – summarize file system ownership
Synopsis       quot [-acfhnv] filesystem...
               quot -a [-cfhnv]
Description    quot displays the number of blocks (1024 bytes) in the named filesystem (one or more)
currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be
counted as a 2048 block file, but the total block count will be correct.
Options        The following options are supported:
               -a             Generate a report for all mounted file systems.
               -c             Display three columns giving a file size in blocks, the number of files of that size, and a
                              cumulative total of blocks containing files of that size or a smaller size.
               -f             Display three columns giving, for each user, the number of blocks owned, the count of
                              number of files, and the user name. This option is incompatible with the -c and -v
                              options.
               -h             Estimate the number of blocks in the file. This does not account for files with holes in
                              them.
               -n             Attach names to the list of files read from standard input. quot -n cannot be used alone,
because it expects data from standard input. For example, the pipeline
                              ncheck myfilesystem | sort +0n | quot -n myfilesystem
                              will produce a list of all files and their owners. This option is incompatible with all other
                              options.
               -v             In addition to the default output, display three columns containing the number of
                              blocks not accessed in the last 30, 60, and 90 days.
Operands       filesystem       mount-point of the filesystem(s) being checked
Usage          See largefile(5) for the description of the behavior of quot when encountering files greater
               than or equal to 2 Gbyte ( 2^31 bytes).
Exit Status    0             Successful operation.
               32            Error condition (bad or missing argument, bad path, or other error).
Files          /etc/mnttab    Lists mounted file systems.
               /etc/passwd    Used to obtain user names
Attributes     See attributes(5) for descriptions of the following attributes:

<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  du(1), mnttab(4), passwd(4), attributes(5), largefile(5)

Notes  This command can only be used by the super-user.
Name quota – display a user’s UFS or ZFS file system disk quota and usage

Synopsis quota [-v] [username]

Description quota displays users’ UFS or ZFS disk usage and limits. Only the super-user may use the optional username argument to view the limits of other users.

quota without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored.

username can be the numeric UID of a user.

Options -v Display user’s quota on all mounted file systems where quotas exist.

Usage See largefile(5) for the description of the behavior of quota when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Files /etc/mnttab list of currently mounted filesystems

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also edquota(1M), quotaon(1M), quotacheck(1M), repquota(1M), rquotad(1M), attributes(5), largefile(5), zones(5)

Notes quota displays quotas for NFS mounted UFS- or ZFS-based file systems if the rquotad daemon is running. See rquotad(1M). In a zones(5) environment, quota displays quotas only for the zone in which it is invoked.

quota can display entries for the same file system multiple times for multiple mount points. For example,

```
# quota -v user1
```

might display identical quota information for user1 at the mount points /home/user1, /home/user2, and /home/user, if all three mount points are mounted from the same file system with quotas turned on.
**Name**  
quotacheck – ufs file system quota consistency checker

**Synopsis**  
`quotacheck [-fp] [-v] filesystem...`  
`quotacheck -a [-fpv]`

**Description**  
`quotacheck` examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system’s disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.

`filesystem` is either a file system mount point or the block device on which the file system resides.

`quotacheck` expects each file system to be checked to have a quota file named `quotas` in the root directory. If none is present, `quotacheck` will not check the file system.

`quotacheck` accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while `quotacheck` is running.

**Options**  
The following options are supported:

- `-a` Check the file systems which `/etc/mnttab` indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an `rq` entry in the `mntopts` field in `/etc/vfstab`.

- `-f` Force check on file systems with logging enabled. Use in combination with the `-p` option.

- `-p` Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the `-f` option is also specified.

- `-v` Indicate the calculated disk quotas for each user on a particular file system. `quotacheck` normally reports only those quotas modified.

**Usage**  
See `largefile(5)` for the description of the behavior of `quotacheck` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**Files**  
`/etc/mnttab` Mounted file systems  
`/etc/vfstab` List of default parameters for each file system

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>

See Also  edquota(1M), quota(1M), quotaon(1M), repquota(1M), attributes(5), largefile(5), quotactl(7I), mount_ufs(1M)
**Name**
quotaon, quotaoff – turn ufs file system quotas on and off

**Synopsis**

```bash
quotaon [-v] filesystem...
quotaon -a [-v]
quotaoff [-v] filesystem...
quotaoff -a [-v]
```

**Description**

`quotaon` turns on disk quotas for one or more ufs file systems.

Before a file system may have quotas enabled, a file named `quotas`, owned by root, must exist in the root directory of the file system. See `edquota(1M)` for details on how to modify the contents of this file.

`quotaoff` turns off disk quotas for one or more ufs file systems.

The file systems specified must already be mounted.

These commands update the `mntopts` field of the appropriate entries in `/etc/mnttab` to indicate when quotas are on or off for each file system. If quotas are on, the string `quota` will be added to `mntopts`; if quotas are off, the `quota` string is not present.

`filesystem` must be either the mount point of a file system, or the block device on which the file system resides.

**Options**

- **quotaon**
  - `-a` This option is normally used at boot time to enable quotas. It applies only to those file systems in `/etc/vfstab` which have “rq” in the `mntopts` field, are currently mounted “rw”, and have a quotas file in the root directory.
  - `-v` Display a message for each file system after quotas are turned on.

- **quotaoff**
  - `-a` Force all file systems in `/etc/mnttab` to have their quotas disabled.
  - `-v` Display a message for each file system affected.

**Usage**

See `largefile(5)` for the description of the behavior of `quotaon` and `quotaoff` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

**Files**

- `/etc/mnttab` mounted file systems
- `/etc/vfstab` list of default parameters for each file system

**Attributes**

See Also  edquota(1M), quota(1M), quotacheck(1M), repquota(1M), mnttab(4), vfstab(4), attributes(5), largefile(5), quotactl(7I)
The *raidctl* utility is a hardware RAID configuration tool that supports different RAID controllers by providing a CLI (command-line interface) to end-users to create, delete or display RAID volume(s). The utility can also be used to set properties of a volume, assign hot-spare (HSP) disks to volumes or controllers, and to update firmware/fcode/BIOS for RAID controllers.

The *raidctl* utility requires privileges that are controlled by the underlying file-system permissions. Only privileged users can manipulate the RAID system configuration. If a non-privileged user attempts to run *raidctl*, the command fails with an exit status of 1.

The *raidctl* utility, as described in this man page, defines a broad set of command line options to provide management for full-featured RAID controllers. However, support for a given option depends on two elements:

- the presence of a software driver
- the firmware level of the RAID device

The dependency on a software driver is due to the design of *raidctl*. The utility is built on a common library that enables the insertion of plug-in modules for different drivers. Currently, the Solaris operating system is shipped with a plug-in for the *mpt* driver. This plug-in does not support all of the *raidctl* options. On a given storage device, options might be further limited by the device’s firmware level.

The level of support for the various *raidctl* options cannot be determined by *raidctl*. The user must rely on the documentation for his RAID controller or hardware platform.
Currently, `raidctl` provides some level of support for the following RAID controllers:

- LSI1020 SCSI HBA
- LSI1030 SCSI HBA
- LSI1064 SAS HBA
- LSI1068 SAS HBA

All of the above HBAs are maintained by the `mpt` driver, on X86-32/64 and SPARC platforms.

**Options**

The following options are supported:

```
-C "disks" [-r raid_level] [-z capacity] [-s stripe_size] [-f] controller
```

Create a RAID volume using specified disks.

When creating a RAID volume using this option, the identity of the newly created volume is automatically generated and `raidctl` reports it to the user.

The argument specified by this option contains the elements used to form the volume that will be created. Elements can be either disks or sub-volumes, where disks are separated by space(s) and a sub-volume is a set of disks grouped by parenthesis. All disks should be in C.ID.L expression (for example, 0.1.2 represents a physical disk of channel 0, target id 1, and logical unit number 2). The argument must match the RAID level specified by the `-r` option, even if it's omitted. This means the argument can only be:

- for RAID 0
  - At least 2 disks

- for RAID 1
  - Only 2 disks

- for RAID 1E
  - At least 3 disks

- for RAID 5
  - At least 3 disks

- for RAID 10
  - At least 2 sub-volumes, each sub-volume must be formed by 2 disks

- for RAID 50
  - At least 2 sub-volumes, each sub-volume must be formed by at least 3 disks, and the disk amount in each sub-volume should be the same

For example, the expression “0.0.0 0.1.0” means that the 2 specified disks form a RAID volume, which can either be a RAID 0 or a RAID 1 volume. “(0.0.0 0.1.0)(0.2.0 0.3.0)” means that the first 2 disks and the last 2 disks form 2 sub-volumes, and that these 2 sub-volumes form a RAID 10 volume. See the EXAMPLES section for more samples.

The `-r` option specifies the RAID level of the volume that will be created. Possible levels are 0, 1, 1E, 5, 10, 50. If this option is omitted, `raidctl` creates a RAID 1 volume by default.
The -z option specifies the capacity of the volume that will be created. The unit can be tera-bytes, giga-bytes, or mega-bytes (for example, 2t, 10g, 20m, and so on). If this option is omitted, raidctl calculates the maximum capacity of the volume that can be created by the specified disks and uses this value to create the volume.

The -s option specifies the stripe size of the volume that will be created. The possible values are 512, 1k, 2k, 4k, 8k, 16k, 32k, 64k, or 128k. If this option is omitted, raidctl chooses an appropriate value for the volume (for example, 64k).

In some cases, the creation of a RAID volume may cause data on specified disks to be lost (for instance, on LSI1020, LSI1030, SAS1064, or SAS1068 HBAs), and raidctl prompts the user for confirmation about the creation. Use the -f option to force the volume creation without prompting the user for confirmation.

The controller argument is used to identify which RAID controller the specified disks belongs. The -l option can be used to list the controller's ID number.

-a [ -f ] volume
Delete the RAID volume specified as volume. The volume is specified in canonical form (for example, c0t0d0).

When a volume is deleted, all data is lost. Therefore, unless the -f option is specified, raidctl prompts the user for confirmation before deleting the volume.

When a RAID 1 volume is deleted from a LSI1020, LSI1030, SAS1064, or SAS1068 HBA, the primary and secondary disks are "split". If the volume was in SYNCHING state, the primary will contain the data, and the secondary will not. If the volume state was OPTIMAL, both disks will contain a complete image of the data.

-F filename [ -f ] controller...
Update the firmware running on the specified controller(s). The raidctl utility prompts the user for confirmation of this action, unless the -f option is provided.

-a { set | unset } -g disk { volume | controller }
If the volume is specified, raidctl sets or unsets the disk as a local hot-spare disk dedicated to the volume, depending on the value specified by the -a option. If the controller is specified, raidctl sets or unsets the disk as a global hot-spare disk.

-p "param=value" [ -f ] volume
Change the property value for a given RAID volume. This option can be used to change cache write policy or to activate a volume. When changing the cache write policy, param should be the string wp (SET_WR_POLICY), and value can be either on or off. When used to activate a volume, param should be state and value should be activate.

Changing a RAID volume's property may affect the internal behavior of the RAID controller, so raidctl prompts the user for a confirmation before applying the change, unless the -f option is specified.
Create a volume using the specified disks. This is an alternative to the -C option with similar functionality. This option is preserved for compatibility reasons, but only works with LSI1020, LSI1030, SAS1064, and SAS1068 HBAs to create RAID 0, RAID 1, or RAID 1E volumes. For other HBAs, the user can only use the -C option.

The -r option can be used to specify the RAID level of the target volume. If the -r option is omitted, raidctl will create a RAID 1 volume.

Disks must be specified in Solaris canonical format (for example, c0t0d0).

Creating a RAID 1 volume with this option replaces the contents of disk2 with the contents of disk1.

When the user creates a RAID volume with this option, the RAID volume assumes the identity of disk1. Other disks become invisible and the RAID volume appears as one disk.

Creating a volume with this option is by default interactive. The user must answer a prompt affirmatively to create the volume. Use the -f option to force the volume creation without prompting the user for confirmation.

Display information about the specified disk of the given controller. The output includes the following information:

```
Disk
  Displays the disk in C.ID.L expression disk.

Vendor
  Displays the vendor ID string.

Product
  Displays the product ID string.

Capacity
  Displays the total capacity of the disk.

Status
  Displays the current status of disk. The status can be either "GOOD" (operating normally), "FAILED" (non-functional), or "MISSING" (disk not present).

HSP
  Indicates if the disk has been set as a global hot-spare disk, local hot-spare disk, or a normal one. If it is a local hot-spare disk, all volumes which this disk is assigned to are displayed.

GUID
  GUID string for the specified disk. This is an additional datum and might be unavailable in some cases.
```
```
-1 volume
    Display information about the specified volume. The output includes the following information:

    Volume
        Displays volume in canonical format.

    Sub
        Displays sub-volumes, if the specified volume is of RAID 10 or RAID 50 volume.

    Disk
        Displays all disks that form the specified volume.

    Stripe Size
        Displays the stripe size of the volume.

    Status
        Displays the status of the specified volume, or the sub-volumes or disks that form the specified volume. For an inactive volume, the status should be INACTIVE; otherwise it can be OPTIMAL (operating optimally), DEGRADED (operating with reduced functionality), FAILED (non-functional), or SYNC (disks are syncing). For a disk, the status can be GOOD, FAILED, or MISSING.

    Cache
        Indicates whether the cache is applied to I/O write activities. The cache can be either "ON" or "OFF".

    RAID level
        Displays the RAID level. The RAID level can be either 0, 1, 1E, 5, 10, or 50.

-1 controller ...
    Display information about the specified controller(s). The output includes the following information:

    Controller
        Displays the RAID controller's ID number.

    Type
        Displays the RAID controller's product type.

    fw_version
        Displays the controller's firmware version.

[ -l ]
    List all RAID related objects that the raidctl utility can manipulate, including all available RAID controllers, RAID volumes, and physical disks. The -l option can be omitted.

    The output includes the following information:

    Controller
        Displays the RAID controller's ID number.
```
Volume
  Displays the logical RAID volume name.

Disk
  Displays the RAID disk in C.ID.L expression.

-S [volume | controller]
  Takes a snapshot of the RAID configuration information including all available RAID devices, RAID controllers, volumes, and disks.

Each line of the output specifies a RAID device and its related information, separated by space(s). All volumes and disks belong to the last specified controller.

The output lists the following information:

Controller
  Displays the controller ID number, and the controller type string in double-quotiation marks.

Volume
  Displays the RAID volume name, number of component disks, the C.ID.L expression of the component disks, the RAID level, and the status. The status can be either OPTIMAL, DEGRADED, FAILED, or SYNCING.

Disk
  Displays the C.ID.L expression of the disk, and the status. The status can be either GOOD, FAILED, or HSP (disk has been set as a stand-by disk).

If a volume or a controller is specified, a snapshot is only taken of the information for the specified volume or controller.

-S -g disk controller
  Takes a snapshot of the information for the specified disk.

-h
  Print out the usage string.

Examples

EXAMPLE 1  Creating the RAID Configuration

The following command creates a RAID 0 volume of 10G on controller 0, and the stripe size will be set to 64k:

# raidctl -C "0.0.0 0.2.0" -r 0 -z 10g -s 64k 0

The following command creates a RAID 1 volume on controller 2:

# raidctl -C "0.0.0 1.1.0" -r 1 2

The following command creates a RAID 5 volume on controller 2:

# raidctl -C "0.0.0 0.1.0 0.2.0" -r 5 2

The following command creates a RAID 10 volume on controller 0:
EXAMPLE 1  Creating the RAID Configuration  (Continued)

```
# raidctl -C "(0.0.0 0.1.0)(0.2.0 0.3.0)" -r 10 0
```

The following command creates a RAID 50 volume on controller 0:

```
# raidctl -C "(0.0.0 0.1.0 0.2.0)(0.3.0 0.4.0 0.5.0)" -r 50 0
```

EXAMPLE 2  Displaying the RAID Configuration

The following command displays all available controllers, volumes, and disks:

```
# raidctl -l
```

Controller: 0
Controller: 2
Volume: c2t0d0
Disk: 0.0.0
Disk: 0.1.0
Disk: 0.2.0
Disk: 0.3.0 (HSP)

The following command displays information about controller 2:

```
# raidctl -l 2
```

```
Controller  Type  Fw_version
-------------  --------  ------------
c2  LSI 1030  1.03.39.00
```

The following command displays information about the specified volume:

```
# raidctl -l c2t0d0
```

```
Volume Size Stripe Status Cache RAID Sub Size Level
----------  ------  -------  ------  ------  ---------
c2t0d0 10240M 64K OPTIMAL ON RAID5

Disk
----------
0.0.0 5120M GOOD
0.1.0 5120M GOOD
0.2.0 5120M GOOD
```

The following command displays information about disk 0.0.0 on controller 0:

```
# raidctl -l -g 0.0.0 0
```

```
Disk  Vendor  Product  Firmware Capacity Status  HSP
-------  --------  ----------  --------  ------  --------
0.0.0  HITACHI  H101473SCSUN72G S002  68.3G  GOOD  N/A
GUID:2000000cca02536c
```
EXAMPLE 3  Deleting the RAID Configuration
The following command deletes a volume:

```
# raidctl -d c0t0d0
```

EXAMPLE 4  Updating Flash Images on the Controller
The following command updates flash images on the controller 0:

```
# raidctl -F lsi_image.fw 0
```

EXAMPLE 5  Setting or Unsetting a Hot-Spare Disk
The following command sets disk 0.3.0 on controller 2 as a global hot-spare disk:

```
# raidctl -a set -g 0.3.0 2
```

The following command sets disk 0.3.0 on controller 2 as a local hot-spare disk to volume c2t0d0:

```
# raidctl -a set -g 0.3.0 c2t0d0
```

The following command converts disk 0.3.0 on controller 2 from a global hot-spare disk to a normal one:

```
# raidctl -a unset -g 0.3.0 2
```

The following command removes disk 0.3.0 from being a local hot-spare disk from volume c2t0d0:

```
# raidctl -a unset -g 0.3.0 c2t0d0
```

EXAMPLE 6  Setting the Volume's Property
The following command sets the write policy of the volume to "off":

```
# raidctl -a set -p "wp=off" c0t0d0
```

EXAMPLE 7  Creating Volumes with the -c Option
The following command creates a RAID 1 volume:

```
# raidctl -c c0t0d0 c0t1d0
```

The following command creates a RAID 0 volume:

```
# raidctl -c -r 0 c0t1d0 c0t2d0 c0t3d0
```

EXAMPLE 8  Taking a Snapshot of the RAID Configuration
The following command takes a snapshot of all RAID devices:

```
# # raidctl -S
1 "LSI 1030"
```
EXAMPLE 8 Taking a Snapshot of the RAID Configuration (Continued)

c1t1d0 2 0.2.0 0.3.0 1 DEGRADED
0.2.0 GOOD
0.3.0 FAILED

The following command takes a snapshot about volume c1t0d0:

# raidctl -S c1t0d0

c1t0d0 2 0.0.0 0.1.0 1 OPTIMAL

The following command takes a snapshot about disk 0.1.0 on controller 1:

# raidctl -S -g 0.1.0 1

0.1.0 GOOD

Exit Status The following exit values are returned:

0
Successful completion.

1
Invalid command line input or permission denied.

2
Request operation failed.

System Administration Guide: Basic Administration

Warnings Do not create raid volumes on internal SAS disks if you are going to use the Solaris Multipathing I/O feature (also known as MPxIO). Creating a new raid volume under Solaris Multipathing will give your root device a new GUID which does not match the GUID for the existing devices. This will cause a boot failure since your root device entry in /etc/vfstab will not match.
Notes  The -z option is not supported on systems that use the mpt driver and LSI RAID controllers.
Name  ramdiskadm – administer ramdisk pseudo device

Synopsis  /usr/sbin/ramdiskadm -a name size [g | m | k | b]
/usr/sbin/ramdiskadm -d name
/usr/sbin/ramdiskadm

Description  The ramdiskadm command administers ramdisk(7D), the ramdisk driver. Use ramdiskadm to create a new named ramdisk device, delete an existing named ramdisk, or list information about existing ramdisks.

Ramdisks created using ramdiskadm are not persistent across reboots.

Options  The following options are supported:

-a name size  Create a ramdisk named name of size size and its corresponding block and character device nodes.

name must be composed only of the characters a-z, A-Z, 0-9, _ (underbar), and - (hyphen), but it must not begin with a hyphen. It must be no more than 32 characters long. Ramdisk names must be unique.

The size can be a decimal number, or, when prefixed with 0x, a hexadecimal number, and can specify the size in bytes (no suffix), 512-byte blocks (suffix b), kilobytes (suffix k), megabytes (suffix m) or gigabytes (suffix g). The size of the ramdisk actually created might be larger than that specified, depending on the hardware implementation.

If the named ramdisk is successfully created, its block device path is printed on standard out.

-d name  Delete an existing ramdisk of the name name. This command succeeds only when the named ramdisk is not open. The associated memory is freed and the device nodes are removed.

You can delete only ramdisks created using ramdiskadm. It is not possible to delete a ramdisk that was created during the boot process.

Without options, ramdiskadm lists any existing ramdisks, their sizes (in decimal), and whether they can be removed by ramdiskadm (see the description of the -d option, above).

Examples  EXAMPLE 1  Creating a 2MB Ramdisk Named mydisk

# ramdiskadm -a mydisk 2m
/dev/ramdisk/mydisk
EXAMPLE 2  Listing All Ramdisks

# ramdiskadm

<table>
<thead>
<tr>
<th>Block Device</th>
<th>Size</th>
<th>Removable</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/ramdisk/miniroot</td>
<td>134217728</td>
<td>No</td>
</tr>
<tr>
<td>/dev/ramdisk/certfs</td>
<td>1048576</td>
<td>No</td>
</tr>
<tr>
<td>/dev/ramdisk/mydisk</td>
<td>2097152</td>
<td>Yes</td>
</tr>
</tbody>
</table>

ramdiskadm returns the following exit values:

  0  Successful completion.

  >0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>

<td>Evolving</td>
</tr>
</tbody>
</table>

See Also  attributes(5), ramdisk(7D)

Notes  The abilities of ramdiskadm and the privilege level of the person who uses the utility are controlled by the permissions of /dev/ramdiskctl. Read access allows query operations, for example, listing device information. Write access is required to do any state-changing operations, for example, creating or deleting ramdisks.

As shipped, /dev/ramdiskctl is owned by root, in group sys, and mode 0644, so all users can do query operations but only root can perform state-changing operations. An administrator can give write access to non-privileged users, allowing them to add or delete ramdisks. However, granting such ability entails considerable risk; such privileges should be given only to a trusted group.
Name  rcapadm – configure resource capping daemon

Synopsis  

rcapadm  

[ -n ]  

[-E | -D]  

[-i  

interval=value,...,interval=value]  

[-c percent]  

[-z zonename -m maxvalue]

Description  The rcapadm command allows a user with the privileges described below to configure various attributes of the resource capping daemon. If used without arguments, rcapadm displays the current status of the resource capping daemon if it has been configured. See rcapd(1M) for more information.

In the current release of the Solaris operating environment, rcapadm is available to users with all privileges and to users who have the Process Management profile in their list of profiles. The System Administrator role includes the Process Management profile.

Options  

-c percent  

Set the minimum physical memory utilization for memory cap enforcement. Caps will not be enforced until the physical memory available to processes is low. The percent value should be in the range 0 to 100. The minimum (and default) value is 0, which means that memory caps are always enforced.

-D  

Disable the resource capping daemon so that it will not be started when the system is booted. Also stop the resource capping daemon now, if the -n option is not specified and it is currently running.

-E  

Enable the resource capping daemon so that it will be started each time the system is booted. Also start the resource capping daemon now, if the -n option is not specified and it is not currently running.

-i interval=value,...,interval=value  

Set intervals for various periodic operations performed by rcapd. All intervals are specified in seconds. You can set the following intervals:

   scan  

The interval at which rcapd scans for new processes. The default scan interval is every 15 seconds. The minimum value is 1 second.

   sample  

The interval of process resident set size sampling. The default sample interval is every 5 seconds. The minimum value is 1 second.
The interval at which various paging statistics are updated by rcapd, in seconds. These statistics can be viewed by using rcapstat(1SRM). The default reporting interval is every 5 seconds. When the interval is set to 0, statistics will not be updated.

**Note** – Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. rcapd pages out the most infrequently used pages.

The reconfiguration interval, in seconds. At each reconfiguration event, rcapd checks its configuration file for updates, and scans the project databases for new project caps. The default reconfiguration interval is every 60 seconds. The minimum interval is 0. When the interval is set to 0, no periodic reconfiguration occurs, although the running daemon can still be reconfigured by sending it SIGHUP.

Used in conjunction with the -z option. Specifies a value for rcap.max-rss, a dynamically-set cap on the usage of physical memory for the zone specified by -z. You can apply a scale (K, M, G, T) to the value you specify. K means kilobyte; M, megabyte; G, gigabyte; and T, terabyte. For example, 100M is 100 megabytes.

Do not affect the running state of the resource capping daemon when enabling or disabling it.

Used in conjunction with the -m option. Specifies the zone for which you are dynamically specifying a cap on physical memory usage (using -m).

**Note** – To set a persistent cap on memory usage within a zone, use zonecfg(1M).

**Examples**

**EXAMPLE 1** Configuring the Resource Capping Daemon with Immediate Enforcement

```bash
# rcapadm -E -i scan=15,sample=5,report=5,config=60 -c 0
```
EXAMPLE 2  Specifying a Resource Cap for a Zone
The command shown below specifies the maximum amount of memory that can be
consumed by a specified zone. Note that this value lasts only until the next reboot. To set a
persistent cap, use zonecfg(1M).

# rcapadm -z testzone -m 512M

Exit Status  The following exit values are returned:

0  Successful completion. The modifications to the current configuration were valid and
made successfully.
1  An error occurred. A fatal error occurred either in obtaining or modifying the resource
capping configuration.
2  Invalid command-line options were specified.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>

The -z and -m options are committed interfaces.

See Also  rcapstat(1), rcapd(1M), zonecfg(1M), project(4), attributes(5), zones(5)

“Physical Memory Control Using the Resource Capping Daemon” in System Administration
The rcapd daemon enforces resource caps on collections of processes. Per-project and per-zone physical memory caps are supported. For information about projects, see project(4). For zones information, see zones(5).

When the resident set size (RSS) of a collection of processes exceeds its cap, rcapd takes action and reduces the RSS of the collection.

The virtual memory system divides physical memory into segments known as pages. To read data from a file into memory, the virtual memory system reads in individual pages. To reduce resource consumption, the daemon can page out, or relocate, infrequently used pages to an area outside of physical memory.

In the project file, caps are defined for projects that have positive values for the following project attribute:

rcap.max-rss The total amount of physical memory, in bytes, that is available to the project's member processes

See project(4) for a description of project attributes.

For a system with one or more zones, you can dynamically set the rcap.max-rss value for a zone with rcapadm(1M). To set a persistent cap on memory usage within a zone, you use zonecfg(1M).

You configure rcapd through the use of rcapadm(1M). The daemon can be monitored with rcapstat(1). Configuration changes are incorporated into rcapd by sending it SIGHUP (see kill(1)), or according to the configuration interval (see rcapadm(1M)).

Options
The following option is supported:

- d Enable debug mode. Messages are displayed on the invoking user's terminal.

Examples

**EXAMPLE 1** Setting Resident Set Size Cap Attribute

The following line in the /etc/project database sets an RSS cap of 1073741824 bytes for a project named foo.

foo:100::foo,root::rcap.max-rss=10737418240

Exit Status
The following exit values are returned:

0 Successful completion.
1 An error occurred.
2 Invalid command-line options were specified.
Files

/etc/project   Project database.

Attributes

</tbody>
</table>

See Also

rcapstat(1), svcs(1), rcapadm(1M), zonecfg(1M), svcadm(1M), project(4), attributes(5), smf(5), zones(5)

Notes

If killed with SIGKILL, rcapd can leave processes in a stopped state. Use SIGTERM to cause rcapd to terminate properly.

A collection's RSS can exceed its cap for some time before the cap is enforced, even if sufficient pageable memory is available. This period of time can be reduced by shortening the RSS sampling interval with rcapadm.

The rcapd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/rcap:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
rctladm(1M)

Name  rctladm – display or modify global state of system resource controls

Synopsis  rctladm [-lu] [-e action] [-d action] [name...]

Description  The rctladm command allows the examination and modification of active resource controls on the running system. An instance of a resource control is referred to as an rctl. See setrctl(2) for a description of an rctl; see resource_controls(5) for a list of the rctls supported in the current release of the Solaris operating system. Logging of rctl violations can be activated or deactivated system-wide and active rctls (and their state) can be listed.

An rctladm command without options is the equivalent of an rctladm with the -l option. See the description of -l below.

Options  The following options are supported:

- d action
- e action

Disable (-d) or enable (-e) the global action on the specified rctls. If no rctl is specified, no action is taken and an error status is returned. You can use the special token all with the disable option to deactivate all global actions on a resource control.

You can set the syslog action to a specific degree by assigning a severity level. To do this, specify syslog=level, where level is one of the string tokens given as valid severity levels in syslog(3C). You can omit the common LOG_ prefix on the severity level. Note that not all rctls support the syslog action. See resource_controls(5).

- l
List information about rctls. The name, global event actions and statuses, and global flags are displayed. If one or more name operands are specified, only those rctls matching the names are displayed.

- u
Configure resource controls based on the contents of /etc/rctladm.conf. Any name operands are ignored.

Operands  The following operands are supported:

name
The name of the rctl to operate on. Multiple rctl names can be specified. If no names are specified, and the list action has been specified, then all rctls are listed. If the enable or disable action is specified, one or more rctl names must be specified.

Examples  EXAMPLE 1  Activating System Logging for Specific Violations

The following command activates system logging of all violations of task.max-lwps.

# rctladm -e syslog task.max-lwps
#

1916  man pages section 1M: System Administration Commands • Last Revised 2 Jul 2007
EXAMPLE 2  Examining the Current Status of a Specific Resource

The following command examines the current status of the `task.max-lwps` resource.

```bash
$ rctladm -l task.max-lwps
  task.max-lwps    syslog=DEBUG
$ 
```

**Exit Status**  The following exit values are returned:

0  Successful completion.

1  A fatal error occurred. A message is written to standard error to indicate each resource control for which the operation failed. The operation was successful for any other resource controls specified as operands.

2  Invalid command line options were specified.

**Files**  `/etc/rctladm.conf`

Each time `rctladm` is executed, it updates the contents of `rctladm.conf` with the current configuration.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>

</tbody>
</table>

**See Also**  `setrctl(2), getrctl(2), prctl(1), rctlblk_get_global_flags(3C), rctlblk_get_global_action(3C), attributes(5), resource_controls(5)`

**Notes**  By default, there is no global logging of `rctl` violations.
rdate(1M)

Name  rdate – set system date from a remote host

Synopsis  rdate hostname

Description  rdate sets the local date and time from the hostname given as an argument. You must have the authorization solars.system.date on the local system. Typically, rdate is used in a startup script.

rdate requests are responded to by the “time” service on the specified host. To enable the “time” service, use the following commands:

svcadm enable time:stream
svcadm enable time:dgram

Usage  The rdate command is IPv6–enabled. See ip6(7P).

Attributes  See attributes(5) for descriptions of the following attributes:

**reboot(1M)**

**Name**
reboot – restart the operating system

**Synopsis**
/usr/sbin/reboot [-dlnq] [boot_arguments]

**Description**
The `reboot` utility restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel.

Although `reboot` can be run by the super-user at any time, `shutdown(1M)` is normally used first to warn all users logged in of the impending loss of service. See `shutdown(1M)` for details.

The `reboot` utility performs a `sync(1M)` operation on the disks, and then a multi-user reboot is initiated. See `init(1M)` for details. On x86 systems, reboot may also update the boot archive as needed to ensure a successful reboot.

The `reboot` utility normally logs the reboot to the system log daemon, `syslogd(1M)`, and places a shutdown record in the login accounting file `/var/adm/wtmpx`. These actions are inhibited if the `-n` or `-q` options are present.

Normally, the system reboots itself at power-up or after crashes.

**Options**
The following options are supported:

- `-d` Force a system crash dump before rebooting. See `dumpadm(1M)` for information on configuring system crash dumps.
- `-f` For x86 systems:
  
  Fast reboot, bypassing firmware and boot loader. The new kernel will be loaded into memory by the running kernel, and control will be transferred to the newly loaded kernel. If disk or kernel arguments are specified, they must be specified before other boot arguments.

  For SPARC systems:
  
  Speeds up rebooting by skipping some POST tests.

- `-l` Suppress sending a message to the system log daemon, `syslogd(1M)` about who executed `reboot`.
- `-n` Avoid calling `sync(2)` and do not log the reboot to `syslogd(1M)` or to `/var/adm/wtmpx`. The kernel still attempts to sync filesystems prior to reboot, except if the `-d` option is also present. If `-d` is used with `-n`, the kernel does not attempt to sync filesystems.
- `-q` Quick. Reboot quickly and ungracefully, without shutting down running processes first.

**Operands**
The following operands are supported:
**boot_arguments**

An optional *boot_arguments* specifies arguments to the *uadmin(2)* function that are passed to the boot program and kernel upon restart. The form and list of arguments is described in the *boot(1M)* and *kernel(1M)* man pages. If the arguments are specified, whitespace between them is replaced by single spaces unless the whitespace is quoted for the shell. If the *boot_arguments* begin with a hyphen, they must be preceded by the -- delimiter (two hyphens) to denote the end of the reboot argument list.

**Examples**

**EXAMPLE 1**  Passing the -r and -v Arguments to boot

In the following example, the delimiter -- (two hyphens) must be used to separate the options of reboot from the arguments of *boot(1M)*.

```
example# reboot -dl -- -rv
```

**EXAMPLE 2**  Rebooting Using a Specific Disk and Kernel

The following example reboots using a specific disk and kernel.

```
example# reboot disk1 kernel.test/unix
```

**Files**  /var/adm/wtmpx      login accounting file

**Attributes**

See *attributes(5)* for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**  *mdb(1), boot(1M), dumpadm(1M), fsck(1M), halt(1M), init(1M), kernel(1M), shutdown(1M), sync(1M), syslogd(1M), sync(2), uadmin(2), reboot(3C), attributes(5)*

**Notes**

The *reboot* utility does not execute the scripts in */etc/rcnum.d* or execute shutdown actions in *inittab(4)*. To ensure a complete shutdown of system services, use *shutdown(1M)* or *init(1M)* to reboot a Solaris system.
Name  regadm – Solaris system registration utility

Synopsis  regadm auth [-u username] [-p password_file]
          regadm register [-q] [-d]
          regadm list
          regadm clear
          regadm set [-n name] [-v value]
          regadm status
          regadm disable
          regadm enable

Description  The regadm utility is used by a privileged system administrator to register products on a given Solaris system with My Oracle Support (MOS), and to manage the background auto-registration service that runs at system boot time. Registered products are extracted from the Service Tag Registry (see stclient(1M)) and uploaded to MOS by means of a secure HTTPS connection.

You can use regadm to explicitly register products. In addition, an smf(5) service runs at boot time that attempts to refresh the registration if the product installation base has changed. This service can be administratively enabled or disabled by means of subcommands of regadm. By default, the service is enabled.

Options  The following options are supported:

-d  Dry-run mode. Show the registration information that will be transmitted to MOS but do not perform the actual registration. Output is displayed in XML format.

-p password_file  Used with the authentication subcommand, the -p option specifies a file name containing the password associated with the MOS username (the -u option). This should be a single-line file and it can be immediately removed after running this command.

-q  Quiet mode. Do not show any output during a registration.

-u username  Used with the authentication subcommand, the -u option specifies the MOS user name to be associated with registrations of products on a given system.

Sub-commands  The subcommands for regadm are as follows:

auth  Each system must be authenticated with valid MOS credentials before its products can be registered. A successful authentication is made persistent and thus only needs to be done once.
clear
Remove all configured authentication and HTTPS connectivity information. This effectively configures an anonymous registration with no HTTP proxy information.

disable
Disable the auto-registration service at system boot time.

enable
Enable the auto-registration service at system boot time.

list
Displays the current authenticated MOS user name and the network connectivity information needed for HTTPS communication with MOS. If no authentication has yet been done (by means of the auth command), the anonymous account will be displayed.

register
Registers each product from the Solaris Service Tag registry (see stclient(1M)) with MOS, using the current authentication credentials. If no credentials have been supplied, the registration is performed using an anonymous MOS account.

set
Configure HTTP proxy information, to be used for HTTPS communication with the MOS backend.

status
Report the status (enabled/disabled) of the Solaris auto-registration smf(5) service. See the disable and enable subcommands.

Examples

**EXAMPLE 1**  Authenticating with MOS Interactively
The following command is used to interactively authenticate this system with MOS. You will be prompted for your support username and password.

```
# regadm auth
```

**EXAMPLE 2**  Authenticating Non-Interactively
This is similar to the interactive example, but specifies the MOS username and password on the command line.

```
# regadm auth -u "pat.smith@example.com" -p mypassword
```

The file mypassword must contain the MOS password.

**EXAMPLE 3**  Setting HTTP Proxy Information
The following command sequence configures an HTTP proxy and port, used for HTTPS communication with the MOS.

```
# regadm set -n http_proxy -v webcache.example.com
# regadm set -n http_proxy_port -v 8080
```
EXAMPLE 4  Setting HTTP Proxy Authentication Information

Some HTTP proxies require authentication. This example shows the configuring of a username/password for basic RFC 2617 HTTP authentication. Note that a filename containing the password (mypassword) is specified, not the actual password itself.

```
# regadm set -n http_proxy_user -v webuser
# regadm set -n http_proxy_user_pw -v mypassword
```

</tr>
</tbody>
</table>

See Also  stclient(1M), attributes(5), smf(5)
Name  rem_drv – remove a device driver from the system

Synopsis  rem_drv [-b basedir] device_driver

Description  The rem_drv command informs the system that the device driver device_driver is no longer valid. If possible, rem_drv unloads device_driver from memory. rem_drv also updates the system driver configuration files.

If rem_drv has been executed, the next time the system is rebooted it automatically performs a reconfiguration boot (see kernel(1M)).

Options  The following options are supported:

- b basedir
  Sets the path to the root directory of the diskless client. Used on the server to execute rem_drv for a client. The client machine must be rebooted to unload the driver.

  Note – The root file system of any non-global zones must not be referenced with the - b option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

- C
  Remove dangling device attribute nodes bound to the driver being removed. This causes any device ownership or permissions customizations made to any node not to be preserved if the driver is added back. Recommended for use when reprovisioning a machine from one configuration or use to another where past administrative customizations might not be desired.

Examples  EXAMPLE 1  Removing the sd Driver

The following example removes the sd driver from use:

drvcاورrem_drv sd

EXAMPLE 2  Removing a Diskless Client

The following example removes the driver from the sun1 diskless client. The driver is not uninstalled or unloaded until the client machine is rebooted.

drvcاورrem_drv -b /export/root/sun1 sd

Note the caveat on the use of the - b option in the description of that option, above.

remove_allocatable(1M)

**Name**  
remove_allocatable – remove entries from allocation databases

**Synopsis**  
/usr/sbin/remove_allocatable  [-f]  [-n  name]
/usr/sbin/remove_allocatable  [-f]  [-d]  [-t  dev-type]

**Description**  
remove_allocatable removes entries of user allocatable devices from the device allocation mechanism. remove_allocatable also removes entries of some non-allocatable devices, such as printers, whose label range is managed by the mechanism.

**Options**  
The following options are supported:

- **-d**  
  Removes system-supplied default attributes of the device type that is specified with -t.

- **-f**  
  Force the removal of an entry. remove_allocatable exits with an error if this option is not specified when an entry with the specified device name no longer exists.

- **-n name**  
  Removes the entry for the device name.

- **-t dev-type**  
  Removes devices of type dev-type.

**Exit Status**  
When successful, remove_allocatable returns an exit status of 0 (true). remove_allocatable returns a nonzero exit status in the event of an error. The exit codes are as follows:

1  Invocation syntax error
2  Unknown system error
3  Device name or dev-type not found. This error occurs only when the -f option is not specified.
4  Permission denied. User does not have DAC or MAC access to database.

**Attributes**  
See attributes(5) for descriptions of the following attributes:

The functionality described on this manual page is available only if the system is configured with Trusted Extensions.
Name  removef – remove a file from software database

Synopsis  removef [-f] [-M] [-R root_path] [-V fs_file] pkginst path ...
         removef [ -f ] [ -M ] [ -R root_path ] [ -V fs_file ] pkginst

Description  removef informs the system that the user, or software, intends to remove a pathname. Output from removef is the list of input pathnames that may be safely removed (no other packages have a dependency on them).

Options  The following options are supported:

- f
  After all files have been processed, removef should be invoked with the -f option to indicate that the removal phase is complete.

- M
  Instruct removef not to use the $root_path/etc/vfstab file for determining the client’s mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

- R root_path
  Define the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path. The root_path may be specified when installing to a client from a server (for example, /export/root/client1).

  removef inherits the value of the PKG_INSTALL_ROOT environment variable. (See ENVIRONMENT VARIABLES, below.) If PKG_INSTALL_ROOT is set, such as when the -R option is used with pkgadd(1M) or pkgrm(1M)

  Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

- V fs_file
  Specify an alternative fs_file to map the client’s file systems. For example, used in situations where the $root_path/etc/vfstab file is non-existent or unreliable.

Operands  The following operands are supported:

path
  The pathname to be removed.

pkginst
  The package instance from which the pathname is being removed.
Examples

**EXAMPLE 1** Using removef

The following example uses the removef command in an optional pre-install script:

```bash
echo "The following files are no longer part of this package
   and are being removed."
removef $PKGINST /myapp/file1 /myapp/file2 |
while read pathname
do
   echo "$pathname"
   rm -f $pathname
done
removef -f $PKGINST || exit 2
```

Environment Variables

`removef` inherits the value of the following environment variable. This variable is set when `pkgadd(1M)` or `pkgrm(1M)`

- **PKG_INSTALL_ROOT**
  - If present, defines the full path name of a directory to use as the system’s
    `PKG_INSTALL_ROOT` path. All product and package information files are then looked for in
    the directory tree, starting with the specified `PKG_INSTALL_ROOT` path. If not present, the
    default system path of `/` is used.

Exit Status

- **0**
  - Successful completion.
- **>0**
  - An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also

Application Packaging Developer's Guide

Notes

Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd(1M)`, `pkgtrans(1)` and other package commands can process a datastream of up to 4 GB.
repquota(1M)

Name
repquota – summarize quotas for a ufs file system

Synopsis
repquota [-v] filesystem...
repquota -a [-v]

Description
repquota prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with edquota(1M).

The filesystem must have the file quotas in its root directory.

Only the super-user may view quotas which are not their own.

Options
The following options are supported:

- a Report on all mounted ufs file systems that have rq in the mntops field of the /etc/vfstab file.

- v Report quotas for all users, even those who do not consume resources.

Usage
See largefile(5) for the description of the behavior of repquota when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>

re-preinstall(1M)

**Name**
re-preinstall – installs the JumpStart software on a system

**Synopsis**
```
cdrom-mnt-pt/Solaris_XX/Tools/Boot/usr/sbin/install.d/re-preinstall
    [-m Solaris_boot_dir]
    [-k platform_name] target-slice
```

**Description**
re-preinstall installs the JumpStart software (preinstall boot image) on a system, so you can power-on the system and have it automatically install the Solaris software (perform a JumpStart installation on the system). When you turn on a re-preinstalled system, the system looks for the JumpStart software on the system’s default boot disk. All new SPARC systems have the JumpStart software already preinstalled. The XX in Solaris_XX is the version number of the Solaris release being used.

You can use the re-preinstall command in several ways. The most common way is to run re-preinstall on a system to install the JumpStart software on its own default boot disk. This is useful if you want to restore a system to its original factory conditions. (See the first procedure described in EXAMPLES.)

You can also run re-preinstall on a system to install JumpStart software on any attached disk (non-boot disk). After you install the JumpStart software on a disk, you can move the disk to a different system and perform a JumpStart installation on the different system. (See the second procedure described in EXAMPLES.)

re-preinstall creates a standard file system on the specified target-slice (usually slice 0), and re-preinstall makes sure there is enough space on the target-slice for the JumpStart software. If sufficient space is not available, re-preinstall fails with the following message:

```
re-preinstall: target-slice too small xx Megabytes required
```

You can use the `format(1M)` command to create sufficient space on the target-slice for the JumpStart software.

**Options**
The following options are supported:

- `-k platform_name` Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. (Use the `uname(1)` command (-i option) to determine a system’s platform name.)

- `-m Solaris_boot_dir` Absolute path to the Solaris_XX/Tools/Boot subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that re-preinstall uses to install the JumpStart software. The default is root (/), which is where the Solaris CD is mounted in single-user mode.

**Operands**
The following operands are supported:

- `target-slice` Device name of the disk slice where the JumpStart software will be installed (usually slice 0), for example, c0t3d0s0.
EXAMPLE 1  Installing the JumpStart Software on a System's Own Default Boot Disk

The following procedure installs the JumpStart software on a system's own default boot disk:

1. From the ok prompt, boot the system from the Solaris media CD or DVD in single-user mode:
   
   ```
   ok boot cdrom -s
   ```

2. The following command installs the Jumpstart software on the System default boot disk, c0t0d0s0 on a Solaris system:

   ```
   example# /usr/sbin/install.d/re-preinstall c0t0d0s1
   ```

3. Reboot the slice:

   ```
   example# reboot disk:b
   ```

EXAMPLE 2  Installing the JumpStart Software on a System's Attached (non-boot) Disk

The following procedure installs the JumpStart software on a system's attached (non-boot) disk:

1. Mount the Solaris CD or DVD if `vold(1M)` is not running or CD or DVD is not mounted.

2. Use the `format(1M)` command to determine the target-slice where JumpStart will be installed.

3. Use the `uname(1)` command (`-i` option) to determine the platform name of the system that will use the re-preinstalled disk

4. Run `re-preinstall` with the `-m Solaris_boot_dir` option if the Solaris CD or DVD is not mounted on `/cdrom`.

   The following command installs the JumpStart software on the system's attached disk for a system with a Sun4u kernel architecture, and it uses the Solaris CD or DVD mounted with `vold(1M)` on a Solaris system:

   ```
   example# /cdrom/cdrom/sl/usr/bin/install.d/re-preinstall -m /cdrom/cdrom/sl -k sun4u c0t2d0s0
   ```

Exit Status  The following exit values are returned:

0  Successful completion.

1  An error has occurred.

Oracle Solaris 10 08/11 Installation Guide: Basic Installations
rmmount – removable media mounter for CD-ROM, floppy, Jaz drive, and others

/sbin/rmmount [-D]

The `rmmount` utility is a removable media mounter that is executed by Volume Management whenever a removable medium, such as a CD-ROM or a floppy, is inserted. The Volume Management daemon, `vold(1M)`, manages removable media. `rmmount` can also be called by using `volrmmount(1)`.

Upon insertion of a medium and following invocation of the `volcheck(1)` command, `rmmount` determines what type of file system (if any) is on that medium. If a file system is present, `rmmount` mounts the file system in one of the locations listed below.

For a diskette (floppy):

`/floppy/floppy0` symbolic link to mounted floppy in local floppy drive

`/floppy/floppy_name` mounted named floppy

`/floppy/unnamed_floppy` mounted unnamed floppy

For a CD-ROM or a DVD-ROM:

`/cdrom/cdrom0` symbolic link to mounted CD-ROM in local CD-ROM drive

`/cdrom/CD-ROM_name` mounted named CD-ROM

`/cdrom/CD-ROM_name/partition` mounted named CD-ROM with partitioned file system

`/cdrom/unnamed_cdrom` mounted unnamed CD-ROM

For a Zip drive:

`/rmdisk/zip0` symbolic link to mounted Zip medium in local Zip drive

`/rmdisk/Zip_name` mounted named Zip medium

`/rmdisk/Zip_name/partition` mounted named Zip medium with partitioned file system

`/rmdisk/unnamed_zip` mounted unnamed Zip medium

For a Jaz drive:

`/rmdisk/jaz0` symbolic link to mounted Jaz medium in local Jaz drive

`/rmdisk/Jaz_name` mounted named Jaz medium

`/rmdisk/Jaz_name/partition` mounted named Jaz medium with partitioned file system

`/rmdisk/unnamed_jaz` mounted unnamed Jaz medium

For a generic “rmdisk” drive:
symbolic link to mounted removable medium in local removable medium drive

mounted named removable medium

mounted named removable medium with partitioned file system

mounted unnamed removable medium

If the media is read-only (for example, a CD-ROM or a floppy with write-protect tab set), the file system is mounted read-only.

If a file system is not identified, rmmount does not mount a file system. See the System Administration Guide: Basic Administration for more information on the location of CD-ROM, floppy, and other media without file systems. Also see volfs(7FS).

