Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question "What does it do?" The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.
Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the intro pages for more information and detail about each section, and man(1) for more information about man pages in general.

NAME
This section gives the names of the commands or functions documented, followed by a brief description of what they do.

SYNOPSIS
This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

- [ ] Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.
- . . . Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename...".
- | Separator. Only one of the arguments separated by this character can be specified at a time.
- { } Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.

PROTOCOL
This section occurs only in subsection 3R to indicate the protocol description file.

DESCRIPTION
This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.

IOCTL
This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called ioctl and generates its own
heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device). ioctl calls are used for a particular class of devices all of which have an io ending, such as mtsio(7I).

OPTIONS
This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS
This section lists the command operands and describes how they affect the actions of the command.

OUTPUT
This section describes the output – standard output, standard error, or output files – generated by the command.

RETURN VALUES
If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.

ERRORS
On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.

USAGE
This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality:

Commands
Modifiers
Variables
Expressions
Input Grammar
EXAMPLES
This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as example%, or if the user must be superuser, example#. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.

ENVIRONMENT VARIABLES
This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

EXIT STATUS
This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.

FILES
This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

ATTRIBUTES
This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See attributes(5) for more information.

SEE ALSO
This section lists references to other man pages, in-house documentation, and outside publications.

DIAGNOSTICS
This section lists diagnostic messages with a brief explanation of the condition causing the error.

WARNINGS
This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.

NOTES
This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.

BUGS
This section describes known bugs and, wherever possible, suggests workarounds.
REFERENCE

Introduction
This section describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.

Because of command restructuring for the Virtual File System architecture, there are several instances of multiple manual pages that begin with the same name. For example, the mount, mount_cachefs(1M), mount_hsfs(1M), mount_nfs(1M), mount_tmpfs(1M), and mount_ufs(1M). In each such case the first of the multiple pages describes the syntax and options of the generic command, that is, those options applicable to all FSTypes (file system types). The succeeding pages describe the functionality of the FSType-specific modules of the command. These pages list the command followed by an underscore (_), and the FSType to which they pertain. Note that the administrator should not attempt to call these modules directly. The generic command provides a common interface to all of them. Thus the FSType-specific manual pages should not be viewed as describing distinct commands, but rather as detailing those aspects of a command that are specific to a particular FSType.

Command Syntax

Unless otherwise noted, commands described in this section accept options and other arguments according to the following syntax:

```
name [option(s)] [cmdarg(s)]
```

where:

- `name` The name of an executable file.
- `option` `- noargletter(s) or,`
  `- argletter<>optarg`
  
  where <> is optional white space.
- `noargletter` A single letter representing an option without an argument.
- `argletter` A single letter representing an option requiring an argument.
- `optarg` Argument (character string) satisfying preceding `argletter`.
- `cmdarg` Pathname (or other command argument) not beginning with `-` or, `-` by itself indicating the standard input.

Attributes

See `attributes(5)` for a discussion of the attributes listed in this section.

See Also

`getopt(1), getopt(3C), attributes(5)`

Diagnostics

Upon termination, each command returns 0 for normal termination and non-zero to indicate troubles such as erroneous parameters, bad or inaccessible data, or other inability to cope with the task at hand. It is called variously “exit code,” “exit status,” or “return code,” and is described only where special conventions are involved.
Notes  Unfortunately, not all commands adhere to the standard syntax.
REFERENCE

System Administration Commands - Part 1
The `6to4relay` command is used to configure 6to4 relay router communication. Relay router communication support is enabled by setting the value of a variable that stores an IPv4 address within the tun module. This variable is global to all tunnels and defines the policy for communication with relay routers. By default, the address is set to `INADDR_ANY (0.0.0.0)`, and the kernel interprets the value to indicate that support for relay router communication is disabled. Otherwise, support is enabled, and the specified address is used as the IPv4 destination address when packets destined for native IPv6 (non-6to4) hosts are sent through the 6to4 tunnel interface. The `6to4relay` command uses a project private ioctl to set the variable.

`6to4relay` used without any options outputs the current, in-kernel, configuration status. Use the `-a` option to send packets to a specific relay router’s unicast address instead of the default anycast address. The address specified with the `-a` option does not specify the policy for receiving traffic from relay routers. The source relay router on a received packet is non-deterministic, since a different relay router may be chosen for each sending native IPv6 end-point.

Configuration changes made by using the `6to4relay` are not persistent across reboot. The changes will persist in the kernel only until you take the tunnel down.

**Options**
The `6to4relay` command supports the following options:

- `-a addr` Use the specified address, `addr`.
- `-e` Enable support for relay router. Use `-a addr` if it is specified. Otherwise, use the default anycast address, 192.88.99.1.
- `-d` Disable support for the relay router.
- `-h` Help

**Operands**
The following operands are supported:

- `addr` A specific relay router’s unicast address. `addr` must be specified as a dotted decimal representation of an IPv4 address. Otherwise, an error will occur, and the command will fail.

**Examples**

**EXAMPLE 1** Printing the In-Kernel Configuration Status

Use `/usr/sbin/6to4relay` without any options to print the in-kernel configuration status.

```
example# /usr/sbin/6to4relay
```
EXAMPLE 1  Printing the In-Kernel Configuration Status  (Continued)

If 6to4 relay router communication is disabled, the administrator will see the following message:

6to4relay: 6to4 Relay Router communication support is disabled.

If 6to4 router communication is enabled, the user will see this message:

6to4relay: 6to4 Relay Router communication support is enabled.
IPv4 destination address of Relay Router = 192.88.99.1

Exit Status  The following exit values are returned:
0    Successful completion.
>0   An error occurred.

Files  /usr/sbin/6to4relay   The default installation root

<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also  ifconfig(1M), attributes(5)

Diagnostics  The 6to4relay reports the following messages:

6to4relay: input (0.0.0.0) is not a valid IPv4 unicast address

Example: The following example provides an incorrect unicast address.

example# 6to4relay -e -a 0.0.0.0

Description: The address specified with the -a option must be a valid unicast address.

6to4relay: option requires an argument -a
usage:
6to4relay
6to4relay -e [-a <addr>]
Example: The following example does not include an argument for the -a option.

example# 6to4relay -e -a

Description: The -a option requires an argument.

Example: The following example specifies options that are not permitted.

example# 6to4relay -e -d

Description: The options specified are not permitted. A usage message is output to the screen.

Example: The following example specifies the -a option without specifying the -e option.

example# 6to4relay -a 1.2.3.4

Description: The -e option is required in conjunction with the -a option. A usage message is output to the screen.

6to4relay: ioctl (I_STR) : Invalid argument

Example: The following example specifies an invalid address.

example# 6to4relay -e -a 239.255.255.255

Description: The address specified with the -a option must not be a class d addr.
Name accept, reject – accept or reject print requests

Synopsis accept destination...
   reject [-r reason] destination...

Description accept allows the queueing of print requests for the named destinations.
   reject prevents queueing of print requests for the named destinations.

Use \texttt{lpstat -a} to check if destinations are accepting or rejecting print requests.

Generally, accept and reject are run on the print server to control local print queues. Under
some configurations, accept and reject are run on client systems when IPP is being used to
communicate between client and server.

Options The following options are supported for reject:
   -r reason Assigns a reason for rejection of print requests for destination.
     
   reason is reported by \texttt{lpstat -a}. By default, reason is unknown reason for
   existing destinations, and new printer for destinations added to the system but
   not yet accepting requests. Enclose reason in quotes if it contains blanks.

Operands The following operands are supported:
   destination The name of the destination accepting or rejecting print requests. Destination
   specifies the name of a printer or class of printers (see \texttt{lpadmin(1M)}). Specify
   destination using atomic name or URI-style (scheme://endpoint) names. See
   printers.conf(4) for information regarding the naming conventions for
   destinations.

Exit Status The following exit values are returned:
   0 Successful completion.
   non-zero An error occurred.

Files /etc/printers.conf System printer configuration database
   $HOME/.printers User-configurable printer database
   ou=printers LDAP version of /etc/printers.conf
   printers.conf.byname NIS version of /etc/printers.conf
   printers.org_dir NIS+ version of /etc/printers.conf

Attributes See attributes(5) for descriptions of the following attributes:
accept(1M)

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWlp-cmds</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled. See NOTES.</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Obsolete</td>
</tr>
</tbody>
</table>

See Also  enable(1), lp(1), lpstat(1), lpadmin(1M), lpsched(1M), printers.conf(4), attributes(5)

Notes  accept and reject affect only queueing on the print server’s spooling system. Requests made from a client system remain queued in the client system’s queueing mechanism until they are cancelled or accepted by the print server’s spooling system.

accept is CSI-enabled except for the destination name.

When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.
acct(1M)

Name acct, acctdisk, acctdusg, accton, acctwtmp, closewtmp, utmp2wttmp – overview of accounting and miscellaneous accounting commands

Synopsis /usr/lib/acct/acctdisk
/usr/lib/acct/acctdusg [-u filename] [-p filename]
/usr/lib/acct/accton [filename]
/usr/lib/acct/acctwtmp reason filename
/usr/lib/acct/closewtmp
/usr/lib/acct/utmp2wttmp

Description Accounting software is structured as a set of tools (consisting of both C programs and shell procedures) that can be used to build accounting systems. acctsh(1M) describes the set of shell procedures built on top of the C programs.

Connect time accounting is handled by various programs that write records into /var/adm/wtmpx, as described in utmpx(4). The programs described in acctcon(1M) convert this file into session and charging records, which are then summarized by acctmerg(1M).

Process accounting is performed by the system kernel. Upon termination of a process, one record per process is written to a file (normally /var/adm/pacct). The programs in acctprc(1M) summarize this data for charging purposes; acctcms(1M) is used to summarize command usage. Current process data may be examined using acctcom(1).

Process accounting records and connect time accounting records (or any accounting records in the tacct format described in acct.h(3HEAD)) can be merged and summarized into total accounting records by acctmerg (see tacct format in acct.h(3HEAD)). prtacct (see acctsh(1M)) is used to format any or all accounting records.

acctdisk reads lines that contain userID, login name, and number of disk blocks and converts them to total accounting records that can be merged with other accounting records. acctdisk returns an error if the input file is corrupt or improperly formatted.

acctdusg reads its standard input (usually from find / -print) and computes disk resource consumption (including indirect blocks) by login.

accton without arguments turns process accounting off. If filename is given, it must be the name of an existing file, to which the kernel appends process accounting records (see acct(2) and acct.h(3HEAD)).

acctwtmp writes a utmpx(4) record to filename. The record contains the current time and a string of characters that describe the reason. A record type of ACCOUNTING is assigned (see utmpx(4)) reason must be a string of 11 or fewer characters, numbers, $, or spaces. For example, the following are suggestions for use in reboot and shutdown procedures, respectively:

acctwtmp "acctg on" /var/adm/wtmpx
acctwtmp "acctg off" /var/adm/wtmpx

Name acct, acctdisk, acctdusg, accton, acctwtmp, closewtmp, utmp2wttmp – overview of accounting and miscellaneous accounting commands

Synopsis /usr/lib/acct/acctdisk
/usr/lib/acct/acctdusg [-u filename] [-p filename]
/usr/lib/acct/accton [filename]
/usr/lib/acct/acctwtmp reason filename
/usr/lib/acct/closewtmp
/usr/lib/acct/utmp2wttmp

Description Accounting software is structured as a set of tools (consisting of both C programs and shell procedures) that can be used to build accounting systems. acctsh(1M) describes the set of shell procedures built on top of the C programs.

Connect time accounting is handled by various programs that write records into /var/adm/wtmpx, as described in utmpx(4). The programs described in acctcon(1M) convert this file into session and charging records, which are then summarized by acctmerg(1M).

Process accounting is performed by the system kernel. Upon termination of a process, one record per process is written to a file (normally /var/adm/pacct). The programs in acctprc(1M) summarize this data for charging purposes; acctcms(1M) is used to summarize command usage. Current process data may be examined using acctcom(1).

Process accounting records and connect time accounting records (or any accounting records in the tacct format described in acct.h(3HEAD)) can be merged and summarized into total accounting records by acctmerg (see tacct format in acct.h(3HEAD)). prtacct (see acctsh(1M)) is used to format any or all accounting records.

acctdisk reads lines that contain userID, login name, and number of disk blocks and converts them to total accounting records that can be merged with other accounting records. acctdisk returns an error if the input file is corrupt or improperly formatted.

acctdusg reads its standard input (usually from find / -print) and computes disk resource consumption (including indirect blocks) by login.

accton without arguments turns process accounting off. If filename is given, it must be the name of an existing file, to which the kernel appends process accounting records (see acct(2) and acct.h(3HEAD)).

acctwtmp writes a utmpx(4) record to filename. The record contains the current time and a string of characters that describe the reason. A record type of ACCOUNTING is assigned (see utmpx(4)) reason must be a string of 11 or fewer characters, numbers, $, or spaces. For example, the following are suggestions for use in reboot and shutdown procedures, respectively:

acctwtmp "acctg on" /var/adm/wtmpx
acctwtmp "acctg off" /var/adm/wtmpx

Name acct, acctdisk, acctdusg, accton, acctwtmp, closewtmp, utmp2wttmp – overview of accounting and miscellaneous accounting commands

Synopsis /usr/lib/acct/acctdisk
/usr/lib/acct/acctdusg [-u filename] [-p filename]
/usr/lib/acct/accton [filename]
/usr/lib/acct/acctwtmp reason filename
/usr/lib/acct/closewtmp
/usr/lib/acct/utmp2wttmp

Description Accounting software is structured as a set of tools (consisting of both C programs and shell procedures) that can be used to build accounting systems. acctsh(1M) describes the set of shell procedures built on top of the C programs.

Connect time accounting is handled by various programs that write records into /var/adm/wtmpx, as described in utmpx(4). The programs described in acctcon(1M) convert this file into session and charging records, which are then summarized by acctmerg(1M).

Process accounting is performed by the system kernel. Upon termination of a process, one record per process is written to a file (normally /var/adm/pacct). The programs in acctprc(1M) summarize this data for charging purposes; acctcms(1M) is used to summarize command usage. Current process data may be examined using acctcom(1).

Process accounting records and connect time accounting records (or any accounting records in the tacct format described in acct.h(3HEAD)) can be merged and summarized into total accounting records by acctmerg (see tacct format in acct.h(3HEAD)). prtacct (see acctsh(1M)) is used to format any or all accounting records.

acctdisk reads lines that contain userID, login name, and number of disk blocks and converts them to total accounting records that can be merged with other accounting records. acctdisk returns an error if the input file is corrupt or improperly formatted.

acctdusg reads its standard input (usually from find / -print) and computes disk resource consumption (including indirect blocks) by login.

accton without arguments turns process accounting off. If filename is given, it must be the name of an existing file, to which the kernel appends process accounting records (see acct(2) and acct.h(3HEAD)).

acctwtmp writes a utmpx(4) record to filename. The record contains the current time and a string of characters that describe the reason. A record type of ACCOUNTING is assigned (see utmpx(4)) reason must be a string of 11 or fewer characters, numbers, $, or spaces. For example, the following are suggestions for use in reboot and shutdown procedures, respectively:

acctwtmp "acctg on" /var/adm/wtmpx
acctwtmp "acctg off" /var/adm/wtmpx
For each user currently logged on, closewtmp puts a false DEAD_PROCESS record in the 
/var/adm/wtmpx file. runacct (see runacct(1M)) uses this false DEAD_PROCESS record so that
the connect accounting procedures can track the time used by users logged on before runacct
was invoked.

For each user currently logged on, runacct uses utmp2wtmp to create an entry in the file
/var/adm/wtmpx, created by runacct. Entries in /var/adm/wtmpx enable subsequent
invocations of runacct to account for connect times of users currently logged in.

**Options**
The following options are supported:

- `-u filename` Places in filename records consisting of those filenames for which acctdusg
  charges no one (a potential source for finding users trying to avoid disk
  charges).

- `-p filename` Specifies a password file, filename. This option is not needed if the password
  file is /etc/passwd.

**Environment Variables**
If any of the LC_* variables (LC_TYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and
LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of
acct for each corresponding locale category is determined by the value of the LANG
environment variable. If LC_ALL is set, its contents are used to override both the LANG and the
other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S.
style) locale determines how acct behaves.

- **LC_CTYPE** Determines how acct handles characters. When LC_CTYPE is set to a valid value,
  acct can display and handle text and filenames containing valid characters for
  that locale. acct can display and handle Extended Unix Code (EUC) characters
  where any character can be 1, 2, or 3 bytes wide. acct can also handle EUC
  characters of 1, 2, or more column widths. In the "C" locale, only characters
  from ISO 8859-1 are valid.

- **LC_TIME** Determines how acct handles date and time formats. In the "C" locale, date and
time handling follows the U.S. rules.

**Files**
- `/etc/passwd` Used for login name to user ID conversions.
- `/usr/lib/acct` Holds all accounting commands listed in sub-class 1M of this manual.
- `/var/adm/wtmpx` History of user access and administration information.

**Attributes**

System Administration Guide: Basic Administration
Name
acctadm – configure extended accounting facility

Synopsis
/usr/sbin/acctadm [-D Erux] [-d resource_list]
[-e resource_list] [-f filename]
[task | process | flow]

Description
acctadm configures various attributes of the extended accounting facility. Without arguments, acctadm displays the current status of the extended accounting facility.

Options
The following options are supported:

- **d resource_list**
  Disable reporting of resource usage for resource. Specify resource_list as a comma-separated list of resources or resource groups.

  This option requires an operand. See OPERANDS.

- **D**
  Disable accounting of the given operand type without closing the accounting file. This option can be used to temporarily stop writing accounting records to the accounting file without closing it. To close the file use the -x option. See -x.

- **e resource_list**
  Enable reporting of resource usage for resource. Specify resource_list as a comma-separated list of resources or resource groups.

  This option requires an operand. See OPERANDS.

- **E**
  Enable accounting of the given operand type without sending the accounting output to a file. This option requires an operand. See OPERANDS.

- **f filename**
  Send the accounting output for the given operand type to filename. If filename exists, its contents are lost.

  This option requires an operand. See OPERANDS.

- **r**
  Display available resource groups.

  When this option is used with an operand, it displays resource groups available for a given accounting type. When no operand is specified, this option displays resource groups for all available accounting types. See OPERANDS.

- **u**
  Configure accounting based on the contents of /etc/acctadm.conf.

- **x**
  Deactivate accounting of the given operand type. This option also closes the accounting file for the given accounting type if it is currently open.

  This option requires an operand. See OPERANDS.
### Operands

The -d, -D, -e, -f, and -x options require an operand.

The following operands are supported:

- **process**: Run `acctadm` on the process accounting components of the extended accounting facility.
- **task**: Run `acctadm` on the task accounting components of the extended accounting facility.
- **flow**: Run `acctadm` on the IPQoS accounting components of the extended accounting facility.

The optional final parameter to `acctadm` represents whether the command should act on the process, system task or IPQoS accounting components of the extended accounting facility.

### Examples

**EXAMPLE 1  Displaying the Current Status**

The following command displays the current status. In this example, system task accounting is active and tracking only CPU resources. Process and flow accounting are not active.

```bash
$ acctadm
Task accounting: active
Task accounting file: /var/adm/exacct/task
Tracked task resources: extended
Untracked task resources: host
Process accounting: inactive
Process accounting file: none
Tracked process resources: none
Untracked process resources: extended,host
Flow accounting: inactive
Flow accounting file: none
Tracked flow resources: none
Untracked flow resources: extended
```

**EXAMPLE 2  Activating Basic Process Accounting**

The following command activates basic process accounting:

```bash
$ acctadm -e basic -f /var/adm/exacct/proc process
```

**EXAMPLE 3  Displaying Available Resource Groups**

The following command displays available resource groups:

```bash
$ acctadm -r
```

```bash
process:
extended pid,uid,gid,cpu,time,command/tty/projid, 
\taskid,ancpid,wait-status,zone,flag,memory,mstate
basic pid,uid,gid,cpu,time,command/tty/flag
```

---

**acctadm(1M)**
EXAMPLE 3  Displaying Available Resource Groups  (Continued)

extended taskid,projid,cpu,time,host,mstate,anctaskid,zone
basic taskid,projid,cpu,time
flow:
extended saddr,daddr,sport,dport,proto,dsfield,nbytes,npkts, \n action,ctime,lseen,projid,uid
basic saddr,daddr,sport,dport,proto,nbytes,npkts,action

In the output above, the lines beginning with extended are shown with a backslash character. In actual acctadm output, these lines are displayed as unbroken, long lines.

EXAMPLE 4  Displaying Resource Groups for Task Accounting

The following command displays resource groups for task accounting:

$ acctadm -r task
extended taskid,projid,cpu,time,host,mstate,anctaskid,zone
basic taskid,projid,cpu,time

Exit Status  The following exit values are returned:

0  Successful completion.
   The modifications to the current configuration were valid and made successfully.
1  An error occurred.
   A fatal error occurred either in obtaining or modifying the accounting configuration.
2  Invalid command line options were specified.

Files  /etc/acctadm.conf

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  acct(2), attributes(5), ipqos(7ipp)

Notes  Both extended accounting and regular accounting can be active.
   Available resources can vary from system to system, and from platform to platform.
**Name**
acctcms – command summary from process accounting records

**Synopsis**
/usr/lib/acct/acctcms [-a [-o] [-p]] [-c] [-j] [-n] [-s] [-t] filename ...

**Description**
acctcms reads one or more filenames, normally in the form described in acct.h(3HEAD). It adds all records for processes that executed identically named commands, sorts them, and writes them to the standard output, normally using an internal summary format.

Use the following options only with the -a option:

- **-o** Output a (non-prime) offshift-time-only command summary.
- **-p** Output a prime-time-only command summary.

When -o and -p are used together, a combination prime-time and non-prime-time report is produced. All the output summaries are total usage except number of times executed, CPU minutes, and real minutes, which are split into prime and non-prime.

- **-c** Sort by total CPU time, rather than total kcore-minutes.
- **-j** Combine all commands invoked only once under "**other".
- **-n** Sort by number of command invocations.
- **-s** Any file names encountered hereafter are already in internal summary format.
- **-t** Process all records as total accounting records. The default internal summary format splits each field into prime and non-prime-time parts. This option combines the prime and non-prime time parts into a single field that is the total of both, and provides upward compatibility with old style acctcms internal summary format records.

**Examples**

**Example 1**
Using the acctcms command.

A typical sequence for performing daily command accounting and for maintaining a running total is:

```bash
example% acctcms filename ... > today
example% cp total previoustital
example% acctcms -s today previoustital > total
example% acctcms -a -s today
```

**Attributes**
See attributes(5) for descriptions of the following attributes:
### See Also

acctcom(1), acct(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M),
fwtmp(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

### Notes

Unpredictable output results if -t is used on new style internal summary format files, or if it is not used with old style internal summary format files.
acctcon(1M)

**Name**
acctcon, acctcon1, acctcon2 – connect-time accounting

**Synopsis**
/usr/lib/acct/acctcon [-l lineuse] [-o reboot]
/usr/lib/acct/acctcon1 [-p] [-t] [-l lineuse] [-o reboot]
/usr/lib/acct/acctcon2

**Description**
acctcon converts a sequence of login/logoff records to total accounting records (see the tacct format in acct.h(3HEAD)). The login/logoff records are read from standard input. The file /var/adm/wtmpx is usually the source of the login/logoff records; however, because it might contain corrupted records or system date changes, it should first be fixed using wtmpfix. The fixed version of file /var/adm/wtmpx can then be redirected to acctcon. The tacct records are written to standard output.

acctcon is a combination of the programs acctcon1 and acctcon2. acctcon1 converts login/logoff records, taken from the fixed /var/adm/wtmpx file, to ASCII output. acctcon2 reads the ASCII records produced by acctcon1 and converts them to tacct records. acctcon1 can be used with the -l and -o options, described below, as well as with the -p and -t options.

**Options**

- **-p**
  Print input only, showing line name, login name, and time (in both numeric and date/time formats).

- **-t**
  acctcon1 maintains a list of lines on which users are logged in. When it reaches the end of its input, it emits a session record for each line that still appears to be active. It normally assumes that its input is a current file, so that it uses the current time as the ending time for each session still in progress. The -t flag causes it to use, instead, the last time found in its input, thus assuring reasonable and repeatable numbers for non-current files.

- **-l lineuse**
  lineuse is created to contain a summary of line usage showing line name, number of minutes used, percentage of total elapsed time used, number of sessions charged, number of logins, and number of logoffs. This file helps track line usage, identify bad lines, and find software and hardware oddities. Hangup, termination of login(1) and termination of the login shell each generate logoff records, so that the number of logoffs is often three to four times the number of sessions. See init(1M) and utmpx(4).

- **-o reboot**
  reboot is filled with an overall record for the accounting period, giving starting time, ending time, number of reboots, and number of date changes.

**Examples**

**EXAMPLE 1** Using the acctcon command.

The acctcon command is typically used as follows:

```bash
example% acctcon -l lineuse -o reboots < tmpwtmp > ctacct
```

The acctcon1 and acctcon2 commands are typically used as follows:
EXAMPLE 1  Using the acctcon command.  (Continued)

example% acctcon1 -l lineuse -o reboots < tmpwtmp | sort +1n +2 > ctmp
example% acctcon2 < ctmp > ctacct

Files  /var/adm/wtmpx  History of user access and administration information

Attributes  See attributes(5) for descriptions of the following attributes:

fwtmp(1M), init(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

System Administration Guide: Basic Administration

Notes  The line usage report is confused by date changes. Use wtmpfix (see fwtmp(1M)), with the
/var/adm/wtmpx file as an argument, to correct this situation.

During a single invocation of any given command, the acctcon, acctcon1, and acctcon2
commands can process a maximum of:

- 6000 distinct session
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the
command will not succeed.
Name acctmerg – merge or add total accounting files

Synopsis /usr/lib/acct/acctmerg [-a] [-i] [-p] [-t] [-u] [-v] [filename] ...

Description acctmerg reads its standard input and up to nine additional files, all in the tacct format (see acct.h(3HEAD)) or an ASCII version thereof. It merges these inputs by adding records whose keys (normally user ID and name) are identical, and expects the inputs to be sorted on those keys.

Options
- **a** Produce output in ASCII version of tacct.
- **i** Produce input in ASCII version of tacct.
- **p** Print input with no processing.
- **t** Produce a single record that totals all input.
- **u** Summarize by user ID, rather than by user ID and name.
- **v** Produce output in verbose ASCII format, with more precise notation for floating-point numbers.

Examples
**EXAMPLE 1** Using the acctmerg command.
The following sequence is useful for making "repairs" to any file kept in this format:
```bash
example% acctmerg -v <filename1 >filename2
```
Edit `filename2` as you want:
```bash
example% acctmerg -i <filename2 >filename1
```

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWaccu</td>
</tr>
</tbody>
</table>

*System Administration Guide: Basic Administration*
acctprc(1M)

Name acctprc, acctprc1, acctprc2 – process accounting

Synopsis /usr/lib/acct/acctprc
/usr/lib/acct/acctprc1 [ctmp]
/usr/lib/acct/acctprc2

Description acctprc reads the standard input and converts it to total accounting records (see the tacct record in acct.h(3HEAD)). acctprc divides CPU time into prime time and non-prime time and determines mean memory size (in memory segment units). acctprc then summarizes the tacct records, according to user IDs, and adds login names corresponding to the user IDs. The summarized records are then written to the standard output. acctprc1 reads input in the form described by acct.h(3HEAD), adds login names corresponding to user IDs, then writes for each process an ASCII line giving user ID, login name, prime CPU time (tics), non-prime CPU time (tics), and mean memory size (in memory segment units). If ctmp is given, it should contain a list of login sessions sorted by user ID and login name. If this file is not supplied, it obtains login names from the password file, just as acctprc does. The information in ctmp helps it distinguish between different login names that share the same user ID.

From the standard input, acctprc2 reads records in the form written by acctprc1, summarizes them according to user ID and name, then writes the sorted summaries to the standard output as total accounting records.

Examples EXAMPLE 1 Examples of acctprc.
The acctprc command is typically used as shown below:
example% acctprc < /var/adm/pacct > ptacct

The acctprc1 and acctprc2 commands are typically used as shown below:
example% acctprc1 ctmp < /var/adm/pacct
example% acctprc2 > ptacct

Files /etc/passwd system password file

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWaccu</td>
</tr>
</tbody>
</table>

See Also acctcom(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctsh(1M), cron(1M), fwtmp(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

Notes Although it is possible for acctprc1 to distinguish among login names that share user IDs for commands run from a command line, it is difficult for acctprc1 to make this distinction for commands invoked in other ways. A command run from cron(1M) is an example of where
acctprc1 might have difficulty. A more precise conversion can be done using the acctwtmp program in acct(1M). acctprc does not distinguish between users with identical user IDs.

A memory segment of the mean memory size is a unit of measure for the number of bytes in a logical memory segment on a particular processor.

During a single invocation of any given command, the acctprc, acctprc1, and acctprc2 commands can process a maximum of

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.
Name
acctsh, chargefee, ckpacct, dodisk, lastlogin, monacct, nulladm, prctmp, prdaily, prtacct, shutacct, startup, turnacct – shell procedures for accounting

Synopsis
/usr/lib/acct/chargefee login-name number
/usr/lib/acct/ckpacct [blocks]
/usr/lib/acct/dodisk [-o] [filename]...
/usr/lib/acct/lastlogin
/usr/lib/acct/monacct number
/usr/lib/acct/nulladm filename...
/usr/lib/acct/prctmp filename
/usr/lib/acct/prdaily [-c] [-l] [mmdd]
/usr/lib/acct/prtacct filename ['' heading '']
/usr/lib/acct/shutacct ['' reason '']
/usr/lib/acct/startup
/usr/lib/acct/turnacct on | off | switch

Description

chargefee Command
chargefee can be invoked to charge a number of units to login-name. A record is written to /var/adm/fee, to be merged with other accounting records by runacct(1M).

ckpacct Command
ckpacct should be initiated using cron(1M) to periodically check the size of /var/adm/pacct. If the size exceeds blocks, 500 by default, turnacct will be invoked with argument switch. To avoid a conflict with turnacct switch execution in runacct, do not run ckpacct and runacct simultaneously. If the number of free disk blocks in the /var file system falls below 500, ckpacct will automatically turn off the collection of process accounting records via the off argument to turnacct. When at least 500 blocks are restored, the accounting will be activated again on the next invocation of ckpacct. This feature is sensitive to the frequency at which ckpacct is executed, usually by the cron(1M) command.

dodisk Command
dodisk should be invoked by cron(1M) to perform the disk accounting functions.

lastlogin Command
lastlogin is invoked by runacct(1M) to update /var/adm/acct/sum/loginlog, which shows the last date on which each person logged in.

monacct Command
monacct should be invoked once each month or each accounting period. number indicates which month or period it is. If number is not given, it defaults to the current month (01–12). This default is useful if monacct is to executed using cron(1M) on the first day of each month. monacct creates summary files in /var/adm/acct/fiscal and restarts the summary files in /var/adm/acct/sum.
nulladm Command
nulladm creates filename with mode 664 and ensures that owner and group are adm. It is called by various accounting shell procedures.

prctmp Command
prctmp can be used to print the session record file (normally /var/adm/acct/nite/ctmp created by acctcon1 (see acctcon(1M)).

prdaily Command
prdaily is invoked by runacct(1M) to format a report of the previous day's accounting data. The report resides in /var/adm/acct/sum/rprt/mmdd where mmdd is the month and day of the report. The current daily accounting reports may be printed by typing prdaily. Previous days' accounting reports can be printed by using the mmdd option and specifying the exact report date desired.

prtacct Command
prtacct can be used to format and print any total accounting (tacct) file.

shutacct Command
shutacct is invoked during a system shutdown to turn process accounting off and append a reason record to /var/adm/wtmpx.

startup Command
startup can be invoked when the system is brought to a multi-user state to turn process accounting on.

turnacct Command
turnacct is an interface to accton (see acct(1M)) to turn process accounting on or off. The switch argument moves the current /var/adm/pacct to the next free name in /var/adm/pacct.incrr (where incr is a number starting with 0 and incrementing by one for each additional pacct file), then turns accounting back on again. This procedure is called by ckpacct and thus can be taken care of by the cron(1M) command and used to keep pacct to a reasonable size. shutacct uses turnacct to stop process accounting. startup uses turnacct to start process accounting.

Options
The following options are supported:

-c This option prints a report of exceptional resource usage by command, and may be used on current day's accounting data only.

-l This option prints a report of exceptional usage by login id for the specified date. Previous daily reports are cleaned up and therefore inaccessible after each invocation of monacct.

-o This option uses acctdusg (see acct(1M)) to do a slower version of disk accounting by login directory. filenames specifies the one or more filesystem names where disk accounting will be done. If filenames are used, disk accounting will be done on these filesystems only. If the -o option is used, filenames should be mount points of mounted filesystems. If the -o option is omitted, filenames should be the special file names of mountable filesystems.

Files
/etc/logadm.conf Configuration file for the logadm(1M) command
/usr/lib/acct Holds all accounting commands listed in section 1M of this manual
Contains the limits for exceptional usage by command name.

Contains the limits for exceptional usage by login ID.

Fiscal reports directory.

Working directory.

Summary directory that contains information for monacct.

File updated by last login.

Accumulator for fees.

Current file for per-process accounting.

Used if pacct gets large and during execution of daily accounting procedure.

History of user access and administration information.

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>

</table>

See Also acctcom(1), acct(1M), acctcom(1M), acctcon(1M), acctmerg(1M), acctprc(1M), cron(1M), fwtmp(1M), logadm(1M), runacct(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5).

Notes See runacct(1M) for the main daily accounting shell script, which performs the accumulation of connect, process, fee, and disk accounting on a daily basis. It also creates summaries of command usage.
adbgen – generate adb script

### Synopsis

`/usr/lib/adb/adbgen [-m model] filename.adb`

### Description

adbgen makes it possible to write adb(1) scripts that do not contain hard-coded dependencies on structure member offsets. The input to adbgen is a file named `filename.adb` that contains header information, then a null line, then the name of a structure, and finally an adb script. adbgen only deals with one structure per file; all member names are assumed to be in this structure. The output of adbgen is an adb script in `filename.adb`. adbgen operates by generating a C program which determines structure member offsets and sizes, which in turn generate the adb script.

The header lines, up to the null line, are copied verbatim into the generated C program. Typically, these are `#include` statements, which include the headers containing the relevant structure declarations.

The adb script part may contain any valid adb commands (see adb(1)), and may also contain adbgen requests, each enclosed in braces `{ }`. Request types are:

- **Print a structure member.** The request form is `{member, format}`. `member` is a member name of the `structure` given earlier, and `format` is any valid adb format request or any of the adbgen format specifiers (such as `{POINTER}`) listed below. For example, to print the `p_pid` field of the `proc` structure as a decimal number, you would write `{p_pid, d}`.

- **Print the appropriate adb format character for the given adbgen format specifier.** This action takes the data model into consideration. The request form is `{format specifier}`. The valid adbgen format specifiers are:

  - `{POINTER}` pointer value in hexadecimal
  - `{LONGDEC}` long value in decimal
  - `{ULONGDEC}` unsigned long value in decimal
  - `{ULONGHEX}` unsigned long value in hexadecimal
  - `{LONGOCT}` long value in octal
  - `{ULONGOCT}` unsigned long value in octal

- **Reference a structure member.** The request form is `{*member, base}`. `member` is the member name whose value is desired, and `base` is an adb register name which contains the base address of the structure. For example, to get the `p_pid` field of the `proc` structure, you would get the `proc` structure address in an adb register, for example `<f`, and write `{*p_pid, <f}`.

- **Tell adbgen that the offset is valid.** The request form is `{OFFSETOK}`. This is useful after invoking another adb script which moves the adb `dot`.

- **Get the size of the structure.** The request form is `{SIZEOF}`. adbgen replaces this request with the size of the structure. This is useful in incrementing a pointer to step through an array of structures.
Calculate an arbitrary C expression. The request form is \{EXPR, expression\}. adbgen replaces this request with the value of the expression. This is useful when more than one structure is involved in the script.

- Get the offset to the end of the structure. The request form is \{END\}. This is useful at the end of the structure to get adb to align the dot for printing the next structure member.

adbgen keeps track of the movement of the adb dot and generates adb code to move forward or backward as necessary before printing any structure member in a script. adbgen’s model of the behavior of adb’s dot is simple: it is assumed that the first line of the script is of the form \struct_address/adb text and that subsequent lines are of the form +/adb text. The adb dot then moves in a sane fashion. adbgen does not check the script to ensure that these limitations are met. adbgen also checks the size of the structure member against the size of the adb format code and warns if they are not equal.

### Options
The following option is supported:

- `-m model` Specifies the data type model to be used by adbgen for the macro. This affects the outcome of the \{format specifier\} requests described under DESCRIPTION and the offsets and sizes of data types. model can be ilp32 or ilp64. If the `-m` option is not given, the data type model defaults to ilp32.

### Operands
The following operand is supported:

- `filename. adb` Input file that contains header information, followed by a null line, the name of the structure, and finally an adb script.

### Examples
**EXAMPLE 1** A sample adbgen file.

For an include file `x.h` which contained:

```c
struct x {
    char   *x_cp;
    char   x_c;
    int    x_i;
};
```

then, an adbgen file (call it `script.adb`) to print the file `x.h` would be:

```bash
#include "x.h"
x ./"x_cp"16t"x_c"8t"x_i"n{x_cp, {POINTER}}{x_c, C}{x_i, D}
```

After running adbgen as follows,

```bash
% /usr/lib/adb/adbgen   script.adb
```

the output file `script` contains:

```bash
./"x_cp"16t"x_c"8t"x_i"nXC3+D
```
EXAMPLE 1  A sample adbgen file.  (Continued)

For a macro generated for a 64-bit program using the \lp64 data model as follows,
\%
/usr/lib/adb/adbgen/ -m lp64 script.adb
the output file script would contain:
\.
/x_cp"16t"x_c"8t"x_i"n3C3+D
To invoke the script, type:
example% adb program
x$<script

Files  /usr/platform/platform-name/lib/adb/*
   platform-specific adb scripts for debugging the 32-bit kernel
/usr/platform/platform-name/lib/adb/sparcv9/*
   platform-specific adb scripts for debugging the 64-bit SPARC V9 kernel
/usr/lib/adb/*
   adb scripts for debugging the 32-bit kernel
/usr/lib/adb/sparcv9/*
   adb scripts for debugging the 64-bit SPARC V9 kernel

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWesu</td>
</tr>
</tbody>
</table>

See Also  adb(1), uname(1), kadb(1M), attributes(5)

Diagnostics  Warnings are given about structure member sizes not equal to adb format items and about badly formatted requests. The C compiler complains if a structure member that does not exist is referenced. It also complains about an ampersand before array names; these complaints may be ignored.

Notes  platform-name can be found using the -i option of uname(1).

Bugs  adb syntax is ugly; there should be a higher level interface for generating scripts.

Structure members which are bit fields cannot be handled because C will not give the address of a bit field. The address is needed to determine the offset.
**add_allocatable(1M)**

**Name**
add_allocatable – add entries to allocation databases

**Synopsis**
/usr/sbin/add_allocatable [-f] [-s] [-d] -n name -t type -l device-list
[-a authorization] [-c clean] [-o key=value]

**Description**
add_allocatable creates new entries for user allocatable devices that are to be managed by
the device allocation mechanism. add_allocatable can also be used to update existing entries
of such devices.

add_allocatable can also create and update entries for non-allocatable devices, such as
printers, whose label range is managed by the device allocation mechanism.

add_allocatable can be used in shell scripts, such as installation scripts for driver packages,
to automate the administrative work of setting up a new device.

Use list_devices(1) to see the names and types of allocatable devices, their attributes, and
device paths.