If a file system type has been determined, it is then checked to see that it is “clean.” If the file system is “dirty,” fsck -p (see fsck(1M)) is run in an attempt to clean it. If fsck fails, the file system is mounted read-only.

After the mount is complete, “actions” associated with the media type are executed. These actions allow for the notification to other programs that new media are available. These actions are shared objects and are described in the configuration file, /etc/rmmount.conf. See rmmount.conf(4).

Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, rmmount performs a dlopen(3C) on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in /usr/include/rmmount.h.

File systems mounted by rmmount are always mounted with the nosuid flag set, thereby disabling setuid programs and access to block or character devices in that file system. Upon ejection, rmmount unmounts mounted file systems and executes actions associated with the media type. If a file system is “busy” (that is, it contains the current working directory of a live process), the ejection will fail.

Options  
-D Turn on the debugging output from the rmmount dprintf calls.

Files  
/etc/rmmount.conf removable media mounter configuration file
/usr/lib/rmmount/*.so.1 shared objects used by rmmount.

`System Administration Guide: Basic Administration`
rmt is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. rmt is normally started up with an reexec(3SOCKET) or rcmd(3SOCKET) call.

The rmt program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of:

A

where number is an ASCII representation of a decimal number.

Unsuccessful commands are responded to with:

E

where error-number is one of the possible error numbers described in Intro(3), and error-message is the corresponding error string as printed from a call to perror(3C).

The protocol consists of the following commands:

S

Return the status of the open device, as obtained with a MTIOCGET ioctl call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).

Cdevice

Close the currently open device. The device specified is ignored.

Ioperation\ncount

Perform a MTIOCOP ioctl(2) command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the mt_op and mt_count fields of the structure used in the ioctl call. When the operation is successful the return value is the count parameter.

Loffset\nhence

Perform an lseek(2) operation using the specified parameters. The response value is returned from the lseek call.

Odevice\nmode

Open the specified device using the indicated mode. device is a full pathname, and mode is an ASCII representation of a decimal number suitable for passing to open(9E). If a device is already open, it is closed before a new open is performed.

Rcount

Read count bytes of data from the open device. rmt performs the requested read(9E) and responds with Acount-read if the read was successful; otherwise an error in standard format is returned. If the read was successful, the data read is sent.

Wcount

Write data onto the open device. rmt reads count bytes from the connection, aborting if a premature EOF is encountered.
response value is returned from the `write(9E)` call.

Any other command causes `rmt` to exit.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWrcmdc</td>
</tr>
</tbody>
</table>

**See Also**  `ufsdump(1M), ufsrestore(1M), Intro(3), ioctl(2), lseek(2), perror(3C), rcmd(3SOCKET), rexec(3SOCKET), attributes(5), mtio(7I), open(9E), read(9E), write(9E)`

**Diagnostics**  All responses are of the form described above.

**Bugs**  Do not use this for a remote file access protocol.
rndc – name server control utility

Synopsis

rndc [-V] [-b src-addr] [-c config-file] [-k key-file] [-s server]
[-p port] [-y key_id] command

Description

The rndc utility controls the operation of a name server. It supersedes the ndc utility that was provided in previous BIND releases. If rndc is invoked with no command line options or arguments, it prints a short summary of the supported commands and the available options and their arguments.

The rndc utility communicates with the name server over a TCP connection, sending commands authenticated with digital signatures. The only supported authentication algorithm in the current versions of rndc and named(1M) is HMAC-MD5, which uses a shared secret on each end of the connection. This algorithm provides TSIG-style authentication for the command request and the name server's response. All commands sent over the channel must be signed by a key_id known to the server.

The rndc utility reads a configuration file to determine how to contact the name server and decide what algorithm and key it should use.

Options

The following options are supported:

- `b source-address`
  Use source-address as the source address for the connection to the server. Multiple instances are permitted to allow setting of both the IPv4 and IPv6 source addresses.

- `c config-file`
  Use config-file as the configuration file instead of the default /etc/rndc.conf.

- `k key-file`
  Use key-file as the key file instead of the default, /etc/rndc.key. The key in /etc/rndc.key is used to authenticate commands sent to the server if the config-file does not exist.

- `s server`
  The server argument is the name or address of the server that matches a server statement in the configuration file for rndc. If no server is supplied on the command line, the host named by the default-server clause in the options statement of the rndc configuration file is used.

- `p port`
  Send commands to TCP port port instead of BIND 9's default control channel port, 953.

- `V`
  Enable verbose logging.

- `y key_id`
  Use the key key_id from the configuration file. The key_id argument must be known by named with the same algorithm and secret string for control message validation to succeed. If no key_id is specified, rndc will first look for a key clause in the server statement of the
server being used, or if no server statement is present for that host, then the default-key clause of the options statement. The configuration file contains shared secrets that are used to send authenticated control commands to name servers. It should therefore not have general read or write access.

For the complete set of commands supported by `rndc`, see the **BIND 9 Administrator Reference Manual** or run `rndc` without arguments to see its help message.

**Limitations**

The `rndc` utility does not support all the commands of the BIND 8 `ndc` utility.

There is no way to provide the shared secret for a `key_id` without using the configuration file.

Several error messages tend toward the cryptic.

**Attributes**

**Name**  
rndc-confgen – rndc key generation tool

**Synopsis**  
rndc-confgen [-ah] [-b keysize] [-c keyfile] [-k keyname]  
[-p port] [-r randomfile] [-s address] [-t chrootdir]  
[-u user]

**Description**  
The `rndc-confgen` utility generates configuration files for `rndc(1M)`. This utility can be used as a convenient alternative to writing by hand the `rndc.conf(4)` file and the corresponding `controls` and `key` statements in `named.conf`. It can also be run with the `-a` option to set up a `rndc.key` file and avoid altogether the need for a `rndc.conf` file and a `controls` statement.

The following options are supported:

- **-a**  
  Perform automatic rndc configuration. This option creates a file `rndc.key` in `/etc` (or however `sysconfdir` was specified when BIND was built) that is read by both `rndc` and `named(1M)` on startup. The `rndc.key` file defines a default command channel and authentication key allowing `rndc` to communicate with `named` with no further configuration.

  Running `rndc-confgen` with `-a` specified allows BIND 9 and `rndc` to be used as drop-in replacements for BIND 8 and `ndc`, with no changes to the existing BIND 8 `named.conf` file.

  If a more elaborate configuration than that generated by `rndc-confgen -a` is required, for example if `rndc` is to be used remotely, you should run `rndc-confgen` without the `-a` option and set up `rndc.conf` and `named.conf` files, as directed.

- **-b keysize**  
  Specify the size of the authentication key in bits. The `keysize` argument must be between 1 and 512 bits; the default is 128.

- **-c keyfile**  
  Used with the `-a` option to specify an alternate location for `rndc.key`.

- **-h**  
  Print a short summary of the options and arguments to `rndc-confgen`.

- **-k keyname**  
  Specify the key name of the `rndc` authentication key. The `keyname` argument must be a valid domain name. The default is `rndc.key`.

- **-p port**  
  Specify the command channel port where `named` listens for connections from `rndc`. The default is 953.

- **-r randomfile**  
  Specify a source of random data for generating the authorization. By default, `/dev/random` is used. The `randomdev` argument specifies the name of a character device or file containing random data to be used instead of the default. The special value `keyboard` indicates that keyboard input should be used.
Specify the IP address where named listens for command channel connections from \texttt{rndc}.
The default is the loopback address 127.0.0.1.

\texttt{-t chrootdir}
Used with the \texttt{-a} option to specify a directory where named will run after the root directory is changed with \texttt{chroot(2)}. An additional copy of the \texttt{rndc.key} will be written relative to this directory so that it will be found by the named in the new directory.

\texttt{-u user}
Used with the \texttt{-a} option to set the owner of the \texttt{rndc.key} file generated. If \texttt{-t} is also specified only the file in the chroot area has its owner changed.

**Examples**

**EXAMPLE 1** Create Automatic \texttt{rndc} Configuration
The following command creates an automatic \texttt{rndc} configuration, so that \texttt{rndc} can be used immediately.

\begin{verbatim}
# rndc-confgen -a
\end{verbatim}

**EXAMPLE 2** Print a Sample \texttt{rndc.conf} File
The following command prints a sample \texttt{rndc.conf} file with corresponding \texttt{controls} and \texttt{key} statements. These statements can subsequently be manually inserted in the file \texttt{named.conf}.

\begin{verbatim}
# rndc-confgen
\end{verbatim}

Roleadd – administer a new role account on the system

**Synopsis**

```bash
roleadd [-c comment] [-d dir] [-e expire] [-f inactive]
[-g group] [-G group [ , group...]] [-m [-k skel_dir]]
[-u uid [-o]] [-s shell]
[-A authorization [ , authorization...]] [-K key=value] role

roleadd -D [-b base_dir] [-e expire] [-f inactive]
[-g group] [-A authorization [ , authorization...]]
[-P profile [ , profile...]] [-K key=value]
```

**Description**

Roleadd adds a role entry to the `/etc/passwd` and `/etc/shadow` and `/etc/user_attr` files. The `-A` and `-P` options respectively assign authorizations and profiles to the role. Roles cannot be assigned to other roles. The `-K` option adds a `key=value` pair to `/etc/user_attr` for a role. Multiple `key=value` pairs can be added with multiple `-K` options.

Roleadd also creates supplementary group memberships for the role (-G option) and creates the home directory (-m option) for the role if requested. The new role account remains locked until the `passwd(1)` command is executed.

Specifying `roleadd -D` with the `-g`, `-b`, `-f`, `-e`, or `-K` option (or any combination of these option) sets the default values for the respective fields. See the `-D` option. Subsequent `roleadd` commands without the `-D` option use these arguments.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit.

The role (`role`) field accepts a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underscore (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message is written if these restrictions are not met. A future Solaris release might refuse to accept role fields that do not meet these requirements.

The role field must contain at least one character and must not contain a colon (:) or a newline (`
`).

**Options**

The following options are supported:

- `-A authorization` One or more comma separated authorizations defined in `auth_attr(4)`. Only a user or role who has grant rights to the authorization can assign it to an account.

- `-b base_dir` The default base directory for the system if `-d dir` is not specified. `base_dir` is concatenated with the account name to define the home directory. If the `-m` option is not used, `base_dir` must exist.

- `-c comment` Any text string. It is generally a short description of the role. This information is stored in the role's `/etc/passwd` entry.
The home directory of the new role. It defaults to base_dir/account_name, where base_dir is the base directory for new login home directories and account_name is the new role name.

Display the default values for group, base_dir, skel_dir, shell, inactive, expire and key=value pairs. When used with the -g, -b, -f, or -K options, the -D option sets the default values for the specified fields. The default values are:

- group: other (GID of 1)
- base_dir: /home
- skel_dir: /etc/skel
- shell: /bin/pfsh
- inactive: 0
- expire: Null
- auths: Null
- profiles: Null
- key=value (pairs defined in user_attr) not present

Specify the expiration date for a role. After this date, no user is able to access this role. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

If the date format that you choose includes spaces, it must be quoted. For example, you can enter 10/6/90 or October 6, 1990. A null value (""") defeats the status of the expired date. This option is useful for creating temporary roles.

The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

An existing group’s integer ID or character-string name. Without the -D option, it defines the new role’s primary group membership and defaults to the default group. You can reset this default value by invoking roleadd -D -g group.

An existing group’s integer ID or character-string name. It defines the new role’s supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_MAX groups can be specified.
roleadd(1M)

-k skel_dir  A directory that contains skeleton information (such as .profile) that can be copied into a new role's home directory. This directory must already exist. The system provides the /etc/skel directory that can be used for this purpose.

-K key=value  A key=value pair to add to the role's attributes. Multiple -K options can be used to add multiple key=value pairs. The generic -K option with the appropriate key can be used instead of the specific implied key options (-A and -P). See user_attr(4) for a list of valid key=value pairs. The “type” key is not a valid key for this option. Keys can not be repeated.

-m  Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by group, where group is the role's primary group.

-o  This option allows a UID to be duplicated (non-unique).

-P profile  One or more comma-separated execution profiles defined in prof_attr(4).

-s shell  Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use /bin/pfsh as the default. The value of shell must be a valid executable file.

-u uid  The UID of the new role. This UID must be a non-negative decimal integer below MAXUID as defined in <sys/param.h>. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number is 201. (UIDs from 0-99 are reserved for possible use in future applications.)

Files  /etc/datemsk
        /etc/passwd
        /etc/shadow
        /etc/group
        /etc/skel
        /usr/include/limits.h
        /etc/user_attr

Attributes  See attributes(5) for descriptions of the following attributes:
roleadd(1M)

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>

Diagnostics  In case of an error, roleadd prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

UX: roleadd: ERROR: login is already in use. Choose another.

The following indicates that the uid specified with the -u option is not unique:

UX: roleadd: ERROR: uid uid is already in use. Choose another.

The following indicates that the group specified with the -g option is already in use:

UX: roleadd: ERROR: group group does not exist. Choose another.

The following indicates that the uid specified with the -u option is in the range of reserved UIDs (from 0-99):

UX: roleadd: WARNING: uid uid is reserved.

The following indicates that the uid specified with the -u option exceeds MAXUID as defined in <sys/param.h>:

UX: roleadd: ERROR: uid uid is too big. Choose another.

The following indicates that the /etc/passwd or /etc/shadow files do not exist:

UX: roleadd: ERROR: Cannot update system files - login cannot be created.

Notes  If a network nameservice such as NIS or NIS+ is being used to supplement the local /etc/passwd file with additional entries, roleadd cannot change information supplied by the network nameservice.
Name

roledel – delete a role’s login from the system

Synopsis

roledel [-r] role

Description

The roledel utility deletes a role account from the system and makes the appropriate
account-related changes to the system file and file system. roledel also removes the role from
each user’s list of assumable roles.

Options

The following options are supported:

- r  Remove the role’s home directory from the system. This directory must exist. The files
and directories under the home directory will no longer be accessible following
successful execution of the command.

Operands

The following operands are supported:

role  An existing role name to be deleted.

Exit Status

The following exit values are returned:

0  Successful completion.
2  Invalid command syntax. A usage message for the roledel command is displayed.
6  The account to be removed does not exist.
8  The account to be removed is in use.
10  Cannot update the /etc/group or /etc/user_attr file but the login is removed from
the /etc/passwd file.
12  Cannot remove or otherwise modify the home directory.

Files

/etc/passwd  system password file
/etc/shadow  system file containing roles’ encrypted passwords and related
information
/etc/group  system file containing group definitions
/etc/user_attr  system file containing additional role attributes

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also

auths(1), passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M),
groupmod(1M), logins(1M), roleadd(1M), rolemod(1M), useradd(1M), userdel(1M),
usermod(1M), passwd(4), prof_attr(4), user_attr(4), attributes(5)
Notes  The `roledel` utility only deletes an account definition that is in the local `/etc/group`, `/etc/passwd`, `/etc/shadow`, and `/etc/user_attr` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `roledel` cannot change information supplied by the network name service.
rolemod(1M)

Name
rolemod – modify a role’s login information on the system

Synopsis
rolemod [-u uid [-o]] [-g group] [-G group [ , group ...]]
   [-d dir [-m]] [-s shell] [-c comment] [-l new_name]
   [-f inactive] [-e expire]
   [-A authorization [ , authorization]]
   [-P profile [ , profile]] [-K key=value] role

Description
The rolemod utility modifies a role’s login information on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.

Options
The following options are supported:

-A authorization
   One or more comma separated authorizations as defined in auth_attr(4). Only roles with grant rights to the authorization can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

-c comment
   Specify a comment string. comment can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s /etc/passwd entry.

-d dir
   Specify the new home directory of the role. It defaults to base_dir/login, where base_dir is the base directory for new login home directories, and login is the new login.

-e expire
   Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

   For example, you may enter 10/6/90 or October 6, 1990. A value of "" defeats the status of the expired date.

-f inactive
   Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

-g group
   Specify an existing group’s integer ID or character-string name. It redefines the role’s primary group membership.
-G group
Specify an existing group's integer ID or character string name. It redefines the role's supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_U_MAX groups may be specified as defined in <param.h>.

-K key=value
Replace existing or add to a role's key=value pair attributes. Multiple -K options can be used to replace or add multiple key=value pairs. However, keys must not be repeated. The generic -K option with the appropriate key may be used instead of the specific implied key options (-A and -P). See user_attr(4) for a list of valid key=value pairs.

The keyword type can be specified with the value role or the value normal. When using the value normal, the account changes from a role user to a normal user; using the value role keeps the account a role user.

-\ new_logname
Specify the new login name for the role. The new_logname argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The new_logname argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).

-m
Move the role's home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by group, where group is the role's primary group.

-o
This option allows the specified UID to be duplicated (non-unique).

-P profile
One or more comma-separated execution profiles defined in auth_attr(4). This replaces any existing profile setting. If no profile list is specified, the existing setting is removed.

-s shell
Specify the full pathname of the program that is used as the role's shell on login. The value of shell must be a valid executable file.

-u uid
Specify a new UID for the role. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the role's home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using chown(1).
The following operands are supported:

login
   An existing login name to be modified.

Exit Status  In case of an error, rolemod prints an error message and exits with one of the following values:

2
   The command syntax was invalid. A usage message for the rolemod command is displayed.

3
   An invalid argument was provided to an option.

4
   The uid given with the -u option is already in use.

5
   The password files contain an error. pwconv(1M) can be used to correct possible errors. See passwd(4).

6
   The login to be modified does not exist, the group does not exist, or the login shell does not exist.

8
   The login to be modified is in use.

9
   The new_logname is already in use.

10
   Cannot update the /etc/group or /etc/user_attr file. Other update requests will be implemented.

11
   Insufficient space to move the home directory (-m option). Other update requests will be implemented.

12
   Unable to complete the move of the home directory to the new home directory.

Files

/etc/group
   system file containing group definitions

/etc/datemsk
   system file of date formats

/etc/passwd
   system password file

/etc/shadow
   system file containing users’ and roles’ encrypted passwords and related information
/etc/user_attr
    system file containing additional user and role attributes

The `root_archive` utility is used to manipulate boot archives and the bootable miniroot(s) in a Solaris install image. The utility can pack and unpack boot archives and image miniroots. Both ufs and hsfs (iso9660) format archives can be unpacked, although only ufs format is generated when packing.

For normal, boot-related system administration, `bootadm(1M)` is recommended. `root_archive`'s primary purpose is to enable OEMs to add or update a driver or other component on the Solaris install media.

A miniroot and a boot archive is closely associated with the release it is intended to boot. To ensure that the tools and system services used to construct the miniroot match, miniroot manipulation must be performed only on a system running the same release for which the miniroot is intended to install.

The `root_archive` command has the following subcommands:

- `pack archive root`: Pack the contents of the root directory into the boot archive `archive`.
- `unpack archive root`: Unpack the contents of the boot archive named `archive` to the directory named `root`.
- `packmedia solaris_image root`: Create and pack the miniroot(s) in `solaris_image` from the contents of the directory named `root`.
- `unpackmedia solaris_image root`: Unpack the contents of the miniroot(s) in `solaris_image` to the directory named `root`.

The contents of a miniroot are constructed to need the requirements of the release. When unpacking a miniroot, all the contents of the miniroot(s) are unpacked. When packing a miniroot, the source directory must contain all the necessary components with which to construct a miniroot. In general, this can only be achieved by first unpacking an existing miniroot.

**Examples**

**EXAMPLE 1** Unpacking the Miniroots in a Solaris x86 Install Image

The following command unpacks the miniroots in a Solaris image to the root directory in `/export/release/latest`.

```
# root_archive unpackmedia \\
/export/nv/solarisdvd.nvx_dvd/latest /export/release/latest/root
```
EXAMPLE 1  Unpacking the Miniroots in a Solaris x86 Install Image  (Continued)

In the preceding, /export/nv/solarisdvd.nvx_dvd/latest represents a path to a Solaris x86 install image and /export/release/latest/root is a directory that will be purged or created, as necessary.

EXAMPLE 2  Packing the Miniroots in a Solaris x86 Install Image

The following command creates and packs the miniroot(s) in a Solaris image from the contents of the directory /export/release/latest/root.

# root_archive packmedia \n/export/nv/solarisdvd.nvx_dvd/latest /export/release/latest/root

**Exit Status**  The following exit values are returned:

- 0  The command completed successfully.
- 1  The command exited due to an error.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

route(1M)

Name  route – manually manipulate the routing tables

Synopsis  route [-fnvq] sub-command [ [modifiers] args]
          route [-fnvq] [-p [-R root-dir]] add | delete [modifiers] destination gateway [args]
          route [-fnvq] change | get [modifiers] destination [gateway [args]]
          route [-fn] monitor [modifiers]
          route [-fnvq] flush [modifiers]
          route -p [-R root-dir] show

Description  route manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, such as in.routed(1M) and in.ripngd(1M).

route supports a limited number of general options, but a rich command language. Users can specify an arbitrary request that can be delivered by means of the programmatic interface discussed in route(7P).

route uses a routing socket and the new message types RTM_ADD, RTM_DELETE, RTM_GET, and RTM_CHANGE. While only superusers can modify routing tables, the RTM_GET operation is allowed for non-privileged users.

Options  -f  Flush the routing tables of all gateway entries. If you use the -f option in conjunction with any of the route sub-commands, route flushes the gateways before performing the sub-command. Specify the table to flush by placing the inet or inet6 modifier immediately after the -f option. If unspecified, flushing IPv4 (inet) routes is the default.

-n  Prevent attempts to print host and network names symbolically when reporting actions. This option is useful when name servers are unavailable.

-p  Make changes to the network route tables persistent across system restarts. The operation is applied to the network routing tables first and, if successful, is then applied to the list of saved routes used at system startup. In determining whether an operation was successful, a failure to add a route that already exists or to delete a route that is not in the routing table is ignored. Particular care should be taken when using host or network names in persistent routes, as network-based name resolution services are not available at the time routes are added at startup.

-q  Suppress all output.

-R root-dir  Specify an alternate root directory where route applies changes. This option is ignored unless used in conjunction with the -p option. When -R is specified, route changes are applied only to the list of saved routes to be used at startup, not to the network routing tables. In addition, certain checks, such as the
existence of network interfaces used with -ifp, are skipped. This can be useful from within JumpStart scripts, where the root directory of the system being modified is in a location other than /.

-v Print additional details in verbose mode.

Subcommands

The following subcommands are supported:

**add**
Add a route.

**change**
Change aspects of a route (such as its gateway).

**delete**
Delete a specific route.

**flush**
Remove all gateway entries from the routing table.

**get**
Look up and display the route for a destination.

**monitor**
Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings.

**show**
Display the list of routes to be applied at system startup. Can be used only in conjunction with the -p option.

The add and delete sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination gateway [metric/netmask]
```

where cmd is add or delete, destination is the destination host or network, and gateway is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The get and change sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination [gateway [metric/netmask]]
```

where cmd is get or change, destination is the destination host or network, and gateway is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The monitor sub-command has the following syntax:

```
route monitor [ -inet | -inet6 ]
```

Operands

route executes its sub-commands on routes to destinations by way of gateways.

Destinations and Gateways

By default, destination and gateway addresses are interpreted as IPv4 addresses. All symbolic names are tried first as a host name, using getipnodebyname(3SOCKET). If this lookup fails in the AF_INET case, getnetbyname(3SOCKET) interprets the name as that of a network.
Including an optional modifier on the command line before the address changes how the route sub-command interprets it.

The following modifiers are supported:

- **-inet** Force the address to be interpreted as an IPv4 address, that is, under the `AF_INET` address family.
- **-inet6** Force the address to be interpreted as an IPv6 address, that is, under the `AF_INET6` address family.

For IPv4 addresses, routes to a particular host are by default distinguished from those to a network by interpreting the Internet address specified as the destination. If the destination has a **local address part** (that is, the portion not covered by the netmask) of 0, or if the destination is resolved as the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

You can force this selection by using one of the following modifiers:

- **-host** Force the destination to be interpreted as a host.
- **-net** Force the destination to be interpreted as a network.

For example:

<table>
<thead>
<tr>
<th>Destination</th>
<th>Destination Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>128.32</td>
<td>-host 128.0.0.32</td>
</tr>
<tr>
<td>128.32.130</td>
<td>-host 128.32.0.130</td>
</tr>
<tr>
<td>-net 128.32</td>
<td>128.32.0.0</td>
</tr>
<tr>
<td>-net 128.32.130</td>
<td>128.32.130.0</td>
</tr>
</tbody>
</table>

Two modifiers avoid confusion between addresses and keywords (for example., `host` used as a symbolic host name). You can distinguish a **destination** by preceding it with the `-dst` modifier. You can distinguish a gateway address by using the `-gateway` modifier. If the destination is directly reachable by way of an interface requiring no intermediary IP router to act as a gateway, this can be indicated by using the `-interface` or `-iface` modifier.

In the following example, the route does not refer to an external gateway (router), but rather to one of the machine's interfaces. Packets with IP destination addresses matching the destination and mask on such a route are sent out on the interface identified by the gateway address. For interfaces using the ARP protocol, this type of route is used to specify that all matching destinations are local to the physical link. That is, a host could be configured to ARP for all addresses, without regard to the configured interface netmask, by adding a default route using this command. For example:
example# route add default hostname -interface

where gateway address hostname is the name or IP address associated with the network interface over which all matching packets should be sent. On a host with a single network interface, hostname is usually the same as the nodename returned by the uname -n command. See uname(1).

For backward compatibility with older systems, directly reachable routes can also be specified by placing a 0 after the gateway address:

example# route add default hostname 0

This value was once a route metric, but this metric is no longer used. If the value is specified as 0, then the destination is directly reachable (equivalent to specifying -interface). If it is non-zero but cannot be interpreted as a subnet mask, then a gateway is used (default).

With the AF_INET address family or an IPv4 address, a separate subnet mask can be specified. This can be specified in one of the following ways:

- IP address following the gateway address. This is typically specified in decimal dot notation as for inet_addr(3SOCKET) rather than in symbolic form.
- IP address following the -netmask qualifier.
- Slash character and a decimal length appended to the destination address.

If a subnet mask is not specified, the mask used is the subnet mask of the output interface selected by the gateway address, if the classful network of the destination is the same as the classful network of the interface. Otherwise, the classful network mask for the destination address is used.

Each of the following examples creates an IPv4 route to the destination 192.0.2.32 subnet with a subnet mask of 255.255.255.224:

example# route add 192.0.2.32/27 somegateway
example# route add 192.0.2.32 -netmask 255.255.255.224 somegateway
example# route add 192.0.2.32 somegateway 255.255.255.224

For IPv6, only the slash format is accepted. The following example creates an IPv6 route to the destination 3ffe:: with a netmask of 16 one-bits followed by 112 zero-bits.

example# route add -inet6 3ffe::/16 somegateway

In cases where the gateway does not uniquely identify the output interface (for example, when several interfaces have the same address), you can use the -ifp ifname modifier to specify the interface by name. For example, -ifp lo0 associates the route with the lo0 interface.

Routing Flags Routes have associated flags that influence operation of the protocols when sending to destinations matched by the routes. These flags can be set (and in some cases cleared, indicated by ~) by including the following modifiers on the command line:
<table>
<thead>
<tr>
<th>Modifier</th>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-interface</td>
<td>-RTF_GATEWAY</td>
<td>Destination is directly reachable</td>
</tr>
<tr>
<td>-iface</td>
<td>-RTF_GATEWAY</td>
<td>Alias for interface modifier</td>
</tr>
<tr>
<td>-static</td>
<td>RTF_STATIC</td>
<td>Manually added route</td>
</tr>
<tr>
<td>-nostatic</td>
<td>-RTF_STATIC</td>
<td>Pretend route was added by kernel or routing daemon</td>
</tr>
<tr>
<td>-reject</td>
<td>RTF_REJECT</td>
<td>Emit an ICMP unreachable when matched</td>
</tr>
<tr>
<td>-blackhole</td>
<td>RTF_BLACKHOLE</td>
<td>Silently discard packets during updates</td>
</tr>
<tr>
<td>-proto1</td>
<td>RTF_PROTO1</td>
<td>Set protocol specific routing flag #1</td>
</tr>
<tr>
<td>-proto2</td>
<td>RTF_PROTO2</td>
<td>Set protocol specific routing flag #2</td>
</tr>
<tr>
<td>-private</td>
<td>RTF_PRIVATE</td>
<td>Do not advertise this route</td>
</tr>
<tr>
<td>-multirt</td>
<td>RTF_MULTIRT</td>
<td>Creates the specified redundant route</td>
</tr>
<tr>
<td>-setsrc</td>
<td>RTF_SETSRC</td>
<td>Assigns the default source address</td>
</tr>
</tbody>
</table>

The optional modifiers -rtt, -rttvar, -sendpipe, -recvpipe, -mtu, -hopcount, -expire, and -ssthresh provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These can be individually locked either by preceding each modifier to be locked by the -lock meta-modifier, or by specifying that all ensuing metrics can be locked by the -lockrest meta-modifier.

Some transport layer protocols can support only some of these metrics. The following optional modifiers are supported:

- expire  Lifetime for the entry. This optional modifier is not currently supported.
- hopcount Maximum hop count. This optional modifier is not currently supported.
- mtu     Maximum MTU in bytes.
- recvpipe Receive pipe size in bytes.
- rtt     Round trip time in microseconds.
- rttvar  Round trip time variance in microseconds.
- sendpipe Send pipe size in bytes.
- ssthresh Send pipe size threshold in bytes.
- secattr Security attributes of the route. This modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

The -secattr modifier has the following format:

```
min_sl=val, max_sl=val, doi=val, cipso
```
or:

```
sl=VAL,doi=VAL,cipso
```

In the first form, above, the `val` for `min_sl` and `max_sl` is a sensitivity label in either hex or string form. The `val` for `doi` is a non-negative integer. The route will apply only for packets with the same domain of interpretation as defined by the `doi` value and within the accreditation range defined by the `min_sl` and `max_sl` values. The `cipso` keyword is optional and set by default. Valid `min_sl`, `max_sl` and `doi` keyword/value pairs are mandatory. Note that if `val` contains a space, it must be protected by double quotes.

The second form, above, is equivalent to specifying the first form with the same `VAL` for `min_sl` and `max_sl`. The second form should be used for the `get` command, because `get` uses only a single sensitivity label.

**Compatibility**
The modifiers `host` and `net` are taken to be equivalent to `-host` and `-net`. To specify a symbolic address that matches one of these names, use the `dst` or `gateway` keyword to distinguish it. For example: `-dst host`

The following two flags are also accepted for compatibility with older systems, but have no effect.

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Flag</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-cloning</code></td>
<td>RTF_CLONING</td>
</tr>
<tr>
<td><code>-xresolve</code></td>
<td>RTF_XRESOLVE</td>
</tr>
</tbody>
</table>

The `-ifa hostname` modifier is also accepted, but has no effect.

**Files**
- `/etc/defaultrouter` List of default routers
- `/etc/hosts` List of host names and net addresses
- `/etc/networks` List of network names and addresses

**Attributes** See `attributes(5)` for descriptions of the following attributes:

Diagnoses: add [ host | network ] destination:gatewayflags

The specified route is being added to the tables. The values printed are from the
routing table entry supplied in the ioctl(2) call. If the gateway address
used was not the primary address of the gateway (the first one returned by
getipnodebyname(3SOCKET)) the gateway address is printed
numerically as well as symbolically.

deleเทe| host | network ] destination:gatewayflags

As add, but when deleting or changing
an entry.

der ty tination done

As add, but when deleting or changing
an entry.

Network is unreachable

An attempt to add a route failed
because the gateway listed was not on
a directly-connected network. Give
the next-hop gateway instead.

not in table

A delete operation was attempted for
an entry that is not in the table.

entry exists

An add operation was attempted for a
route that already exists in the kernel.

routing table overflow

An operation was attempted, but the
system was unable to allocate memory
to create the new entry.

insufficient privileges

An attempt to add, delete, change, or
flush a route failed because the calling
process does not have appropriate
privileges.

Notes: Specifying that destinations are local (with the -interface modifier) assumes that the routers
implement proxy ARP, meaning that they respond to ARP queries for all reachable
destinations. Normally, using either router discovery or RIP is more reliable and scalable than
using proxy ARP. See in.routed(1M) for information related to RIP.

Combining the all destinations are local route with subnet or network routes can lead to
unpredictable results. The search order as it relates to the all destinations are local route are
undefined and can vary from release to release.
routeadm (1M)

**Name**
routeadm – IP forwarding and routing configuration

**Synopsis**

```
routeadm [-p [option]]
routeadm [-R root-dir] [-e option ...] [-d option ...]
            [-r option...] [-s var=value]
routeadm [-l fmri]
routeadm [-m fmri key=value [key=value]...]
routeadm [-u]
```

**Description**
The `routeadm` command is used to administer system-wide configuration for IP forwarding and routing. IP forwarding is the passing of IP packets from one network to another; IP routing is the use of a routing protocol to determine routes.

IP forwarding and routing functions are also represented as services within the service management facility (SMF), and can be administered by means of `svcadm(1M)` also, using the following fault management resource identifiers (FMRIs):

```
svc:/network/ipv4-forwarding:default
svc:/network/ipv6-forwarding:default
svc:/network/routing/route:default
svc:/network/routing/ripng:default
```

See EXAMPLES for relevant examples.

In addition to enabling and disabling routing and forwarding, `routeadm` is used to interact with SMF-based routing daemon services. Routing daemon services are identified by the presence of a `routeadm` application property group, which `routeadm` uses in administering the given service. Routing daemon services can also specify properties relating to their operation in the `routing` application property group; these can be modified by means of `routeadm -m`. If an FMRI for a service without such a property group is specified, an error is issued and the operation is not carried out. If a routing daemon has not been converted to SMF, the `ipv4/or 6]-routing-daemon, ipv4/or 6]-routing-daemon-args, and ipv4/or 6]-routing-stop-cmd` variables can be used to specify the appropriate daemon for IPv4 or IPv6 routing. `routeadm` will then run that daemon using the `svc:/network/routing/legacy-routing:ipv4/or 6]` service as appropriate. This conversion process occurs when you issue an enable (-e), disable (-d) or an update (-u) command.

The first usage, in the SYNOPSIS above, reports the current configuration.

**Options**
The following command-line options are supported:

```
-p [option]
```

Print the configuration in parseable format. If option is specified, only the configuration for the specified option or variable is displayed.
-R root-dir
Specify an alternate root directory where routeadm applies changes. This can be useful from within JumpStart scripts, where the root directory of the system being modified is mounted elsewhere.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-e option...
Enable the specified option. The effect is to prepare the associated services 
(svc:/network/ipv4-forwarding:default in the case of ipv4-forwarding) for enabling. 
By means of the routing-svcs variable, the routing daemons are specified to be enabled on subsequent boot or when routeadm -u is run.

-d option...
Disable the specified option. The effect is to prepare the associated services 
(svc:/network/ipv4-forwarding:default in the case of ipv4-forwarding) for enabling. 
By means of the routing-svcs variable, the routing daemons are specified to be disabled on subsequent boot or when routeadm -u is run.

-fmri
List all properties in the routing application property group for the SMF routing daemon service.

-m fmri key=value
Change property value of property key to value in routing application property group for the SMF routing daemon service. For multi-valued properties, the property name can be used multiple times in the modify operation, and each associated value will be added.

-r option...
Revert the specified option to the system default. The system defaults are specified in the description of each option.

-u
Apply the currently configured options to the running system. These options might include enabling or disabling IP forwarding and launching or killing routing daemons, if any are specified. It does not alter the state of the system for those settings that have been set to default. This option is meant to be used by administrators who do not want to reboot to apply their changes. In addition, this option upgrades non-SMF configurations from the invocations of daemon stop commands, which might include a set of arguments, to a simple enabling of the appropriate service.

-s key=value
Specify string values for specific variables in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is displayed and the program exits. The following variables can be specified:
specifying the routing daemons to be enabled. Routing daemons are determined to be IPv4 or IPv6 (and so enabled or disabled when `routeadm -e/-d ipv4(6)` is run) on the basis of property values in the `routeadm` application property group. Default: `route:default ripng:default`.

**ipv4-routing-daemon=**<full_path_to_routing_daemon>
Specifies the routing daemon to be started when `ipv4-routing` is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: **

**ipv4-routing-daemon-args=**<args>
Specifies the startup arguments to be passed to the `ipv4-routing-daemon` when `ipv4-routing` is enabled. Default: no arguments

**ipv4-routing-stop-cmd=**<command>
Specifies the command to be executed to stop the routing daemon when `ipv4-routing` is disabled. `<command>` can be an executable binary or shell-script, or a string that can be parsed by `system(3C)`. Default: **

**ipv6-routing-daemon=**<full_path_to_routing_daemon>
Specifies the routing daemon to be started when `ipv6-routing` is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: **

**ipv6-routing-daemon-args=**<args>
Specifies the startup arguments to be passed to the `ipv6-routing-daemon` when `ipv6-routing` is enabled. Default: **

**ipv6-routing-stop-cmd=**<command>
Specifies the command to be executed to stop the routing daemon when `ipv6-routing` is disabled. `<command>` can be an executable binary or shell-script, or a string that can be parsed by `system(3C)`. Default: **

Multiple `-e`, `-d`, and `-r` options can be specified on the command line. Changes made by `-e`, `-d`, and `-r` are persistent, but are not applied to the running system unless `routeadm` is called later with the `-u` option.

Use the following options as arguments to the `-e`, `-d`, and `-r` options (shown above as `option...`).

**ipv4-forwarding**
Controls the global forwarding configuration for all IPv4 interfaces. The system default is disabled. If enabled, IP will forward IPv4 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv4 packets to and from interfaces when appropriate. The SMF service associated with this configuration variable is
ipv4-forwarding

This service will be enabled or disabled as appropriate when `routeadm` is called with the `u` option. As an alternative, you can use `svcadm(1M)`. Services that require `ipv4-forwarding` to be enabled should specify a dependency on this service.

ipv4-routing

Determines whether an IPv4 routing daemon is run. The system default is enabled unless the `/etc/default/remote` file exists (see `defaultrouter(4)`), in which case the default is disabled. The value of this option reflects the state of all IPv4 routing services, such that if any IPv4 routing service is enabled, `ipv4-forwarding` is enabled. This allows users to interact with routing services using `svcadm(1M)`, as well as through `routeadm`. IPv4 routing services, specified by means of the `routing-svcs` variable, will be prepared for enable on next boot when the user explicitly enables `ipv4-forwarding`. The SMF routing daemon service for `in.routed (svc:/network/routing/route:default)` is specified by default.

ipv6-forwarding

Controls the global forwarding configuration for all IPv6 interfaces. The system default is disabled. If enabled, IP will forward IPv6 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv6 packets to and from interfaces when appropriate. The SMF service associated with this configuration variable is `svc:/network/routing/ipv6-forwarding`. This service will be enabled or disabled as appropriate when `routeadm` is called with the `-u` option, or `svcadm(1M)` is used. Services that require `ipv6-forwarding` to be enabled should specify a dependency on this service.

ipv6-routing

Determines whether an IPv6 routing daemon is run. The system default is disabled. The value of this option reflects the state of all IPv6 routing services, such that, if any IPv6 routing service is enabled, `ipv6-forwarding` is enabled. This allows users to interact with routing services via `svcadm(1M)` as well as through `routeadm`. IPv6 routing services, specified by means of the `routing-svcs` variable, will be prepared for enable on next boot when the user explicitly enables `ipv6-forwarding`. The SMF routing daemon service for `in.ripngd (svc:/network/routing/ripng:default)` is specified by default.

The forwarding and routing settings are related but not mutually dependent. For example, a router typically forwards IP packets and uses a routing protocol, but nothing would prevent an administrator from configuring a router that forwards packets and does not use a routing protocol. In that case, the administrator would enable forwarding, disable routing, and populate the router's routing table with static routes.

The forwarding settings are global settings. Each interface also has an `IFF_ROUTER` forwarding flag that determines whether packets can be forwarded to or from a particular interface. That flag can be independently controlled by means of `ifconfig(1M)`'s `router` option. When the global forwarding setting is changed (that is, `-u` is issued to change the value from enabled to disabled or vice-versa), all interface flags in the system are changed simultaneously to reflect the new global policy. Interfaces configured by means of DHCP automatically have their interface-specific `IFF_ROUTER` flag cleared.
When a new interface is plumbed by means of `ifconfig`, the value of the interface-specific forwarding flag is set according to the current global forwarding value. Thus, the forwarding value forms the "default" for all new interfaces.

**Examples**

**EXAMPLE 1**  Enabling IPv4 Forwarding
IPv4 forwarding is disabled by default. The following command enables IPv4 forwarding:

```
example# routeadm -e ipv4-forwarding
```

**EXAMPLE 2**  Apply Configured Settings to the Running System
In the previous example, a system setting was changed, but will not take effect until the next reboot unless a command such as the following is used:

```
example# routeadm -u
```

An alternative to the above two steps is to simply enable the equivalent SMF service:

```
example# svcadm enable svc:/network/ipv4-forwarding
```

...or, using the abbreviated FMRI:

```
example# svcadm enable ipv4-forwarding
```

**EXAMPLE 3**  Making a Setting Revert to its Default
To make the setting changed in the first example revert to its default, enter the following:

```
example# routeadm -r ipv4-forwarding
example# routeadm -u
```

**EXAMPLE 4**  Starting `in.routed` with the `-q` Flag
Setting the `-q` flag is represented in the SMF service by setting the `quiet_mode` property to true. The following sequence of commands starts `in.routed` with the `-q` flag:

```
example# routeadm -m route:default quiet_mode=true
example# routeadm -e ipv4-routing -u
```

See `in.routed(1M)` for details of property names and how they relate to daemon behavior.

**Exit Status**  The following exit values are returned:

- 0  Successful completion.
- !=0  An error occurred while obtaining or modifying the system configuration.

**Files**  `/etc/inet/routing.conf`  Parameters for IP forwarding and routing. (Not to be edited.)

**rpcbind(1M)**

**Name**  
rpcbind – universal addresses to RPC program number mapper

**Synopsis**  
rpcbind [-d] [-w]

**Description**  
rpcbind is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.

When an RPC service is started, it tells rpcbind the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts rpcbind on the server machine to determine the address where RPC requests should be sent.

rpcbind should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so rpcbind must be started before port monitors are invoked.

When rpcbind is started, it checks that certain name-to-address translation calls function correctly. If they fail, the network configuration databases can be corrupt. Since RPC services cannot function correctly in this situation, rpcbind reports the condition and terminates.

rpcbind maintains an open transport end for each transport that it uses for indirect calls. This is the UDP port on most systems.

The rpcbind service is managed by the service management facility, *smf*(5), under the service identifier:

svc:/network/rpc/bind

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). rpcbind can only be started by the superuser or someone in the Primary Administrator role.

The configuration properties of this service can be modified with svccfg(1M).

The following SMF property is used to allow or disallow access to rpcbind by remote clients:

```plaintext
config/local_only = true
```

The default value, true, shown above, disallows remote access; a value of false allows remote access. See EXAMPLES.

The FMRI svc:network/rpc/bind property group config contains the following property settings:

```plaintext
enable_tcpwrappers
```

Specifies that the TCP wrappers facility is used to control access to TCP services. The value true enables checking. The default value for enable_tcpwrappers is false. If the enable_tcpwrappers parameter is enabled, then all calls to rpcbind originating from non-local addresses are automatically wrapped by the TCP wrappers facility. The syslog facility code daemon is used to log
allowed connections (using the info severity level) and denied traffic (using the warning severity level). See syslog.conf(4) for a description of syslog codes and severity levels. The stability level of the TCP wrappers facility and its configuration files is External. As the TCP wrappers facility is not controlled by Sun, intrarelase incompatibilities are not uncommon. See attributes(5).

**verbose_logging**

Specifies whether the TCP wrappers facility logs all calls or just the denied calls. The default is false. This option has no effect if TCP wrappers are not enabled.

**allow_indirect**

Specifies whether rpcbind allows indirect calls at all. By default, rpcbind allows most indirect calls, except to a number of standard services (keyserv, automount, mount, nfs, rquota, and selected NIS and rpcbind procedures). Setting allow_indirect to false causes all indirect calls to be dropped. The default is true. NIS broadcast clients rely on this functionality on NIS servers.

### Options

The following options are supported:

- `-d`
  Run in debug mode. In this mode, rpcbind does not fork when it starts. It prints additional information during operation, and aborts on certain errors. With this option, the name-to-address translation consistency checks are shown in detail.

- `-w`
  Do a warm start. If rpcbind aborts or terminates on SIGINT or SIGTERM, it writes the current list of registered services to /var/run/portmap.file and /var/run/rpcbind.file. Starting rpcbind with the `-w` option instructs it to look for these files and start operation with the registrations found in them. This allows rpcbind to resume operation without requiring all RPC services to be restarted.

### Examples

**EXAMPLE 1**

Allowing Remote Access

The following sequence of commands allows remote access to rpcbind.

```
# svccfg -s svc:/network/rpc/bind setprop config/local_only = false
# svcadm refresh svc:/network/rpc/bind
```

### Files

- `/var/run/portmap.file`
  Stores the information for RPC services registered over IP based transports for warm start purposes.

- `/var/run/rpcbind.file`
  Stores the information for all registered RPC services for warm start purposes.

### Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
TCP wrappers is External.

**See Also**  
smf(5), rpcinfo(1M), svcadm(1M), svccfg(1M), rpcbind(3NSL), syslog.conf(4), attributes(5), smf(5)

For information on the TCP wrappers facility, see the hosts_access(4) man page, delivered as part of the Solaris operating environment in /usr/sfw/man and available in the SUNWtcpd package.

**Notes**  
Terminating rpcbind with SIGKILL prevents the warm-start files from being written.

All RPC servers are restarted if the following occurs: rpcbind crashes (or is killed with SIGKILL) and is unable to to write the warm-start files; rpcbind is started without the -w option after a graceful termination. Otherwise, the warm start files are not found by rpcbind.
rpc.bootparamd(1M)

Name  rpc.bootparamd, bootparamd – boot parameter server

Synopsis  /usr/sbin/rpc.bootparamd [-d]

Description  rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See bootparams(4)

The source for the bootparams database is determined by the nsswitch.conf(4) file (on the machine running the rpc.bootparamd process).

Options  The following options are supported:

- -d  Display debugging information.

Files  /etc/bootparams  boot parameter database

/etc/nsswitch.conf  configuration file for the name-service switch

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbsu</td>
</tr>
</tbody>
</table>

See Also  svcs(1), svcadm(1M), bootparams(4), nsswitch.conf(4), attributes(5), smf(5)

Notes  A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

The rpc.bootparamd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/bootparams

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
rpcinfo(1M)

Name  rpcinfo - report RPC information

Synopsis  rpcinfo [-m | -s] [host]

            rpcinfo -p [host]

            rpcinfo -T transport host prognum [versnum]

            rpcinfo -l [-T transport] host prognum versnum

            rpcinfo [-n portnum] -u host prognum [versnum]

            rpcinfo [-n portnum] -t host prognum [versnum]

            rpcinfo -a serv_address -T transport prognum [versnum]

            rpcinfo -b [-T transport] prognum versnum

            rpcinfo -d [-T transport] prognum versnum

Description  rpcinfo makes an RPC call to an RPC server and reports what it finds.

In the first synopsis, rpcinfo lists all the registered RPC services with rpcbind on host. If host
is not specified, the local host is the default. If -s is used, the information is displayed in a
concise format.

In the second synopsis, rpcinfo lists all the RPC services registered with rpcbind, version 2.
Note that the format of the information is different in the first and second synopsis. This is
because the second synopsis is an older protocol used to collect the information displayed
(version 2 of the rpcbind protocol).

The third synopsis makes an RPC call to procedure 0 of prognum and versnum on the specified
host and reports whether a response was received. transport is the transport which has to be
used for contacting the given service. The remote address of the service is obtained by making
a call to the remote rpcbind.

The prognum argument is a number that represents an RPC program number (see rpc(4)).

If a versnum is specified, rpcinfo attempts to call that version of the specified prognum.
Otherwise, rpcinfo attempts to find all the registered version numbers for the specified
prognum by calling version 0, which is presumed not to exist; if it does exist, rpcinfo attempts
to obtain this information by calling an extremely high version number instead, and attempts
to call each registered version. Note that the version number is required for -b and -d options.

The EXAMPLES section describe other ways of using rpcinfo.

Options  -T transport  Specify the transport on which the service is required. If this option is not
specified, rpcinfo uses the transport specified in the NETPATH
environment variable, or if that is unset or NULL, the transport in the
netconfig(4) database is used. This is a generic option, and can be used in
conjunction with other options as shown in the SYNOPSIS.
-a serv_address

Use serv_address as the (universal) address for the service on transport to ping procedure 0 of the specified prognum and report whether a response was received. The -T option is required with the -a option. If versnum is not specified, rpcinfo tries to ping all available version numbers for that program number. This option avoids calls to remote rpcbind to find the address of the service. The serv_address is specified in universal address format of the given transport.

-b

Make an RPC broadcast to procedure 0 of the specified prognum and versnum and report all hosts that respond. If transport is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.

-d

Delete registration for the RPC service of the specified prognum and versnum. If transport is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser, who can delete any service.

-l

Display a list of entries with a given prognum and versnum on the specified host. Entries are returned for all transports in the same protocol family as that used to contact the remote rpcbind.

-m

Display a table of statistics of rpcbind operations on the given host. The table shows statistics for each version of rpcbind (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on host.

-n portnum

Use portnum as the port number for the -t and -u options instead of the port number given by rpcbind. Use of this option avoids a call to the remote rpcbind to find out the address of the service. This option is made obsolete by the -a option.

-p

Probe rpcbind on host using version 2 of the rpcbind protocol, and display a list of all registered RPC programs. If host is not specified, it defaults to the local host. This option is not useful for IPv6; use -s (see below) instead. Note that version 2 of the rpcbind protocol was previously known as the portmapper protocol.

-s

Display a concise list of all registered RPC programs on host. If host is not specified, it defaults to the local host.
-t  Make an RPC call to procedure 0 of prognum on the specified host using TCP, and report whether a response was received. This option is made obsolete by the -T option as shown in the third synopsis.

-u  Make an RPC call to procedure 0 of prognum on the specified host using UDP, and report whether a response was received. This option is made obsolete by the -T option as shown in the third synopsis.

Examples  

**EXAMPLE 1**  RPC services.

To show all of the RPC services registered on the local machine use:

```
example% rpcinfo
```

To show all of the RPC services registered with rpcbind on the machine named klaxon use:

```
example% rpcinfo klaxon
```

The information displayed by the above commands can be quite lengthy. Use the -s option to display a more concise list:

```
example% rpcinfo -s klaxon
```

<table>

</tbody>
</table>

To show whether the RPC service with program number prognum and version versnum is registered on the machine named klaxon for the transport TCP use:

```
example% rpcinfo -T tcp klaxon prognum versnum
```
To show all RPC services registered with version 2 of the rpcbind protocol on the local machine use:

example% rpcinfo -p

To delete the registration for version 1 of the walld (program number 100008) service for all transports use:

example# rpcinfo -d 100008 1

or

example# rpcinfo -d walld 1

The service’s status can be queried using the svcs(1) command.
**Name**

rpc.nisd, nisd – NIS+ service daemon

**Synopsis**

```
/usr/sbin/rpc.nisd [-ACDFhlv] [-Y [-B [-t netid]]]
               [-d dictionary] [-L load] [-S level] [-m mappingfile]
               [-x attribute=value]... [-z number]
```

**Description**

The `rpc.nisd` daemon is an RPC service that implements the NIS+ service. This daemon must be running on all machines that serve a portion of the NIS+ namespace.

`rpc.nisd` is usually started from a system startup script.

The `-B` option causes `rpc.nisd` to start an auxiliary process, `rpc.nisd_resolv`, which provides ypserv compatible DNS forwarding for NIS host requests. `rpc.nisd_resolv` can also be started independently. See `rpc.nisd_resolv(1M)` for more information on using `rpc.nisd_resolv` independently.

The `/etc/default/rpc.nisd` file contains the following default parameter settings. See FILES.

```
ENABLE_NIS_YP_EMULATION
```

Specifies whether the server is put into NIS (YP) compatibility mode. `ENABLE_NIS_YP_EMULATION=YES` is equivalent to the `-Y command-line option. The default value for `ENABLE_NIS_YP_EMULATION` is `NO`.

**Options**

- `-A` Authentication verbose mode. The daemon logs all the authentication related activities to `syslogd(1M)` with `LOG_INFO` priority.

- `-B` Provide ypserv compatible DNS forwarding for NIS host requests. The DNS resolving process, `rpc.nisd_resolv`, is started and controlled by `rpc.nisd`. This option requires that the `/etc/resolv.conf` file be setup for communication with a DNS nameserver. The `nslookup` utility can be used to verify communication with a DNS nameserver. See `resolv.conf(4)` and `nslookup(1M)`.

- `-C` Open diagnostic channel on `/dev/console`.

- `-D` Debug mode. Do not fork.

- `-d dictionary` Specify an alternate dictionary for the NIS+ database. The primary use of this option is for testing. Note that the string is not interpreted, rather it is simply passed to the `db_initialize` function.

- `-F` Force the server to do a checkpoint of the database when it starts up. Forced checkpoints may be required when the server is low on disk space. This option removes updates from the transaction log that have propagated to all of the replicas.

- `-h` Print list of options.
-L *number* Specify the "load" the NIS+ service is allowed to place on the server. The load is specified in terms of the *number* of child processes that the server may spawn. The value of *number* must be at least 1 for the callback functions to work correctly. The default is 128.

-m *mappingfile* Specify the name of a configuration file that maps NIS+ objects (especially tables and columns) to LDAP (entries and attributes). See NIS+LDAPmapping(4). The default path is */var/nis*. The default mapping file is NIS+LDAPmapping. If this file exists, the rpc.nisd daemon will map data to and from LDAP. A template mapping file that covers the normal NIS+ directories and tables is installed as */var/nis/NIS+LDAPmapping.template*.

A NIS+ object must have a valid mapping entry in the mapping file in order to have data for that table read from or written to the LDAP repository.

The rpc.nisd(4) file contains specifications for LDAP server addresses, LDAP authentication method, and the like. See NIS+LDAPmapping(4) for an overview of the setup you need to map NIS+ data to or from LDAP.

-S *level* Set the authorization security level of the service. The argument is a number between 0 and 2. By default, the daemon runs at security level 2.

   0 Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. When running at level 0, the daemon does not enforce any access controls. Any client is allowed to perform any operation, including updates and deletions.

   1 At security level 1, the daemon accepts both AUTH_SYS and AUTH_DES credentials for authenticating clients and authorizing them to perform NIS+ operations. This is not a secure mode of operation since AUTH_SYS credentials are easily forged. It should not be used on networks in which any untrusted users may potentially have access.

   2 At security level 2, the daemon only accepts authentication using the security mechanisms configured by nisauthconf(1M). The default security mechanism is AUTH_DES. Security level 2 is the default if the -S option is not used.

-t *netid* Use *netid* as the transport for communication between rpc.nisd and rpc.nisd_resolv. The default transport is ticots(7D) (tcp on SunOS 4.x systems).
-v       VERBOSE. With this option, the daemon sends a running narration of
what it is doing to the syslog daemon (see syslogd(1M)) at LOG_INFO
priority. This option is most useful for debugging problems with the
service. See also -A option.

-x attribute=value Specify the value of the named attribute. Attributes that control the
NIS+ to LDAP mapping operation are derived as follows:
1. Retrieve from LDAP.
2. Override with values from the mappingfile, if any. See the -m
   option.
3. Override with values from the command line -x options.

See NIS+LDAPmapping(4) and rpc.nisd(4) for the recognized
attributes and their syntax.

As a special case, you can use the nisplusLdapConfig* attributes to
derive additional information from LDAP. You can only specify the
nisplusLdapConfig* attributes in rpc.nisd(4) or by means of the
command line.

-Y       Put the server into NIS (YP) compatibility mode. When operating in
this mode, the NIS+ server will respond to NIS Version 2 requests
using the version 2 protocol. Because the YP protocol is not
authenticated, only those items that have read access to nobody (the
unauthenticated request) will be visible through the V2 protocol. It
supports only the standard Version 2 maps in this mode (see -B option
and NOTES in ypfiles(4)). See FILES.

-z number Specify the maximum RPC record size that can be used over
connection oriented transports. The default is 9000 bytes. If you
specify a size less than the default value, the default value will be used
instead.

Examples

EXAMPLE 1 Setting up the NIS+ Service
The following example sets up the NIS+ service.

example% rpc.nisd

EXAMPLE 2 Setting Up NIS+ Service Emulating YP With DNS Forwarding
The following example sets up the NIS+ service, emulating YP with DNS forwarding.

example% rpc.nisd -YB
**EXAMPLE 3  Specifying NIS+ and LDAP Mapping Information**

The following example shows how to specify that all additional NIS+ and LDAP mapping information should be retrieved from DN "dc=x,dc=y,dc=z", from the LDAP server at IP address 1.2.3.4, port 389. The examples uses the simple authentication method and the cn=nispplusAdmin, ou=People, proxy user. The -m option is omitted for clarity in this example.

```
-x nispplusLDAPconfigDN=dc=x,dc=y,dc=z \ 
-x nispplusLDAPconfigPreferredServerList=127.0.0.1:389 \ 
-x nispplusLDAPconfigAuthenticationMethod=simple \ 
-x nispplusLDAPconfigProxyUser=cn=nispplusAdmin,ou=People, \ 
-x nispplusLDAPconfigProxyPassword=xyzzy
```

**Environment Variables**

**NETPATH**  The transports that the NIS+ service will use can be limited by setting this environment variable. See netconfig(4).

**Files**

`/var/nis/data/parent.object`  This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.

`/var/nis/data/root.object`  This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the nis_modify(3NSL) interface.

`/etc/default/rpc.nisd`  LDAP connection and general rpc.nisd configuration. You can override some of the settings by command-line options.

`/var/nis/NIS+LDAPmapping`  Default path for LDAP mapping file. See the discussion of the -m option.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>

**Notes**  NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit [http://www.sun.com/directory/nisplus/transition.html](http://www.sun.com/directory/nisplus/transition.html).
The rpc.nisd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/nisplus:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
rpc.nisd_resolv(1M)

Name  
rpc.nisd_resolv, nisd_resolv – NIS+ service daemon

Synopsis  
rpc.nisd_resolv [-v | -V] [-F [-C fd]] [-t xx] [-p yy]

Description  
rpc.nisd_resolv is an auxiliary process which provides DNS forwarding service for NIS hosts requests to both ypserv and rpc.nisd that are running in the NIS compatibility mode. It is generally started by invoking rpc.nisd(1M) with the -B option or ypserv(1M) with the -d option. Although it is not recommended, rpc.nisd_resolv can also be started independently with the following options.

This command requires that the /etc/resolv.conf file be setup for communication with a DNS nameserver. The nslookup utility can be used to verify communication with a DNS nameserver. See resolv.conf(4) and nslookup(1M).

Options

- F  Run in foreground.
- C fd  Use fd for service xprt (from nisd).
- v  Verbose. Send output to the syslog daemon.
- V  Verbose. Send output to stdout.
- t xx  Use transport xx.
- p yy  Use transient program# yy.

Attributes  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

Notes  
NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.
rpc.nispasswdd daemon is an ONC+ RPC service that services password update requests from nispasswd(1) and yppasswd(1). It updates password entries in the NIS+ passwd table.

rpc.nispasswdd is normally started from a system startup script after the NIS+ server (rpc.nisd(1M)) has been started. rpc.nispasswdd will determine whether it is running on a machine that is a master server for one or more NIS+ directories. If it discovers that the host is not a master server, then it will promptly exit. It will also determine if rpc.nisd(1M) is running in NIS (YP) compatibility mode (the -Y option) and will register as yppasswd for NIS (YP) clients as well.

rpc.nispasswdd will syslog all failed password update attempts, which will allow an administrator to determine whether someone was trying to "crack" the passwords.

rpc.nispasswdd has to be run by a superuser.

Options

- `-a attempts` Set the maximum number of attempts allowed to authenticate the caller within a password update request session. Failed attempts are syslogd(1M) and the request is cached by the daemon. After the maximum number of allowed attempts the daemon severs the connection to the client. The default value is set to 3.

- `-c minutes` Set the number of minutes a failed password update request should be cached by the daemon. This is the time during which if the daemon receives further password update requests for the same user and authentication of the caller fails, then the daemon will simply not respond. The default value is set to 30 minutes.

- `-D` Debug. Run in debugging mode.

- `-g` Generate DES credential. By default the DES credential is not generated for the user if they do not have one. By specifying this option, if the user does not have a credential, then one will be generated for them and stored in the NIS+ cred table.

- `-v`Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon. This option is useful for debugging problems.

Exit Status

0 success

1 an error has occurred.
**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

**See Also**  svcs(1), nisspasswd(1), passwd(1), yppasswd(1), rpc.nisd(1M), syslogd(1M), svcadm(1M), nsswitch.conf(4), attributes(5), smf(5)

**Notes**  NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The rpc.nisspasswd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/nisplus:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
rpc.rexd(1M)

Name  rpc.rexd, rexd – RPC-based remote execution server

Synopsis  /usr/sbin/rpc.rexd [-s]

Description  rpc.rexd is the Sun RPC server for remote program execution. This daemon is started by inetd(1M) whenever a remote execution request is made.

For non-interactive programs, the standard file descriptors are connected directly to TCP connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the login sessions provided by rlogin(1). This daemon may use NFS to mount file systems specified in the remote execution request.

There is a 10240 byte limit for arguments to be encoded and passed from the sending to the receiving system.

Options  The following option is supported:

- s  Secure. When specified, requests must have valid DES credentials. If the request does not have a DES credential it is rejected. The default publickey credential is rejected. Only newer on(1) commands send DES credentials.

If access is denied with an authentication error, you may have to set your publickey with the chkey(1) command.

Specifying the -s option without presenting secure credentials will result in an error message: Unix too weak auth (DesONLY)!

Security  rpc.rexd uses pam(3PAM) for account and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for rpc.rexd. Here is a partial pam.conf file with rpc.rexd entries for account and session management using the UNIX module.

```
rpc.rexd  account requisite     pam_roles.so.1
rpc.rexd  account required      pam_projects.so.1
rpc.rexd  account required      pam_unix_account.so.1
rpc.rexd  session required      pam_unix_session.so.1
```

If there are no entries for the rpc.rexd service, the entries for the "other" service will be used.

rpc.rexd uses the getpwuid() call to determine whether the given user is a legal user.

Files  /dev/pts

Pseudo-terminals used for interactive mode

/etc/passwd

Authorized users

/tmp_rex/rexd??????  Temporary mount points for remote file systems

1988  man pages section 1M: System Administration Commands  •  Last Revised 5 Nov 2004
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

           pam.conf(4), publickey(4), attributes(5), pam_authtok_check(5), pam_authtok_get(5),
           pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5),
           pam_unix_auth(5), pam_unix_session(5), smf(5)

Diagnostics  Diagnostic messages are normally printed on the console, and returned to the requestor.

Notes  Root cannot execute commands using rexd client programs such as on(1).

The pam_unix(5) module is no longer supported. Similar functionality is provided by
pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5),
par_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).

The rpc.rexd service is managed by the service management facility, smf(5), under the
service identifier:

svc:/network/rpc/rex:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is
delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view
configuration information for this service. The service's status can be queried using the
svcs(1) command.
Name  rpc.rstatd, rstatd – kernel statistics server

Synopsis  /usr/lib/netsvc/rstat/rpc.rstatd

Description  rpc.rstatd is a server which returns performance statistics obtained from the kernel. rup(1) uses rpc.rstatd to collect the uptime information that it displays.

rpc.rstatd is an RPC service.

Attributes  See attributes(5) for descriptions of the following attributes:

Notes  The rpc.rstatd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/rstat:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
Name
rpc.rusersd, rusersd – network username server

Synopsis
/usr/lib/netsvc/rusers/rpc.rusersd

Description
rpc.rusersd is a server that returns a list of users on the host. The rpc.rusersd daemon may be started by inetd(1M) or listen(1M).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWrcmds</td>
</tr>
</tbody>
</table>

Notes
The rpc.rusersd service is managed by the service management facility, smf(5), under the service identifier:
svc:/network/rpc/rusers:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
Name  rpc.rwalld, rwalld – network rwall server

Synopsis  /usr/lib/netsvc/rwall/rpc.rwalld

Description  rpc.rwalld is a server that handles rwall(1M) requests. It is implemented by calling wall(1M) on all the appropriate network machines. The rpc.rwalld daemon may be started by inetd(1M) or listen(1M).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWrcmds</td>
</tr>
</tbody>
</table>

See Also  svcs(1), inetadm(1M), inetd(1M), listen(1M), rwall(1M), svcadm(1M), wall(1M), attributes(5), smf(5)

Notes  The rpc.rwalld service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/wall:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
Name  rpc.smserverd – removable media device server

Synopsis  /usr/lib/smedia/rpc.smserverd

Description  rpc.smserverd is a server that handles requests from client applications, including the Volume Management daemon (vold(1M)), for access to removable media devices. In addition to vold, rmformat(1) and the CDE Filemanager (when performing removable media operations) are rpc.smserverd clients. The rpc.smserverd daemon is started by inetd(1M) when a client makes a call to a Solaris-internal library to access a SCSI, IDE, or USB device. The daemon is not started if a client attempts to access a floppy or PCMCIA device. Once started, the daemon remains active until such time as it is idle for three minutes or more.

The rpc.smserverd daemon is provided for the exclusive use of the client applications mentioned above. It has no external, customer-accessible interfaces, including no configuration file.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWvolu</td>
</tr>
</tbody>
</table>

See Also  svc(1), inetadm(1M), inetd(1M), svcadm(1M), vold(1M), vold.conf(4), attributes(5), smf(5)

Notes  The rpc.smserverd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/smserver

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svc(1) command.
rpc.sprayd(1M)

Name  rpc.sprayd, sprayd – spray server

Synopsis  /usr/lib/netsvc/spray/rpc.sprayd

Description  rpc.sprayd is a server that records the packets sent by spray(1M). The rpc.sprayd daemon may be started by inetd(1M) or listen(1M).

The service provided by rpc.sprayd is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>

Notes  The rpc.sprayd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/spray:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetad(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
Name  rpc.yppasswdd, yppasswdd – server for modifying NIS password file

Synopsis  /usr/lib/netsvc/yp/rpc.yppasswdd [-D directory]
          [-nogecos] [-noshell] [-nopw]
          [-m argument1 argument2...]

/usr/lib/netsvc/yp/rpc.yppasswdd
          [passwordfile adjunctfile]
          [-nogecos] [-noshell] [-nopw]
          [-m argument1 argument2...]

Description  rpc.yppasswdd is a server that handles password change requests from yppasswd(1). It changes a password entry in the passwd, shadow, and security/passwd.adjunct files. The passwd and shadow files provide the basis for the passwd.byname and passwd.byuid maps. The passwd.adjunct file provides the basis for the passwd.adjunct.byname and passwd.adjunct.byuid maps. Entries in the passwd, shadow or passwd.adjunct files are changed only if the password presented by yppasswd(1) matches the encrypted password of the entry. All password files are located in the PWDIR directory.

If the -D option is given, the passwd, shadow, or passwd.adjunct files are placed under the directory path that is the argument to -D.

If the -noshell, -nogecos or -nopw options are given, these fields cannot be changed remotely using chfn, chsh, or passwd(1).

If the -m option is given, a make(1S) is performed in /var/yp after any of the passwd, shadow, or passwd.adjunct files are modified. All arguments following the flag are passed to make.

The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used, the passwordfile is the full pathname of the password file and adjunctfile is the full pathname of the optional passwd.adjunct file. If a shadow file is found in the same directory as passwordfile, the shadowfile is used as described above. Use of this syntax and the discovery of a shadowfile file generates diagnostic output. The daemon, however, starts normally.

The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the passwd, passwd.adjunct files and use the -D option at the same time.

The daemon is started automatically on the master server of the passwd map by ypstart(1M), which is invoked at boot time by the svcs:/network/nis/server:default service.

The server does not insist on the presence of a shadow file unless there is no -D option present or the directory named with the -D option is /etc. In addition, a passwd.adjunct file is not necessary. If the -D option is given, the server attempts to find a passwd.adjunct file in the security subdirectory of the named directory. For example, in the presence of -D /var/yp the server checks for a /var/yp/security/passwd.adjunct file.
If only a passwd file exists, then the encrypted password is expected in the second field. If both a passwd and a passwd.adjunct file exist, the encrypted password is expected in the second field of the adjunct file with #username in the second field of the passwd file. If all three files are in use, the encrypted password is expected in the shadow file. Any deviation causes a password update to fail.

If you remove or add a shadow or passwd.adjunct file after rpc.yppasswd has started, you must stop and restart the daemon to enable it to recognize the change. See ypstart(1M) for information on restarting the daemon.

The rpc.yppasswd daemon considers a shell that has a name that begins with 'r' to be a restricted shell. By default, the daemon does not check whether a shell begins with an 'r'. However, you can tell it to do so by uncommenting the check_restricted_shell_name=1 line in /etc/default/yppasswd. The result will be to restrict a user's ability to change from his default shell. See yppasswd(4).

On start up, yppasswd checks for the existence of a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping. If the configuration file is present, the daemon runs in N2L mode. If the file is not present, yppasswd runs in traditional, non-N2L mode.

In N2L mode, changes are written directly to the Directory Information Tree (DIT). If the changes are written successfully, the NIS map is updated. The NIS source files, passwd, shadow, and passwd.adjunct, for example, are not updated. Thus, in N2L mode, the -D option is meaningless. In N2L mode, yppasswd propagates changes by calling yppush(1M) instead of ypmake(1M). The -m option is thus unused.

During an NIS-to-LDAP transition, the yppasswd daemon uses the N2L-specific map, ageingbyname, to read and write password aging information to the DIT. If you are not using password aging, then the ageingbyname mapping is ignored.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

Notes

If make has not been installed and the -m option is given, the daemon outputs a warning and proceeds, effectively ignoring the -m flag.

When using the -D option, you should make sure that the PWDIR of the /var/yp/Makefile is set accordingly.

The second listed syntax is supplied only for backward compatibility and might be removed in a future release of this daemon.
The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and cannot be used without permission.

The NIS server service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svcs:/network/nis/server:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
rpc.ypupdated(1M)

Name     rpc.ypupdated, ypupdated – server for changing NIS information

Synopsis  /usr/lib/netsvc/yp/rpc.ypupdated [-is]

Description ypupdated is a daemon that updates information in the Network Information Service (NIS). ypupdated consults the updaters(4) file in the /var/yp directory to determine which NIS maps should be updated and how to change them.

By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure).

On start up, ypupdated checks for the existence of a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping. If the file is present, ypupdated generates an informational message and exits. ypupdated is not supported in N2L mode.

Options  
-1   Accept RPC calls with the insecure AUTH_UNIX credentials. This allows programmatic updating of the NIS maps in all networks.

-5   Accept only calls authenticated using the secure RPC mechanism (AUTH_DES authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.

Files   
/var/yp/updaters       Configuration file for rpc.ypupdated command.

/var/yp/NISLDAPmapping       Configuration file for N2L

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes  The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and it must not be used without permission.
The RPL server provides network booting functionality to x86 clients by listening to boot requests from them according to the RPL protocol specifications. rpld runs on both x86 and SPARC systems. Boot requests can be generated by clients using the boot floppy supplied in the distribution. Once the request has been received, the server validates the client and adds it to its internal service list. Subsequent requests from the client to download bootfiles will result in the sending of data frames from the server to the client specifying where to load the boot program in memory. When all the bootfiles have been downloaded, the server specifies where to start execution to initiate the boot process.

In the first synopsis, the interface parameter names the network interface upon which rpld is to listen for requests. For example:

```
/usr/sbin/rpld /dev/eri0
```

In the second synopsis, rpld locates all of the network interfaces present on the system and starts a daemon process for each one.

The server starts by reading the default configuration file, or an alternate configuration file if one is specified. If no configuration file can be found, internal default values will be used. Alternatively, command line options are available to override any of the values in the configuration file. After the configuration options are set, it then opens the network interface as specified in the command line and starts listening to RPL boot requests.

Network boot clients have to have information pre-configured on a server for the RPL server to validate and serve them. This involves putting configuration information in both the ethers(4) and the bootparams(4) databases. The ethers database contains a translation from the physical node address to the IP address of the clients and is normally used by the RARP server. The bootparams database stores all other information needed for booting off this client, such as the number of bootfiles and the file names of the various boot components. Both databases can be looked up by the RPL server through NIS. See the sub-section Client Configuration for information on how to set up these databases.

To assist in the administration and maintenance of the network boot activity, there are two run-time signals that the server will accept to change some run-time parameters and print out useful status information. See the sub-section Signals for details.

The RPL server is not limited to the ability to boot only clients. If properly configured, the server should be able to download any bootfiles to the clients.
The following configuration information is specific to booting x86 clients.

In order to allow clients to boot x86 from across the network, the client's information has to be pre-configured in two databases: ethers(4) and bootparams(4). Both databases can be accessed through NIS. Refer to Oracle Solaris 10 08/11 Installation Guide: Basic Installations for information on how to configure a diskless x86 client. The discussion contained in the rest of this section is provided for your information only and should not be performed manually.

The ethers database contains a translation table to convert the physical node address to the IP address of the client. Therefore, an IP address must be assigned to the client (if this has not been done already), the node address of the client must be obtained, and then this information needs to be entered in the ethers database.

The bulk of the configuration is done in the bootparams database. This is a free-format database that essentially contains a number of keyword-value string pairs. A number of keywords have been defined for specific purposes, like the bootparams RPC in bootparamd(1M). Three more keywords have been defined for the RPL server. They are numbootfiles, bootfile, and bootaddr. All three keywords must be in lowercase letters with no spaces before or after the equals symbol following the keyword.

numbootfiles Specifies the number of files to be downloaded to the network boot client. The format of this option is:

numbootfiles=n

Always use numbootfiles=3 to boot x86 across the network.

bootfile Specifies the path name of the bootfile to be downloaded and where in memory to start loading the bootfile. A complete path name should be used. For example, assuming the client's IP address is 172.16.32.15:

bootfile=/rplboot/172.16.32.15.hw.com:45000
bootfile=/rplboot/172.16.32.15.glue.com:35000
bootfile=/rplboot/172.16.32.15.inetboot=8000

The path name following the equals symbol specifies the bootfile to be downloaded, and the hex address following the colon (:) is the absolute address of the memory location to start loading that bootfile. These addresses should be in the range of 7c00 to a0000 (i.e., the base 640K range excluding the interrupt vector and BIOS data areas). Address 45000 for this hw.com bootfile is also a suggested value and if possible should not be changed. The address of 35000 for glue.com is a suggested value that, if possible, should not be changed. The address of 8000 for inetboot is an absolute requirement and should never be changed.

These files, when created following the procedures in the Oracle Solaris 10 08/11 Installation Guide: Basic Installations are actually symbolic links to the real file to be downloaded to the
client. hw. com is linked to a special driver that corresponds to the network interface card of the client. glue. com and inetboot are generic to all network boot clients.

The order of these bootfile lines is not significant, but because problems have been found with certain boot PROMs, it is highly recommended that the bootfile lines be ordered in descending order of the load addresses.

**boot addr**  The absolute address in memory to start executing after all the bootfiles have been downloaded. This address should always correspond to the address where glue. com is being loaded. If possible, always use:

```
boot addr=35000
```

### Options

The following options are supported:

- **-b background_mode**  Specify 1 to run the server in the background and relinquish the controlling terminal, or 0 to run in the foreground without relinquishing the controlling terminal. This option corresponds to the BackGround setting in the configuration file. If you have specified that the error or warning messages be sent to standard output in the configuration file or by using the -D option above, the server cannot be run in background mode. Doing so will cause the server to exit after announcing the error.

- **-d debug_level**  Specify a level of 0 if you do not want any error or warning messages to be generated, or a level from 1 to 9 for increasing amounts of messages. This option corresponds to the DebugLevel setting in the configuration file. The default value is 0. Note that it is best to limit the level to 8 or below; use of level 9 may generate so many debug messages that the performance of the RPL server may be impacted.

- **-D debug_destination**  Specify 0 to send error or warning messages to standard output, 1 to syslogd, and 2 to the log file. This option corresponds to the DebugDest setting in the configuration file. The default value is 2.

- **-f config_filename**  Use this to specify a configuration file name other than the system default /etc/rpld.conf file.

- **-g delay_granularity**  This corresponds to the DelayGran setting in the configuration file. If retransmission requests from clients do occur, the delay granularity factor will be used to adjust the delay count for this client upwards or downwards. If the retransmission request is caused by data overrun, the delay count will be incremented by delay granularity units to increase the delay between data frames. If the retransmission request is caused by sending data too slowly, this will be used to adjust the delay count downwards to shorten the delay. Eventually the server will settle at the delay count value that
works best with the speed of the client and no retransmission request will be needed. The default value is 2.

-\ log_filename

Specify an alternate log file name to hold the error or warning messages in connection with the -D 2 option or the configuration file DebugDest = 2 setting. This option corresponds to the LogFile setting in the configuration file. The default is /var/spool/rpld.log.

-M maximum_clients

Specify the maximum number of simultaneous network boot clients to be served. This option corresponds to the MaxClients setting in the configuration file. A value of −1 means unlimited, and the actual number will depend on available system resources. The default value is −1.

-s start_delay_count

This option corresponds to the StartDelay setting in the configuration file. Specify the number of delay units between outgoing data frames sent to clients to avoid retransmission requests from them. Using the LLC type 1 protocol, data transfer is a one-way, best-effort delivery mechanism. The server, without any type of delay mechanism, can overrun the client by sending data frames too quickly. Therefore, a variable delay is built into the server to limit the speed of sending data to the clients, thus avoiding the clients sending back retransmission requests. This value should be machine environment specific. If you have a fast server machine but slow client machines, you may want to set a large start delay count. If you have comparable server and client machines, the delay count may be set to 1. The delay is only approximate and should not be taken as an accurate measure of time. There is no specific correlation between the delay unit and the actual time of delay. The default value is 20.

-z frame_size

This option corresponds to the FrameSize setting in the configuration file. This specifies the size of the data frames used to send data to the clients. This is limited by the underlying physical medium. For ethernet/802.3, the maximum physical frame size is 1500 octets. The default value is 1500. Note that the protocol overhead of LLC1 and RPL is 32 octets, resulting in a maximum data length of 1468 octets.

Signals

The RPL server accepts two signals to change run-time parameters and display status information, respectively:

HANGUP

This will cause the RPL server to reread the default configuration file /etc/rpld.conf or an alternate configuration file if one is specified when the server is started. New values of certain parameters can be used immediately, such
as DebugLevel, DebugDest, LogFile, DelayGran, and FrameSize. For MaxClients, if the server is already serving more than the new value, the server will not accept additional boot requests until the number has fallen below the MaxClients parameter. For StartDelay, this will only affect new boot requests. All the existing delay counts for the various clients in service will not be affected. Finally, the BackGround parameter will have no effect once the server has been running. You cannot change the mode of service without first killing the server and then restarting it.

USR1 This signal will cause the server to dump all the parameter values and the status of each individual boot client to the destination specified by DebugDest.

rquotad(1M)

**Name**
rquotad – remote quota server

**Synopsis**
/usr/lib/nfs/rquotad

**Description**
rquotad is an *rpc*(4) server which returns quotas for a user of a local file system which is mounted by a remote machine over the NFS. The results are used by *quota*(1M) to display user quotas for remote file systems. The rquotad daemon is normally invoked by *inetd*(1M).

**Usage**
See *largefile*(5) for the description of the behavior of rquotad when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

**Files**
quotas quota file at a UFS file system root

**Attributes**
See *attributes*(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnfsu</td>
</tr>
</tbody>
</table>

*Oracle Solaris 10 08/11 Installation Guide: Basic Installations*

**Notes**
The rquotad service is managed by the service management facility, *smf*(5), under the service identifier:

svc:/network/nfs/rquota

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to *inetd*(1M). Use *inetadm*(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svc(1) command.

If it is disabled, it will be enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M) unless its application/auto_enable property is set to false.
rsh(1M)

**Name**
rsh, restricted_shell – restricted shell command interpreter

**Synopsis**
/usr/lib/rsh [-acefhiknprstuvx] [argument]...

**Description**
rsh is a limiting version of the standard command interpreter sh, used to restrict logins to execution environments whose capabilities are more controlled than those of sh (see sh(1) for complete description and usage).

When the shell is invoked, it scans the environment for the value of the environmental variable, SHELL. If it is found and rsh is the file name part of its value, the shell becomes a restricted shell.

The actions of rsh are identical to those of sh, except that the following are disallowed:

- changing directory (see cd(1)),
- setting the value of $PATH,
- specifying path or command names containing /,
- redirecting output (> and >>).

The restrictions above are enforced after .profile is interpreted.

A restricted shell can be invoked in one of the following ways:

1. rsh is the file name part of the last entry in the /etc/passwd file (see passwd(4));
2. the environment variable SHELL exists and rsh is the file name part of its value; the environment variable SHELL needs to be set in the .login file;
3. the shell is invoked and rsh is the file name part of argument 0;
4. the shell is invoke with the -r option.

When a command to be executed is found to be a shell procedure, rsh invokes sh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the .profile (see profile(4)) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably not the login directory).

The system administrator often sets up a directory of commands (that is, /usr/rbin) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, red.

**Exit Status**
Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  Intro(1), cd(1), login(1), rsh(1), sh(1), exec(2), passwd(4), profile(4), attributes(5)

Notes  The restricted shell, /usr/lib/rsh, should not be confused with the remote shell, /usr/bin/rsh, which is documented in rsh(1).
Name  rtc – provide all real-time clock and GMT-lag management

Synopsis  /usr/sbin/rtc [-c] [-z zone-name]

Description  On x86 systems, the rtc command reconciles the difference in the way that time is established between UNIX and MS-DOS systems. UNIX systems utilize Greenwich Mean Time (GMT), while MS-DOS systems utilize local time.

Without arguments, rtc displays the currently configured time zone string. The currently configured time zone string is based on what was last recorded by rtc -z zone-name.

The rtc command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as date(1) and rdate(1M), which are used to set the time on a system, invoke /usr/sbin/rtc -c to ensure that daylight savings time (DST) is corrected for properly.

Options  -c  This option checks for DST and makes corrections if necessary. It is normally run once a day by a cron job.

If there is no RTC time zone or /etc/rtc_config file, this option will do nothing.

-z zone-name  This option, which is normally run by the system at software installation time, is used to specify the time zone in which the RTC is to be maintained. It updates the configuration file /etc/rtc_config with the name of the specified zone and the current GMT lag for that zone. If there is an existing rtc_config file, this command will update it. If not, this command will create it.

Files  /etc/rtc_config  The data file used to record the time zone and GMT lag. This file is completely managed by /usr/sbin/rtc, and it is read by the kernel.

rtquery (1M)

Name
rtquery – query routing daemons for their routing tables

Synopsis
rtquery [-np1] [-w timeout] [-r addr] [-a secret] host...
rtquery [-t operation] host...

Description
The rtquery command is used to query a RIP network routing daemon, \texttt{in.routed(1M)} or \texttt{Gate\text{\textregistered}D}, for its routing table by sending a request or poll command. The routing information in any routing response packets returned is displayed numerically and symbolically.

By default, \texttt{rtquery} uses the request command. When the \texttt{-p} option is specified, \texttt{rtquery} uses the poll command, an undocumented extension to the RIP protocol supported by \texttt{Gate\text{\textregistered}D}.

When querying \texttt{Gate\text{\textregistered}D}, the poll command is preferred over the request command because the response is not subject to Split Horizon and/or Poisoned Reverse, and because some versions of \texttt{Gate\text{\textregistered}D} do not answer the request command. \texttt{in.routed} does not answer the poll command, but recognizes requests coming from \texttt{rtquery} and so answers completely.

The \texttt{rtquery} command is also used to turn tracing on or off in \texttt{in.routed}.

Options
The following options are supported:

- \texttt{-a passwd=XXX}  
  Causes the query to be sent with the indicated cleartext or MD5 password.

- \texttt{-a md5\textunderscore passwd=XXX[KeyID]}  
  Causes the query to be sent with the indicated cleartext or MD5 password.

- \texttt{-n}  
  Displays only the numeric network and host addresses instead of both numeric and symbolic names.

- \texttt{-p}  
  Uses the poll command to request full routing information from \texttt{Gate\text{\textregistered}D}. This is an undocumented extension RIP protocol supported only by \texttt{Gate\text{\textregistered}D}.

- \texttt{-r addr}  
  Asks about the route to destination \texttt{addr}.

- \texttt{-t operation}  
  Changes tracing, where \texttt{operation} is one of the actions listed below. Requests from processes not running with UID 0 or on distant networks are generally ignored by the daemon except for a message in the system log. \texttt{Gate\text{\textregistered}D} is likely to ignore these debugging requests.

  - \texttt{on=tracefile}  
    Turns tracing on, directing tracing into the specified file. That file must have been specified when the daemon was started or have the name, \texttt{/var/log/in.routed.trace}.

  - \texttt{more}  
    Increases the debugging level.

  - \texttt{off}  
    Turns off tracing.
dump  Dumps the daemon's routing table to the
current trace file.

-w timeout  Changes the delay for an answer from each host. By default,
each host is given 15 seconds to respond.

-1  Queries using RIP version 1 instead of RIP version 2.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Routing Information Protocol, RIPv1, RFC 1058

Routing Information Protocol, RIPv2, RFC 2453, STD 0056
Name runacct – run daily accounting

Synopsis /usr/lib/acct/runacct [mmd [state]]

Description runacct is the main daily accounting shell procedure. It is normally initiated using cron.

runacct processes connect, fee, disk, and process accounting files. It also prepares summary files for prweekly or billing purposes. runacct is distributed only to source code licensees.

runacct takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into active. When an error is detected, a message is written to /dev/console, mail (see mail(1)) is sent to root and adm, and runacct terminates. runacct uses a series of lock files to protect against re-invocation. The files lock and lock1 are used to prevent simultaneous invocation, and lastdate is used to prevent more than one invocation per day.

runacct breaks its processing into separate, restartable states using statefile to remember the last state completed. It accomplishes this by writing the state name into statefile. runacct then looks in statefile to see what it has done and to determine what to process next. states are executed in the following order:

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETUP</td>
<td>Move active accounting files into working files.</td>
</tr>
<tr>
<td>WTMPFIX</td>
<td>Verify integrity of wtmpx file, correcting date changes if necessary.</td>
</tr>
<tr>

</tr>
<tr>
<td>CMS</td>
<td>Produce command summaries.</td>
</tr>
<tr>
<td>USEREXIT</td>
<td>Any installation dependent accounting programs can be included here.</td>
</tr>
<tr>
<td>CLEANUP</td>
<td>Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument mmd is necessary if runacct is being restarted. mmd specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based on the contents of statefile; to override this, include the desired state on the command line to designate where processing should begin.</td>
</tr>
</tbody>
</table>
Examples

**EXAMPLE 1**  Starting runacct

The following example starts runacct:

```
example% nohup runacct 2> /var/adm/acct/nite/fd2log &
```

**EXAMPLE 2**  Restarting runacct

The following example restarts runacct:

```
example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &
```

**EXAMPLE 3**  Restarting runacct at a Specific State

The following example restarts runacct at a specific state:

```
example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &
```

Files

- `/var/adm/wtmpx`  History of user access and administration information
- `/var/adm/pacctincr`
- `/var/adm/acct/nite/active`
- `/var/adm/acct/nite/daytacct`
- `/var/adm/acct/nite/lock`
- `/var/adm/acct/nite/lock1`
- `/var/adm/acct/nite/lastdate`
- `/var/adm/acct/nite/statefile`

<td>SUNWaccu</td>
</tr>
</tbody>
</table>

See Also  `acctcom(1), mail(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M), cron(1M), fwtmp(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)`

Notes

It is not recommended to restart `runacct` in the **SETUP state**. Run SETUP manually and restart using:

```
runacct mmdd WTMPFIX
```

If `runacct` failed in the **PROCESS state**, remove the last `ptacct` file because it will not be complete.

The `runacct` command can process a maximum of

- 6000 distinct sessions
• 1000 distinct terminal lines
• 2000 distinct login names

during a single invocation of the command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Do not invoke `runacct` at the same time as `ckpacct`, as there may be a conflict if both scripts attempt to execute `turnacct switch` simultaneously.
Name  
rwall – write to all users over a network

Synopsis  
/usr/sbin/rwall  hostname...
/usr/sbin/rwall  -n netgroup...
/usr/sbin/rwall  -h hostname  -n netgroup

Description  
rwall reads a message from standard input until EOF. It then sends this message, preceded by the line:

    Broadcast Message . . .

to all users logged in on the specified host machines. With the -n option, it sends to the specified network groups.

Options  
- n netgroup     Send the broadcast message to the specified network groups.
- h hostname     Specify the hostname, the name of the host machine.

Attributes

Notes  
The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.
The Service Access Controller (SAC) is the overseer of the server machine. It is started when the server machine enters multiuser mode. The SAC performs several important functions as explained below.

**Customizing the SAC Environment**

When `sac` is invoked, it first looks for the per-system configuration script `/etc/saf/_sysconfig`. `sac` interprets `_sysconfig` to customize its own environment. The modifications made to the SAC environment by `_sysconfig` are inherited by all the children of the SAC. This inherited environment may be modified by the children.

**Starting Port Monitors**

After it has interpreted the `_sysconfig` file, the `sac` reads its administrative file `/etc/saf/_sactab`. `_sactab` specifies which port monitors are to be started. For each port monitor to be started, `sac` forks a child (see `fork(2)`) and creates a `utmpx` entry with the type field set to LOGIN_PROCESS. Each child then interprets its per-port monitor configuration script `/etc/saf/pmtag/_config`, if the file exists. These modifications to the environment affect the port monitor and will be inherited by all its children. Finally, the child process execs the port monitor, using the command found in the `_sactab` entry. (See `sacadm`; this is the command given with the `-c` option when the port monitor is added to the system.)

**Polling Port Monitors to Detect Failure**

The `-t` option sets the frequency with which `sac` polls the port monitors on the system. This time may also be thought of as half of the maximum latency required to detect that a port monitor has failed and that recovery action is necessary.

**Administrative functions**

The Service Access Controller represents the administrative point of control for port monitors. Its administrative tasks are explained below.

When queried (`sacadm` with either `-l` or `-L`), the Service Access Controller returns the status of the port monitors specified, which `sacadm` prints on the standard output. A port monitor may be in one of six states:

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENABLED</td>
<td>The port monitor is currently running and is accepting connections. See <code>sacadm(1M)</code> with the <code>-e</code> option.</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The port monitor is currently running and is not accepting connections. See <code>sacadm</code> with the <code>-d</code> option, and see NOTRUNNING, below.</td>
</tr>
<tr>
<td>STARTING</td>
<td>The port monitor is in the process of starting up. STARTING is an intermediate state on the way to ENABLED or DISABLED.</td>
</tr>
<tr>
<td>FAILED</td>
<td>The port monitor was unable to start and remain running.</td>
</tr>
<tr>
<td>STOPPING</td>
<td>The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING.</td>
</tr>
</tbody>
</table>
NOTRUNNING  The port monitor is not currently running. (See sacadm with -k.) This is the normal "not running" state. When a port monitor is killed, all ports it was monitoring are inaccessible. It is not possible for an external user to tell whether a port is not being monitored or the system is down. If the port monitor is not killed but is in the DISABLED state, it may be possible (depending on the port monitor being used) to write a message on the inaccessible port telling the user who is trying to access the port that it is disabled. This is the advantage of having a DISABLED state as well as the NOTRUNNING state.

When a port monitor terminates, the SAC removes the utmpx entry for that port monitor.

The SAC receives all requests to enable, disable, start, or stop port monitors and takes the appropriate action.

The SAC is responsible for restarting port monitors that terminate. Whether or not the SAC will restart a given port monitor depends on two things:

- The restart count specified for the port monitor when the port monitor was added by sacadm; this information is included in /etc/saf/pmtag/_sactab.
- The number of times the port monitor has already been restarted.

Security  sac uses pam(3PAM) for session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the session management module to be used for sac. Here is a partial pam.conf file with entries for sac using the UNIX session management module.

sac session required pam_unix_session.so.1

If there are no entries for the sac service, then the entries for the "other" service will be used.

Options  -t sanity_interval  Sets the frequency (sanity_interval) with which sac polls the port monitors on the system.

sacadm is the administrative command for the upper level of the Service Access Facility hierarchy (port monitor administration). sacadm performs the following functions:

- adds or removes a port monitor
- starts or stops a port monitor
- enables or disables a port monitor
- installs or replaces a per-system configuration script
- installs or replaces a per-port monitor configuration script
- prints requested port monitor information

Requests about the status of port monitors (-l and -L) and requests to print per-port monitor and per-system configuration scripts (-g and -G without the -z option) may be executed by any user on the system. Other sacadm commands may be executed only by the super-user.

Options

-a Add a port monitor. When adding a port monitor, sacadm creates the supporting directory structure in /etc/saf and /var/saf and adds an entry for the new port monitor to /etc/saf/_sactab. The file _sactab already exists on the delivered system. Initially, it is empty except for a single line, which contains the version number of the Service Access Controller. Unless the command line that adds the new port monitor includes the -f argument, the new port monitor will be started. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add port monitors.

-c cmd Execute the command string cmd to start a port monitor. The -c option may be used only with a -a. A -a option requires a -c.
-d  Disable the port monitor pmtag.
-e  Enable the port monitor pmtag.
-f dx The -f option specifies one or both of the following two flags which are then included in the flags field of the _sactab entry for the new port monitor. If the -f option is not included on the command line, no flags are set and the default conditions prevail. By default, a port monitor is started. A -f option with no following argument is illegal.

  d   Do not enable the new port monitor.
  x   Do not start the new port monitor.

-g  The -g option is used to request output or to install or replace the per-port monitor configuration script /etc/saf/pmtag/_config. -g requires an -p option. The -g option with only an -p option prints the per-port monitor configuration script for port monitor pmtag. The -g option with an -p option and an -z option installs the file script as the per-port monitor configuration script for port monitor pmtag. Other combinations of options with -g are invalid.

-G  The -G option is used to request output or to install or replace the per-system configuration script /etc/saf/_sysconfig. The -G option by itself prints the per-system configuration script. The -G option in combination with an -z option installs the file script as the per-system configuration script. Other combinations of options with -G are invalid.

-k  Stop port monitor pmtag.
-l  The -l option is used to request port monitor information. The -l by itself lists all port monitors on the system. The -l option in combination with the -p option lists only the port monitor specified by pmtag. A -l in combination with the -t option lists all port monitors of type type. Any other combination of options with the -l option is invalid.

-L  The -L option is identical to the -l option except that the output appears in a condensed format.

-n count Set the restart count to count. If a restart count is not specified, count is set to 0. A count of 0 indicates that the port monitor is not to be restarted if it fails.

-p pmtag Specifies the tag associated with a port monitor.

-r  Remove port monitor pmtag. sacadm removes the port monitor entry from /etc/saf/_sactab. If the removed port monitor is not running, no further action is taken. If the removed port monitor is running, the Service Access Controller (SAC) sends it SIGTERM to indicate that it should shut down. Note that the port monitor's directory structure remains intact.
-s
Start a port monitor. The SAC starts the port monitor pmtag.

-t type
Specifies the port monitor type.

-v ver
Specifies the version number of the port monitor. This version number may be given as
-v 'pmspec -V'
where pmspec is the special administrative command for port monitor pmtag. This special command is ttysadm for ttymon and nlsadmin for listen. The version stamp of the port monitor is known by the command and is returned when pmspec is invoked with a -V option.

-x
The -x option by itself tells the SAC to read its database file (_sactab). The -x option with the -p option tells port monitor pmtag to read its administrative file.

-y comment
Include comment in the _sactab entry for port monitor pmtag.

-z script
Used with the -g and -G options to specify the name of a file that contains a configuration script. With the -g option, script is a per-port monitor configuration script; with -G it is a per-system configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (-g or -G). Then the copy is edited. Finally, the copy is put in place over the existing script (-g or -G with -z).

Output
If successful, sacadm will exit with a status of 0. If sacadm fails for any reason, it will exit with a nonzero status. Options that request information will write the information on the standard output. In the condensed format (-L), port monitor information is printed as a sequence of colon-separated fields; empty fields are indicated by two successive colons. The standard format (-l) prints a header identifying the columns, and port monitor information is aligned under the appropriate headings. In this format, an empty field is indicated by a hyphen. The comment character is #.

Examples
EXAMPLE 1  A sample output of the sacadm command.

The following command line adds a port monitor. The port monitor tag is npack; its type is listen; if necessary, it will restart three times before failing; its administrative command is nlsadmin; and the configuration script to be read is in the file script:

sacadm -a -p npack -t listen -c /usr/lib/saf/listen npack
-v 'nlsadmin -V' -n 3 -z script

Remove a port monitor whose tag is pmtag:

sacadm -r -p pmtag

Start the port monitor whose tag is pmtag:
EXAMPLE 1  A sample output of the `sacadm` command.  (Continued)

```
sacadm -s -p pmtag
Stop the port monitor whose tag is pmtag:
sacadm -k -p pmtag
Enable the port monitor whose tag is pmtag:
sacadm -e -p pmtag
Disable the port monitor whose tag is pmtag:
sacadm -d -p pmtag
List status information for all port monitors:
sacadm -l
List status information for the port monitor whose tag is pmtag:
sacadm -l -p pmtag
List the same information in condensed format:
sacadm -L -p pmtag
List status information for all port monitors whose type is listen:
sacadm -l -t listen
Replace the per-port monitor configuration script associated with the port monitor whose tag is pmtag with the contents of the file `file.config`:
sacadm -g -p pmtag -z file.config
```

**Files**

```
/etc/saf/_sactab
/etc/saf/_sysconfig
/etc/saf/pmtag/_config
```

The SAF generalizes the procedures for service access so that login access on the local system and network access to local services are managed in similar ways. Under the SAF, systems may access services using a variety of port monitors, including ttymon, the listener, and port monitors written expressly for a user’s application. The manner in which a port monitor observes and manages access ports is specific to the port monitor and not to any component of the SAF. Users may therefore extend their systems by developing and installing their own port monitors. One of the important features of the SAF is that it can be extended in this way by users.