**Options**
- **-f** Force an update of an already-existing entry with the specified
  information. add_allocatable exits with an error if this option is not
  specified when an entry with the specified device name already exists.
- **-s** Turn on silent mode. add_allocatable does not print any error or
  warning messages.
- **-d** If this option is present, add_allocatable updates the system-supplied
default attributes of the device type specified with -t.
- **-n name** Adds or updates an entry for device that is specified by name.
- **-t type** Adds or updates device entries that are of a type that are specified by type.
- **-l device-list** Adds or updates device paths to the device that is specified with -n.
  Multiple paths in device-list must be separated by white spaces and the
  list must be quoted.
- **-a authorization** Adds or updates the authorization that is associated with either the
device that is specified with -n or with devices of the type that is specified
with -t. When more than one authorization is specified, the list must be
separated by commas and must be quoted. When the device is not
allocatable, authorization is specified with an asterisk (*) and must be
quoted. When the device is allocatable by any user, authorization is
specified with the at sign (@) and must be quoted. Default authorization
is '@'.
- **-c clean** Specifies the device_clean(5) program clean to be used with the device
  that is specified with -n or with devices of the type that is specified with
  -t. The default clean program is /bin/true.
-o key=value Accepts a string of colon-separated key=value pairs for a device that is specified with -n or with devices of the type that is specified with -t. The following keys are currently interpreted by the system:

minlabel The minimum label at which the device can be used.

maxlabel The maximum label at which the device can be used.

class Specifies a logical grouping of devices. For example, all Sun Ray devices of all device types is a logical grouping. The class keyword has no default value.

xdpy Specifies the display name of the X session. This keyword is used to identify devices that are associated with the X session. The xdpy keyword has no default value.

**Exit Status** When successful, add_allocate returns an exit status of 0 (true). add_allocate returns a nonzero exit status in the event of an error. The exit codes are as follows:

1 Invocation syntax error

2 Unknown system error

3 An entry already exists for the specified device. This error occurs only when the -f option is not specified.

4 Permission denied. User does not have DAC or MAC access record updates.

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWtsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

**See Also** allocate(1), deallocate(1), list_devices(1), remove_allocatable(1M), attributes(5), device_clean(5)

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.
addbadsec(1M)

Name  addbadsec – map out defective disk blocks

Synopsis  addbadsec [-p] [-a blkno [blkno]... ] [-f filename] raw_device

Description  addbadsec is used by the system administrator to map out bad disk blocks. Normally, these blocks are identified during surface analysis, but occasionally the disk subsystem reports unrecoverable data errors indicating a bad block. A block number reported in this way can be fed directly into addbadsec, and the block will be remapped. addbadsec will first attempt hardware remapping. This is supported on SCSI drives and takes place at the disk hardware level. If the target is an IDE drive, then software remapping is used. In order for software remapping to succeed, the partition must contain an alternate slice and there must be room in this slice to perform the mapping.

It should be understood that bad blocks lead to data loss. Remapping a defective block does not repair a damaged file. If a bad block occurs to a disk-resident file system structure such as a superblock, the entire slice might have to be recovered from a backup.

Options  The following options are supported:

- a    Adds the specified blocks to the hardware or software map. If more than one block number is specified, the entire list should be quoted and block numbers should be separated by white space.

- f    Adds the specified blocks to the hardware or software map. The bad blocks are listed, one per line, in the specified file.

- p    Causes addbadsec to print the current software map. The output shows the defective block and the assigned alternate. This option cannot be used to print the hardware map.

Operands  The following operand is supported:

raw_device   The address of the disk drive (see FILES).

Files  The raw device should be /dev/rdsk/c?[t?]d?p0. See disks(1M) for an explanation of SCSI and IDE device naming conventions.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Architecture</td>
<td>x86</td>
</tr>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  disks(1M), diskscan(1M), fdisk(1M), fmthard(1M), format(1M), attributes(5)
The `format(1M)` utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the `addbadsec`, `diskscan(1M)`, `fdisk(1M)`, and `fmthard(1M)` commands available for x86. To format an IDE disk, use the DOS "format" utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris `format(1M)` utility.

**Notes**
### add_drv(1M)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_drv</td>
<td>add a new device driver to the system</td>
</tr>
</tbody>
</table>

#### Synopsis

```
add_drv [-b basedir] [-c class_name] [-i 'identify_name...']
[-m 'permission','...'] [-p 'policy'] [-P privilege]
[-n] [-f] [-v] device_driver
```

#### Description

The `add_drv` command is used to inform the system about newly installed device drivers.

Each device on the system has a name associated with it. This name is represented by the `name` property for the device. Similarly, the device may also have a list of driver names associated with it. This list is represented by the `compatible` property for the device.

The system determines which devices will be managed by the driver being added by examining the contents of the `name` property and the `compatible` property (if it exists) on each device. If the value in the `name` property does not match the driver being added, each entry in the `compatible` property is tried, in order, until either a match occurs or there are no more entries in the `compatible` property.

In some cases, adding a new driver may require a reconfiguration boot. See the NOTES section.

Aliases might require quoting (with double-quotes) if they contain numbers. See EXAMPLES.

#### The /etc/minor_perm File

`add_drv` and `update_drv(1M)` read the `/etc/minor_perm` file to obtain permission information. The permission specified is applied to matching minor nodes created when a device bound to the driver is attached. A minor node’s permission may be manually changed by `chmod(1)`. For such nodes, the specified permissions apply, overriding the default permissions specified via `add_drv` or `update_drv(1M)`.

The format of the `/etc/minor_perm` file is as follows:

```
name:minor_name permissions owner group
```

`minor_name` may be the actual name of the minor node, or contain shell metacharacters to represent several minor nodes (see `sh(1)`).

For example:

```
sd:* 0640 root sys
zs:[a-z],cu 0600 uucp uucp
mm:kmem 0640 root bin
```

The first line sets all devices exported by the `sd` node to `0640` permissions, owned by `root`, with group `sys`. In the second line, devices such as `a`, `cu` and `z`, `cu` exported by the `zs` driver are set to `0600` permission, owned by `uucp`, with group `uucp`. In the third line the `kmem` device exported by the `mm` driver is set to `0640` permission, owned by `root`, with group `bin`.

#### Running add_drv from a Postinstall Script

When running `add_drv` from within the context of a package’s postinstall script, you must consider whether the package is being added to a system image or to a running system. When a package is being installed on a system image, such as occurs with the Live Upgrade or flash
features (see `live_upgrade(5)` and `fllarcreate(1M)`), the BASEDIR variable refers to the image’s base directory. In this situation, `add_drv` should be invoked with `-b $BASEDIR`. This causes `add_drv` only to update the image’s system files; a reboot of the system or client would be required to make the driver operational.

When a package is being installed on the running system itself, the system files need to be updated, as in the case above. However, the running kernel can be informed of the existence of the new driver without requiring a reboot. To accomplish this, the postinstall script must invoke `add_drv` without the `-b` option. Accordingly, postinstall scripts invoking `add_drv` should be written thusly:

```bash
if [ "$BASEDIR:=/" = "/" ]
then
    ADD_DRV="add_drv"
else
    ADD_DRV="add_drv -b $BASEDIR"
fi
ADD_DRV [options] <driver>
```

...or, alternatively:

```bash
if [ "$BASEDIR:=/" != "/" ]
then
    BASEDIR_OPT="-b $BASEDIR"
fi
add_drv $BASEDIR_OPT [options] <driver>
```

The `-b` option is described below.

**Options**

- **-b basedir**
  
  Installs the driver on the system with a root directory of `basedir` rather than installing on the system executing `add_drv`. This option is typically used in package post-installation scripts when the package is not being installed on the system executing the `pkgadd` command. The system using `basedir` as its root directory must reboot to complete the driver installation.

  **Note** – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See `zones(5)`.

- **-c class_name**
  
  The driver being added to the system exports the class `class_name`.

- **-f**
  
  Normally if a reconfiguration boot is required to complete the configuration of the driver into the system, `add_drv` will not add the driver. The force flag forces `add_drv` to add the driver even if a reconfiguration boot is required. See the `-v` flag.
A white-space separated list of aliases for the driver device_driver.

Specify the file system permissions for device nodes created by the system on behalf of device_driver.

Do not try to load and attach device_driver, just modify the system configuration files for the device_driver.

Specify an additional device security policy.

The device security policy consists of several whitespace separated tokens:

{minorspec {token=value}+}

minorspec is a simple wildcard pattern for a minor device. A single * matches all minor devices. Only one * is allowed in the pattern.

Patterns are matched in the following order:
- entries without a wildcard
- entries with wildcards, longest wildcard first

The following tokens are defined: read_priv_set and write_priv_set. read_priv_set defines the privileges that need to be asserted in the effective set of the calling process when opening a device for reading. write_priv_set defines the privileges that need to be asserted in the effective set of the calling process when opening a device for writing. See privileges(5).

A missing minor spec is interpreted as a *.

Specify additional, comma-separated privileges used by the driver. You can also use specific privileges in the device’s policy.

The verbose flag causes add_drv to provide additional information regarding the success or failure of a driver’s configuration into the system. See the EXAMPLES section.

**Examples**

**EXAMPLE 1** Adding SUNW Example Driver to the System

The following example adds the SUNW_example driver to a 32–bit system, with an alias name of SUNW, alias. It assumes the driver has already been copied to /usr/kernel/drv.

```
example# add_drv -m '*' 0666 bin bin,'a 0644 root sys' 
          -p 'a write_priv_set=sys_config * write_priv_set=none' 
          -i 'SUNW,alias' SUNW,example
```
EXAMPLE 1 Adding SUNW Example Driver to the System  (Continued)

Every minor node created by the system for the SUNW, example driver will have the permission 0666, and be owned by user bin in the group bin, except for the minor device a, which will be owned by root, group sys, and have a permission of 0644. The specified device policy requires no additional privileges to open all minor nodes, except minor device a, which requires the sys_config privilege when opening the device for writing.

EXAMPLE 2 Adding Driver to the Client /export/root/sun1
The following example adds the driver to the client /export/root/sun1. The driver is installed and loaded when the client machine, sun1, is rebooted. This second example produces the same result as the first, except the changes are on the diskless client, sun1, and the client must be rebooted for the driver to be installed.

```
example# add_drv -m '* 0666 bin bin', 'a 0644 root sys' \ 
   -i 'SUNW,alias' -b /export/root/sun1 \ 
   SUNW,example
```

See the note in the description of the -b option, above, specifying the caveat regarding the use of this option with the Solaris zones feature.

EXAMPLE 3 Adding Driver for a Device Already Managed by an Existing Driver
The following example illustrates the case where a new driver is added for a device that is already managed by an existing driver. Consider a device that is currently managed by the driver dumb_framebuffer. The name and compatible properties for this device are as follows:

```
name="display"
compatible="whizzy_framebuffer", "dumb_framebuffer"
```

If add_drv is used to add the whizzy_framebuffer driver, the following will result.

```
example# add_drv whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
```

If the -v flag is specified, the following will result.

```
example# add_drv -v whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
Driver installation failed because the following entries in /devices would be affected:

    /devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
    (Device currently managed by driver "dumb_framebuffer")
```

The following entries in /dev would be affected:

```
/dev/fbs/dumb_framebuffer0
```
EXAMPLE 3 Adding Driver for a Device Already Managed by an Existing Driver

(Continued)

If the -v and -f flags are specified, the driver will be added resulting in the following.

example# add_drv -vf whizzy_framebuffer
A reconfiguration boot must be performed to complete the installation of this driver.

The following entries in /devices will be affected:

/devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
(Device currently managed by driver "dumb_framebuffer"

The following entries in /dev will be affected:

/dev/fbs/dumb_framebuffer0

The above example is currently only relevant to devices exporting a generic device name.

EXAMPLE 4 Use of Double Quotes in Specifying Driver Alias

The following example shows the use of double quotes in specifying a driver alias that contains numbers.

example# add_drv -i "pci10c5,25" smc

Exit Status add_drv returns 0 on success and 1 on failure.

Writing Device Drivers

Notes
It is possible to add a driver for a device already being managed by a different driver, where the
driver being added appears in the device's compatible list before the current driver. In such
cases, a reconfiguration boot is required (see boot(1M) and kernel(1M)). After the
reconfiguration boot, device links in /dev and references to these files may no longer be valid
(see the -v flag). If a reconfiguration boot would be required to complete the driver
installation, add_drv will fail unless the -f option is specified. See Example 3 in the EXAMPLES
section.

With the introduction of the device policy several drivers have had their minor permissions
changed and a device policy instated. The typical network driver should use the following
device policy:

```
add_drv -p 'read_priv_set=net_rawaccess
write_priv_set=net_rawaccess' -m "" 666 root sys"
mynet
```
This document does not constitute an API. /etc/minor_perm, /etc/name_to_major, /etc/driver_classes, and /devices may not exist or may have different contents or interpretations in a future release. The existence of this notice does not imply that any other documentation that lacks this notice constitutes an API.

/etc/minor_perm can only be updated by add_drv, rem_drv(1M) or update_drv(1M).

**Bugs** Previous versions of add_drv accepted a pathname for *device_driver*. This feature is no longer supported and results in failure.
**Name**

`afbconfig`, `SUNWafb_config` – configure the AFB Graphics Accelerator

**Synopsis**

```
/usr/sbin/afbconfig [-dev device-filename]
    [-res video-mode [now | try] [noconfirm | nocheck]]
    [-file machine | system] [-deflinear true | false]
    [-defoverlay true | false]
    [-overlayorder first | last]
    [-expvis enable | disable] [-sov enable | disable]
    [-maxwinds n] [-extovl enable | disable]
    [-g gamma-correction-value]
    [-gfile gamma-correction-file] [-propt] [-prconf]
    [-defaults]
```

```
/usr/sbin/afbconfig [-propt] [-prconf]
```

```
/usr/sbin/afbconfig [-help] [-res ?]
```

**Description**

`afbconfig` configures the AFB Graphics Accelerator and some of the X11 window system defaults for AFB.

The following form of `afbconfig` stores the specified options in the `OWconfig` file:

```
/usr/sbin/afbconfig [-dev device-filename]
    [-res video-mode [now | try] [noconfirm | nocheck]]
    [-file machine | system] [-deflinear true | false]
    [-defoverlay true | false]
    [-overlayorder first | last]
    [-expvis enable | disable] [-sov enable | disable]
    [-maxwinds n] [-extovl enable | disable]
    [-g gamma-correction-value]
    [-gfile gamma-correction-file] [-propt] [-prconf]
    [-defaults]
```

The options are used to initialize the AFB device the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots.

The following forms of the `afbconfig` command invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options. None of these options update the `OWconfig` file.

```
/usr/sbin/afbconfig [-propt] [-prconf]
```

```
/usr/sbin/afbconfig [-help] [-res ?]
```

Additionally, the following invocation of `afbconfig` ignores all other options:

```
/usr/sbin/afbconfig [-help] [-res ?]
```

You can only specify options for one AFB device at a time. Specifying options for multiple AFB devices requires multiple invocations of the `afbconfig` command.

Only AFB-specific options can be specified through `afbconfig`. The normal window system options for specifying default depth, visual class and so forth are still specified as device modifiers on the `openwin` command line.
You can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the afbconfig program, which is owned by the root user, always runs with setuid root permission.

For a given invocation of afbconfig command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value. When the window system is run, if an AFB option has never been specified by way of afbconfig, a default value is used. The option defaults are as follows:

- **dev**  
  /dev/fbs/afb0
- **file**  
  machine
- **res**  
  none
- **deflinear**  
  false
- **defoverlay**  
  false
- **linearorder**  
  last
- **overlayorder**  
  last
- **expvis**  
  enabled
- **sov**  
  enabled
- **maxwids**  
  32
- **extovl**  
  enabled
- **g**  
  2.22

The default for the -res option of none means that when the window system is run the screen resolution is the video mode currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, 6X) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default AFB video mode.

The following options are supported:

- **defaults**
  
  Resets all option values to their default values.
-deflinear true | false
AFB possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

If true, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the Xsun(1) defdepth and defclass options described in the OpenWindows Reference Manual).

If false, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options are chosen as the default. This option cannot be used when the -defoverlay option is present, because AFB doesn’t possess a linear overlay visual.

-defoverlay true | false
The AFB provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the AFB visuals. This is called the overlay visual. Windows created in this visual do not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals damage overlay windows.

The number of colors available to the windows created using this visual depends on the settings for the -extovl option. If the -extovl is enabled, extended overlay with 256 opaque color values is available. See -extovl. If -extovl is disabled, extended overlay is not available and the visual has 256 -maxwids) number of opaque color values. See -maxwids.

If the value of -defoverlay is true, the overlay visual is made the default visual. If the value of -defoverlay is false, the nonoverlay visual that satisfies the other default visual selection options, such as def, depth, and defclass, are chosen as the default visual. See the OpenWindows Reference Manual.

Whenever the defoverlay true option is used, the default depth and class specified on the openwin command line must be 8-bit PseudoColor. If not, a warning message is printed and the -defoverlay option is treated as false.

The -defoverlay option can not be used when the -deflinear option specified, because AFB doesn’t possess a linear overlay visual.

-dev device-filename
Specifies the AFB special file. The default is /dev/fbs/afb0.

-expvis enable | disable
If enabled, activates OpenGL Visual Expansion. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor and so forth) are in the screen visual list.

-extovl enable | disable
If enabled, makes extended overlay available. The overlay visuals have 256 opaque colors. The SOV visuals have 255 opaque colors and 1 transparent color.
This option also enables hardware supported transparency, thus provides better performance for windows using the SOV visuals.

-\texttt{file machine|system}
  Specifies which OWconfig file to update. If \texttt{machine} is specified, the machine-specific OWconfig file in the /etc/openwin directory tree is updated. If \texttt{system} is specified, the global OWconfig file in the /usr/openwin directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is \texttt{machine}.

-\texttt{g gamma-correction \texttt{value}}
  Allows changing the gamma correction value. All linear visuals provide gamma correction. By default, the \texttt{gamma-correction-value} is 2.22. Any value less than 0 is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by XSolarisGetVisualGamma(3). See XSolarisGetVisualGamma(3) for a description of that function.

This option can be used while the window system is running. Changing the gamma correction value affects all the windows being displayed using the linear visuals.

-\texttt{gfile gamma-correction-file}
  Loads the gamma correction table from the specified file (\texttt{gamma-correction-file}). This file should be formatted to provide the gamma correction values for R, G and B channels on each line. Each of these values should be in hexadecimal format and separated from each other by at least one space. \texttt{gamma-correction-file} should also provide 256 such triplets.

An example of a \texttt{gamma-correction-file} follows.

\begin{verbatim}
  0x00 0x00 0x00
  0x01 0x01 0x01
  0x02 0x02 0x02
  ...
  ...
  0xff 0xff 0xff
\end{verbatim}

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is being done using user specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

-\texttt{help}
  Prints a list of the afbconfig command line options, along with a brief explanation of each.

-\texttt{linearorder first|last}
  If \texttt{first}, linear visuals come before their non-linear counterparts on the X11 screen visual list for the AFB screen. If \texttt{last}, the nonlinear visuals come before the linear ones.
-maxwids n
Specifies the maximum number of AFB X channel pixel values that are reserved for use as window IDs (WIDs). The remainder of the pixel values in overlay colormaps are used for normal X11 opaque color pixels. The reserved WIDs are allocated on a first-come first-serve basis by 3D graphics windows (such as XGL), MBX windows, and windows that have a non-default visual. The X channel codes 0 to (255 - n) are opaque color pixels. The X channel codes (255 - n + 1) to 255 are reserved for use as WIDs. Legal values are 1, 2, 4, 8, 16, 32, and 64.

This option is available only if the -extovl is disabled.

-overlayorder first|last
If first, the depth 8 PseudoColor Overlay visual comes before the non-overlay visual on the X11 screen visual list for the AFB screen. If last, the non-overlay visual comes before the overlay one.

-propt
Prints the current values of all AFB options in the OWconfig file specified by the -file option for the device specified by the -dev option. Prints the values of options as they will be in the OWconfig file after the call to afbconfig completes.

The following is a typical display:

--- OpenWindows Configuration for /dev/fbs/afb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
Overlay Visuals are last
OpenGL Visual Expansion: enabled
Server Overlay Visuals: enabled
Extended Overlay: enabled
Underlay WIDs: 64 (not configurable)
Overlay WIDs: 4 (not configurable)
Gamma Correction Value: 2.220
Gamma Correction Table: Available

-prconf
Prints the AFB hardware configuration.

The following is a typical display:

--- Hardware Configuration for /dev/fbs/afb0 ---
Type: double-buffered AFB with Z-buffer
Board: rev 0 (Horizontal)
Number of Floats: 6
PROM Information: @(#)afb.fth x.xx xx/xx/xx
AFB ID: 0x101df06d
DAC: Brooktree 9870, version 1 (Pac2)
3DRAM: Mitsubishi 130a, version x
EDID Data: Available - EDID version 1 revision x
Monitor Sense ID: 4 (Sun 37x29cm RGB color monitor)
Monitor possible resolutions: 1024x768x77, 1024x800x84, 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680x108s
Current resolution setting: 1280x1024x76

-sov enable | disable
If enabled, the root window’s SERVER_OVERLAY_VISUALS property are advertised. SOV visuals are exported and their transparent types, values and layers can be retrieved through this property. If disabled, the SERVER_OVERLAY_VISUALS property are not defined and SOV visuals are not exported.

-res video-mode [ now | try [ noconfirm | nocheck ] ]
Specifies the video mode used to drive the monitor connected to the specified AFB device.

The format of these built-in video modes is: widthxheightxrate, where width is the screen width in pixels, height is the screen height in pixels, and rate is the vertical frequency of the screen refresh.

The s suffix of 960x680x112s and 960x680x108s means that these are stereo video modes. The i suffix of 640x480x60i and 768x575x50i designates interlaced video timing. If absent, non-interlaced timing is used.

As a convenience, the -res also accepts formats with an at sign (@) in front of the refresh rate instead of n, (1280x1024@76). Some video-modes, supported by AFB, may not be supported by the monitor. The list of video-modes supported by the AFB device and the monitor can be obtained by running afbconfig with the -res ? option (the third form shown SYNONYMS).

A list of all possible video-modes supported on AFB follows:

1024x768x60
1024x768x70
1024x768x75
1024x768x77
1024x800x84
1152x900x66
1152x900x76
1280x800x76
1280x1024x60
1280x1024x67
1280x1024x76
960x680x112s (Stereo)
960x680x108s (Stereo)
640x480x60
640x480x60i (Interlaced)
768x575x50i (Interlaced)
For convenience, some of the video-modes supported on the AFB have *symbolic names* defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to the `-res` option. The meaning of the symbolic name `none` is that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

A list of symbolic names for video-modes supported on AFB follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Corresponding Video Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>svga</td>
<td>1024x768x60</td>
</tr>
<tr>
<td>1152</td>
<td>1152x900x76</td>
</tr>
<tr>
<td>1280</td>
<td>1280x1024x76</td>
</tr>
<tr>
<td>stereo</td>
<td>960x680x112s</td>
</tr>
<tr>
<td>ntsc</td>
<td>640x480x60i</td>
</tr>
<tr>
<td>pal</td>
<td>768x575x50i</td>
</tr>
<tr>
<td>none</td>
<td>(see text above)</td>
</tr>
</tbody>
</table>

The `-res` option also accepts the additional, optional arguments immediately following the video mode specification. Any or all of the following arguments can be specified:

- **noconfirm**: Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `afbconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `afbconfig` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `afbconfig` is being run from a shell script.

- **nocheck**: If present, the normal error checking based on the monitor sense code is suspended. The video mode specified by the user is accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the AFB device). Use of this option implies `noconfirm` well.

- **now**: Updates the video mode in the OWconfig file, and immediately programs the AFB device to display this video mode. This is useful for changing the video mode before starting the window system.

  This argument should not be used with `afbconfig` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `afbconfig` with the `now` argument, first bring the window system down. If the `now` argument is used within a window system session, the video mode is changed immediately, but the width and height of the affected screen won’t change until the window system is exited and re-entered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.
try

If present, the specified video mode is programmed on a trial basis. The user
is asked to confirm the video mode by typing y within 10 seconds. Or the
user may terminate the trial before 10 seconds are up by typing any
character. Any character other than y or Return is considered a no. The
previous video mode is restored and afbconfig does not change the video
mode in the OWconfig file (other options specified still take effect). If a
Return is typed, the user is prompted for a yes or no answer on whether to
keep the new video mode.

This sub-option should not be used with afbconfig while the configured
device is being used (for example, while running the window system) as
unpredictable results may occur. To run afbconfig with the try
sub-option, the window system should be brought down first.

Examples

EXAMPLE 1  Switching the monitor type

The following example switches the monitor type to a resolution of 1280 x 1024 at 76 Hz:

    example% /usr/sbin/afbconfig -res 1280x1024x76

**Name**  
aliasadm – manipulate the NIS+ aliases map

**Synopsis**  
aliasadm -a alias expansion [options comments] optional flags
    aliasadm -c alias expansion [options comments] [optional flags]
    aliasadm -d alias [optional flags]
    aliasadm -e alias [optional flags]
    aliasadm -l alias [optional flags]
    aliasadm -m alias [optional flags]
    aliasadm [-I] [-D domainname] [-f filename] [-M mapname]

**Description**  
aliasadm makes changes to the alias map.

The alias map is an NIS+ table object with four columns:

- **alias**  
The name of the alias as a null terminated string.

- **expansion**  
The value of the alias as it would appear in a sendmail /etc/aliases file.

- **options**  
A list of options applicable to this alias. The only option currently supported is CANON. With this option, if the user has requested an inverse alias lookup, and there is more than one alias with this expansion, this alias is given preference.

- **comments**  
An arbitrary string containing comments about this alias. The sendmail(1M) command reads this map in addition to the NIS aliases map and the local /etc/aliases database.

**Options**  

- **-a**  
Add an alias.

- **-c**  
Change an alias.

- **-d**  
Delete an alias.

- **-e**  
Edit the alias map.

- **-I**  
Initialize the NIS+ aliases database.

- **-l**  
List the alias map.

- **-m**  
Print or match an alias.

- **-D domainname**  
Edit the map in domain domainname instead of the current domain.

- **-f filename**  
When editing or listing the database, use filename instead of invoking the editor.

- **-M mapname**  
Edit mapname instead of mail_aliases.

Notes

In addition to the documentation and man pages included with Solaris, more information is available at http://www.apache.org

The Apache man pages are provided with the programming modules. To view the manual pages for the Apache modules with the man command, add /usr/apache/man to the MANPATH environment variable. See man(1) for more information. Running catman(1M) on the Apache manual pages is not supported.
**Name**
arp – address resolution display and control

**Synopsis**
arp  hostname
    arp  -a  [-n]
    arp  -d  hostname
    arp  -f  filename
    arp  -s  hostname  ether_address  [temp]  [pub]  [trail]
        [permanent]

**Description**
The `arp` program displays and modifies the Internet-to-MAC address translation tables used by the address resolution protocol (see `arp(7P)`).

With no flags, the program displays the current ARP entry for `hostname`. The host may be specified by name or by number, using Internet dot notation.

Options that modify the ARP translation tables (`-d`, `-f`, and `-s`) can be used only when the invoked command is granted the `sys_net_config` privilege. See `privileges(5)`.

**Options**
- **-a**
  Display all of the current ARP entries. The definition for the flags in the table are:

  - **d**
    Unverified; this is a local IP address that is currently undergoing Duplicate Address Detection. ARP will not respond to requests for this address until Duplicate Address Detection completes.

  - **o**
    Old; this entry is aging away. If IP requests it again, a new ARP query will be generated. This state is used for detecting peer address changes.

  - **y**
    Delayed; periodic address defense and conflict detection was unable to send a packet due to internal network use limits for non-traffic-related messages (100 packets per hour per interface). This occurs only on interfaces with very large numbers of aliases.

  - **A**
    Authority; this machine is authoritative for this IP address. ARP will not accept updates from other machines for this entry.

  - **L**
    Local; this is a local IP address configured on one of the machine’s logical interfaces. ARP will defend this address if another node attempts to claim it.

  - **M**
    Mapping; only used for the multicast entry for 224.0.0.0

  - **P**
    Publish; includes IP address for the machine and the addresses that have explicitly been added by the `-s` option. ARP will respond to ARP requests for this address.

  - **S**
    Static; entry cannot be changed by learned information. This indicates that the `permanent` flag was used when creating the entry.

  - **U**
    Unresolved; waiting for ARP response.
You can use the -n option with the -a option to disable the automatic numeric IP address-to-name translation. Use arp -an or arp -na to display numeric IP addresses. The arp -a option is equivalent to:

```
# netstat -p -f inet
```

...and -an and -na are equivalent to:

```
# netstat -pn -f inet
```

- **d** Delete an entry for the host called *hostname*.
- **f** Read the file named *filename* and set multiple entries in the ARP tables. Entries in the file should be of the form:

```
hostname MACaddress [temp] [pub] [trail] [permanent]
```

See the -s option for argument definitions.

- **s** Create an ARP entry for the host called *hostname* with the MAC address *MACaddress*. For example, an Ethernet address is given as six hexadecimal bytes separated by colons. The entry will not be subject to deletion by aging unless the word temp is specified in the command. If the word pub is specified, the entry will be published, which means that this system will respond to ARP requests for *hostname* even though the *hostname* is not its own. The word permanent indicates that the system will not accept MAC address changes for *hostname* from the network.

Solaris does not implement trailer encapsulation, and the word trail is accepted on entries for compatibility only.

arp -s can be used for a limited form of proxy ARP when a host on one of the directly attached networks is not physically present on a subnet. Another machine can then be configured to respond to ARP requests using arp -s. This is useful in certain SLIP configurations.

The Automated Security Enhancement Tool (ASET) is a set of administrative utilities that can improve system security by allowing the system administrators to check the settings of system files, including both the attributes (permissions, ownership, and the like) and the contents of the system files. It warns the users of potential security problems and, where appropriate, sets the system files automatically according to the security level specified.

The security level for aset can be specified by setting the `-l` command line option or the `ASETSECLEVEL` environment variable to be one of 3 values: `low`, `med`, or `high`. All the functionality operates based on the value of the security level.

At the `low` level, aset performs a number of checks and reports any potential security weaknesses.

At the `med` level, aset modifies some of the settings of system files and parameters, thus restricting system access, to reduce the risks from security attacks. Again reports the security weaknesses and the modifications performed to restrict access. This does not affect the operations of system services. All the system applications and commands maintain all of their original functionality.

At the `high` level, further restrictions are made to system access, rendering a very defensive system. Security practices which are not normally required are included. Many system files and parameters settings are modified to minimum access permissions. At this level, security is the foremost concern, higher than any other considerations that affect system behavior. The vast majority of system applications and commands maintain their functionality, although there may be a few that exhibit behaviors that are not familiar in normal system environment.

More exact definitions of what exactly aset does at each level can be found in the *System Administration Guide: Basic Administration*. The `asetenv(4)` file and the `master files` determine to a large extent what aset performs at each level, and can be used by the experienced administrators to redefine the definitions of the levels to suit their particular needs. See `asetmasters(4)`. These files are provided by default to fit most security conscious environments and in most cases provide adequate security safeguards without modification. They are, however, designed in a way that can be easily edited by experienced administrators with specific needs.

aset can be periodically activated at the specified security level with default definitions using the `-p` option. aset is automatically activated at a frequency specified by the administrator starting from a designated future time (see `asetenv(4)`). Without the `-p` option, aset operates only once immediately.
Options

The following options are supported:

- `d aset_dir`
  Specifies a working directory other than `/usr/aset` for ASET. `/usr/aset` is the default working directory. It is where ASET is installed, and is the root directory of all ASET utilities and data files. If another directory is to be used as the ASET working directory, you can either define it with the `-d` option, or set the `ASETDIR` environment variable before invoking `aset`. The command line option, if specified, overwrites the environment variable.

- `\ sec_level`
  Specifies a security level, `low`, `med`, or `high`, for `aset` to operate at. The default level is `low`. Each security level is explained in detail above. The level can also be specified by setting the `ASETSECLEVEL` environment variable before invoking `aset`. The command line option, if specified, overwrites the environment variable.

- `n user@host`
  Notifies `user` at machine `host`. Send the output of `aset` to `user` through e-mail. If this option is not specified, the output is sent to the standard output. Note that this is not the reports of ASET, but rather an execution log including error messages if there are any. This output is typically brief. The actual reports of ASET are found in the `/usr/aset/reports/latest` directory. See the `-d` option.

- `p`
  Schedules `aset` to be executed periodically. This adds an entry for `aset` in the `/etc/crontab` file. The `PERIODIC_SCHEDULE` environment variable in the `/usr/aset/asetenv` file is used to define the time for execution. See `crontab(1)` and `asetenv(4)`. If a `crontab(1)` entry for `aset` already exists, a warning is produced in the execution log.

- `u userlist_file`
  Specifies a file containing a list of users. `aset` performs environment checks, for example, `UMASK` and `PATH` variables, on these users. By default, `aset` only checks for root. `userlist_file` is an ASCII text file. Each entry in the file is a line that contains only one user name (login name).

Usage

The following paragraphs discuss the features provided by ASET. Hereafter, each feature is referred to as a `task`. The first task, `tune`, is executed only once per installation of ASET. The other tasks are executed periodically at the specified frequency.

**tune Task**

This task is used to tighten system file permissions. In standard releases, system files or directories have permissions defined to maximize open information sharing. In a more
security conscious environment, the administrator may want to redefine these permission settings to more restrictive values. `aset` allows resetting of these permissions, based on the specified security level. Generally, at the low level the permissions are set to what they should be as released. At the medium level, the permissions are tightened to ensure reasonable security that is adequate for most environments. At the high level they are further tightened to very restrictive access. The system files affected and the respective restrictions at different levels are configurable, using the `tune.low`, `tune.med`, and `tune.high` files. See `asetmasters(4)`.

**cklist Task**
System directories that contain relatively static files, that is, their contents and attributes do not change frequently, are examined and compared with a master description file. The `/usr/aset/masters/cklist.level` files are automatically generated the first time the `cklist` task is executed. See `asetenv(4)`. Any discrepancy found is reported. The directories and files are compared based on the following:

- owner and group
- permission bits
- size and checksum (if file)
- number of links
- last modification time

The lists of directories to check are defined in `asetenv(4)`, based on the specified security level, and are configurable using the `CKLISTPATH_LOW`, `CKLISTPATH_MED`, and `CKLISTPATH_HIGH` environment variables. Typically, the lower level lists are subsets of the higher level lists.

**usrgrp Task**
`aset` checks the consistency and integrity of user accounts and groups as defined in the `passwd` and `group` databases, respectively. Any potential problems are reported. Potential problems for the `passwd` file include:

- `passwd` file entries are not in the correct format.
- User accounts without a password.
- Duplicate user names.
- Duplicate user IDs. Duplicate user IDs are reported unless allowed by the `uid_alias` file. See `asetmasters(4)`.
- Invalid login directories.
- If C2 is enabled, check C2 hidden `passwd` format.

Potential problems for the group file include:

- Group file entries not in the right format.
- Duplicate group names.
- Duplicate group IDs.
- Null group passwords.
aset(1M)

As a set checks the local passwd file. If the YPCHECK environment variable is set to true, aset also checks the NIS passwd files. See asetenv(4). Problems in the NIS passwd file are only reported and not corrected automatically. The checking is done for all three security levels except where noted.

sysconf_task

Aset checks various system configuration tables, most of which are in the /etc directory. Aset checks and makes appropriate corrections for each system table at all three levels except where noted. The following discussion assumes familiarity with the various system tables. See the manual pages for these tables for further details.

The operations for each system table are:

/ etc /hosts. equiv

The default file contains a single "+" line, thus making every known host a trusted host, which is not advised for system security. Aset performs the following operations:

Low

Warns the administrators about the "+" line.

Medium

Warns about and deletes that entry.

High

Warns about and deletes that entry.

/ etc /inetd. conf

The following entries for system daemons are checked for possible weaknesses.

tftp(1) does not do any authentication. Aset ensures that in. tftpd(1M) is started in the right directory on the server and is not running on clients. At the low level, it gives warnings if the mentioned condition is not true. At the medium and high levels it gives warnings, and changes (if necessary) the in. tftpd entry to include the -s /tftpboot option after ensuring the directory /tftpboot exists.

ps(1) and netstat(1M) provide valuable information to potential system crackers. These are disabled when Aset is executed at a high security level.

rxd is also known to have poor authentication mechanism. Aset disables rxd for medium and high security levels by commenting out this entry. If rxd is activated with the -s (secure RPC) option, it is not disabled.

/ etc /aliases

The decode alias of UUCP is a potential security weakness. Aset disables the alias for medium and high security levels by commenting out this entry.

/ etc /default/login

The CONSOLE= line is checked to allow root login only at a specific terminal depending on the security level:
Low
No action taken.

Medium

High
Adds the following line to the file:

```bash
CONSOLE=/dev/console
```

/etc/vfstab
aset checks for world-readable or writable device files for mounted file systems.

/etc/dfs/dfstab
aset checks for file systems that are exported without any restrictions.

/etc/ftpd/ftpdas
At high security level, aset ensures root is in

```bash
/etc/ftpd/ftpdas, thus disallowing root from logging into in.ftpd(1M). If necessary, create
```

```bash
/etc/ftpd/ftpdas. See ftpusers(4).
```

/var/adm/utmpx
aset makes these files not world-writable for the high level

(some applications may not run properly with this setting.)

/.rhosts
The usage of a .rhosts file for the entire system is not advised. aset gives warnings for the low level and moves it to

```bash
/.rhosts.bak for levels medium and high.
```

env Task
aset checks critical environment variables for root and users specified with the `-u userlist_file` option by parsing the `.profile`, `.login`, and `.cshrc` files. This task checks the `PATH` variable to ensure that it does not contain `.` as a directory, which makes an easy target for `trojan horse` attacks. It also checks that the directories in the `PATH` variable are not world-writable. Furthermore, it checks the `UMASK` variable to ensure files are not created as readable or writable by world. Any problems found by these checks are reported.

eeprom Task
Newer versions of the EEPROM allow specification of a secure parameter. See `eeprom(1M)`. aset recommends that the administrator sets the parameter to `command` for the medium level and to `full` for the high level. It gives warnings if it detects the parameter is not set adequately.

firewall Task
At the high security level, aset takes proper measures such that the system can be safely used as a firewall in a network. This mainly involves disabling IP packets forwarding and making routing information invisible. Firewalling provides protection against external access to the network.

Environment Variables

- `ASETDIR`
  Specify ASET's working directory. Defaults to `/usr/aset`.

- `ASETSECLEVEL`
  Specify ASET's security level. Defaults to `low`.

- `TASKS`
  Specify the tasks to be executed by aset. Defaults to all tasks.
Files /usr/aset/reports directory of ASET reports

System Administration Guide: Basic Administration
aset.restore – restores system files to their content before ASET is installed

**Synopsis**

```bash
ASET.restore [-d aset_dir]
```

**Description**

`ASET.restore` restores system files that are affected by the Automated Security Enhancement Tool (ASET) to their pre-ASET content. When ASET is executed for the first time, it saves and archives the original system files in the `/usr/aset/archives` directory. The `ASET.restore` utility reinstates these files. It also deschedules ASET, if it is currently scheduled for periodic execution. See `asetenv(4)`.

If you have made changes to system files after running ASET, these changes are lost when you run `ASET.restore`. If you want to be absolutely sure that you keep the existing system state, it is recommended that you back-up your system before using `ASET.restore`.

You should use `ASET.restore`, under the following circumstances:

You want to remove ASET permanently and restore the original system (if you want to deactivate ASET, you can remove it from scheduling).

You are unfamiliar with ASET and want to experiment with it. You can use `ASET.restore` to restore the original system state.

When some major system functionality is not working properly and you suspect that ASET is causing the problem; you may want to restore the system to see if the problem persists without ASET.

`ASET.restore` requires root privileges to execute.

**Options**

The following options are supported:

- `-d aset_dir` Specify the working directory for ASET. By default, this directory is `/usr/ASET`. With this option the `archives` directory will be located under `aset_dir`.

**Files**

`/usr/ASET/archives` archive of system files prior to executing `ASET`

*System Administration Guide: Basic Administration*
atohexlabel(1M)

Name  atohexlabel – convert a human readable label to its internal text equivalent

Synopsis  /usr/sbin/atohexlabel [human-readable-sensitivity-label]

/usr/sbin/atohexlabel -c [human-readable-clearance]

Description  atohexlabel converts a human readable label into an internal text representation that is safe for storing in a public object. If no option is supplied, the label is assumed to be a sensitivity label.

Internal conversions can later be parsed to their same value. This internal form is often hexadecimal. The converted label is written to the standard output file. If no human readable label is specified, the label is read from the standard input file. The expected use of this command is emergency repair of labels that are stored in internal databases.

Options  -c Identifies the human readable label as a clearance.

Exit Status  The following exit values are returned:

0  On success.

1  On failure, and writes diagnostics to the standard error file.

Files  /etc/security/tsol/label_encodings

The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWtsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The command output is Committed for systems with the same label_encodings file. The command invocation is Committed for systems that implement the DIA MAC policy.