Relative to the SAF, a service is a process that is started. There are no restrictions on the functions a service may provide. The SAF consists of a controlling process, the service access controller (SAC), and two administrative levels corresponding to two levels in the supporting directory structure. The top administrative level is concerned with port monitor administration, the lower level with service administration. The SAC is documented in the sac(1M) man page. The administrative levels and associated utilities are documented in the System Administration Guide - Volume II. The requirements for writing port monitors and the functions a port monitor must perform to run under the SAF and the SAC are documented here.

A port monitor is a process that is responsible for monitoring a set of homogeneous, incoming ports on a machine. A port monitor’s major purpose is to detect incoming service requests and to dispatch them appropriately.

A port is an externally seen access point on a system. A port may be an address on a network (TSAP or PSAP), a hardwired terminal line, an incoming phone line, etc. The definition of what constitutes a port is strictly a function of the port monitor itself.

A port monitor performs certain basic functions. Some of these are required to conform to the SAF; others may be specified by the requirements and design of the port monitor itself. Port monitors have two main functions: managing ports and monitoring ports for indications of activity.

Port Management

The first function of a port monitor is to manage a port. The actual details of how a port is managed are defined by the person who defines the port monitor. A port monitor is not restricted to handling a single port; it may handle multiple ports simultaneously.

Some examples of port management are setting the line speed on incoming phone connections, binding an appropriate network address, reinitializing the port when the service terminates, outputting a prompt, etc.

Activity Monitoring

The second function of a port monitor is to monitor the port or ports for which it is responsible for indications of activity. Two types of activity may be detected.
The first is an indication to the port monitor to take some port monitor-specific action. Pressing the break key to indicate that the line speed should be cycled is an example of a port monitor activity. Not all port monitors need to recognize and respond to the same indications. The indication used to attract the attention of the port monitor is defined by the person who defines the port monitor.

The second is an incoming service request. When a service request is received, a port monitor must be able to determine which service is being requested from the port on which the request is received. The same service may be available on more than one port.

### Restricting Access to the System

A port monitor must be able to restrict access to the system without disturbing services that are still running. In order to do this, a port monitor must maintain two internal states: enabled and disabled. The port monitor starts in the state indicated by the ISTATE environment variable provided by the sac. See sac(1M) for details. Enabling or disabling a port monitor affects all ports for which the port monitor is responsible. If a port monitor is responsible for a single port, only that port will be affected. If a port monitor is responsible for multiple ports, the entire collection of ports will be affected. Enabling or disabling a port monitor is a dynamic operation: it causes the port monitor to change its internal state. The effect does not persist across new invocations of the port monitor. Enabling or disabling an individual port, however, is a static operation: it causes a change to an administrative file. The effect of this change will persist across new invocations of the port monitor.

### Creating utmpx Entries

Port monitors are responsible for creating utmpx entries with the type field set to USER_PROCESS for services they start. If this action has been specified, by using the -fu option in the pmadm command line that added the service, these utmpx entries may
in turn be modified by the service. When the service terminates, the utmpx entry must be set to DEAD_PROCESS.

**Port Monitor Process IDs and Lock Files**

When a port monitor starts, it writes its process id into a file named _pid in the current directory and places an advisory lock on the file.

**Changing the Service Environment: Running**

`doconfig(3NSL)` Before invoking the service designated in the port monitor administrative file, _pmtab, a port monitor must arrange for the per-service configuration script to be run, if one exists, by calling the library function `doconfig(3NSL)`. Because the per-service configuration script may specify the execution of restricted commands, as well as for other security reasons, port monitors are invoked with root permissions. The details of how services are invoked are specified by the person who defines the port monitor.

**Terminating a Port Monitor**

A port monitor must terminate itself gracefully on receipt of the signal SIGTERM. The termination sequence is the following:

1. The port monitor enters the stopping state; no further service requests are accepted.
2. Any attempt to re-enable the port monitor will be ignored.
3. The port monitor yields control of all ports for which it is responsible. It must be possible for a new instantiation of the port monitor to start correctly while a previous instantiation is stopping.
4. The advisory lock on the process id file is released. Once this lock is released, the contents of the process id file are undefined and a new invocation of the port monitor may be started.
**SAF Files**

This section briefly covers the files used by the SAF.

**The Port Monitor Administrative File**

A port monitor's current directory contains an administrative file named `_pmtab`; `_pmtab` is maintained by the `pmadm` command in conjunction with a port monitor-specific administrative command.

The port monitor administrative command for a listen port monitor is `nlsadmin(1M)`; the port monitor administrative command for ttymon is `ttyadm(1M)`. Any port monitor written by a user must be provided with an administrative command specific to that port monitor to perform similar functions.

**Per-Service Configuration Files**

A port monitor's current directory also contains the per-service configuration scripts, if they exist. The names of the per-service configuration scripts correspond to the service tags in the `_pmtab` file.

**Private Port Monitor Files**

A port monitor may create private files in the directory `/var/saf/tag`, where `tag` is the name of the port monitor. Examples of private files are log files or temporary files.

---

**The SAC/Port Monitor Interface**

The SAC creates two environment variables for each port monitor it starts: `PMTAG` and `ISTATE`.

This variable is set to a unique port monitor tag by the SAC. The port monitor uses this tag to identify itself in response to SAC messages. `ISTATE` is used to indicate to the port monitor what its initial internal state should be. `ISTATE` is set to “enabled” or “disabled” to indicate that the port monitor is to start in the enabled or disabled state respectively.

The SAC performs a periodic sanity poll of the port monitors. The SAC communicates with port monitors through FIFOs. A port monitor should open `_pmpipe`, in the current directory, to receive messages from the SAC and `../_sacpipe` to send return messages to the SAC.

**Message Formats**

This section describes the messages that may be sent from the SAC to a port monitor (SAC messages), and from a port monitor to the SAC (port monitor messages). These messages are sent through FIFOs and are in the form of C structures.

**sac Messages**

The format of messages from the SAC is defined by the structure `sacmsg`:

```c
define sacmsg
{
    int sc_size; /* size of optional data portion */
    char sc_type; /* type of message */
```
The SAC may send four types of messages to port monitors. The type of message is indicated by setting the `sc_type` field of the `sacmsg` structure to one of the following:

- **SC_STATUS** status request
- **SC_ENABLE** enable message
- **SC_DISABLE** disable message
- **SC_READDB** message indicating that the port monitor's `_pmtab` file should be read

The `sc_size` field indicates the size of the optional data part of the message. See “Message Classes.” For Solaris, `sc_size` should always be set to 0. A port monitor must respond to every message sent by the SAC.

The format of messages from a port monitor to the SAC is defined by the structure `pmmsg`:

```c
struct pmmsg {
    char pm_type; /* type of message */
    uchar_t pm_state; /* current state of port monitor */
    char pm_maxclass; /* maximum message class this port
                       monitor understands */
    char pm_tag[PMTAGSIZE + 1]; /* port monitor's tag */
    int pm_size; /* size of optional data portion */
};
```

Port monitors may send two types of messages to the SAC. The type of message is indicated by setting the `pm_type` field of the `pmmsg` structure to one of the following:

- **PM_STATUS** state information
- **PM_UNKNOWN** negative acknowledgment

For both types of messages, the `pm_tag` field is set to the port monitor’s tag and the `pm_state` field is set to the port monitor’s current state. Valid states are:

- **PM_STARTING** starting
- **PM_ENABLED** enabled
- **PM_DISABLED** disabled
- **PM_STOPPING** stopping

The current state reflects any changes caused by the last message from the SAC. The status message is the normal return message. The negative acknowledgment should be sent only when the message received is not understood. `pm_size` indicates the size of the optional data part of the message. `pm_maxclass` is used to specify a message class. Both are discussed under...
“Message Classes.” In Solaris, always set \texttt{pm\_maxclass} to 1 and \texttt{sc\_size} to 0. Port monitors may never initiate messages; they may only respond to messages that they receive.

**Message Classes**

The concept of message class has been included to accommodate possible SAF extensions. The messages described above are all class 1 messages. None of these messages contains a variable data portion; all pertinent information is contained in the message header. If new messages are added to the protocol, they will be defined as new message classes (for example, class 2). The first message the SAC sends to a port monitor will always be a class 1 message. Since all port monitors, by definition, understand class 1 messages, the first message the SAC sends is guaranteed to be understood. In its response to the SAC, the port monitor sets the \texttt{pm\_maxclass} field to the maximum message class number for that port monitor. The SAC will not send messages to a port monitor from a class with a larger number than the value of \texttt{pm\_maxclass}. Requests that require messages of a higher class than the port monitor can understand will fail. For Solaris, always set \texttt{pm\_maxclass} to 1.

For any given port monitor, messages of class \texttt{pm\_maxclass} and messages of all classes with values lower than \texttt{pm\_maxclass} are valid. Thus, if the \texttt{pm\_maxclass} field is set to 3, the port monitor understands messages of classes 1, 2, and 3. Port monitors may not generate messages; they may only respond to messages. A port monitor’s response must be of the same class as the originating message. Since only the SAC can generate messages, this protocol will function even if the port monitor is capable of dealing with messages of a higher class than the SAC can generate. \texttt{pm\_size} (an element of the pmmsg structure) and \texttt{sc\_size} (an element of the sacmsg structure) indicate the size of the optional data part of the message. The format of this part of the message is undefined. Its definition is inherent in the type of message. For Solaris, always set both \texttt{sc\_size} and \texttt{pm\_size} to 0.

This section discusses the port monitor administrative files available under the SAC.

**Administrative Interface**

The service access controller’s administrative file contains information about all the port monitors for which the SAC is responsible. This file exists on the delivered system. Initially, it is empty except for a single comment line that contains the version number of the SAC. Port monitors are added to the system by making entries in the SAC’s administrative file. These entries should be made using the administrative command \texttt{sacadm(1M)} with a -a option. \texttt{sacadm(1M)} is also used to remove entries from the SAC’s administrative file. Each entry in the SAC’s administrative file contains the following information.

- **PMTAG** A unique tag that identifies a particular port monitor. The system administrator is responsible for naming a port monitor. This tag is then used by the SAC to identify the port monitor for all administrative purposes. PMTAG may consist of up to 14 alphanumeric characters.

- **PMTYPE** The type of the port monitor. In addition to its unique tag, each port monitor has a type designator. The type designator identifies a group of port monitors that are different invocations of the same entity. tymon and listen are examples of valid port monitor types. The type designator is used to facilitate the administration of
groups of related port monitors. Without a type designator, the system administrator has no way of knowing which port monitor tags correspond to port monitors of the same type. PMTYPE may consist of up to 14 alphanumeric characters.

**FLGS**

The flags that are currently defined are:

- d  When started, do not enable the port monitor.
- x  Do not start the port monitor.

If no flag is specified, the default action is taken. By default a port monitor is started and enabled.

**RCNT**

The number of times a port monitor may fail before being placed in a failed state. Once a port monitor enters the failed state, the SAC will not try to restart it. If a count is not specified when the entry is created, this field is set to 0. A restart count of 0 indicates that the port monitor is not to be restarted when it fails.

**COMMAND**

A string representing the command that will start the port monitor. The first component of the string, the command itself, must be a full path name.

Each port monitor will have two directories for its exclusive use. The current directory will contain files defined by the SAF (_pmtab, _pid) and the per-service configuration scripts, if they exist. The directory /var/saf/pmtag, where pmtag is the tag of the port monitor, is available for the port monitor’s private files. Each port monitor has its own administrative file. The pmadm(1M) command should be used to add, remove, or modify service entries in this file. Each time a change is made using pmadm(1M), the corresponding port monitor rereads its administrative file. Each entry in a port monitor’s administrative file defines how the port monitor treats a specific port and what service is to be invoked on that port. Some fields must be present for all types of port monitors. Each entry must include a service tag to identify the service uniquely and an identity to be assigned to the service when it is started (for example, root).

The combination of a service tag and a port monitor tag uniquely define an instance of a service. The same service tag may be used to identify a service under a different port monitor. The record must also contain port monitor specific data (for example, for a ttymon port monitor, this will include the prompt string which is meaningful to ttymon). Each type of port monitor must provide a command that takes the necessary port monitor-specific data as arguments and outputs these data in a form suitable for storage in the file. The ttyadm(1M) command does this for ttymon and nlsadmin(1M) does it for listen. For a user-defined port monitor, a similar administrative command must also be supplied. Each service entry in the port monitor administrative file must have the following format and contain the information listed below:

```
svctag:flgs:id:reserved:reserved:reserved:pmspecific# comment
```
SVCTAG is a unique tag that identifies a service. This tag is unique only for the port monitor through which the service is available. Other port monitors may offer the same or other services with the same tag. A service requires both a port monitor tag and a service tag to identify it uniquely. SVCTAG may consist of up to 14 alphanumeric characters. The service entries are defined as:

**FLGS**

Flags with the following meanings may currently be included in this field:

- x: Do not enable this port. By default the port is enabled.
- u: Create a utmpx entry for this service. By default no utmpx entry is created for the service.

**ID**

The identity under which the service is to be started. The identity has the form of a login name as it appears in `/etc/passwd`.

**PMSPECIFIC**

Examples of port monitor information are addresses, the name of a process to execute, or the name of a STREAMS-based pipe to pass a connection through. This information will vary to meet the needs of each different type of port monitor.

**COMMENT**

A comment associated with the service entry. Port monitors may ignore the u flag if creating a utmpx entry for the service is not appropriate to the manner in which the service is to be invoked. Some services may not start properly unless utmpx entries have been created for them (for example, login). Each port monitor administrative file must contain one special comment of the form:

```
# VERSION=value
```

where `value` is an integer that represents the port monitor's version number. The version number defines the format of the port monitor administrative file. This comment line is created automatically when a port monitor is added to the system. It appears on a line by itself, before the service entries.

Previously, two pieces of information included in the `_pmtab` file were described: the port monitor's version number and the port monitor part of the service entries in the port monitor's `_pmtab` file. When a new port monitor is added, the version number must be known so that the `_pmtab` file can be correctly initialized. When a new service is added, the port monitor part of the `_pmtab` entry must be formatted correctly. Each port monitor must have an administrative command to perform these two tasks. The person who defines the port monitor must also define such an administrative command and its input options. When the command is invoked with these options, the information required for the port monitor part of the service entry must be correctly formatted for inclusion in the port monitor's `_pmtab` file and must be written to the standard output. To request the version number the command must be invoked with a `-V` option; when it is invoked in this way, the port monitor's current
version number must be written to the standard output. If the command fails for any reason during the execution of either of these tasks, no data should be written to standard output.

The interface between a port monitor and a service is determined solely by the service. Two mechanisms for invoking a service are presented here as examples.

New Service Invocations

The first interface is for services that are started anew with each request. This interface requires the port monitor to first \texttt{fork(2)} a child process. The child will eventually become the designated service by performing an \texttt{exec(1)}. Before the \texttt{exec(1)} happens, the port monitor may take some port monitor-specific action; however, one action that must occur is the interpretation of the per-service configuration script, if one is present. This is done by calling the library routine \texttt{doconfig(3NSL)}.

Standing Service Invocations

The second interface is for invocations of services that are actively running. To use this interface, a service must have one end of a stream pipe open and be prepared to receive connections through it.

To implement a port monitor, several generic requirements must be met. This section summarizes these requirements. In addition to the port monitor itself, an administrative command must be supplied.

Initial Environment

When a port monitor is started, it expects an initial execution environment in which:

- It has no file descriptors open
- It cannot be a process group leader
- It has an entry in \texttt{/etc/utmpx} of type LOGIN\_PROCESS
- An environment variable, ISTATE, is set to "enabled" or "disabled" to indicate the port monitor's correct initial state
- An environment variable, PMTAG, is set to the port monitor's assigned tag
- The directory that contains the port monitor's administrative files is its current directory
- The port monitor is able to create private files in the directory \texttt{/var/saf/tag}, where \texttt{tag} is the port monitor's tag
- The port monitor is running with user id 0 (root)

Important Files

Relative to its current directory, the following key files exist for a port monitor.
Port Monitor Responsibilities

A port monitor is responsible for performing the following tasks in addition to its port monitor function:

- Write its process id into the file _pid and place an advisory lock on the file
- Terminate gracefully on receipt of the signal SIGTERM
- Follow the protocol for message exchange with the SAC

A port monitor must perform the following tasks during service invocation:

- Create a utmpx entry if the requested service has the u flag set in _pmtab
- Port monitors may ignore this flag if creating a utmpx entry for the service does not make sense because of the manner in which the service is to be invoked. On the other hand, some services may not start properly unless utmpx entries have been created for them.
- Interpret the per-service configuration script for the requested service, if it exists, by calling the doconfig(3NSL) library routine

The library routine doconfig(3NSL), defined in libnsl.so, interprets the configuration scripts contained in the files /etc/saf/_sysconfig (the per-system configuration file), and /etc/saf/pmtag/_config (per-port monitor configuration files); and in /etc/saf/pmtag/svctag (per-service configuration files). Its syntax is:

```c
#include <sac.h>
int doconfig (int fd, char *script, long rflag);
```

script is the name of the configuration script; fd is a file descriptor that designates the stream to which stream manipulation operations are to be applied; rflag is a bitmask that indicates the mode in which script is to be interpreted. rflag may take two values, NORUN and NOASSIGN,
which may be or'd. If rflag is zero, all commands in the configuration script are eligible to be interpreted. If rflag has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If rflag has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns. If a command in the script fails, the interpretation of the script ceases at that point and a positive integer is returned; this number indicates which line in the script failed. If a system error occurs, a value of −1 is returned. If a script fails, the process whose environment was being established should not be started. In the example, doconfig(3NSL) is used to interpret a per-service configuration script.

```c
if ((i = doconfig (fd, svctag, 0)) != 0){
  error ("doconfig failed on line %d of script %s",i,svctag);
}
```

The Per-System Configuration File

The per-system configuration file, `/etc/saf/_sysconfig`, is delivered empty. It may be used to customize the environment for all services on the system by writing a command script in the interpreted language described in this chapter and on the doconfig(3NSL) manpage. When the SAC is started, it calls the doconfig(3NSL) function to interpret the per-system configuration script. The SAC is started when the system enters multiuser mode.

Per-Port Monitor Configuration Files

Per-port monitor configuration scripts (`/etc/saf/pmtag/_config`) are optional. They allow the user to customize the environment for any given port monitor and for the services that are available through the ports for which that port monitor is responsible. Per-port monitor configuration scripts are written in the same language used for per-system configuration scripts. The per-port monitor configuration script is interpreted when the port monitor is started. The port monitor is started by the SAC after the SAC has itself been started and after it has run its own configuration script, `/etc/saf/_sysconfig`. The per-port monitor configuration script may override defaults provided by the per-system configuration script.

Per-Service Configuration Files

Per-service configuration files allow the user to customize the environment for a specific service. For example, a service may require special privileges that are not available to the general user.
Using the language described in the `doconfig(3NSL)` manpage, you can write a script that will grant or limit such special privileges to a particular service offered through a particular port monitor. The per-service configuration may override defaults provided by higher-level configuration scripts. For example, the per-service configuration script may specify a set of STREAMS modules other than the default set.

The language in which configuration scripts are written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: `assign`, `push`, `pop`, `runwait`, and `run`. The comment character is `#`. Blank lines are not significant. No line in a command script may exceed 1024 characters.

`assign variable=value`  
Used to define environment variables; `variable` is the name of the environment variable and `value` is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. `value` may be quoted. The quoting rules are those used by the shell for defining environment variables. `assign` will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.

`push module1[,module2,module3,...]`  
Used to push STREAMS modules onto the stream designated by `fd`; `module1` is the name of the first module to be pushed, `module2` is the name of the second module to be pushed, and so on. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.

`pop [module]`  
Used to pop STREAMS modules off the designated stream. If `pop` is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If `module` is the special
keyword ALL, then all modules on the stream will be popped. Only modules above the topmost driver are affected.

runwait command

The runwait command runs a command and waits for it to complete; command is the path name of the command to be run. The command is run with /bin/sh -c prepended to it; shell scripts may thus be executed from configuration scripts. The runwait command will fail if command cannot be found or cannot be executed, or if command exits with a nonzero status.

run command

The run command is identical to runwait except that it does not wait for command to complete; command is the path name of the command to be run. run will not fail unless it is unable to create a child process to execute the command. Although they are syntactically indistinguishable, some of the commands available to run and runwait are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The doconfig interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See the sh(1) man page. The initial set of built-in commands is: cd, ulimit, umask.

Sample Port Monitor Code

This example shows an example of a "null" port monitor that simply responds to messages from the SAC.

```c
#include <stdlib.h>
#include <stdio.h>
#include <unistd.h>
#include <fcntl.h>
#include <signal.h>
#include <sac.h>

char Scratch[BUFSIZE]; /* scratch buffer */
char Tag[PMTAGSIZE + 1]; /* port monitor's tag */
FILE *Fp; /* file pointer for log file */
FILE *Tfp; /* file pointer for pid file */
char State; /* portmonitor's current state*/

main(argc, argv)
```
int argc;
char *argv[];
{
    char *istate;
    strcpy(Tag, getenv("PMTAG"));
    /*
     * open up a log file in port monitor's private directory
     */
    sprintf(Scratch, "/var/saf/%s/log", Tag);
    Fp = fopen(Scratch, "a+");
    if (Fp == (FILE *)NULL)
        exit(1);
    log(Fp, "starting");
    /*
     * retrieve initial state (either "enabled" or "disabled") and set
     * State accordingly
     */
    istate = getenv("ISTATE");
    sprintf(Scratch, "ISTATE is %s", istate);
    log(Fp, Scratch);
    if (!strcmp(istate, "enabled"))
        State = PM_ENABLED;
    else if (!strcmp(istate, "disabled"))
        State = PM_DISABLED;
    else {
        log(Fp, "invalid initial state");
        exit(1);
    }
    sprintf(Scratch, "PMTAG is %s", Tag);
    log(Fp, Scratch);
    /*
     * set up pid file and lock it to indicate that we are active
     */
    Tfp = fopen("_pid", "w");
    if (Tfp == (FILE *)NULL) {
        log(Fp, "couldn't open pid file");
        exit(1);
    }
    if (lockf(fileno(Tfp), F_TEST, 0) < 0) {
        log(Fp, "pid file already locked");
        exit(1);
    }
    log(Fp, "locking file");
    if (lockf(fileno(Tfp), F_LOCK, 0) < 0) {
        log(Fp, "lock failed");
        exit(1);
fprintf(Tfp, "%d", getpid());
fflush(Tfp);

/*
 * handle poll messages from the sac ... this function never returns
 */
handlepoll();
pause();
fclose(Tfp);
fclose(Fp);
}

handlepoll()
{
  int pfd; /* file descriptor for incoming pipe */
  int sfd; /* file descriptor for outgoing pipe */
  struct sacmsg sacmsg; /* incoming message */
  struct pmmsg pmmsg; /* outgoing message */

  /* open pipe for incoming messages from the sac */
  pfd = open("_pmpipe", O_RDONLY|O_NONBLOCK);
  if (pfd < 0) {
    log(Fp, "_pmpipe open failed");
    exit(1);
  }

  /* open pipe for outgoing messages to the sac */
  sfd = open("../_sacpipe", O_WRONLY);
  if (sfd < 0) {
    log(Fp, "sacpipe open failed");
    exit(1);
  }

  /* start to build a return message; we only support class 1 messages */
  strcpy(pmmsg.pm_tag, Tag);
  pmmsg.pm_size = 0;
  pmmsg.pm_maxclass = 1;

  /* keep responding to messages from the sac */
  for (;;) {
    if (read(pfd, &sacmsg, sizeof(sacmsg)) != sizeof(sacmsg)) {
      log(Fp, "pmpipe read failed");
exit(1);

/*
 * determine the message type and respond appropriately
 */
switch (sacmsg.sc_type) {
    case SC_STATUS:
        log(Fp, "Got SC_STATUS message");
        pmmsg.pm_type = PM_STATUS;
        pmmsg.pm_state = State;
        break;
    case SC_ENABLE:
        /*note internal state change below*/
        log(Fp, "Got SC_ENABLE message");
        pmmsg.pm_type = PM_STATUS;
        State = PM_ENABLED;
        pmmsg.pm_state = State;
        break;
    case SC_DISABLE:
        /*note internal state change below*/
        log(Fp, "Got SC_DISABLE message");
        pmmsg.pm_type = PM_STATUS;
        State = PM_DISABLED;
        pmmsg.pm_state = State;
        break;
    case SC_READDB:
        
        /* if this were a fully functional port
         * monitor it would read _pmtab here
         * and take appropriate action
         */
        log(Fp, "Got SC_READDB message");
        pmmsg.pm_type = PM_STATUS;
        pmmsg.pm_state = State;
        break;
    default:
        sprintf(Scratch, "Got unknown message <%d>",
            sacmsg.sc_type);
        log(Fp, Scratch);
        pmmsg.pm_type = PM_UNKNOWN;
        pmmsg.pm_state = State;
        break;
}

/*
 * send back a response to the poll
 * indicating current state
 */
if (write(sfd, &pmmsg, sizeof(pmmsg)) != sizeof(pmmsg))
    log(Fp, "sanity response failed");
}

/*
 * general logging function
 */
log(fp, msg)
    FILE *fp;
    char *msg;
{
    fprintf(fp, "%d; %s\n", getpid(), msg);
    fflush(fp);
}

The following examples show the sac.h header file.

/* length in bytes of a utmpx id */
# define IDLEN 4
/* wild character for utmpx ids */
# define SC_WILDC 0xff
/* max len in bytes for port monitor tag */
# define PMTAGSIZE 14
/*
 * values for rflag in doconfig()
 */
/* don't allow assign operations */
# define NOASSIGN 0x1
/* don't allow run or runwait operations */
# define NORUN 0x2
/*
 * message to SAC (header only). This header is forever fixed. The
 * size field (pm_size) defines the size of the data portion of the
 * message, which follows the header. The form of this optional data
 * portion is defined strictly by the message type (pm_type).
 */
struct pmmsg {
    char pm_type; /* type of message */
    uchar_t pm_state; /* current state of pm */
    char pm_maxclass; /* max message class this port monitor
        understands */
    char pm_tag[PMTAGSIZE + 1]; /* pm's tag */
    int pm_size; /* size of opt data portion */
};
/*

This section gives a description of the SAF files and directories.

### Directory Structure

- **/etc/saf/_sysconfig**
  - The per-system configuration script.
- **/etc/saf/_sactab**
  - The SAC's administrative file. Contains information about the port monitors for which the SAC is responsible.
- **/etc/saf/pmtag**
  - The home directory for port monitor `pmtag`.
- **/etc/saf/pmtag/_config**
  - The per-port monitor configuration script for port monitor `pmtag`.
- **/etc/saf/pmtag/_pmtab**
  - Port monitor `pmtag`'s administrative file. Contains information about the services for which `pmtag` is responsible.
- **/etc/saf/pmtag/svctag**
  - The file in which the per-service configuration script for service `svctag` (available through port monitor `pmtag`) is placed.
- **/etc/saf/pmtag/_pid**
  - The file in which a port monitor writes its process id in the current directory and places an advisory lock on the file.
- **/etc/saf/pmtag/_pmpipe**
  - The file in which the port monitor receives messages from the SAC and `./_sacpipe` and sends return messages to the SAC.
- **/var/saf/_log**
  - The SAC's log file.
- **/var/saf/pmtag**
  - The directory for files created by port monitor `pmtag`, for example its log file.

### List Of Commands

The following administrative commands relate to SAF.

- **sacadm(1M)**
  - port monitor administrative command
- **pmadm(1M)**
  - service administration command

### Attributes

See **attributes(5)** for descriptions of the following attributes:
exec(1), sh(1), init(1M), nlsadmin(1M), pmadm(1M), sac(1M), sacadm(1M), ttyadm(1M),
fork(2), doconfig(3NSL), attributes(5)
System Administration Commands - Part 2

**Name** sar, sa1, sa2, sadc – system activity report package

**Synopsis**

```
/usr/lib/sa/sadc [t n] [ofile]
/usr/lib/sa/sa1 [t n]
/usr/lib/sa/sa2 [-aAbcdgkmpqruvwy] [-e time] [-f filename]
       [-i sec] [-s time]
```

**Description** System activity data can be accessed at the special request of a user (see sar(1)) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use iostat(1M), sar(1), or vmstat(1M).

sadc and two shell procedures, sa1 and sa2, are used to sample, save, and process this data.

sadc, the data collector, samples system data n times, with an interval of t seconds between samples, and writes in binary format to ofile or to standard output. The sampling interval t should be greater than 5 seconds; otherwise, the activity of sadc itself may affect the sample. If t and n are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the svc:/system/sar:default service writes the restart mark to the daily data file using the command entry:

```
su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa
       /var/adm/sa/saddd date +%d"
```

The shell script sa1, a variant of sadc, is used to collect and store data in the binary file /var/adm/sa/sadd, where dd is the current day. The arguments t and n cause records to be written n times at an interval of t seconds, or once if omitted. The following entries in /var/spool/cron/crontabs/sys will produce records every 20 minutes during working hours and hourly otherwise:

```
0 * * 0-6 /usr/lib/sa/sa1
20,40 8-17 * * 1-5 /usr/lib/sa/sa1
```

See crontab(1) for details.

The shell script sa2, a variant of sar, writes a daily report in the file /var/adm/sa/saradd. See the OPTIONS section in sar(1) for an explanation of the various options. The following entry in /var/spool/cron/crontabs/sys will report important activities hourly during the working day:

```
5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
```

**Files**

```
/tmp/sa.adrfl address file
/var/adm/sa/saddd Daily data file
/var/adm/sa/saradd Daily report file
```
See attributes(5) for descriptions of the following attributes:

System Administration Guide: Advanced Administration

Notes The sar service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/sar

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
savecore (1M)

**Name**
savecore – save a crash dump of the operating system

**Synopsis**
/usr/bin/savecore [-Lvd] [-f dumpfile] [directory]

**Description**
The `savecore` utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the `dumpadm` service each time the system boots.

`savecore` can be configured by `dumpadm(1M)` to save crash dump data in either a compressed or uncompressed format. For the compressed format, `savecore` saves the crash dump data in the file `directory/vmcore.N.z`, where `N` in the pathname is replaced by a number which increments by one each time `savecore` is run in `directory`. The compressed file can be uncompressed in a separate step using the `-f dumpfile` option. For the uncompressed format, `savecore` saves the crash dump data in the file `directory/vmcore.N` and the kernel’s namelist in `directory/unix.N`

Before writing out a crash dump, `savecore` reads a number from the file `directory/minfree`. This is the minimum number of kilobytes that must remain free on the file system containing `directory`. If after saving the crash dump the file system containing `directory` would have less free space the number of kilobytes specified in `minfree`, the crash dump is not saved. If the `minfree` file does not exist, `savecore` assumes a `minfree` value of 1 megabyte.

The `savecore` utility also logs a reboot message using facility `LOG_AUTH` (see `syslog(3C)`). If the system crashed as a result of a panic, `savecore` logs the panic string too.

**Options**
The following options are supported:

- `-d` Disregard dump header valid flag. Force `savecore` to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.

- `-f dumpfile` Save a crash dump from the specified file instead of from the system’s current dump device. When given `directory/vmcore.N.z`, uncompress the file to `vmcore.N` and `unix.N`, where `N` is the same number as in the compressed name.

  This option may also be useful if the information stored on the dump device has been copied to an on-disk file by means of the `dd(1M)` command.

- `-L` Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces `savecore` to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps can only be performed if you have configured your system to have a dedicated dump device using `dumpadm(1M)`.

This manual page is from the Solaris System Administration Guide for SunOS 5.11, Copyright © 2011, 2015 Oracle and/or its affiliates. All rights reserved.
savecore -L does not suspend the system, so the contents of memory continue to change while the dump is saved. This means that live crash dumps are not fully self-consistent.

-v Verbose. Enables verbose error messages from savecore.

Operands The following operands are supported:

directory Save the crash dump files to the specified directory. If directory is not specified, savecore saves the crash dump files to the default savecore directory, configured by dumpadm(1M).

Files

- directory/vmcore.N
- directory/unix.N
- directory/bounds
- directory/minfree
- /var/crash/’uname -n’ (default crash dump directory)

See Also adb(1), mdb(1), svcs(1), dd(1M), dumpadm(1M), svcadm(1M), syslog(3C), attributes(5), smf(5)

Notes The system crash dump service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/dumpadm:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service’s status can be queried using the svcs(1) command.

If the dump device is also being used as a swap device, you must run savecore very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.
**Name**  
scadm – administer System Controller (SC)

**Synopsis**  
/usr/platform/platform-name/sbin/scadm subcommand [option] [argument]...

**Description**  
The scadm utility administers the System Controller (SC). This utility allows the host server to interact with the SC.

The scadm utility must be run as root.

The interface, output, and location in the directory hierarchy for scadm are uncommitted and might change.

*platform-name* is the name of the platform implementation. Use the *uname -i* command to identify the platform implementation. See *uname(1)*.

The scadm utility has a number of subcommands. Some subcommands have specific options and arguments associated with them. See SUBCOMMANDS, OPTIONS, OPERANDS, and USAGE.

**SUBCOMMANDS**  
Subcommands immediately follow the scadm command on the command line, and are separated from the command by a SPACE.

The following subcommands are supported

consolehistory  
Display the SC's console log. The SC maintains a running log which captures all console output. This log is maintained as a first-in, first-out buffer: New console output may displace old console output if the buffer is full. By default, only the last eight kilobytes of the console log file are displayed.

The optional -a argument specifies that the entire console log file be displayed.

It is possible for the SC to fill this log more quickly than the consolehistory subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the consolehistory subcommand displays "scadm: lost <number> bytes of console log data" in the log output, to indicate that some data was lost.

The format for the consolehistory subcommand is:

```
scadm consolehistory [-a]
```

The consolehistory subcommand is not available on all platforms. If this command is used on a platform that does not support it, scadm prints this message:

```
scadm: command/option not supported
```

and exit with non-zero status.
**date**
Display the SC's time and date

The format for the date subcommand is:
```
scadm date
```

**download**
Program the SC's firmware.

There are two parts to the firmware, the boot monitor and the main image.

By default, the `scadm` command's download programs the main firmware image. The boot argument selects programming of the boot monitor.

The format for the download subcommand is:
```
scadm download [boot] file
```

**fruhistory**
Display the contents of the “field replaceable unit” log maintained by the SC. By default, only the last eight kilobytes of the fru history log file are displayed. The data in contained this log contains snapshots of the SC’s "showfru" command, taken whenever the system is reset, or a hot-plug event is detected by the SC.

The optional -a argument specifies that the entire fru log file be displayed.

It is possible for the SC to fill this log more quickly than the fruhistory subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the fruhistory subcommand displays “scadm: lost <number> bytes of fru log data” in the log output, to indicate that some data was lost.

The format for the fruhistory subcommand is:
```
scadm fruhistory [-a]
```

The fruhistory subcommand is not available on all platforms. If this command is used on a platform which does not support it, scadm prints this message:
```
scadm: command/option not supported
```
and exit with non-zero status.

**help**
Display a list of commands.

The format for the help subcommand is:
```
scadm help
```

**loghistory**
Display the most recent entries in the SC event log. The optional -a argument causes the entire event log history to be displayed. The -a
The argument is available only on platforms which support large log files. On platforms which do not support large log files, this flag has no additional effect.

It is possible for the SC to fill this log more quickly than the `loghistory` subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the `loghistory` subcommand displays "scadm: lost <number> events" in the log output, to indicate that some data was lost.

The format for the `loghistory` subcommand is:
```
scadm loghistory [-a]
```

`resetsc`  
Reset the SC. There are two types of resets allowed, a `hard` reset and a `soft` reset. The `hard` reset is done by default. The `soft` reset can be selected by using the `-s` option.

The format for the `resetsc` subcommand is:
```
scadm resetsc [-s]
```

`send_event`  
Manually send a text based event. The SC can forward the event to the SC event log. You can configure the `-c` option to send a critical warning to email, alert to logged in SC users, and `syslog`. Critical events are logged to `syslog(3C)`. There is an 80 character limit to the length of the associated text message.

The format for the `send_event` subcommand is:
```
scadm send_event [-c] "message"
```

`set`  
Set SC configuration variables to a value.

Examples of SC configuration variables include: SC IP address `netsc_ipaddr` and SC Customer Information `sc_custominfo`. See the output from the `scadm help` command for a complete list of SC configuration variables.

The format for the `set` subcommand is:
```
scadm set variable value
```

`show`  
Display the current SC configuration variable settings. If no variable is specified, `scadm` shows all variable settings.

The format for the `show` subcommand is:
```
scadm show [variable]
```

`shownetwork`  
Display the current network configuration parameters for SC.
The format for the `shownetwork` subcommand is:
```
scadm shownetwork
```

**useradd**
Add user accounts to the SC. The SC supports up to sixteen separate users.

The format for the `useradd` subcommand is:
```
scadm useradd username
```

**userdel**
Delete a user account from SC.

The format for the `userdel` subcommand is:
```
scadm userdel username
```

**userpassword**
Set a password for the user account specified. This password overrides any existing password currently set. There is no verification of the old password before setting the new password.

The format for the `userpassword` subcommand is:
```
scadm userpassword username
```

**userperm**
Set the permission level for the user.

The format for the `userperm` subcommand is:
```
scadm userperm username [aucr]
```

**usershow**
Display details on the specified user account. If a username is not specified, all user accounts are displayed.

The format for the `usershow` subcommand is:
```
scadm usershow username
```

**version**
Display the version numbers of the SC and its components.

The format for the `version` subcommand is:
```
scadm version [-v]
```

**Options**
The `resetrsc`, `send_event`, and `version` subcommands have associated options. Options follow subcommands on the command line and are separated from the subcommand by a SPACE.

The `resetrsc` subcommand supports the following options:

- **-s**
  Perform a soft reset instead of a hard reset. A hard reset physically resets the SC hardware. The SC software jumps to the boot firmware, simulating a reset, for a soft reset.
The `send_event` subcommand supports the following options:

- `-c` Send a critical event. Without the `-c`, `-send_event` sends a warning.

The `version` subcommand supports the following options:

- `-v` Display a verbose output of version numbers and associated information.

The `consolehistory`, `fruhistory`, and `loghistory` subcommands support the following option:

- `-a` Display the entire log. These subcommands normally display only the most recent log data. This flag causes them to display the entire log.

### Operands

The `download`, `send_event`, `set`, `show`, `useradd`, `userdel`, `userperm`, `usershow`, `userpassword`, and `userperm` subcommands have associated arguments (operands).

If the subcommand has an option, the arguments follow the option on the command line and is separated from the option by a SPACE. If the subcommand does not have an option, the arguments follow the subcommand on the command line and are separated from the subcommand by a SPACE. If there are more than one arguments, they are separated from each other by a SPACE.

The `download` subcommand supports the following arguments:

- `boot` Program the boot monitor portion of the flash. The main portion of the flash is programmed without any arguments.

  - `file` Specify `file` as the path to where the boot or main firmware image resides for download.

    Examples of `file` are:

    ```
    /usr/platform/platform_type/lib/image/alommainfw
    or
    /usr/platform/platform_type/lib/image/alombootfw
    ```

The `send_event` subcommand supports the following arguments:

- "message" Describe event using the test contained in `message`. Enclose `message` in quotation marks.

The `set` subcommand supports the following arguments:

- `variable` Set SC configuration `variable`.

- `value` Set SC configuration variable to `value`.

The `show` subcommand supports the following arguments:
variable    Display the value of that particular variable.

The useradd subcommand supports the following arguments:

    username    Add new SC account username.

The userdel subcommand supports the following arguments:

    username    Remove SC account username.

The userperm subcommand supports the following arguments:

    -aucr    Set permissions for SC user accounts. If no permissions are specified, all four permissions are disabled and read only access is assigned.

    The following are the definitions for permissions:

    a    Allow user to administer or change the SC configuration variables

    u    Allow user to use the user commands to modify SC accounts

    c    Allow user to connect to console.

    r    Allow user to reset SC and to power on and off the host.

    username    Change permissions on SC account username.

The -usershow subcommand supports the following arguments:

    username    Display information on SC account username. If username is not specified, all accounts are displayed.

The userpassword subcommand supports the following arguments:

    username    Set SC password for username.

The userperm subcommand supports the following arguments:

    username    Change SC permissions for username.

Examples

EXAMPLE 1    Displaying the SC’s Date and Time
The following command displays the SC’s date and time.

    scadm date

EXAMPLE 2    Setting the SC’s Configuration Variables
The following command sets the SC’s configuration variable netsc_ipaddr to 192.168.1.2:

    scadm set netsc_ipaddr 192.168.1.2
EXAMPLE 3  Displaying the Current SC's Configuration Settings:
The following command displays the current SC configuration settings:
```
scadm show
```

EXAMPLE 4  Displaying the Current Settings for a Variable
The following command displays the current settings for the `sys_hostname` variable:
```
scadm show sys_hostname
```

EXAMPLE 5  Sending a Text-Based Critical Event
The following command sends a critical event to the SC logs, alerts the current SC users, and sends an event to `syslog(3C)`:
```
scadm send_event -c "The UPS signaled a loss in power"
```

EXAMPLE 6  Sending an Informational Text-Based Event
The following command sends an non-critical informational text based event to the SC event log:
```
scadm send_event "The disk is close to full capacity"
```

EXAMPLE 7  Adding a User To the SC
The following command adds user `rscroot` to the SC:
```
scadm useradd rscroot
```

EXAMPLE 8  Deleting a User From the SC
The following command deletes user `olduser` from the SC:
```
scadm userdel olduser
```

EXAMPLE 9  Displaying User Details
The following command displays details of all user accounts:
```
scadm usershow
```

EXAMPLE 10  Displaying Details for a Specific User
The following command displays details of user account `rscroot`:
```
scadm usershow rscroot
```

EXAMPLE 11  Setting the User Permission Level
The following command sets the full permission level for user `rscroot` to `aucr`:
```
scadm userperm rscroot aucr
```
EXAMPLE 12  Setting the User Permission Level
The following command sets only console access for user newuser to c:
scadm userperm newuser c

EXAMPLE 13  Setting the User Permission Level
The following command sets the permission level for user newuser to read only access:
scadm userperm newuser

EXAMPLE 14  Displaying the Current Network Parameters
The following command displays the current network configuration parameters for the SC:
scadm shownetwork

EXAMPLE 15  Viewing the Consolehistory
The following command displays the content console in the SC event log:
scadm consolehistory [-a]

EXAMPLE 16  Viewing the Fruhistory
The following command displays the content of the “field replacable unit” in the SC event log:
scadm fruhistory [-a]

EXAMPLE 17  Viewing the Loghistory
The following command displays the most recent entries in the SC event log:
scadm loghistory [-a]

EXAMPLE 18  Displaying Verbose Information
The following command displays verbose version information on the SC and its components:
scadm version -v

Exit Status  The following exit values are returned:
0           Successful completion.
non-zero    An error occurred.

Name  sckmd – Sun cryptographic key management daemon

Synopsis  /usr/platform/sun4u/lib/sckmd

Description  sckmd is a server process that resides on a high-end system domain to maintain the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure communications between a Service Processor or System Controller (SC) and platform management software running within a domain. The cvcd(1M) and dcs(1M) daemons use these Security Associations. See ipsec(7P) for a description of Security Associations.

The sckmd daemon receives SAs from the Service Processor or SC and installs these SAs in a domain’s Security Association Database (SADB) using pf_key(7P).

sckmd starts up at system boot time as an SMF service. The FMRI for the sckmd service is:

`svc:/platform/sun4u/sckmd:default`

A domain supports only one running sckmd process at a time.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>

</tbody>
</table>

See Also  cvcd(1M), dcs(1M), ipsecconf(1M), ipsecalgs(1M), attributes(5), ipsec(7P), ipsecah(7P), ipsecesp(7P), pf_key(7P)

Notes  The sckmd service is used only on Sun Fire high-end systems and the SPARC Enterprise Server family. It provides a mechanism for exchanging IPsec keys between a domain and its System Controller (SC) or Service Processor. These platforms use IPsec to secure the communications between the SC or Service Processor and certain platform-specific daemons in the domain. Such daemons currently include cvcd(1M) and dcs(1M).

The documentation for each platform that supports sckmd describes how to configure its use of IPsec for such communications. Also, the documentation for each specific application describes how to configure its security policies and IPsec options in a manner appropriate for the target platform. Refer to the platform- and application-specific documentation for detailed information.
sconadm – register system information

Synopsis
/usr/sbin/sconadm register -a
    [-e softwareUpdate | -E softwareUpdate]
    [-h hostname] [-l logfile] [-N]
    [-p proxy_host[:proxy_port]]
    [-r registration_profile] [-u username]
    [-x proxy_username]

/usr/sbin/sconadm proxy [-l logfile]
    [-p proxy_host[:proxy_port]]
    [-r registration_profile] [-x proxy_username]

Description
The sconadm utility is a command-line version of the Basic Registration GUI. In the first form
of the command in the SYNOPSIS, sconadm uses the register subcommand to register a host
with a registration server. In the second form, sconadm uses the proxy subcommand to
configure all of the components for software update to use an HTTP web proxy.

The parameters specified with -u, -e (or -E), -h, -p, and -x override values specified in your
registration profile. A template for this profile, owned by root, with read-only permissions, is
stored in /usr/lib/breg/data/RegistrationProfile.properties. See
registration_profile(4).

For the proxy subcommand, the proxy password is stored in the
RegistrationProfile.properties file, available if proxy authentication is needed. Storage
in the profile prevents proxy passwords from being exposed as part of a listing of processes on
a system.

Options
The following options are supported:

-a        Accept “Terms of Use and Binary Code License”. Absence of
          this option means that you do not accept the license.       
-e softwareUpdate Enable client to be managed at the Sun-hosted Update
          Connection Service.                                      
-E softwareUpdate Disable client’s ability to be managed at the Sun-hosted
          Update Connection Service.                               
-h hostname Hostname of the machine you want to register.      
-l logfile  Pathname of log file.                              
-N         Never register.                                     
-p proxy_host[:proxy_port] Proxy host name and optional proxy port number. 
-r registration_profile Pathname to a registration profile.    
-u username User name (a Sun Online Account).                  
-x proxy_username User name on the proxy host.
Examples  Unless specified otherwise, the commands below require root privileges or privileges equivalent to root. See privileges(5).

EXAMPLE 1  Registering a New System

Assume a file registrationprofile.properties in /tmp that contains the following:

```plaintext
userName=user123
password=abc123
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To register a new system using the profile above, you enter:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

EXAMPLE 2  Reregistering a System with a Different User

Assume a file registrationprofile.properties in /tmp with the contents shown below. Note the changed specification for userName and password.

```plaintext
userName=newuser
password=newpassword
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To reregister a new system using the profile above, you enter the same command you entered to register the system:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

EXAMPLE 3  Reregistering a System, Adding a Sun Subscription Key

Modify registrationprofile.properties as follows:

```plaintext
userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
```
EXAMPLE 3  Reregistering a System, Adding a Sun Subscription Key  (Continued)

proxyPort=
proxyUserName=
proxyPassword=

Run the command:
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties

EXAMPLE 4  Reregistering and Enabling Access to all Update Connection Services
Modify registrationprofile.properties as follows:

userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=

Note that portalEnabled is set to false. Run the command:
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties -e softwareUpdate

EXAMPLE 5  Never Registering
To never register a system, enter:
/usr/sbin/sconadm register -N

EXAMPLE 6  Using a Proxy Server With Proxy Authentication
Edit registrationprofile.properties as follows:

userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8800
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword

Run the command:
EXAMPLE 6  Using a Proxy Server With Proxy Authentication  
(Continued)

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties

EXAMPLE 7  Changing Proxy Host Settings

Edit registrationprofile.properties as follows:

userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword

Run the command:

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties

Then, change the proxyHostName value by running the following command:

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties \ 
-p newproxy.mycompany.com

After the preceding command all proxies use newproxy.mycompany.com.

EXAMPLE 8  Resetting a System Not to Use a Proxy

Edit registrationprofile.properties as follows:

userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=

Note that values for all proxy fields are null.

Run the command:

/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
Exit Status  0      Success.
>0      An error occurred.

Files  /usr/lib/breg/data/RegistrationProfile.properties
       Registration profile template.

The `sdpadm` command is used to display the system state of the Sockets Direct Protocol (SDP) protocol. The `sdpadm` command can optionally be used to set the state of the SDP protocol. See `sdp(7D)`.

By default the SDP protocol is disabled on the system. It can be enabled by using `sdpadm enable`.

The following subcommands are supported:
- **status**: Displays the system status of the SDP protocol
- **enable**: Enables the SDP protocol
- **disable**: Disables the SDP protocol

The required privileges to change the state of the SDP protocol are controlled by the network configuration policy. If a user does not have the correct privileges to set the SDP policy, `sdpadm` returns the current state of SDP without having changed the state.

Infiniband Specification Volume 1 (http://www.infinibandta.org)
The sendmail utility sends a message to one or more people, routing the message over whatever networks are necessary. sendmail does internetwork forwarding as necessary to deliver the message to the correct place.

sendmail is not intended as a user interface routine. Other programs provide user-friendly front ends. sendmail is used only to deliver preformatted messages.

With no flags, sendmail reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.

Local addresses are looked up in the local aliases file, or in a name service as defined by the nsswitch.conf file, and aliased appropriately. In addition, if there is a .forward file in a recipient's home directory, sendmail forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about .forward files.

Aliasing can be prevented by preceding the address with a backslash.

There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. This cannot occur under any circumstances unless root owns and has exclusive write permission to the /etc/mail/aliases* files.

If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a dead.letter file in the sender's home directory.

The sendmail service is managed by the service management facility, smf(5), under the service identifiers:

svc:/network/smtp:sendmail
svc:/network/sendmail-client:default

Administrative actions on these services, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The services' status can be queried using the svc(1) command.

These are separate services rather than instances of the same service so that other services can properly express any dependencies. In particular, here are some guidelines about which service/instance should be depended on for which purposes:
For a service that uses sendmail to send mail, an optional dependency on the service svc:/network/sendmail-client might be in order.

For a service that needs to receive mail in general, but does not depend on sendmail being the particular SMTP receiver, a dependency on the service svc:/network/smtp might be in order.

For a service that needs to interact with sendmail in particular, such as a Milter, a dependency on the instance svc:/network/smtp:sendmail might be in order.

For the last two, note the difference, as the latter has the ":sendmail" instance specification, whereas the former does not, thus representing the more general service.

On an unmodified system, access to sendmail by remote clients is enabled and disabled through the service management facility (see smf(5)). In particular, remote access is determined by the value of the local_only SMF property:

svc:/network/smtp:sendmail/config/local_only = true

A setting of true, as above, disallows remote access; false allows remote access. The default value is true.

The following example shows the sequence of SMF commands used to enable sendmail to allow access to remote systems:

```
# svccfg -s svc:/network/smtp:sendmail setprop config/local_only = false
# svcadm refresh svc:/network/smtp:sendmail
# svcadm restart svc:/network/smtp:sendmail
```

See svcadm(1M) and svccfg(1M).

Note, however, on a system where any of the sendmail(4) files have been customized, setting this property might not have the intended effect. See sendmail(4) for details.

Automated Rebuilding of Configuration Files

Sendmail uses TCP Wrappers to restrict access to hosts. It uses the service name of sendmail for hosts_access(). For more information on TCP Wrappers, see tcpd(1M) and hosts_access(4) in the SUNWtcpd package. tcpd(1M) and hosts_access(4) are not part of the Solaris man pages.

Startup Options

The /etc/default/sendmail file stores startup options for sendmail so that the options are not removed when a host is upgraded. See also sendmail(4) for details on which service properties can be set to automate (re)building of configuration files when the service is started.

You can use the following variables in the /etc/default/sendmail startup file:
CLIENTOPTIONS=string
Selects additional options to be used with the client daemon, which looks in the client-only queue (/var/spool/clientmqueue) and acts as a client queue runner. No syntax checking is done, so be careful when making changes to this variable.

CLIENTQUEUEINTERVAL=#
Similar to the QUEUEINTERVAL option, CLIENTQUEUEINTERVAL sets the time interval for mail queue runs. However, the CLIENTQUEUEINTERVAL option controls the functions of the client daemon, instead of the functions of the master daemon. Typically, the master daemon is able to deliver all messages to the SMTP port. However, if the message load is too high or the master daemon is not running, then messages go into the client-only queue, /var/spool/clientmqueue. The client daemon, which checks in the client-only queue, then acts as a client queue processor.

ETRN_HOSTS=string
Enables an SMTP client and server to interact immediately without waiting for the queue run intervals, which are periodic. The server can immediately deliver the portion of its queue that goes to the specified hosts. For more information, refer to the etrn(1M) man page.

MODE=-bd
Selects the mode to start sendmail with. Use the -bd option or leave it undefined.

OPTIONS=string
Selects additional options to be used with the master daemon. No syntax checking is done, so be careful when making changes to this variable.

QUEUEINTERVAL=#
Sets the interval for mail queue runs on the master daemon. # can be a positive integer that is followed by either s for seconds, m for minutes, h for hours, d for days, or w for weeks. The syntax is checked before sendmail is started. If the interval is negative or if the entry does not end with an appropriate letter, the interval is ignored and sendmail starts with a queue interval of 15 minutes.

QUEUEOPTIONS=p
Enables one persistent queue runner that sleeps between queue run intervals, instead of a new queue runner for each queue run interval. You can set this option to p, which is the only setting available. Otherwise, this option is not set.

Mail Filter API  sendmail supports a mail filter API called "milter". For more information, see /usr/include/libmilter/README and http://www.milter.org

Options  The following options are supported:

   -Ac
       Uses submit.cf even if the operation mode does not indicate an initial mail submission.

   -Am
       Uses sendmail.cf even if the operation mode indicates an initial mail submission.
-ba
  Goes into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all
  messages are generated with a RETURN-LINEFEED at the end. Also, the From: and
  Sender: fields are examined for the name of the sender.

-bd
  Runs as a daemon in the background, waiting for incoming SMTP connections.

-bD
  Runs as a daemon in the foreground, waiting for incoming SMTP connections.

-bi
  Initializes the aliases(4) database. Root must own and have exclusive write permission to
  the /etc/mail/aliases* files for successful use of this option.

-bI
  Runs as a daemon (like -bd) but accepts only loopback SMTP connections.

-bm
  Delivers mail in the usual way (default).

-bp
  Prints a summary of the mail queues.

-bP
  Prints the number of entries in the queues. This option is only available with shared
  memory support.

-bs
  Uses the SMTP protocol as described in RFC 2821. This flag implies all the operations of
  the -ba flag that are compatible with SMTP.

-bt
  Runs in address test mode. This mode reads addresses and shows the steps in parsing; it is
  used for debugging configuration tables.

-bv
  Verifies names only. Does not try to collect or deliver a message. Verify mode is normally
  used for validating users or mailing lists.

-B type
  Indicates body type (7BIT or 8BITMIME).

-C file
  Uses alternate configuration file.

-D logfile
  Send debugging output to the indicated log file instead of stdout.

-d X
  Sets debugging value to X.
-f name
   Sets the name of the "from" person (that is, the sender of the mail).

-F fullname
   Sets the full name of the sender.

-G
   When accepting messages by way of the command line, indicates that they are for relay (gateway) submission. When this flag is set, sendmail might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. sendmail does not do any canonicalization in this mode.

-h N
   Sets the hop count to N. The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.

-L tag
   Sets the identifier used in syslog messages to the supplied tag.

-M x=value
   Sets macro x to the specified value.

-n
   Does not do aliasing.

-N notifications
   Tags all addresses being sent as wanting the indicated notifications, which consists of the word "NEVER" or a comma-separated list of "SUCCESS", "FAILURE", and "DELAY" for successful delivery, failure and a message that is stuck in a queue somewhere. The default is "FAILURE,DELAY".

-o x=value
   Sets option x to the specified value. Processing Options are described below.

-0 option=value
   Sets option to the specified value (for long from names). Processing Options are described below.

-p protocol
   Sets the sending protocol. The protocol field can be in form protocol: host to set both the sending protocol and the sending host. For example: -pUUCP:uunet sets the sending protocol to UUCP and the sending host to uunet. Some existing programs use -oM to set the r and s macros; this is equivalent to using -p.

-q[time]
   Processes saved messages in the queue at given intervals. If time is omitted, processes the queue once. time is given as a tagged number, where s is seconds, m is minutes, h is hours, d is days, and w is weeks. For example, -q1h30m or -q90m would both set the timeout to one hour thirty minutes.
By default, sendmail runs in the background. This option can be used safely with -bd.

-qp [time ]
Similar to -q [time], except that instead of periodically forking a child to process the queue, sendmail forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time (time) is specified as the argument; it defaults to 1 second. The process always sleeps at least 5 seconds if the queue was empty in the previous queue run.

-qf
Processes saved messages in the queue once and does not fork (2), but runs in the foreground.

-q6 name
Processes jobs in queue group called name only.

-q[!]I substr
Limits processed jobs to those containing substr as a substring of the queue ID or not when ! is specified.

-q[!]Q substr
Limits processed jobs to those quarantined jobs containing substr as a substring of the quarantine reason or not when ! is specified.

-q[!]R substr
Limits processed jobs to those containing substr as a substring of one of the recipients or not when ! is specified.

-q[!]S substr
Limits processed jobs to those containing substr as a substring of the sender or not when ! is specified.

-q[reason]
Quarantines a normal queue item with the given reason or unquarantines a quarantined queue item if no reason is given. This should only be used with some sort of item matching as described above.

-r name
An alternate and obsolete form of the -f flag.

-R ret
Identifies the information you want returned if the message bounces. ret can be HDRS for headers only or FULL for headers plus body.

-t
Reads message for recipients. To:, Cc:, and Bcc: lines are scanned for people to send to. The Bcc: line is deleted before transmission. Any addresses in the argument list is suppressed. The NoRecipientAction Processing Option can be used to change the behavior when no legal recipients are included in the message.
-v
   Goes into verbose mode. Alias expansions are announced, and so forth.

-\v \envid
   The indicated \envid is passed with the envelope of the message and returned if the message
   bounces.

-\x \logfile
   Logs all traffic in and out of sendmail in the indicated \logfile for debugging mailer
   problems. This produces a lot of data very quickly and should be used sparingly.

Processing Options
   There are a number of “random” options that can be set from a configuration file. Options are
   represented by a single character or by multiple character names. The syntax for the single
   character names of is:

   0\xvalue
   This sets option \x to be \value. Depending on the option, \value may be a string, an integer, a
   boolean (with legal values t, T, f, or F; the default is TRUE), or a time interval.

   The multiple character or long names use this syntax:

   0 \Longname=\argument
   This sets the option \Longname to be \argument. The long names are beneficial because they are
   easier to interpret than the single character names.

   Not all processing options have single character names associated with them. In the list below,
   the multiple character name is presented first followed by the single character syntax enclosed
   in parentheses.

   AliasFile (Afile)
      Specifies possible alias files.

   AliasWait (a N)
      If set, waits up to \N minutes for an “@:@” entry to exist in the \aliases(4) database before
      starting up. If it does not appear in \N minutes, issues a warning. Defaults to 10 minutes.

   AllowBogusHELO
      Allows a HELO SMTP command that does not include a host name. By default this option is
      disabled.

   BadRcptThrottle=N
      If set and more than the specified number of recipients in a single SMTP envelope are
      rejected, sleeps for one second after each rejected RCPT command.

   BlankSub (Bc)
      Sets the blank substitution character to \c. Unquoted spaces in addresses are replaced by this
      character. Defaults to SPACE (that is, no change is made).
CACertFile
File containing one CA cert.

CACertPath
Path to directory with certs of CAs.

CheckAliases \((n)\)
Validates the RHS of aliases when rebuilding the aliases\((4)\) database.

CheckpointInterval \((\text{CN})\)
Checkpoints the queue every \(N\) (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last \(N\) recipients.

ClassFactor \((z\text{fact})\)
The indicated factor \(\text{fact}\) is multiplied by the message class (determined by the Precedence: field in the user header and the P lines in the configuration file) and subtracted from the priority. Thus, messages with a higher Priority: are favored. Defaults to 1800.

ClientCertFile
File containing the cert of the client, that is, this cert is used when sendmail acts as client.

ClientKeyFile
File containing the private key belonging to the client cert.

ClientPortOptions
Sets client SMTP options. The options are key=value pairs. Known keys are:

\text{Addr Address Mask}
Address Mask defaults to INADDR\_ANY. The address mask can be a numeric address in dot notation or a network name.

\text{Family}
Address family (defaults to INET).

\text{Listen}
Size of listen queue (defaults to 10).

\text{Port}
Name/number of listening port (defaults to smtp).

\text{RcvBufSize}
The size of the TCP/IP receive buffer.

\text{SndBufSize}
The size of the TCP/IP send buffer.

\text{Modifier}
Options (flags) for the daemon. Can be:

\text{h}
Uses name of interface for HELO command.
If $h$ is set, the name corresponding to the outgoing interface address (whether chosen by means of the Connection parameter or the default) is used for the HELO/EHLO command.

**ColonOkInAddr**
If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 "group" syntax. This option is on for version 5 and lower configuration files.

**ConnectionCacheSize ($kN$)**
The maximum number of open connections that are to be cached at a time. The default is 1. This delays closing the current connection until either this invocation of sendmail needs to connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is, connections are closed immediately.

**ConnectionCacheTimeout ($Ktimeout$)**
The maximum amount of time a cached connection is permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before sendmail uses a cached connection, it always sends a NOOP (no operation) command to check the connection. If the NOOP command fails, it reopens the connection. This keeps your end from failing if the other end times out. The point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

**ConnectionRateThrottle**
The maximum number of connections permitted per second. After this many connections are accepted, further connections are delayed. If not set or <= 0, there is no limit.

**ConnectionRateWindowSize**
Define the length of the interval for which the number of incoming connections is maintained. The default is 60 seconds.

**ControlSocketName**
Name of the control socket for daemon management. A running sendmail daemon can be controlled through this Unix domain socket. Available commands are: help, restart, shutdown, and status. The status command returns the current number of daemon children, the free disk space (in blocks) of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket is available. For the sake of security, this Unix domain socket must be in a directory which is accessible only by root; /var/spool/mqueue/.smcontrol is recommended for the socket name.

**CRLFile**
File containing certificate revocation status, useful for X.509v3 authentication.

**DaemonPortOptions ($0ptions$)**
Sets server SMTP options. The options are key=value pairs. Known keys are:

**Name**
User-definable name for the daemon (defaults to "Daemon#"). Used for error messages and logging.
Addr
    Address mask (defaults `INADDR_ANY`).
    The address mask may be a numeric address in dot notation or a network name.

Family
    Address family (defaults to `INET`).

InputMailFilters
    List of input mail filters for the daemon.

Listen
    Size of listen queue (defaults to 10).

Modifier
    Options (flags) for the daemon; can be a sequence (without any delimiters) of:
    a
        Requires authentication.
    b
        Binds to interface through which mail has been received.
    c
        Performs hostname canonification (`.cf`).
    f
        Requires fully qualified hostname (`.cf`).
    h
        Uses name of interface for \texttt{HELO} command.
    u
        Allows unqualified addresses (`.cf`).
    C
        Does not perform hostname canonification.
    E
        Disallows \texttt{ETRN} (see RFC 2476).

Name
    User-definable name for the daemon (defaults to `Daemon#`). Used for error messages and logging.

Port
    Name/number of listening port (defaults to `smtp`).

ReceiveSize
    The size of the TCP/IP receive buffer.

SendSize
    The size of the TCP/IP send buffer.
children
   Maximum number of children per daemon. See MaxDaemonChildren.

DeliveryMode
   Delivery mode per daemon. See DeliveryMode.

refuseLA
   RefuseLA per daemon.

delayLA
   DelayLA per daemon.

queueLA
   QueueLA per daemon.

sendmail listens on a new socket for each occurrence of the DaemonPortOptions option in a configuration file.

DataFileBufferSize
   Sets the threshold, in bytes, before a memory-based queue data file becomes disk-based.
   The default is 4096 bytes.

DeadLetterDrop
   Defines the location of the system-wide dead.letter file, formerly hard-coded to /var/tmp/dead.letter. If this option is not set (the default), sendmail does not attempt to save to a system-wide dead.letter file in the event it cannot bounce the mail to the user or postmaster. Instead, it renames the qf file as it has in the past when the dead.letter file could not be opened.

DefaultCharSet
   Sets the default character set to use when converting unlabeled 8 bit input to MIME.

DefaultUser (gid) or (uid)
   Sets the default group ID for mailers to run in to gid or set the default userid for mailers to uid. Defaults to 1. The value can also be given as a symbolic group or user name.

DelayLA=LA
   When the system load average exceeds LA, sendmail sleeps for one second on most SMTP commands and before accepting connections.

DeliverByMin=time
   Sets minimum time for Deliver By SMTP Service Extension (RFC 2852). If 0, no time is listed, if less than 0, the extension is not offered, if greater than 0, it is listed as minimum time for the EHLO keyword DELIVERBY.

DeliveryMode (dx)
   Delivers in mode x. Legal modes are:
   i
      Delivers interactively (synchronously).
b  Delivers in background (asynchronously).

d  Deferred mode. Database lookups are deferred until the actual queue run.

q  Just queues the message (delivers during queue run).

Defaults to b if no option is specified, i if it is specified but given no argument (that is, Od is equivalent to OdI).

DHPARAMETERS  
   File containing the DH parameters.

DIALDELAY  
   If a connection fails, waits this many seconds and tries again. Zero means “do not retry”.

DON'TBLAMESENDMAIL  
   If set, overrides the file safety checks. This compromises system security and should not be used. See http://www.sendmail.org/tips/dontBlameSendmail for more information.

DON'TEXPANDCNAMES  
   If set, $[ ... $] lookups that do DNS-based lookups do not expand CNAME records.

DON'TINITGROUPS  
   If set, the initgroups(3C) routine is never invoked. If you set this, agents run on behalf of users only have their primary (/etc/passwd) group permissions.

DON'TPROBEINTERFACES  
   If set, sendmail does not insert the names and addresses of any local interfaces into the $=w class. If set, you must also include support for these addresses, otherwise mail to addresses in this list bounces with a configuration error.

DON'TPRUNERoutes (R)  
   If set, does not prune route-addr syntax addresses to the minimum possible.

DOUBLEBOUNCEADDRESS  
   If an error occurs when sending an error message, sends that “double bounce” error message to this address.

EIGHTBITMODE (8)  
   Uses 8–bit data handling. This option requires one of the following keys. The key can selected by using just the first character, but using the full word is better for clarity.

   mimify  
      Does any necessary conversion of 8BITMIME to 7–bit.

   pass  
      Passes unlabeled 8–bit input through as is.
strict
  Rejects unlabeled 8–bit input.

ErrorHeader (Efile/message)
  Appends error messages with the indicated message. If it begins with a slash, it is assumed
to be the pathname of a file containing a message (this is the recommended setting).
Otherwise, it is a literal message. The error file might contain the name, email address,
and/or phone number of a local postmaster who could provide assistance to end users. If
the option is missing or NULL, or if it names a file which does not exist or which is not
readable, no message is printed.

ErrorMode (ex)
  Disposes of errors using mode x. The values for x are:
  
  e
    Mails back errors and gives 0 exit status always.
  
  m
    Mails back errors.
  
  p
    Prints error messages (default).
  
  q
    No messages, just gives exit status.
  
  w
    Writes back errors (mail if user not logged in).

FallbackMXhost (Vfallbackhost)
  If specified, the fallbackhost acts like a very low priority MX on every host. This is intended
to be used by sites with poor network connectivity.

FallBackSmartHost
  If specified, the fallBackSmartHost is used in a last-ditch effort for each host. This is
intended to be used by sites with "fake internal DNS". That is, a company whose DNS
accurately reflects the world inside that company's domain but not outside.

FastSplit
  If set to a value greater than zero (the default is one), it suppresses the MX lookups on
addresses when they are initially sorted, that is, for the first delivery attempt. This usually
results in faster envelope splitting unless the MX records are readily available in a local
DNS cache. To enforce initial sorting based on MX records set FastSplit to zero. If the
mail is submitted directly from the command line, then the value also limits the number of
processes to deliver the envelopes; if more envelopes are created they are only queued up
and must be taken care of by a queue run. Since the default submission method is by way of
SMTP (either from a MUA or by way of the Message Submission Program [MSP]), the
value of FastSplit is seldom used to limit the number of processes to deliver the
envelopes.
ForkEachJob (Y)
    If set, delivers each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.

ForwardPath (J path)
    Sets the path for searching for users' .forward files. The default is $z/.forward. Some sites that use the automounter may prefer to change this to /var/forward/$u to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; sendmail stops at the first file it can successfully and safely open. For example, /var/forward/$u:$z/.forward searches first in /var/forward/username and then in ~username/.forward (but only if the first file does not exist). Refer to the NOTES section for more information.

HeloName=name
    Sets the name to be used for HELO/EHLO (instead of $j).

HelpFile (H file)
    Specifies the help file for SMTP.

HoldExpensive (c)
    If an outgoing mailer is marked as being expensive, does not connect immediately.

HostsFile
    Sets the file to use when doing "file" type access of host names.

HostStatusDirectory
    If set, host status is kept on disk between sendmail runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.

IgnoreDots (i)
    Ignores dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

LogLevel (L n)
    Sets the default log level to n. Defaults to 9.

(M x value)
    Sets the macro x to value. This is intended only for use from the command line.

MailboxDatabase
    Type of lookup to find information about local mail boxes, defaults to pw which uses getpwnam(3C). Other types can be introduced by adding them to the source code, see libsm/mbdb.c for details.

MatchGECOS (G)
    Tries to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in /etc/passwd as well as the login name.
MaxDaemonChildren
The maximum number of children the daemon permits. After this number, connections are rejected. If not set or \( \leq 0 \), there is no limit.

MaxHopCount (\( hN \))
The maximum hop count. Messages that have been processed more than \( N \) times are assumed to be in a loop and are rejected. Defaults to 25.

MaxMessageSize
The maximum size of messages that are accepted (in bytes).

MaxMimeHeaderLength=\( M[/N] \)
Sets the maximum length of certain MIME header field values to \( M \) characters. For some of these headers which take parameters, the maximum length of each parameter is set to \( N \) if specified. If \( /N \) is not specified, one half of \( M \) is used. By default, these values are 0, meaning no checks are done.

MaxNOOPCommands=\( N \)
Overrides the default of 20 for the number of useless commands.

MaxQueueChildren=\( N \)
When set, this limits the number of concurrent queue runner processes to \( N \). This helps to control the amount of system resources used when processing the queue. When there are multiple queue groups defined and the total number of queue runners for these queue groups would exceed \( \text{MaxQueueChildren} \) then the queue groups are not all run concurrently. That is, some portion of the queue groups run concurrently such that \( \text{MaxQueueChildren} \) is not be exceeded, while the remaining queue groups are run later (in round robin order). See \text{MaxRunnersPerQueue}.

MaxQueueRunSize
If set, limits the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

MaxRunnersPerQueue=\( N \)
This sets the default maximum number of queue runners for queue groups. Up to \( N \) queue runners work in parallel on a queue group’s messages. This is useful where the processing of a message in the queue might delay the processing of subsequent messages. Such a delay can be the result of non-erroneous situations such as a low bandwidth connection. The can be overridden on a per queue group basis by setting the \text{Runners} option. The default is 1 when not set.

MeToo (\( m \))
Sends to me too, even if I am in an alias expansion.

MaxRecipientsPerMessage
If set, allows no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.
MinFreeBlocks (bN/M)
Insists on at least N blocks free on the file system that holds the queue files before accepting email by way of SMTP. If there is insufficient space, sendmail gives a 452 response to the MAIL command. This invites the sender to try again later. The optional M is a maximum message size advertised in the ESMTP EHLO response. It is currently otherwise unused.

MinQueueAge
Specifies the amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

MustQuoteChars
Specifies the characters to be quoted in a full name phrase. &,.;:()[] are quoted automatically.

NiceQueueRun
Specifies the priority of queue runners. See nice(1).

NoRecipientAction
Sets action if there are no legal recipient files in the message. The legal values are:

  add-apparently-to
  Adds an Apparently-to: header with all the known recipients (which may expose blind recipients).

  add-bcc
  Adds an empty Bcc: header.

  add-to
  Adds a To: header with all the known recipients (which may expose blind recipients).

  add-to-undisclosed
  Adds a To: undisclosed-recipients: header.

  none
  Does nothing, that is, leaves the message as it is.

OldStyleHeaders (o)
Assumes that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it is assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.

OperatorChars or $o
Defines the list of characters that can be used to separate the components of an address into tokens.

PidFile
Specifies the filename of the pid file. The default is /var/run/sendmail.pid. The filename is macro-expanded before it is opened, and unlinked when sendmail exits.
PostmasterCopy (Ppostmaster)
If set, copies of error messages are sent to the named postmaster. Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.

PrivacyOptions (popt, opt,...)
Sets privacy options. Privacy is really a misnomer; many of these options are just a way of insisting on stricter adherence to the SMTP protocol.

The goaway pseudo-flag sets all flags except noreceipts, restrictmailq, restrictqrun, restrictexpand, noetrn, and nobodyreturn. If mailq is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. The restrict-expand pseudo-flag instructs sendmail to drop privileges when the -bv option is given by users who are neither root nor the TrustedUser so users cannot read private aliases, forwards, or :include: files. It adds the NonRootSafeAddr to the “DontBlame-Sendmail” option to prevent misleading unsafe address warnings. It also overrides the -v (verbose) command line option to prevent information leakage. AuthenticationWarnings add warnings about various conditions that may indicate attempts to fool the mail system, such as using an non-standard queue directory.

The options can be selected from:

authwarnings
  Puts X-Authentication-Warning: headers in messages.

goaway
  Disallows essentially all SMTP status queries.

needexpnheho
  Insists on HELO or EHL0 command before EXPN.

needmailheho
  Insists on HELO or EHL0 command before MAIL.

needvrfyheho
  Insists on HELO or EHL0 command before VRFY.

noactualrecipient
  Do not put an X-Actual-Recipient line in a DNS that reveals the actual account to which an address is mapped.

noetrn
  Disallows ETRN entirely.

noexpn
  Disallows EXPN entirely.
noreceipts
Prevents return receipts.

nobodyreturn
Does not return the body of a message with DSNs.

novrfy
Disallows VRFY entirely.

public
Allows open access.

restrictexpand
Restricts -bv and -v command line flags.

restrictmailq
Restricts mailq command.

restrictqrun
Restricts -q command line flag.

ProcessTitlePrefix string
Prefixes the process title shown on “/usr/ucb/ps auxww” listings with string. The string is macro processed.

QueueDirectory (Q dir)
Uses the named dir as the queue directory.

QueueFactor (Q factor)
Uses factor as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (x flag) to determine the maximum message priority to be sent. Defaults to 600000.

QueueFileMode=mode
Defaults permissions for queue files (octal). If not set, sendmail uses 0600 unless its real and effective uid are different in which case it uses 0644.

QueueLA (Q LA)
When the system load average exceeds LA, just queues messages (that is, does not try to send them). Defaults to eight times the number of processors online when sendmail starts.

QueueSortOrder=algorithm
Sets the algorithm used for sorting the queue. Only the first character of the value is used. Legal values are host (to order by the name of the first host name of the first recipient), filename (to order by the name of the queue file name), time (to order by the submission/creation time), random (to order randomly), modification (to order by the modification time of the qf file (older entries first)), none (to not order), and priority (to order by message priority). Host ordering makes better use of the connection cache, but may tend to process low priority messages that go to a single host over high priority.
messages that go to several hosts; it probably shouldn't be used on slow network links. Filename and modification time ordering saves the overhead of reading all of the queued items before starting the queue run. Creation (submission) time ordering is almost always a bad idea, since it allows large, bulk mail to go out before smaller, personal mail, but may have applicability on some hosts with very fast connections. Random is useful if several queue runners are started by hand which try to drain the same queue since odds are they are working on different parts of the queue at the same time. Priority ordering is the default.

QueueTimeout (Trtime/wtime)
Sets the queue timeout to rtime. After this interval, messages that have not been successfully sent are returned to the sender. Defaults to five days (5d). The optional wtime is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.

RandFile
File containing random data (use prefix file:) or the name of the UNIX socket if EGDS is used (use prefix egd:). Note that Solaris supports random(7D), so this does not need to be specified.

RecipientFactor (yfact)
The indicated factor fact is added to the priority (thus lowering the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.

RefuseLA (XLA)
When the system load average exceeds LA, refuses incoming SMTP connections. Defaults to 12 times the number of processors online when sendmail starts.

RejectLogInterval
Log interval when refusing connections for this long (default: 3h).

ResolverOptions (I)
Tunes DNS lookups.

RetryFactor (Zfact)
The indicated factor fact is added to the priority every time a job is processed. Thus, each time a job is processed, its priority is decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

RrtImpliesDsn
If this option is set, a Return-Receipt-To: header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

RunAsUser
If set, becomes this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.
SafeFileEnvironment
   If set, sendmail does a chroot into this directory before writing files.

SaveFromLine (f)
   Saves Unix-style From lines at the front of headers. Normally they are assumed redundant
   and discarded.

SendMimeErrors (j)
   If set, sends error messages in MIME format (see RFC 2045 and RFC 1344 for details). If
   disabled, sendmail does not return the DSN keyword in response to an EHLO and does not
   do Delivery Status Notification processing as described in RFC 1891.

ServerCertFile
   File containing the cert of the server, that is, this cert is used when sendmail acts as server.

ServerKeyFile
   File containing the private key belonging to the server cert.

ServiceSwitchFile
   Defines the path to the service-switch file. Since the service-switch file is defined in the
   Solaris operating environment this option is ignored.

SevenBitInput (7)
   Strips input to seven bits for compatibility with old systems. This should not be necessary.

SharedMemoryKey
   Specifies key to use for shared memory segment. If not set (or 0), shared memory is not be
   used. If this option is set, sendmail can share some data between different instances. For
   example, the number of entries in a queue directory or the available space in a file system.
   This allows for more efficient program execution, since only one process needs to update
   the data instead of each individual process gathering the data each time it is required.

SharedMemoryKeyFile=file
   If SharedMemoryKeyFile is set to -1, the automatically selected shared memory key will be
   stored in the specified file.

SingleLineFromHeader
   If set, From: lines that have embedded newlines are unwrapped onto one line.

SingleThreadDelivery
   If this option and the HostStatusDirectory option are both set, uses single thread
   deliveries to other hosts.

SMTPGreetingMessage or $e
   Specifies the initial SMTP greeting message.

SoftBounce
   If set, issue temporary errors (4xy) instead of permanent errors (5xy). This can be useful
   during testing of a new configuration to avoid erroneous bouncing of mail.
StatusFile (Sfile)
Logs statistics in the named file. By default, this is /etc/mail/sendmail.st. As root, you must touch(1) this file to enable mailstats(1).

SuperSafe (s)
This option can be set to True, False, Interactive, or PostMilter. If set to True, sendmail is set to super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. sendmail always instantiates the queue file before returning control to the client under any circumstances. This should really always be set to True. The Interactive value has been introduced in 8.12 and can be used together with DeliveryMode=i. It skips some synchronization calls which are effectively doubled in the code execution path for this mode. If set to PostMilter, sendmail defers synchronizing the queue file until any milters have signaled acceptance of the message. PostMilter is useful only when sendmail is running as an SMTP server; in all other situations it acts the same as True.

TempFileMode (Fmode)
Specifies the file mode for queue files.

Timeout (rtimeouts)
Timeout reads after time interval. The timeouts argument is a list of keyword=value pairs. All but command apply to client SMTP. For backward compatibility, a timeout with no keyword= part is set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

- aconnect: all connections for a single delivery attempt [0, unspecified]
- command: command read [1h, 5m]
- connect: initial connect [0, unspecified]
- control: complete control socket transaction [2m, none]
- datablock: data block read [1h, 3m]
- datafinal: reply to final . in data [1h, 10m]
- datainit: reply to DATA command [5m, 2m]
- fileopen: file open [60sec, none]
- helo: reply to HELO or EHLO command [5m, none]

</tr>
<tr>
<td><strong>resolver.retry.first</strong></td>
<td>Number of times to retransmit a resolver query for the first attempt to deliver a message [varies].</td>
</tr>
</tbody>
</table>
resolver.retry.normal
   Number of times to retransmit a resolver query for all look-ups except the first delivery attempt [varies].

rset
   reply to RSET command [5m, none]

starttls
   response to an SMTP STARTTLS command [1h]

TimeZoneSpec (ttzinfo)
   Sets the local time zone info to tzinfo, for example, "PST8PDT". Actually, if this is not set, the TZ environment variable is cleared (so the system default is used); if set but null, the user's TZ variable is used, and if set and non-null, the TZ variable is set to this value.

TLSSrvOptions
   If this option is 'V', then no client verification is performed, that is, the server does not ask for a certificate.

TrustedUser
   The user parameter can be a user name (looked up in the passwd map) or a numeric user id. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) are automatically owned by this user.

TryNullMXList (w)
   If you are the “best” (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes sendmail to try this. The downside is that errors in your configuration are likely to be diagnosed as “host unknown” or “message timed out” instead of something more meaningful. This option is deprecated.

UnixFromLine or $l
   The “From” line used when sending to files or programs.

UnsafeGroupWrites
   If set, group-writable .include: and .forward files are considered “unsafe”, that is, programs and files cannot be directly referenced from such files.

UseErrorsTo ()
   If there is an Errors-To: header, sends error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes sendmail to violate RFC 1123. This option is not recommended and deprecated.

UseMSP
   Uses as mail submission program, that is, allows group writable queue files if the group is the same as that of a set-group-id sendmail binary.
UserDatabaseSpec (U)
    Defines the name and location of the file containing User Database information.

Verbose (v)
    Runs in verbose mode. If this is set, sendmail adjusts the HoldExpensive and
    DeliveryMode options so that all mail is delivered completely in a single job so that you can
    see the entire delivery process. The Verbose option should never be set in the configuration
    file; it is intended for command line use only.

XscriptFileSizeBufferSize
    Sets the threshold, in bytes, before a memory-based queue transcript file becomes
    disk-based. The default is 4096 bytes.

If the first character of the username is a vertical bar, the rest of the username is used as the
name of a program to pipe the mail to. It may be necessary to quote the name of the user to
keep sendmail from suppressing the blanks from between arguments.

If invoked as newaliases, sendmail rebuilds the alias database, so long as the
/etc/mail/aliases* files are owned by root and root has exclusive write permission. If
invoked as mailq, sendmail prints the contents of the mail queue.

Operands
    address
    address of an intended recipient of the message being sent.

Usage
    See largefile(5) for the description of the behavior of sendmail when encountering files
greater than or equal to 2 Gbyte (2^31 bytes).

Exit Status
    sendmail returns an exit status describing what it did. The codes are defined in
    /usr/include/sysexits.h.

    EX_OK
    Successful completion on all addresses.

    EX_NOUSER
    User name not recognized.

    EX_UNAVAILABLE
    Catchall. Necessary resources were not available.

    EX_SYNTAX
    Syntax error in address.

    EX_SOFTWARE
    Internal software error, including bad arguments.

    EX_OSERR
    Temporary operating system error, such as “cannot fork”.

    EX_NOHOST
    Host name not recognized.
EX_TEMPFAIL
Message could not be sent immediately, but was queued.

Environment Variables
No environment variables are used. However, sendmail's start-up script, invoked by
`svcadm(1M)`, reads `/etc/default/sendmail`. In this file, if the variable `ETRN_HOSTS` is set, the
start-up script parses this variable and invokes `etrn(1M)` appropriately. `ETRN_HOSTS` should
be of the form:

"s1:c1.1,c1.2 s2:c2.1 s3:c3.1,c3.2,c3.3"

That is, white-space separated groups of `server:client` where `client` can be one or more
comma-separated names. The `:client` part is optional. `server` is the name of the server to prod; a
mail queue run is requested for each `client` name. This is comparable to running:

`/usr/lib/sendmail -qR client`
on the host `server`.

Files
dead.letter
Unmailable text

`/etc/default/sendmail`
Contains default settings. You can override some of the settings by command line options.

`/etc/mail/aliases`
Mail aliases file (ASCII)

`/etc/mail/aliases.db`
Database of mail aliases (binary)

`/etc/mail/aliases.dir`
Database of mail aliases (binary)

`/etc/mail/aliases.pag`
Database of mail aliases (binary)

`/etc/mail/sendmail.cf`
Defines environment for sendmail

`/etc/mail/submit.cf`
Defines environment for MSP

`/etc/mail/trusted-users`
Lists users that are "trusted", that is, able to set their envelope from address using `-f`
without generating a warning message. Note that this file is consulted by the default
`sendmail.cf`, but not by the default `submit.cf`, in which the line referring to
`/etc/mail/trusted-users` is commented out. See `sendmail(4)` for instructions on
making changes to `submit.cf` and `sendmail.cf`.

`/var/spool/clientmqueue/*`
Temporary files and queued mail
sendmail(1M)

/var/spool/mqueue/*
   Temporary files and queued mail

~/.forward
   List of recipients for forwarding messages

/usr/include/libmilter/README
   Describes the steps needed to compile and run a filter

http://www.milter.org

Notes
   The sendmail program requires a fully qualified host name when starting. A script has been
   included to help verify if the host name is defined properly (see check-hostname(1M)).

   The permissions and the ownership of several directories have been changed in order to
   increase security. In particular, access to /etc/mail and /var/spool/mqueue has been
   restricted.

   Security restrictions have been placed users using .forward files to pipe mail to a program or
   redirect mail to a file. The default shell (as listed in /etc/passwd) of these users must be listed
   in /etc/shells. This restriction does not affect mail that is being redirected to another alias.

   Additional restrictions have been put in place on .forward and :include: files. These files
   and the directory structure that they are placed in cannot be group- or world-writable. See
   check-permissions(1M).

   If you have interfaces that map to domains that have MX records that point to non-local
   destinations, you might need to enable the DontProbeInterfaces option to enable delivery to
   those destinations. In its default startup behavior, sendmail probes each interface and adds an
interface’s IP addresses, as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with localhost as the MX value. If this is not the result you want, enable Don’t Probe Interfaces.
setuname(1M)

**Name**
setuname – change machine information

**Synopsis**
setuname [-t] [-n node] [-s name]

**Description**
The setuname utility changes the parameter value for the system name and node name. Each parameter can be changed using setuname and the appropriate option.

Either or both the -s and -n options must be given when invoking setuname.

The system architecture may place requirements on the size of the system and network node name. The command will issue a fatal warning message and an error message if the name entered is incompatible with the system requirements.

**Options**
The following options are supported:

- **-n node** Changes the node name. node specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.

- **-s name** Changes the system name. name specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.

- **-t** Temporary change. No attempt will be made to create a permanent change.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**
attributes(5)

**Notes**
setuname attempts to change the parameter values in two places: the running kernel and, as necessary per implementation, to cross system reboots. A temporary change changes only the running kernel.
sf880drd – Sun Fire 880 Dynamic Reconfiguration daemon

sf880drd

The Sun Fire 880 Dynamic Reconfiguration daemon, sf880drd, is part of the PCI and system bus hotplug framework. sf880drd starts at boot time. It has no configuration options and does not report any system status.

sf880drd implements the Sun Fire 880 console-less system administration (per-slot pushbuttons and LED status indicators). It also manages various aspects of CPU/memory hotplug.

Files
/usr/platform/SUNW,Sun-Fire-880/lib/sf880drd

Attributes
See attributes(5) for descriptions of the following attributes:

<table>

</tr>
</tbody>
</table>

See Also
svcs(1), cfgadm(1M), cfgadm_pci(1M), cfgadm_sbd(1M), svcadm(1M), attributes(5), smf(5)

Notes
The sf880drd service is managed by the service management facility, smf(5), under the service identifier:

svc:/platform/sun4u/sf880drd

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
**Name**  
sftp-server – SFTP server subsystem

**Synopsis**  
/usr/lib/ssh/sftp-server

**Description**  
sftp-server implements the server side of the SSH File Transfer Protocol as defined in the IETF draft-ietf-secsh-filexfer.

sftp-server is a subsystem for sshd(1M) and must not be run directly. There are no options or config settings.

To enable the sftp-server subsystem for sshd add the following to /etc/ssh/sshd_config:

```
Subsystem sftp /usr/lib/ssh/sftp-server
```

See ssdh_config(4) for a description of the format and contents of that file.

There is no relationship between the protocol used by sftp-server and the FTP protocol (RFC 959) provided by in.ftpd.

**Exit Status**  
The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.

**Files**  
/usr/lib/ssh/sftp-server  Server-side binary

**Attributes**

To view license terms, attribution, and copyright for OpenSSH, the default path is /var/sadm/pkg/SUNWsshdr/install/copyright. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

**Author**  
Markus Friedl
The `share` command exports, or makes a resource available for mounting, through a remote file system of type `FSType`. If the option `-F FSType` is omitted, the first file system type listed in `/etc/dfs/fstypes` is used as default. For a description of NFS specific options, see `share_nfs(1M)`. `pathname` is the pathname of the directory to be shared. When invoked with no arguments, `share` displays all shared file systems.

**Options**

- `-F FSType` Specify the filesystem type.
- `-o specific_options` The `specific_options` are used to control access of the shared resource. (See `share_nfs(1M)` for the NFS specific options.) They may be any of the following:
  - `rw` `pathname` is shared read/write to all clients. This is also the default behavior.
  - `rw=client[:client]...` `pathname` is shared read/write only to the listed clients. No other systems can access `pathname`.
  - `ro` `pathname` is shared read-only to all clients.
  - `ro=client[:client]...` `pathname` is shared read-only only to the listed clients. No other systems can access `pathname`.

Separate multiple options with commas. Separate multiple operands for an option with colons. See EXAMPLES.

- `-d description` The `-d` flag may be used to provide a description of the resource being shared.

**Examples**

**EXAMPLE 1** Sharing a Read-Only Filesystem

This line will share the `/disk` file system read-only at boot time.

```
share -F nfs -o ro /disk
```

**EXAMPLE 2** Invoking Multiple Options

The following command shares the filesystem `/export/manuals`, with members of the netgroup having read-only access and users on the specified host having read-write access.

```
share -F nfs -o ro=netgroup_name,ro=host1:host2:host3 /export/manuals
```

**Files**

- `/etc/dfs/dfstab` list of share commands to be executed at boot time
- `/etc/dfs/fstypes` list of file system types, NFS by default
- `/etc/dfs/sharetab` system record of shared file systems
Attributes  See attributes(5) for descriptions of the following attributes:

<table>

Notes  Export (old terminology): file system sharing used to be called exporting on SunOS 4.x, so the share command used to be invoked as exportfs(1B) or /usr/sbin/exportfs.

If share commands are invoked multiple times on the same filesystem, the last share invocation supersedes the previous—the options set by the last share command replace the old options. For example, if read-write permission was given to usera on /somefs, then to give read-write permission also to userb on /somefs:

example% share -F nfs -o rw=usera:userb /somefs

This behavior is not limited to sharing the root filesystem, but applies to all filesystems.
Name  shareall, unshareall – share, unshare multiple resources

Synopsis  shareall [-F FSType [,FSType]...] [-] file
          unshareall [-F FSType [,FSType]...]

Description  When used with no arguments, shareall shares all resources from file, which contains a list of share command lines. If the operand is a hyphen (-), then the share command lines are obtained from the standard input. Otherwise, if neither a file nor a hyphen is specified, then the file /etc/dfs/dfstab is used as the default.

Resources may be shared by specific file system types by specifying the file systems in a comma-separated list as an argument to -F.

unshareall unshares all currently shared resources. Without a -F flag, it unshares resources for all distributed file system types.

Options  -F FSType Specify file system type. Defaults to the first entry in /etc/dfs/fstypes.

Files  /etc/dfs/dfstab

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  share(1M), unshare(1M), attributes(5)
share_nfs(1M)

Name
share_nfs – make local NFS file systems available for mounting by remote systems

Synopsis
share [ -d description ] [ -F nfs ] [ -o specific_options ] pathname

Description
The share utility makes local file systems available for mounting by remote systems. It starts the nfsd(1M) and mountd(1M) daemons if they are not already running.

If no argument is specified, then share displays all file systems currently shared, including NFS file systems and file systems shared through other distributed file system packages.

Options
The following options are supported:

- d description
  Provide a comment that describes the file system to be shared.

- F nfs
  Share NFS file system type.

- o specific_options
  Specify specific_options in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If specific_options is not specified, then by default sharing is read-write to all clients.
  specific_options can be any combination of the following:

  aclok
  Allows the NFS server to do access control for NFS Version 2 clients (running SunOS 2.4 or earlier). When aclok is set on the server, maximal access is given to all clients. For example, with aclok set, if anyone has read permissions, then everyone does. If aclok is not set, minimal access is given to all clients.

  anon=uid
  Set uid to be the effective user ID of unknown users. By default, unknown users are given the effective user ID UID_NOBODY. If uid is set to −1, access is denied.

  index=file
  Load file rather than a listing of the directory containing this file when the directory is referenced by an NFS URL.

  log=tag
  Enables NFS server logging for the specified file system. The optional tag determines the location of the related log files. The tag is defined in etc/nfs/nfslog.conf. If no tag is specified, the default values associated with the global tag in etc/nfs/nfslog.conf is used. Support of NFS server logging is only available for NFS Version 2 and Version 3 requests.

  nosub
  Prevents clients from mounting subdirectories of shared directories. For example, if /export is shared with the nosub option on server fooey then a NFS client cannot do:

  mount -F nfs fooey:/export/home/mnt
NFS Version 4 does not use the MOUNT protocol. The nosub option only applies to NFS Version 2 and Version 3 requests.

**nosuid**
By default, clients are allowed to create files on the shared file system with the setuid or setgid mode enabled. Specifying nosuid causes the server file system to silently ignore any attempt to enable the setuid or setgid mode bits.

**public**
Moves the location of the public file handle from root (/) to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service; WebNFS is always on. Only one file system per server may use this option. Any other option, including the `-ro=list` and `-rw=list` options can be included with the public option.

**ro**
Sharing is read-only to all clients.

**ro=access_list**
Sharing is read-only to the clients listed in access_list; overrides the `rw` suboption for the clients specified. See access_list below.

**root=access_list**
Only root users from the hosts specified in access_list have root access. See access_list below. By default, no host has root access, so root users are mapped to an anonymous user ID (see the anon=uid option described above). Netgroups can be used if the file system shared is using UNIX authentication (AUTH_SYS).

**rw**
Sharing is read-write to all clients.

**rw=access_list**
Sharing is read-write to the clients listed in access_list; overrides the `ro` suboption for the clients specified. See access_list below.

**sec=mode[:mode]...**
Sharing uses one or more of the specified security modes. The `mode` in the `sec=mode` option must be a node name supported on the client. If the `sec` option is not specified, the default security mode used is AUTH_SYS. Multiple `sec` options can be specified on the command line, although each mode can appear only once. The security modes are defined in nfssec(5).

Each `sec` option specifies modes that apply to any subsequent `window=`, `rw`, `ro`, `rw=`; `ro=` and `root=` options that are provided before another `sec=` option. Each additional `sec=` resets the security mode context, so that more `window=`, `rw`, `ro`, `rw=`, `ro=` and `root=` options can be supplied for additional modes.
If the option sec=none is specified when the client uses AUTH_NONE, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the anon=uid option for a description of how unauthenticated requests are handled.

secure
This option has been deprecated in favor of the sec=dh option.

window=value
When sharing with sec=dh, set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server allows. If a credential arrives with a lifetime larger than what is allowed, the NFS server rejects the request. The default value is 30000 seconds (8.3 hours).

access_list
The access_list argument is a colon-separated list whose components may be any number of the following:

hostname
The name of a host. With a server configured for DNS or LDAP naming in the nsswitch "hosts" entry, any hostname must be represented as a fully qualified DNS or LDAP name.

netgroup
A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the nsswitch "hosts" entry, any hostname in a netgroup must be represented as a fully qualified DNS or LDAP name.

domain name suffix
To use domain membership the server must use DNS or LDAP to resolve hostnames to IP addresses; that is, the "hosts" entry in the /etc/nsswitch.conf must specify "dns" or "ldap" ahead of "nis" or "nisplus", since only DNS and LDAP return the full domain name of the host. Other name services like NIS or NIS+ cannot be used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example,

NIS or NIS+ 172.16.45.9 --> "myhost"

and

dns or LDAP 172.16.45.9 -->
"myhost.mydomain.mycompany.com"

The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot. For example,

"rw=.mydomain.mycompany.com"

A single dot can be used to match a hostname with no suffix. For example,

"rw=."

sec=none
matches "mydomain" but not "mydomain.mycompany.com". This feature can be used to match hosts resolved through NIS and NIS+ rather than DNS and LDAP.

network
The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it is converted to a dotted address by `getnetbyname(3SOCKET)`. For example,

```
@mynet
```

would be equivalent to:

```
=172.16 or =172.16.0.0
```

The network prefix assumes an octet-aligned netmask determined from the zeroth octet in the low-order part of the address up to and including the high-order octet, if you want to specify a single IP address (see below). In the case where network prefixes are not byte-aligned, the syntax allows a mask length to be specified explicitly following a slash (/) delimiter. For example,

```
@theothernet/17 or =172.16.132/22
```

...where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

When specifying individual IP addresses, use the same @ notation described above, without a netmask specification. For example:

```
=172.16.132.14
```

Multiple, individual IP addresses would be specified, for example, as:

```
root=@172.16.132.20:@172.16.134.20
```

A prefixed minus sign (−) denies access to that component of access_list. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, then

```
 rw=−terra:engineering
```

denies access to terra but

```
 rw=engineering:−terra
```

grants access to terra.