See Also  hextoalabel(1M), label_to_str(3TSOL), str_to_label(3TSOL), label_encodings(4), attributes(5)

“How to Obtain the Hexadecimal Equivalent for a Label” in Oracle Solaris Trusted Extensions Administrator's Procedures

Notes  The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.
The audit command is the system administrator’s interface to maintaining the audit trail. The audit daemon can be notified to read the contents of the audit_control file and re-initialize the current audit directory to the first directory listed in the audit_control file or to open a new audit file in the current audit directory specified in the audit_control file, as last read by the audit daemon. Reading audit_control also causes the minfree and plugin configuration lines to be re-read and reset within auditd. The audit daemon can also be signaled to close the audit trail and disable auditing.

**Options**

- **-n** Notify the audit daemon to close the current audit file and open a new audit file in the current audit directory.
- **-s** Notify the audit daemon to read the audit control file. The audit daemon stores the information internally. If the audit daemon is not running but audit has been enabled by means of `bsmconv(1M)`, the audit daemon is started.
- **-t** Direct the audit daemon to close the current audit trail file and exit. Use `-s` to restart auditing. To disable auditing, use `bsmunconv(1M)`.
- **-v path** Verify the syntax for the audit control file stored in `path`. The audit command displays an approval message or outputs specific error messages for each error found.

**Diagnostics**

The audit command will exit with 0 upon success and a positive integer upon failure.

**Files**

- `/etc/security/audit_user`
- `/etc/security/audit_control`

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>

</tr>
</tbody>
</table>

**See Also**

`bsmconv(1M), praudit(1M), audit(2), audit_control(4), audit_user(4), attributes(5)`

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

**Notes**

The functionality described in this man page is available only if the Solaris Auditing feature has been enabled. See `bsmconv(1M)` for more information.

The audit command does not modify a process’s preselection mask. It functions are limited to the following:

- affects which audit directories are used for audit data storage;
- specifies the minimum free space setting;
- resets the parameters supplied by means of the plugin directive.

For the `-s` option, audit validates the `audit_control` syntax and displays an error message if a syntax error is found. If a syntax error message is displayed, the audit daemon does not re-read `audit_control`. Because `audit_control` is processed at boot time, the `-v` option is provided to allow syntax checking of an edited copy of `audit_control`. Using `-v`, audit exits with 0 if the syntax is correct; otherwise, it returns a positive integer.

The `-v` option can be used in any zone, but the `-t`, `-s`, and `-n` options are valid only in local zones and, then, only if the per-zone audit policy is set. See `auditd(1M)` and `auditconf(1M)` for per-zone audit configuration.
auditconfig(1M)

Name    auditconfig – configure auditing
Synopsis auditconfig option...
Description auditconfig provides a command line interface to get and set kernel audit parameters.

This functionality is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

The setting of the per zone policy determines the scope of the audit setting controlled by auditconfig. If per zone is set, then the values reflect the local zone except as noted. Otherwise, the settings are for the entire system. Any restriction based on the per zone setting is noted for each option to which it applies.

A non-global zone administrator can set all audit policy options except per zone and ahlt. per zone and ahlt apply only to the global zone; setting these policies requires the privileges of a global zone administrator. per zone and ahlt are described under the -setpolicy option, below.

Options
-aconf
Set the non-attributable audit mask from the audit_control(4) file. For example:

    # auditconfig -aconf
    Configured non-attributable events.

-audit event sorf retval string
This command constructs an audit record for audit event event using the process’s audit characteristics containing a text token string. The return token is constructed from the sorf (success/failure flag) and the retval (return value). The event is type char*, the sorf is 0/1 for success/failure, retval is an errno value, string is type *char. This command is useful for constructing an audit record with a shell script. An example of this option:

    # auditconfig -audit AUE_ftpd 0 0 "test string"
    
    audit record from audit trail:
    header,76,2,ftp access,,Fri Dec 08 08:44:02 2000, + 669 msec
    subject,abc,root,other,root,other,104449,102336,235 197121 elbow
    text,test string
    return,success,0

-bchkconf
Checks the configuration of the non-attributable events set in the kernel against the entries in audit_control(4). If the runtime class mask of a kernel audit event does not match the configured class mask, a mismatch is reported.

-bchkconf
Check the configuration of kernel audit event to class mappings. If the runtime class mask of a kernel audit event does not match the configured class mask, a mismatch is reported.
-conf
Configure kernel audit event to class mappings. Runtime class mappings are changed to match those in the audit event to class database file.

-getasid
Prints the audit session ID of the current process. For example:

  # auditconfig -getasid
  audit session id = 102336

-getaudit
Returns the audit characteristics of the current process.

  # auditconfig -getaudit
  audit id = abc(666)
  process preselection mask = lo(0x1000,0x1000)
  terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
  audit session id = 102336

-getauid
Prints the audit ID of the current process. For example:

  # auditconfig -getauid
  audit id = abc(666)

-getcar
Prints current active root location (anchored from root [or local zone root] at system boot). For example:

  # auditconfig -getcar
  current active root = /

-getclass event
Display the preselection mask associated with the specified kernel audit event. event is the kernel event number or event name.

-getcond
Display the kernel audit condition. The condition displayed is the literal string auditing meaning auditing is enabled and turned on (the kernel audit module is constructing and queuing audit records); noaudit, meaning auditing is enabled but turned off (the kernel audit module is not constructing and queuing audit records); disabled, meaning that the audit module has not been enabled; or nospace, meaning there is no space for saving audit records. See auditon(2) and auditd(1M) for further information.

-getestate event
For the specified event (string or event number), print out classes event has been assigned. For example:

  # auditconfig -getestate 20
  audit class mask for event AUE_REBOOT(20) = 0x800
  # auditconfig -getestate AUE_RENAME
  audit class mask for event AUE_RENAME(42) = 0x30
-getkaudit
Get audit characteristics of the current zone. For example:

```
# auditconfig -getkaudit
audit id = unknown(-2)
process preselection mask = lo,na(0x1400,0x1400)
terminal id (maj,min,host) = 0,0,(0.0.0.0)
audit session id = 0
```

If the audit policy per zone is not set, the terminal id is that of the global zone. Otherwise, it is the terminal id of the local zone.

-getkmask
Get non-attributable pre-selection mask for the current zone. For example:

```
# auditconfig -getkmask
audit flags for non-attributable events = lo,na(0x1400,0x1400)
```

If the audit policy per zone is not set, the kernel mask is that of the global zone. Otherwise, it is that of the local zone.

-getinfo pid
Display the audit ID, preselection mask, terminal ID, and audit session ID for the specified process.

-getpolicy
Display the kernel audit policy. The ahlt and per zone policies reflect the settings from the global zone. If per zone is set, all other policies reflect the local zone’s settings. If per zone is not set, the policies are machine-wide.

-getcwd
Prints current working directory (anchored from zone root at system boot). For example:

```
# cd /usr/tmp
# auditconfig -getcwd
current working directory = /var/tmp
```

-getqbufsz
Get audit queue write buffer size. For example:

```
# auditconfig -getqbufsz
audit queue buffer size (bytes) = 1024
```

-getqctrl
Get audit queue write buffer size, audit queue hi water mark, audit queue low water mark, audit queue prod interval (ticks).

```
# auditconfig -getqctrl
audit queue hi water mark (records) = 100
audit queue low water mark (records) = 10
audit queue buffer size (bytes) = 1024
audit queue delay (ticks) = 20
```
-getqdelay
  Get interval at which audit queue is prodded to start output. For example:
  
  # auditconfig -getqdelay
  audit queue delay (ticks) = 20

-getqhiwater
  Get high water point in undelivered audit records when audit generation will block. For example:
  
  # ./auditconfig -getqhiwater
  audit queue hiwater mark (records) = 100

-getqlowater
  Get low water point in undelivered audit records where blocked processes will resume. For example:
  
  # auditconfig -getqlowater
  audit queue lowater mark (records) = 10

-getstat
  Print current audit statistics information. For example:
  
  # auditconfig -getstat
  gen nona kern aud ctl enq wrtn wblk rblk drop tot mem
  910 1 725 184 0 910 910 0 231 0 88 48

  See auditstat(1M) for a description of the headings in -getstat output.

-gettid
  Print audit terminal ID for current process. For example:
  
  # auditconfig -gettid
  terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)

-lsevent
  Display the currently configured (runtime) kernel and user level audit event information.

-lspolicy
  Display the kernel audit policies with a description of each policy.

-setasid session-ID [cmd]
  Execute shell or cmd with specified session-ID. For example:
  
  # ./auditconfig -setasid 2000 /bin/ksh
  #
  # # ./auditconfig -getpinfo 104485
  audit id = abc(666)
  process preselection mask = lo(0x1000,0x1000)
  terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
  audit session id = 2000

-setaudit audit-ID preselect_flags term-ID session-ID [cmd]
  Execute shell or cmd with the specified audit characteristics.
- **setuid audit-ID [cmd]**
  Execute shell or cmd with the specified audit-ID.

- **setclass event audit_flag[,audit_flag ...]**
  Map the kernel event event to the classes specified by audit_flags. event is an event number or name. An audit_flag is a two character string representing an audit class. See audit_control(4) for further information. If perzone is not set, this option is valid only in the global zone.

- **setkaudit IP-address_type IP_address**
  Set IP address of machine to specified values. IP-address_type is ipv6 or ipv4.
  If perzone is not set, this option is valid only in the global zone.

- **setkmask audit_flags**
  Set non-attributes selection flags of machine.
  If perzone is not set, this option is valid only in the global zone.

- **setpmask pidflags**
  Set the preselection mask of the specified process. flags is the ASCII representation of the flags similar to that in audit_control(4).
  If perzone is not set, this option is valid only in the global zone.

- **setpolicy [+]|[policy_flag,[policy_flag ...]**
  Set the kernel audit policy. A policy policy_flag is literal strings that denotes an audit policy. A prefix of + adds the policies specified to the current audit policies. A prefix of - removes the policies specified from the current audit policies. No policies can be set from a local zone unless the perzone policy is first set from the global zone. The following are the valid policy flag strings (auditconfig -lspolicy also lists the current valid audit policy flag strings):

  **all**      Include all policies that apply to the current zone.
  **ahlt**    Panic is called and the system dumps core if an asynchronous audit event occurs that cannot be delivered because the audit queue has reached the high-water mark or because there are insufficient resources to construct an audit record. By default, records are dropped and a count is kept of the number of dropped records.
  **arge**    Include the execv(2) system call environment arguments to the audit record. This information is not included by default.
  **argv**    Include the execv(2) system call parameter arguments to the audit record. This information is not included by default.
cnt

Do not suspend processes when audit resources are exhausted. Instead, drop audit records and keep a count of the number of records dropped. By default, processes are suspended until audit resources become available.

group

Include the supplementary group token in audit records. By default, the group token is not included.

none

Include no policies. If used in other than the global zone, the ahlt and perzone policies are not changed.

path

Add secondary path tokens to audit records. These are typically the pathnames of dynamically linked shared libraries or command interpreters for shell scripts. By default, they are not included.

perzone

Maintain separate configuration, queues, and logs for each zone and execute a separate version of auditd(1M) for each zone.

public

Audit public files. By default, read-type operations are not audited for certain files which meet public characteristics: owned by root, readable by all, and not writable by all.

trail

Include the trailer token in every audit record. By default, the trailer token is not included.

seq

Include the sequence token as part of every audit record. By default, the sequence token is not included. The sequence token attaches a sequence number to every audit record.

windata_down

Include in an audit record any downgraded data moved between windows. This policy is available only if the system is configured with Trusted Extensions. By default, this information is not included.

windata_up

Include in an audit record any upgraded data moved between windows. This policy is available only if the system is configured with Trusted Extensions. By default, this information is not included.

zonename

Include the zonename token as part of every audit record. By default, the zonename token is not included. The zonename token gives the name of the zone from which the audit record was generated.

-setqbufsz buffer_size

Set the audit queue write buffer size (bytes).

-setqctrl hiwater lowater bufsz interval

Set the audit queue write buffer size (bytes), hiwater audit record count, lowater audit record count, and wakeup interval (ticks). Valid within a local zone only if perzone is set.
-setqdelay **interval**
  Set the audit queue wakeup interval (ticks). This determines the interval at which the
  kernel pokes the audit queue, to write audit records to the audit trail. Valid within a local
  zone only if `perzone` is set.

-setqhiwater **hiwater**
  Set the number of undelivered audit records in the audit queue at which audit record
  generation blocks. Valid within a local zone only if `perzone` is set.

-setqlowater **lowater**
  Set the number of undelivered audit records in the audit queue at which blocked auditing
  processes unblock. Valid within a local zone only if `perzone` is set.

-setsmask **asid flags**
  Set the preselection mask of all processes with the specified audit session ID. Valid within a
  local zone only if `perzone` is set.

-setstat
  Reset audit statistics counters. Valid within a local zone only if `perzone` is set.

-setumask **auid flags**
  Set the preselection mask of all processes with the specified audit ID. Valid within a local
  zone only if `perzone` is set.

**Examples**

**EXAMPLE1**  Using `auditconfig`

The following is an example of an `auditconfig` program:

```
#  # map kernel audit event number 10 to the "fr" audit class  
#  #  auditconfig -setclass 10 fr

#  # turn on inclusion of exec arguments in exec audit records
#  % auditconfig -setpolicy +argv
```

**Exit Status**

0  Successful completion.
1  An error occurred.

**Files**

/etc/security/audit_event  Stores event definitions used in the audit system.
/etc/security/audit_class  Stores class definitions used in the audit system.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

audit(1M), auditd(1M), auditstat(1M), bsmconv(1M), praudit(1M), auditon(2), execv(2), audit_class(4), audit_control(4), audit_event(4), attributes(5), audit_binfile(5)

See the section on Solaris Auditing in System Administration Guide: Security Services.

Notes

If plugin output is selected using audit_control(4), the behavior of the system with respect to the -setpolicy +cnt and the -setqhiwater options is modified slightly. If -setpolicy +cnt is set, data will continue to be sent to the selected plugin, even though output to the binary audit log is stopped, pending the freeing of disk space. If -setpolicy -cnt is used, the blocking behavior is as described under OPTIONS, above. The value set for the queue high water mark is used within auditd as the default value for its queue limits unless overridden by means of the qsize attribute as described in audit_control(4).

The auditconfig options that modify or display process-based information are not affected by the per zone policy. Those that modify system audit data such as the terminal id and audit queue parameters are valid only in the global zone, unless the per zone policy is set. The display of a system audit reflects the local zone if per zone is set. Otherwise, it reflects the settings of the global zone.

The -setcond option has been removed. Use audit(1M) to enable or disable auditing.

The -getsizes and -setfsize options have been removed. Use audit_binfile(5) p_fsize to set the audit file size.

<table>
<thead>

<td>Committed</td>
</tr>
</tbody>
</table>
The audit daemon, auditd, controls the generation and location of audit trail files and the generation of syslog messages based on the definitions in audit_control(4). If auditing is enabled, auditd reads the audit_control(4) file to do the following:

- reads the path to a library module for realtime conversion of audit data into syslog messages;
- reads other parameters specific to the selected plugin or plugins;
- obtains a list of directories into which audit files can be written;
- obtains the percentage limit for how much space to reserve on each filesystem before changing to the next directory.

audit(1M) is used to control auditd. It can cause auditd to:

- close the current audit file and open a new one;
- close the current audit file, re-read /etc/security/audit_control and open a new audit file;
- close the audit trail and terminate auditing.

Auditing Conditions

The audit daemon invokes the program audit_warn(1M) under the following conditions with the indicated options:

audit_warn soft pathname
The file system upon which pathname resides has exceeded the minimum free space limit defined in audit_control(4). A new audit trail has been opened on another file system.

audit_warn allsoft
All available file systems have been filled beyond the minimum free space limit. A new audit trail has been opened anyway.

audit_warn hard pathname
The file system upon which pathname resides has filled or for some reason become unavailable. A new audit trail has been opened on another file system.

audit_warn allhard count
All available file systems have been filled or for some reason become unavailable. The audit daemon will repeat this call to audit_warn at intervals of at least twenty seconds until space becomes available. count is the number of times that audit_warn has been called since the problem arose.

audit_warn ebusy
There is already an audit daemon running.

audit_warn tmpfile
The file /etc/security/audit/audit_tmp exists, indicating a fatal error.
Audit Warning: Audit daemon not started

The internal system audit condition is AUC_FCHDONE. Auditing cannot be started without rebooting the system.

Audit Warning: Audit daemon off

The internal system audit condition has been changed to not be AUC_AUDITING by someone other than the audit daemon. This causes the audit daemon to exit.

Audit Warning: Post Sigterm

An error occurred during the orderly shutdown of the auditing system.

Audit Warning: Get Ac Dir

There is a problem getting the directory list from /etc/security/audit/audit_control.

The audit daemon will hang in a sleep loop until this file is fixed.

**Files**

/etc/security/audit/audit_control

/etc/security/audit/audit_data

See the section on Solaris Auditing in System Administration Guide: Security Services.

**Notes**

The functionality described in this man page is available only if the Solaris Auditing feature has been enabled. See bsmconv(1M) for more information.

Auditd is loaded in the global zone at boot time if auditing is enabled. See bsmconv(1M).

If the audit policy per zone is set, auditd runs in each zone, starting automatically when the local zone boots. If a zone is running when the perzone policy is set, auditing must be started manually in local zones. It is not necessary to reboot the system or the local zone to start auditing in a local zone. Auditd can be started with "/usr/sbin/audit -s" and will start automatically with future boots of the zone.

When auditd runs in a local zone, the configuration is taken from the local zone's /etc/security directory's files: audit_control, audit_class, audit_user, audit_startup, and audit_event.
Configuration changes do not affect audit sessions that are currently running, as the changes do not modify a process's preselection mask. To change the preselection mask on a running process, use the `–setpmask` option of the `auditconfig` command (see `auditconfig(1M)`). If the user logs out and logs back in, the new configuration changes will be reflected in the next audit session.
auditreduce(1M)

Name
auditreduce – merge and select audit records from audit trail files

Synopsis
auditreduce [options] [audit-trail-file] ...

Description
auditreduce allows you to select or merge records from audit trail files. Audit files can be from one or more machines.

The merge function merges together audit records from one or more input audit trail files into a single output file. The records in an audit trail file are assumed to be sorted in chronological order (oldest first) and this order is maintained by auditreduce in the output file.

Unless instructed otherwise, auditreduce will merge the entire audit trail, which consists of all the audit trail files in the directory structure audit_root_dir/*files (see audit_control(4) for details of the structure of the audit root). Unless specified with the -R or -S option, audit_root_dir defaults to /etc/security/audit. By using the file selection options it is possible to select some subset of these files, or files from another directory, or files named explicitly on the command line.

The select function allows audit records to be selected on the basis of numerous criteria relating to the record’s content (see audit.log(4) for details of record content). A record must meet all of the record-selection-option criteria to be selected.

Audit Trail Filename Format
Any audit trail file not named on the command line must conform to the audit trail filename format. Files produced by the audit system already have this format. Output file names produced by auditreduce are in this format. It is:

start-time. end-time. suffix

where start-time is the 14-character timestamp of when the file was opened, end-time is the 14-character timestamp of when the file was closed, and suffix is the name of the machine which generated the audit trail file, or some other meaningful suffix (for example, all, if the file contains a combined group of records from many machines). The end-time can be the literal string not_terminated, to indicate that the file is still being written to by the audit system. Timestamps are of the form yyyymmddhhmnmss (year, month, day, hour, minute, second). The timestamps are in Greenwich Mean Time (GMT).

Options

File Selection Options
The file selection options indicate which files are to be processed and certain types of special treatment.

-A
All of the records from the input files will be selected regardless of their timestamp. This option effectively disables the -a, -b, and -d options. This is useful in preventing the loss of records if the -D option is used to delete the input files after they are processed. Note, however, that if a record is not selected due to another option, then -A will not override that.
-C
  Only process complete files. Files whose filename end-time timestamp is not terminated are not processed (such a file is currently being written to by the audit system). This is useful in preventing the loss of records if -D is used to delete the input files after they are processed. It does not apply to files specified on the command line.

-D suffix
  Delete input files after they are read if the entire run is successful. If audit reduce detects an error while reading a file, then that file is not deleted. If -D is specified, -A, -C and -O are also implied. suffix is given to the -O option. This helps prevent the loss of audit records by ensuring that all of the records are written, only complete files are processed, and the records are written to a file before being deleted. Note that if both -D and -O are specified in the command line, the order of specification is significant. The suffix associated with the latter specification is in effect.

-M machine
  Allows selection of records from files with machine as the filename suffix. If -M is not specified, all files are processed regardless of suffix. -M can also be used to allow selection of records from files that contain combined records from many machines and have a common suffix (such as a11).

-N
  Select objects in new mode. This flag is off by default, thus retaining backward compatibility. In the existing, old mode, specifying the -e, -f, -g, -r, or -u flags would select not only actions taken with those IDs, but also certain objects owned by those IDs. When running in new mode, only actions are selected. In order to select objects, the -O option must be used.

-0 suffix
  Direct output stream to a file in the current audit_root_dir with the indicated suffix. suffix can alternatively contain a full pathname, in which case the last component is taken as the suffix, ahead of which the timestamps will be placed, ahead of which the remainder of the pathname will be placed. If the -O option is not specified, the output is sent to the standard output. When audit reduce places timestamps in the filename, it uses the times of the first and last records in the merge as the start-time and end-time.

-Q
  Quiet. Suppress notification about errors with input files.

-R pathname
  Specify the pathname of an alternate audit root directory audit_root_dir to be pathname. Therefore, rather than using /etc/security/audit/*/files by default, pathname/*/files will be examined instead.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).
-S server
This option causes auditreduce to read audit trail files from a specific location (server directory). server is normally interpreted as the name of a subdirectory of the audit root, therefore auditreduce will look in audit_root_dir/server/files for the audit trail files. But if server contains any ‘/’ characters, it is the name of a specific directory not necessarily contained in the audit root. In this case, server/files will be consulted. This option allows archived files to be manipulated easily, without requiring that they be physically located in a directory structure like that of /etc/security/audit.

-V
Verbose. Display the name of each file as it is opened, and how many records total were written to the output stream.

The record selection options listed below are used to indicate which records are written to the output file produced by auditreduce.

Multiple arguments of the same type are not permitted.

-a date-time
Select records that occurred at or after date-time. The date-time argument is described under Option Arguments, below. date-time is in local time. The -a and -b options can be used together to form a range.

-b date-time
Select records that occurred before date-time.

-c audit-classes
Select records by audit class. Records with events that are mapped to the audit classes specified by audit-classes are selected. Audit class names are defined in audit_class(4). The audit-classes can be a comma separated list of audit flags like those described in audit_control(4). Using the audit flags, one can select records based upon success and failure criteria.

-d date-time
Select records that occurred on a specific day (a 24-hour period beginning at 00:00:00 of the day specified and ending at 23:59:59). The day specified is in local time. The time portion of the argument, if supplied, is ignored. Any records with timestamps during that day are selected. If any hours, minutes, or seconds are given in time, they are ignored. -d can not be used with -a or -b.

-e effective-user
Select records with the specified effective-user.

-f effective-group
Select records with the specified effective-group.

-g real-group
Select records with the specified real-group.
- j subject-ID
  Select records with the specified subject-ID where subject-ID is a process ID.

- l label
  Select records with the specified label (or label range), as explained under “Option Arguments,” below. This option is available only if the system is configured with the Solaris Trusted Extensions feature.

- m event
  Select records with the indicated event. The event is the literal string or the event number.

- o object_type=objectID_value
  Select records by object type. A match occurs when the record contains the information describing the specified object_type and the objectID equals the value specified by objectID_value. The allowable object types and values are as follows:

  file=pathname
  Select records containing file system objects with the specified pathname, where pathname is a comma separated list of regular expressions. If a regular expression is preceded by a tilde (~), files matching the expression are excluded from the output. For example, the option file=/usr/openwin, /usr, /etc would select all files in /usr or /etc except those in /usr/openwin. The order of the regular expressions is important because auditreduce processes them from left to right, and stops when a file is known to be either selected or excluded. Thus the option file=/usr, /etc, ~/usr/openwin would select all files in /usr and all files in /etc. Files in /usr/openwin are not excluded because the regular expression /usr is matched first. Care should be given in surrounding the pathname with quotes so as to prevent the shell from expanding any tildes.

  filegroup=group
  Select records containing file system objects with group as the owning group.

  fileowner=user
  Select records containing file system objects with user as the owning user.

  msgqid=ID
  Select records containing message queue objects with the specified ID where ID is a message queue ID.

  msgqgroup=group
  Select records containing message queue objects with group as the owning or creating group.

  msgqowner=user
  Select records containing message queue objects with user as the owning or creating user.

  pid=ID
  Select records containing process objects with the specified ID where ID is a process ID. Process are objects when they are receivers of signals.
procgroup=group
Select records containing process objects with group as the real or effective group.

procowner= user
Select records containing process objects with user as the real or effective user.

semid= ID
Select records containing semaphore objects with the specified ID where ID is a semaphore ID.

semgroup= group
Select records containing semaphore objects with group as the owning or creating group.

semowner= user
Select records containing semaphore objects with user as the owning or creating user.

shmid= ID
Select records containing shared memory objects with the specified ID where ID is a shared memory ID.

shmgroup= group
Select records containing shared memory objects with group as the owning or creating group.

shmowner= user
Select records containing shared memory objects with user as the owning or creating user.

sock= port_number | machine
Select records containing socket objects with the specified port_number or the specified machine where machine is a machine name as defined in hosts(4).

- r real-user
Select records with the specified real-user.

- u audit-user
Select records with the specified audit-user.

- z zone-name
Select records from the specified zone name. The zone name selection is case-sensitive.

When one or more filename arguments appear on the command line, only the named files are processed. Files specified in this way need not conform to the audit trail filename format. However, -M, -S, and -R must not be used when processing named files. If the filename is "-" then the input is taken from the standard input.

Option Arguments

audit-trail-file
An audit trail file as defined in audit.log(4). An audit trail file not named on the command line must conform to the audit trail file name format. Audit trail files produced as output of audit reduce are in this format as well. The format is:
start-time .  end-time .  suffix

start-time is the 14 character time stamp denoting when the file was opened. end-time is the 14 character time stamp denoting when the file was closed. end-time can also be the literal string not_terminated, indicating the file is still be written to by the audit daemon or the file was not closed properly (a system crash or abrupt halt occurred). suffix is the name of the machine that generated the audit trail file (or some other meaningful suffix; for example, a'll would be a good suffix if the audit trail file contains a combined group of records from many machines).

date-time
The date-time argument to -a, -b, and -d can be of two forms: An absolute date-time takes the form:

```
yyyyymmd [ hh [ mm [ ss ]]]
```

where yyyy specifies a year (with 1970 as the earliest value), mm is the month (01-12), dd is the day (01-31), hh is the hour (00-23), mm is the minute (00-59), and ss is the second (00-59). The default is 00 for hh, mm and ss.

An offset can be specified as: +n d|h|m| s where n is a number of units, and the tags d, h, m, and s stand for days, hours, minutes and seconds, respectively. An offset is relative to the starting time. Thus, this form can only be used with the -b option.

event
The literal string or ordinal event number as found in audit_event(4). If event is not found in the audit_event file it is considered invalid.

group
The literal string or ordinal group ID number as found in group(4). If group is not found in the group file it is considered invalid. group can be negative.

label
The literal string representation of a MAC label or a range of two valid MAC labels. To specify a range, use “x:y” where x and y are valid MAC labels. Only those records that are fully bounded by x and y will be selected. If x or y is omitted, the default uses ADMIN_LOW or ADMIN_HIGH, respectively. Note that quotes must be used when specifying a range.

pathname
A regular expression describing a pathname.

user
The literal username or ordinal user ID number as found in passwd(4). If the username is not found in the passwd file it is considered invalid. user can be negative.
The auditreduce command.

`praudit(1M)` is available to display audit records in a human-readable form.

This will display the entire audit trail in a human-readable form:

```
% auditreduce | praudit
```

If all the audit trail files are being combined into one large file, then deleting the original files could be desirable to prevent the records from appearing twice:

```
% auditreduce -V -D /etc/security/audit/combined/all
```

This displays what user milner did on April 13, 1988. The output will be displayed in a human-readable form to the standard output:

```
% auditreduce -d 19880413 -u milner | praudit
```

The above example might produce a large volume of data if milner has been busy. Perhaps looking at only login and logout times would be simpler. The `-c` option will select records from a specified class:

```
% auditreduce -d 19880413 -u milner -c lo | praudit
```

To see milner’s login/logout activity for April 13, 14, and 15 the following is used. The results are saved to a file in the current working directory. Note that the name of the output file will have milnerlo as the suffix, with the appropriate timestamp prefixes. Note that the long form of the name is used for the `-c` option:

```
% auditreduce -a 19880413 -b +3d -u milner -c login_logout -O milnerlo
```

To follow milner’s movement about the file system on April 13, 14, and 15 the `chdir` record types could be viewed. Note that in order to get the same time range as the above example we needed to specify the `-b` time as the day after our range. This is because 19880416 defaults to midnight of that day, and records before that fall on 0415, the end-day of the range.

```
% auditreduce -a 19880413 -b 19880416 -u milner -m AUE_CHDIR | praudit
```

In this example the audit records are being collected in summary form (the login/logout records only). The records are being written to a summary file in a different directory than the normal audit root to prevent the selected records from existing twice in the audit root.

```
% auditreduce -d 19880330 -c lo -O /etc/security/audit_summary/logins
```

If activity for user ID 9944 has been observed, but that user is not known to the system administrator, then the following example will search the entire audit trail for any records generated by that user. auditreduce will query the system as to the current validity of ID 9944, and display a warning message if it is not currently active:

```
% auditreduce -O /etc/security/audit_suspect/user9944 -u 9944
```

To get an audit log of only the global zone:
The auditreduce command.

(Continued)

% auditreduce -z global

Files
/etc/security/audit/server/files/*
location of audit trails, when stored

Attributes
See attributes(5) for descriptions of the following attributes:

<table>

See the section on Solaris Auditing in System Administration Guide: Security Services.

Diagnostics
auditreduce displays error messages if there are command line errors and then exit. If there are fatal errors during the run auditreduce displays an explanatory message and exit. In this case the output file might be in an inconsistent state (no trailer or partially written record) and auditreduce displays a warning message before exiting. Successful invocation returns 0 and unsuccessful invocation returns 1.

Since auditreduce might be processing a large number of input files, it is possible that the machine-wide limit on open files will be exceeded. If this happens, auditreduce displays a message to that effect, give information on how many file there are, and exit.

If auditreduce displays a record’s timestamp in a diagnostic message, that time is in local time. However, when filenames are displayed, their timestamps are in GMT.

Bugs
Conjunction, disjunction, negation, and grouping of record selection options should be allowed.

Notes
The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

The -z option should be used only if the audit policy zonename is set. If there is no zonename token, then no records will be selected.
The `audit_startup` script is used to initialize the audit subsystem before the audit deamon is started. This script is configurable by the system administrator, and currently consists of a series of `auditconfig(1M)` commands to set the system default policy, and download the initial event to class mapping.

auditstat – display kernel audit statistics

**Synopsis**

```
auditstat [-c count] [-h numlines] [-i interval] [-n] [-v]
```

**Description**

`auditstat` displays kernel audit statistics. The fields displayed are as follows:

- **aud**  The total number of audit records processed by the `audit(2)` system call.
- **ctl**  This field is obsolete.
- **drop** The total number of audit records that have been dropped. Records are dropped according to the kernel audit policy. See `auditon(2)`, `AUDIT_CNT` policy for details.
- **enq**  The total number of audit records put on the kernel audit queue.
- **gen**  The total number of audit records that have been constructed (not the number written).
- **kern** The total number of audit records produced by user processes (as a result of system calls).
- **mem**  The total number of Kbytes of memory currently in use by the kernel audit module.
- **nona** The total number of non-attributable audit records that have been constructed. These are audit records that are not attributable to any particular user.
- **rblk** The total number of times that `auditsvc(2)` has blocked waiting to process audit data.
- **tot**  The total number of Kbytes of audit data written to the audit trail.
- **wblk** The total number of times that user processes blocked on the audit queue at the high water mark.
- **wrttn** The total number of audit records written. The difference between `enq` and `wrttn` is the number of outstanding audit records on the audit queue that have not been written.

**Options**

- `-c count` Display the statistics a total of `count` times. If `count` is equal to zero, statistics are displayed indefinitely. A time interval must be specified.
- `-h numlines` Display a header for every `numlines` of statistics printed. The default is to display the header every 20 lines. If `numlines` is equal to zero, the header is never displayed.
- `-i interval` Display the statistics every `interval` where `interval` is the number of seconds to sleep between each collection.
- `-n` Display the number of kernel audit events currently configured.
- `-v` Display the version number of the kernel audit module software.
auditstat(1M)

Exit Status  auditstat returns 0 upon success and 1 upon failure.

Notes  The functionality described in this man page is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.
The audit_warn utility processes warning or error messages from the audit daemon. When a problem is encountered, the audit daemon, auditd(1M) calls audit_warn with the appropriate arguments. The option argument specifies the error type.

The system administrator can specify a list of mail recipients to be notified when an audit_warn situation arises by defining a mail alias called audit_warn in aliases(4). The users that make up the audit_warn alias are typically the audit and root users.

Options

The following options are supported:

- `allhard count` Indicates that the hard limit for all filesystems has been exceeded `count` times. The default action for this option is to send mail to the audit_warn alias only if the `count` is 1, and to write a message to the machine console every time. It is recommended that mail not be sent every time as this could result in a the saturation of the file system that contains the mail spool directory.

- `allsoft` Indicates that the soft limit for all filesystems has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

- `auditoff` Indicates that someone other than the audit daemon changed the system audit state to something other than AUC_AUDITING. The audit daemon will have exited in this case. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

- `ebusy` Indicates that the audit daemon is already running. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

- `getacdir count` Indicates that there is a problem getting the directory list or plugin list from audit_control(4). The audit daemon will hang in a sleep loop until the file is fixed. The default action for this option is to send mail to the audit_warn alias only if `count` is 1, and to write a message to the machine console every time. It is recommended that mail not be sent every time as this could result in a the saturation of the file system that contains the mail spool directory.
hard filename Indicates that the hard limit for the file has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

nostart Indicates that auditing could not be started. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console. Some administrators may prefer to modify audit_warn to reboot the system when this error occurs.

plugin name error count text Indicates that an error occurred during execution of the auditd plugin name. The default action for this option is to send mail to the audit_warn alias only if count is 1, and to write a message to the machine console every time. (Separate counts are kept for each error type.) It is recommended that mail not be sent every time as this could result in the saturation of the file system that contains the mail spool directory. The text field provides the detailed error message passed from the plugin. The error field is one of the following strings:

<table>
<thead>
<tr>
<th>error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_error</td>
<td>Unable to load the plugin name.</td>
</tr>
<tr>
<td>sys_error</td>
<td>The plugin name is not executing due to a system error such as a lack of resources.</td>
</tr>
<tr>
<td>config_error</td>
<td>No plugins loaded (including the binary file plugin, audit_binfile(5)) due to configuration errors in audit_control(4). The name string is -- to indicate that no plugin name applies.</td>
</tr>
<tr>
<td>retry</td>
<td>The plugin name reports it has encountered a temporary failure. For example, the audit_binfree.so plugin uses retry to indicate that all directories are full.</td>
</tr>
<tr>
<td>no_memory</td>
<td>The plugin name reports a failure due to lack of memory.</td>
</tr>
<tr>
<td>invalid</td>
<td>The plugin name reports it received an invalid input.</td>
</tr>
<tr>
<td>failure</td>
<td>The plugin name has reported an error as described in text.</td>
</tr>
</tbody>
</table>
postsigterm Indicates that an error occurred during the orderly shutdown of the audit daemon. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

soft filename Indicates that the soft limit for filename has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

tmpfile Indicates that the temporary audit file already exists indicating a fatal error. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.

See Also audit(1M), auditd(1M), bsmconv(1M), aliases(4), audit.log(4), audit_control(4), attributes(5)

See the section on Solaris Auditing in System Administration Guide: Security Services.

Notes This functionality is available only if the Solaris Auditing feature has been enabled. See bsmconv(1M) for more information.

If the audit policy perzone is set, the /etc/security/audit_warn script for the local zone is used for notifications from the local zone’s instance of auditd. If the perzone policy is not set, all auditd errors are generated by the global zone’s copy of /etc/security/audit_warn.
The automount utility installs autofs mount points and associates an automount map with each mount point. It starts the automountd(1M) daemon if it finds any non-trivial entries in either local or distributed automount maps and if the daemon is not already running. The autofs file system monitors attempts to access directories within it and notifies the automountd(1M) daemon. The daemon uses the map to locate a file system, which it then mounts at the point of reference within the autofs file system. A map can be assigned to an autofs mount using an entry in the /etc/auto_master map or a direct map.

If the file system is not accessed within an appropriate interval (10 minutes by default), the automountd daemon unmounts the file system.

The file /etc/auto_master determines the locations of all autofs mount points. By default, this file contains three entries:

```
# Master map for automounter
#
+auto_master
/net   -hosts  -nosuid
/home  auto_home
```

The +auto_master entry is a reference to an external NIS or NIS+ master map. If one exists, then its entries are read as if they occurred in place of the +auto_master entry. The remaining entries in the master file specify a directory on which an autofs mount will be made followed by the automounter map to be associated with it. Optional mount options may be supplied as an optional third field in the each entry. These options are used for any entries in the map that do not specify mount options explicitly. The automount command is usually run without arguments. It compares the entries /etc/auto_master with the current list of autofs mounts in /etc/mnttab and adds, removes or updates autofs mounts to bring the /etc/mnttab up to date with the /etc/auto_master. At boot time it installs all autofs mounts from the master map. Subsequently, it may be run to install autofs mounts for new entries in the master map or the direct map, or to perform unmounts for entries that have been removed from these maps.

If a system is configured with Solaris Trusted Extensions, additional processing is performed to facilitate multilevel home directory access. A list of zones whose labels are dominated by the current zone is generated and default auto_home automount maps are generated if they do not currently exist. These automount maps are named auto_home_<zonename>, where <zonename> is the name of each zone’s lower-level zone. An autofs mount of each such auto_home map is then performed, regardless of whether it is explicitly or implicitly listed in the master map. Instead of autofs mounting the standard auto_home map, the zone uses an auto_home file appended with its own zone name. Each zone’s auto_home map is uniquely named so that it can be maintained and shared by all zones using a common name server.
By default, the home directories of lower-level zones are mounted read-only under 
/zone/<zonename>/export/home when each zone is booted. The default
auto_home_<zonename> automount map specifies that path as the source directory for an
lofs remount onto /zone/<zonename>/home/<username>. For example, the file
auto_home_public, as generated from a higher level zone would contain:

+auto_home_public

* -fstype=lofs:/zone/public/export/home/&

When a home directory is referenced and the name does not match any other keys in the
auto_home_public map, it will match this loopback mount specification. If this loopback
match occurs and the name corresponds to a valid user whose home directory does not exist
in the public zone, the directory is automatically created on behalf of the user.

Options  The following options are supported:

- t duration Specifies a duration, in seconds, that a file system is to remain mounted
  when not in use. The default is 10 minutes.

- v Verbose mode. Notifies of autofs mounts, unmounts, or other
  non-essential information.

Usage

Map Entry Format  A simple map entry (mapping) takes the form:

key [ -mount-options ] location . . .

where key is the full pathname of the directory to mount when used in a direct map, or the
simple name of a subdirectory in an indirect map. mount-options is a comma-separated list of
mount options, and location specifies a file system from which the directory may be mounted.
In the case of a simple NFS mount, the options that can be used are as specified in
mount_nfs(1M), and location takes the form:

host: pathname

host is the name of the host from which to mount the file system, and pathname is the absolute
pathname of the directory to mount.

Options to other file systems are documented on the other mount_* reference manual pages,
for example, mount_cachefs(1M).