Operands The following operands are supported:

pathname
The pathname of the file system to be shared.
Examples

**Example 1**  Sharing A File System With Logging Enabled

The following example shows the `/export` file system shared with logging enabled:

```bash
example% share -o log /export
```

The default global logging parameters are used since no tag identifier is specified. The location of the log file, as well as the necessary logging work files, is specified by the global entry in `/etc/nfs/nfslog.conf`. The `nfslogd(1M)` daemon runs only if at least one file system entry in `/etc/dfs/dfstab` is shared with logging enabled upon starting or rebooting the system. Simply sharing a file system with logging enabled from the command line does not start the `nfslogd(1M)`.

Exit Status

The following exit values are returned:

- `0`
  - Successful completion.
- `>0`
  - An error occurred.

Files

- `/etc/dfs/fstypes`
  - list of system types, NFS by default
- `/etc/dfs/sharetab`
  - system record of shared file systems
- `/etc/nfs/nfslogtab`
  - system record of logged file systems
- `/etc/nfs/nfslog.conf`
  - logging configuration file

Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>

`mount(1M), mountd(1M), nfsd(1M), nfslogd(1M), share(1M), unshare(1M), getnetbyname(3SOCKET), nfslog.conf(4), netgroup(4), attributes(5), nfssec(5)`

Notes

If the `sec=` option is presented at least once, all uses of the `window=, rw, ro, rw=, ro=` and `root=` options must come after the first `sec=` option. If the `sec=` option is not presented, then `sec=sys` is implied.

If one or more explicit `sec=` options are presented, `sys` must appear in one of the options mode lists for accessing using the AUTH_SYS security mode to be allowed. For example:

```bash
share -F nfs /var
share -F nfs -o sec=sys /var
```
grants read-write access to any host using AUTH_SYS, but

```
share -F nfs -o sec=dh /var
```

grants no access to clients that use AUTH_SYS.

Unlike previous implementations of share_nfs, access checking for the window=, rw, ro, rw=, and ro= options is done per NFS request, instead of per mount request.

Combining multiple security modes can be a security hole in situations where the ro= and rw= options are used to control access to weaker security modes. In this example,

```
share -F nfs -o sec=dh,rw,sec=sys,rw=hosta /var
```

an intruder can forge the IP address for hosta (albeit on each NFS request) to side-step the stronger controls of AUTH_DES. Something like:

```
share -F nfs -o sec=dh,rw,sec=sys,ro /var
```

is safer, because any client (intruder or legitimate) that avoids AUTH_DES only gets read-only access. In general, multiple security modes per share command should only be used in situations where the clients using more secure modes get stronger access than clients using less secure modes.

If rw=, and ro= options are specified in the same sec= clause, and a client is in both lists, the order of the two options determines the access the client gets. If client hosta is in two netgroups - group1 and group2 - in this example, the client would get read-only access:

```
share -F nfs -o ro=group1,rw=group2 /var
```

In this example hosta would get read-write access:

```
share -F nfs -o rw=group2,ro=group1 /var
```

If within a sec= clause, both the ro and rw= options are specified, for compatibility, the order of the options rule is not enforced. All hosts would get read-only access, with the exception to those in the read-write list. Likewise, if the ro= and rw options are specified, all hosts get read-write access with the exceptions of those in the read-only list.

The ro= and rw= options are guaranteed to work over UDP and TCP but may not work over other transport providers.

The root= option with AUTH_SYS is guaranteed to work over UDP and TCP but may not work over other transport providers.

The root= option with AUTH_DES is guaranteed to work over any transport provider.

There are no interactions between the root= option and the rw, ro, rw=, and ro= options. Putting a host in the root list does not override the semantics of the other options. The access the host gets is the same as when the root= options is absent. For example, the following share command denies access to hostb:
The following gives read-only permissions to hostb:

```
share -F nfs -o ro=hostb,root=hostb /var
```

The following gives read-write permissions to hostb:

```
share -F nfs -o ro=hosta,rw=hostb,root=hostb /var
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) are shared. For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following share command results in `/export/bar` as the shared pathname (and not `/export/foo`).

```
example# share -F nfs /export/foo
```

An NFS mount of `server:/export/foo` results in `server:/export/bar` really being mounted.

This line in the `/etc/dfs/dfstab` file shares the `/disk` file system read-only at boot time:

```
share -F nfs -o ro /disk
```

The same command entered from the command line does not share the `/disk` file system unless there is at least one file system entry in the `/etc/dfs/dfstab` file. The `mountd(1M)` and `nfsd(1M)` daemons only run if there is a file system entry in `/etc/dfs/dfstab` when starting or rebooting the system.

The `mountd(1M)` process allows the processing of a path name that contains a symbolic link. This allows the processing of paths that are not themselves explicitly shared with `share_nfs`. For example, `/export/foo` might be a symbolic link that refers to `/export/bar` which has been specifically shared. When the client mounts `/export/foo` the `mountd` processing follows the symbolic link and responds with the `/export/bar`. The NFS Version 4 protocol does not use the `mountd` processing and the client's use of `/export/foo` does not work as it does with NFS Version 2 and Version 3 and the client receives an error when attempting to mount `/export/foo`. 
showmount(1M)

**Name**
showmount – show remote mounts

**Synopsis**
/usr/sbin/showmount [-ade] [hostname]

**Description**
showmount lists the clients that have remotely mounted a filesystem from host. This information is maintained by the mountd(1M) server on host, and is saved across crashes in the file /etc/rmtab. The default value for host is the value returned by hostname(1).

The showmount command does not display the names of NFS Version 4 clients.

**Options**
- a Print all remote mounts in the format:

  hostname : directory

  where hostname is the name of the client, and directory is the root of the file system that has been mounted.
- d List directories that have been remotely mounted by clients.
- e Print the list of shared file systems.

**Files**
/etc/rmtab

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnfscu</td>
</tr>
</tbody>
</table>

**Bugs**
If a client crashes, its entry will not be removed from the list of remote mounts on the server.
showrev(1M)

Name  showrev – show machine, software revision, and patch revision information

Synopsis  
/usr/bin/showrev [-a] [-p | -p -R root_path] [-w]
[-c command] [-s hostname]

Description  showrev displays revision information for the current hardware and software. With no arguments, showrev shows the system revision information including hostname, hostid, release, kernel architecture, application architecture, hardware provider, domain, and kernel version.

If a command is supplied with the -c option, showrev shows the PATH and LD_LIBRARY_PATH and finds out all the directories within the PATH that contain it. For each file found, its file type, revision, permissions, library information, and checksum are printed as well.

Options  The following options are supported:

- a  Print all system revision information available. Window system and patch information are added.

- c command  Print the revision information about command.

- p  Print only the revision information about patches.

- R root_path  Define the full path name of a directory to use as the root_path. By specifying the root path, showrev retrieves the revision information about the patch from package system information files located under a directory tree starting at root_path. The root_path can be specified when retrieving installed patch information in a client from a server, for example, /export/root/client1.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

- s hostname  Perform this operation on the specified hostname. The - s operation completes correctly only when hostname is running Solaris 2.5 or compatible versions.

- w  Print only the OpenWindows revision information.

Output  Varies, based on flags passed. If no flags are passed, output similar to the following appears:

   Hostname: system1
   Hostid: 7233808e
   Release: 5.10
   Kernel architecture: sun4u
   Application architecture: sparc
   Hardware provider: Sun_Microsystems
   Domain: a.network.COM
   Kernel version: SunOS 5.10 generic
Exit Status  The following error values are returned:
    0  Successful completion.
    >0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWadmc</td>
</tr>
</tbody>
</table>

Bugs  For the -s option to work when hostname is running a version of Solaris prior to 2.5, the Solstice AdminSuite must be installed on hostname.
shutdown – shut down system, change system state

**Synopsis**

```
/usr/sbin/shutdown [-y] [-g grace-period] [-i init-state] [message]
```

**Description**

`shutdown` is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.

By default, `shutdown` brings the system to a state where only the console has access to the operating system. This state is called single-user.

Before starting to shut down daemons and killing processes, `shutdown` sends a warning message and, by default, a final message asking for confirmation. `message` is a string that is sent out following the standard warning message “The system will be shut down in...” If the string contains more than one word, it should be contained within single ('') or double (") quotation marks.

The warning message and the user provided `message` are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before `shutdown` begins. See EXAMPLES.

System state definitions are:

- **state 0**  
  Stop the operating system.

- **state 1**  
  State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.

- **state s, S**  
  State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.

- **state 5**  
  Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The `rc0` procedure is called to perform this task.

- **state 6**  
  Stop the operating system and reboot to the state defined by the `init.default` entry in `/etc/inittab`. The `rc6` procedure is called to perform this task.

**Options**

- **-y**  
  Pre-answer the confirmation question so the command can be run without user intervention.

- **-g grace-period**  
  Allow the super user to change the number of seconds from the 60-second default.
-i init-state If there are warnings, init-state specifies the state init is to be in. By default, system state ‘s’ is used.

**Examples**

**EXAMPLE 1 Using shutdown**

In the following example, shutdown is being executed on host foo and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "===== disk replacement ====="
Shutdown started. Tue Jun 7 14:51:40 PDT 1994

Broadcast Message from root (pts/1) on foo Tue Jun 7 14:51:41 . . .
The system will be shut down in 2 minutes
===== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:52:41 . . .
The system will be shut down in 1 minutes
===== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:53:41 . . .
The system will be shut down in 30 seconds
===== disk replacement =====
Do you want to continue? (y or n):
```

**Files**

/etc/inittab controls process dispatching by init

**Attributes**

boot(1M), halt(1M), init(1M), killall(1M), reboot(1M), ufsdump(1M), init.d(4), inittab(4), nologin(4), attributes(5)

**Notes**

When a system transitions down to the S or s state, the /etc/nologin file (see nologin(4)) is created. Upon subsequent transition to state 2 (multi-user state), this file is removed by a script in the /etc/rc2.d directory.
The `slpd` daemon provides common server functionality for the Service Location Protocol ("SLP") versions 1 and 2, as defined by IETF in RFC 2165 and RFC 2608. SLP provides a scalable framework for the discovery and selection of network services.

`slpd` provides the following framework services:

**Directory Agent**
- This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. `slpd` does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.

**Service Agent Server**
- All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, `slpd` is a service agent server.

**Passive Directory Agent Discovery**
- This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query `slpd`, obviating the need to perform discovery by means of multicast. By default, `slpd` performs this service.

**Proxy Registration**
- This service can act as a proxy service agent for services that cannot register themselves. `slpd` reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.

All configuration options are available from the configuration file. `slpd` reads its configuration file upon startup.

Stop and start the `slpd` daemon using `svcadm(1M)`. Use the command `svcadm enable network/slp` to start the `slpd` daemon. Use the command `svcadm disable network/slp` to stop it.

The file `/etc/inet/slp.conf` must exist before the `slp` service can start the daemon. Only the example file `/etc/inet/slp.conf.example` is present by default. To enable SLP, copy `/etc/inet/slp.conf.example` to `/etc/inet/slp.conf`. 

---

**Name**
`slpd` - Service Location Protocol Daemon

**Synopsis**
`/usr/lib/inet/slpd [-f configuration-file]`

**Description**
The `slpd` daemon provides common server functionality for the Service Location Protocol ("SLP") versions 1 and 2, as defined by IETF in RFC 2165 and RFC 2608. SLP provides a scalable framework for the discovery and selection of network services.
Options  The following options are supported:

- `configuration-file`  Specify an alternate configuration file

Examples  

**EXAMPLE 1**  Stopping the `slpd` daemon

The following command stops the `slpd` daemon:

```
example# svcadm disable network/slp
```

**EXAMPLE 2**  Restarting the `slpd` daemon

The following command restarts the `slpd` daemon:

```
example# svcadm restart network/slp
```

Files  

- `/etc/inet/slp.conf`  The default configuration file
- `/etc/inet/slp.reg`  The proxy registration file

*System Administration Guide: Network Services*

Notes  The `slpd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/slp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
smartcard(1M)

Name  smartcard – configure and administer a smart card

Synopsis  smartcard -c admin [-a application] [propertyname]...

smartcard -c admin [-a application]
  [-x { add|delete|modify } propertyname=value]...

smartcard -c admin -t service -j classname -x
  { add|delete|modify }...

smartcard -c admin -t terminal
  { -j classname } -H libraryname } -d device -r userfriendlyreadernname -n readername -x
  { add|delete|modify }...

smartcard -c admin -t debug -j classname -l level -x
  { add|delete|modify }...

smartcard -c admin -t override -x { add|delete|modify }

smartcard -c load -A aid [-r userfriendlyreadernname] -P pin
  [-s slot] [-i inputfile] [-p propfile] [-v]
  [propertyname=value]...

smartcard -c load -u -P pin [-A aid]
  [-r userfriendlyreadernname] [-s slot] [-v]

smartcard -c bin2capx -T cardname [-i inputfile]
  [-o outputfile] [-p propfile] [-I anothercapxfile]
  [-v] [propertyname=value]...

smartcard -c init -A aid [-r readername] [-s slot] -L

smartcard -c init -A aid [-r readername] -P pin [-s slot]
  [propertyname=value]...

smartcard -c enable

smartcard -c disable

Description  The smartcard utility is used for all configurations related to a smart card. It comprises the following subcommands:

1. Administration of OCF properties. (-c admin)

   This subcommand is used to list and modify any of the OCF properties. With no arguments it will list all the current properties. It can only be executed by root. Some OCF properties are:

   - defaultcard
     * default card for an application*
defaultreader
  # default reader for an application

authmechanism
  # authentication mechanism

validcards
  # list of cards valid for an application

A complete listing can be obtained by using the smartcard utility as described in the EXAMPLES section.

2. Loading and Unloading of applets from the smart card (-c load) and performing initial configuration of a non-Java card.

This subcommand administers the applets or properties on a smartcard. It can be used to load or unload applets and/or properties to and from a smart card. The applet is a Java class file that has been run through a converter to make the byte code JavaCard-compliant. This command can be used to load both an applet file in the standard format or a file converted to the capx format. If no -r option is specified, the loader tries to load to any connected reader, provided it has already been inserted using the smartcard -c admin command.

3. Converting card applets or properties to the capx format (-c bin2capx)

This subcommand is used to convert a Java card applet or properties into a new format called capx before downloading it onto the smart card. Converting to this format enables the applet developer to add applet-specific information that is useful during the downloading process and identifies the applet.

In the following example,

```
smartcard -c bin2capx -i cyberflex.bin \\
-T CyberFlex aidto-00102030405060708090A0B0C0D0E0F fileID=2222 \\
instanceID=2223 and more.
```

if no output file is specified, a default file with the name input_filename.capx is created in the current directory. The mandatory -T option requires the user to specify the card name for which the capx file is being generated.

The following example

```
smartcard -c bin2capx -T IButton
```

tells the loader that the capx file contains the binary for IButton. A single capx file can hold binaries for multiple cards (1 per card.) Users can, for example, hold binary files for both CyberFlex and IButton in the same capx file as follows:

```
smartcard -c bin2capx -T IButton -i IButton.jib -o file.capx
```

In the following example,

```
smartcard -c bin2capx -T CyberFlex -i cyberflex.bin \\
-l file.capx -o file.capx
```
the -l option is used to provide an already-generated capx file. The output is directed to the same capx file, resulting in capx file holding binaries for both cards.

4. Personalizing a smart card (-c init)
   This subcommand is used to set user-specific information required by an applet on a smart card. For example, the Sun applet requires a user name to be set on the card. This subcommand is also used to personalize information for non-Java cars.

5. Enabling and disabling the smart card desktop login (-c {enable | disable})

Options

The following options are supported:

- -a application
  Specify application name for the configuration parameter. Parameters may differ depending on the application. If no application name is specified, then ocf is the default application.

- -A aid
  Specify a unique alphanumeric string that identifies the applet. The aid argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical aid already exists on the card, a load will result in an error.

- -c
  Specify subcommand name. Valid options are: admin, load, bin2capx, init, enable, and disable.

- -d device
  Specify device on which the reader is connected (for example, /dev/cua/a).

- -D
  Disable a system from using smart cards.

- -E
  Export the keys to a file.

- -H libraryname
  Specify the full path of the IFD handler library for the reader.

- -I filename
  Specify input file name.

- -j classname
  Specify fully-qualified class name.

- -k keytype
  Specify type of key (for example, challenge_response, pki.)

- -l
  Specify debug level (0–9), signifying level of debug information displayed.
-L
  List all properties configurable in an applet.

-n readername
  Specify reader name as required by the driver.

-o filename
  Specify output file name.

-p propfile
  Specify properties file name. This file could contain a list of property names and value pairs, in the format propertyname=value.

-P pin
  Specify pin used to validate to the card.

-r userfriendlyreadername
  Specify user-defined reader name where the card to be initialized is inserted.

-R
  Restart the ocf server.

-s slot
  Specify slot number. If a reader has multiple slots, this option specifies which slot to use for initialization. If a reader has only one slot, this option is not required. If no slot number is specified, by default the first slot of the reader is used.

-t
  Specify type of property being updated. The valid values are:
  
  service
    Updating a card service provider details.
  
  terminal
    Updating a card reader provider details.
  
  debug
    OCF trace level.
  
  override
    Override a system property of the same name.

-T cardname
  Specify card name.

-u
  Unload the applet specified by the application ID from the card. If no application ID is specified, all applets are unloaded from the card.

-v
  Verbose mode (displays helpful messages).
Specify action to be taken. Valid values are: add, delete, or modify.

Examples

**EXAMPLE 1**  Viewing the Values of All Properties
Enter the following command to view the values of all the properties that are set:

```bash
% smartcard -c admin
```

**EXAMPLE 2**  Viewing the Values of Specific Properties
Enter the following command to view the values of specific properties:

```bash
% smartcard -c admin language country
```

**EXAMPLE 3**  Adding a Card Service
Enter the following command to add a card service factory for a CyberFlex card, available in the package `com.sun.services.cyberflex`, to the properties:

```bash
% smartcard -c admin -t service -j com.sun.services.cyberflex.CyberFlexCardServiceFactory -x add
```

**EXAMPLE 4**  Adding a Reader
Enter the following command to add the IFD handler for the internal reader:

```bash
% smartcard -c admin -t terminal -H /usr/lib/smartcard/ifdh_scmi2c.so -x add -d /dev/scmi2c0 -r MyInternalReader -n SunISCR
```

**EXAMPLE 5**  Deleting a Reader
Enter the following command to delete the SCM reader, added in the previous example, from the properties:

```bash
% smartcard -c admin -t terminal -r SCM -x delete
```

**EXAMPLE 6**  Changing the Debug Level
Enter the following command to change the debug level for all of the com.sun package to 9:

```bash
% smartcard -c admin -t debug -j com.sun -l 9 -x modify
```

**EXAMPLE 7**  Setting the Default Card for an Application
Enter one of the following commands to set the default card for an application (dtlogin) to be CyberFlex.

If the property default card does not exist, enter the following command:

```bash
% smartcard -c admin -a dtlogin -x add defaultcard=CyberFlex
```

If the property default card exists, enter the following command:
EXAMPLE 7  Setting the Default Card for an Application  (Continued)

% smartcard -c admin -a dtlogin -x modify defaultcard=CyberFlex

EXAMPLE 8  Exporting Keys for a User into a File

Enter the following command to export the challenge-response keys for a user into a file:

% smartcard -c admin -k challenge_response -E -o /tmp/mykeys

EXAMPLE 9  Importing Keys from a File

Enter the following command to import the challenge-response keys for a user from a file:

% smartcard -c admin -k challenge_response -I -i /tmp/mykeys

EXAMPLE 10  Downloading an Applet into a Java Card

Enter the following command to download an applet into a Java card or to configure a PayFlex (non-Java) card inserted into an SCM reader for the capx file supplied in the /usr/share/lib/smartcard directory:

% smartcard -c load -r SCM \n  -i /usr/share/lib/smartcard/SolarisAuthApplet.capx

EXAMPLE 11  Downloading an Applet Binary

Enter the following command to download an applet binary from some place other that the capx file supplied with Solaris 8 into an IButton (the aid and input file are mandatory, the remaining parameters are optional):

% smartcard -c load -A A000000062030400 -i newapplet.jib

EXAMPLE 12  Downloading an Applet on a CyberFlex Access Card

On a CyberFlex Access Card, enter the following command to download an applet newapplet.bin at fileID 2222, instanceID 3333 using the specified verifyKey and a heap size of 2000 bytes:

% smartcard -c load -A newaid -i newapplet.bin \n  fileID=2222 instanceID=3333 verifyKey=newKey \n  MAC=newMAC heapsize=2000

EXAMPLE 13  Configuring a PayFlex Card

Enter the following command to configure a PayFlex (non-Java) card with specific aid, transport key, and initial pin:

% smartcard -c load -A A00000006203400 \n  pin=242424246A617661 transportKey=4746584932567840
EXAMPLE 14  Unloading an Applet from a Card
Enter the following command to unload an applet from iButton:

% smartcard -c load -u

EXAMPLE 15  Displaying Usage of smartcard -c load
Enter the following command to display the usage of the smartcard -c load command:

% smartcard -c load

EXAMPLE 16  Displaying All Configurable Parameters for an Applet
Enter the following command to display all the configurable parameters for an applet with aid 123456 residing on a card inserted into an SCM reader:

% smartcard -c init -r SM -A 123456 -L

EXAMPLE 17  Changing the PIN
Enter the following command to change the pin for the SolarisAuthApplet residing on a card or to change the PIN for a PayFlex (non-Java) card inserted into an SCM reader:

% smartcard -c init -A A000000062030400 -P oldpin pin=newpin

EXAMPLE 18  Displaying All Configurable Parameters for the SolarisAuthApplet.
Enter the following command to display all the configurable parameters for the SolarisAuthApplet residing on a card inserted into an SCM reader:

% smartcard -c init -A A000000062030400 -L

EXAMPLE 19  Setting a Property to a Value on a smart card
Enter the following command to set properties called user to the value james and application to the value login on a card inserted into an SCM reader that has a pin testpin:

% smartcard -c init -A A000000062030400 -r CyberFlex -P testpin \ application=login user=james

EXAMPLE 20  Converting an Applet for the CyberFlex Card into capx Format.
Enter the following command to convert an applet for the CyberFlex card into the capx format required for downloading the applet into the card:

% smartcard -c bin2capx \ -i /usr/share/lib/smartcard/SolarisAuthApplet.bin \ -T CyberFlex -o /home/CorporateCard.capx -v memory=128 heapsize=12

EXAMPLE 21  Converting an Applet for the IButton Card into capx Format
Enter the following command to convert an applet for the IButton card into the capx format required for downloading the applet into the button:
EXAMPLE 21  Converting an Applet for the IButton Card into capx Format  (Continued)

% smartcard -c bin2capx \
   -i /usr/share/lib/smartcard/SolarisAuthApplet.jib \
   -T IButton -o /home/CorporateCard.capx -v

Exit Status The following exit values are returned:

0  Successful completion.

1  An error occurred.

smattrpop(1M)

Name
smattrpop – populate security attribute databases in a name service

Synopsis
smattrpop [-c] [-f] [-m [-p policy] [-r] -s scope -t scope
[-v] database

Description
The smattrpop command updates the auth_attr(4), exec_attr(4), prof_attr(4), and user_attr(4) role-based access control databases in a target NIS, NIS+, LDAP, or local /etc files name service from the corresponding databases in a source name service or files.

This command processes the table entries from the source database and merges each source entry field into the same field in the corresponding table entry in the target database. If a source entry does not exist in the target database, the entry is created. If the source entry exists in the target database, the fields are merged or replaced according to the command options.

Any errors encountered while updating the target entry are reported to stdout, and the command continues with the next source database entry.

Options
The following options are supported:

- c
  Performs cross-table checking. If you specify this option and a check error occurs, a message identifying the check error is written to stdout.

  The target entry values are checked against entries in related databases:
  - auths values — Each value must exist as the name of an authorization in the auth_attr(4) database.
  - profiles values — Each value must exist as a name of a profile in the prof_attr(4) database.
  - roles values — Each value must exist as the name of a role identity in the user_attr(4) database.
  - For each exec_attr(4) entry in the source database, the name must exist as the name of a profile in the prof_attr(4) database.

- f
  Specifies that the value in each field in the source entry replaces the value in the corresponding field in the target entry, if the source entry field has a non-empty value.

- m
  For the auths, profiles, and roles attributes, specifies that the values in each field in the source entry are merged with the values in the corresponding target entry field. If a source value does not exist in the target field, the value is appended to the set of target values. If the target field is empty, the source values replace the target field. The attribute values that merge depend on the database being updated:
  - prof_attr(4) — the auths and profiles attribute values are merged.
  - user_attr(4) — the auths, profiles, and roles attribute values are merged.
  - exec_attr(4) — the uid, gid, euid, and egid values are merged.
-p policy  Specifies the value of the policy field in the exec_attr(4) database. Valid values are suser (standard Solaris superuser) and tsol (Trusted Solaris). If you specify this option, only the entries in the source exec_attr database with the specified policy are processed. If you omit this option, all entries in the source exec_attr database are processed.

-r  Specifies that role identities in the user_attr(4) database in the source name service are processed. If you omit this option, only the normal user entries in the user_attr source database are processed.

-s scope  Specifies the source name service or local file directory for database updates, using the following syntax:

\[type:/server/domain\]

where type indicates the type of name service. Valid values for type are:

- file — local files
- nis — NIS name service
- nisplus — NIS+ name service
- ldap — LDAP name service

server indicates the local host name of the Solaris system on which the smattrpop command is executed, and on which both the source and target databases exist.

domain specifies the management domain name for the name service.

You can use two special cases of scope values:

- To indicate the databases in the /etc/security local system directory, use the scope file:/server, where server is the name of the local system.
- To load from databases in an arbitrary directory on the Solaris server, use the scope file:/server/pathname, where where server is the name of the local system and pathname is the fully-qualified directory path name to the database files.

-t scope  Specifies the target name service or local file directory for database updates, using the following syntax:

\[type:/server/domain\]

where type indicates the type of name service. Valid values for type are:

- file — local files
- nis — NIS name service
- nisplus — NIS+ name service
- ldap — LDAP name service

server indicates the local host name of the Solaris system on which the smattrpop command is executed, and on which both the source and target databases exist.
domain specifies the management domain name for the name service.

You can use two special cases of scope values:

- To indicate the databases in the /etc/security local system directory, use the scope file:/server, where server is the name of the local system.
- To update to databases in an arbitrary directory on the Solaris server, use the scope file:/server/pathname, where server is the name of the local system and pathname is the fully-qualified directory path name to the database files.

-v Specifies that verbose messages are written. A message is written to stdout for each entry processed.

Operands

The following operands are supported:

database Populates one or all databases. You can specify either the name of the database you want to process (for example, auth_attr), or all to process all databases. If you specify all, the databases are processed in the following order:

1. auth_attr(4)
2. prof_attr(4)
3. exec_attr(4)
4. user_attr(4)

Examples

EXAMPLE 1 Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the /etc/security directory of the local system into the corresponding tables in the NIS domain, east.example.com. The command is executed on the master server, hoosier, for the NIS domain and the source files are in the /etc and /etc/security directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to stdout.

/usr/sadm/bin/smattrpop -s file:/hoosier \
 -t nis:/hoosier/east.example.com all

EXAMPLE 2 Updating the authorization table in the NIS+ name service

This example merges new authorization data from a local system file in the auth_attr text format into the existing auth_attr database in the NIS+ domain, east.example.com. The command is executed on the NIS+ master server, foobar. Values from the source auth_attr file replace the corresponding field values in the NIS+ tables for each entry. A message is written to stdout for each entry processed. Database cross-checking is performed and any check error is written to stdout. A summary message indicating the number of entries processed and updated for the auth_attr database is written to stdout.

/usr/sadm/bin/smattrpop -c -f -v -s file:/foobar/var/temp \
 -t nisplus:/foobar/East.Sun.COM auth_attr
Environment Variables

See `environ(5)` for a description of the JAVA_HOME environment variable, which affects the execution of the smattrpop command. If this environment variable is not specified, the /usr/java location is used. See `smc(1M)`.

Exit Status

Any errors encountered while updating the target entry are reported to stdout. The following exit values are returned:

- **0**: The specified tables were updated. Individual entries may have encountered checking errors.
- **1**: A syntax error occurred in the command line.
- **2**: A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

Files

/etc/security/auth_attr  
Authorization description database. See `auth_attr(4)`.

/etc/security/exec_attr  
Execution profiles database. See `exec_attr(4)`.

/etc/security/prof_attr  
Profile description database. See `prof_attr(4)`.

/etc/user_attr  
Extended user attribute database. See `user_attr(4)`.

Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
</tbody>
</table>

smbios(1M)

Name
smbios – display the contents of a System Management BIOS image

Synopsis
smbios [-BeOsx] [-i id] [-t type] [-w file] [file]

Description
The smbios utility displays the contents of the System Management BIOS (SMBIOS) image exported by the current system or stored in a file. SMBIOS is an industry-standard mechanism for low-level system software to export hardware configuration information to higher-level system management software. The SMBIOS data format itself is defined by the Distributed Management Task Force (DMTF). Refer to http://www.dmtf.org for more information about SMBIOS and to obtain a copy of the SMBIOS specification and implementation guidelines.

The SMBIOS image consists of a table of structures, each describing some aspect of the system software or hardware configuration. By default, smbios displays the entire contents of the current SMBIOS image. If the -s option is specified, smbios displays a summary of the structures that are present in the image. If the -w option is specified, smbios writes a copy of the SMBIOS image to the specified file. smbios can then be applied to the resulting file to display its content.

smbios attempts to display each structure and its content in a human-readable fashion. If smbios does not recognize a structure's type or content, the raw hexadecimal data for the structure is displayed.

Options
The following options are supported:
- B
  Disable header validation for broken BIOSes.

  By default, smbios attempts to validate the SMBIOS header by verifying the anchor strings, header checksums, and version number. This option might be necessary when a BIOS has a non-compliant header.

- e
  Display the contents of the SMBIOS entry point rather than the contents of the SMBIOS structure table.

- i id
  Display only the specified structure, named by its integer id.

- O
  Display obsolete structure types.

  By default, smbios elides output for structures whose type is marked as obsolete in the DMTF SMBIOS specification.

- s
  Display only a summary listing of the structure identifiers and types, instead of the content of each selected structure.

- t type
  Display only those structures whose type matches the specified integer type, as defined the DMTF SMBIOS specification.

- w file
  Write a copy of the SMBIOS image to the specified file and exit.
The SMBIOS entry point is written to the start of the file with its structure table address set to the file offset of the structure table, and a new entry point checksum is computed.

-x Display raw hexadecimal data for the selected structures in addition to human-readable output.

By default, hexadecimal data is only displayed if `smbios` cannot display human-readable output for the selected structures.

**Operands** The following operands are supported:

- `file` Specifies an alternate SMBIOS image to display instead of the current system's SMBIOS image.

**Exit Status** The following exit values are returned:

- `0` Successful completion. All structures in the SMBIOS image were examined successfully.
- `1` A fatal error occurred, such as failure to open the specified file or device, or corruption in the image.
- `2` Invalid command-line options were specified.

**Files** `/dev/smbios` Kernel SMBIOS image device. This device special file is used to export a snapshot of the current system SMBIOS image.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The command-line options are Evolving. The human-readable output is Unstable.

**See Also** `prtdiag(1M), attributes(5), smbios(7D)`

*System Management BIOS Reference Specification* (see [http://www.dmtf.org](http://www.dmtf.org))

**Notes** The implementation of a System Management BIOS image is entirely at the discretion of the system and BIOS vendors. Not all systems export an SMBIOS. The SMBIOS structure content varies widely between systems and BIOS vendors and frequently does not comply with the guidelines included in the specification. Some structure fields might not be filled in by the BIOS at all, and others might be filled in with non-conforming values.
smc–starttheSolarisManagementConsole

smc [ subcommand] [ args]

smc [ subcommand] [ args] -T tool_name
[ - - tool_args]

The smc command starts the Solaris Management Console. The Solaris Management Console is a graphical user interface that provides access to Solaris system administration tools. It relies on Solaris Management Console servers running on one or more computers to perform modifications and report data. Each of these servers is a repository for code which the console can retrieve after the user of the console has authenticated himself or herself to the server.

The console can also retrieve toolboxes from the server. These toolboxes are descriptions of organized collections of tools available on that and possibly other servers. Once one of these toolboxes is loaded, the console will display it and the tools referenced in it.

The console can also run in a terminal (non-graphically), for use over remote connections or non-interactively from a script.

For information on the use of the graphical console, and for more detailed explanations of authentication, tools, and toolboxes, please refer to the Solaris Management Console online help available under the “Help” menu in the Solaris Management Console. To enable an NIS/NIS+ map to be managed from the Solaris Management Console, you must use the smc edit command to create a new toolbox for that map and enter the information about your NIS/NIS+ server where necessary. For instructions on creating a new toolbox, in the Solaris Management Console Help menu, select “Contents,” then “About the Solaris Management Console Editor,” then “To Create a Toolbox.”

Subcommands The smc subcommands are:

open The default subcommand for the Solaris Management Console is open. This will launch the console and allow you to run tools from the toolboxes you load. It does not need to be specified explicitly on the command line.

edit The edit subcommand will also launch the console, like the open subcommand. However, after loading a toolbox, you will not be able to run the referenced tools. Instead, you will be able to edit that toolbox, that is, add, remove, or modify any tools or folders in that toolbox.

SMF Administration The Solaris Management Console is implemented as a method that is managed by the service management facility (SMF) (see smf(5)), under the fault management resource identifier (FMRI):

svc:/application/management/wbem:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M).
The configuration properties of this service can be modified with `svccfg(1M)`.

Through `svcadm`, the Solaris Management Console supports the following actions:

- **start**: Starts the CIM Object Manager (CIMOM) and Solaris Management Console server on the local host.
- **stop**: Stops the CIMOM and Solaris Management Console server on the local host.
- **status**: Gets the status of the CIMOM and Solaris Management Console server on the local host.

The Solaris Management Console supports an SMF property that controls remote access to WBEM-based applications, which include the Solaris Management Console. The property, `options/tcp_listen`, has default value of `false`, which disallows remote access. The value `true` allows remote access. See EXAMPLES.

The following options are supported. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain` with the `domain` argument.

If `tool_args` are specified, they must be preceded by the `--` option and separated from the double dashes by a space.

- **-auth-data 13;file**: Specifies a file which the console can read to collect authentication data. When running the Solaris Management Console non-interactively, the console will still need to authenticate itself with the server to retrieve tools. This data can either be passed on the command line using the `-u`, `-p`, `-r`, and `-l` options (which is insecure, because any user can see this data), or it can be placed in a file for the console to read. For security reasons, this file should be readable only by the user running the console, although the console does not enforce this restriction.

The format of `file` is:

```
hostname=host name
username=user name
password=password for user name
rolename=role name
rolepassword=password for role name
```

Only one set of `hostname`-`username-password-rolename-rolepassword`
may be specified in any one file. If the rolename is not specified, no role will be assumed.

-B | --toolbox 13:toolbox

Loads the specified toolbox. toolbox can be either a fully-qualified URL or a filename. If you specify an HTTP URL as, for example,

http://host_name:port/... 

it must point to a host_name and port on which an Solaris Management Console server is running. If you omit port, the default port, 898, is used. This option overrides the -H option.

-D | --domain 13:domain

Specifies the default domain that you want to manage. The syntax of domain is

type://host_name/domain_name, where type is nis, nispus, dns, ldap, or file; host_name is the name of the machine that serves the domain; and domain_name is the name of the domain you want to manage. (Note: Do not use nis+ for nispus.) This option applies only to a single tool run in the terminal console.

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-h | --help

Prints a usage statement about the smc command and its subcommands to the terminal window. To print a usage statement for one of the subcommands, enter -h after the subcommand.

-H | --hostname 13:host_name:port

Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the -B option (see above), or set your console preferences to load a "home toolbox" by default.
### java_option
Specifies an option that can be passed directly to the Java runtime (see java(1)). Do not enter a space between -J and the argument. This option is most useful for developers.

### -l | --rolepassword 13;role_password
Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

### -p | --password 13;password
Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

### -r | --rolename 13;role_name
Specifies a role name for authentication. If you are running the Solaris Management Console in a terminal and you do not specify this option, no role is assumed. The GUI console may prompt you for a role name, although you may not need to assume a role.

### -s | --silent
Disables informational messages printed to the terminal.

### -t
Runs the Solaris Management Console in terminal mode. If this option is not given, the Solaris Management Console will automatically run in terminal mode if it cannot find a graphical display.

### -trust
Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

### -T | --tool 13;tool_name
Runs the tool with the Java class name that corresponds to tool_name. If you do not specify this option and the Solaris Management Console is running in terminal mode, the system prompts you. If the Solaris Management Console is running in graphical mode, the system either loads a toolbox or prompts you for one (see options -H and -B).
-u | - --username username

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

-v | - --version

Prints the version of the Solaris Management Console to the terminal. In the graphical console, this information can be found in the About box, available from the Help menu.

-y | - --yes

Answers yes to all yes/no questions. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

**Examples**

**EXAMPLE 1**  Printing a Usage Statement

The following prints a usage statement about the smc command to the terminal window:

```
smc --help
```

**EXAMPLE 2**  Using SMF Property to Allow Remote Access

The following sequence of commands allows remote access to WBEM-based applications, including the Solaris Management Console.

```
# svcadm -s svc:/application/management/wbem \
    setprop options/tcp_listen = true
# svcadm refresh svc:/application/management/wbem
```

**EXAMPLE 3**  Passing an Option to Java

The following passes an option through to the Java VM, which sets the com.example.boolean system property to true. This system property is only an example; the Solaris Management Console does not use it.

```
smc -J-Dcom.example.boolean=true
```

**Environment Variables**

See environ(5) for a description of the following environment variable that affects the execution of the smc command:

- `JAVA_HOME`  If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, the /usr/j2se location is used.

**Exit Status**

The following exit values are returned. Other error codes may be returned if you specify a tool (using -T tool_name) that has its own error codes. See the documentation for the appropriate tool.

- 0  Successful completion.
- 1  An error occurred.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmcc</td>
</tr>
</tbody>
</table>

See Also  auths(1), java(1), profiles(1), roles(1), smcconf(1M), svcadm(1M), svccfg(1M), attributes(5), environ(5), smf(5), X(7)
smccompile(1M)

Name  smccompile – build class list and compile Solaris Management Console service beans for remote use

Synopsis  
/usr/sadm/bin/smccompile -c beanname

/usr/sadm/bin/smccompile -j tool | service [-n altjarname] jarfile

/usr/sadm/bin/smccompile -j library [-n altjarname] ALLTOOL | ALLSERVICE | ALL | attachedBeanname jarfile

Description  The smccompile command is used by developers of tools, services, and libraries for the Solaris Management Console. For information regarding the Solaris Management Console, see smc(1M).

smccompile compiles service class files given by the bean name for use with the Solaris Management Console. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. Solaris Management Console requires running smccompile -c before creating service jar files, and smccompile -j after creating tool, service, and library jars.

smccompile, in conjunction with smcregister(1M), is intended to replace the smcconf command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over smcconf.

Options  The following options are supported:

- ALL Specify that the library being registered to or unregistered from the repository is for use by all tools and services.
- ALLSERVICE Specify that the library being registered to or unregistered from the repository is for use by all services.
- ALLTOOL Specify that the library being registered to or unregistered from the repository is for use by all tools.
- attachedBeanname Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as altjarname (if provided) or jarfile used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.
- beanname The full package path of the bean name to be compiled. An example bean name is: com.mycompany.myproduct.MyService.
- -c Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run smccompile with this option before creating service type jar files.
Build a list of classes in text format, suitable as input to smcregister for registration with the Solaris Management Console repository. The output is written to standard out and should be redirected to a file. You must run smccompile with this option after creating any tool, service, or library jar.

Specify the full path to the jar file to be registered. The name must be in the form beanname.jar, where beanname is the package path to the bean. If it is not, an alternate name must be given in that form using the -n option.

Rename the jar file in the repository to altjarname. Typically, this is the full bean name. For example, if the jar file was MyTool.jar, then altjarname might be com.mycompany.myproduct.MyTool.jar. It is recommended that an altjarname containing the full package path be used. You must use this same name when registering the jar with smcregister.

**Examples**

**EXAMPLE 1**  Compiling a Service

The following command takes a Solaris Management Console service and builds its proxy and stub classes to make the service usable by Solaris Management Console tools:

```
/usr/sadm/bin/smccompile -c com.mycompany.myproject.MyServiceImpl
```

**EXAMPLE 2**  Building a Class List for a Service

The following command builds the class list file (classlist.txt) for a service suitable for use with the smcregister(1M) command:

```
/usr/sadm/bin/smccompile -j service \n   -n com.mycompany.myproject.MyServiceImp\l.jar \n   ${HOME}/workarea/MyServiceImpl.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j service \n   ${HOME}/workarea/com.mycompany.myproject.MyServiceImpl.jar > classlist.txt
```

**EXAMPLE 3**  Building a Class List for a Tool

The following command builds the class list file (classlist.txt) for a tool suitable for use with the smcregister(1M) command:

```
/usr/sadm/bin/smccompile -j tool \n   -n com.mycompany.myproject.MyTool.jar \n   ${HOME}/workarea/MyTool.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:
EXAMPLE 3  Building a Class List for a Tool  (Continued)

/usr/sadm/bin/smccompile -j tool \ 
  ${HOME}/workarea/com.mycompany.myproject.MyTool.jar > classlist.txt

EXAMPLE 4  Building a Class List for a Library Attached to All Tools

The following command builds the class list file (classlist.txt) for a library suitable for use with the smcregister(1M) command, and is attached to all tools:

/usr/sadm/bin/smccompile -j library \ 
  -n com.mycompany.myproject.MyLibrary.jar \ 
  ALLTOOL ${HOME}/workarea/MyLibrary.jar > classlist.txt

The following command does the same thing without specifying an alternate name:

/usr/sadm/bin/smccompile -j library \ 
  ALLTOOL \ 
  ${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt

EXAMPLE 5  Building a Class List for a Library Attached to a Specific Tool

The following command builds the class list file (classlist.txt) for a library suitable for use with the smcregister(1M) command, and is attached to a specific tool:

/usr/sadm/bin/smccompile -j library \ 
  -n com.mycompany.myproject.MyLibrary.jar \ 
  com.mycompany.myproject.MyTool.jar \ 
  ${(HOME)/workarea/MyLibrary.jar > classlist.txt

The following command does the same thing without specifying an alternate name:

/usr/sadm/bin/smccompile -j library \ 
  com.mycompany.myproject.MyTool.jar \ 
  ${(HOME)/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt

Environment Variables  See environ(5) for descriptions of the following environment variables that affect the execution of smccompile:

JAVA_HOME  If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, the /usr/j2se location is used.

Exit Status  The following exit values are returned:

  0  Successful completion.
  1  An error occurred.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWMc</td>
</tr>
</tbody>
</table>

See Also  smc(1M), smcconf(1M), smcregister(1M), attributes(5), environ(5)

Notes  All standard shell quoting rules apply.
Name
smcconf – configure the Solaris Management Console

Synopsis
/usr/sadm/bin/smcconf [-h] [-v] toolbox [action] [target]
[parameters] [options]

/usr/sadm/bin/smcconf [-h] [-v] repository [action]
[parameters] [options]

Description
The smcconf command configures the Solaris Management Console. See smc(1M). This command enables you to add to, remove from, and list the contents of the toolboxes and bean repository.

Using smcconf to edit toolboxes is not as feature-rich as using the graphical editor in Solaris Management Console. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, smc edit. See smc(1M).

smcregister is intended to replace the smcconf command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over smcconf. See smcregister(1M), smccompile(1M), and the Solaris Management Console SDK Guide at /usr/sadm/lib/smc/docs/sdkguide/index.html for details.

Options
The following options are supported:

- **-h**  Prints out a usage summary for the command.
- **-v**  Verbose option. Displays the debugging output at any time.

</tbody>
</table>

<table>
<thead>
<tr>
<th>Target</th>
<th>Legal Values are:</th>
</tr>
</thead>
</table>
tool

If the action is specified as add, this target adds a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you are adding. If you specify a folder name with the -F option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder.

If the action is specified as remove, this target removes a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you want to remove. If you specify a folder name with the -F option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox are removed.

For the tool to appear in the console, the tool must also be registered in the repository. See the repository configuration section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded.

Removing a tool from a toolbox does not remove the tool from the server repository.

tbxURL

If the action is specified as add or remove, this target adds to or removes from the toolbox a link to another toolbox. The required parameter is the URL to the other toolbox.

The properties of addition and removal are the same as for the tool target.

toolbox

If the action is specified as create, this target creates a skeleton toolbox with no tools. The required parameters are: the toolbox name, description, and small and large icon paths. These must be followed by the -B toolboxpath and -D scope options.

legacy

If the action is specified as add or remove, this target adds or removes legacy applications (command-line, X-windows, and web-based) to or from the toolbox. The -N, -T, -E, and -B options are required. The -A option is optional. Placement in the toolbox with the -F option follows the same rules as for the tool and tbxURL targets. See NOTES for more information about legacy applications.
folder  If the action is specified as add, this target adds a folder to the toolbox. The required parameters are: the folder name, description, and small and large icon paths.

If the action is specified as remove, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the -F option.

parameters  Specifies values that might be required, depending on the combination of action and target.

options  Supported options for various action and target combinations for the toolbox configuration are:

    -A parameters  Specifies the parameters to pass to the legacy application. This option is available only for the legacy target.

    -B toolboxpath  Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, "This Computer".

    -D scope  Specifies the scope (domain) in which the tool should be run. The legal values for scope are file, nis, nisplus, dns, and ldap. This can also be specified for a folder or a toolbox.

    -E appPath  Specifies the absolute executable path of the legacy application. This option is available only for the legacy target.

    -F folder  Specifies the full path of the container folder. If this option is not given, the default folder is the 'root' folder of the toolbox.

    -H [host_name][:port]  Specifies the host and port from which a tool should be loaded. If host_name is not given, the default host is used. The default host is localhost, if the toolbox is loaded from the local file system, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server. If :port is not given, the default port will be used. If
this option is not given at all, both the default host and the default port are used.

-locale

Specifies the locale of the toolbox that is being modified. The default is the C locale.

-appName

Specifies the name of the legacy application being registered. This is the name that appears in the console. This option is available only for the legacy target.

-key:value

Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.

-appType

Specifies the legacy application type. Legal values are CLI, XAPP, or HTML. This option is available only for the legacy target.

The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

**repository configuration**

<table>
<thead>
<tr>
<th>action Legal values are:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>Adds information to the repository. If the -f option is given to add, the information overwrites any information of the same name already in the repository. If the -f option is not given, an error might be returned if the information is already in the repository.</td>
</tr>
<tr>
<td>remove</td>
<td>Removes information from the repository.</td>
</tr>
<tr>
<td>list</td>
<td>Lists the contents of the repository:</td>
</tr>
<tr>
<td></td>
<td>• All registered tools</td>
</tr>
<tr>
<td></td>
<td>• All registered services</td>
</tr>
<tr>
<td></td>
<td>• All libraries attached to all tools</td>
</tr>
<tr>
<td></td>
<td>• All libraries attached to all services</td>
</tr>
<tr>
<td></td>
<td>• All libraries attached to all tools and services</td>
</tr>
</tbody>
</table>

**target Legal values are:**

<table>
<thead>
<tr>
<th>bean</th>
<th>If the <strong>action</strong> is specified as add, this target will add a tool or service bean (which kind is determined by the contents of the bean) to the repository. The required <strong>parameter</strong> is the path to the jar file that contains the bean to be added.</th>
</tr>
</thead>
<tbody>
<tr>
<td>remove</td>
<td>If the <strong>action</strong> is specified as remove, this target will remove a tool or service bean from the repository. The required <strong>parameter</strong> is the full Java classname of the desired bean.</td>
</tr>
</tbody>
</table>
If the action is specified as add, this target adds a “library” jar file to a tool or service bean. The two required parameters are the full Java classname of the desired bean and the path to the jar file to be attached. The bean name can also be one of the “pseudo-beans,” ALL, ALLTOOL, or ALLSERVICE, in which case the library is attached, respectively, to all beans, all tools, or all services in the repository.

If the action is specified as remove, this target detaches a “library” jar file from a tool or service bean. The two required parameters are the full Java classname of the desired bean and the name of the jar file that is attached. As with the add action, the three “pseudo-beans” ALL, ALLTOOL, or ALLSERVICE can be used.

If the action is specified as add, this target defines a property on a tool or service. One or more key/value pairs must be specified in the form,

\[-P key=value\]

Following this property list is a “pseudo-bean name,” pseudoBeanName, as defined for the library target, on which the properties are defined. Optionally, a library name can follow the “pseudo-bean” name, in which case the properties are defined on the library that is attached to the named bean.

If the action is specified as remove, this target undefines a property on a tool or service. The key/value pairs, “pseudo-bean” name, and optional library are specified for the add action.

**Examples**

**EXAMPLE 1** Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the command line interface (CLI) application, /usr/bin/ls, with arguments -al -R, giving it the name, Directory Listing:

```
/usr/sadm/bin/smcconf toolbox add legacy -N "Directory Listing" \\
-T CLI -E /usr/bin/ls -A ":al -R"
```

**EXAMPLE 2** Adding a Folder to a Toolbox

The following command adds to the standard Management Tools toolbox a folder with the name, New Folder, the description, This is a new folder, and the small and large icons, folder_s.gif and folder_l.gif:

```
/usr/sadm/bin/smcconf toolbox add folder "New Folder" \\
"This is a new folder" folder_s.gif folder_l.gif \\
-B /var/sadm/smc/toolboxes/smc/smc.tbx
```
EXAMPLE 3  Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is HelloWorld.client.HelloTool (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it is run in the NIS domain, syrinx, which is hosted by the machine, temple, and is retrieved from port 2112 on the machine from which the toolbox was loaded:

```
/usr/sadm/bin/smcconf toolbox add tool HelloWorld.client.HelloTool \
   -D nis:/temple/syrinx -H :2112
```

EXAMPLE 4  Adding a Solaris Management Console Tool to the Repository

The following command adds the Java bean found in HelloWorld.jar to the repository. The jar file contains information that the bean is a tool:

```
/usr/sadm/bin/smcconf repository add bean HelloWorld.jar
```

EXAMPLE 5  Removing a Solaris Management Console Service from the Repository

The following command removes a Java bean from the repository. Although the name of the bean implies that it is a service, that is merely a convention; the repository knows whether a particular registered bean is a tool or a service:

```
/usr/sadm/bin/smcconf repository remove bean \
   HelloWorld.server.HelloService
```

EXAMPLE 6  Attaching a Library to a Tool

The following command adds the library jar file, HelloWorld_fr.jar (probably a French localized version of the HelloTool's resources) to the bean, HelloWorld.client.HelloTool:

```
/usr/sadm/bin/smcconf repository add library \
   HelloWorld.client.HelloTool HelloWorld_fr.jar
```

EXAMPLE 7  Attaching a Library to all Tools

The following command adds the library jar file, widgets.jar, to all tools in the repository. The library probably contains a widget set that might be useful to any registered tools:

```
/usr/sadm/bin/smcconf repository add library ALLTOOL widgets.jar
```

Environment Variables

See environ(5) for descriptions of the following environment variables that affect the execution of the smcconf command:

- **JAVA_HOME**  If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, the /usr/j2se location is used.
- **DISPLAY**  If you do not set this environment variable, set it to null, or set it to an X(7) display to which you are not authorized to connect, the Solaris Management Console starts in terminal mode instead of graphical mode.
**Exit Status**  The following exit values are returned:

0  Successful completion.

1  An error occurred.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmc</td>
</tr>
</tbody>
</table>

**See Also**  smc(1M), smccompile(1M), smcregister(1M), attributes(5), environ(5)

**Notes**  All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from “native” Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, LegacyAppLauncher, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.
smcregister – configure the Solaris Management Console

```
/smcregister [-h] tool [-n altjarname] jarfile classlistfile xmlfile
/smcregister [-h] service [-n altjarname] jarfile classlistfile xmlfile
[ native_lib_list]
/smcregister [-h] library [-n altjarname] jarfile classlistfile | none ALLTOOL | ALLSERVICE | ALL | Attachedbeanname
/smcregister [-h] tool | service -u jarfile
/smcregister [-h] library -u jarfile ALL | ALLTOOL | ALLSERVICE | Attachedbeanname
/smcregister [-h] toolbox [-D] [action] [-f]
[ target] [parameters] [options]
/smcregister [-h] property key value ALL | ALLTOOL | ALLSERVICE | Attachedbeanname
/smcregister [-h] property -u key ALL | ALLTOOL | ALLSERVICE | Attachedbeanname
/smcregister [-h] repository list
/smcregister [-h] scripts regscript unregscript
```

**Description**

The **smcregister** command configures the Solaris Management Console. For information regarding the Solaris Management Console, see **smc**(1M). This command enables you to add to, remove from, and list the contents of toolboxes and the Solaris Management Console repository.

**smcregister** also allows you to register scripts to perform registrations and unregistrations. Typically, a package containing one or more tools or services posts tool and service registrations immediately after installation. On Solaris, this is by way of invocations of **smcregister** from within a package post-install script. Similarly, unregistrations would be posted from within a package pre-remove script. These are per-machine registrations - that is, registration requests must be posted on each machine on which the Solaris Management Console server will be running. However, due to the way that diskless clients are installed, registration requests cannot be made at install time. Therefore, packages should include and install registration and unregistration scripts, and then register these scripts during installation by way of the **scripts** subcommand. These scripts should contain tool, toolbox, service, library or property configurations in any of its forms as listed in this man page. While these scripts function very much like package post-install and pre-remove scripts, do not assume the normal package environment is available. However, **PATH** can assumed to be 

```
/usr/sbin:/usr/bin
```

Using **smcregister** to edit toolboxes is not as feature-rich as using the Solaris Management Console's graphical editor. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, **smc edit**. See **smc**(1M).
smcregister is intended to replace the smcconf command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over smcconf.

**Options**  The following options are supported:

- **-h**   Prints out a usage summary for the command.

**Scripts Configuration**

- **regscript**   The full path of a script containing registration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is installed.

- **unregscript**   The full path of a script containing unregistration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is removed.

**Toolbox Configuration**

- **action**   Legal values are:

  - **add**   Adds a target to the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.

  - **create**   Creates a new toolbox with no tools in it. The only target recognized is `toolbox`.

  - **list**   Lists the contents of the toolbox. No target is recognized. If you specify a parameter, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a parameter, the contents of the default toolbox are listed.

  - **remove**   Removes a target from the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.

- **-D**   Defers execution of the `toolbox` command until the Solaris Management Console server is restarted. This is a convenient option for use in packaging scripts during install and un-install. Additionally, the command runs much faster than if run interactively (without `-D`).

- **target**   Legal values are:

  - **folder**   If the action is specified as **add**, this target adds a folder to the toolbox. There are four required parameters: the folder name, description, and small and large icon paths. If the action is specified as **remove**, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the `-F` option.

  - **legacy**   If the action is specified as **add** or **remove**, this target adds or removes legacy applications (command line, X-windows, and...
web-based) to or from the toolbox. The -N, -T, -E, and -B options are required, and the -A option is optional. Placement in the toolbox with the -F option follows the same rules as for the tool and tbxURL targets. See NOTES for more information about legacy applications.

tbxURL If the action is specified as add or remove, this target adds to or removes from the toolbox a link to another toolbox. The required parameter is the URL to the other toolbox. The properties of addition and removal are the same as for the tool target.

tool If the action is specified as add, this target adds a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you are adding. If you specify a folder name with the -F option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder. If the action is specified as remove, this target removes a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you wish to remove. If you specify a folder name with the -F option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox will be removed. For the tool to show up in the console, the tool must also be registered in the repository. See the repository configuration section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded. Removing a tool from a toolbox does not remove the tool from the server repository.

toolbox If the action is specified as create, this target creates a skeleton toolbox with no tools. There are four required parameters: the toolbox name, description, and small and large icon paths. These must be followed by the -B toolboxpath and -D scope options.

parameters Specifies values that may be required depending on the combination of action and target.

options Supported options for various action and target combinations for the toolbox configuration are:

- A Specifies the parameters to pass to the legacy application. This option is available only for the legacy target.
-B Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, This Computer.

-D Specifies the scope (domain) in which the tool should be run. The legal values for scope are file, nis, nisplus, dns, and ldap. This may also be specified for a folder or a toolbox. In the former case, all tools in that folder and its subfolders will be run in that scope; in the latter, all tools in the toolbox will be run in that scope.

-E Specifies the absolute executable path of the legacy application. This option is available only for the legacy target.

-f If the -f option is given to add, the information will overwrite any information of the same name already in the toolbox. If the -f option is not given, an error may be returned if the information is already in the toolbox.

-F folder Specifies the full path of the container folder. If this option is not given, the default folder is the root folder of the toolbox.

-H [host_name][:port] Specifies the host and port from which a tool should be loaded. If host_name is not given, the default host (localhost, if the toolbox is loaded from the local filesystem, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server) will be used. If :port is not given, the default port will be used. If this option is not given at all, both the default host and the default port will be used.

-L locale Specifies the locale of the toolbox which is being modified. The default is the C locale.

-N appName Specifies the name of the legacy application being registered. This is the name that will appear in the console. This option is available only for the legacy target.
-P key:value

Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.

-T appType

Specifies the legacy application type. Legal values are CLT, XAPP, or HTML. This option is available only for the legacy target.

See NOTES for more information about registration and unregistration of tools, services, and libraries.

ALL

Specify that the library being registered to or unregistered from the repository is for use by all tools and services.

ALLSERVICE

Specify that the library being registered to or unregistered from the repository is for use by all services.

ALLTOOL

Specify that the library being registered to or unregistered from the repository is for use by all tools.

attachedBeanname

The name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as altjarname (if provided) or jarfile used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.

classlistfile

The classlist text file generated from the smccompile(1M) command.

Library registration does not require that a classlist file be specified. Instead, you can substitute the keyword none in place of the classlist path argument to smcregister, in which case one will be generated automatically. Generating the classlist automatically during server startup will cause the next server restart to take longer, so it is strongly suggested that developers always provide a classlist file with their libraries. Auto-generation is more appropriately used to register 3rd-party library jars.

jarfile

The full path to the jar file to be registered/unregistered. The name must be in the form beanname.jar, where beanname is the package path to the bean. If it is not, an alternate name must be given in that form using the -n option.

-n altjarname

Rename the jarfile in the repository to altjarname. This would typically be the full bean name. For example, if the jarfile was MyTool.jar, then altjarname might be com.mycompany.myproduct.MyTool.jar. It is recommended that an altjarname containing the full package path be used.
### Repository Configuration

The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

**list**  
Lists the contents of the repository:
- All registered tools
- All registered services
- All libraries attached to all tools
- All libraries attached to all services
- All libraries attached to all tools and services

### Property Configuration

See NOTES for more information about registration and unregistration of properties. If registering a property, this defines a property on a tool or service. Only one key value pair at a time can be registered.

**beanname**  
The name of a registered jar on which the properties will be defined. Optionally, a library name may follow the bean name, in which case the properties are defined on the library that is attached to the named bean.

If unregistering a property, this undefines a property from a tool or service. Only one key value pair at a time can be registered. The key, beanname, and optional library are specified as for registering a property.

### Examples

#### EXAMPLE 1  
**Adding Legacy Applications to a Toolbox**

The following command adds to the default toolbox the Command Line Interface (CLI) application, `/usr/bin/ls` with arguments `-a` `-R`, giving it the name, Directory Listing:

```
/usr/sadm/bin/smcregister toolbox add legacy -N "Directory Listing" \
  -T CLI -E /usr/bin/ls -A "-a \ -R"
```

Use this variation to defer execution of this command until the Solaris Management Console server is restarted:

```
/usr/sadm/bin/smcregister toolbox -D add legacy -N "Directory Listing" \
  -T CLI -E /usr/bin/ls -A "-a \ -R"
```
EXAMPLE 2  Adding a Folder to a Toolbox
The following command adds to the standard Management Tools toolbox a folder with the name, New Folder, the description, This is a new folder, and the small and large icons, folder_s.gif and folder_l.gif:

```
/usr/sadm/bin/smcregister toolbox add folder "New Folder" "This is a new folder" folder_s.gif folder_l.gif -B /var/sadm/smc/toolboxes/smc.smc.tbx
```

EXAMPLE 3  Adding a Native Solaris Management Console Tool to a Toolbox
The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is com.mycompany.myproject.client.MyTool (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it will be run in the NIS domain, syrinx, which is hosted by the machine, temple, and will be retrieved from port 2112 on the machine from which the toolbox was loaded.

```
```

EXAMPLE 4  Adding an Solaris Management Console Tool to the Repository
The following command adds the Java bean found in MyTool.jar to the repository. The xml file contains information about the tool. The classlist file would have been generated by smccompile -j:

```
/usr/sadm/bin/smcregister tool -n com.mycompany.myproject.client.MyTool.jar \${HOME}/workarea/MyTool.jar \${HOME}/workarea/MyTool_classlist.txt \${HOME}/workarea/MyTool.xml
```
Use this variation to add an Solaris Management Console tool to the repository without specifying an alternate name:

```
/usr/sadm/bin/smcregister tool \${HOME}/workarea/com.mycompany.myproject.client.MyTool.jar \${HOME}/workarea/MyTool_classlist.txt \${HOME}/workarea/MyTool.xml
```

EXAMPLE 5  Adding an Solaris Management Console Service to the Repository
The following command adds the Java bean found in MyServiceImpl.jar to the repository. The xml file contains information about the service. The classlist file would have been generated by smccompile -j. The extra proxy and stub classes included in the jar would have been generated by smccompile -c:

```
/usr/sadm/bin/smcregister service \-n com.mycompany.myproject.server.MyServiceImpl.jar
```
EXAMPLE 5  Adding an Solaris Management Console Service to the Repository  (Continued)

${HOME}/workarea/MyServiceImpl.jar 
${HOME}/workarea/MyServiceImpl_classlist.txt 
${HOME}/workarea/MyServiceImpl.xml

Use this variation to add a Solaris Management Console service to the repository without specifying an alternate name:

/usr/sadm/bin/smcregister service \
 ${HOME}/workarea/com.mycompany.myproject.server.MyServiceImpl.jar \
 ${HOME}/workarea/MyServiceImpl_classlist.txt \
 ${HOME}/workarea/MyServiceImpl.xml

EXAMPLE 6  Removing an Solaris Management Console Tool From the Repository

The following command removes a Java tool bean from the repository:

/usr/sadm/bin/smcregister tool \ 
 -u com.mycompany.myproject.client.MyTool.jar

EXAMPLE 7  Removing an Solaris Management Console Service From the Repository

The following command removes a Java service bean from the repository:

/usr/sadm/bin/smcregister service \ 
 -u com.mycompany.myproject.client.MyTool.jar

EXAMPLE 8  Attaching a Library to a Specific Tool

The following command adds the library jar file, MyTool_fr.jar (probably a French localized version of the MyTool’s resources) to the bean, com.mycompany.myproject.client.MyTool:

/usr/sadm/bin/smcregister library \ 
 -n MyTool_fr.jar \ 
 ${HOME}/workarea/MyTool_fr.jar \ 
 ${HOME}/workarea/MyTool_fr_classlist.txt \ 
 com.mycompany.myproject.client.MyTool

EXAMPLE 9  Attaching a Library to All Tools

The following command adds the library jar file, widgets.jar, to all tools in the repository. The library probably contains a widget set which might be useful to any registered tools. The classlist file would have been generated by smccompile -j.

/usr/sadm/bin/smcregister library \ 
 ${HOME}/workarea/lib/widgets.jar\ 
 ${HOME}/workarea/lib/widgets_classlist.txt \ 
 ALLTOOL

Alternatively, to add a 3rd-party library jar to all tools, replace the classlist file with none:
EXAMPLE 9  Attaching a Library to All Tools  (Continued)

/usr/sadm/bin/smcregister library \
   /opt/lib/XYZwidgets.jar none ALLTOOL

EXAMPLE 10  Detaching a Library from All Tools
The following command removes the Java library bean from the repository:

/usr/sadm/bin/smcregister library -u MyTool_fr.jar ALLTOOL

EXAMPLE 11  Detaching a Library from a Specific Tool
The following command detaches the library jar file, MyTool_fr.jar (probably a French
localized version of the MyTool's resources) from the bean
com.mycompany.myproject.client.MyTool, and removes it from the repository:

/usr/sadm/bin/smcregister library -u MyTool_fr.jar \
   com.mycompany.myproject.client.MyTool

EXAMPLE 12  Registering Scripts
The following command registers the following scripts containing registration and
unregistration commands. MyProduct_reg.sh will be executed upon the next server restart
after the file is installed by the owning package. MyProduct_unreg.sh will be executed upon
the next server restart after the file is removed by the owning package:

/usr/sadm/bin/smcregister scripts \
   /usr/sadm/lib/myProduct/MyProduct_reg.sh \
   /usr/sadm/lib/myProduct/MyProduct_unreg.sh

Environment Variables  See environ(5) for descriptions of the following environment variables that affect the
execution of smcregister:

JAVA_HOME If you do not specify this environment variable, your PATH is searched for a
suitable java. Otherwise, the /usr/j2se location is used.

Exit Status  The following exit values are returned:

   0   Successful completion.
   1   An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmc</td>
</tr>
</tbody>
</table>
See Also  
smc(1M), smcconf(1M), smccompile(1M), attributes(5), environ(5)

Notes  
All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from native Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, LegacyAppLauncher, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

Registration and unregistration of tools, services, libraries, and properties do not take effect until the Solaris Management Console server is restarted. Run /etc/init.d/init.wbem stop followed by /etc/init.d/init.wbem start
Name  smcron – manage jobs in the crontab database

Synopsis  /usr/sadm/bin/smcron subcommand [ auth_args ] - - [ subcommand_args ]

Description  The smcron command manages jobs in the crontab(1) database.

subcommands  smcron subcommands are:

add  Adds a job to the crontab(1) database. To add a job, the administrator must have the solaris.jobs.user authorization. To add a job to another user's crontab file, the administrator must have the solaris.jobs.admin authorization.

delete  Deletes a job from the crontab(1) database. To delete a job, the administrator must have the solaris.jobs.user authorization. To delete a job from another user's crontab file, the administrator must have the solaris.jobs.admin authorization.

list  Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the solaris.jobs.user authorization. To list a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization. No authorization is needed to list a user's own jobs.

modify  Modifies a job in the crontab(1) database. To modify a job, the administrator must have the solaris.jobs.user authorization. To modify a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization.

Options  The smcron authentication arguments, auth_args, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smcron command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, subcommand_args, must come after the auth_args and must be separated from them by the - - option.

auth_args  The valid auth_args are -D, -H, -l, -p, -r, and -u; they are all optional. If no auth_args are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the domain argument.

-D | - -domain 13:domain          Specifies the default domain that you want to manage. smcron accepts only file for this option. file is also the default value.
The file default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-\(\text{-H} \mid \text{-hostname \texttt{13;host_name:port}}\) Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) -B option, or set your console preferences to load a “home toolbox” by default.

-\(\text{-l} \mid \text{-rolepassword \texttt{13;role_password}}\) Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-\(\text{-p} \mid \text{-password \texttt{13;password}}\) Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-\(\text{-r} \mid \text{-rolename \texttt{13;role_name}}\) Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-\(\text{-u} \mid \text{-username \texttt{13;user_name}}\) Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

-\(\text{-} \mid \text{-} \) This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

For the time-related subcommands described below, -m, -M, -t, and -w, you can enter multiple arguments, separated only by commas. smcRon will construct crontab entries appropriate for your arguments. See EXAMPLES.

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.
For subcommand add:

- **c command**
  Specifies the command that you want to run.

- **h**
  (Optional) Displays the command's usage statement.

- **m day_of_month**
  (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both -t and -m options, the job executes one day per month at the time specified by -t.

- **M month**
  (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both -t and -M options, the job executes during the specified month at the time specified by -t.

- **n name**
  Specifies the unique name of the job.

- **o owner**
  (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.

- **t time_of_day**
  Specifies the time (in hh:mm) that you want to execute the command. If no other time-related options are specified (-m, -M, or -w), the job executes every day at the time specified by -t. If you specify both -t and -w options, the job executes one day per week at the time specified by -t. If you specify both -t and -m options, the job executes once per month at the time specified by -t. If you specify both -t and -M options, the job executes each day during the specified month at the time specified by -t.

- **w day_of_week**
  (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:
  - 0=Sunday
  - 1=Monday
  - 2=Tuesday
  - 3=Wednesday
  - 4=Thursday
  - 5=Friday
  - 6=Saturday

  If you specify both -t and -w options, the job executes one day per week at the time specified by -t.

For subcommand delete:

- **h**
  (Optional) Displays the command's usage statement.

- **n name**
  Specifies the unique name of the job.

- **o owner**
  (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.
For subcommand **list**:

- **\(-f n|s|v\)** (Optional) Specifies the format of the output. See EXAMPLES for examples of each output type.
  - **\(n\)** — Displays the data in native format, as it appears in the `crontab(1)` database.
  - **\(s\)** — Default format. Displays the data in summary format.
  - **\(v\)** — Displays the data in verbose format.

- **\(-h\)** (Optional) Displays the command's usage statement.

- **\(-o owner\)** (Optional) Lists all jobs for the specified owner (user name). If you do not specify this option, all jobs in the `crontab(1)` database are listed.

For subcommand **modify**:

- **\(-c command\)** (Optional) Specifies the command that you want to run.

- **\(-h\)** (Optional) Displays the command's usage statement.

- **\(-m day_of_month\)** (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`.

- **\(-M month\)** (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both `-t` and `-M` options, the job executes during the specified month at the time specified by `-t`.

- **\(-n name\)** Specifies the current unique name of the job.

- **\(-N new_name\)** (Optional) Specifies the new unique name of the job.

- **\(-o owner\)** (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the `-U` option is assumed.

- **\(-O new_owner\)** (Optional) Specifies the new owner of the job.

- **\(-t time_of_day\)** (Optional) Specifies the time (in `hh:mm`) that you want to execute the command. If no other time-related options are specified (`-m`, `-M`, or `-w`), then the job executes every day at the time specified by `-t`. If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`. If you specify both `-t` and `-M`, then the job executes each day during the specified month at the time specified by `-t`.

- **\(-w day_of_week\)** (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:
  - **0** = Sunday
If you specify both -t and -w options, the job executes one day per week at the time specified by -t.

**Examples**

**EXAMPLE 1** Adding a Job

The following adds a new job, owned by root, that removes the old log files from /tmp daily at 1:30 AM.

```
./smcron add -H myhost -u root -p mypassword -- -n "Remove old logs" \ 
   -t 1:30 -c "rm /tmp/*.log" -o root
```

**EXAMPLE 2** Deleting a Job

The following deletes the job Remove old logs owned by root:

```
./smcron delete -H myhost -u root -p mypassword -- \ 
   -n "Remove old logs" -o root
```

**EXAMPLE 3** Listing Jobs in Native Format

The following lists all jobs in native, or crontab(1), format:

```
./smcron list -H myhost -u root -p mypassword -- -f n
```

```
MINUTE HOUR DATE MONTH DAY COMMAND
10 3 * * * /usr/sbin/logadm
15 3 * 0 /usr/lib/fs/nfs/nfsfind
1 2 * * [ -x /usr/sbin/rtc ] && /usr/sbin/rtc -c > /dev/null 2>&1
30 3 * * [ -x /usr/lib/gss/gsscred_clean ] && /usr/lib/gss/gsscred_clean
```

**EXAMPLE 4** Listing Jobs in Standard Format

The following lists all jobs owned by lp in standard format:

```
./smcron list -H myhost -u root -p mypassword -- -f s -o lp
NAME::OWNER::SCHEDULE::COMMAND
NoName_1765663371::lp::Weekly on Sundays at 3:13 AM::cd /var/lp/logs; 
   if [ -f requests ]; then if [ -f requests.1 ]; then /bin/mv requests.1 
     requests.2; fi; /usr/bin/cp requests requests.1; > requests; fi
NoName_512822673::lp::Weekly on Sundays at 4:15 AM::cd /var/lp/logs; 
   if [ -f lpsched ]; then if [ -f lpsched.1 ]; then /bin/mv lpsched.1 
     lpsched.2; fi; /usr/bin/cp lpsched lpsched.1; >lpsched; fi
```
EXAMPLE 5  Listing jobs in verbose format

The following lists all jobs in verbose format:

```
./smcron list -H myhost -u root -p mypassword -- -f v
```

<table>
<thead>
<tr>
<th>NAME::OWNER::SCHEDULE::NEXT_RUN::STATUS::COMMAND</th>
</tr>
</thead>
<tbody>
<tr>
<td>NoName_1075488942::root::Advanced::::Finished on Feb 10 3:10 with code 1</td>
</tr>
<tr>
<td>databackup::root::Weekly on Sundays at 3:10 AM::3/19/00 3:10 AM</td>
</tr>
<tr>
<td>runlog::root::Daily at 2:01 AM::3/14/00 2:01 AM::Finished on Feb 11 2:01 AM::usr/sbin/rtc</td>
</tr>
</tbody>
</table>

EXAMPLE 6  Changing a Job

The following modifies the job Remove old logs owned by root to execute daily at 2:00 AM:

```
./smcron modify -H myhost -u root -p mypassword -- -n "Remove old logs" -o root -t 2:00
```

EXAMPLE 7  Specifying Multiple Time Arguments

smcron allows you to specify a range of times for all of its time-related subcommands, -m, -M, -t, and -w. For example, the following command:

```
# smcron add -u root -p xxxx -- -n cronjob1 -w 1-4,5 -t 12:00,13:15,14:30 -c ls
```

...creates the following entry in crontab:

```
0,15,30 12,13,14 * * 1,2,3,4,6 ls cronjob1
```

This job would run on Monday through Thursday and Saturday at the following times:

- 12:00 12:15 12:30
- 13:00 13:15 13:30
- 14:00 14:15 14:30

Environment Variables

See `environ(5)` for a description of the JAVA_HOME environment variable, which affects the execution of the smcron command. If this environment variable is not specified, the /usr/java location is used. See `smc(1M)`.

Exit Status

The following exit values are returned:

- 0  Successful completion.
- 1  Invalid command syntax. A usage message displays.
- 2  An error occurred while executing the command. An error message displays.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
</tbody>
</table>

See Also  crontab(1), cron(1M), smc(1M), attributes(5), environ(5)

Notes  The timezone of the cron daemon sets the system-wide timezone for cron entries. This, in turn, is set by default system-wide using /etc/default/init.

If some form of daylight savings or summer/winter time is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.
smcwebserver(1M)

Name
smcwebserver – manage the server for the Sun Web Console

Synopsis
/usr/sbin/smcwebserver subcommand options

Description
The smcwebserver utility manages the Sun Web Console server. Sun Web Console is a browser-based interface that performs systems management. System administrators can manage systems, devices and services from the console.

When the console webserver is running, you can view the console by opening a browser and pointing to:

https://host:6789

host is the machine where the console has been installed and the console server is running.

The smcwebserver service is managed by the service management facility (SMF) (see smf(5)), under the fault management resource identifier (FMRI):

svc:/system/webconsole

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). smcwebserver can only be started by the superuser or someone in the Primary Administrator role.

The configuration properties of this service can be modified with svccfg(1M).

smcwebserver supports an SMF property that controls remote access to the Sun Web Console server. The property, options/tcp_listen, has a default value of false, which disallows remote access. The value true allows remote access. See EXAMPLES.

Subcommands
The following subcommands are supported:

disable Disable automatic start or stop during system boot or shutdown. Until the administrator reruns the script with the smcwebserver enable subcommand the webserver can be started/stopped only when the administrator executes the script manually using the following command:

# /usr/sbin/smcwebserver [start | stop]

enable Enable the webserver to startup automatically during subsequent system boot and gracefully stop during system shutdown.

restart Stop and subsequently start the console webserver.

The format of the restart subcommand is:

restart [-U username]

start Start the console webserver.

The format of the start subcommand is:
start [-U username]

stop Stop the console webserver.

status Display status of the console webserver.

The format of the status subcommand is:

status [-p]

Options The following options are supported:

- **-U username** | - **--username username** The user identity to run the server as. Once the server has successfully started under the specified identity, all subsequent starts will automatically be done under that identity until you change it via this option, or by changing the com.sun.web.console.user configuration property via the smreg(1M) command. The default is to run the server under the noaccess identity.

- **-p** | - **--parseable** Display non-localized output suitable for programmatic parsing. If the server is running, the output will be:

running=yes

If the server is not running, the output will be:

running=no

- **-h** | - **--help** | - **?-** Display the usage statement.

- **-V** | - **--version** Display console version information.

Examples

**EXAMPLE 1** Displaying the Usage Statement

The following command displays the smcwebserver usage statement:

```
% smcwebserver --help
```

**EXAMPLE 2** Determining if the Server is Running

The following shell command will start the server if it is not already running.

```bash
ans='smcwebserver -p | grep running | cut -d"=" -f2'
if [ "$ans" = "no" ]; then
    smcwebserver start
fi
```
EXAMPLE 3  Using SMF Property to Allow Remote Access

The following sequence of commands allows remote access to the Sun Web Console server.

```
# svcadm -s svc:/system/webconsole \
    setprop options/tcp_listen = true
# svcadm refresh svc:/system/webconsole
```

**Environment Variables**

See `environ(5)` for descriptions of the following environment variables that affect the execution of smcwebserver:

- **JAVA_HOME**
  
  If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, depending on the OS, the following default locations are used:

  - Solaris: `/usr/j2se`
  - Linux: `/usr/java/j2sdk1.4*`

**Exit Status**

The following exit values are returned:

- 0  Successful completion.
- 1  An error occurred.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmcon</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Stable</td>
</tr>
</tbody>
</table>

**See Also**

`smreg(1M), svcadm(1M), svccfg(1M), attributes(5), environ(5), smf(5)`
The `smdiskless` command manages diskless client support for a server.

`smdiskless` subcommands are:

- **add**  
  Adds a new diskless client to a server. There are two usages for this command. The user can either specify all the optional arguments directly on the command line, or provide a `sysidcfg(4)` formatted file as input. A future enhancement will allow specifying both a `sysidcfg(4)` formatted file and optional arguments, which will override the values in the `sysidcfg(4)` file.

- **delete**  
  Deletes an existing diskless client from the system databases and removes any server support associated with the host, depending on the `os_server` type.

- **list**  
  Lists existing diskless clients served by `os_server`.

- **modify**  
  Modifies the specified attributes of the diskless client `os_server`.

The `smdiskless` authentication arguments, `auth_args`, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smdiskless` command requires the Solaris Management Console to be initialized for the command to succeed (see `smdiskless(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, `subcommand_args`, must come after the `auth_args` and must be separated from them by the `- -` option.

The valid `auth_args` are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no `auth_args` are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- domain`.

**Note** – `smdiskless` supports the `--auth-data file` option, which enables you to specify a file the console can read to collect authentication data. See `smc(1M)` for a description of this option.

- `-D | -domain 13:domain`  
  Specifies the default domain that you want to manage. The syntax of `domain` is `type:host_name/domain_name`, where `type` is `nis`, `nis+`, `dns`, `ldap`, or `file`; `host_name` is the name of the machine that serves the domain; and `domain_name` is the name of the domain you want to manage. *(Note: Do not use nis+ for nisplus.)*
If you do not specify this option, the Solaris Management Console assumes the default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

```
-H | -hostname 13;host_name:port
```

Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) -B option, or set your console preferences to load a “home toolbox” by default.

```
-l | -rolepassword 13;role_password
```

Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

```
-p | -password 13;password
```

Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

```
-r | -rolename 13;role_name
```

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

```
-u | -username 13;user_name
```

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

```
-
```

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

**Note:** Descriptions and other arg options that contain white spaces must be enclosed in double quotes.
For subcommand add:

- **-h**  (Optional) Displays the command's usage statement.
- **-i IP_address**  Specifies the IP address for the host in the form of 172.16.200.1.
- **-e ethernet_addr**  Specifies the Ethernet address.
- **-n host**  Specifies the client name.
- **-o os_server**  (optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smdiskless` `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
- **-x os=platform**  Specifies the operating system. The syntax for `platform` is as follows:

```
instruction_set.implementation.Solaris_version
```

where

- **instruction_set** is one of `sparc` or `i386`
- **implementation** is the implementation architecture, that is, `i86pc` and `sun4u`.
- **version** is the Solaris version number. The supported `version` numbers are 2.6, 2.7 (for Solaris 7), 8, 9, and 10. Examples are:

```
sparc.sun4u.Solaris_8
```

- **-x root=pathname**  (Optional) Specifies the absolute path of the directory in which to create the root directory for diskless clients. The default (and recommended) `pathname` is `/export/root/client_name`.

- **-x swap=pathname**  (Optional) Specifies the absolute path of the directory in which to create the swap file for diskless clients. The default (and recommended) `pathname` is `/export/swap/client_name`.

- **-x swapsize=size**  (Optional) Specifies the size, in megabytes, of the swap file for diskless clients. The default swap size is 24M.

- **-x dump=pathname**  (Optional) Specifies the absolute path of the dump directory for diskless clients. The default (and recommended) `pathname` is `/export/dump/client_name`.

- **-x dumpsize=size**  (Optional) Specifies the size, in megabytes, of the dump file for diskless clients. The default swap size is 24M.

- **-x pw=Y**  (Optional) Prompts for the system's root password. The default is not to prompt.
The following options are used to configure workstations on first boot by `sysidtool(1M)`. They can either be specified on the command line, or in a `sysidcfg(4)` formatted file. Note: Use the `sysidcfg(4)` file to:

- Add a DNS client.
- Specify use of the LDAP name service.
- Specify a security policy.

The keywords and functions supported by `sysidtool` and `sysidcfg` vary among Solaris releases. Consult the man pages for your operating system release (`uname -r`) to determine the level of support available.

```
-x tz=timezone  (Optional) Specifies the path of a timezone file, relative to `/usr/share/lib/zoneinfo`. The default is the server's timezone.
-x ns=NIS | NIS+ | NONE (Optional) Specifies the client's nameservice. This is one of NIS, NIS+, or NONE. Use a `sysidcfg(4)` file to specify DNS or LDAP. The default ns value is NONE, which results in the use of the files source in `nsswitch.conf`. See `nsswitch.conf(4)` for a description of the files source.
-x nameserver=hostname (Optional) Specifies the nameserver's hostname. The default is the server's nameserver.
-x domain=domain (Optional) Specifies the client's domain. The default is the server's domain.
-x nameserver_ipaddress=ip_address (Optional) Specifies the nameserver's IP address.
-x netmask=ip_address (Optional) Specifies the client's IP address netmask. The default is the server's netmask.
-x locale=locale (Optional) Specifies the client's system locale. The default is the C locale.
-x terminal=term (Optional) Specifies the workstation's terminal type, typically, `sun` or `xterms`.
-x passwd=root_password (Optional) Specifies the system's root password. The default is no password.
-x sysidcfg=path_to_sysidcfg_file (Optional) Specifies the file to be placed in the `/etc` directory of the diskless client. On first boot, `/etc/.UNCONFIGURED` exists and `sysidtool(1M)` will run. If a file called
```
/etc/sysidcfg exists, sysidtool(1M) reads this file and uses the information for system configuration.

■ For subcommand delete:

- `h` (Optional) Displays the command’s usage statement.
- `n host` Specifies the hostname of the diskless client to delete. This host is deleted from relevant tables and OS Services for this client are deleted.
- `o os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand list:

- `h` (Optional) Displays the command’s usage statement.
- `o os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand modify:

- `e ethernet_addr` Changes the specified diskless client’s ethernet address to `ethernet_addr`.
- `h` (Optional) Displays the command’s usage statement.
- `n host` Specifies the host name of the diskless client to modify.
- `o os_server` (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
- `x tz=timezone` (Optional) Changes the specified diskless client’s timezone.

Examples

**EXAMPLE 1** Creating a new diskless client

The following command adds a new diskless client named `client1` which will run Solaris 10 on a `sun4u` machine:

```bash
example% /usr/sadm/bin/smdiskless add -- -i 172.16.200.1 \
   -e 8:0:11:12:13:14 -n client1 -x os=sparc.sun4u.Solaris_10 \
   -x root=/export/root/client1 -x swap=/export/swap/client1 \
   -x swappsize=32 -x tz=US/Eastern -x locale=en_US
```
EXAMPLE 2  Deleting an existing diskless client

The following command deletes the diskless client named client1 from the OS server named osserver, where the OS server is using NIS+ and the NIS+ server is nisplusserve:

```
example% /usr/sadm/bin/smdiskless delete \ 
  -D nisplus:/nisplusserver/my.domain.com -- \ 
  -o osserver -n client1
```

EXAMPLE 3  Listing the diskless clients served by a host

The following command lists the diskless clients running on the OS server, osserver:

```
example% /usr/sadm/bin/smdiskless list -D file:/osserver/osserver -- \ 
  -o osserver
```

EXAMPLE 4  Modifying the attributes of the diskless client host

The following command modifies the ethernet address for the client named client1 on the OS server, osserver, to be 8:0:11:12:13:15:

```
example% /usr/sadm/bin/smdiskless modify -D file:/osserver/osserver -- \ 
  -o osserver -n client1 -e 8:0:11:12:13:15
```

**Environment Variables**

See `environ(5)` for a description of the JAVA_HOME environment variable, which affects the execution of the smdiskless command. If this environment variable is not specified, the /usr/java1.2 location is used. See `smc(1M)`.

**Exit Status**

The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion.</td>
</tr>
<tr>
<td>1</td>
<td>Invalid command syntax. A usage message displays.</td>
</tr>
<tr>
<td>2</td>
<td>An error occurred while executing the command. An error message displays.</td>
</tr>
</tbody>
</table>

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdclnt</td>
</tr>
</tbody>
</table>

`smdiskless(1M), smosservice(1M), sysidtool(1M), nsswitch.conf(4), sysidcfg(4), attributes(5), environ(5)`
Name  smexec – manage entries in the exec_attr database

Synopsis  

```
/usr/sadm/bin/smexec subcommand [ auth_args ] - - 

[subcommand_args]
```

Description  The smexec command manages an entry in the exec_attr(4) database in the local /etc files name service or a NIS or NIS+ name service.

subcommands  smexec subcommands are:

- **add**  Adds a new entry to the exec_attr(4) database. To add an entry to the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.

- **delete**  Deletes an entry from the exec_attr(4) database. To delete an entry from the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.

- **modify**  Modifies an entry in the exec_attr(4) database. To modify an entry in the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.

Options  The smexec authentication arguments, auth_args, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smexec command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, subcommand_args, must come after the auth_args and must be separated from them by the - - option.

auth_args  The auth_args -D, -H, -l, -p, -r, and -u are described below. They are all optional. These options are a subset of the full complement of supported options described in smc(1M).

If no auth_args are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the domain argument.

- **-D | - -domain 13:domain**  Specifies the default domain that you want to manage. The syntax of domain is type:host_name/domain_name, where type is nis, nisplus, dns, ldap, or file; host_name is the name of the machine that serves the domain; and domain_name is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)
If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | --hostname 13;host_name:port

Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) -B option, or set your console preferences to load a "home toolbox" by default.

-l | --rolepassword 13;role_password

Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | --password 13;password

Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | --rolename 13;role_name

Specify a role name for authentication. If you do not specify this option, no role is assumed.

-u | --username 13;user_name

Specify the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.
To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- **For subcommand add:**
  
  ```
  -c command_path|CDE_action
  ```

  Specifies the full path to the command or CDE action associated with the new `exec_attr` entry. Specifying a CDE action is available only if the system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

  ```
  -g egid
  ```

  (Optional) Specifies the effective group ID that executes with the command.

  ```
  -G gid
  ```

  (Optional) Specifies the real group ID that executes with the command.

  ```
  -h
  ```

  (Optional) Displays the command's usage statement.

  ```
  -n profile_name
  ```

  Specifies the name of the profile associated with the new `exec_attr` entry.

  ```
  -t type
  ```

  Specifies the type for the command. Currently, the only acceptable value for `type` is `cmd`.

  ```
  -u euid
  ```

  (Optional) Specifies the effective user ID that executes with the command.

  ```
  -U uid
  ```

  (Optional) Specifies the real user ID that executes with the command.

  ```
  -M limit_privs
  ```

  Specifies the privilege name(s) to add to the new `exec_attr(4)` entry. The default is `all` for `limit` privilege.

  To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

  ```
  -I inheritable_privs
  ```

  Specifies the inheritable privilege name(s) to add to the new `exec_attr(4)` entry.

- **For subcommand delete:**
  
  ```
  -c command_path|CDE_action
  ```

  Specifies the full path to the command or CDE action associated with the `exec_attr` entry. Specifying a CDE action is available only if the system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.
-h  (Optional) Displays the command's usage statement.

-n profile_name  Specifies the name of the profile associated with the exec_attr entry.

-t type  Specifies the type cmd for command. Currently, the only acceptable value for type is cmd.

- For subcommand modify:

- c command_path|CDE_action  Specifies the full path to the command or CDE action associated with the exec_attr entry you want to modify. Specifying a CDE action is available only if the system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

-g egid  (Optional) Specifies the new effective group ID that executes with the command.

-G gid  (Optional) Specifies the new real group ID that executes with the command.

-h  (Optional) Displays the command's usage statement.

-n profile_name  Specifies the name of the profile associated with the exec_attr entry.

-t type  Specifies the type cmd for command. Currently, the only acceptable value for type is cmd.

-u euid  (Optional) Specifies the new effective user ID that executes with the command.

-U uid  (Optional) Specifies the new real user ID that executes with the command.

-M limit_privs  Specifies the privilege name(s) to modify in an exec_attr(4) entry. The default is all for limit privilege.

To add or change privileges, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

-I inheritable_privs  Specifies the inheritable privilege name(s) to modify in an exec_attr(4) entry.
To use an option that requires the Solaris Trusted Extensions feature, you must use the `-B` toolbox option to specify a toolbox that contains support for Trusted Extensions. For example:

```
# smexec -add -c <CDE action> -n "User Manager" 
-B http://<server>/toolboxes/tsol_files.tbx
```

In the command above, `<server>` is the name of the machine running the Solaris Management Console. See `smc(1M)` for a description of the `-B` option.

**Examples**

**Example 1**  Creating an exec_attr Database Entry

The following creates a new exec_attr entry for the User Manager profile on the local file system. The entry type is `cmd` for the command `/usr/bin/cp`. The command has an effective user ID of 0 and an effective group ID of 0.

```
./smexec add -H myhost -p mypasswd -u root -- -n "User Manager" 
- t cmd -c /usr/bin/cp -u 0 -g 0
```

**Example 2**  Deleting an exec_attr Database Entry

The following example deletes an exec_attr database entry for the User Manager profile from the local file system. The entry designated for the command `/usr/bin/cp` is deleted.

```
./smexec delete -H myhost -p mypasswd -u root -- -n "User Manager" 
- t cmd -c /usr/bin/cp
```

**Example 3**  Modifying an exec_attr Database Entry

The following modifies the attributes of the exec_attr database entry for the User Manager profile on the local file system. The `/usr/bin/cp` entry is modified to execute with the real user ID of 0 and the real group ID of 0.