Replicated File Systems  Multiple location fields can be specified for replicated NFS file systems, in which case
automount and the kernel will each try to use that information to increase availability. If the
read-only flag is set in the map entry, automountd mounts a list of locations that the kernel
may use, sorted by several criteria. Only locations available at mount time will be mounted,
and thus be available to the kernel. When a server does not respond, the kernel will switch to
an alternate server. The sort ordering of automount is used to determine how the next server is
chosen. If the read-only flag is not set, automount will mount the best single location, chosen by the same sort ordering, and new servers will only be chosen when an unmount has been possible, and a remount is done. Servers on the same local subnet are given the strongest preference, and servers on the local net are given the second strongest preference. Among servers equally far away, response times will determine the order if no weighting factors (see below) are used.

If the list includes server locations using both the NFS Version 2 Protocol and the NFS Version 3 Protocol, automount will choose only a subset of the server locations on the list, so that all entries will be the same protocol. It will choose servers with the NFS Version 3 Protocol so long as an NFS Version 2 Protocol server on a local subnet will not be ignored. See the System Administration Guide: IP Services for additional details.

If each location in the list shares the same pathname then a single location may be used with a comma-separated list of hostnames:

```
hostname,hostname . . . : pathname
```

Requests for a server may be weighted, with the weighting factor appended to the server name as an integer in parentheses. Servers without a weighting are assumed to have a value of zero (most likely to be selected). Progressively higher values decrease the chance of being selected. In the example,

```
man -ro alpha,bravo,charlie(1),delta(4) : /usr/man
```

hosts alpha and bravo have the highest priority; host delta has the lowest.

Server proximity takes priority in the selection process. In the example above, if the server delta is on the same network segment as the client, but the others are on different network segments, then delta will be selected; the weighting value is ignored. The weighting has effect only when selecting between servers with the same network proximity. The automounter always selects the localhost over other servers on the same network segment, regardless of weighting.

In cases where each server has a different export point, the weighting can still be applied. For example:

```
man -ro alpha:/usr/man bravo,charlie(1):/usr/share/man
delta(3):/export/man
```

A mapping can be continued across input lines by escaping the NEWLINE with a backslash (\)

Comments begin with a number sign (#) and end at the subsequent NEWLINE.

Map Key Substitution

The ampersand (&) character is expanded to the value of the key field for the entry in which it occurs. In this case:

```
jane sparcserver : /home/&
```
the & expands to jane.

**Wildcard Key**
The asterisk (*) character, when supplied as the key field, is recognized as the catch-all entry. Such an entry will match any key not previously matched. For instance, if the following entry appeared in the indirect map for /config:

```
* & : /export/config/
```

this would allow automatic mounts in /config of any remote file system whose location could be specified as:

```
hostname : /export/config/hostname
```

Note that the wildcard key does not work in conjunction with the -browse option.

**Variable Substitution**
Client specific variables can be used within an automount map. For instance, if $HOST appeared within a map, automount would expand it to its current value for the client’s host name. Supported variables are:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCH</td>
<td>The application architecture is derived from the output of <code>uname -m</code></td>
</tr>
<tr>
<td>CPU</td>
<td>The output of <code>uname -p</code></td>
</tr>
<tr>
<td>HOST</td>
<td>The output of <code>uname -n</code></td>
</tr>
<tr>
<td>OSNAME</td>
<td>The output of <code>uname -s</code></td>
</tr>
<tr>
<td>OSREL</td>
<td>The output of <code>uname -r</code></td>
</tr>
<tr>
<td>OSVERS</td>
<td>The output of <code>uname -v</code></td>
</tr>
<tr>
<td>NATISA</td>
<td>The output of <code>isainfo -n</code></td>
</tr>
</tbody>
</table>

If a reference needs to be protected from affixed characters, you can surround the variable name with curly braces (`{ }`).
Multiple Mounts

A multiple mount entry takes the form:

```
key [-mount-options] [ [mountpoint] [-mount-options] location... ]... 
```

The initial `/mountpoint` is optional for the first mount and mandatory for all subsequent mounts. The optional mountpoint is taken as a pathname relative to the directory named by key. If mountpoint is omitted in the first occurrence, a mountpoint of `/` (root) is implied.

Given an entry in the indirect map for `/src`

```
beta -ro\ 
    /        svr1.svr2:/export/src/beta \ 
    /1.0      svr1.svr2:/export/src/beta/1.0 \ 
    /1.0/man   svr1.svr2:/export/src/beta/1.0/man 
```

All offsets must exist on the server under beta. automount will automatically mount `/src/beta`, `/src/beta/1.0`, and `/src/beta/1.0/man`, as needed, from either svr1 or svr2, whichever host is nearest and responds first.

Other File System Types

The automounter assumes NFS mounts as a default file system type. Other file system types can be described using the `fstype` mount option. Other mount options specific to this file system type can be combined with the `fstype` option. The location field must contain information specific to the file system type. If the location field begins with a slash, a colon character must be prepended, for instance, to mount a CD file system:

```
cdrom -fstype=hsfs,ro : /dev/sr0 
```

or to perform an `autofs` mount:

```
src -fstype=autofs auto_src 
```

Use this procedure only if you are not using Volume Manager.

Mounts using CacheFS are most useful when applied to an entire map as map defaults. The following entry in the master map describes cached home directory mounts. It assumes the default location of the cache directory, `/cache`.

```
/home auto_home -fstype=cachefs,backfstype=nfs 
```

See the NOTES section for information on option inheritance.

Indirect Maps

An indirect map allows you to specify mappings for the subdirectories you wish to mount under the directory indicated on the command line. In an indirect map, each key consists of a simple name that refers to one or more file systems that are to be mounted as needed.

Direct Maps

Entries in a direct map are associated directly with `autofs` mount points. Each key is the full pathname of an `autofs` mount point. The direct map as a whole is not associated with any single directory.

Direct maps are distinguished from indirect maps by the `/` key. For example:
Master Map for Automounter

+auto_master
/net -hosts -nosuid,nobrowse
/home auto_home -nobrowse
/- auto_direct

Included Maps
The contents of another map can be included within a map with an entry of the form
+mapname

If mapname begins with a slash, it is assumed to be the pathname of a local file. Otherwise, the
location of the map is determined by the policy of the name service switch according to the
entry for the automounter in /etc/nsswitch.conf, such as
automount: files nis

If the name service is files, then the name is assumed to be that of a local file in /etc. If the
key being searched for is not found in the included map, the search continues with the next
entry.

Special Maps
There are two special maps available: -hosts and -null. The -hosts map is used with the
/net directory and assumes that the map key is the hostname of an NFS server. The
automountd daemon dynamically constructs a map entry from the server’s list of exported file
systems. References to a directory under /net/hermes will refer to the corresponding
directory relative to hermes root.

The -null map cancels a previous map for the directory indicated. This is most useful in the
/etc/auto_master for cancelling entries that would otherwise be inherited from the
+auto_master include entry. To be effective, the -null entries must be inserted before the
included map entry.

Executable Maps
Local maps that have the execute bit set in their file permissions will be executed by the
automounter and provided with a key to be looked up as an argument. The executable map is
expected to return the content of an automounter map entry on its stdout or no output if the
entry cannot be determined. A direct map cannot be made executable.

Configuration and the auto_master Map
When initiated without arguments, automount consults the master map for a list of autosfs
mount points and their maps. It mounts any autosfs mounts that are not already mounted,
and unmounts autosfs mounts that have been removed from the master map or direct map.

The master map is assumed to be called auto_master and its location is determined by the
name service switch policy. Normally the master map is located initially as a local file
/etc/auto_master.

Browsing
The automountd supports the browsability of indirect maps. This allows all of the potential
mount points to be visible, whether or not they are mounted. The -nobrowse option can be
added to any indirect autosfs map to disable browsing. For example:
In this case, any hostnames would only be visible in /net after they are mounted, but all potential mount points would be visible under /home. The -browse option enables browsability of autofs file systems. This is the default for all indirect maps.

The -browse option does not work in conjunction with the wildcard key.

Options specified for a map are used as the default options for all the entries in that map. They are ignored when map entries specify their own mount options.

In some cases, however, it is desirable to force nosuid, nodevices, nosetuid, or noexec for a complete mount map and its submounts. This can be done by specifying the additional mount option, -restrict.

The -restrict option forces the inheritance of all the restrictive options nosuid, nodevices, nosetuid, and noexec as well as the restrict option itself. In this particular example, the nosuid and restrict option are inherited but the hard option is not. The restrict option also prevents the execution of “executable maps” and is enforced for auto mounts established by programs with fewer than all privileges available in their zone.

The following exit values are returned:

0 Successful completion.
1 An error occurred.

Files
/etc/auto_master Master autount map.
/etc/auto_home Map to support automounted home directories.
/etc/default/autofs Supplies default values for parameters for automount and automountd. See autofs(4).
/etc/nsswitch.conf Name service switch configuration file. See nsswitch.conf(4).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

System Administration Guide: IP Services
autofs mount points must not be hierarchically related. automount does not allow an autofs mount point to be created within another autofs mount.

Since each direct map entry results in a new autofs mount such maps should be kept short.

Entries in both direct and indirect maps can be modified at any time. The new information is used when automountd next uses the map entry to do a mount.

New entries added to a master map or direct map will not be useful until the automount command is run to install them as new autofs mount points. New entries added to an indirect map may be used immediately.

As of the Solaris 2.6 release, a listing (see \texttt{ls(1)}) of the autofs directory associated with an indirect map shows all potential mountable entries. The attributes associated with the potential mountable entries are temporary. The real file system attributes will only be shown once the file system has been mounted.

Default mount options can be assigned to an entire map when specified as an optional third field in the master map. These options apply only to map entries that have no mount options. Note that map entities with options override the default options, as at this time, the options do not concatenate. The concatenation feature is planned for a future release.

When operating on a map that invokes an NFS mount, the default number of retries for the automounter is 0, that is, a single mount attempt, with no retries. Note that this is significantly different from the default (10000) for the \texttt{mount_nfs(1M)} utility.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same.

The automount service is managed by the service management facility, \texttt{smf(5)}, under the service identifier:

\texttt{svc:/system/filesystem/autofs:default}

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using \texttt{svcadm(1M)}. The service's status can be queried using the \texttt{svcs(1)} command.
automountd(1M)

Name  automountd – autofs mount/unmount daemon

Synopsis  automountd [-Tvn] [-D name=value]

Description  automountd is an RPC server that answers file system mount and unmount requests from the autofs file system. It uses local files or name service maps to locate file systems to be mounted. These maps are described with the automount(1M) command.

If automount finds any non-trivial entries in either the local or distributed automount maps and if the daemon is not running already, the automountd daemon is automatically invoked by automount(1M). automountd enables the svc:/network/nfs/nlockmgr service (lockd(1M)), and the svc:/network/nfs/status service (statd(1M)), if NFS mounts need to be done.

At startup, the automountd daemon is invoked as is invoked as the system/filesystem/autofs:default service. See NOTES.

Options  The following options are supported:

-D name=value  Assign value to the indicated automount map substitution variable. These assignments cannot be used to substitute variables in the master map auto_master.

-n  Turn off browsing for all autofs mount points. This option overrides the -browse autofs map option on the local host.

-T  Trace. Expand each RPC call and display it on the standard output.

-v  Verbose. Log status messages to the console.

Usage  See largefile(5) for the description of the behavior of automountd when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Files  /etc/auto_master  Master map for automounter.

/etc/default/autofs  Supplies default values for parameters for automount and automountd. See autofs(4).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  svcs(1), automount(1M), svcadm(1M), autofs(4), attributes(5), largefile(5), smf(5)

Notes  The automountd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/filesystem/autofs
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using `svcs(1)`. If it is disabled, it is enabled by `automount(1M)` unless the `application/auto_enable` property is set to `false`.
autopush(1M)

**Name**
autopush – configures lists of automatically pushed STREAMS modules

**Synopsis**

```
autopush -f filename
autopush -g -M major -m minor
autopush -r -M major -m minor
```

**Description**
The autopush command configures the list of modules to be automatically pushed onto the stream when a device is opened. It can also be used to remove a previous setting or get information on a setting.

**Options**
The following options are supported:

- `-f filename`
  Sets up the autopush configuration for each driver according to the information stored in `filename`. An autopush file consists of lines of four or more fields, separated by spaces as shown below:

  
  major minor last-minor module1 module2 ... module8

  The first field is a string that specifies the `major` device name, as listed in the `/kernel/drv` directory. The next two fields are integers that specify the `minor` device number and `last-minor` device number. The fields following represent the names of modules. If `minor` is −1, then all minor devices of a major driver specified by `major` are configured, and the value for `last-minor` is ignored. If `last-minor` is 0, then only a single minor device is configured. To configure a range of minor devices for a particular `major`, `minor` must be less than `last-minor`.

  The remaining fields list the names of modules to be automatically pushed onto the stream when opened, along with the position of an optional anchor. The maximum number of modules that can be pushed is eight. The modules are pushed in the order they are specified. The optional special character sequence `[anchor]` indicates that a STREAMS anchor should be placed on the stream at the module previously specified in the list; it is an error to specify more than one anchor or to have an anchor first in the list.

  A nonzero exit status indicates that one or more of the lines in the specified file failed to complete successfully.

- `-g`
  Gets the current configuration setting of a particular `major` and `minor` device number specified with the `-M` and `-m` options respectively and displays the autopush modules associated with it. It will also return the starting minor device number if the request corresponds to a setting of a range (as described with the `-f` option).

- `-m minor`
  Specifies the minor device number.

- `-M major`
  Specifies the major device number.
-r Removes the previous configuration setting of the particular major and minor device number specified with the -M and -m options respectively. If the values of major and minor correspond to a previously established setting of a range of minor devices, where minor matches the first minor device number in the range, the configuration would be removed for the entire range.

Exit Status The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

Examples EXAMPLE 1 Using the autopush command.
The following example gets the current configuration settings for the major and minor device numbers as indicated and displays the autopush modules associated with them for the character-special device /dev/term/a:

```
example# autopush -g -M 29 -m 0
Major Minor Lastminor Modules
 29   0   1   ldterm ttcompat
```

STREAMS Programming Guide
bart(1M)

Name   bart – basic audit reporting tool

Synopsis  
/usr/bin/bart create [-n] [-R root_directory]  
[-r rules_file] [-]

/usr/bin/bart create [-n] [-R root_directory] -I [file_name]...

/usr/bin/bart compare [-i attribute] [-p]  
[-r rules_file] [-] control-manifest test-manifest

Description  bart(1M) is a tool that performs a file-level check of the software contents of a system.

You can also specify the files to track and the types of discrepancies to flag by means of a rules file, bart_rules. See bart_rules(4).

The bart utility performs two basic functions:

bart create   The manifest generator tool takes a file-level snapshot of a system. The output is a catalog of file attributes referred to as a manifest. See bart_manifest(4).

You can specify that the list of files be cataloged in three ways. Use bart create with no options, specify the files by name on the command line, or create a rules file with directives that specify which the files to monitor. See bart_rules(4).

By default, the manifest generator catalogs all attributes of all files in the root (/) file system. File systems mounted on the root file system are cataloged only if they are of the same type as the root file system.

For example, /, /usr, and /opt are separate UFS file systems. /usr and /opt are mounted on /. Therefore, all three file systems are cataloged. However, /tmp, also mounted on /, is not cataloged because it is a TMPFS file system. Mounted CD-ROMs are not cataloged since they are HSFS file systems.

bart compare   The report tool compares two manifests. The output is a list of per-file attribute discrepancies. These discrepancies are the differences between two manifests: a control manifest and a test manifest.

A discrepancy is a change to any attribute for a given file cataloged by both manifests. A new file or a deleted file in a manifest is reported as a discrepancy.

The reporting mechanism provides two types of output: verbose and programmatic. Verbose output is localized and presented on multiple lines, while programmatic output is more easily parsable by other programs. See OUTPUT.
By default, the report tool generates verbose output where all discrepancies are reported except for modified directory timestamps (dirmtime attribute).

To ensure consistent and accurate comparison results, control-manifest and test-manifest must be built with the same rules file.

Use the rules file to ignore specified files or subtrees when you generate a manifest or compare two manifests. Users can compare manifests from different perspectives by re-running the bart compare command with different rules files.

**Options**  The following options are supported:

- `-i attribute ...` Specify the file attributes to be ignored globally. Specify attributes as a comma separated list.

  This option produces the same behavior as supplying the file attributes to a global IGNORE keyword in the rules file. See bart_rules(4).

- `-I [file_name...]` Specify the input list of files. The file list can be specified at the command line or read from standard input.

- `-n` Prevent computation of content signatures for all regular files in the file list.

- `-p` Display manifest comparison output in “programmatic mode,” which is suitable for programmatic parsing. The output is not localized.

- `-r rules_file` Use rules_file to specify which files and directories to catalog, and to define which file attribute discrepancies to flag. If rules_file is -, then the rules are read from standard input. See bart_rules(4) for the definition of the syntax.

- `-R root_directory` Specify the root directory for the manifest. All paths specified by the rules, and all paths reported in the manifest, are relative to root_directory.

**Note** - The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

**Operands**  bart allows quoting of operands. This is particularly important for white-space appearing in subtree and subtree modifier specifications.

The following operands are supported:

- `control-manifest` Specify the manifest created by bart create on the control system.

- `test-manifest` Specify the manifest created by bart create on the test system.
### Output

The `bart` create and `bart` compare commands write output to standard output, and write error messages to standard error.

The `bart` create command generates a system manifest. See `bart_manifest(4)`.

When the `bart` compare command compares two system manifests, it generates a list of file differences. By default, the comparison output is localized. However, if the `-p` option is specified, the output is generated in a form that is suitable for programmatic manipulation.

#### Default Format

```
filename attribute control:xxx test:yyy
```

- **filename**: Name of the file that differs between `control-manifest` and `test-manifest`. For file names that contain embedded whitespace or newline characters, see `bart_manifest(4)`.

- **attribute**: The name of the file attribute that differs between the manifests that are compared. `xxx` is the attribute value from `control-manifest`, and `yyy` is the attribute value from `test-manifest`. When discrepancies for multiple attributes occur for the same file, each difference is noted on a separate line.

The following attributes are supported:

- `acl` - ACL attributes for the file. For a file with ACL attributes, this field contains the output from `acltotext()`.
- `all` - All attributes.
- `contents` - Checksum value of the file. This attribute is only specified for regular files. If you turn off context checking or if checksums cannot be computed, the value of this field is `-.`.
- `dest` - Destination of a symbolic link.
- `devnode` - Value of the device node. This attribute is for character device files and block device files only.
- `dirmtime` - Modification time in seconds since 00:00:00 UTC, January 1, 1970 for directories.
- `gid` - Numerical group ID of the owner of this entry.
- `lnmtime` - Creation time for links.
- `mode` - Octal number that represents the permissions of the file.
- `mtime` - Modification time in seconds since 00:00:00 UTC, January 1, 1970 for files.
- `size` - File size in bytes.
- `type` - Type of file.
The following default output shows the attribute differences for the 
/etc/passwd file. The output indicates that the size, mtime, and contents attributes have changed.

/etc/passwd:
    size control:74 test:81
    mtime control:3c165879 test:3c165979
    contents control:daca28ae0de97af7a6b91fde8d57afa
test:84b2b32c4165887355317207b48a6ec7

The following programmatic output shows the attribute differences for the /etc/passwd file. The output indicates that the size, mtime, and contents attributes have changed.

/etc/passwd size 74 81 mtime 3c165879 3c165979
contents daca28ae0de97af7a6b91fde8d57afa 84b2b32c4165887355317207b48a6ec7

Each line of the programmatic output describes all attribute differences for a single file.

The following programmatic output shows the attribute differences for the /etc/passwd file. The output indicates that the size, mtime, and contents attributes have changed.

/etc/passwd size 74 81 mtime 3c165879 3c165979
contents daca28ae0de97af7a6b91fde8d57afa 84b2b32c4165887355317207b48a6ec7

Exit Status

Manifest Generator The manifest generator returns the following exit values:

0  Success
1  Non-fatal error when processing files; for example, permission problems
>1  Fatal error; for example, invalid command-line options

Report Tool The report tool returns the following exit values:

0  No discrepancies reported
1  Discrepancies found
>1  Fatal error executing comparison

Examples

EXAMPLE 1  Creating a Default Manifest Without Computing Checksums

The following command line creates a default manifest, which consists of all files in the / file system. The -n option prevents computation of checksums, which causes the manifest to be generated more quickly.
EXAMPLE 1  Creating a Default Manifest Without Computing Checksums  (Continued)

bart create -n

EXAMPLE 2  Creating a Manifest for a Specified Subtree
The following command line creates a manifest that contains all files in the /home/nickiso subtree.

bart create -R /home/nickiso

EXAMPLE 3  Creating a Manifest by Using Standard Input
The following command line uses output from the find(1) command to generate the list of files to be cataloged. The find output is used as input to the bart create command that specifies the -I option.

find /home/nickiso -print | bart create -I

EXAMPLE 4  Creating a Manifest by Using a Rules File
The following command line uses a rules file, rules, to specify the files to be cataloged.

bart create -r rules

EXAMPLE 5  Comparing Two Manifests and Generating Programmatic Output
The following command line compares two manifests and produces output suitable for parsing by a program.

bart compare -p manifest1 manifest2

EXAMPLE 6  Comparing Two Manifests and Specifying Attributes to Ignore
The following command line compares two manifests. The dirmtime, lnmtime, and mtime attributes are not compared.

bart compare -i dirmtime,lnmtime,mtime manifest1 manifest2

EXAMPLE 7  Comparing Two Manifests by Using a Rules File
The following command line uses a rules file, rules, to compare two manifests.

bart compare -r rules manifest1 manifest2

Notes
The file attributes of certain system libraries can be temporarily altered by the system as it boots. To avoid triggering false warnings, you should compare manifests only if they were both created with the system in the same state; that is, if both were created in single-user or both in multi-user.
**Name**
bdconfig – configures the bd (buttons and dials) stream

**Synopsis**
bdconfig [startup] [off] [on] [term] [status] [verbose]

**Description**
The `bdconfig` utility is responsible for configuring the autopush facility and defining to the system what serial device to use for the bd stream.

**Options**
If no options are given, then an interactive mode is assumed. In this mode the current status is presented along with this usage line, and a series of interactive questions asked to determine the user’s desires.

Root privilege is required to change the configuration. The status option does not require root privilege. `bdconfig` can be installed as a setuid root program.

The non-interactive options below can be given in any order.

- **term**
  Specify to the system the serial device for bd use. This option implies the on option unless the off option is present.

- **iff**
  Reconfigure the configured term for tty use.

- **on**
  Reconfigure the configured term for bd use. If term has not been previously specified, interactive questions are asked to determine the user’s desires.

- **startup**
  Configure as was last configured before the system went down. This option is used by the startup script, and precludes the use of the on, off, and term options. This option implies non-interactive mode.

- **status**
  Emit the current configuration in terms of the words used as options: off, on, /dev/term/a, /dev/term/b, and so forth. This option implies non interactive mode.

- **verbose**
  bdconfig describes what it finds and what it is doing.

**Exit Status**
The `bdconfig` utility returns 0 on success, 1 on general error, and 2 on argument error.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdialh</td>
</tr>
</tbody>
</table>

**See Also**
`autopush(1M), attributes(5), x_buttonstest(6), x_dialtest(6), bd(7M), sad(7D), streamio(7I)`

**Notes**
All `bdconfig` does is configure the AUTOPUSH facility. `bdconfig` does not actually manipulate the serial port or stream in any way. Only the first open of a dismantled stream will see the effects of a previously run `bdconfig`. 
The bdconfig utility is silent except for error messages unless:

a) invoked with no args: status / usage line emitted
b) interactive modes are invoked as described above
c) the verbose option is used

**Bugs** The interface does not support more than one dialbox and one buttonbox, both of which must be on the same serial device.

There should be a library routine to read, parse, and validate records in the `iu.ap` file, so that `bdconfig` could return to the appropriate record in `iu.ap` as the default configuration.
boot – start the system kernel or a standalone program

**Synopsis**

**SPARC**

```
boot [OBP names] [file] [-aLV] [-F object] [-0 default-file]
     [-Z dataset] [boot-flags] [---] [client-program-args]
```

**x86**

```
kernel$ /platform/i86pc/kernel/$ISADIR/unix [boot-args]
     [-B prop= val [, val ...]]
```

**Description**

Bootstrapping is the process of loading and executing a standalone program. For the purpose of this discussion, bootstrapping means the process of loading and executing the bootable operating system. Typically, the standalone program is the operating system kernel (see `kernel(1M)`), but any standalone program can be booted instead. On a SPARC-based system, the diagnostic monitor for a machine is a good example of a standalone program other than the operating system that can be booted. If the standalone is identified as a dynamically-linked executable, `boot` will load the interpreter (linker/loader) as indicated by the executable format and then transfer control to the interpreter. If the standalone is statically-linked, it will jump directly to the standalone.

Once the kernel is loaded, it starts the UNIX system, mounts the necessary filesystems (see `vfstab(4)`), and runs `/sbin/init` to bring the system to the “initdefault” state specified in `/etc/inittab`. See `inittab(4)`.

**SPARC Bootstrap Procedure**

On SPARC based systems, the bootstrap procedure on most machines consists of the following basic phases.

After the machine is turned on, the system firmware (in PROM) executes power-on self-test (POST). The form and scope of these tests depends on the version of the firmware in your system.

After the tests have been completed successfully, the firmware attempts to autoboot if the appropriate flag has been set in the non-volatile storage area used by the firmware. The name of the file to load, and the device to load it from can also be manipulated.

These flags and names can be set using the `eeprom(1M)` command from the shell, or by using PROM commands from the `ok` prompt after the system has been halted.

The second level program is either a filesystem-specific boot block (when booting from a disk), or `inetboot` or `wanboot` (when booting across the network).

**Network Booting**

Network booting occurs in two steps: the client first obtains an IP address and any other parameters necessary to permit it to load the second-stage booter. The second-stage booter in turn loads the boot archive from the boot device.
An IP address can be obtained in one of three ways: RARP, DHCP, or manual configuration, depending on the functions available in and configuration of the PROM. Machines of the sun4u and sun4v kernel architectures have DHCP-capable PROMs.

The boot command syntax for specifying the two methods of network booting are:

```bash
boot net:rarp
boot net:dhcp
```

The command:

```bash
boot net
```

without a `rarp` or `dhcp` specifier, invokes the default method for network booting over the network interface for which `net` is an alias.

The sequence of events for network booting using RARP/bootparams is described in the following paragraphs. The sequence for DHCP follows the RARP/bootparams description.

When booting over the network using RARP/bootparams, the PROM begins by broadcasting a reverse ARP request until it receives a reply. When a reply is received, the PROM then broadcasts a TFTP request to fetch the first block of `inetboot`. Subsequent requests will be sent to the server that initially answered the first block request. After loading, `inetboot` will also use reverse ARP to fetch its IP address, then broadcast `bootparams` RPC calls (see `bootparams(4)`) to locate configuration information and its root file system. `inetboot` then loads the boot archive by means of NFS and transfers control to that archive.

When booting over the network using DHCP, the PROM broadcasts the hardware address and kernel architecture and requests an IP address, boot parameters, and network configuration information. After a DHCP server responds and is selected (from among potentially multiple servers), that server sends to the client an IP address and all other information needed to boot the client. After receipt of this information, the client PROM examines the name of the file to be loaded, and will behave in one of two ways, depending on whether the file’s name appears to be an HTTP URL. If it does not, the PROM downloads `inetboot`, loads that file into memory, and executes it. `inetboot` loads the boot archive, which takes over the machine and releases `inetboot`. Startup scripts then initiate the DHCP agent (see `dhcppagent(1M)`), which implements further DHCP activities.

If the file to be loaded is an HTTP URL, the PROM will use HTTP to load the referenced file. If the client has been configured with an HMAC SHA-1 key, it will check the integrity of the loaded file before proceeding to execute it. The file is expected to be the `wanboot` binary. The WAN boot process can be configured to use either DHCP or NVRAM properties to discover the install server and router and the proxies needed to connect to it. When `wanboot` begins executing, it determines whether sufficient information is available to it to allow it to proceed. If any necessary information is missing, it will either exit with an appropriate error or bring up a command interpreter and prompt for further configuration information. Once `wanboot` has
obtained the necessary information, it loads the boot loader into memory by means of HTTP.
If an encryption key has been installed on the client, wanboot will verify the boot loader’s
signature and its accompanying hash. Presence of an encryption key but no hashing key is an
error.

The wanboot boot loader can communicate with the client using either HTTP or secure HTTP.
If the former, and if the client has been configured with an HMAC SHA-1 key, the boot loader
will perform an integrity check of the root file system. Once the root file system has been
loaded into memory (and possibly had an integrity check performed), the boot archive is
transferred from the server. If provided with a boot_logger URL by means of the
wanboot.conf(4) file, wanboot will periodically log its progress.

Not all PROMs are capable of consuming URLs. You can determine whether a client is so
capable using the list-security-keys OBP command (see monitor(1M)).

WAN booting is not currently available on the x86 platform.

The wanboot Command Line

When the client program is wanboot, it accepts client-program-args of the form:

   boot ... -o opt1[,opt2[,...]]

where each option may be an action:

dhcp
   Require wanboot to obtain configuration parameters by means of DHCP.

prompt
   Cause wanboot to enter its command interpreter.

<cmd>
   One of the interpreter commands listed below.

...or an assignment, using the interpreter's parameter names listed below.

The wanboot Command Interpreter

The wanboot command interpreter is invoked by supplying a client-program-args of
"-o prompt" when booting. Input consists of single commands or assignments, or a
comma-separated list of commands or assignments. The configuration parameters are:

host-ip
   IP address of the client (in dotted-decimal notation)

router-ip
   IP address of the default router (in dotted-decimal notation)

subnet-mask
   subnet mask (in dotted-decimal notation)
client-id
  DHCP client identifier (a quoted ASCII string or hex ASCII)
hostname
  hostname to request in DHCP transactions (ASCII)
http-proxy
  HTTP proxy server specification ([IPADDR[:PORT]])

The key names are:

3des
  the triple DES encryption key (48 hex ASCII characters)
aes
  the AES encryption key (32 hex ASCII characters)
sha1
  the HMAC SHA-1 signature key (40 hex ASCII characters)

Finally, the URL or the WAN boot CGI is referred to by means of:

bootserver
  URL of WAN boot's CGI (the equivalent of OBP's file parameter)

The interpreter accepts the following commands:

help
  Print a brief description of the available commands

var=val
  Assign val to var, where var is one of the configuration parameter names, the key names, or bootserver.

var=
  Unset parameter var.

list
  List all parameters and their values (key values retrieved by means of OBP are never shown).

prompt
  Prompt for values for unset parameters. The name of each parameter and its current value (if any) is printed, and the user can accept this value (press Return) or enter a new value.

go
  Once the user is satisfied that all values have been entered, leave the interpreter and continue booting.

exit
  Quit the boot interpreter and return to OBP's ok prompt.
Any of these assignments or commands can be passed on the command line as part of the -o options, subject to the OBP limit of 128 bytes for boot arguments. For example, -o list, go would simply list current (default) values of the parameters and then continue booting.

**Booting from Disk**

When booting from disk, the OpenBoot PROM firmware reads the boot blocks from blocks 1 to 15 of the partition specified as the boot device. This standalone booter usually contains a file system-specific reader capable of reading the boot archive.

If the pathname to the standalone is relative (does not begin with a slash), the second level boot will look for the standalone in a platform-dependent search path. This path is guaranteed to contain /platform/platform-name. Many SPARC platforms next search the platform-specific path entry /platform/hardware-class-name. See filesystem(5). If the pathname is absolute, boot will use the specified path. The boot program then loads the standalone at the appropriate address, and then transfers control.

Once the boot archive has been transferred from the boot device, Solaris can initialize and take over control of the machine. This process is further described in the "Boot Archive Phase," below, and is identical on all platforms.

If the filename is not given on the command line or otherwise specified, for example, by the boot-file NVRAM variable, boot chooses an appropriate default file to load based on what software is installed on the system and the capabilities of the hardware and firmware.

The path to the kernel must not contain any whitespace.

**Booting from ZFS**

Booting from ZFS differs from booting from UFS in that, with ZFS, a device specifier identifies a storage pool, not a single root file system. A storage pool can contain multiple bootable datasets (that is, root file systems). Therefore, when booting from ZFS, it is not sufficient to specify a boot device. One must also identify a root file system within the pool that was identified by the boot device. By default, the dataset selected for booting is the one identified by the pool's bootfs property. This default selection can be overridden by specifying an alternate bootable dataset with the -Z option.

**Boot Archive Phase**

The boot archive contains a file system image that is mounted using an in-memory disk. The image is self-describing, specifically containing a file system reader in the boot block. This file system reader mounts and opens the RAM disk image, then reads and executes the kernel contained within it. By default, this kernel is in:

/platform/ uname -i/kernel/unix

If booting from ZFS, the pathnames of both the archive and the kernel file are resolved in the root file system (that is, dataset) selected for booting as described in the previous section.

The initialization of the kernel continues by loading necessary drivers and modules from the in-memory filesystem until I/O can be turned on and the root filesystem mounted. Once the root filesystem is mounted, the in-memory filesystem is no longer needed and is discarded.
The OpenBoot boot command takes arguments of the following form:

```
ok boot [device-specifier] [arguments]
```

The default boot command has no arguments:

```
ok boot
```

If no `device-specifier` is given on the `boot` command line, OpenBoot typically uses the `boot-device` or `diag-device` NVRAM variable. If no optional `arguments` are given on the command line, OpenBoot typically uses the `boot-file` or `diag-file` NVRAM variable as default boot arguments. (If the system is in diagnostics mode, `diag-device` and `diag-file` are used instead of `boot-device` and `boot-file`).

`arguments` may include more than one string. All argument strings are passed to the secondary booter; they are not interpreted by OpenBoot.

If any `arguments` are specified on the `boot` command line, then neither the `boot-file` nor the `diag-file` NVRAM variable is used. The contents of the NVRAM variables are not merged with command line arguments. For example, the command:

```
ok boot -s
```

ignores the settings in both `boot-file` and `diag-file`; it interprets the string "-s" as arguments. boot will not use the contents of `boot-file` or `diag-file`.

With older PROMs, the command:

```
ok boot net
```

took no arguments, using instead the settings in `boot-file` or `diag-file` (if set) as the default file name and arguments to pass to boot. In most cases, it is best to allow the boot command to choose an appropriate default based upon the system type, system hardware and firmware, and upon what is installed on the root file system. Changing `boot-file` or `diag-file` can generate unexpected results in certain circumstances.

This behavior is found on most OpenBoot 2.x and 3.x based systems. Note that differences may occur on some platforms.

The command:

```
ok boot cdrom
```

...also normally takes no arguments. Accordingly, if `boot-file` is set to the 64-bit kernel filename and you attempt to boot the installation CD or DVD with `boot cdrom`, boot will fail if the installation media contains only a 32-bit kernel.

Because the contents of `boot-file` or `diag-file` can be ignored depending on the form of the boot command used, reliance upon `boot-file` should be discouraged for most production systems.

When executing a WAN boot from a local (CD or DVD) copy of wanboot, one must use:
Modern PROMs have enhanced the network boot support package to support the following syntax for arguments to be processed by the package:

\[protocol,][key=value,]*

All arguments are optional and can appear in any order. Commas are required unless the argument is at the end of the list. If specified, an argument takes precedence over any default values, or, if booting using DHCP, over configuration information provided by a DHCP server for those parameters.

*protocol*, above, specifies the address discovery protocol to be used.

Configuration parameters, listed below, are specified as *key=value* attribute pairs.

- **tftp-server**
  - IP address of the TFTP server
- **file**
  - file to download using TFTP or URL for WAN boot
- **host-ip**
  - IP address of the client (in dotted-decimal notation)
- **router-ip**
  - IP address of the default router
- **subnet-mask**
  - subnet mask (in dotted-decimal notation)
- **client-id**
  - DHCP client identifier
- **hostname**
  - hostname to use in DHCP transactions
- **http-proxy**
  - HTTP proxy server specification (IPADDR[:PORT])
- **tftp-retries**
  - maximum number of TFTP retries
- **dhcp-retries**
  - maximum number of DHCP retries

The list of arguments to be processed by the network boot support package is specified in one of two ways:

- As arguments passed to the package's `open` method, or
- arguments listed in the NVRAM variable `network-boot-arguments`.
Arguments specified in network-boot-arguments will be processed only if there are no arguments passed to the package’s open method.

Argument Values

protocol specifies the address discovery protocol to be used. If present, the possible values are rarp or dhcp.

If other configuration parameters are specified in the new syntax and style specified by this document, absence of the protocol parameter implies manual configuration.

If no other configuration parameters are specified, or if those arguments are specified in the positional parameter syntax currently supported, the absence of the protocol parameter causes the network boot support package to use the platform-specific default address discovery protocol.

Manual configuration requires that the client be provided its IP address, the name of the boot file, and the address of the server providing the boot file image. Depending on the network configuration, it might be required that subnet-mask and router-ip also be specified.

If the protocol argument is not specified, the network boot support package uses the platform-specific default address discovery protocol.

tftp-server is the IP address (in standard IPv4 dotted-decimal notation) of the TFTP server that provides the file to download if using TFTP.

When using DHCP, the value, if specified, overrides the value of the TFTP server specified in the DHCP response.

The TFTP RRQ is unicast to the server if one is specified as an argument or in the DHCP response. Otherwise, the TFTP RRQ is broadcast.

file specifies the file to be loaded by TFTP from the TFTP server, or the URL if using HTTP. The use of HTTP is triggered if the file name is a URL, that is, the file name starts with http: (case-insensitive).

When using RARP and TFTP, the default file name is the ASCII hexadecimal representation of the IP address of the client, as documented in a preceding section of this document.

When using DHCP, this argument, if specified, overrides the name of the boot file specified in the DHCP response.

When using DHCP and TFTP, the default file name is constructed from the root node’s name property, with commas (,) replaced by periods (.).

When specified on the command line, the filename must not contain slashes (/).

The format of URLs is described in RFC 2396. The HTTP server must be specified as an IP address (in standard IPv4 dotted-decimal notation). The optional port number is specified in decimal. If a port is not specified, port 80 (decimal) is implied.
The URL presented must be "safe-encoded", that is, the package does not apply escape encodings to the URL presented. URLs containing commas must be presented as a quoted string. Quoting URLs is optional otherwise.

host -ip specifies the IP address (in standard IPv4 dotted-decimal notation) of the client, the system being booted. If using RARP as the address discovery protocol, specifying this argument makes use of RARP unnecessary.

If DHCP is used, specifying the host -ip argument causes the client to follow the steps required of a client with an "Externally Configured Network Address", as specified in RFC 2131.

router -ip is the IP address (in standard IPv4 dotted-decimal notation) of a router on a directly connected network. The router will be used as the first hop for communications spanning networks. If this argument is supplied, the router specified here takes precedence over the preferred router specified in the DHCP response.

subnet -mask (specified in standard IPv4 dotted-decimal notation) is the subnet mask on the client’s network. If the subnet mask is not provided (either by means of this argument or in the DHCP response), the default mask appropriate to the network class (Class A, B, or C) of the address assigned to the booting client will be assumed.

client -id specifies the unique identifier for the client. The DHCP client identifier is derived from this value. Client identifiers can be specified as:

- The ASCII hexadecimal representation of the identifier, or
- a quoted string

Thus, client -id="openboot" and client -id=6f70656e626f6f74 both represent a DHCP client identifier of 6F70656E626F6F74.

Identifiers specified on the command line must not include slash (/) or spaces.

The maximum length of the DHCP client identifier is 32 bytes, or 64 characters representing 32 bytes if using the ASCII hexadecimal form. If the latter form is used, the number of characters in the identifier must be an even number. Valid characters are 0-9, a-f, and A-F.

For correct identification of clients, the client identifier must be unique among the client identifiers used on the subnet to which the client is attached. System administrators are responsible for choosing identifiers that meet this requirement.

Specifying a client identifier on a command line takes precedence over any other DHCP mechanism of specifying identifiers.

hostname (specified as a string) specifies the hostname to be used in DHCP transactions. The name might or might not be qualified with the local domain name. The maximum length of the hostname is 255 characters.
Note – The `hostname` parameter can be used in service environments that require that the client provide the desired hostname to the DHCP server. Clients provide the desired hostname to the DHCP server, which can then register the hostname and IP address assigned to the client with DNS.

`http-proxy` is specified in the following standard notation for a host:

```
host [";"" port]
```

...where `host` is specified as an IP address (in standard IPv4 dotted-decimal notation) and the optional `port` is specified in decimal. If a port is not specified, port 8080 (decimal) is implied.

`tftp-retries` is the maximum number of retries (specified in decimal) attempted before the TFTP process is determined to have failed. Defaults to using infinite retries.

`dhcp-retries` is the maximum number of retries (specified in decimal) attempted before the DHCP process is determined to have failed. Defaults to of using infinite retries.

On x86 based systems, the bootstrapping process consists of two conceptually distinct phases, kernel loading and kernel initialization. Kernel loading is implemented in GRUB (GRand Unified Bootloader) using the BIOS ROM on the system board, and BIOS extensions in ROMs on peripheral boards. The BIOS loads GRUB, starting with the first physical sector from a hard disk, DVD, or CD. If supported by the ROM on the network adapter, the BIOS can also download the `pxegrub` binary from a network boot server. Once GRUB is located, it executes a command in a menu to load the `unix` kernel and a pre-constructed boot archive containing kernel modules and data.

If the device identified by GRUB as the boot device contains a ZFS storage pool, the `menu.lst` file used to create the GRUB menu will be found in the dataset at the root of the pool’s dataset hierarchy. This is the dataset with the same name as the pool itself. There is always exactly one such dataset in a pool, and so this dataset is well-suited for pool-wide data such as the `menu.lst` file. After the system is booted, this dataset is mounted at `/poolname` in the root file system.

There can be multiple bootable datasets (that is, root file systems) within a pool. By default, the file system in which file name entries in a `menu.lst` file are resolved is the one identified by the pool’s `bootfs` property (see `zpool(1M)`). However, a `menu.lst` entry can contain a `bootfs` command, which specifies an alternate dataset in the pool. In this way, the `menu.lst` file can contain entries for multiple root file systems within the pool.

Kernel initialization starts when GRUB finishes loading the boot archive and hands control over to the `unix` binary. At this point, GRUB becomes inactive and no more I/O occurs with the boot device. The Unix operating system initializes, links in the necessary modules from the boot archive and mounts the root file system on the real root device. At this point, the kernel regains storage I/O, mounts additional file systems (see `vfstab(4)`), and starts various operating system services (see `smf(5)`).
The Solaris operating system supports an `smf(5)` property that enables a system to automatically reboot from the current boot device, to recover from conditions such as an out-of-date boot archive.

The service `svc:/system/boot-config:default` contains the boolean property `auto-reboot-safe`, which is set to `false` by default. Setting it to `true` communicates that both the system's BIOS and default GRUB menu entry are set to boot from the current boot device. The value of this property can be changed using `svccfg(1M)` and `svcadm(1M)`. For example, to set `auto-reboot-safe` to enable automatic rebooting, enter a command such as:

```
example# svccfg -s svc:/system/boot-config:default \
    setprop config/auto-reboot-safe = true
```

Most systems are configured for automatic reboot from the current boot device. However, in some instances, automatic rebooting to an unknown operating system might produce undesirable results. For these instances, the `auto-reboot-safe` property allows you to specify the behavior you want.

Failsafe Mode

A requirement of booting from a root filesystem image built into a boot archive then remounting root onto the actual root device is that the contents of the boot archive and the root filesystem must be consistent. Otherwise, the proper operation and integrity of the machine cannot be guaranteed.

The term “consistent” means that all files and modules in the root filesystem are also present in the boot archive and have identical contents. Since the boot strategy requires first reading and mounting the boot archive as the first-stage root image, all unloadable kernel modules and initialization derived from the contents of the boot archive are required to match the real root filesystem. Without such consistency, it is possible that the system could be running with a kernel module or parameter setting applied to the root device before reboot, but not yet updated in the root archive. This inconsistency could result in system instability or data loss.

Once the root filesystem is mounted, and before relinquishing the in-memory filesystem, Solaris performs a consistency verification against the two file systems. If an inconsistency is detected, Solaris suspends the normal boot sequence and falls back to failsafe mode. Correcting this state requires the administrator take one of two steps. The recommended procedure is to reboot to the failsafe archive and rebuild the boot archive. This ensures that a known kernel is booted and functioning for the archive rebuild process. Alternatively, the administrator can elect to clear the inconsistent boot archive service state and continue system bring-up if the inconsistency is such that correct system operation will not be impaired. See `svcadm(1M)`.

If the boot archive service is cleared and system bring-up is continued (the second alternative above), the system may be running with unloadable kernel drivers or other modules that are out-of-date with respect to the root filesystem. As such, correct system operation may be compromised.
To ensure that the boot archive is consistent, the normal system shutdown process, as initiated by `reboot(1M)` and `shutdown(1M)`, checks for and applies updates to the boot archive at the conclusion of the `umountall(1M)` milestone.

An update to any kernel file, driver, module or driver configuration file that needs to be included in the boot archive after the `umountall` service is complete will result in a failed boot archive consistency check during the next boot. To avoid this, it is recommended to always shut down a machine cleanly.

If an update is required to the kernel after completion of the `umountall` service, the administrator may elect to rebuild the archive by invoking:

```
# bootadm update-archive
```

The failsafe archive can be used to boot the machine at any time for maintenance or troubleshooting. The failsafe boot archive is installed on the machine, sourced from the miniroot archive. Booting the failsafe archive causes the machine to boot using the in-memory filesystem as the root device.

**SPARC**

The SPARC failsafe archive is:

```
/platform/ uname -i/ failsafe
```

...and can be booted as follows:

```
ok boot [device-specifier] -F failsafe
```

If a user wishes to boot a failsafe archive from a particular ZFS bootable dataset, this can be done as follows:

```
ok boot [device-specifier] -Z dataset -F failsafe
```

**x86**

The x86 failsafe archive is:

```
/boot/x86.miniroot-safe
```

...and can be booted by selecting the Solaris failsafe item from the GRUB menu.

**Options**

**SPARC**

The following SPARC options are supported:

- `-a`

  The boot program interprets this flag to mean ask me, and so it prompts for the name of the standalone. The ‘-a’ flag is then passed to the standalone program.
Explicitly specify the default-file. On some systems, boot chooses a dynamic default file, used when none is otherwise specified. This option allows the default-file to be explicitly set and can be useful when booting kmdb(1) since, by default, kmdb loads the default-file as exported by the boot program.

Boot using the named object. The object must be either an ELF executable or bootable object containing a boot block. The primary use is to boot the failsafe or wanboot boot archive.

List the bootable datasets within a ZFS pool. You can select one of the bootable datasets in the list, after which detailed instructions for booting that dataset are displayed. Boot the selected dataset by following the instructions. This option is supported only when the boot device contains a ZFS storage pool.

Display verbose debugging information.

The boot program passes all boot-flags to file. They are not interpreted by boot. See the kernel(1M) and kmdb(1) manual pages for information about the options available with the default standalone program.

The boot program passes all client-program-args to file. They are not interpreted by boot.

Name of a standalone program to boot. If a filename is not explicitly specified, either on the boot command line or in the boot-file NVRAM variable, boot chooses an appropriate default filename.

 Specify the open boot prom designations. For example, on Desktop SPARC based systems, the designation /sbus/esp@0,800000/sd@3,0:a indicates a SCSI disk (sd) at target 3, lun0 on the SCSI bus, with the esp host adapter plugged into slot 0.

Boot from the root file system in the specified ZFS dataset.

The following x86 options are supported:

One or more property-value pairs to be passed to the kernel. Multiple property-value pairs must be separated by a comma. Use of this option is the equivalent of the command: eeprom prop=val. See eeprom(1M) for available properties and valid values.

If the root file system corresponding to this menu entry is a ZFS dataset, the menu entry needs the following option added:
The boot program passes all boot-args to file. They are not interpreted by boot. See kernel(1M) and kmdb(1) for information about the options available with the kernel.

/platform/186pc/kernel/$ISADIR/unix
Name of the kernel to boot. When using the kernel $ token, $ISADIR expands toamd64 on 64-bit machines, and a null string on other machines. As a result of this dereferencing, this path expands to the proper kernel for the machine.

x86 Boot Sequence Details
After a PC-compatible machine is turned on, the system firmware in the BIOS ROM executes a power-on self test (POST), runs BIOS extensions in peripheral board ROMs, and invokes software interrupt INT 19h, Bootstrap. The INT 19h handler typically performs the standard PC-compatible boot, which consists of trying to read the first physical sector from the first diskette drive, or, if that fails, from the first hard disk. The processor then jumps to the first byte of the sector image in memory.

x86 Primary Boot
The first sector on a floppy disk contains the master boot block (GRUB stage1). The stage 1 is responsible for loading GRUB stage2. Now GRUB is fully functional. It reads and executes the menu file /boot/grub/menu.lst. A similar sequence occurs for DVD or CD boot, but the master boot block location and contents are dictated by the El Torito specification. The El Torito boot also leads to strap.com, which in turn loads boot.bin.

The first sector on a hard disk contains the master boot block, which contains the master boot program and the FDISK table, named for the PC program that maintains it. The master boot finds the active partition in the FDISK table, loads its first sector (GRUB stage1), and jumps to its first byte in memory. This completes the standard PC-compatible hard disk boot sequence. If GRUB stage1 is installed on the master boot block (see the -m option of installgrub(1M)), then stage2 is loaded directly from the Solaris FDISK partition regardless of the active partition.

An x86 FDISK partition for the Solaris software begins with a one-cylinder boot slice, which contains GRUB stage1 in the first sector, the standard Solaris disk label and volume table of contents (VTOC) in the second and third sectors, and GRUB stage2 in the fiftieth and subsequent sectors. The area from sector 4 to 49 might contain boot blocks for older versions of Solaris. This makes it possible for multiple Solaris releases on the same FDISK to coexist.

When the FDISK partition for the Solaris software is the active partition, the master boot program (mboot) reads the partition boot program in the first sector into memory and jumps to it. It in turn reads GRUB stage2 program into memory and jumps to it. Once the GRUB menu is displayed, the user can choose to boot an operating system on a different partition, a different disk, or possibly from the network.

For network booting, the supported method is Intel’s Preboot eXecution Environment (PXE) standard. When booting from the network using PXE, the system or network adapter BIOS uses DHCP to locate a network bootstrap program (pxegrub) on a boot server and reads it.
using Trivial File Transfer Protocol (TFTP). The BIOS executes the pxegrub by jumping to its first byte in memory. The pxegrub program downloads a menu file and presents the entries to user.

**x86 Kernel Startup**  
The kernel startup process is independent of the kernel loading process. During kernel startup, console I/O goes to the device specified by the console property.

When booting from UFS, the root device is specified by the bootpath property, and the root file system type is specified by the fstype property. These properties should be setup by the Solaris Install/Upgrade process in /boot/solaris/bootenv.rc and can be overridden with the -B option, described above (see the eeprom(1M) man page).

When booting from ZFS, the root device is specified by a boot parameter specified by the -B $ZFS-BOOTFS parameter on either the kernel or module line in the GRUB menu entry. This value (as with all parameters specified by the -B option) is passed by GRUB to the kernel.

If the console properties are not present, console I/O defaults to screen and keyboard. The root device defaults to ramdisk and the file system defaults to ufs.

### Examples

#### SPARC

**EXAMPLE 1**  
To Boot the Default Kernel In Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, respond to the ok prompt with one of the following:

```
boot -as
```

```
boot disk3 -as
```

**EXAMPLE 2**  
Network Booting with WAN Boot-Capable PROMs

To illustrate some of the subtle repercussions of various boot command line invocations, assume that the network-boot-arguments are set and that net is devaliased as shown in the commands below.

In the following command, device arguments in the device alias are processed by the device driver. The network boot support package processes arguments in network-boot-arguments.

```
boot net
```

The command below results in no device arguments. The network boot support package processes arguments in network-boot-arguments.

```
boot net:
```

The command below results in no device arguments. rarp is the only network boot support package argument. network-boot-arguments is ignored.

```
boot net:rarp
```
The command below results in the wanboot binary being loaded from DVD or CD, at which time wanboot will perform DHCP and then drop into its command interpreter to allow the user to enter keys and any other necessary configuration.

```
boot cdrom -F wanboot -o dhcp,prompt
```

**Example 4** To Boot the Default Kernel In 32-bit Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, edit the GRUB kernel command line to read:

```
kernel /platform/i86pc/kernel/unix -as
```

**Example 5** To Boot the Default Kernel In 64-bit Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, edit the GRUB kernel command line to read:

```
kernel /platform/i86pc/kernel/amd64/unix -as
```

**Example 6** Switching Between 32-bit and 64-bit Kernels on 64-bit x86 Platform

To be able to boot both 32-bit and 64-bit kernels, add entries for both kernels to 

```
/platform/grub/menu.lst
```

and use the set-menu subcommand of `bootadm(1M)` to switch. See `bootadm(1M)` for an example of the `bootadm set-menu`.

### Files

- `platform/platform-name/ufsboot`: Second-level program to boot from a disk, DVD, or CD
- `/etc/inittab`: Table in which the initdefault state is specified
- `/sbin/init`: Program that brings the system to the initdefault state
- `platform/platform-name/kernel/sparcv9/unix`: Default program to boot system.
- `/boot`: Directory containing boot-related files.
- `/boot/grub/menu.lst`: Menu of bootable operating systems displayed by GRUB.

---

**Example 2** Network Booting with WAN Boot-Capable PROMs  

(Continued)

In the command below, the specified device arguments are honored. The network boot support package processes arguments in `network-boot-arguments`.

```
boot net:speed=100,duplex=full
```

---

**Example 3** Using wanboot with Older PROMs

The command below results in the wanboot binary being loaded from DVD or CD, at which time wanboot will perform DHCP and then drop into its command interpreter to allow the user to enter keys and any other necessary configuration.

```
boot cdrom -F wanboot -o dhcp,prompt
```
The boot utility is unable to determine which files can be used as bootable programs. If the booting of a file that is not bootable is requested, the boot utility loads it and branches to it. What happens after that is unpredictable.

Notes  
`platform-name` can be found using the `-i` option of `uname(1)`. `hardware-class-name` can be found using the `-m` option of `uname(1)`.

The current release of the Solaris operating system does not support machines running an UltraSPARC-I CPU.
The `bootadm` command manages the boot archive and, with x86 boot environments, the GRUB (GRand Unified Bootloader) menu. The `update-archive` option provides a way for user to update the boot archive as a preventative measure or as part of a recovery procedure. The `set-menu` subcommand allows you to switch the auto-boot timeout and default boot entry in the GRUB menu.

The `list-menu` subcommand displays the location of the GRUB menu and the current GRUB menu entries. While the typical location of the GRUB menu is `/boot/grub/menu.lst`, depending on the install method used the active GRUB menu might be located somewhere else. Use the `list-menu` subcommand to locate the active GRUB menu. For example, if a system was installed using Live Upgrade, the GRUB menu might not be located in the current boot environment. See the EXAMPLES section for typical output from the `list-menu` option.

Note that OpenBoot PROM (OBP)-based machines, such as SPARC systems, do not use GRUB and have no boot menu manageable by `bootadm`.

The `bootadm` command determines dynamically the options supported by the image to be managed, so that `bootadm` invoked on one platform can be used to manage diskless clients of a different platform type.

### Subcommands

The `bootadm` command has the following subcommands:

- **update-archive**
  Updates current boot archive if required. Applies to both SPARC and x86 platforms.

- **list-archive**
  Lists the files and directories to be included in the boot archive. Applies to both SPARC and x86 platforms.

- **set-menu**
  Maintain the GRUB menu. The current GRUB menu is `/boot/grub/menu.lst`, relative to root. Do not depend on this location, because it is subject to change. Applies to x86 platforms only.

- **list-menu**
  Lists the location of the active GRUB menu, as well as the current GRUB menu entries. This includes the autoboost-timeout, the default entry number, and the title of each entry. Applies to x86 platforms only.

### Options

The `bootadm` command has the following options:
In an update-archive operation, stale files are displayed on stderr.

In an update-archive operation, archive content is checked but not updated.

The platform, or machine hardware class, of the client. The platform type can only be specified together with -R, and is generally useful only for managing a diskless client where the client is of a different platform class than the server. Platform must be one of i86pc, sun4u, or sun4v.

Operation is applied to an alternate root path.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

Possible values are:

default=entrynum
   The item number (for example, 0, 1, or 2) in the GRUB menu designating the operating system to boot when the timer expires.

timeout=seconds
   The number of seconds before the operating system designated by the default item number is booted. If the value is –1, auto boot is disabled.

Examples

EXAMPLE 1  Updating the Current Boot Archive
The following command updates the current boot archive:

# bootadm update-archive

EXAMPLE 2  Updating the Boot Archive on an Alternate Root
The following command updates the boot archive on an alternate root:

# bootadm update-archive -R /a

EXAMPLE 3  Listing Installed OS Instances
The following command lists the installed operating system instances in a GRUB menu:

# bootadm list-menu

default=0
timeout=10
(0) Solaris10
EXAMPLE 3  Listing Installed OS Instances  (Continued)

(1) Solaris10 Failsafe
(2) Linux

EXAMPLE 4  Switching Default Boot Entry

The following command refers to the menu displayed in the previous example. The user selects Linux (item 2).

```
# bootadm set-menu default=2
```

EXAMPLE 5  Listing GRUB Menu Entries and Location of GRUB Menu

The following command lists the GRUB menu entries and the location of the GRUB menu:

```
# bootadm list-menu
The location for the active GRUB menu is: /stubboot/boot/grub/menu.lst
default 0
timeout 10
  0 Solaris10
  1 Solaris10 failsafe
  2 Linux
```

EXAMPLE 6  Displaying Location of GRUB Menu

The following command displays the location of the GRUB menu:

```
# bootadm list-menu
The location for the active GRUB menu is: /dev/dsk/c0t1d0s0 (not mounted)
The filesystem type of the menu device is <ufs>
default 2
timeout 10
  0 c0t1d0s3
  1 c0t1d0s3 failsafe
  2 Solaris10
  3 Solaris10 failsafe
```

In this example, the active GRUB menu is located on a device which is not mounted. To access the GRUB menu, mount the device and access the GRUB menu at `<mountpoint>/boot/grub/menu.lst`.

**Exit Status**  The following exit values are returned:

0  The command completed successfully.
1  The command exited due to an error.

http://www.gnu.org/
bootconfchk – verify the integrity of a network boot configuration file

**Synopsis**  
/usr/sbin/bootconfchk [bootconf-file]

**Description**  
The `bootconfchk` command checks that the file specified is a valid network boot configuration file as described in `wanboot.conf(4)`.

Any discrepancies are reported on standard error.

**Exit Status**  
0  Successful completion.
1  An error occurred.
2  Usage error.

bsmconv(1M)

Name bsmconv, bsmunconv – enable or disable Solaris Auditing

Synopsis /etc/security/bsmconv [rootdir]...
/etc/security/bsmunconv [rootdir]...

Description The bsmconv and bsmunconv scripts are used to enable or disable the BSM features on a Solaris system. The optional argument rootdir is a list of one or more root directories of diskless clients that have already been configured. See smdiskless(1M).

To enable or disable BSM on a diskless client, a server, or a stand-alone system, logon as super-user to the system being converted and use the bsmconv or bsmunconv commands without any options.

To enable or disable BSM on a diskless client from that client’s server, logon to the server as super-user and use bsmconv, specifying the root directory of each diskless client you wish to affect. For example, the command:

myhost# bsmconv /export/root/client1 /export/root/client2

enables BSM on the two machines named client1 and client2. While the command:

myhost# bsmconv

enables BSM only on the machine called myhost. It is no longer necessary to enable BSM on both the server and its diskless clients.

After running bsmconv the system can be configured by editing the files in /etc/security. Each diskless client has its own copy of configuration files in its root directory. You might want to edit these files before rebooting each client.

Following the completion of either script, the affected system(s) should be rebooted to allow the auditing subsystem to come up properly initialized.

Files The following files are created by bsmconv:

/etc/security/device_maps Administrative file defining the mapping of device special files to allocatable device names.
/etc/security/device_allocate Administrative file defining parameters for device allocation.

Attributes See attributes(5) for descriptions of the following attributes:

See Also  auditconfig(1M), auditd(1M), audit_startup(1M), audit.log(4), audit_control(4), attributes(5)

See the section on Solaris Auditing in System Administration Guide: Security Services.

Notes  bsmconv and bsmunconv are not valid in a non-global zone.

These commands are Obsolete and may be removed and replaced with equivalent functionality in a future release of Solaris.
bsmrecord(1M)

<table>
<thead>
<tr>
<th>Name</th>
<th>bsmrecord – display Solaris audit record formats</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synopsis</td>
<td>/usr/sbin/bsmrecord [-d] [-a] [-e string] [-c class]</td>
</tr>
<tr>
<td></td>
<td>[-i id] [-p programname] [-s syscall] [-h]</td>
</tr>
<tr>
<td>Description</td>
<td>The bsmrecord utility displays the event ID, audit class and selection mask, and record format for audit record event types defined in audit_event(4). You can use bsmrecord to generate a list of all audit record formats, or to select audit record formats based on event class, event name, generating program name, system call name, or event ID.</td>
</tr>
<tr>
<td>Options</td>
<td>The following options are supported:</td>
</tr>
</tbody>
</table>

- `-a`  
  List all audit records.

- `-c class`  
  List all audit records selected by class. class is one of the two-character class codes from the file /etc/security/audit_class.

- `-d`  
  Debug mode. Display number of audit records that are defined in audit_event, the number of classes defined in audit_class, any mismatches between the two files, and report which defined events do not have format information available to bsmrecord.

- `-e string`  
  List all audit records for which the event ID label contains the string string. The match is case insensitive.

- `-h`  
  Generate the output in HTML format.

- `-i id`  
  List the audit records having the numeric event ID id.

- `-p programname`  
  List all audit records generated by the program programname, for example, audit records generated by a user-space program.

- `-s syscall`  
  List all audit records generated by the system call syscall, for example, audit records generated by a system call.

The `-p` and `-s` options are different names for the same thing and are mutually exclusive. The `-a` option is ignored if any of `-c`, `-e`, `-i`, `-p`, or `-s` are given. Combinations of `-c`, `-e`, `-i`, and either `-p` or `-s` are ANDed together.
**Examples**

**EXAMPLE 1**  Displaying an Audit Record with a Specified Event ID

The following example shows how to display the contents of a specified audit record.

```bash
% bsmrecord -i 6152
terminal login
program /usr/sbin/login see login(1)
/usr/dt/bin/dtlogin See dtlogin
event ID 6152 AUE_login
class lo (0x00001000)
header
subject
[text] error message
return
```

**EXAMPLE 2**  Displaying an Audit Record with an Event ID Label that Contains a Specified String

The following example shows how to display the contents of an audit record with an event ID label that contains the string login.

```bash
# bsmrecord -e login
terminal login
program /usr/sbin/login see login(1)
/usr/dt/bin/dtlogin See dtlogin
event ID 6152 AUE_login
class lo (0x00001000)
header
subject
[text] error message
return
```

```bash
rlogin
program /usr/sbin/login see login(1) - rlogin
event ID 6155 AUE_rlogin
class lo (0x00001000)
header
subject
[text] error message
return
```

**Exit Status**

- 0  Successful operation
- non-zero  Error

**Files**

- /etc/security/audit_class  Provides the list of valid classes and the associated audit mask.

*System Administration Commands - Part 1*  163
/etc/security/audit_event
   Provides the numeric event ID, the literal event name, and the name of the associated
   system call or program.

Attributes  See attributes(5) for descriptions of the following attributes:

          attributes(5)

See the section on Solaris Auditing in System Administration Guide: Security Services.

Diagnostics  If unable to read either of its input files or to write its output file, bsmrecord shows the name of
   the file on which it failed and exits with a non-zero return.

   If no options are provided, if an invalid option is provided, or if both -s and -p are provided,
   an error message is displayed and bsmrecord displays a usage message then exits with a
   non-zero return.

Notes  This command is Obsolete and may be removed and replaced with equivalent functionality in
   a future release of Solaris.

   If /etc/security/audit_event has been modified to add user-defined audit events, bsmrecord displays the record format as undefined.

   The audit records displayed by bsmrecord are the core of the record that can be produced.
   Various audit policies and optional tokens, such as those shown below, might also be present.

   The following is a list of praudit(1M) token names with their descriptions.

   group
      Present if the group audit policy is set.

   sensitivity label
      Present when Trusted Extensions is enabled and represents the label of the subject or object
      with which it is associated. The mandatory_label token is noted in the basic audit record
      where a label is explicitly part of the record.

   sequence
      Present when the seq audit policy is set.

   trailer
      Present when the trail audit policy is set.
zone
   The name of the zone generating the record when the zonename audit policy is set. The zonename token is noted in the basic audit record where a zone name is explicitly part of the record.
busstat(1M)

Name
busstat – report bus-related performance statistics

Synopsis
busstat [-a] [-e device-inst | -h | -l

busstat [-w device-inst [,pic0=event,picn=event]... [device-inst]... [interval [count]]

Description
busstat provides access to the bus-related performance counters in the system. These performance counters allow for the measurement of statistics like hardware clock cycles, bus statistics including DMA and cache coherency transactions on a multiprocessor system. Each bus device that supports these counters can be programmed to count a number of events from a specified list. Each device supports one or more Performance Instrumentation Counters (PIC) that are capable of counting events independently of each other.

Separate events can be selected for each PIC on each instance of these devices. busstat summarizes the counts over the last interval seconds, repeating forever. If a count is given, the statistics are repeated count times.

Only root users can program these counters. Non-root users have the option of reading the counters that have been programmed by a root user.

The default value for the interval argument is 1 second, and the default count is unlimited.

The devices that export these counters are highly platform-dependent and the data may be difficult to interpret without an in-depth understanding of the operation of the components that are being measured and of the system they reside in.

Options
The following options are supported:

- a  Display absolute counter values. The default is delta values.
- e device-inst  Display the list of events that the specified device supports for each pic.
- w device-inst [,pic0=event,picn=event]...  Specify device-inst as device(name) followed by an optional instance number. If an instance number is specified, the events for that instance are displayed. If no instance number is specified, the events for the first instance of the specified device are displayed.
- h  Print a usage message.
- l  List the devices in the system which support performance counters.
- n  Do not display a title in the output. The default is to display titles.
**-r device-inst**

Read and display all pic values for the specified device.

Specify `device-inst` as `device (name)` followed by `instance number`, if specifying an instance number of a device whose counters are to be read and displayed. If all instances of this device are to be read, use `device (name)` without an instance number. All pic values will be sampled when using the `-r` option.

**-w device-inst [,.pic0=event] [,.picn=event]**

Program (write) the specified devices to count the specified events. Write access to the counters is restricted to root users only. Non-root users can use `-r` option.

Specify `device-inst` as `device (name)` followed by an optional `instance number`. If specifying an instance number of a device to program these events on. If all instances of this device are to be programmed the same, then use `device` without an instance number. Specify an event to be counted for a specified pic by providing a comma separated list of `picn=event` values.

The `-e` option displays all valid event names for each device. Any devices that are programmed will be sampled every interval seconds and repeated count times. It is recommended that the interval specified is small enough to ensure that counter wraparounds will be detected. The rate at which counters wraparound varies from device to device. If a user is programming events using the `-w` option and `busstat` detects that another user has changed the events that are being counted, the tool will terminate as the programmed devices are now being controlled by another user. Only one user can be programming a device instance at any one time. Extra devices can be sampled using the `-r` option. Using multiple instances of the `-w` option on the same command line, with the same `device-inst` specifying a different list of events for the pics will give the effect of multiplexing for that device. `busstat` will
switch between the list of events for that device every interval seconds. Event can be a string representing the event name, or even a number representing the bit pattern to be programmed into the Performance Control Register (PCR). This assumes explicit knowledge of the meaning of the control register bits for a device. The number can be specified in hexadecimal, decimal, or octal, using the usual conventions of \texttt{strtol(3C)}.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Another user is writing to the same devices.

Examples

SPARC Only

EXAMPLE 1 Programming and monitoring the Address Controller counters

In this example, \texttt{ac0} refers to the Address Controller instance 0. The counters are programmed to count Memory Bank stalls on an Ultra Enterprise system at 10 second intervals with the values displayed in absolute form instead of deltas.

\begin{verbatim}
# busstat -a -w ac0,pic0=mem_bank0_stall,pic1=mem_bank1_stall 10
time  dev  event0        pic0  event1        pic1
10    ac0  mem_bank0_stall 1234  mem_bank1_stall 5678
20    ac0  mem_bank0_stall 5678  mem_bank1_stall 12345
30    ac0  mem_bank0_stall 12345 mem_bank1_stall 56789
...
\end{verbatim}

For a complete list of the supported events for a device, use the \texttt{-e} option.

EXAMPLE 2 Programming and monitoring the counters on all instances of the Address Controller

In this example, \texttt{ac} refers to all \texttt{ac} instances. This example programs all instances of the Address Controller counters to count \texttt{clock\_cycles} and \texttt{mem\_bank0\_rds} at 2 second intervals, 100 times, displaying the values as deltas.

\begin{verbatim}
# busstat -w ac,pic0=\texttt{clock\_cycles},pic1=\texttt{mem\_bank0\_rds} 2 100
time  dev  event0        pic0        event1        pic1
 2    ac0  clock\_cycles 167242902 mem\_bank0\_rds 3144
 2    ac1  clock\_cycles 167254476 mem\_bank0\_rds 1392
 4    ac0  clock\_cycles 168025190 mem\_bank0\_rds 40302
 4    ac1  clock\_cycles 168024056 mem\_bank0\_rds 40580
...
\end{verbatim}
EXAMPLE 3  Monitoring the events being counted

This example monitors the events that are being counted on the sbus1 device, 100 times at 1 second intervals. It suggests that a root user has changed the events that sbus1 was counting to be dvma_tlb_misses and interrupts instead of pio_cycles.

% busstat -r sbus0 1 100

time  dev  event0  pic0  event1  pic1
1    sbus1  pio_cycles  2321  pio_cycles  2321
2    sbus1  pio_cycles  48   pio_cycles  48
3    sbus1  pio_cycles  49   pio_cycles  49
4    sbus1  pio_cycles  2281 pio_cycles  2281
5    sbus1  dvma_tlb_misses 0 interrupts 0
6    sbus1  dvma_tlb_misses 6 interrupts 2
7    sbus1  dvma_tlb_misses 0 interrupts 11
...

EXAMPLE 4  Event Multiplexing

This example programs ac0 to alternate between counting (clock cycles, mem_bank0_rds) and (addr_pkts, data_pkts) at 2 second intervals while also monitoring what ac1 is counting.

It shows the expected output of the above busstat command. Another root user on the machine has changed the events that this user had programmed and busstat has detected this and terminates the command with a message.

# busstat -w ac0,pic0=clock_cycles,pic1=mem_bank0_rds \ 
  -w ac0,pic0=addr_pkts,pic1=data_pkts \ 
  -r ac1 2

time  dev  event0  pic0  event1  pic1
2    ac0  addr_pkts  12866 data_pkts  17015
2    ac1  rio_pkts  385   rio_pkts  385
4    ac0  clock_cycles 168018914 mem_bank0_rds 2865
4    ac1  rio_pkts  506   rio_pkts  506
6    ac0  addr_pkts  144236 data_pkts  149223
6    ac1  rio_pkts  522   rio_pkts  522
8    ac0  clock_cycles 168021245 mem_bank0_rds 2564
8    ac1  rio_pkts  387   rio_pkts  387
10   ac0  addr_pkts  144292 data_pkts  159645
10   ac1  rio_pkts  506   rio_pkts  506
12   ac0  clock_cycles 168020364 mem_bank0_rds 2665
12   ac1  rio_pkts  522   rio_pkts  522

busstat: events changed (possibly by another busstat).

cachefsd - CacheFS daemon

/usr/lib/fs/cachefs/cachefsd

The cachefsd server implements features of the cache filesystem (CacheFS). It is invoked at boot time and run if the / (root) and /usr filesystems are being cached. If /usr is being cached, cachefsd is invoked by inetd(1M) from inetd.conf(4). At run time, cachefsd is invoked by the inetd mechanism in response to an RPC request from a user command such as mount_cachefs(1M).

The cachefsd server supports the “disconnected mode” of CacheFS. In this mode, a user can continue to read and, depending on the option selected, write to files in a cached filesystem when the NFS server for the cached files is not available.

The cachefsd daemon performs the following functions in support of the CacheFS:

- Implements the connection policy. The daemon determines whether the NFS server backing the cache is connected or disconnected from the cache, or is in transition from the connected or disconnected states.
- Implements “log rolling,” wherein the daemon monitors a disconnected NFS server for reconnection. After such a server returns to a connected state, cachefsd rolls any local changes to cached files (kept in a log) back to the server.
- Manages “packing,” wherein cachefsd makes a best effort to ensure that files in a user-specified list are available in the cache in disconnected mode.
- Supports user interfaces by supplying statistics, reporting conflicts between the cache and the back filesystem, and supporting a list of files for packing.

The running of cachefsd is required for the disconnected mode of CacheFS.

Options

The following options are supported:

- r   Used for invoking cachefsd for the / filesystem.

System Administration Guide: Basic Administration
The `cachefslog` command displays where CacheFS statistics are being logged. Optionally, it sets where CacheFS statistics are being logged, or it halts logging for a cache specified by `cachefs_mount_point`. The `cachefs_mount_point` argument is a mount point of a cache file system. All file systems cached under the same cache as `cachefs_mount_point` will be logged.

The following options are supported. You must be super-user to use the `-f` and `-h` options.

- `-f` `logfile` Specify the log file to be used.
- `-h` Halt logging.

`cachefs_mount_point` A mount point of a cache file system.

See `largefile(5)` for the description of the behavior of `cachefslog` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

**Examples**

**EXAMPLE 1** Checking the Logging of a directory.
The example below checks if the directory `/home/sam` is being logged:

```
example% cachefslog /home/sam
not logged: /home/sam
```

**EXAMPLE 2** Changing the `logfile`.
The example below changes the `logfile` of `/home/sam` to `/var/tmp/samlog`:

```
example# cachefslog -f /var/tmp/samlog /home/sam
/var/tmp/samlog: /home/sam
```

**EXAMPLE 3** Verifying the change of a `logfile`.
The example below verifies the change of the previous example:

```
example% cachefslog /home/sam
/var/tmp/samlog: /home/sam
```

**EXAMPLE 4** Halting the logging of a directory.
The example below halts logging for the `/home/sam` directory:

```
example# cachefslog -h /home/sam
not logged: /home/sam
```

**Exit Status**
The following exit values are returned:

- `0` success
- non-zero an error has occurred.
Attributes  See `attributes(5)` for descriptions of the following attributes:

Diagnostics  Invalid path  It is illegal to specify a path within a cache file system.
cachefspack(1M)

Name cachefspack – pack files and file systems in the cache

Synopsis cachefspack [-h] [-i | -p | -u] [-f packing-list]
                   [-U cache-directory] [file]...

Description The cachefspack utility is used to set up and maintain files in the cache. This utility affords greater control over the cache, ensuring that the specified files are in the cache whenever possible.

cachefspack does not pack files when the backfile system type for the cachefs mount is NFSv4. This is because only pass-through support is available for cachefs with NFSv4.

Options The following options are supported:

- **-f packing-list** Specify a file containing a list of files and directories to be packed. Options within subdirectories and files can also be specified. The format and rules governing packing-list are described on the packingrules(4) manual page. Directories are packed recursively. Symlinks that match a regular expression on a LIST command are followed. Symlinks encountered while recursively processing directories are not followed.

- **-h** Help. Print a brief summary of all the options.

- **-i** View information about the packed files.

- **-p** Pack the file or files specified by file. This is the default behavior.

- **-u** Unpack the file or files specified by file.

- **-U cache-directory** Unpack all files in the specified cache directory.

Operands The following operands are supported:

- **file** A path name of a file to be packed or unpacked.

Usage See largefile(5) for the description of the behavior of cachefspack when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Packing a File in the Cache

The following example packs the file projects in the cache:

% cachefspack -p projects

**EXAMPLE 2** Packing Files in the Cache

The following example packs the files projects, updates, and master_plan in the cache:

% cachefspack -p projects updates master_plan
EXAMPLE 3  Unpacking a File From the Cache
The following example unpacks the file projects from the cache:
% cachefspack -u projects

EXAMPLE 4  Unpacking Files From the Cache
The following example unpacks the files projects, updates, and master_plan from the cache:
% cachefspack -u projects updates master_plan

EXAMPLE 5  Unpacking All Files From in a Cache Directory
The following example unpacks all files in the cache directory cache1:
% cachefspack -U /cache/cache1

EXAMPLE 6  Using a Packing List
The following example illustrates the use of a packing list to specify files to be packed in the cache.

The contents of lists.pkg are as follows:
IGNORE SCCS BASE /src/junk LIST *.c LIST *.h

The following command packs all files in the /src/junk directory which have .c and .h extensions, and do contain the string SCCS in the file's path name:
% cachefspack -f lists.pkg

Exit Status 0  Successful completion.
>0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>

cachefsstat – Cache FileSystem statistics

/usr/bin/cachefsstat [-z] [path]...

declaration: The cachefsstat command displays statistical information about the cache file system mounted on path. The statistical information includes cache hits and misses, consistency checking, and modification operations. If path is not specified, all mounted cache file systems are used.

cachefsstat can also be used to reinitialize this information (see -z option).

The statistical information has the following format:

<hit rate>
<consistency checks>
<modifies>

where:

hit rate The percentage of cache hits over the total number of attempts, followed by the actual numbers of hits and misses.

consistency checks The number of consistency checks performed, followed by the number that passed, and the number that failed.

modifies The number of modify operations, including writes, creates, etc.

options: The following option is supported:

-z Zero (reinitialize) statistics. Execute cachefsstat -z before executing cachefsstat again to gather statistics on the cache performance. This option can only be use by the superuser. The statistics printed reflect those just before the statistics are reinitialized.

usage: See largefile(5) for the description of the behavior of cachefsstat when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

examples: Using cachefsstat

The following example shows the cachefsstat command run on file system /test:

example# cachefsstat /test
/test
  cache hit rate: 100% (0 hits, 0 misses)
  consistency checks: 0 (0 pass, 0 fail)
  modifies: 0
  garbage collection: 0

exit status: The following exit values are returned:

0 Successful completion.

non-zero An error occurred.
Attributes  See attributes(5) for descriptions of the following attributes:

<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  cacheslog(1M), cachefswsize(1M), cfsadmin(1M), attributes(5), largefile(5)
cachefswssize(1M)

Name cachefswssize – determine working set size for cachefs

Synopsis cachefswssize logfile

Description The cachefswssize command displays the workspace size determined from logfile. This includes the amount of cache space needed for each filesystem that was mounted under the cache, as well as a total.

Usage See largefile(5) for the description of the behavior of cachefswssize when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Examples EXAMPLE 1 A sample output of cachefswssize.

example% cachefswssize /var/tmp/samlog

/home/sam

   end size: 10688k
   high water size: 10704k

/foo

   end size: 128k
   high water size: 128k

/usr/dist

   end size: 1472k
   high water size: 1472k

total for cache

   initial size: 110960k
   end size: 12288k
   high water size: 12304k

Exit Status The following exit values are returned:

0 success
non-zero an error has occurred.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

See Also  cachefslog(1M), cachefsstat(1M), cfsadmin(1M), attributes(5), largefile(5)

Diagnostics  problems were encountered writing log file  There were problems encountered when the kernel was writing the logfile. The most common problem is running out of disk space.

invalid log file  The logfile is not a valid logfile or was created with a newer version of Solaris than the one where cachefswsize is running.
Name: captoinfo – convert a termcap description into a terminfo description

Synopsis: captoinfo [-1] [-v]... [-V] [-w width] filename...

Description: captoinfo looks in filename for termcap descriptions. For each one found, an equivalent terminfo description is written to standard output, along with any comments found. A description which is expressed as relative to another description (as specified in the termcap tc = field) is reduced to the minimum superset before being displayed.

If no filename is given, then the environment variable TERMCAP is used for the filename or entry. If TERMCAP is a full pathname to a file, only the terminal whose name is specified in the environment variable TERM is extracted from that file. If the environment variable TERMCAP is not set, then the file /usr/share/lib/termcap is read.

Options:
-1  Display the fields one to a line. Otherwise, the fields are printed several to a line, with a maximum width of 60 characters.
-v  Display tracing information on the standard error as the program runs. Specifying additional -v options displays more detailed information.
-V  Display the version of the program in use on the standard error and then exit.
-w width  Change the output to width characters.