```
./smexec modify -H myhost -p mypasswd -u root -- -n "User Manager" 
- t cmd -c /usr/bin/cp -U 0 -G 0
```

**Environment Variables**

See `environ(5)` for a description of the JAVA_HOME environment variable, which affects the execution of the smexec command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

**Exit Status**

The following exit values are returned:

- 0  Successful completion.
- 1  Invalid command syntax. A usage message displays.
- 2  An error occurred while executing the command. An error message displays.

**Files**

The following file is used by the smexec command:

```
/etc/security/exec_attr    Rights profiles database. See exec_attr(4).
```
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also  smc(1M), exec_attr(4), attributes(5), environ(5)
### smgroup(1M)

<table>
<thead>
<tr>
<th>Name</th>
<th>smgroup – manage group entries</th>
</tr>
</thead>
</table>
| Synopsis | /usr/sadm/bin/smgroup subcommand [ auth_args ] -  
  [subcommand_args] |
| Description | The smgroup command manages one or more group definitions in the group database for the appropriate files in the local /etc files name service or a NIS or NIS+ name service. |

The following `smgroup` subcommands are supported:

- **add** Adds a new group entry. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

- **delete** Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. **Note:** You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.

- **list** Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the `solaris.admin.usermgr.read` authorization.

- **modify** Modifies a group entry. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

### Options

The `smgroup` authentication arguments, `auth_args`, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smgroup` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, `subcommand_args`, must come after the `auth_args` and must be separated from them by the `-` option.

#### auth_args

The valid `auth_args` are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no `auth_args` are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

The following `auth_args` are supported:

- `-D` | `--domain 13:domain` Specifies the default domain that you want to manage. The syntax of `domain` is `type/host_name/domain_name`, where `type` is `nis`, `nisplus`, `dns`, `ldap`, or `file`; `host_name` is the name of the machine that serves the domain;
and \textit{domain\_name} is the name of the domain you want to manage. (\textit{Note: Do not use nis+ for nisplus.})

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

\textbf{-H | --hostname 13;host\_name:port} Specifies the \textit{host\_name} and \textit{port} to which you want to connect. If you do not specify a \textit{port}, the system connects to the default port, 898. If you do not specify \textit{host\_name:port}, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the \texttt{smc(1M)} -B option, or set your console preferences to load a "home toolbox" by default.

\textbf{-l | --rolepassword 13;role\_password} Specifies the password for the \textit{role\_name}. If you specify a \textit{role\_name} but do not specify a \textit{role\_password}, the system prompts you to supply a \textit{role\_password}. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

\textbf{-p | --password 13;password} Specifies the password for the \textit{user\_name}. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

\textbf{-r | --rolename 13;role\_name} Specifies a role name for authentication. If you do not specify this option, no role is assumed.

\textbf{-u | --username 13;user\_name} Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

\textbf{- -} This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the \textbf{- -} option.
subcommand_args

Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

The `add` subcommand supports the following `subcommand_args`:

- `-g gid` (Optional) Specifies the group ID for the new group. The group ID must be a non-negative decimal integer with a maximum value of 2MB (2,147,483,647). Group IDs 0–99 are reserved for the system and should be used with care. If you do not specify a `gid`, the system automatically assigns the next available `gid`. To maximize interoperability and compatibility, administrators are recommended to assign groups using the range of GIDs below 60000 where possible.

- `-h` (Optional) Displays the command’s usage statement.

- `-m group_member1 -m group_member2 ...` (Optional) Specifies the new members to add to the group.

- `-n group_name` Specifies the name of the new group. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

The `delete` subcommand supports the following `subcommand_args`:

- `-h` (Optional) Displays the command’s usage statement.

- `-n group_name` Specifies the name of the group you want to delete.

The `list` subcommand supports the following `subcommand_args`:

- `-h` (Optional) Displays the command’s usage statement.

- `-n group_name` (Optional) Specifies the name of the group you want to list. If you do not specify a group name, all groups are listed.

The `modify` subcommand supports the following `subcommand_args`:

- `-h` (Optional) Displays the command’s usage statement.
-m group_member1 -m group_member2…  (Optional) Specifies the new members to add to the group. Note that group_member overwrites the existing member list in the group file.

-n group_name  Specifies the name of the group you want to modify.

-N new_group  (Optional) Specifies the new group name. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

**Examples**

**EXAMPLE 1  Creating a Test Group**

The following creates the test_group group entry with a group ID of 123 and adds test_member1 and test_member2 to the group:

```
./smgroup add -H myhost -p mypasswd -u root -- -n test_group \
    -m test_member1 -m test_member2 -g 123
```

**EXAMPLE 2  Deleting a Group**

The following deletes test_group:

```
./smgroup delete -H myhost -p mypasswd -u root -- -n test_group
```

**EXAMPLE 3  Displaying All Groups**

The following displays all groups in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root --
```

**EXAMPLE 4  Displaying a Group**

The following displays the group_1 data in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root -- -n group_1
```

**EXAMPLE 5  Renaming a Group**

The following renames a group from finance to accounting:

```
./smgroup modify -H myhost -p mypasswd -u root -- \ 
    -n finance -N accounting
```
Environment Variables
See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smgroup command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

Exit Status
The following exit values are returned:

0  Successful completion.
1  Invalid command syntax. A usage message displays.
2  An error occurred while executing the command. An error message displays.

Files
The following files are used by the smgroup command:

/etc/group  Group file. See group(4).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
</tbody>
</table>

See Also
smc(1M), group(4), attributes(5), environ(5)
The smlog command manages WBEM log files and allows a user to view WBEM log file records.

Subcommands

- **backup** Backs up the entries in the current WBEM log file. The backup command then creates a new log file and makes this log file the current log file.
- **delete** Deletes an existing (backed up) WBEM log file.
- **list** Lists the names of all the WBEM log files available for viewing.
- **view** Allows the user to view the contents of the specified WBEM log file.

Options

The smlog command supports the following options:

- **-D** | **--domain** 13;domain

  Specifies the default domain that you want to manage. smlog accepts only file for this option. file is also the default value.

  The file default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

- **-H** | **--hostname** 13;host_name:port

  Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a
toolbox to load into the console. To override this behavior, use the `smc -B` option (see `smc(1M)`), or set your console preferences to load a "home toolbox" by default.

- `l` | `-rolepassword 13;role_password` Specifies the password for the `role_name`. If you specify a `role_name` but do not specify a `role_password`, the system prompts you to supply a `role_password`. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

- `p` | `-password 13;password` Specifies the password for the `user_name`. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

- `r` | `-rolename 13;role_name` Specifies a role name for authentication. If you do not specify this option, no role is assumed.

- `u` | `-username 13;user_name` Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- `−` | `−` This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `−` option.

**subcommand_args**

Descriptions and other `arg` options that contain white spaces must be enclosed in double quotes.

The `backup` subcommand supports the following `subcommand_args`:

- `h` Displays the command's usage statement.

  This `subcommand_arg` is optional.

The `delete` subcommand supports the following `subcommand_args`

- `h` Displays the command's usage statement.

  This `subcommand_arg` is optional.

- `n name` Specifies the name of the log file you want to delete.

The `list` subcommand supports the following `subcommand_args`:
-h Displays the command's usage statement.
   
   This subcommand_arg is optional.

The view subcommand supports the following subcommand_args:
- h Displays the command's usage statement.
   
   This subcommand_arg is optional.
- n name Specifies the name of the log file you want to view.
- v Displays the data in verbose format.
   
   This subcommand_arg is optional.

Examples

EXAMPLE 1  Listing WBEM Log Files
The following command lists all available WBEM log files:

   ./smlog list -H myhost -p mypasswd -u root --

Log.01/03/2001.14:38:29
Log.01/04/2001.16:34:59
Log.01/08/2001.14:13:33
Log.01/11/2001.18:39:53
Log.01/12/2001.10:31:31

EXAMPLE 2  Displaying a WBEM Log File
The following command displays the contents of a log file:

   ./smlog view -H myhost -p mypasswd -u root -- -n Log.01/04/2001.16:34:59

Date and Time  Client User   Source    Severity Category
 Summary
 1/5/01 5:22:47 PM  hostname1 root Solaris_OsService Informational Application log No services found.
 1/5/01 5:21:46 PM  hostname1 root Solaris_OsService Informational Application log No services found.

The smlog output wraps when it exceeds 80 characters.

Environment Variables

See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smlog command. If this environment variable is not specified, the /usr/java1.2 location is used. See smc(1M).

Exit Status

The following exit values are returned:

   0  Successful completion.
1  Invalid command syntax. A usage message displays.
2  An error occurred while executing the command. An error message displays.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmgas</td>
</tr>
</tbody>

smmaillist – manage email alias entries

**Synopsis**

```
/sm/sadm/bin/smmailist subcommand [ auth_args ] -
[ subcommand_args ]
```

**Description**

The `smmailist` command manages one or more email alias entries for the appropriate files in the local `/etc` files or a NIS or NIS+ name service.

**subcommands**

The `smmailist` subcommands are:

- **add**
  Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

- **delete**
  Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. **Note:** You cannot delete Postmaster or Mailer-Daemon aliases.

- **list**
  Lists one or more email alias entries. To list an entry, the administrator must have the `solaris.admin.usermgr.read` authorization.

- **modify**
  Modifies an email alias entry. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

**Options**

The `smmailist` authentication arguments, `auth_args`, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smmailist` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, `subcommand_args`, must come after the `auth_args` and must be separated from them by the `-` option.

**auth_args**

The valid `auth_args` are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no `auth_args` are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain` with the `domain` argument.

- `-D | --domain type:domain_name`
  Specifies the default domain that you want to manage. The syntax of `domain` is `type:host_name/domain_name`, where `type` is `nis`, `nisplus`, `dns`, `ldap`, or `file`; `host_name` is the name of the machine that serves the domain; and `domain_name` is the name of the domain you want to manage. **(Note: Do not use nis+ for nisplus.)**
If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | -hostname 13;host_name:port

Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) -B option, or set your console preferences to load a “home toolbox” by default.

-l | -rolepassword 13;role_password

Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | -password 13;password

Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | -rolename 13;role_name

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | -username 13;user_name

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.
- For subcommand **add**:  
  - **-a address1 -a address2...** (Optional) Specifies the new email address. See `sendmail(1M)`.  
  - **-h** (Optional) Displays the command’s usage statement.  
  - **-n alias_name** Specifies the name of the alias you want to add. See `sendmail(1M)`.  

- For subcommand **delete**:  
  - **-h** (Optional) Displays the command’s usage statement.  
  - **-n alias_name** Specifies the alias you want to delete.  

- For subcommand **list**:  
  - **-h** (Optional) Displays the command’s usage statement.  
  - **-n alias_name** (Optional) Specifies the name of the alias you want to display. If you do not specify an alias, all aliases are listed.  

- For subcommand **modify**:  
  - **-a address1 -a address2...** (Optional) Specifies new email address(es) to replace the existing one(s). See `sendmail(1M)`.  
  - **-h** (Optional) Displays the command’s usage statement.  
  - **-n alias_name** (Optional) Specifies the name of the alias you want to modify.  
  - **-N new_alias_name** Specifies the new alias name. Use only when renaming an alias. See `sendmail(1M)`.  

**Examples**

**EXAMPLE 1**  Creating an alias  
The following creates the coworkers alias and adds the following member list: bill@machine1, sue@machine2, and me@machine3 to the alias.  

```
./smmaillist add -H myhost -p mypasswd -u root -- -n coworkers \ 
  -a bill@machine1 -a sue@machine2 -a me@machine3
```

**EXAMPLE 2**  Deleting a mail alias  
The following deletes the my_alias alias:  

```
./smmaillist delete -H myhost -p mypasswd -u root -- -n my_alias
```

**EXAMPLE 3**  Displaying members of a mail alias  
The following displays the list of members belonging to the my_alias alias:  

```
./smmaillist list -H myhost -p mypasswd -u root -- -n my_alias
```
EXAMPLE 4 Displaying members of all mail aliases
The following displays the list of members belonging to all mail aliases:

./smmaillist list -H myhost -p mypasswd -u root --

EXAMPLE 5 Renaming a mail alias
The following renames the current_name mail alias to new_name:

./smmaillist modify -H myhost -p mypasswd -u root --
   -n current_name -N new_name

EXAMPLE 6 Redefining an address list
The following changes the recipients of the alias my_alias to bill@machine1. Any previous
recipients are deleted from the alias.

./smmaillist modify -H myhost -p mypasswd -u root --
   -n my_alias -a bill@machine1

Environment Variables
See environ(5) for a description of the JAVA_HOME environment variable, which affects the
execution of the smmaillist command. If this environment variable is not specified, the
/usr/java location is used. See smc(1M).

Exit Status
The following exit values are returned:
0 Successful completion.
1 Invalid command syntax. A usage message displays.
2 An error occurred while executing the command. An error message displays.

Files
The following files are used by the smmaillist command:
/var/mail/aliases Aliases for sendmail(1M). See aliases(4).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
</tbody>
</table>

See Also sendmail(1M), smc(1M), aliases(4), attributes(5), environ(5)
The `smmultiuser` command allows bulk operations on user entries in the local `/etc` filesystem or a NIS or NIS+ name service, using either an input file or piped input. Note: Both input files and piped input contain a cleartext (non-encrypted) password for each new user entry.

**subcommands** `smmultiuser` subcommands are:

- **add**  
  Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

- **delete**  
  Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

- **modify**  
  Modifies existing user entries in the user account database. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. Here is the list of what can be modified using the `modify` subcommand:
  1. UserName (only under certain conditions; see Note 2 in NOTES).
  2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the `solaris.admin.usermgr.pswd` authorization.
  3. Description.
  4. Primary Group ID.
  5. Shell type.
  6. FullName.

**Options** The `smmultiuser` authentication arguments, `auth_args`, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smmultiuser` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might timeout, so you might need to retry the command.

The subcommand-specific options, `subcommand_args`, must come after the `auth_args` and must be separated from them by the `- -` option.

- **auth_args**  
  The valid `auth_args` are `-D`, `-H`, `-l`, `-p`, `-r`, `-trust`, and `-u`; they are all optional. If no `auth_args` are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `-domain`.

```
-D | - -domain 13:domain
```

Specifies the default domain that you want to manage. The syntax of `domain` is
type:/host_name/domain_name, where type is nis, nisplus, dns, ldap, or file; host_name is the name of the machine that serves the domain; and domain_name is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | --hostname 13;host_name:port
    Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) -B option, or set your console preferences to load a "home toolbox" by default.

-l | --rolepassword 13;role_password
    Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | --password 13;password
    Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | --rolename 13;role_name
    Specifies a role name for authentication. If you do not specify this option, no role is assumed.

- -trust
    Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.
If using piped input into any of the `smmultiuser` subcommands, it will now be necessary to use the `-trust` option with the `-L logfile` option. See EXAMPLES.

```
-u -username user_name
```

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

```
-
```

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `-` option.

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:
  - `-h` (Optional) Displays the command's usage statement.
  - `-i input_file` Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i input_file` option, you must include a `piped_input` operand immediately before the command. See EXAMPLES.
  - `-L logfile` (Optional) Specifies the full pathname to the text file that stores the command's success/failure data. Note: This text file is an ASCII—formatted log file; it is different from and unrelated to the output of the normal logging mechanism that also occurs within the Log Viewer tool. The `-L logfile` option is used to dump additional logging information to a text file.

- For subcommand `delete`:
  - `-h` (Optional) Displays the command's usage statement.
  - `-i input_file` Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i input_file` option, you must include a `piped_input` operand immediately before the command. See EXAMPLES.
  - `-L logfile` (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

- For subcommand `modify`:
  - `-h` (Optional) Displays the command's usage statement.
-i input_file  Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the /etc/passwd file format. If you do not specify the -i input_file option, you must include a piped_input operand immediately before the command. See EXAMPLES. Note: When modifying passwords, use the piped input, since it is more secure than keeping passwords in a file. See Note 1 in NOTES.

-L logfile  (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

Operands  The following operands are supported:

piped_input  You must include piped_input if you do not specify an input_file. Include the piped input immediately before the command. The piped input must follow the /etc/passwd file format. See EXAMPLES. Note: Use the -trust option when using piped input with the -L logfile option to avoid the user prompt from the Security Alert Manager, which normally asks the user whether the log file should be created. Without the -trust option, the piped input is improperly taken as the answer to the prompt before the user can answer "Y" or "N", and the logging operation will probably fail.

Examples  EXAMPLE 1  Creating multiple user accounts

The following reads in user account data from the /tmp/foo file and creates new user accounts on the local file system. The input file is formatted in the /etc/passwd format.

./smmultiuser add -H myhost -p mypasswd -u root -- -i /tmp/foo

EXAMPLE 2  Deleting multiple user accounts

The following reads in user account data from the /tmp/foo file and deletes the named user accounts from the local file system:

./smmultiuser delete -H myhost -p mypasswd -u root -- -i /tmp/foo

EXAMPLE 3  Creating a log file with piped input

The following example shows the use of the smc(1M) -trust option that is required when creating a log file. It is applicable to the delete and modify subcommands also.

cat /tmp/users.txt | smmultiuser add --trust -- -L /tmp/mylog.txt

Environment Variables  See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smprofile command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).
Exit Status  The following exit values are returned:
0  Successful completion.
1  Invalid command syntax. A usage message displays.
2  An error occurred while executing the command. An error message displays.

Files  The following files are used by the smprofile command:
/etc/passwd  Contains the file format to use for the input_file and piped_input. See passwd(4).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
</tbody>
</table>

See Also  smc(1M), passwd(4), attributes(5), environ(5)

Notes  1. The file format used by both the add and modify subcommands is the /etc/passwd format. But there is an allowance for a mutated version of this file format that contains an extra field at the end of each line to be used for the Full Name. If the extra field is appended to the end of each line, it will be used for the Full Name value, but if it is omitted, it will be assumed that no Full Name modification is being done. The extra field is separated with a colon (:), just like all the other fields.

Example of regulation /etc/passwd entry:
rick2:x:101:10:description1:/home/rick2:/bin/sh

Example of /etc/passwd variant entry:
rick2:x:101:10:description1:/home/rick2:/bin/sh:Ricks_fullname

2. The modifies are all done based on lookups of the user name in the user tables. If a user name can not be found in this lookup, a secondary check will be made to see if the uid and Full Name can be found in the user tables. If they are both found, assume that a user rename has occurred. If neither can be found, assume that the user account does not exist and cannot be modified.

3. If no password is supplied, assume that there is no change to the password information. If a password is being changed, it should be supplied in cleartext as piped input, although this is not required. The password can be supplied in the input file also. Once read in, the password will be changed accordingly.
The smosservice command manages OS services.

**Synopsis**

```
/usr/sadm/bin/smosservice subcommand [ auth_args ] - -
[ subcommand_args ]
```

**Description**

The smosservice command manages OS services.

**smosservice subcommands are:**

- **add**
  - Adds the specified OS services.

- **delete**
  - Deletes the specified OS services.

- **list**
  - Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.

- **patch**
  - Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.

**Options**

The smosservice authentication arguments, **auth_args**, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smosservice command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, **subcommand_args**, must come after the **auth_args** and must be separated from them by the - - option.

**auth_args**

The valid **auth_args** are -D, -H, -l, -p, -r, and -u; they are all optional. If no **auth_args** are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain.

- **-D** | - -domain 13:domain
  - Specifies the default domain that you want to manage. The syntax of **domain** is type/host_name/domain_name, where **type** is nis, nis+, dns, ldap, or file; **host_name** is the name of the machine that serves the domain; and **domain_name** is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)
If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-\[H|\-\-hostname 13;host\_name:port\] Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host\_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the \texttt{smc(1M)} -B option, or set your console preferences to load a “home toolbox” by default.

-\[l|\-\-rolepassword 13;role\_password\] Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-\[p|\-\-password 13;password\] Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-\[r|\-\-rolename 13;role\_name\] Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-\[u|\-\-username 13;user\_name\] Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

\[\ldots\] This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - option.

\textit{Note:} Descriptions and other arg options that contain white spaces must be enclosed in double quotes.
For subcommand add:

- **h**
  (Optional) Displays the command's usage statement.

- **-o os_server**
  (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

- **-x mediapath=path**
  Specifies the full path to the Solaris CD image.

- **-x platform=platform**
  Specifies the OS service to add. The instruction architecture, machine class, OS, and version are given in the form:

  \[instruction_set.machine_class.Solaris_os_version\]

  For example, `sparc.sun4m.Solaris_10`.

- **-x cluster=cluster**
  Specifies the Solaris cluster to install. For example, `SUNWCall`.

- **-x locale=locale[locale,...]**
  (Optional) Specifies the locales to install from the specified cluster. A comma-delimited list of locales can be specified.

For subcommand delete:

- **h**
  (Optional) Displays the command's usage statement.

- **-o os_server**
  (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

- **-x rmplatform=platform**
  Specifies the OS service to remove. The instruction architecture, machine class, OS, and version are given in the form:

  \[instruction_set.machine_class.Solaris_os_version\]

  For example, `sparc.all.Solaris_10`. Note: Only a machine class of `all` is supported.

For subcommand list:

- **h**
  (Optional) Displays the command's usage statement.

- **-o os_server**
  (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that
specified in the `smc(1M)` -D option. This option is useful in the event that
the name service server and the OS server are not the same machine.

- For subcommand `patch`:

  `-a patch_directory/patch_ID` 
  Adds the specified patch, `patch_ID`, to the spool
directory. `patch_directory` specifies the source path of the
patch to be spooled which includes the patchid directory
name. Patches are spooled to
/export/diskless/Patches/. If the patch being added
obsoletes an existing patch in the spool, the obsolete
patch is moved to the archive area,
/export/diskless/Patches/Archive (to be restored if
this new patch is ever removed).

  `-h` 
  (Optional) Displays the command’s usage statement.

  `-m` 
  (Optional) Synchronizes spooled patches with offline
copies of each diskless client OS service on the server.
Spooled patches and applied patches are compared so
that newly spooled patches can be installed and patches
recently removed from the spool can be backed out. This
option does not apply to patches directly to diskless
client OS services or diskless clients; the `-u` option must
be used to update the services and clients with the
changes. Clients are not required to be down at this time,
as all patching is done off line. Note: The server is fully
available during this operation.

  `-P` 
  Lists all currently spooled patches with an associated
synopsis. The list is split up into sections detailing the
patches for each OS and architecture in this format:

    Solaris os_rel1 architecture1:
    patchid Synopsis
    patchid Synopsis
    ........

    Solaris os_rel1 architecture2:
    patchid Synopsis
    ........

  `-r patchid` 
  Removes the specified patchid from the spool if it is not a
requirement for any of the other patches in the spool. All
archived patches that were obsoleted by the removed
patch are restored to the spool.

  `-U` 
  (Optional) Updates all diskless client OS services and
diskless clients with any changes after synchronizing
patches with the `-m` option. Clients must be brought down during this operation. Once execution has completed, each client should be booted again.

**Examples**

**EXAMPLE 1** Creating a new OS service

The following command adds an OS service for Solaris 10 for the `sun4u` machine class where the OS server is *not* using a name service:

```
example% /usr/sadm/bin/smosservice add -- \n  -x mediapath=/net/imageserver/5.8/sparc \n  -x platform=sparc.sun4u.Solaris_10 \n  -x cluster=SUNWCXall -- locale=en_US
```

The following command adds an OS service for Solaris 10 for the `sun4u` machine class where the OS server is using NIS, the NIS server is `nisserver`, the OS server is `osserver`, and the port to which you connect on `osserver` is 898:

```
example% /usr/sadm/bin/smosservice add -D nis:/nisserver/my.domain.com -- \n  -H osserver:898 -- \n  -x mediapath=/net/imageserver/5.8/sparc \n  -x platform=sparc.sun4u.Solaris_10 \n  -x cluster=SUNWCXall -x locale=en_US --osserver
```

In the preceding example, the OS service is placed in `/export` on `osserver`, while the `hosts.byaddr`, `ethers`, and `bootparams` maps are updated on the NIS server.

**EXAMPLE 2** Deleting an OS service

The following command deletes the OS service for Solaris 10 for the `sun4u` machine class where the OS server is using NIS, the NIS server is `nisserver`, and the OS server is `osserver`:

```
example% /usr/sadm/bin/smosservice delete \n  -D nis:/nisserver/my.domain.com -- \n  -x rmplatform=sparc.all.Solaris_10 \n  -o osserver
```

**EXAMPLE 3** Listing installed OS services

The following command lists the OS services installed on the machine, `osserver`:

```
example% /usr/sadm/bin/smosservice list \n  -D file:/osserver/osserver -- -o osserver
```

**Environment Variables**

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smosservice` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See `smc(1M)`.
Exit Status  The following exit values are returned:
0  Successful completion.
1  Invalid command syntax. A usage message displays.
2  An error occurred while executing the command. An error message displays.

Attributes  See attributes(5) for descriptions of the following attributes:

Name  smpatch – download, apply, and remove updates

Synopsis  
```bash
/usr/sbin/smpatch add -i update-id [auth-opts]
   [-i update-id] ... [-d update-dir] [-b BE_name]
   [-n system-name] ... [-x idlist=system-list-file] [-V]

/usr/sbin/smpatch add -x idlist=update-list-file
   [auth-opts]
   [-d update-dir] [-n system-name] ...
   [-b BE_name] [-x idlist=system-list-file] [-V]

/usr/sbin/smpatch analyze [auth-opts] [-i update-id] ...
   [-n system-name] ...
   [-x idlist=update-list-file] [-V]

/usr/sbin/smpatch download [auth-opts] [-i update-id] ...
   [-d update-dir] [-f] [-n system-name] ...
   [-t] [-x idlist=update-list-file] [-V]

/usr/sbin/smpatch get [auth-opts] [-n system-name] ...
   [parameter-name]... [-V]

/usr/sbin/smpatch messages [-a] [-V]

/usr/sbin/smpatch order -i update-id [auth-opts]
   [-i update-id] ... [-d update-dir]
   [-n system-name] ... [-V]

/usr/sbin/smpatch order -x idlist=update-list-file
   [auth-opts]
   [-d update-dir] [-n system-name] ... [-V]

/usr/sbin/smpatch remove -i update-id [auth-opts]
   [-i update-id] ... [-d update-dir]
   [-n system-name] ... [-b BE_name] [-V]

/usr/sbin/smpatch set [auth-opts] [-n system-name] ...
   parameter-name=parameter-value... [-V]

/usr/sbin/smpatch unset [auth-opts] [-n system-name] ...
   parameter-name... [-V]

/usr/sbin/smpatch update [auth-opts] [-i update-id] ...
   [-d update-dir] [-n system-name] ... [-b BE_name]
   [-x idlist=update-list-file] [-V]
```

Description  
The smpatch command manages the update process on a single system or on multiple systems. Use this command to download, apply, and remove updates. Also, use the smpatch command to configure the update management environment for your system.

If you want to run the smpatch command in remote mode, your system must run at least the Developer Solaris Software Group of the Solaris 10 system.

The smpatch analyze command determines the updates that are appropriate for the systems you want to update. The smpatch command can download and apply updates that you specify
on the command line. Or, smpatch can download and apply updates based on an analysis of one or more systems. Use the -i option or the -x idlist= option to specify the particular updates.

All of the systems on which you want to apply updates must be running the same version of the Solaris Operating System, have the same hardware architecture, and have the same updates applied.

The list of updates that is generated by the analysis is based on all of the available updates from the Sun update server. No explicit information about your host system or its network configuration is transmitted to Sun. Only a request for the Sun update set is transmitted. The update set is scanned for updates that are appropriate for this host system, the results are displayed, and those updates are optionally downloaded.

smpatch supports the Live Upgrade feature of the Solaris operating system (see live_upgrade(5)). Through the add, remove, and update subcommands, described below, smpatch enables you to perform operations on a boot environment (BE). A BE is an operating system image, consisting of a particular set of operating system and application software packages.

The smpatch command supports the following subcommands:

add
Applies one or more updates to one or more systems. You must specify at least one update to apply. By default, updates are applied to the local system.

This subcommand attempts to apply only the updates you specify. If you specify an update that depends on another that has not been applied, the add command fails to apply the update you specified.

This subcommand does not apply updates based on the specified update policy. To apply updates based on the update policy, use the update subcommand.

Use the -i or -x idlist= option to specify the updates to apply. Note that all of the updates you specify, and those on which they depend, must exist in the download directory.

Use the -n or the -x mlist= option to specify the systems on which to apply updates.

Optionally use the -d option to specify an alternate download directory.

If the updates on which the specified updates depend are unavailable, run the smpatch download subcommand to obtain the updates you need.

When you use the -b BE_name option, the add subcommand applies a specified update to the BE BE_name, rather than to the currently running operating system. Upon successful installation of the update, smpatch activates BE_name (see luactivate(1M)) and informs you that you can, at that point, boot from BE_name.

analyze
Analyzes a system to generate a list of the appropriate updates.
After analyzing the system, use the `update` subcommand or the `download` and `add` subcommands to download and apply the updates to your systems.

The list of updates is written to standard output, so you can redirect standard output to a file to create an update list.

If you supply a list of one or more updates, the list is augmented with the updates on which those updates depend. The list is also put in an order suitable for applying updates.

The `smpatch analyze` command depends on network services that are not available while the system is in single-user mode.

download

Downloads updates from the Sun update server to a system. You can optionally specify which updates to download. You can also specify the name of a system and download the appropriate updates to that system.

Use the `-i` or `-x id=list=` option to specify the updates to download.

Use the `-t` option to force the download of the exact update revision specified by `-i update-id`. If `-i update-id` does not specify a revision, the highest revision of the update is downloaded.

Use the `-t` option to download the README file for the update specified by `-i update-id`. If `-i update-id` does not specify a revision, the README file for the highest revision of the update is downloaded.

Use the `-n` option to analyze a remote system and to determine which updates to download. The updates, and those on which they depend, are downloaded from the Sun update server to the download directory of the system you specified.

The `smpatch download` command depends on network services that are not available while the system is in single-user mode.

get

Lists one or more of the `smpatch` configuration parameter values. See “Configuring Your Update Management Environment.”

To see values for all parameters, run the `smpatch get` command with no arguments. The output shows an entry for all configuration parameters. Each entry appears on a line by itself. Each entry includes three fields: the parameter name, the value you have assigned it, and its default value. The fields are separated by one or more tab characters.

The following values have special meaning: `-` means that no value is set, `""` means that the value is the null string, `\-` means that the value is `-`, and `""` means that the value is `""` (two double quotes).

In addition to these special values, these special characters might appear in the output: `\t` for a tab, `\n` for a newline, and `\\` for a backslash.
To see values for particular parameters, run the `smpatch get` command with one or more parameter names. The output lists one parameter value per line in the order in which the parameter names are specified on the command line.

**messages**
Displays messages from the message-of-the-day (MOTD) file. This file stores messages, some of which can be urgent, from Sun. By default, when there is a new message in this file, the message shown below is displayed in stderr:

```
You have new messages. To retrieve: smpatch messages [-a]
```

The preceding message appears at the top of any `smpatch analyze/download/update` reports. The `-a` option to the `messages` subcommand displays all messages. Without the `-a` option, only new (that is, as yet unread) messages are displayed.

The receiving of messages from the software update client is controlled by the property:

```
patchpro.report.motd.messages
```

When this property is enabled, the default condition, the client receives messages from Sun. To disable this property, enter:

```
# smpatch set patchpro.report.motd.messages=false
```

**order**
Sorts a list of updates into an order that can be used to apply updates.

The list of updates is written to standard output, so you can redirect standard output to a file to create an update list.

Use the `-i` or `-x idlist=` option to specify the updates to order. Note that all of the updates you specify must exist in the download directory.

**remove**
Removes a single update from a single system.

Use the `-i` option to specify which update to remove. Do not use the `-x idlist=` option. Optionally, use the `-n` option to specify the name of a system. Do not use the `-x mlist=` option. By default, the update is removed from the local system.

If the update that you want to remove is required by one or more of the updates that have already been applied to the system, the update is not removed.

When you use the `-b BE_name` option, the `remove` subcommand removes a specified update from the BE `BE_name`, rather than from the currently running operating system.

**set**
Sets the values of one or more configuration parameters. Nothing is written to standard output or standard error when you set parameters, even if a parameter value you set is invalid. This command does not validate the values you set.
unset
   Resets one or more configuration parameters to the default values. You must specify at least one configuration parameter.

update
   Updates a single local or remote system by applying appropriate updates. This subcommand analyzes the system, then downloads the appropriate updates from the Sun update server to your system. After the availability of the updates has been confirmed, the updates are applied based on the update policy.

   By default, standard updates and those that have rebootafter or reconfigafter properties are applied.

   If an update does not meet the policy for applying updates, the update is not applied. Instead, the ID of the update is written to a file in the download directory. After the update ID is written to the file, smpatch continues to apply the other updates. Later, you can use patchadd to manually apply any updates listed in this file. The updates listed in the file are still in the download directory.

   When you use the -b BE_name option, the update subcommand applies an update to the BE BE_name, rather than to the currently running operating system. Upon successful installation of the update, smpatch activates BE_name (see luactivate(1M)) and informs you that you can, at that point, boot from BE_name.

   Installation instructions for updates that require special handling are included in the README file for each update.

   The smpatch update command depends on network services that are not available while the system is in single-user mode.

Starting with Solaris 9, the smpatch command is available in two modes: local mode and remote mode. Local mode can be run only on the local system and can be run by users who have the appropriate authorizations. This mode can be run while the system is in single-user mode. Remote mode can be used to perform tasks on remote systems and can be run by users or roles that have the appropriate authorizations.

By default, local mode is run. In local mode, the Solaris WBEM services are not used, and none of the authentication options or those options that refer to remote systems are available. The command in local mode runs faster than in remote mode.

If the Solaris WBEM services are running and you specify any of the remote or authentication options, the command in remote mode is used.

On Solaris 8 systems, the smpatch command only supports local mode operations.
Your system must specify the source of updates to use. By default, you obtain updates from the Sun update server. However, you can also obtain updates from an update server on your intranet or from a local collection of updates on your system.

You must specify the URL that points to the collection of updates. By default, the Sun update server is the source of updates. The URL is:

https://getupdates.sun.com/solaris/

The URL must point to an update server or to a collection of updates that is available to the local system. The value of this URL cannot be null.

You can use the `smpatch set` command to configure the update management environment for your system. Use these parameters:

- `patchpro.patchset` Name of the update set to use. The default name is `current`.
- `patchpro.download.directory` Path of the directory where downloaded updates are stored and from which updates are applied. The default location is `/var/sadm/spool`.
- `patchpro.backout.directory` Path of the directory where update backout data is saved. When an update is removed, the data is retrieved from this directory as well. By default, backout data is saved in the package directories.
- `patchpro.patch.source` URL that points to the collection of updates. The default URL is that of the Sun update server, `https://getupdates.sun.com/solaris/`.
- `patchpro.proxy.host` Host name of your web proxy. By default, no web proxy is specified, and a direct connection to the Internet is assumed.
- `patchpro.proxy.port` Port number used by your web proxy. By default, no web proxy is specified, and a direct connection to the Internet is assumed. The default port is `8080`.
- `patchpro.proxy.user` Your user name used by your web proxy for authentication.
- `patchpro.proxy.passwd` Password used by your web proxy for authentication.
- `patchpro.install.types` Your policy for applying updates. The value is a list of zero or more colon-separated update properties that are permitted to be applied by an update operation (`smpatch update`).

This policy only affects which updates are installed on your system. The policy does not affect which updates are downloaded.
By default, updates that have the standard, rebootafter, and reconfigafter properties can be applied. See “Setting an Update Policy.”

### Setting an Update Policy

| Updates are classified as being standard or nonstandard. A *standard update* can be applied by `smpatch` update. Such an update is associated with the *standard update property*. `smpatch` applies standard updates immediately. These updates require no system restart. A *nonstandard update* has one of the following characteristics:
|
| - An update that is associated with the *rebootafter*, *rebootimmediate*, *reconfigafter*, *reconfigimmediate*, or *singleuser* properties. Such a nonstandard update can be applied automatically during a system shutdown if permitted by the policy.
| - An update that is associated with the *interactive* property. Such an update cannot be applied by using automated installation mechanisms like `smpatch` update. When you attempt to apply one of these updates using `smpatch` update, the update will be downloaded but not installed. You must examine the update’s README file and perform whatever manual steps it describes. Typically, you are instructed to apply the update manually using `patchadd` or `smpatch` add.

Use `smpatch set` to specify the types of updates that `smpatch` can additionally apply during an update operation. Such updates might include those that require a reboot and those that must be applied while the system is in single-user mode.

This policy only affects which updates are installed on your system. The policy does not affect which updates are downloaded.

Specify the types of updates that can be applied by using the following command:

```
# smpatch set patchpro.install.types=update-property-list
```

`update-property-list` is a colon-separated list of one or more of the following update properties:

- **interactive**
  - An update that cannot be applied by running the usual update management tools (`pprosvc`, `smpatch`, or `patchadd`). Before this update is applied, the user must perform special actions. Such actions might include checking the serial number of a disk drive, stopping a critical daemon, or reading the update’s README file.

- **rebootafter**
  - The effects of this update are not visible until after the system is rebooted.

- **rebootimmediate**
  - When this update is applied, the system becomes unstable until the system is rebooted. An unstable system is one in which the behavior is unpredictable and data might be lost.

- **reconfigafter**
  - The effects of this update are not visible until after a reconfiguration reboot (`boot -r`). See the `boot(1M)` man page.
**reconfigimmediate**
When this update is applied, the system becomes unstable until the system gets a
reconfiguration reboot (`boot -r`). An unstable system is one in which the behavior is
unpredictable and data might be lost.

**singleuser**
Do not apply this update while the system is in multiuser mode. You must apply this
update on a quiet system with no network traffic and with extremely restricted I/O activity.

**standard**
This update can be applied while the system is in multiuser mode. The effects of the update
are visible as soon as it is applied unless the application being updated is running while the
update is applied. In this case, the effects of the update are visible after the affected
application is restarted.

**Options**
The `smpatch` command supports two kinds of options: authentication options and
subcommand options.

**Authentication Options**
The `smpatch` authentication options, `auth-opt`, apply to all of the subcommands.

If no authentication options are specified, certain defaults are assumed and the user might be
prompted for additional information, such as a password for authentication purposes.

These authentication options are only available if the Solaris Management Console and the
Solaris WBEM services are available on the local system. If the WBEM services are not
running on the local system, `smpatch` performs update operations on the local system only.
You can also "force" the use of the local-mode `smpatch` command by using the `-L` option.

The single letter options can also be specified by their equivalent option words preceded by
two hyphens. For example, you can specify either `-l` or `--role=passlword`.

The following authentication options are supported:

- **-H | --hostname host-name:port**
  Specifies the host and port to which you want to connect. If you do not specify a port, the
  system connects to the default port, 898. If you do not specify a host (`host-name:port`), the
  Solaris Management Console connects to the local host on port 898. You might still have to
  choose a toolbox to load into the console. To override this behavior, use the `smc -B` command, or set your console preferences to load a home toolbox by default.

- **-L**
  Forces the `smpatch` command to use local mode, which does not rely on Solaris WBEM
  services. On Solaris 8 systems, this option does not do anything.

  This option is mutually exclusive with the other authentication options.
-l | --rolepassword role-password
Specifies the password for role-name. If you specify role-name but do not specify
role-password, you are prompted to supply role-password. Because passwords specified on
the command line can be seen by any user on the system, this option is considered to be
insecure.

-p | --password password
Specifies the password for user-name. If you do not specify a password, you are prompted
to supply one. Because passwords specified on the command line can be seen by any user
on the system, this option is considered to be insecure.

-r | --rolename role-name
Specifies a role name for authentication. If this option is not specified, no role is assumed.

-u | --username user-name
Specifies the user name for authentication. If you do not specify this option, the user
identity running the console process is assumed.

Subcommand Options
The following options pertain to the smpatch subcommands:

- b BE_name
Specifies the name of BE that is to be created and updated (for the add and update
subcommands), or to be removed, for the remove subcommand.

- d update-dir
Specifies an alternate download directory in which updates are downloaded and from
which they are applied.

The default download directory is /var/sadm/spool.

The directory must be writable by root and be publicly readable.

update-dir uses one of the following forms:

- For remote mode, specify host-name:/update-dir, where /update-dir is a fully qualified,
shared directory.
- For local mode, specify /update-dir, which is a fully qualified, shared directory.

This option is supported by the add, download, order, and update subcommands.

- f
Forces the download of the exact update revision specified by -i update-id. If -i update-id
does not specify a revision, the highest revision of the update is downloaded.

This option is supported by the download subcommand.

- h
Displays information about the command-line options for the specified subcommand.
This option is mutually exclusive with all other options.
-i update-id
  Specifies the ID of an update.

  You can specify more than one update ID by using the -i option for each update. You can also use the -x idlist= option to point to a list of update IDs.

  When using the remove subcommand, you can specify exactly one update ID.

  This option is supported by the add, analyze, download, order, remove, and update subcommands.

-n system-name
  Specifies the name of the system on which to manage updates.

  When using the add subcommand, you can specify more than one system by using the -n option for each system. When using the analyze, download, remove, and update subcommands, you can only specify a single system.

  To specify more than one system for the smpatch add command, use the -x mlist= option. This option enables you to specify a list of systems instead of using the -n option to specify each system. The -n option and the -x mlist= option are mutually exclusive.

  If you do not specify this option, the system is assumed to be the one specified by the -H option.

  This option is supported only if the Solaris Management Console and the Solaris WBEM services are running on the local system and any system that is specified by this option.

  This option is supported by the add, analyze, download, get, order, remove, set, unset, and update subcommands.

-t
  Downloads the README file associated with the update specified by -i update-id. If -i update-id does not specify a revision, the README file for the highest revision of the update is downloaded.

  This option is supported by the download subcommand.

-V
  Displays version information for an smpatch subcommand.

-x idlist=update-list-file
  Specifies the name of a file, update-list-file, that contains a list of updates to download or apply.

  Each update ID in the file must be terminated by a newline character. The file name you specify must be a full path name.

  You can use the -i option to specify a list of update IDs.
This option is supported by the add, analyze, download, order, and update subcommands.

-x mlist=system-list-file
Specifications the name of a file, system-list-file, that contains a list of systems on which to manage updates.

Each system name must be terminated by a newline character. The file name you specify must be a full path name.

You can use the -n option to specify a list of systems instead of using the -x mlist= option. The -n option and the -x mlist= option are mutually exclusive.

This option is supported only if the Solaris Management Console and the Solaris WBEM services are running on the local system and any system that is specified in system-list-file.

This option is supported by the add subcommand.

Examples

EXAMPLE 1 Analyzing Your System to Obtain the List of Appropriate Updates for the Local System

```
# smpatch analyze
```

Shows how to analyze your system to obtain the list of appropriate updates. After the analysis, you can download and apply the updates to your system.

EXAMPLE 2 Analyzing Your System to Obtain the List of Appropriate Updates for Another System

```
# smpatch analyze -n lab1
```

Shows how to analyze a different system, lab1, to obtain the list of appropriate updates. After the analysis, you can download and apply the updates to that system.

EXAMPLE 3 Applying Updates to Multiple Systems

```
# smpatch add -i 102893-01 -i 106895-09 -i 106527-05 \
-d fileserver:/files/updates/s10 -n lab1 -n lab2
```

Applies updates 102893-01, 106895-09, and 106527-05 to the systems lab1 and lab2. The updates are located in the /files/updates/s10 directory on the system named fileserver.

EXAMPLE 4 Applying Updates by Using an Update List File

```
# smpatch add -x idlist=/tmp/update/update_file \
-d /net/fileserver/export/updatespool/Solaris10 -n lab1 -n lab2
```

Applies the updates specified in the file /tmp/update/update_file to the systems lab1 and lab2. The updates are located in the NFS-mounted directory named /net/fileserver/export/updatespool/Solaris10.
EXAMPLE 5  Applying Updates by Using an Update List File and a System List File

```
# smpatch add -x idlist=/tmp/update/update_file \
   -x mlist=/tmp/update/sys_file
```

Applies the updates listed in the file /tmp/update/update_file to the systems listed in the file /tmp/update/sys_file. The updates are located in the default /var/sadm/spool directory on the local system.

EXAMPLE 6  Analyzing a System and Downloading Updates From the Sun Update Server

```
# smpatch download -n lab1
```

Analyzes the lab1 system and downloads the appropriate updates from the Sun update server to the download directory.

EXAMPLE 7  Downloading Updates From the Sun Update Server

The command below downloads the 102893-01 and 106895-09 updates from the Sun update server to the /files/updates/s10 directory.

```
# smpatch download -i 102893-01 -i 106895-09 -d /files/updates/s10
```

EXAMPLE 8  Downloading Specific Update Revisions From the Sun Update Server

The command below downloads the 102893-01 and 106895-02 updates from the Sun update server. The specific revisions are downloaded, not the highest available revision.

```
# smpatch download -f -i 102893-01 -i 106895-02
```

EXAMPLE 9  Downloading the Highest Available Update Revisions From the Sun Update Server

The command below downloads the 102893-01 and 106895-09 updates, which are the highest available revisions, from the Sun update server.

```
# smpatch download -f -i 102893 -i 106895
```

EXAMPLE 10  Downloading Update README Files From the Sun Update Server

The command below downloads the README files for updates 102893-01 and 106895-02. Because update 102893 was specified without a revision number, the README file for the highest available update revision, 102893-01, is downloaded from the Sun update server.

```
# smpatch download -t -i 102893 -i 106895-02
```

EXAMPLE 11  Listing All Configuration Parameter Values

```
# smpatch get -p password
```

Loading Tool: com.sun.admin.patchmgr.cli.PatchMgrCli from mars
Login to mars as user root was successful.
Download of com.sun.admin.patchmgr.cli.PatchMgrCli from mars was successful.
EXAMPLE 11  Listing All Configuration Parameter Values  (Continued)

On machine mars:

- patchpro.backout.directory - ""
- patchpro.download.directory - /var/sadm/spool
- patchpro.install.types - rebootafter:reconfigafter:standard
- patchpro.patchset - current
- patchpro.proxy.host - ""
- patchpro.proxy.passwd **** ****
- patchpro.proxy.port - 8080
- patchpro.proxy.user - ""
- patchpro.sun.passwd **** ****
- patchpro.sun.user - ""

Lists the configuration settings for the system.

EXAMPLE 12  Listing One or More Configuration Parameter Values

```
# smpatch get -L patchpro.patch.source patchpro.download.directory
https://getupdates.sun.com/solaris/
/var/sadm/spool
```

Uses smpatch in local mode to list the values of the patchpro.patch.source and the patchpro.download.directory parameters.

EXAMPLE 13  Reordering a List of Updates

```
# smpatch order -x idlist=/tmp/plist
```

Reorders the update list called /tmp/plist in an order that is suitable for applying the updates.

EXAMPLE 14  Removing an Update

```
# smpatch remove -i 102893-01
```

Removes update 102893-01.

EXAMPLE 15  Specifying the Update Policy

The following command specifies the update policy.

```
# smpatch set \
patchpro.install.types=standard:singleuser:reconfigafter:rebootafter
```

Specifies the update policy for your system. The following types of updates are allowed to be applied to your system:

- Standard updates
- Updates that must be applied in single-user mode
EXAMPLE 15  Specifying the Update Policy  (Continued)

- Updates that require that the system undergo a reconfiguration reboot after they have been applied
- Updates that require that the system undergo a reboot after they have been applied

EXAMPLE 16  Changing the Download Directory Location

# smpatch set patchpro.download.directory=/export/home/updates

EXAMPLE 17  Specifying a Local Web Proxy

# smpatch set patchpro.proxy.host=webaccess.corp.net.com \
    patchpro.proxy.port=8080

Specifies the host name, webaccess.corp.net.com, and port, 8080, of the local web proxy.

EXAMPLE 18  Resetting a Configuration Parameter Value

# smpatch unset patchpro.patch.source

Resets the value of the patchpro.patch.source parameter to its default value, which is the URL that points to the Sun update server.

EXAMPLE 19  Updating Your System

# smpatch update -L

Analyzes your local system, determines the appropriate updates, downloads those updates to the download directory, and applies those updates.

EXAMPLE 20  Adding an Update to a BE

The following command adds a specific update to the BE altboot.

# smpatch add -b altboot 111111-01

Following successful completion of this command, you can then boot from altboot.

EXAMPLE 21  Updating a BE

The following command performs an update on the BE altboot.

# smpatch update -b altboot

This command performs all of the usual analysis and dependency checking that occurs with any update command. Following successful completion of this command, you can then boot from altboot.

EXAMPLE 22  Obtaining smpatch Version Number

The following command returns the version number for an smpatch subcommand.
EXAMPLE 22 Obtaining smpatch Version Number (Continued)

    # smpatch update -V
    1.0.9

Environment Variables
See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smpatch command. The default value of this variable is /usr/java. See the smc(1M) man page.

Exit Status
The following exit values are returned:

0
  Successful completion.

1
  Invalid command syntax. A usage message displays.

2
  An error occurred while executing the command. An error message displays.

Attributes
See the attributes(5) man page for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWswmt</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

Sun Update Manager 1.0 Administration Guide
smprofile – manage profiles in the prof_attr and exec_attr databases

/smprofile

The smprofile command manages one or more profiles in the prof_attr(4) or exec_attr(4) databases in the local /etc files name service or a NIS or NIS+ name service.

subcommands

smprofile subcommands are:

add
Adds a new profile (right) to the prof_attr(4) database. To add a profile, the administrator must have the solaris.profmgr.write authorization.

delete
Deletes a profile from the prof_attr(4) database, deletes all associated entries from the exec_attr(4) database, and deletes the assigned profile from the user_attr(4) database. To delete a profile, the administrator must have the solaris.profmgr.execattr.write and solaris.profmgr.write authorization.

list
Lists one or more profiles from the prof_attr(4) or exec_attr(4) databases. To list a profile, the administrator must have the solaris.profmgr.read authorization.

modify
Modifies a profile in the prof_attr(4) database. To modify a profile, the administrator must have the solaris.profmgr.write authorization.

Options

The smprofile authentication arguments, auth_args, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smprofile command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, subcommand_args, must come after the auth_args and must be separated from them by the - option.

auth_args

The valid auth_args are -D, -H, -l, -p, -r, and -u; they are all optional. If no auth_args are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or --domain with the domain argument.

-D | --domain 13:domain
Specifies the default domain that you want to manage. The syntax of domain is type:host_name/domain_name, where type is nis, nisplus, dns, ldap, or file; host_name is the name of the machine that serves the domain; and domain_name is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)
If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

```
-H | -hostname 13;host_name:port
```

Specifies the `host_name` and `port` to which you want to connect. If you do not specify a `port`, the system connects to the default port, 898. If you do not specify `host_name:port`, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M)` `-B` option, or set your console preferences to load a “home toolbox” by default.

```
-l | -rolepassword 13;role_password
```

Specifies the password for the `role_name`. If you specify a `role_name` but do not specify a `role_password`, the system prompts you to supply a `role_password`. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

```
-p | -password 13;password
```

Specifies the password for the `user_name`. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

```
-r | -rolename 13;role_name
```

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

```
-u | -username 13;user_name
```

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

```
-
```

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `-` option.

```
subcommand_args
```

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.
To add privileges to or modify privileges in a profile entry, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

For subcommand add:

- addauth1 - addauth2 ... (Optional) Specifies the authorization name(s) to add to the new profile. The administrator must have the solaris.profmgr.write authorization and must have the corresponding “grant” authorization. A “grant” authorization is one in which the lowest component of the authorization name is replaced by the word grant. For example, to grant some profile the solaris.role.write authorization, the administrator needs that authorization and also the solaris.role.grant authorization. For more information on granting authorizations, see auth_attr(4).

- description Specifies the description of the new profile.

- h (Optional) Displays the command’s usage statement.

- m html_help Specifies the HTML help file name for the new profile. The help file name must be put in the /usr/lib/help/profiles/locale/C directory.

- n name Specifies the name of the new profile.

- p addprof1 - p addprof2 ... (Optional) Specifies the supplementary profile name(s) to add to the new profile.

- inherited_privs Specifies the inherited privilege name(s) to add to the new prof_attr(4) entry.

For subcommand delete:

- h (Optional) Displays the command’s usage statement.

- n name Specifies the name of the profile you want to delete.

For subcommand list:

- h (Optional) Displays the command’s usage statement.

- l (Optional) Displays the detailed output for each profile in a block of key:value pairs, followed by a blank line that delimits
each profile block. Each key:value pair is displayed on a separate line. All the attributes associated with a profile from the prof attr and exec_attr databases are displayed. If you do not specify this option, only the specified profile name(s) and associated profile description(s) are displayed.

- `n name1 - n name2...` (Optional) Specifies the profile(s) that you want to display. If you do not specify a profile name, all profiles are displayed.

- For subcommand `modify`:
  - `-a addauth1 -a addauth2...` (Optional) Specifies the authorization name(s) to add to the profile. The administrator must currently have been granted each of the specified authorizations and must have the ability to grant each of those authorizations to other users or roles. For more information on granting authorizations, see `auth_attr(4)`.
  - `-d description` (Optional) Specifies the new description of the profile.
  - `-h` (Optional) Displays the command's usage statement.
  - `-m html_help` (Optional) Specifies the new HTML help file name of the profile. If you change this name, you must accordingly rename the help file name entered in the `/usr/lib/help/profiles/locale/C` directory.
  - `-n name` Specifies the name of the profile you want to modify.
  - `-p addprof1 -p addprof2...` (Optional) Specifies the supplementary profile name(s) to add to the profile. The administrator must have the `solaris.profmgr.assign` authorization to add any profile and the `solaris.profmgr.delegate` authorization to add any profile that has been assigned to the authenticated user.
  - `-q delprof1 - q delprof2...` (Optional) Specifies the supplementary profile name(s) to delete from the profile. The administrator must have the `solaris.profmgr.assign` authorization to delete any profile and the `solaris.profmgr.delegate` authorization to delete any profile that has been assigned to the authenticated user.
  - `-r delauth1 - r delauth2...` (Optional) Specifies the authorization name(s) to delete from the profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding "grant" authorization. For more information about "grant" authorizations, see the `-a` option description for the `add` subcommand above.
-I inherited_privs

Specifies the inherited privilege name(s) to modify in the prof_attr(4) entry.