Files:
/usr/share/lib/terminfo/*  compiled terminal description database
/usr/share/lib/termcap

Attributes: See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also: infocmp(1M), curses(3CURSES), terminfo(4), attributes(5)

Notes: captoinfo should be used to convert termcap entries to terminfo entries because the termcap database may not be supplied in future releases.
The `catman` utility creates the preformatted versions of the on-line manual from the `nroff(1)` or `sgml(5)` input files. This feature allows easy distribution of the preformatted manual pages among a group of associated machines (for example, with `rdist(1)`), since it makes the directories of preformatted manual pages self-contained and independent of the unformatted entries.

`catman` also creates the `windex` database file in the directories specified by the `MANPATH` or the `-M` option. The `windex` database file is a three column list consisting of a keyword, the reference page that the keyword points to, and a line of text that describes the purpose of the utility or interface documented on the reference page. Each keyword is taken from the comma separated list of words on the `NAME` line before the `−` (dash). The reference page that the keyword points to is the first word on the `NAME` line. The text after the `−` on the `NAME` line is the descriptive text in the third column. The `NAME` line must be immediately preceded by the page heading line created by the `.TH` macro (see `NOTES` for required format).

Each manual page is examined and those whose preformatted versions are missing or out of date are recreated. If any changes are made, `catman` recreates the `windex` database.

If a manual page is a `shadow` page, that is, it sources another manual page for its contents, a symbolic link is made in the `cat` or `fmt` directory to the appropriate preformatted manual page.

Shadow files in an unformatted `nroff` source file are identified by the first line being of the form `.so manx/yyyy.x`.

Shadow files in the `SGML` sources are identified by the string `SHADOW_PAGE`. The file entity declared in the shadow file identifies the file to be sourced.

The following options are supported:

- `-c` Create unformatted `nroff` source files in the appropriate `man` subdirectories from the `SGML` sources. This option will overwrite any existing file in the `man` directory of the same name as the `SGML` file.
- `-n` Do not create (or recreate) the `windex` database. If the `-n` option is specified, the `windex` database is not created and the `apropos`, `whatis`, `man -f`, and `man -k` commands will fail.
- `-p` Print what would be done instead of doing it.
- `-t` Create `troff`ed entries in the appropriate `fmt` subdirectories instead of `nroff`ing into the `cat` subdirectories.
- `-w` Only create the `windex` database that is used by `whatis(1)` and the `man(1) -f` and `-k` options. No manual reformatting is done.
-M directory  
Update manual pages located in the specified directory, 
(/usr/share/man by default). If the -M option is specified, the directory 
argument must not contain a ‘,’ (comma), since a comma is used to 
delineate section numbers. See man(1).

-T macro-package  
Use macro-package in place of the standard manual page macros, ( 
man(5) by default).

Operands  
The following operand is supported:

sections  
If there is one parameter not starting with a ‘-’, it is taken to be a space separated 
list of manual sections to be processed by catman. If this operand is specified, only 
the manual sections in the list will be processed. For example,

catman 1 2 3

only updates manual sections 1, 2, and 3. If specific sections are not listed, all 
sections in the man directory specified by the environment variable MANPATH are 
processed.

Environment Variables  
TROFF  
The name of the formatter to use when the -t flag is given. If not set, troff(1) is 
used.

MANPATH  
A colon-separated list of directories that are processed by catman and man(1). 
Each directory can be followed by a comma-separated list of sections. If set, its 
value overrides /usr/share/man as the default directory search path, and the 
man .cf file as the default section search path. The -M and -s flags, in turn, 
override these values.

Files  
/usr/share/man  
default manual directory location
/usr/share/man/man*/*.*  
raw nroff input files
/usr/share/man/sman*/*.*  
raw SGML input files
/usr/share/man/cat*/*.*  
preformatted nroffed manual pages
/usr/share/man/fmt*/*.*  
preformatted troffed manual pages
/usr/share/man/windex  
table of contents and keyword database
/usr/lib/makewhatis  
command script to make windex database
/usr/share/lib/tmac/an  
default macro package

Attributes

## See Also
  apropos(1), man(1), nroff(1), rdist(1), rm(1), troff(1), whatis(1), attributes(5), man(5), sgml(5)

## Diagnostics
  **man?/xxx.? (.so’ed from man?/yyy.?): No such file or directory**
  The file outside the parentheses is missing, and is referred to by the file inside them.

  **target of .so in man?/xxx.? must be relative to /usr/man**
  catman only allows references to filenames that are relative to the directory /usr/man.

  **opendir:man?: No such file or directory**
  A harmless warning message indicating that one of the directories catman normally looks for is missing.

  ***.*: No such file or directory**
  A harmless warning message indicating catman came across an empty directory.

## Warnings
  If a user, who has previously run catman to install the cat* directories, upgrades the operating system, the entire cat* directory structure should be removed prior to running catman. See rm(1).

  Do not re-run catman to re-build the whatis database unless the complete set of man* directories is present. catman builds this windex file based on the man* directories.

## Notes
  To generate a valid windex index file, catman has certain requirements. Within the individual man page file, catman requires two macro lines to have a specific format. These are the .TH page heading line and the .SH NAME line.

  The .TH macro requires at least the first three arguments, that is, the filename, section number, and the date. The .TH line starts off with the .TH macro, followed by a space, the man page filename, a single space, the section number, another single space, and the date. The date should appear in double quotes and is specified as "day month year," with the month always abbreviated to the first three letters (Jan, Feb, Mar, and so forth).

  The .SH NAME macro, also known as the NAME line, must immediately follow the .TH line, with nothing in between those lines. No font changes are permitted in the NAME line. The NAME line is immediately followed by a line containing the man page filename; then shadow page names, if applicable, separated by commas; a dash; and a brief summary statement. These elements should all be on one line; no carriage returns are permitted.

  An example of proper coding of these lines is:

  ```
  .TH nismatch 1M "10 Apr 1998"
  .SH NAME
  nismatch, nisgrep \- utilities for searching NIS+ tables
  ```
The `cfgadm` command provides configuration administration operations on dynamically reconfigurable hardware resources. These operations include displaying status, initiating testing, invoking configuration state changes, invoking hardware specific functions, and obtaining configuration administration help messages. Configuration administration is performed at *attachment points*, which are places where system software supports dynamic reconfiguration of hardware resources during continued operation of Solaris.

Configuration administration makes a distinction between hardware resources that are physically present in the machine and hardware resources that are configured and visible to Solaris. The nature of configuration administration functions are hardware specific, and are performed by calling hardware specific libraries.

Configuration administration operates on an *attachment point*. Hardware resources located at attachment points can or cannot be physically replaceable during system operation, but are dynamically reconfigurable by way of the configuration administration interfaces.

An attachment point defines two unique elements, which are distinct from the hardware resources that exist beyond the attachment point. The two elements of an attachment point are a *receptacle* and an *occupant*. Physical insertion or removal of hardware resources occurs at attachment points and results in a receptacle gaining or losing an occupant. Configuration administration supports the physical insertion and removal operations as well as other configuration administration functions at an attachment point.

Attachment points have associated state and condition information. The configuration administration interfaces provide control for transitioning attachment point states. A receptacle can exist in one of three states: empty, disconnected or connected, while an occupant can exist in one of two states: configured or unconfigured.

A receptacle can provide the empty state, which is the normal state of a receptacle when the attachment point has no occupants. A receptacle can also provide the disconnected state if it has the capability of isolating its occupants from normal system access. Typically this state is used for various hardware specific testing prior to bringing the occupant’s resources into full...
use by the system, or as a step in preparing an occupant for physical removal or
reconfiguration. A receptacle in the disconnected state isolates its occupant from the system as
much as its hardware allows, but can provide access for testing and setup. A receptacle must
provide the connected state, which allows normal access to hardware resources contained on
any occupants. The connected state is the normal state of a receptacle that contains an
occupant and that is not currently undergoing configuration administration operations.

The hardware resources contained on an occupant in the unconfigured state are not
represented by normal Solaris data structures and are thus not available for use by Solaris.
Operations allowed on an unconfigured occupant are limited to configuration administration
operations. The hardware resources of an occupant in the configured state are represented by
normal Solaris data structures and thus some or all of those hardware resources can be in use
by Solaris. All occupants provide both the configured and unconfigured states,

An attachment point can be in one of five conditions: unknown, ok, failing, failed, or
unusable. An attachment point can enter the system in any condition depending upon results
of power-on tests and non-volatile record keeping.

An attachment point with an occupant in the configured state is in one of four conditions:
unknown, ok, failing, or failed. If the condition is not failing or failed an attachment
point can change to failing during the course of operation if a hardware dependent
recoverable error threshold is exceeded. If the condition is not failed an attachment point
can change to failed during operation as a result of an unrecoverable error.

An attachment point with an occupant in the unconfigured state can be in any of the defined
conditions. The condition of an attachment point with an unconfigured occupant can decay
from ok to unknown after a machine dependent time threshold. Initiating a test function
changes the attachment point’s condition to ok, failing or failed depending on the outcome
of the test. An attachment point that does not provide a test function can leave the attachment
point in the unknown condition. If a test is interrupted, the attachment point’s condition can be
set to the previous condition, unknown or failed. An attachment point in the unknown, ok,
failing, or failed conditions can be re-tested.

An attachment point can exist in the unusable condition for a variety of reasons, such as
inadequate power or cooling for the receptacle, an occupant that is unidentifiable,
unsupported, incorrectly configured, etc. An attachment point in the unusable condition can
never be used by the system. It typically remains in this condition until the physical cause is
remedied.

An attachment point also maintains busy information that indicates when a state change is in
progress or the condition is being reevaluated.

Attachment points are referred to using hardware specific identifiers (ap_ids) that are related
to the type and location of the attachment points in the system device hierarchy. An ap_id can
not be ambiguous, it must identify a single attachment point. Two types of ap_id
specifications are supported: physical and logical. A physical ap_id contains a fully specified pathname, while a logical ap_id contains a shorthand notation that identifies an attachment point in a more user-friendly way.

For example, an attachment point representing a system’s backplane slot number 7 could have a physical ap_id of /devices/central/fhc/sysctrl:slot7 while the logical ap_id could be system:slot7. Another example, the third receptacle on the second PCI I/O bus on a system could have a logical ap_id of pc12:plug3.

Attachment points may also be created dynamically. A dynamic attachment point is named relative to a base attachment point which is present in the system. ap_ids for dynamic attachment points consist of a base component followed by two colons (::) and a dynamic component. The base component is the base attachment point ap_id. The dynamic component is hardware specific and generated by the corresponding hardware specific library.

For example, consider a base attachment point, which represents a SCSI HBA, with the physical ap_id /devices/sbus@1f,0/SUNW,fas@e,8800000:scsi and logical ap_id c0. A disk attached to this SCSI HBA could be represented by a dynamic attachment point with logical ap_id c0::dsk/c0t0d0 where c0 is the base component and dsk/c0t0d0 is the hardware specific dynamic component. Similarly the physical ap_id for this dynamic attachment point would be: /devices/sbus@1f,0/SUNW,fas@e,8800000:scsi::dsk/c0t0d0

An ap_type is a partial form of a logical ap_id that can be ambiguous and not specify a particular attachment point. An ap_type is a substring of the portion of the logical ap_id up to but not including the colon (:) separator. For example, an ap_type of pci would show all attachment points whose logical ap_ids begin with pci.

The use of ap_types is discouraged. The new select sub-option to the -s option provides a more general and flexible mechanism for selecting attachment points. See OPTIONS.

The cfgadm command interacts primarily with hardware dependent functions contained in hardware specific libraries and thus its behavior is hardware dependent.

For each configuration administration operation a service interruption can be required. Should the completion of the function requested require a noticeable service interruption to interactive users, a prompt is output on the standard error output for confirmation on the standard input before the function is started. Confirmation can be overridden using the -y or -n options to always answer yes or no respectively. Hardware specific options, such as test level, are supplied as sub-options using the -o option.

Operations that change the state of the system configuration are audited by the system log daemon syslogd(1M).

The arguments for this command conform to the getopt(3C) and getsubopt(3C) syntax convention.
Options

The following options are supported:

- **a**
  Specifies that the -l option must also list dynamic attachment points.

- **cfunction**
  Performs the state change function on the attachment point specified by ap_id.

Specify function as insert, remove, disconnect, connect, configure or unconfigure. These functions cause state transitions at the attachment point by calling hardware specific library routines and are defined in the following list.

- **insert**
  Performs operations that allows the user to manually insert an occupant or to activate a hardware supplied mechanism that performs the physical insertion. insert can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.

- **remove**
  Performs operations that allow the user to manually remove an occupant or to activate a hardware supplied mechanism to perform the physical removal. remove can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.

- **disconnect**
  Performs hardware specific operations to put a receptacle in the disconnected state, which can prevent an occupant from operating in a normal fashion through the receptacle.
connect  Performs hardware specific operations to put the receptacle in the connected state, which allows an occupant to operate in a normal fashion through the receptacle.

configure  Performs hardware specific operations that allow an occupant’s hardware resources to be usable by Solaris. Occupants that are configured are part of the system configuration and are available for manipulation by Solaris device manipulation maintenance commands (eg: psadm(1M), mount(1M), ifconfig(1M)).

unconfigure  Performs hardware specific operations that logically remove an occupant’s hardware resources from the system. The occupant must currently be configured and its hardware resources must not be in use by Solaris.

State transition functions can fail due to the condition of the attachment point or other hardware dependent considerations. All state change functions in the direction of adding resources, (insert, connect and configure) are passed onto the hardware specific library when the attachment point is in the ok or unknown condition. All other conditions require the use of the force option to allow these functions to be passed on to the hardware specific library. Attachment point condition does not prevent a hardware specific library being called for related to the removal (remove, disconnect and unconfigure), of hardware resources from the system. Hardware specific libraries can reject state change functions if the attachment point is in the unknown condition.

The condition of an attachment point is not necessarily changed by the state change functions, however errors during state change operations can change the attachment point condition. An attempt to override a condition and force a state change that would otherwise fail can be made by specifying the force option (-f). Hardware specific safety and integrity checks can prevent the force option from having any effect.

-f  Forces the specified action to occur. Typically, this is a hardware dependent override of a safety feature. Forcing a state change operation can allow use of the hardware resources of occupant that is not in the ok or unknown conditions, at the discretion of any hardware dependent safety checks.
-h [ap_id | ap_type ...]  Prints out the help message text. If ap_id or ap_type is specified, the help routine of the hardware specific library for the attachment point indicated by the argument is called.

-\l [ap_id | ap_type ...]  Lists the state and condition of attachment points specified. Attachment points can be filtered by using the -s option and select sub-option. Invoking cfgadm without one of the action options is equivalent to -\l without an argument. The format of the list display is controlled by the -v and -s options. When the -a option is specified attachment points are dynamically expanded.

-n  Suppress any interactive confirmation and assume that the answer is no. If neither -n or -y is specified, interactive confirmation is obtained through the standard error output and the standard input. If either of these standard channels does not correspond to a terminal (as determined by isatty(3C)) then the -n option is assumed.

-o hardware_options  Supplies hardware specific options to the main command option. The format and content of the hardware option string is completely hardware specific. The option string hardware_options conforms to the getoptopt(3C) syntax convention.

-s listing_options  Supplies listing options to the list (-l) command. listing_options conforms to the getoptopt(3C) syntax convention. The sub-options are used to specify the attachment point selection criteria (select=select_string), the type of matching desired (match=match_type), order of listing (sort=field_spec), the data that is displayed (cols=field_spec and cols2=field_spec), the column delimiter (delim=string) and whether to suppress column headings (noheadings).

When the select sub-option is specified, only attachment points which match the specified criteria will be listed. The select sub-option has the following syntax:

cfgadm -s select=attr1(value1):attr2(value2)...

where an attr is one of ap_id, class or type. ap_id refers to the logical ap_id field, class refers to attachment point class and type refers to the type field. value1, value2, etc. are the corresponding values to be matched. The type of match can be specified by the match sub-option as follows:

cfgadm -s match=match_type,select=attr1(value1)...

where `match_type` can be either exact or partial. The default value is exact.

Arguments to the `select` sub-option can be quoted to protect them from the shell.

A `field_spec` is one or more `data-fields` concatenated using colon (`:`), as in `data-field: data-field: data-field`. A `data-field` is one of `ap_id`, `physid`, `r_state`, `o_state`, `condition`, `type`, `busy`, `status_time`, `status_time_p`, `class`, and `info`. The `ap_id` field output is the logical name for the attachment point, while the `physid` field contains the physical name. The `r_state` field can be empty, disconnected or connected. The `o_state` field can be configured or unconfigured. The `busy` field can be `y` if the attachment point is busy, or `n` if it is not. The `type` and `info` fields are hardware specific. The `status_time` field provides the time at which either the `r_state`, `o_state`, or condition of the attachment point last changed. The `status_time_p` field is a parsable version of the `status_time` field. If an attachment point has an associated class, the `class` field lists the class name. If an attachment point does not have an associated class, the `class` field lists `none`.

The order of the fields in `field_spec` is significant: For the `sort` sub-option, the first field given is the primary sort key. For the `cols` and `cols2` sub-options, the fields are printed in the order requested. The order of sorting on a `data-field` can be reversed by placing a minus (`−`) before the `data-field` name within the `field_sec` for the `sort` sub-option. The default value for `sort` is `ap_id`. The defaults values for `cols` and `cols2` depend on whether the `-v` option is given: Without it `cols` is `ap_id:r_state:o_state:condition` and `cols2` is not set. With `-v cols` is `ap_id:r_state:o_state:condition:info` and `cols2` is `status_time:type:busy:physid:`. The default value for `delim` is a single space. The value of `delim` can be a string of arbitrary length. The delimiter cannot include comma (`,`) character, see `getsubopt(3C)`. These listing options can be used to create parsable output. See `NOTES`.

**-t**

Performs a test of one or more attachment points. The test function is used to re-evaluate the condition of the attachment point. Without a test level specifier in `hardware_options`, the fastest test that identifies hard faults is used.
More comprehensive tests are hardware specific and are selected using the *hardware_options*.

The results of the test are used to update the condition of the specified occupant to either ok if no faults are found, failing if recoverable faults are found or failed if any unrecoverable faults are found.

If a test is interrupted, the attachment point's condition can be restored to its previous value or set to *unknown* if no errors were found or *failing* if only recoverable errors were found or to *failed* if any unrecoverable errors were found. The attachment point should only be set to *ok* upon normal completion of testing with no errors.

- **v**
  Executes in verbose mode. For the *-c*, *-t* and *-x* options outputs a message giving the results of each attempted operation. Outputs detailed help information for the *-h* option. Outputs verbose information for each attachment point for the *-l* option.

- **xhardware_function**
  Performs hardware specific functions. Private hardware specific functions can change the state of a receptacle or occupant. Attachment point conditions can change as the result of errors encountered during private hardware specific functions. The format and content of the *hardware_function* string is completely hardware specific. The option string *hardware_function* conforms to the *getsubopt(3C)* syntax convention.

- **y**
  Suppresses any interactive confirmation and assume that the answer is yes.

**Usage**

The required privileges to use this command are hardware dependent. Typically, a default system configuration restricts all but the *list* option to the superuser.

**Examples**

**EXAMPLE 1** Listing Attachment Points in the Device Tree

The following example lists all attachment points except dynamic attachment points.

```
example# cfgadm

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>

EXAMPLE 3  Listing Selectively, Based on Attachment Point Attributes

The following example lists all attachment points whose class begins with `scsi`, `ap_id` begins with `c` and type field begins with `scsi`. The argument to the `-s` option is quoted to protect it from the shell.

```
extample# cfgadm -s "match=partial,select=class(scsi):ap_id(c):type(scsi)"
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Cond</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c1</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
</tbody>
</table>

EXAMPLE 4  Listing Current Configurable Hardware Information in Verbose Mode

The following example lists current configurable hardware information for `ap-type system` in verbose mode:

```
extample# cfgadm -v -l system
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>When</td>
<td>Type</td>
<td>Busy</td>
<td>Phys_Id</td>
</tr>
</tbody>
</table>
**EXAMPLE 4**  Listing Current Configurable Hardware Information inVerbose Mode  

(Continued)

- system:slot1 connected configured ok
- Apr 4 23:50 sbus-upa n /devices/central/fhc/sysctrl:slot1
- system:slot3 connected configured ok non-detachable
- Apr 17 11:20 cpu/mem n /devices/central/fhc/sysctrl:slot3
- system:slot5 connected configured ok
- Apr 4 23:50 cpu/mem n /devices/central/fhc/sysctrl:slot5
- system:slot7 connected configured ok
- Apr 4 23:50 dual-sbus n /devices/central/fhc/sysctrl:slot7

The **When** column represents the **status_time** field.

**EXAMPLE 5**  Testing Two Occupants Using the Hardware Specific Extended Test

The following example tests two occupants using the hardware specific extended test:

```sh
eexample# cfgadm -v -o extended -t system:slot3 system:slot5
Testing attachment point system:slot3 ... ok
Testing attachment point system:slot5 ... ok
```

**EXAMPLE 6**  Configuring an Occupant Using the Force Option

The following example configures an occupant in the failing state to the system using the force option:

```sh
eexample# cfgadm -f -c configure system:slot3
```

**EXAMPLE 7**  Unconfiguring an Occupant From the System

The following example unconfigures an occupant from the system:

```sh
eexample# cfgadm -c unconfigure system:slot4
```

**EXAMPLE 8**  Configuring an Occupant at an Attachment Point

The following example configures an occupant:

```sh
eexample# cfgadm -c configure c0::dsk/c0t0d0
```

See **environ(5)** for descriptions of the following environment variables that affect the execution of **cfgadm**: **LC_TIME**, **LC_MESSAGES**, **NLSPATH** and **TZ**.

- **LC_Messages**  Determines how **cfgadm** displays column headings and error messages. Listing output data is not affected by the setting of this variable.
- **LC_TIME**  Determines how **cfgadm** displays human readable status changed time (**status_time**).
- **TZ**  Specifies the timezone used when converting the status changed time. This applies to both the human readable (**status_time**) and parsable
The following exit values are returned:

0  Successful completion.
1  An error occurred.
2  Configuration administration not supported on specified target.
3  Usage error.

Attributes  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  `cfgadm(1M), cfgadm_ib(1M), cfgadm_pci(1M), cfgadm_sbd(1M), cfgadm_scsi(1M),
           cfgadm_usb(1M), ifconfig(1M), mount(1M), prtdiag(1M), psradm(1M), syslogd(1M),
           config_admin(3CFGADM), getopt(3C), getsubopt(3C), isatty(3C), attributes(5),
           environ(5)`

Diagnostics  Diagnostic messages appear on the standard error output. Other than options and usage errors, the following are diagnostic messages produced by this utility:

- `cfgadm: Configuration administration not supported on ap_id`
- `cfgadm: No library found for ap_id`
- `cfgadm: ap_id is ambiguous`
- `cfgadm: operation: Insufficient privileges`
- `cfgadm: Attachment point is busy, try again`
- `cfgadm: No attachment points with specified attributes found`
- `cfgadm: System is busy, try again`
- `cfgadm: operation: Operation requires a service interruption`
- `cfgadm: operation: Data error: error_text`
- `cfgadm: operation: Hardware specific failure: error_text`

See `config_admin(3CFGADM)` for additional details regarding error messages.

Notes  Hardware resources enter the unconfigured pool in a hardware specific manner. This can occur at various times such as: system initialization or as a result of an unconfigure operation. An occupant that is in the unconfigured state is not available for use by the system until specific intervention occurs. This intervention can be manifested as an operator initiated command or it can be by way of an automatic configuring mechanism.
The listing option of the `cfgadm` command can be used to provide parsable input for another command, for example within a shell script. For parsable output, the `--s` option must be used to select the fields required. The `--s` option can also be used to suppress the column headings. The following fields always produce parsable output: `ap_id`, `physid`, `r_state`, `o_state`, `condition`, `busy status_time_p`, `class`, and `type`. Parsable output never has white-space characters embedded in the field value.

The following shell script fragment finds the first good unconfigured occupant of type CPU.

```bash
found=
find=
while read ap_id r_state cond type
do
  if [ "$r_state" = unconfigured -a "$cond" = ok -a "$type" = CPU ]
    then
      if [ -z "$found" ]
        then
          found=$ap_id
        fi
      fi
  done
if [ -n "$found" ]
then
  echo "Found CPU $found"
fi
```

The format of the parsable time field (`status_time_p`) is `YYYYMMDhmmss`, giving the year, month, day, hour, minute and second in a form suitable for string comparison.

Reference should be made to the hardware specific documentation for details of System Configuration Administration support.
**Name**  
cfgadm_ac – EXX00 memory system administration

**Synopsis**  
`/usr/sbin/cfgadm [-c configure] [-f]`  
`[-o disable-at-boot | enable-at-boot] ac#:bank# ...`

`/usr/sbin/cfgadm [-c unconfigure]`  
`[-o disable-at-boot | enable-at-boot] ac#:bank# ...`

`/usr/sbin/cfgadm [-v]`  
`[-o quick | normal | extended, [max_errors=#]] -t ac#:bank# ...`

`/usr/sbin/cfgadm -x relocate-test ac#:bank# ...`

`/usr/sbin/cfgadm [-l] -o disable-at-boot | enable-at-boot ac#:bank# ...`

**Description**  
The ac hardware specific library `/usr/platform/sun4u/lib/cfgadm/cfgadm_ac.so.1` provides the functionality for configuring and unconfiguring memory banks on E6X00, E5X00, E4X00 and E3X00 systems as part of the Dynamic Reconfiguration of CPU/Memory boards using `cfgadm_sysctrl(1M)`.

Memory banks appear as attachment points in the device tree. For each CPU/Memory board, two attachment points are published, one for each bank on the board: bank0 and bank1. If the bank is unpopulated, the receptacle state is empty. If the bank is populated, the receptacle state is connected. The receptacle state of a memory bank can never be disconnected. The occupant state of a connected memory bank can be configured or unconfigured. If the occupant state is configured, the memory is in use by Solaris, if unconfigured it is not.

**Options**  
Refer to `cfgadm(1M)` for complete descriptions of the command options.

The following options are supported:

- `-c configure | unconfigure`  
  Change the occupant state. The `configure` argument ensures that the memory is initialized and adds the memory to the Solaris memory pool. The `unconfigure` argument removes the memory from use by Solaris. When a CPU/Memory board is to be removed from a system, both banks of memory must be unconfigured.

  `cfgadm` refuses the `configure` operation if the memory on the board is marked `disabled-at-boot` (see `info` field), unless either the `-f` (force) option or the `enable at boot` flag, (`-o enable-at-boot`), is given. The `configure` operation takes a short time proportional to the size of memory that must be initialized.

  `cfgadm` refuses the `unconfigure` operation if there is not enough uncommitted memory in the system (`VM viability error`) or if the bank to be unconfigured has memory that can’t be removed (`non-relocatable`)
pages error). The presence of non-relocatable pages is indicated by the word permanent in the info listing field. Removing memory from use by Solaris may take a significant time due to factors such as system load and how much paging to secondary storage is required. The unconfigure operation can be cancelled at any time and the memory returned to the fully configured state by interrupting the command invocation with a signal. The unconfigure operation self-cancels if no memory can be removed within a timeout period. The default timeout period of 60 seconds can be changed using the -o timeout=# option, with a value of 0 disabling the timeout.

-f

Force option. Use this option to override the block on configuring a memory bank marked as disabled at boot in the non-volatile disabled-memory-list variable. See Platform Notes: Sun Enterprise 6x00/5x00/4x00/3x00 Systems.

-l

List option. This option is supported as described in cfdadm(1M).

The type field is always memory.

The info field has the following information for empty banks:

<table>
<thead>
<tr>
<th>slot#</th>
<th>empty</th>
</tr>
</thead>
</table>

The slot# indicates the system slot into which the CPU/Memory board is inserted. For example, if this were slot11 the attachment point for use with cfdadm to manipulate the associated board would be sysctl0:slot11. The info field has the following information for connected banks:

<table>
<thead>
<tr>
<th>slot#</th>
<th>sizeMb</th>
<th>sizeGb</th>
<th>sizeMb</th>
<th>sizeGb</th>
<th>used</th>
<th>base</th>
<th>interleaved</th>
<th>disabled</th>
<th>boot</th>
<th>permanent</th>
</tr>
</thead>
</table>

The size of the bank is given in Mb or Gb as appropriate. If the memory is less than completely used, the used size is reported. The physical base address is given in hexadecimal. If the memory bank is interleaved with some other bank, the interleave factor is reported. If the memory on the board is disabled at boot using the non-volatile disabled-memory-list
variable, this is reported. If the bank has memory that cannot be removed this is reported as permanent.

- `o disable-at-boot | enable-at-boot` These options allow the state of the non-volatile disabled-memory-list variable to be modified. These options can be used in conjunction with the issuing of a `-c` option or with the explicit or implied listing command, `-l`, if no command is required. Use of `-o enable-at-boot` with the `configure` command to override the block on configuring memory on a board in the disabled memory list.

- `o extended | normal | quick` Use with the `-t` option to specify test level.

  The `normal` test level ensures that each memory cell stores both a `0` and a `1`, and checks that all cells are separately addressable. The `quick` test level only does the `0`s and `1`s test, and typically misses address line problems. The `extended` test uses patterns to test for adjacent cell interference problems. The default test level is `normal`. See `-t` option.

- `o max_errors=#` Use with the `-t` option to specify the maximum number of allowed errors. If not specified, a default of `32` is assumed.

- `o timeout=#` Use with the `unconfigure` command to set the self-cancelling timeout. The default value is `60` and the unit is seconds. A value of `0` means no timeout.

- `-t` Test an unconfigured bank of memory. Specify the test level using the `-o quick | normal | extended` option.

  `cfgadm` exits with a `0` (success) if the test was able to run on the memory bank. The result of the test is available in the condition for the attachment point.

- `-v` Verbose option. Use this option in combination with the `-t` option to display detailed progress and results of tests.

- `-x relocate-test` For all pages of memory in use on the specified memory bank, a relocation operation as used in the unconfigure command is attempted. The success of this operation does not guarantee that the bank can be unconfigured. Failure indicates that it probably cannot be unconfigured. This option is for test purposes only.
The following operand is supported:

`ac#:bank#` The attachment points for memory banks are published by instances of the address controller (ac) driver (`ac#`). One instance of the ac driver is created for each system board, but only those instances associated with CPU/Memory boards publish the two bank attachment points, bank0 and bank1.

This form conforms to the logical `ap_id` specification given in `cfgadm(1M)`. The corresponding physical `ap_ids` are listed in the `FILES` section.

The ac driver instance numbering has no relation to the slot number for the corresponding board. The full physical attachment point identifier has the slot number incorporated into it as twice the slot number in hexadecimal directly following the `fhc@` part.

```
/devices/fhc@*,f8800000/ac@0,1000000:bank? attachment points
/usr/platform/sun4u/lib/cfgadm/cfgadm_ac.so.1 hardwarespecificlibraryfile
```

cfgadm_cardbus(1M)

Name  
cfgadm_cardbus – cardbus hardware specific commands for cfgadm

Synopsis  
```
/usr/sbin/cfgadm [-f] [-y | -n] [-v]
    [-o hardware_options] -c function ap_id [ap_id]

/usr/sbin/cfgadm [-f] [-y | -n] [-v]
    [-o hardware_options] -x hardware_function ap_id
    [ap_id]

/usr/sbin/cfgadm [-v] [-s listing_options]
    [-o hardware_options] [-l [ap_id | ap_type]]

/usr/sbin/cfgadm [-v] [-o harware_options] -t ap_id [ap_id]

/usr/sbin/cfgadm [-v] [-o hardware_function] -h
    [ap_id | ap_type]
```

Description  
The CardBus slots in Solaris are hot plug capable. This capability is supported by the PCI
hardware specific library /usr/lib/cfgadm/pci.so.1 through the cfgadm command (see
cfgadm(1M)).

The hot plug administrative models between CardBus, PCI, CompactPCI, and PCI Express
operate the same fashion. Please refer to cfgadm_pci(1M) for the usage information.

*System Administration Guide: Basic Administration*
The fp port driver plug-in /usr/lib/cfgadm/fp.so.1 provides the functionality for Fibre Channel Fabric device node management through cfgadm(1M). cfgadm operates on attachment points. Attachment points are locations in the system where hardware resources can be dynamically reconfigured. Refer to cfgadm(1M) for additional details on attachment points.

For Fibre Channel Fabric device node management, each fp port node is represented by an attachment point in the device tree. In addition, each Fibre Channel device is represented by a dynamic attachment point. Attachment points are named through ap_ids. Two types of ap_ids are defined: logical and physical. The physical ap_id is based on the physical pathname. The logical ap_id is a shorter, more user-friendly name. For fp port nodes, the logical ap_id is the corresponding disk controller number. For example, c0 is a typical logical ap_id.

Fibre Channel devices are named with a port World Wide Name (WWN). If a disk device is connected to controller c0, its ap_id can be:

c0::50020f2300006077

where 50020f2300006077 identifies the port WWN of a specific Fibre Channel device.

Each device on the Fibre Channel private loop port, Fabric port or public loop port is probed and made available to Solaris by default. Devices connected to the Fibre Channel Fabric port or public loop port can be made unavailable to Solaris by initiating an application or an end user operation. The operation is similar to the hot unplugging of devices by way of management user interfaces. Applications or users can use the /usr/lib/cfgadm/fp.so.1 library to enable Libcfgadm to provide interfaces to accomplish this task.

The list of currently connected Fabric devices is generated in the form of the attachment point.

A simple listing of attachment points in the system includes attachment points at fp port nodes but not Fibre Channel devices. The following example uses the -a flag to the list option (-l) to list Fibre Channel devices:

```
# cfgadm -l

Ap_Id      Type     Receptacle  Occupant  Condition
---------- ---------- ---------- ---------- ----------
c0         fc-fabric connected configured unknown
cl         fc-private connected configured unknown
с2         fc         connected     unconfigured unknown
sysctrl0:slot0 cpu/mem connected configured ok
sysctrl0:slot1 sbus-upa connected configured ok
```
The following example lists Fibre Channel devices connected to fp ports.

```
# cfgadm -al

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0</td>
<td>fc-fabric</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>

</tr>
</tbody>
</table>
```

In this example, the `fc-fabric` type of ap_id c0 indicates that the fp port is connected to Fabric. For an fp port with Fabric related type such as fc-fabric and fc-public, device node creation happens by default at the boot time and can be managed by the `cfgadm configure` and `unconfigure` operations. The `fc-private` type of ap_id c1 indicates that fp port is connected to private-loop and device node creation happens by default as well. The fc type of ap_id c2 indicates that nothing is attached to fp port c2. The Type field of a Fibre Channel device ap_id shows the SCSI device type of LUN 0 in the device.

A Fibre Channel device with multiple FCP SCSI LUNs is configured into Solaris and each FCP SCSI LUN is available as a Solaris device. Suppose that ap_ids c0::50020f2300006077 and c0::50020f23000063a9 represent Fibre Channel devices with multiple FCP SCSI LUNs.

The following example shows how to list ap_ids with FCP SCSI LUN information:

```
# cfgadm -al -o show_SCSI_LUN

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0::50020f2300006077,0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f2300006077,1</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f2300006077,2</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f2300006077,3</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f23000063a9,0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f23000063a9,1</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f23000063a9,2</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f23000063a9,3</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f23000065f24,0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f23000065f24,1</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f2300006107,0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0::50020f2300006107,1</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c1</td>
<td>fc-private</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
</tbody>
</table>
```
In this example, the ap_id c0::50020f2300006077, 0 identifies the FCP SCSI LUN 0 of the Fibre Channel device which is represented by port WWN 50020f2300006077. The Fibre Channel device is reported to have 4 FCP SCSI LUNs and they are all configured. 4 FCP SCSI LUN level ap_ids associated with port WWN 50020f2300006077 are listed. The listing also displays FCP SCSI LUNs for unconfigured Fibre Channel devices. The Fibre Channel device represented by c0::50020f2300005f24 is reported to have two FCP SCSI LUNs. The configure operation on c0::50020f2300005f24 creates two Solaris devices. The Type field of FCP SCSI LUN level ap_ids show the SCSI device type of each LUN. When a Fibre Channel device has different device type LUNs, the Type field reflects that.

The receptacle and occupant state for attachment points at the fp port have the following meanings:

- **configured**: One or more devices configured on the fp port
- **connected**: fp port active
- **disconnected**: fp port quiesced (IO activity is suspended)
- **empty**: Not applicable
- **unconfigured**: No devices configured on the fp port

The state for individual Fibre Channel devices on an fp port:

- **configured**: Device is configured into Solaris and is available for use
- **connected**: fp port to which the device is connected to is active
- **disconnected**: fp port to which the device is attached is quiesced
- **unconfigured**: Device is available to be configured

The condition field for attachment points at the fp port has the following meanings:

- **failed**: An error condition has prevented the fp port from being able to detect the presence or type of a Fibre Channel connection.

The condition field for individual Fibre Channel devices on an fp port has the following meanings:

- **failed**: An error is encountered while probing a device on Fabric.
- **failing**: A device was configured on a host and its state as seen by Solaris appears to be normal (i.e., online) but it is either not
Currently present or visible in the fabric or its presence could not be verified due to an error condition on the local port through which the device was configured.

**Unusable**

A device has been configured on the host, but is currently offline or failed.

The unknown condition indicates that probing a device on Fabric completed without an error and the device state within Solaris host is normal if the device was configured previously. The internal condition of the device cannot be guaranteed.

**Options**

`cfgadm` defines several types of operations in addition to listing (`-l`). These operations include invoking configuration state changes and obtaining configuration administration help messages (`-h`).

The following options are supported:

- `-c function`

  The following generic commands are defined for the fp-transport-specific library:

  For Fibre Channel device attachment points on the `fc-fabric` type fp port attachment point, the following configuration state change operations are supported:

  **configure**

  Configure a connected Fibre Channel Fabric device to a host. When a Fibre Channel device is listed as an unknown type in the output of the list operation the device might not be configurable. No attempt is made to configure devices with unknown types. The force option (`-f`) can be used to force the fp port driver plug-in to make an attempt to configure any devices. Any errors in the process are reported. By default, each FCP SCSI LUN that is discovered on a Fibre channel Fabric device is configured. However, FCP SCSI LUNs that are specified in the “pwn-lun-blacklist” property in the `fp.conf` file will remain unconfigured. The FCP SCSI LUN level listing reflects the state of such FCP SCSI LUNs. They stay in the “unconfigured” state after reboot or Solaris Dynamic Reconfiguration on the controller that they are connected through. Refer to `fp(7d)` for additional details on the “pwn-lun-blacklist” property.

  **unconfigure**

  Unconfigure a Fibre Channel Fabric device from a host. This device stays unconfigured until the next reboot or Solaris Dynamic Reconfiguration on the controller that the device is connected, at which time all fabric devices are automatically enumerated. The default behavior may be changed through the use of the “manual_configuration_only” property in the `fp.conf` file. If the property is set, the device remains unconfigured after reboot. Refer to `fp(7d)` for additional details on the "manual_configuration_only" property.
For Fibre Channel private loop devices, the configure command returns success without doing any operation. The unconfigure command is not supported on the private loop devices. The private loop devices are configured by Solaris Fibre Channel drivers by default and are not managed through end user- or application-initiated operations. The “pwnn-lun-blacklist” property in the fp.conf file is applied to the private loop device in the same way it works on a Fabric device.

- \f
  Force the configure change state operation to occur irrespective of the condition or type.
  Refer to the above description of the configure change state operation.

- \h \ap_id
  Obtain fp—transport-specific help. Specify any fp attachment point.

- \o \hardware_options
  The following hardware options are supported.

  \b show_SCSI_LUN \b
  Lists ap_ids associated with each FCP SCSI LUN for discovered Fibre Channel devices when specified with the \b list option -al. Refer to the previously mentioned description and example of FCP SCSI LUN level listing.
  Device node creation is not supported on the FCP SCSI LUN level. See \b NOTES\b.

All Fibre Channel devices are available to Solaris by default. Enabling only a subset of Fabric devices available to Solaris by default can be accomplished by setting the property “manual_configuration_only” in /kernel/drv/fp.conf file. When “manual_configuration_only” in fp.conf is set, all Fabric devices are not available to Solaris unless an application or an end user had previously requested the device be configured into Solaris. The configure state-change command makes the device available to Solaris. After a successful configure operation on a Fabric device, the associated links are added to the /dev namespace. The unconfigure state-change command makes a device unavailable to Solaris.

When a Fibre Channel Fabric device is configured successfully to a host using the -c configure operation, its physical ap_id is stored in a repository. When a Fibre Channel Fabric device is unconfigured using the -c unconfigure operation, its physical ap_id is deleted from the same repository. All fabric devices are automatically enumerated by default and the repository is used only if the fp.conf "manual_configuration_only” property is set. Refer to \b fp(7d)\b for additional details on the "manual_configuration_only” property.

You can specify the following commands with the -c option to control the update behavior of the repository:
force_update  For configure, the attachment point is unconditionally added to the repository; for unconfigure, the attachment point is unconditionally deleted.

no_update  No update is made to the repository regardless of the operation.

These options should not be used for normal configure and unconfigure operations. See WARNINGS.

When a Fibre Channel device has multiple FCP SCSI LUNs configured and any Solaris device associated with its FCP SCSI LUN is in the unusable condition, the whole Fibre Channel device is reported as unusable. The following option with the -c unconfigure command removes only Solaris devices with the unusable condition for a Fibre Channel device.

unusable_SCSI_LUN  For unconfigure operation, any offlined device nodes for a target device is removed.

-s listing_options
Refer to cfgadm(1M) for usage information.

-t ap_id
No test commands are available at present.

-x hardware_function
No hardware specific functions are available at present.

All other options have the same meaning as defined in the cfgadm(1M) man page.

**Examples**

**EXAMPLE 1**  Unconfiguring a Disk
The following command unconfigures a disk:

```
# cfgadm -c unconfigure c0::2100020370b606
```

**EXAMPLE 2**  Unconfigure all the Configured Disks under Single Attachment Point
The following command unconfigures all configured disks under the attachment point c0.

```
# cfgadm -c unconfigure c0
```

**EXAMPLE 3**  Configuring a Disk
The following command configures a disk:

```
# cfgadm -c configure c0::2100020370b606
```

**EXAMPLE 4**  Configure all the Unconfigured Disks under Single Attachment Point
The following command configures all unconfigured disks under the attachment point c0.

```
# cfgadm -c configure c0
```
**EXAMPLE 5**  Removing the Fibre Channel Fabric Device Attachment Point from Repository

The following command unconditionally removes the fibre channel fabric device attachment point from the Fabric device repository.

```
# cfgadm -c unconfigure -o force_update c0::210000203708b606
```

**EXAMPLE 6**  Removing Offlined Solaris Device Nodes for a Target Device

The following command removes offlined Solaris device nodes for a target device:

```
# cfgadm -c unconfigure -o unusable_SCSI_LUN c0::210000203708b606
```

**Files**  
/usr/lib/cfgadm/fp.so.1  
Hardware-specific library for Fibre Channel Fabric device node management.

/etc/cfg/fp/fabric_WWN_map  
Repository of physical ap_ids of Fabric devices currently configured. It is used only to reconfigure those Fabric devices at boot time. This repository is only used when the “manual_configuration_only” /kernel/drv/fp.conf file is set.

/etc/rcS.d/fdevattach  
Reconfigures Fabric device(s) of which physical ap_id is listed in /etc/cfg/fp/fabric_WWN_map on boot time.

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcfpl, SUNWcfplx</td>
</tr>
</tbody>
</table>

**See Also**  
svcs(1), cfgadm(1M), svcadm(1M), config_admin(3CFGADM), libcfgadm(3LIB), attributes(5), smf(5), fp(7d)

**Warnings**  
Do not use hardware-specific options for the repository update under normal configure/unconfigure operations. The hardware-specific options are expected to be used when the node creation of a Fabric device fails at boot time and the error condition is considered to be permanent. The unconfigure command with force_update hardware-specific option unconditionally removes the attachment point of a failing Fabric device from the repository.

**Notes**  
For devices with unknown or no SCSI device type (for example, a Fibre Channel Host Bus Adapter), the configure operation might not be applicable.

The configure and unconfigure commands operate on the Fibre Channel device level which is represented by port WWN ap_id. If a Fibre Channel device has multiple FCP SCSI LUNs configured, the configure command on the associated port WWN ap_id results in creating a Solaris device for each FCP SCSI LUN unless it is specified in the "pwwn-lun-blacklist"
property in the fp.conf file. The unconfigure command removes all Solaris devices associated with the port WWN ap_id. The FCP SCSI LUN level ap_id is not valid for the configure and unconfigure commands.

The deprecated show_FCP_dev option has been replaced by the new show_SCSI_LUN option, and the deprecated unusable_FCP_dev option has been replaced by the new unusable_SCSI_LUN option.

The cfgadm_fp service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/device/fc-fabric:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

No administrative actions on this service are required for Fabric device configuration once this service is started on boot time.
Name  
cfgadm_ib – InfiniBand hardware specific commands for cfgadm

Synopsis
/usr/sbin/cfgadm -f [-y | -n] [-v] -c function ap_id...

/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_options]
   -x hardware_function ap_id...

/usr/sbin/cfgadm -v [-a] [-s listing_option] [-] [ap_id | ap_type...]

/usr/sbin/cfgadm -v -h [ap_id]...

Description

The InfiniBand hardware specific library /usr/lib/cfgadm/ib.so.1 provides
the functionality for administering its fabric through the cfgadm(1M) utility. cfgadm operates on
attachment points. See cfgadm(1M).

An InfiniBand (IB) device is enumerated by the IB nexus driver, ib(7D), based on the services
from the IB Device Manager (IBDM).

The IB nexus driver creates and initializes five types of child device nodes:

- IB Port devices
- IB HCA service (HCA_SVC) devices
- IB Virtual Physical Point of Attachment (VPPA) devices
- I/O Controller (IOC)
- IB Pseudo devices

See ib(7D) for details on enumeration of IB Port, IB VPPA, and IB HCA_SVC devices. For
additional information on IBDM, see ibdm(7D). See ib(4) for details on IB Pseudo devices.

For IB administration, two types of static attachment point are created for the fabric
administration as seen by the given host. There is one static attachment point ib and all IB
devices (either an IOC, Port, VPPA, HCA_SVC, or a Pseudo device) in the fabric are
represented as dynamic attachment points based off of it. There is another static attachment
point for each Host Channel Adapter (HCA) in the host based on its node Globally Unique
Identifier (GUID) value.

Attachment points are named through ap_ids. There are two types of ap_ids: logical and
physical. The physical ap_id is based on the physical path name. For the IB fabric it is
/devices/ib:/fabric. The logical ap_id is a shorter, and has a more user friendly name.

The static ap_id for the IB fabric is ib. The IB devices are dynamic attachment points and have
no physical ap_id. The logical ap_id of an IOC contains its GUID, ib::IOC_GUID. An
example of an IOC ap_id is ib:::80020123456789a. The logical ap_id of a Pseudo device, see
ib(4) for details, is of the format ib::driver_name,unit-address. An example of a pseudo
ap_id would be ib::sdp,0 where “sdp” is the driver name and “0” is its unit-address property.
The logical ap_id of Port, VPPA and HCA_SVC device contains its Partition Key (P_Key),
Port GUID / Node GUID and a communication service-name. The format of ap_id is as below:

Port device
   ib::PORT_GUID,0,service-name
VPPA device
  ib::PORT_GUID,P_Key,service-name

HCA_SVC device
  ib::HCA_GUID,0,serviceName

The Partition Key (P_Key) is 0 for Port and HCA_SVC devices. The P_Key helps determine the partition to which this port belongs for a VPPA device node. A port might have more than one P_Key. An example of a VPPA device logical ap_id point is ib::80245678,ffff,ipib. The port-GUID is 80245678, the P_Key is 0xffff, and the service name is ipib. The service-name information is obtained from the file /kernel/drv/ib.conf which contains service-name strings. The HCA’s logical ap_id contains its node GUID value, hca:HCA-GUID. An example is hca:21346543210a987.

A listing of the IB attachment points includes information on all IB devices (IOC, VPPA, HCA_SVC, Pseudo, and Port devices seen by the IBDM and the IB nexus driver) in the fabric even if they are not seen by the host and configured for use.

The following shows a listing of five IB devices (two IOC, one VPPA, one Port, one HCA_SVC) and one HCA:

```
example# cfgadm -al
Ap_Id     Type       Receptacle  Occupant     Condition
hca:21346543210a987 IB-HCA connected configured ok
ib        IB-FABRIC connected configured ok
ib::80020123456789a IB-IOC connected configured ok
ib::802abc9876543  IB-IOC connected unconfigured unknown
ib::80245678,ffff,ipib IB-VPPA connected configured ok
ib::12245678,0,nfs IB-PORT connected configured ok
ib::21346543,0,hnfs IB-HCA_SVC connected configured ok
ib::sdp,0           IB-PSEUDO connected configured ok
```

The ap_id ib::802abc9876543 shows an IOC device that is not yet configured by the host for use or had been previously offline by an explicit

```
cfgadm -c unconfigure
```

operation. The distinction was made by the information displayed under the Condition column. The IB device with a zero P_Key and HCA GUID is a HCA_SVC device. Refer to cfgadm(1M) for more information regarding listing attachment points.

The receptacle state for attachment points have the following meanings:

connected
  For an IOC/VPPA/Port/Pseudo/HCA_SVC device, connected implies that it has been seen by the host. The device might not have been configured for use by Solaris.

  For a HCA attachment point, connected implies that it has been configured and is in use.

All IB ap_ids are always shown as connected.
The occupant state for attachment points have the following meanings:

configured
   The IB device, and the HCA ap_id, are configured and usable by Solaris.

unconfigured
   The IB device at the ap_id was explicitly offline using `cfgadm -c unconfigure`, was not successfully configured. This could be because it was not successfully configured for use with Solaris (no driver, or a device problem), or because it was never configured for use by the IB nexus driver.

   The `unconfigured` operation is not supported for the HCA attachment point. The IB static apid, `ib`, is shown unconfigured if the system has no IB hardware.

The attachment point conditions are:

failed
   Not used.

failing
   Not used.

ok
   Normal state. Ready for use.

unknown
   This state is only valid for IB device that have been probed by IBDM but not yet configured for use by Solaris. It is also shown for devices that have been explicitly offline by a `cfgadm -c unconfigure` operation. This condition does not apply to a HCA attachment point.

unusable
   Not used.

Options
The following options are supported:

`-c function`
   The IB hardware specific library supports two generic commands (`functions`). These commands are not supported on the static attachment points (that is, the HCA ap_ids and the IB static `ib` ap_id).

The following generic commands are supported:

configure
   Configure the IB device to be used by Solaris.

unconfigure
   Unconfigure the IB device. If successful, `cfgadm` reports the condition of this ap_id as `unknown`.

`-f`
   Not supported.
-h ap_id
  Obtain IB specific help for an IB attachment point.

-\l
  List the state and condition of IB attachment points. The -\l option works as described in \texttt{cfgadm(1M)}.

  When paired with the -a option, displays the dynamic attachment points as well (IOC, VPPA, Port, Pseudo, and HCA_SVC devices).

  When paired with -v option, displays verbose data about the ap_ids. For an IOC, the Info field in the
  \texttt{cfgadm -avl} output displays the following information: VendorID, IOCDeviceID, DeviceVersion, SubsystemVendorID, SubsystemID, Class, Subclass, Protocol, ProtocolVersion and IDString from the IOCControllerProfile. If the ID string isn’t provided then nothing is displayed in its place. These fields are defined in the InfiniBand Specification Volume 1 (http://www.infinibandta.org).

  For a VPPA, Port, or HCA_SVC device the Info field in the \texttt{cfgadm -lav} display shows the service name information to which this device is bound. If no such information exists, nothing is displayed.

  For a Pseudo device \texttt{cfgadm -alv} displays the driver name and its unit-address information. For a HCA the verbose listing displays the VendorID, ProductID of the HCA, number of ports it has, and the PortGUID value of its ports. See \texttt{EXAMPLES}.

-o hardware_option
  This option is not currently defined.

-s listing_option
  Attachment points of class ib can be listed by using the select sub-option. Refer to the \texttt{cfgadm(1M)} man page for more information.

-x hardware_function
  Perform a hardware specific function. Note that the name can not be more than 4 characters long.

  The following hardware specific functions are supported:

  \texttt{add_service -ocomm=[port|vppa|hca_svc],service=name}
  This hardware specific function is supported on the static IB attachment point. It can be used to add a new service to /kernel/drv/ib.conf file and to update the \texttt{ib(7D)} driver.

  You must use the \texttt{service=name} option to indicate the new service to be added. You must use the option \texttt{comm=[port|vppa|hca_svc]} option to add the name service to either \texttt{port-svc-list} or to the \texttt{hca-svc-list} in the /kernel/drv/ib.conf file. See \texttt{EXAMPLES}.
delete_service -ocomm=[port|vppa|hca_svc],service=name

This hardware specific function is supported on the static IB attachment point only. It can be used to delete an existing service from the /kernel/drv/ib.conf file and also from the ib(7D) driver's database. You must use the service=name option to indicate which service to delete. You must use the comm=[port|vppa|hca_svc] option to delete this service from the port-svc-list, vppa-svc-list, or vppa-svc-list of the /kernel/drv/ib.conf file. See EXAMPLES.

list_clients

Supported on HCA attachment points. Displays all the kernel IB clients using this HCA. It also displays the respective ap_ids of these kernel IB clients and if they have opened an alternate HCA device. See EXAMPLES.

If a given kernel IB client does not have a valid ap_id then a - is displayed in that column.

list_services

This hardware specific function is supported on the static IB attachment point only. It lists all the Port and VPPA services as read from the /kernel/drv/ib.conf file. See EXAMPLES.

unconfig_clients

This hardware specific function is supported on the static HCA attachment point only. It can be used to unconfigure all IB kernel clients of this given HCA. Only IB kernel clients that do not have an alternate HCA are unconfigured. See EXAMPLES.

update_ioc_config

This hardware specific function is supported on static ib attachment point and the IOC attachment points. For the ib APID, this function updates properties of all the IOC device nodes. For the IOC APID, this function updates the properties of specified IOC device node. This command updates the port-list, port-entries, service-id, and service-name IOC node properties.

See ib(7D).

update_pkey_tbls

Supported on the static ib attachment point. Updates the PKEY information inside IBTL. IBTL re-reads the P_Key tables for all the ports on each HCA present on the host.

See ibtl(7D).

Examples

**EXAMPLE 1**  Listing the State and Condition of IB Devices

The following command lists the state and condition of IB devices on the system. It only shows the static attachment points.
EXAMPLE 1  Listing the State and Condition of IB Devices  (Continued)

example# cfgadm
hca:21346543210a987  IB-HCA connected configured ok
ib              IB-FABRIC connected configured ok

The -a option lists all attachment points. The following example uses the -a option and lists all attachment points:

example# cfgadm -a
hca:21346543210a987  IB-HCA connected configured ok
ib               IB-FABRIC connected configured ok
ib::80020123456789a  IB-IOC connected unconfigured ok
ib::80245678,ffff,ipib  IB-VPPA connected configured ok
ib::21346543,0,hnfs IB-HCA_SVC connected configured ok
ib::12245678,0,nfs  IB-PORT connected configured ok
ib::sdp,0            IB-PSEUDO connected configured ok

EXAMPLE 2  Listing the Verbose Status of a IB VPPA Device

The following command lists the verbose status of a IB VPPA device:

example# cfgadm -alv ib::80245678,ffff,ipib
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
ib::80245678,ffff,ipib connected configured ok ipib
unavailable IB-VPPA n /devices/ib:fabric::80245678,ffff,ipib

A verbose listing of an IOC shows additional information. The following command shows a verbose listing:

example# cfgadm -alv ib::80020123456789a
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
ib::80020123456789a connected configured ok VID: 0xeaea
DEVID: 0xeaea VER: 0x5 SUBSYS_VID: 0x0 SUBSYS_ID: 0x0 CLASS: 0xffff
SUBCLASS: 0xff PROTO: 0xff PROTOVER: 0x1 ID_STRING: Sample Host Adapter
unavailable IB-IOC n /devices/ib:fabric::80020123456789a

A verbose listing of a Pseudo device shows:

example# cfgadm -alv ib::sdp,0
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
ib::sdp,0 connected configured ok Driver = "sdp"
unavailable IB-PSEUDO n /devices/ib:fabric::sdp,0

A verbose listing of a HCA shows:
EXAMPLE 2  Listing the Verbose Status of an IB VPPA Device  (Continued)

eexample# cfgadm -alv hca:21346543210a987

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>hca:21346543210a987</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
<td>VID: 0x15b3, PID: 0x5a44, #ports: 0x2, port1 GUID: 0x80245678, port2 GUID: 0x80245679</td>
</tr>
</tbody>
</table>

You can obtain more user-friendly output if you specify these following `cfgadm` class and field selection options: `-s "select=class(ib),cols=ap_id:info"`

The following command displays only IB ap_ids. The output only includes the ap_id and Information fields.

```
# cfgadm -al -s "cols=ap_id:info" ib::80245678,ffff,ipib
```

### EXAMPLE 3  Unconfiguring an Existing IBIOC

The following command unconfigures the IB IOC attached to `ib::80020123456789a`, then displays the status of the ap_id:

```
# cfgadm -c unconfigure ib::80020123456789a
```

```
Unconfigure the device: /devices/ib:fabric::80020123456789a
This operation will suspend activity on the IB device
Continue (yes/no)?
```

Enter: y

```
IB device unconfigured successfully.
```

```
# cfgadm -al ib::80020123456789a
```

```
<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ib::80020123456789a</td>
<td>IB-IOC</td>
<td>connected</td>
<td>unconfigured</td>
<td>unknown</td>
</tr>
</tbody>
</table>

```

The condition unknown implies that the device node doesn’t exist anymore and this IB device's existence is known only to the IB Device Manager.

### EXAMPLE 4  Configuring an IB IOC

The following series of commands configures an IB device attached to `ib::80020123456789a`:

```
# cfgadm -yc configure ib::80020123456789a
```

```
# cfgadm -al ib::80020123456789a
```

```
<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ib::80020123456789a</td>
<td>IB-IOC</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
</tbody>
</table>
```
EXAMPLE 5  Listing All Kernel IB Clients of a HCA

The following command lists all kernel IB clients of an HCA attached to
hca:21346543210a987:

# cfgadm -x list_clients hca:21346543210a987

<table>
<thead>
<tr>
<th>Attachment Point</th>
<th>Clients</th>
<th>Alternate HCA</th>
</tr>
</thead>
<tbody>
<tr>
<td>ib::0002123456789a</td>
<td>iocl</td>
<td>Yes</td>
</tr>
<tr>
<td>ib::00245678,ffff,ipib</td>
<td>ipib</td>
<td>No</td>
</tr>
<tr>
<td>ib::21346543,0,hnfs</td>
<td>bnfs</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>ibdm</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>ibmf</td>
<td>No</td>
</tr>
</tbody>
</table>

EXAMPLE 6  Adding a Port Service

The following command adds a new Port service called srp:

# cfgadm -o comm=port,service=srp -x add_service ib

EXAMPLE 7  Deleting a VPPA Service

The following command deletes the ibd VPPA service ibd:

# cfgadm -o comm=vppa,service=ipib -x delete_service ib

EXAMPLE 8  Listing Port, VPPA, HCA_SVC Services

The following command lists all Port, VPPA, and HCA_SVC services:

# cfgadm -x list_services ib

Port communication services:

  srp

VPPA communication services:

  ipib
  nfs

HCA_SVC communication services:

  hnfs

EXAMPLE 9  Reprobing IOC Devices

The following command reprobes all IOC device nodes.

# cfgadm -x update_ioc_config ib

This operation can update properties of IOC devices.

Continue (yes/no)?

Enter: y

#
EXAMPLE 10  Unconfiguring All Kernel Clients of a HCA

The following command unconfigures all kernel clients of a HCA

# cfgadm -x unconfig_clients hca:21346543
This operation will unconfigure clients of this HCA.
Continue (yes/no)?
Enter: y

InfiniBand Specification Volume 1 (http://www.infinibandta.org)

Notes  Apart from the listing (cfgadm -l or cfgadm -x list_clients), only the superuser can execute any functions on an attachment point.
**Name**

`cfgadm_pci` – PCI, CompactPCI, and PCI Express Hotplug hardware specific commands for `cfgadm`

**Synopsis**

```
/usr/sbin/cfgadm [-f] [-y | -n] [-v]
    [-o hardware_options] -c function ap_id [ap_id]

/usr/sbin/cfgadm [-f] [-y | -n] [-v]
    [-o hardware_options] -x hardware_function ap_id [ap_id]

/usr/sbin/cfgadm [-v] [-s listing_options]
    [-o hardware_options] [-l [ap_id | ap_type]]

/usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id [ap_id]

/usr/sbin/cfgadm [-v] [-o hardware_function] -h
    [ap_id | ap_type]
```

**Description**

The PCI hardware specific library, `/usr/lib/cfgadm/pci.so.1`, provides the support for hotplugging PCI and CompactPCI adapter cards into the respective hotpluggable slots in a system that is hotplug capable, through the `cfgadm` command (see `cfgadm(1M)`). This library does not include support for PCI Express Hotplug or Standard PCI Hotplug adapter cards, which are provided by a different library (see `cfgadm_shp(1M)`). Hotplug administrative models between PCI, CompactPCI remain the same except where noted in this document.

For PCI Hot Plug, each hotplug slot on a specific PCI bus is represented by an attachment point of that specific PCI bus.

An attachment point consist of two parts: a receptacle and an occupant. The receptacle under PCI Hot Plug is usually referred to as the physical hotpluggable slot; and the occupant is usually referred to as the PCI adapter card that plugs into the slot.

Attachment points are named through `ap_ids`. There are two types of `ap_ids`: logical and physical. The physical `ap_id` is based on the physical pathname, that is, `/devices/pci@1/hpc0_SLOT3`, whereas the logical `ap_id` is a shorter, and more user-friendly name. For PCI hotpluggable slots, the logical `ap_id` is usually the corresponding hotplug controller driver name plus the logical slot number, that is, `pci0:hpc0:slot1`; PCI nexus driver, with hotplug controller driver named `hpc` and slot number 1. The `ap_type` for PCI Hot Plug is `pci`.

Note that the `ap_type` is not the same as the information in the `Type` field.

See the `System Administration Guide: Basic Administration` for a detailed description of the hotplug procedure.

**Options**

The following options are supported:

- `-c function`
  The following `functions` are supported for PCI hotpluggable slots:
configure
  Configure the PCI device in the slot to be used by Solaris.

connect
  Connect the slot to PCI bus.

disconnect
  Disconnect the slot from the PCI bus.

insert
  Not supported.

remove
  Not supported.

unconfigure
  Logically remove the PCI device's resources from the system.

-f
  Not supported.

-h ap_id | ap_type
  Print out PCI Hot Plug-specific help message.

-l list
  List the values of PCI Hot Plug slots.

-o hardware_options
  No hardware specific options are currently defined.

-s listing_options
  Same as the generic cfgadm(1M).

-t ap_id
  This command is only supported on platforms which support testing capability on the slot.

-v
  Execute in verbose mode.

When the -v option is used with the -l option, the cfgadm command outputs information
about the attachment point. For PCI Hotplug attachment points located in a PCI PCI
Express hierarchy, see cfgadm_shp(1M) for details. For PCI Hot Plug attachment points
not located in a PCI Express hierachry, the Information field will be the slot's system
label, if any. This string will be obtained from the slot-name property of the slot's bus
node. The information in the Type field is printed with or without the v option. The
occupant Type field will describe the contents of the slot. There are 2 possible values:

unknown
  The slot is empty. If a card is in the slot, the card is not configured or there is no driver
  for the device on the card.
subclass/board
The card in the slot is either a single-function or multi-function device.

subclass is a string representing the subclass code of the device, for example, SCSI, ethernet, pci-isa, and so forth. If the card is a multi-functional device, MULT will get printed instead.

board is a string representing the board type of the device. For example, hp is the string used for a PCI Hot Plug adapter, hs is used for a Hot Swap Board, nhs for a Non-Hot Swap cPCI Board, bhs for a Basic Hot Swap cPCI Board, and fhs for a Full Hot Swap cPCI Board.

Most PCI cards with more than one device are not multi-function devices, but are implemented as a PCI bridge with arbitrary devices behind them. In those cases, the subclass displayed is that of the PCI bridge. Most commonly, the bridges are pci-pci, a generic PCI to PCI bridge or stpci, a semi-transparent PCI bridge.

-x hardware_function
Perform hardware specific function. These hardware specific functions should not normally change the state of a receptacle or occupant.

The following hardware_functions are supported:

enable_slot | disable_slot
Change the state of the slot and preserve the state of slot across reboot. Preservation of state across reboot is only supported on select platforms.

enable_slot enables the addition of hardware to this slot for hotplugging and at boot time.

disable_slot disables the addition of hardware to this slot for hotplugging and at boot time. When a slot is disabled its condition is shown as unusable.

enable_autoconfig | disable_autoconfig
Change the ability to autoconfigure the occupant of the slot. Only platforms that support auto configuration support this feature.

enable_autoconfig enables the ability to autoconfigure the slot.

disable_autoconfig disables the ability to autoconfigure the slot.

Autoconfiguration is done through the attention button on the PCI Express platforms and through the injector/ejector latch on the CompactPCI platforms. When autoconfiguration is disabled, the attention button or latch mechanism cannot be used to configure the occupant of the slot.

led=[led_sub_arg],mode=[mode_sub_arg]
Without sub-arguments, print a list of the current LED settings. With sub-arguments, set the mode of a specific LED for a slot.
Specify `led_sub_arg` as `fault`, `power`, `attn`, or `active`.

Specify `mode_sub_arg` as `on`, `off` or `blink`.

Changing the state of the LED does not change the state of the receptacle or occupant. Normally, the LEDs are controlled by the hotplug controller, no user intervention is necessary. Use this command for testing purposes.

**Caution:** Changing the state of the LED can misrepresent the state of occupant or receptacle.

The following command prints the values of LEDs:

```
example# cfgadm -x led pci0:hpc0_slot1
Ap_Id   Led
pci0:hpc0_slot1 power=on,fault=off,active=off,attn=off
```

The following command turns on the Fault LED:

```
example# cfgadm -x led=fault,mode=on pci0:hpc0_slot1
```

The following command turns off the Power LED:

```
example# cfgadm -x led=power,mode=off pci0:hpc0_slot0
```

The following command sets the `active` LED to blink to indicate the location of the slot:

```
example# cfgadm -x led=active,mode=on pci0:hpc0_slot3
```

**Examples**

**EXAMPLE 1** Printing out the Value of Each Slot

The following command prints out the values of each slot:

```
example# cfgadm -l
Ap_Id    Type      Receptacle Occupant    Condition
c0       scsi-bus  connected configured unknown
cl       scsi-bus  connected unconfigured unknown
c2       scsi-bus  connected unconfigured unknown
cpci_slot1 stpci/fhs connected configured ok
clcpci_slot2 unknown empty unconfigured unknown
cpci_slot4 stpci/fhs connected configured ok
cpci_slot5 stpci/fhs connected configured ok
```

**EXAMPLE 2** Replacing a Card

The following command lists all DR-capable attachment points:

```
example# cfgadm
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured unknown</td>
</tr>
<tr>
<td>cl</td>
<td>scsi-bus</td>
<td>connected</td>
<td>unconfigured unknown</td>
</tr>
</tbody>
</table>
EXAMPLE 2 Replacing a Card  (Continued)

```
c2  scsi-bus  connected  unconfigured  unknown

cpci_slot1  stpci/fhs  connected  configured  ok

cpci_slot2  unknown  empty  unconfigured  unknown

cpci_slot4  stpci/fhs  connected  configured  ok

cpci_slot5  stpci/fhs  connected  configured  ok
```

The following command unconfigures and electrically disconnects the card:

```
example# cfgadm -c disconnect cpci_slot4
```

The change can be verified by entering the following command:

```
example# cfgadm cpci_slot4
```

```
Ap_Id    Type   Receptacle     Occupant     Condition
         unknown        disconnected  unconfigured  unknown
```

Now the card can be swapped. The following command electrically connects and configures the card:

```
example# cfgadm -c configure cpci_slot4
```

The change can be verified by entering the following command:

```
example# cfgadm cpci_slot4
```

```
Ap_Id    Type   Receptacle   Occupant       Condition
         stpci/fhs   connected   configured     ok
```

System Administration Guide: Basic Administration
The SATA hardware specific library, /usr/lib/cfgadm/sata.so.1, provides the functionality for SATA hot plugging through the cfgadm command. cfgadm operates on attachment points, which are locations in the system where hardware resources can be dynamically reconfigured. See cfgadm(1M) for information regarding attachment points.

Each SATA controller’s and port multiplier’s device port is represented by an attachment point in the device tree. SATA devices, connected and configured in the system are shown as the attachment point name extension. The terms “attachment point” and “SATA port” are used interchangeably in the following description.

Attachment points are named through ap_ids. All the SATA attachment points ap_id consist of a string in the following form:

```
sataX/P[.M][::dsk/cXtYd0]
```

where

- **X** is the SATA controller number
- **P** is the SATA controller’s device port number (0 to 31)
- **M** is the port multiplier’s device port number (0 to 14) the port multiplier host port number (15). It is used only when the port multiplier is attached to the SATA controller’s device port.
- **dev/cXtYd0** identifies the attached SATA device
- **Y** is a target number

In general, the device identifier is derived from the corresponding logical link for the device in /dev. Because only one LUN (LUN 0) is supported by the SATA device, the “d” component of the device string will always have number 0 (zero).

For example, the logical ap_id of the device port 4 of the port multiplier connected to the device port 5 of the SATA controller 2 would be:

```
sata2/5.4
```
If the SATA disk or CD/DVD device is connected to this attachment point, and the device is configured, the `ap_id` would be:

```
sata2/5.4::dsk/c2t645d0
```

The `cXyYd0` string identifying a device has one-to-one correspondence to the device attachment point.

A simple listing of attachment points in the system will include all SATA device ports and attached devices. For example:

```
# cfgadm -l

<table>
<thead>
<tr>
<th>Ap_Id</th>

```

See `cfgadm(1M)` for more information regarding listing of attachment points.

The receptacle state for attachment point at the SATA port have the following meanings:

- **empty** The SATA port is powered-on and enabled. No device presence was detected on this port.
- **disconnected** The SATA port is not enabled or the SATA device presence was detected but no communication with the device was established, or the port has failed.
- **connected** The SATA device is detected on the port the communication with the device is established.

The occupant (device attached to the SATA port) state have the following meanings:

- **configured** The attached SATA device is configured and ready to use by the operating system.
- **unconfigured** No device is attached, or the SATA device attached to the SATA port was not yet configured. To configure it, run the command "`cfgadm -c configure ap_id`".
The attachment point (SATA port) condition have the following meanings:

**ok**  The SATA port is powered-on and enabled, and is ready for use.

**failed**  The SATA port failed. It may be disabled and/or powered-off by the system. It is unusable and its condition is unknown. It may be due to the device plugged-in.

**unknown**  The SATA port is disabled and its condition is unknown.

A "state table" is the combination of an attachment point receptacle state, an occupant state, and an attachment point (SATA port) condition. The valid states are:

- **empty/unconfigured/ok**: The SATA port is enabled and active. No device presence was detected.

- **disconnected/unconfigured/ok**: The SATA port is enabled and a device presence was detected but no communications with the device was established.

- **disconnected/unconfigured/unknown**: The SATA Port is disabled and its condition is unknown.

- **disconnected/unconfigured/failed**: The SATA Port is disabled and unusable. The port was disabled by the system due to a system-detected failure.

- **connected/unconfigured/ok**: The SATA Port is enabled and active. A device presence was detected and the communication with a device was established. The device is not configured to be used by the OS.

- **connected/configured/ok**: The device is present and configured, and is ready to use by the OS.

### Options

`cfgadm` defines several types of operations besides listing (-l). These operations include testing, (-t), invoking configuration state changes, (-c), invoking hardware specific functions (-x), and obtaining configuration administration help messages (-h).

- **-c function**
  The following generic functions are defined for the SATA hardware specific library. For SATA port attachment point, the following configuration state change operations are supported:

  - **connect**
    Enable (activate) the SATA port and establish the communication with an attached device. This operation implies powering-on the port if necessary.

  - **disconnect**
    Unconfigure the attached device, if it is not already unconfigured, and disable (deactivate) the SATA port. A subsequent "connect" command enables SATA port
operation but does not bring a device to the “configured” state.

For a SATA device attached to the SATA port following state change operations are supported:

configure Configure new device for use by the operating system if it is not already configured. This command also implies connect operation, if necessary.

unconfigure Unconfigure the device connected to the SATA port if it is not already unconfigured.

The configure and unconfigure operations cannot be used for an attachment point where the port multiplier is connected. Port multipliers are configured and unconfigured automatically by the system. However, configure and unconfigure operations apply to all SATA devices connected to the port multiplier's device ports.

- f
  Not supported.

- h ap_id
  SATA specific help can be obtained by using the help option with any SATA attachment point.

- l [ -v ]
  The - l option works as described in `cfgadm(1M)`. When paired with the - v option, the “Information” field contains the following SATA-specific information:
  □ Mfg: manufacturer string
  □ Product: product string
  □ No: product Serial Number

- o hardware_options
  No hardware specific options are currently defined.

- s listing_options
  Attachment points of class SATA can be listed by using the select suboption. See `cfgadm(1M)`.

- t ap_id
  Perform self-test of the SATA port, if supported by the SATA controller. If a port self-test operation is not supported by the SATA controller, an error message is issued.

- x hardware_function
  Perform hardware specific function.

Some of the following commands used on the SATA ports or the SATA controller may affect any SATA devices that have been attached, as noted. ap_id refers to SATA port or the entire SATA controller, as noted. If the operation implies unconfiguring a device, but it cannot be unconfigured (that is, the device contains a mounted filesystem), an error
message is issued and the operation is not performed. An error message will be also issued if the SATA controller does not support specified operation.

`sata_reset_device ap_id`
Reset the SATA device attached to `ap_id` SATA port. The SATA port state does not change.

`sata_reset_port ap_id`
Reset the SATA port specified by `ap_id`. If a SATA device is attached to the port, it is also reset. This operation may be also performed on the port to which a port multiplier is connected. If a port multiplier is connected to the SATA controller port, the SATA devices attached to the port multiplier may not be reset.

`sata_reset_all ap_id`
Reset SATA controller specified by the controller number part in `ap_id` and all attached devices and re-enumerate all connected devices, including port multipliers and devices connected to port multipliers’ device ports.

This operations implies unconfiguring all attached devices prior to the operation. Any newly enumerated devices will be left unconfigured.

`sata_port_deactivate ap_id`
Force the deactivation of the port when all else fails. This is meant as an emergency step; use with caution.

`sata_port_activate ap_id`
Force the activation of a port. This is meant for emergency situations on a port which was deactivated to recover from errors.

`sata_port_self_test ap_id`
Perform self-test operation on the SATA controller. This operation implies unconfiguring all devices and resetting the SATA controller.

`-v`
Execute in verbose mode.

The following Transitions table reports the state transitions resulting from the `-c` operations and hotplugging actions:

Examples

EXAMPLE 1 Configuring a Disk
The following command configures a disk attached to SATA controller 0, port 0:
example# cfgadm -c configure sata0/0
This command should be issued only when there is a device connected to the SATA port.

EXAMPLE 2 Unconfiguring a Disk
The following command unconfigures a disk attached to SATA controller 0, port 3:
example# cfgadm -c unconfigure sata0/3::dsk/c0t3d0
The device identifying string is shown when the attachment point receptacle state is
“connected” and occupant state is “configured”.

EXAMPLE 3 Encountering a Mounted File System While Unconfiguring a Disk
The following command illustrates encountering a mounted file system while unconfiguring a
disk:
example# cfgadm -c unconfigure sata1/5::dsk/c01t35d0
The system responds with the following:
cfgadm: Component system is busy, try again: failed to offline:
    /devices/pci@0,0/pci8086,244e@1e/pci1095,3124@1/sd@5,0
    Resource Information
    -------------- --------------------------
    /dev/dsk/c1t5d0s0 mounted filesystem "/mnt"

Files /usr/lib/cfgadm/sata.so.1 Hardware specific library for generic SATA hot plugging.

Notes The emergency “sata_port_deactivate” operation is not supported on ports with attached
disks containing critical partitions such as root (/), /usr, swap, or /var. The deactivate
operation should not be attempted on such ports. Incorrect usage can result in a system hang
and require a reboot.
Hotplugging operations are not supported by all SATA controllers.

If SATA connectors are the hot-pluggable type and the SATA controller supports hotplugging, a SATA device can be hotplugged at any time. The system detects the event and establishes the communication with the device. The device has to be configured by the explicit "cfgadm -c configure ap_id" command.

If the SATA connectors are the hot-pluggable type and the SATA controller supports hotplugging, unplugging a device without unconfiguring it may result in system hang or data loss. If a device is unconfigured but receptacle state is not in a disconnected state, unplugging a device from the SATA port will result in error message.

**Warnings**  
The connectors on some SATA devices do not conform to SATA hotplug specifications. Performing hotplug operations on such devices can cause damage to the SATA controller and/or the SATA device.
The `cfgadm_sbd` plugin provides dynamic reconfiguration functionality for connecting, configuring, unconfiguring, and disconnecting class `sbd` system boards. It also enables you to connect or disconnect a system board from a running system without having to reboot the system.

The `cfgadm` command resides in `/usr/sbin`. See `cfgadm(1M)`. The `cfgadm_sbd` plugin resides `/usr/platform/sun4u/lib/cfgadm`.

Each board slot appears as a single attachment point in the device tree. Each component appears as a dynamic attachment point. You can view the type, state, and condition of each component, and the states and condition of each board slot by using the `-a` option.

The `cfgadm` options perform differently depending on the platform. Additionally, the form of the attachment points is different depending on the platform. See the Platform Notes section for more information.

### Component Conditions

- **failed**: The component failed testing.
- **ok**: The component is operational.
- **unknown**: The component has not been tested.

### Component States

- **connected**: The component is connected to the board slot.

The following are the names and descriptions of the occupant states for components:

- **configured**: The component is available for use by the Solaris operating environment.
- **unconfigured**: The component is not available for use by the Solaris operating environment.

### Board Conditions

The following are the names and descriptions of the board conditions.

- **failed**: The board failed testing.
- **ok**: The board is operational.
- **unknown**: The board has not been tested.
unusable  The board slot is unusable.

Board States  Inserting a board changes the receptacle state from empty to disconnected. Removing a board changes the receptacle state from disconnected to empty.

Caution:  Removing a board that is in the connected state or that is powered on and in the disconnected state crashes the operating system and can result in permanent damage to the system.

The following are the names and descriptions of the receptacle states for boards:

- **connected**  The board is powered on and connected to the system bus. You can view the components on a board only after it is in the connected state.

- **disconnected**  The board is disconnected from the system bus. A board can be in the disconnected state without being powered off. However, a board must be powered off and in the disconnected state before you remove it from the slot.

- **empty**  A board is not present.

The occupant state of a disconnected board is always unconfigured. The following table contains the names and descriptions of the occupant states for boards:

- **configured**  At least one component on the board is configured.

- **unconfigured**  All of the components on the board are unconfigured.

Dynamic System Domains  Platforms based on dynamic system domains (DSDs, referred to as domains in this document) divide the slots in the chassis into electrically isolated hardware partitions (that is, DSDs). Platforms that are not based on DSDs assign all slots to the system permanently.

A slot can be empty or populated, and it can be assigned or available to any number of domains. The number of slots available to a given domain is controlled by an available component list (ACL) that is maintained on the system controller. The ACL is not the access control list provided by the Solaris operating environment.

A slot is visible to a domain only if the slot is in the domain’s ACL and if it is not assigned to another domain. An unassigned slot is visible to all domains that have the slot in their ACL. After a slot has been assigned to a domain, the slot is no longer visible to any other domain.

A slot that is visible to a domain, but not assigned, must first be assigned to the domain before any other state changing commands are applied. The assign can be done explicitly using `-x assign` or implicitly as part of a connect. A slot must be unassigned from a domain before it can be used by another domain. The unassign is always explicit, either directly using `-x unassign` or as an option to disconnect using `-o unassign`. 
Functions that change the state of a board slot or a component on the board can be issued concurrently against any attachment point. Only one state changing operation is permitted at a given time. A \( Y \) in the Busy field in the state changing information indicates an operation is in progress.

The following list contains the functions that change the state:

- configure
- unconfigure
- connect
- disconnect

Commands that change the availability of a board can be issued concurrently against any attachment point. Only one availability change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A \( Y \) in the Busy field indicates that an operation is in progress.

The following list contains the functions that change the availability:

- assign
- unassign

Functions that change the condition of a board slot or a component on the board can be issued concurrently against any attachment point. Only one condition change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A \( Y \) in the Busy field indicates an operation is in progress.

The following list contains the functions that change the condition:

- poweron
- poweroff
- test

This section contains a description of the unconfigure process, and illustrates the states of source and target boards at different stages during the process of moving permanent memory.

In the following code examples, the permanent memory on board 0 must be moved to another board in the domain. Thus, board 0 is the source, and board 1 is the target.

A status change operation cannot be initiated on a board while it is marked as busy. For brevity, the CPU information has been removed from the code examples.

The process is started with the following command:

```
# cfgadm -c unconfigure -y SB0::memory &
```
First, the memory on board 1 in the same address range as the permanent memory on board 0 must be deleted. During this phase, the source board, the target board, and the memory attachment points are marked as busy. You can display the status with the following command:

# cfgadm -a -s cols=ap_id:type:r_state:o_state:busy SB0 SB1

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Busy</th>
</tr>
</thead>
<tbody>
<tr>
<td>SB0</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
<tr>
<td>SB0::memory</td>
<td>memory</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
<tr>
<td>SB1</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
<tr>
<td>SB1::memory</td>
<td>memory</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
</tbody>
</table>

After the memory has been deleted on board 1, it is marked as unconfigured. The memory on board 0 remains configured, but it is still marked as busy, as in the following example.

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Busy</th>
</tr>
</thead>
<tbody>
<tr>
<td>SB0</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
<tr>
<td>SB0::memory</td>
<td>memory</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
<tr>
<td>SB1</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
<tr>
<td>SB1::memory</td>
<td>memory</td>
<td>connected</td>
<td>configured</td>
<td>n</td>
</tr>
</tbody>
</table>

The memory from board 0 is then copied to board 1. After it has been copied, the occupant state for the memory is switched. The memory on board 0 becomes unconfigured, and the memory on board 1 becomes configured. At this point in the process, only board 0 remains busy, as in the following example.

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Busy</th>
</tr>
</thead>
<tbody>
<tr>
<td>SB0</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>y</td>
</tr>
<tr>
<td>SB0::memory</td>
<td>memory</td>
<td>connected</td>
<td>unconfigured</td>
<td>n</td>
</tr>
<tr>
<td>SB1</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>n</td>
</tr>
<tr>
<td>SB1::memory</td>
<td>memory</td>
<td>connected</td>
<td>configured</td>
<td>n</td>
</tr>
</tbody>
</table>

After the entire process has been completed, the memory on board 0 remains unconfigured, and the attachment points are not busy, as in the following example.

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Busy</th>
</tr>
</thead>
<tbody>
<tr>
<td>SB0</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>n</td>
</tr>
<tr>
<td>SB0::memory</td>
<td>memory</td>
<td>connected</td>
<td>unconfigured</td>
<td>n</td>
</tr>
<tr>
<td>SB1</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>n</td>
</tr>
<tr>
<td>SB1::memory</td>
<td>memory</td>
<td>connected</td>
<td>configured</td>
<td>n</td>
</tr>
</tbody>
</table>

The permanent memory has been moved, and the memory on board 0 has been unconfigured. At this point, you can initiate a new state changing operation on either board.
You can specify platform-specific options that follow the options interpreted by the system board plugin. All platform-specific options must be preceded by the `platform` keyword. The following example contains the general format of a command with platform-specific options:

```
command -o sbd_options,platform=platform_options
```

### Options

This man page does not include the `-v`, `-a`, `-s`, or `-h` options for the `cfgadm` command. See `cfgadm(1M)` for descriptions of those options. The following options are supported by the `cfgadm_sbd` plugin:

- `-c function`  
  Performs a state change function. You can use the following functions:
  
  - `unconfigure`  
    Changes the occupant state to unconfigured. This function applies to system board slots and to all of the components on the system board.

    The `unconfigure` function removes the CPUs from the CPU list and deletes the physical memory from the system memory pool. If any device is still in use, the `cfgadm` command fails and reports the failure to the user. You can retry the command as soon as the device is no longer busy. If a CPU is in use, you must ensure that it is offline before you proceed. See `pbind(1M), psradm(1M)` and `psrinfo(1M)`.

    The `unconfigure` function moves the physical memory to another system board before it deletes the memory from the board you want to unconfigure. Depending of the type of memory being moved, the command fails if it cannot find enough memory on another board or if it cannot find an appropriate physical memory range.

    For permanent memory, the operating system must be suspended (that is, quiesced) while the memory is moved and the memory controllers are reprogrammed. If the operating system must be suspended, you will be prompted to proceed with the operation. You can use the `-y` or `-n` options to always answer yes or no respectively.

    Moving memory can take several minutes to complete, depending on the amount of memory and the system load. You can monitor the progress of the operation by issuing a status command against the memory attachment point. You can also interrupt the memory operation by stopping the `cfgadm` command. The deleted memory is returned to the system memory pool.
disconnect  Changes the receptacle state to disconnected. This function applies only to system board slots.

If the occupant state is configured, the disconnect function attempts to unconfigure the occupant. It then powers off the system board. At this point, the board can be removed from the slot.

This function leaves the board in the assigned state on platforms that support dynamic system domains.

If you specify -o nopoweroff, the disconnect function leaves the board powered on. If you specify -o unassign, the disconnect function unassigns the board from the domain.

If you unassign a board from a domain, you can assign it to another domain. However, if it is assigned to another domain, it is not available to the domain from which it was unassigned.

configure  Changes the occupant state to configured. This function applies to system board slots and to any components on the system board.

If the receptacle state is disconnected, the configure function attempts to connect the receptacle. It then walks the tree of devices that is created by the connect function, and attaches the devices if necessary. Running this function configures all of the components on the board, except those that have already been configured.

For CPUs, the configure function adds the CPUs to the CPU list. For memory, the configure function ensures that the memory is initialized then adds the memory to the system memory pool. The CPUs and the memory are ready for use after the configure function has been completed successfully.

For I/O devices, you must use the mount and the ifconfig commands before the devices can be used. See ifconfig(1M) and mount(1M).

connect  Changes the receptacle state to connected. This function applies only to system board slots.
If the board slot is not assigned to the domain, the `connect` function attempts to assign the slot to the domain. Next, it powers on and tests the board, then it connects the board electronically to the system bus and probes the components.

After the `connect` function is completed successfully, you can use the `-a` option to view the status of the components on the board. The `connect` function leaves all of the components in the unconfigured state.

The assignment step applies only to platforms that support dynamic system domains.

- `-f`

  Overrides software state changing constraints.

  The `-f` option never overrides fundamental safety and availability constraints of the hardware and operating system.

- `-l`

  Lists the state and condition of attachment points specified in the format controlled by the `-s`, `-v`, and `-a` options as specified in `cfgadm(1M)`. The `cfgadm_sbd` plugin provides specific information in the info field as described below. The format of this information might be altered by the `-o parsable` option.

  The parsable `info` field is composed of the following:

  cpu

  The `cpu` type displays the following information:

  `cpuid=#[, #...]`

  Where `#` is a number, and represents the ID of the CPU. If more than one `#` is present, this CPU has multiple active virtual processors.

  `speed=#[, #...]`

  Where `#` is a number and represents the speed of the CPU in MHz.

  `ecache=#[, #...]`

  Where `#` is a number and represents the size of the ecache in MBytes. If the CPU has multiple active virtual processors, the ecache could either be shared among the virtual processors, or divided between them.

  memory

  The `memory` type displays the following information, as appropriate:

  `address=#[, #...]`

  Where `#` is a number, representing the base physical address.

  `size=#[, #...]`

  Where `#` is a number, representing the size of the memory in KBytes.
permanent=#  Where # is a number, representing the size of permanent memory in KBytes.

unconfigurable  An operating system setting that prevents the memory from being unconfigured.

inter-board-interleave The board is participating in interleaving with other boards.

source=ap_id  Represents the source attachment point.

target=ap_id  Represents the target attachment point.

deleted=#  Where # is a number, representing the amount of memory that has already been deleted in KBytes.

remaining=#  Where # is a number, representing the amount of memory to be deleted in KBytes.

io  The io type displays the following information:

device=path  Represents the physical path to the I/O component.

referenced  The I/O component is referenced.

board  The board type displays the following boolean names. If they are not present, then the opposite applies.

assigned  The board is assigned to the domain.

powered-on  The board is powered on.

The same items appear in the info field in a more readable format if the -o parsable option is not specified.

-o parsable  Returns the information in the info field as a boolean name or a set of name=value pairs, separated by a space character.

The -o parsable option can be used in conjunction with the -s option. See the cfgadm(1M) man page for more information about the -s option.

-t  Tests the board.

Before a board can be connected, it must pass the appropriate level of testing.
Use of this option always attempts to test the board, even if it has already passed the appropriate level of testing. Testing is also performed when a -c connect state change function is issued, in which case the test step can be skipped if the board already shows an appropriate level of testing. Thus the -t option can be used to explicitly request that the board be tested.

- x function

Performs an sbd-class function. You can use the following functions:

assign
Assigns a board to a domain.

The receptacle state must be disconnected or empty. The board must also be listed in the domain available component list. See Dynamic System Domains.

unassign
Unassigns a board from a domain.

The receptacle state must be disconnected or empty. The board must also be listed in the domain available component list. See Dynamic System Domains.

poweron
Powers the system board on.

The receptacle state must be disconnected.

poweroff
Powers the system board off.

The receptacle state must be disconnected.

Operands

The following operands are supported:

Receptacle ap_id
For the Sun Fire high-end systems such as the Sun Fire 15K, the receptacle attachment point ID takes the form SBX or IOX, where X equals the slot number.

The exact format depends on the platform and typically corresponds to the physical labelling on the machine. See the platform specific information in the NOTES section.

Component ap_id
The component attachment point ID takes the form component_typeX, where component_type equals one of the component types described in “Component Types” and X equals the component number. The component number is a board-relative unit number.

The above convention does not apply to memory components. Any DR action on a memory attachment point affects all of the memory on the system board.
The following examples show user input and system output on a Sun Fire 15K system. User input, specifically references to attachment points and system output might differ on other Sun Fire systems, such as the Sun Fire midrange systems such as the 6800. Refer to the Platform Notes for specific information about using the `cfgadm_sbd` plugin on non-Sun Fire high-end models.

**EXAMPLE 1**  Listing All of the System Board

```
# cfgadm -a -s "select=class(sbd)"
```

<table>
<thead>
<tr>
<th>Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>SB0</td>
<td>CPU</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>SB0::cpu0</td>
<td>cpu</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>SB0::memory</td>
<td>memory</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>IO1</td>
<td>HPCI</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>IO1::pci0</td>
<td>io</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>IO1::pci1</td>
<td>io</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>SB2</td>
<td>CPU</td>
<td>disconnected</td>
<td>unconfigured</td>
<td>failed</td>
</tr>
<tr>
<td>SB3</td>
<td>CPU</td>
<td>disconnected</td>
<td>unconfigured</td>
<td>unusable</td>
</tr>
<tr>
<td>SB4</td>
<td>unknown</td>
<td>empty</td>
<td>unconfigured</td>
<td>unknown</td>
</tr>
</tbody>
</table>

This example demonstrates the mapping of the following conditions:

- The board in Slot 2 failed testing.
- Slot 3 is unusable; thus, you cannot hot plug a board into that slot.

**EXAMPLE 2**  Listing All of the CPUs on the System Board

```
# cfgadm -a -s "select=class(sbd):type(cpu)"
```

<table>
<thead>
<tr>
<th>Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>SB0::cpu0</td>
<td>cpu</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>SB0::cpu1</td>
<td>cpu</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>SB0::cpu2</td>
<td>cpu</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>SB0::cpu3</td>
<td>cpu</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
</tbody>
</table>

**EXAMPLE 3**  Displaying the CPU Information Field

```
# cfgadm -l -s noheadings,cols=info SB0::cpu0
```

cpuid 16, speed 400 MHz, ecache 8 Mbytes

**EXAMPLE 4**  Displaying the CPU Information Field in Parsable Format

```
# cfgadm -l -s noheadings,cols=info -o parsable SB0::cpu0
```

cpuid=16 speed=400 ecache=8
EXAMPLE 5  Displaying the Devices on an I/O Board

# cfgadm -a -s noheadings,cols=ap_id:info -o parsable IO1

IO1 powered-on assigned
IO1::pci0 device=/devices/saf@0/pci@0,2000 referenced
IO1::pci1 device=/devices/saf@0/pci@1,2000 referenced

EXAMPLE 6  Monitoring an Unconfigure Operation

In the following example, the memory sizes are displayed in Kbytes.

# cfgadm -c unconfigure -y SB0::memory &
# cfgadm -l -s noheadings,cols=info -o parsable SB0::memory SB1::memory

address=0x0 size=2097152 permanent=752592 target=SB1::memory
        deleted=1273680 remaining=823472
address=0x1000000 size=2097152 source=SB0::memory

EXAMPLE 7  Assigning a Slot to a Domain

# cfgadm -x assign SB2

EXAMPLE 8  Unassigning a Slot from a Domain

# cfgadm -x unassign SB3

Attributes  See attributes(5) for a description of the following attribute:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWkvm.u</td>
</tr>
<tr>
<td>Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The interface stability is evolving. The output stability is unstable.

Notes  This section contains information on how to monitor the progress of a memory delete operation. It also contains platform specific information.

Memory Delete Monitoring  The following shell script can be used to monitor the progress of a memory delete operation.

#!/bin/sh
# This is the watch_memdel script.

# watch_memdel SB0

# This is the watch_memdel script.
The following syntax is used to refer to Platform Notes attachment points on the Sun Enterprise 10000 system:

```
board:component
```

where `board` refers to the system board; and `component` refers to the individual component. System boards can range from SB0 (zero) to SB15. A maximum of sixteen system boards are available.

The DR 3.0 model running on a Sun Enterprise 10000 domain supports a limited subset of the functionality provided by the `cfgadm_sbd` plugin. The only supported operation is to view the status of attachment points in the domain. This corresponds to the `-l` option and all of its associated options.
Attempting to perform any other operation from the domain will result in an error that states that the operation is not supported. All operations to add or remove a system board must be initiated from the System Service Processor.

The following syntax is used to refer to attachment points on the Sun Fire high-end systems:

```
board::component
```

where board refers to the system board or I/O board; and component refers to the individual component.

Depending on the system's configuration, system boards can range from SB0 (zero) through SB17, and I/O boards can range from IO0 (IO zero) through IO17. (A maximum of eighteen system and I/O boards are available).

The -t and -x options behave differently on the Sun Fire high-end system platforms. The following list describes their behavior:

- **-t**
  The system controller uses a CPU to test system boards by running LP0ST, sequenced by the hpost command. To test I/O boards, the driver starts the testing in response to the -t option, and the test runs automatically without user intervention. The driver unconfigures a CPU and a stretch of contiguous physical memory. Then, it sends a command to the system controller to test the board. The system controller uses the CPU and memory to test the I/O board from inside of a transaction/error cage. You can only use CPUs from system boards (not MCPU boards) to test I/O boards.

- **-x assign | unassign**
  In the Sun Fire high-end system administration model, the platform administrator controls the platform hardware through the use of an available component list for each domain. This information is maintained on the system controller. Only the platform administrator can modify the available component list for a domain.

  The domain administrator is only allowed to assign or unassign a board if it is in the available component list for that domain. The platform administrator does not have this restriction, and can assign or unassign a board even if it is not in the available component list for a domain.

The following are the names and descriptions of the component types:

- **cpu** CPU
- **io** I/O device
- **memory** Memory

---

Sun Fire High-End System Platform Notes

Sun Fire 15K Component Types
Note: An operation on a memory component affects all of the memory components on the board.

References to attachment points are slightly different on Sun Fire midrange servers such as the 6800, 4810, 4800, and 3800 systems than on the Sun Fire high-end systems. The following syntax is used to refer to attachment points on Sun Fire systems other than the Sun Fire 15K:

N#.board: .component

where N# refers to the node; board refers to the system board or I/O board; and component refers to the individual component.

Depending on the system’s configuration, system boards can range from SB0 through SB5, and I/O boards can range from IB6 through IB9. (A maximum of six system and four I/O boards are available).

The following are the names and descriptions of the component types:

- cpu  CPU
- pci  I/O device
- memory  Memory

Note: An operation on a memory component affects all of the memory components on the board.
The SCSI hardware specific library /usr/lib/cfgadm/scsi.so.1 provides the functionality for SCSI hot-plugging through the \texttt{cfgadm(1M)} command. \texttt{cfgadm} operates on attachment points, which are locations in the system where hardware resources can be dynamically reconfigured. Refer to \texttt{cfgadm(1M)} for information regarding attachment points.

For SCSI hot-plugging, each SCSI controller is represented by an attachment point in the device tree. In addition, each SCSI device is represented by a dynamic attachment point. Attachment points are named through \texttt{ap_ids}. Two types of \texttt{ap_ids} are defined: logical and physical. The physical \texttt{ap_id} is based on the physical pathname, whereas the logical \texttt{ap_id} is a shorter more user-friendly name. For SCSI controllers, the logical \texttt{ap_id} is usually the corresponding disk controller number. For example, a typical logical \texttt{ap_id} would be \texttt{c0}.

SCSI devices are named relative to the controller \texttt{ap_id}. Thus if a disk device is attached to controller \texttt{c0}, its \texttt{ap_id} can be:

\texttt{c0::dsk/c0t0d0}

where \texttt{dsk/c0t0d0} identifies the specific device. In general, the device identifier is derived from the corresponding logical link for the device in \texttt{/dev}. For example, a SCSI tape drive logical \texttt{ap_id} could be \texttt{c0::rmt/0}. Here \texttt{c0} is the logical \texttt{ap_id} for the SCSI controller and \texttt{rmt/0} is derived from the logical link for the tape drive in \texttt{/dev/rmt}. If an identifier can not be derived from the link in \texttt{/dev}, a unique identifier will be assigned to it. For example, if the tape device has no link in \texttt{/dev}, it can be assigned an \texttt{ap_id} of the form \texttt{c0::st3} where \texttt{st3} is a unique internally generated identifier.

When a controller is capable of supporting the Solaris I/O multipathing feature (formerly known as MPxIO or the Sun StorEdge Traffic Manager [STMS]) and is enabled, the controller provides a path to a \texttt{scsi_vhci(7D)} multipath device. If a device attached to such controller is supported by \texttt{scsi_vhci(7D)} its \texttt{ap_id} can be:

\texttt{c0::0,0}
...where 0, 0 uniquely identifies the target and logical unit information. The Type field for a path of such ap_ids indicates if it represent a path to the scsi_vhci(7D) multipath devices, along with the type of device that is connected to through the path.

A simple listing of attachment points in the system will include attachment points at SCSI controllers but not SCSI devices. Use the -a flag to the list option (-l) to list SCSI devices as well. For example:

```
# cfgadm -l
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0:</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>sysctrl0:slot0</td>
<td>cpu/mem</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>sysctrl0:slot1</td>
<td>sbus-upa</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
</tbody>
</table>

To list SCSI devices in addition to SCSI controllers:

```
# cfgadm -al
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0:</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t14d0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t11d0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t8d0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t0d0</td>
<td>disk</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:rmr/0</td>
<td>tape</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>sysctrl0:slot0</td>
<td>cpu/mem</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>sysctrl0:slot1</td>
<td>sbus-upa</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
</tbody>
</table>

If the controller c0 was enabled with Solaris I/O multipathing and the connected disk and tape devices are supported by Solaris I/O multipathing the output would be:

```
# cfgadm -al
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0:</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t14d0</td>
<td>disk-path</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t11d0</td>
<td>disk-path</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t8d0</td>
<td>disk-path</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:disk/c0t0d0</td>
<td>disk-path</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c0:rmr/0</td>
<td>tape-path</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>sysctrl0:slot0</td>
<td>cpu/mem</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>sysctrl0:slot1</td>
<td>sbus-upa</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
</tbody>
</table>

Refer to `cfgadm(1M)` for more information regarding listing attachment points. The receptacle and occupant state for attachment points at the SCSI controller have the following meanings:

- empty
- not applicable
disconnected
  bus quiesced (I/O activity on bus is suspended)
connected
  bus active
configured
  one or more devices on the bus is configured
unconfigured
  no device on the bus is configured

The corresponding states for individual SCSI devices are:
empty
  not applicable
disconnected
  bus to which the device is attached is quiesced
connected
  bus to which device is attached is active
configured
  device or path to a multipath SCSI device is configured
unconfigured
  device or path to a multipath SCSI device is not configured

Options  

cfgadm defines several types of operations besides listing (-l). These operations include testing, (-t), invoking configuration state changes, (-c), invoking hardware specific functions (-x), and obtaining configuration administration help messages (-h).

  -c function
  The following generic commands are defined for the SCSI hardware specific library:

For SCSI controller attachment points, the following configuration state change operations are supported:
connect
  Unquiesce the SCSI bus.
disconnect
  Quiesce the bus (suspend I/O activity on bus).
  Incorrect use of this command can cause the system to hang. See NOTES.
configure
  Configure new devices on SCSI bus.
unconfigure
  Unconfigure all devices connected to bus.
The following generic commands are defined for SCSI devices and for paths to multipath SCSI devices:

**configure**
Configure a specific device or a specific path to a multipath SCSI device.

**unconfigure**
Unconfigure a specific device or a specific path to a multipath SCSI device.

**-f**
When used with the `disconnect` command, forces a quiesce of the SCSI bus, if supported by hardware.

Incorrect use of this command can cause the system to hang. See NOTES.

**-h ap_id**
SCSI specific help can be obtained by using the help option with any SCSI attachment point.

**-o hardware_option**
No hardware specific options are currently defined.

**-s listing_option**
Attachment points of class `scsi` can be listed by using the `select` sub-option. Refer to the `cfgadm(1M)` man page for additional information.

**-t ap_id**
No test commands are available at present.

**-x hardware_function**
Some of the following commands can only be used with SCSI controllers and some only with SCSI devices.

In the following, `controller_ap_id` refers to an `ap_id` for a SCSI controller, for example, `c0`
`device_ap_id` refers to an `ap_id` for a SCSI device, for example: `c0::dsk/c0dt3d0`.

The following hardware specific functions are defined:

**insert_device controller_ap_id**
Add a new device to the SCSI controller, `controller_ap_id`.

This command is intended for interactive use only.

**remove_device device_ap_id**
Remove device `device_ap_id`.

This command is intended for interactive use only.

**replace_device device_ap_id**
Remove device `device_ap_id` and replace it with another device of the same kind.

This command is intended for interactive use only.
reset_device device_ap_id
Reset device_ap_id.

reset_bus controller_ap_id
Reset bus controller_ap_id without resetting any devices attached to the bus.

reset_all controller_ap_id
Reset bus controller_ap_id and all devices on the bus.

locator [=on|off] device_ap_id
Sets or gets the hard disk locator LED, if it is provided by the platform. If the [on|off]
suboption is not set, the state of the hard disk locator is printed.

led[=LED,mode=on|off|blink] device_ap_id
If no sub-arguments are set, this function print a list of the current LED settings. If
sub-arguments are set, this function sets the mode of a specific LED for a slot.

Examples

EXAMPLE 1 Configuring a Disk
The following command configures a disk attached to controller c0:

```
# cfgadm -c configure c0::dsk/c0t3d0
```

EXAMPLE 2 Unconfiguring a Disk
The following command unconfigures a disk attached to controller c0:

```
# cfgadm -c unconfigure c0::dsk/c0t3d0
```

EXAMPLE 3 Adding a New Device
The following command adds a new device to controller c0:

```
# cfgadm -x insert_device c0
```

The system responds with the following:

```
Adding device to SCSI HBA: /devices/sbus@1f,0/SUNW,fas@e,8800000
This operation will suspend activity on SCSI bus c0
Continue (yes/no)?
```

Enter:
```
y
```

The system responds with the following:

```
SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?
```

Enter:
```
y
```
EXAMPLE 4  Replacing a Device
The following command replaces a device attached to controller c0:

```bash
# cfgadm -x replace_device c0::dsk/c0t3d0
```

The system responds with the following:

Replacing SCSI device: /devices/sbus@1f,0/SUNW,fas@e,88000000/sd@3,0
This operation will suspend activity on SCSI bus: c0
Continue (yes/no)?

Enter:

```
y
```

The system responds with the following:

SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?

Enter:

```
y
```

EXAMPLE 5  Encountering a Mounted File System While Unconfiguring a Disk
The following command illustrates encountering a mounted file system while unconfiguring a disk:

```bash
# cfgadm -c unconfigure c1::dsk/c1t0d0
```

The system responds with the following:

cfgadm: Component system is busy, try again: failed to offline:
/devices/pci@1f,4000/scsi@3,1/sd@1,0
Resource Information
----------------------------------------
/dev/dsk/c1t0d0s0 mounted filesystem "/mnt"

EXAMPLE 6  Displaying the Value of the Locator for a Disk
The following command displays the value of the locator for a disk. This example is specific to the SPARC Enterprise Server family:

```bash
# cfgadm -x locator c0::dsk/c0t6d0
```

The system responds with the following:

<table>
<thead>
<tr>
<th>Disk</th>
<th>Led</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0t6d0</td>
<td>locator=on</td>
</tr>
</tbody>
</table>
EXAMPLE 7 Setting the Value of the Locator for a Disk

The following command sets the value of the locator for a disk. This example is specific to the SPARC Enterprise Server family:

```
# cfgadm -x locator=off c0::dsk/c0t6d0
```

The system does not print anything in response.

EXAMPLE 8 Configuring a Path to a Multipath SCSI Disk

The following command configures a path connected through controller c0:

```
# cfgadm -c configure c0::2,0
```

EXAMPLE 9 Unconfiguring a Path to a Multipath SCSI Disk

The following command unconfigures a path connected through controller c0:

```
# cfgadm -c unconfigure c0::2,0
```

Files

```
/usr/lib/cfgadm/scsi.so.1
   hardware-specific library for generic SCSI hot-plugging

/usr/platform/SPARC-Enterprise/lib/cfgadm/scsi.so.1
   platform-specific library for generic SCSI hot-plugging
```

Attributes

Notes

The disconnect (quiesce) operation is not supported on controllers which control disks containing critical partitions such as root (/), /usr, swap, or /var. The disconnect operation should not be attempted on such controllers. Incorrect usage can result in a system hang and require a reboot.

When a controller is in the disconnected (quiesced) state, there is a potential for deadlocks occurring in the system. The disconnect operation should be used with caution. A controller should be kept in the disconnected state for the minimum period of time required to accomplish the DR operation. The disconnect command is provided only to allow the replacement of the SCSI cables while the system is running. It should not be used for any other purpose. The only fix for a deadlock (if it occurs) is to reboot the system.

Hotplugging operations are not supported by all SCSI controllers.
The connectors on some SCSI devices do not conform to SCSI hotplug specifications. Performing hotplug operations on such devices can cause damage to the hardware on the SCSI bus. Refer to your hardware manual for additional information.

**Warnings**

The connectors on some SCSI devices do not conform to SCSI hotplug specifications. Performing hotplug operations on such devices can cause damage to the hardware on the SCSI bus. Refer to your hardware manual for additional information.
Name  cfgadm_shp – PCI Express and Standard PCI Hotplug hardware-specific commands for cfgadm

Synopsis  
/usr/sbin/cfgadm [-f] [-y | -n] [-v]
   [-o hardware_options] -c function ap_id [ap_id]

/usr/sbin/cfgadm [-f] [-y | -n] [-v]
   [-o hardware_options] -x hardware_function ap_id [ap_id]

/usr/sbin/cfgadm [-v] [-s listing_options]
   [-o hardware_options] -x hardware_function ap_id [ap_id]

/usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id [ap_id]

/usr/sbin/cfgadm [-v] [-o hardware_function] -h [ap_id | ap_type]

Description  The PCI Express and Standard PCI Hotplug hardware-specific library,
/usr/lib/cfgadm/shp.so.1, provides support for hotplugging PCI Express and Standard
PCI Hotplug adapter cards into the respective hotpluggable slots in a system that is
hotplug-capable, through the cfgadm command (see cfgadm(1M)). Support for the rest PCI
Hotplug adapter cards (other than PCI Express and Standard PCI Hotplug cards) are provided
by cfgadm_pci library (see cfgadm_pci(1M)). Hotplug administrative models between PCI
Express Hotplug and Standard PCI Hotplug remain the same except where noted in this man
page.

For PCI hotplug, each hotplug slot on a specific PCI bus is represented by an attachment point
of that PCI bus.

An attachment point consist of two parts: a receptacle and an occupant. The receptacle under
PCI hotplug is usually referred to as the physical hot pluggable slot; and the occupant is
usually referred to as the PCI adapter card that plugs into the slot.

Attachment points are named through ap_ids. There are two types of ap_ids: logical and
physical. The physical ap_id is based on the physical pathname, for example:
/devices/pci@7c,0/pci10de,5d@d:pcie2

Whereas the logical ap_id is a shorter, more user-friendly name, for example, pcie2. The
ap_type for Hotplug PCI is pci.

Note that the ap_type is not the same as the information in the Type field.

Grammar:

APID : absolute-slot-path
   Fundamental term.
First, an `absolute-slot-path` is constructed that attempts to describe the attachment point's topological location in more physically identifiable terms for the user. This `absolute-slot-path` consists of `slot-path` components each separated by a `:` (colon). The leaf or leftmost `slot-path` component describes the device of the attachment point itself, while its right-adjacent `slot-path` component up to the rightmost or topmost `slot-path` component describes the parent up to the root devices, respectively.

Each `slot-id` consists of a `slot-id` optionally preceded by a `fru-id`, which identifies an expansion chassis containing the device described by `slot-id` (detailed below). `fru-id` consists of `fru-type` followed by an optional `serialid#`. `fru-type` is “iob” for PCI Express expansion chassis types, while `serialid#` is either a 64-bit hexadecimal number indicating a raw serial number obtained from the expansion chassis hardware, or an upper-case, ASCII four-character sequence for a Sun-branded expansion chassis.

Each slot-id consists of one of three possible forms:

- `slot-id` form (1)
  - `slot-names`

- `slot-id` form (2)
  - `device-type physical-slot#`

- `slot-id` form (3)
  - `nexus-driver-name nexus-driver-instance device-type pci-device-number`

The precedence of which form to select flows from the lowest form number to the highest form number, or from top to bottom as described above. If a form cannot be successfully constructed, then the next numerically higher form is attempted.

The `slot-names` in `slot-id` form (1) is taken from the `slot-names` property of the corresponding node in the evicetree and is a name assigned by hardware or the platform. This format is not predefined or established.
In `slot-id` form (2), `device-type` indicates the device type of the component's slot, and is either `pcie` for PCI Express or `pci` for PCI, while `physical-slot#`, taken from the `physical-slot#` property of its corresponding device node, indicates the hardware slot number of the component.

`slot-id` form (3) is used when all other forms cannot be successfully constructed, and is considered to be the default form. `nexus-driver-name` is the component's driver name; `nexus-driver-instance` is this driver's instance; `device-type` is the same as described in form (2); `pci-device-number` is the PCI device number as described and used for device configuration cycles in standard PCI nomenclature.

In summary of the `slot-path` component, expanding the optional FRU component that might precede it, `slot-path` will consist one of the following forms in order:

1. `[iob[serialid#].] slot-names`
2. `[iob[serialid#].] device_type physical_slot#
3. `[iob[serialid#].] nexus-driver-name nexus-driver-instance. device_type pci-device-number

Lastly, the final form of the actual `ap_id` name used in `cfgadm` is decided as follows, specified in order of precedence:

1. `ap_id` form (1)
   If the `absolute-slot-path` can fit within the fixed length limit of `cfgadm's ap_id field, then `absolute-slot-path` itself is used
2. `ap_id` form (2)
   (`absolute-slot-path` exceeds the `ap_id` length limit) If the last `slot_path` component is contained within an expansion chassis, and it contains a `serialid#`, then the last `slot_path` component is used. The requirement for a `serialid#` in this form is to ensure a globally unique `ap_id`
3. `ap_id` form (3)
   (`absolute-slot-path` exceeds the `ap_id` length limit) The default form, `slot-id` form (3), of the last `slot_path` component is used.

Whichever final `ap_id` name is used, the `absolute-slot-path` is stored in the Information (info) field which can be displayed using the `-s` or `-v` options. This information can be used to physically locate any `ap_ids` named using `ap_id` form (2) or `ap_id` form (3). The `absolute-slot-path` is transformed slightly when stored in the information field, by the replacement of a colon (:) with forward slashes (/) to more closely denote a topological context. The `absolute-slot-path` can include `slot-path` components that are not hotpluggable above the leaf or rightmost `slot-path` component up to the onboard host slot.
See the Examples section for a list of hotpluggable examples.

**Options**

The following options are supported:

- **-c function**
  The following functions are supported for PCI hotpluggable slots:
  - configure
    Configure the PCI device in the slot to be used by Solaris.
  - connect
    Connect the slot to PCI bus.
  - disconnect
    Disconnect the slot from the PCI bus.
  - insert
    Not supported.
  - remove
    Not supported.
  - unconfigure
    Logically remove the PCI device's resources from the system.

- **-f**
  Not supported.

- **-h ap_id | ap_type**
  Display PCI hotplug-specific help message.

- **-l list**
  List the values of PCI Hot Plug slots.

- **-o hardware_options**
  No hardware specific options are currently defined.

- **-s listing_options**
  Same as the generic `cfgadm(1M)`.

- **-t ap_id**
  This command is only supported on platforms that support testing capability on the slot.

- **-v**
  Execute in verbose mode.

When the `-v` option is used with the `-l` option, the `cfgadm` command outputs information about the attachment point. For attachment points located in a PCI Express hierarchy, the Information field will contain the attachment point's absolute slot path location, including any hardware- or platform-specific labeling information for each component in the slot path. Each component in the slot path will be separated by a `/` (forward slash). See "PCI Express ap_id Naming," above. For PCI Hot Plug attachment points not located in a PCI
Express hierarchy, see `cfgadm_pci(1M)`. The information in the Type field is printed with or without the -v option. The occupant Type field will describe the contents of the slot. There are two possible values:

unknown
   The slot is empty. If a card is in the slot, the card is not configured or there is no driver for the device on the card.

subclass/board
   The card in the slot is either a single-function or multi-function device.

   subclass is a string representing the subclass code of the device, for example, SCSI, ethernet, pci-isa, and so forth. If the card is a multi-functional device, MULT will get displayed instead.

   board is a string representing the board type of the device. For example, hp is the string used for a PCI Hot Plug adapter.

-x `hardware_function`
   Perform hardware-specific function. These hardware-specific functions should not normally change the state of a receptacle or occupant.

   The following `hardware_function` is supported:

   \[\text{led}=[\text{led\_sub\_arg}],\text{mode}=[\text{mode\_sub\_arg}]\]
   Without subarguments, display a list of the current LED settings. With subarguments, set the mode of a specific LED for a slot.

   Specify \text{led\_sub\_arg} as fault, power, attn, or active.

   Specify \text{mode\_sub\_arg} as on, off, or blink.

   For PCI Express, only the power and attn LEDs are valid and only the state of the attn LED can be changed.

   Changing the state of the LED does not change the state of the receptacle or occupant. Normally, the LEDs are controlled by the hotplug controller, no user intervention is necessary. Use this command for testing purposes.

   \textbf{Caution} – Changing the state of the LED can misrepresent the state of occupant or receptacle.

   The following command displays the values of LEDs:

   `example# \text{cfgadm -x led pcie2}`

   \begin{verbatim}
   Ap_Id    Led
   pcie2    power=on, fault=off, active=off, attn=off
   \end{verbatim}

   The following command sets the attn LED to blink to indicate the location of the slot:

   `example# \text{cfgadm -x led=attn, mode=blink pcie2}`
**Examples**

**EXAMPLE 1**  Displaying the Value of Each Slot

The following command displays the values of each slot:

```
example# cfgadm -l
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured</td>
<td>unknown</td>
</tr>
<tr>
<td>c1</td>
<td>scsi-bus</td>
<td>connected</td>
<td>unconfigured</td>
<td>unknown</td>
</tr>
<tr>
<td>c2</td>
<td>scsi-bus</td>
<td>connected</td>
<td>unconfigured</td>
<td>unknown</td>
</tr>
<tr>
<td>pcie7</td>
<td>etherne/hp</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>

<tr>
<td>pcie8</td>
<td>unknown</td>
<td>empty</td>
<td>unconfigured</td>
<td>unknown</td>
</tr>
<tr>
<td>pcie9</td>
<td>fibre/hp</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
</tbody>
</table>

**EXAMPLE 2**  Replacing a Card

The following command lists all DR-capable attachment points:

```
example# cfgadm
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>c0</td>
<td>scsi-bus</td>
<td>connected</td>
<td>configured</td>
</tr>
<tr>
<td>c1</td>
<td>scsi-bus</td>
<td>connected</td>
<td>unconfigured</td>
</tr>
<tr>
<td>c2</td>
<td>scsi-bus</td>
<td>connected</td>
<td>unconfigured</td>
</tr>
<tr>
<td>pcie7</td>
<td>etherne/hp</td>
<td>connected</td>
<td>configured</td>
</tr>
<tr>
<td>pcie8</td>
<td>unknown</td>
<td>empty</td>
<td>unconfigured</td>
</tr>
<tr>
<td>pcie9</td>
<td>fibre/hp</td>
<td>connected</td>
<td>configured</td>
</tr>
</tbody>
</table>

The following command unconfigures and electrically disconnects the card identified by pcie7:

```
exmple# cfgadm -c disconnect pcie7
```

The change can be verified by entering the following command:

```
exmple# cfgadm pcie7
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>pcie7</td>
<td>unknown</td>
<td>disconnected</td>
<td>unconfigured</td>
<td>unknown</td>
</tr>
</tbody>
</table>

At this point the card can be swapped. The following command electrically connects and configures the replacement card:

```
exmple# cfgadm -c configure pcie7
```

The change can be verified by entering the following command:

```
exmple# cfgadm pcie7
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>pcie7</td>
<td>etherne/hp</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
</tbody>
</table>

**EXAMPLE 3**  Interpreting ApIds in a PCI Express Topology

The following command shows a listing for a topology with both PCI Express and PCI attachment points in an I/O expansion chassis connected to hotpluggable slots at the host level:

```
exmple# cfgadm -s
```

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>iou#0-pci#2:iob58071.pcie1</td>
<td>Location: iou#0-pci#2/iob58071.pcie1</td>
</tr>
<tr>
<td>iou#0-pci#2:iob58071.special</td>
<td>Location: iou#0-pci#2/iob58071.special</td>
</tr>
<tr>
<td>iou#0-pci#3</td>
<td>Location: iou#0-pci#3</td>
</tr>
<tr>
<td>iou#0-pci#3:iobBADF.pcie1</td>
<td>Location: iou#0-pci#3/iobBADF.pcie1</td>
</tr>
<tr>
<td>iou#0-pci#3:iobBADF.pcie2</td>
<td>Location: iou#0-pci#3/iobBADF.pcie2</td>
</tr>
<tr>
<td>iou#0-pci#3:iobBADF.pcie3</td>
<td>Location: iou#0-pci#3/iobBADF.pcie3</td>
</tr>
<tr>
<td>iou#0-pci#3:iobBADF.pcie1</td>
<td>Location: iou#0-pci#3/iobBADF.pcie1</td>
</tr>
<tr>
<td>iou#0-pci#3:iobBADF.pcie2</td>
<td>Location: iou#0-pci#3/iobBADF.pcie2</td>
</tr>
</tbody>
</table>

In this example, the iou#0-pci#[0-3] entries represent the topmost hotpluggable slots in the system. Because the iou#n-pci#n form does not match any of the forms stated in the grammar specification section described above, we can infer that such a name for the base component in this hotplug topology is derived from the platform through the slot-names property.

The slots in the preceding output are described as follows:

Slot iou#0-pci#0
   This slot is empty or its occupant is unconfigured.

Slot iou#0-pci#1
   This slot contains an expansion chassis with two hotpluggable slots, pci3 and pci4. pci3 and pci4 represent two PCI slots contained within that expansion chassis with physical slot numbers 3 and 4, respectively. The expansion chassis in this case does not have or export a serial-id.

Slot iou#0-pci#2
   This slot contains a third-party expansion chassis with a hexadecimal serial-id of 58071. Within that expansion chassis are two hotpluggable slots, pcie1 and special. pcie1 represents a PCI Express slot with physical slot number 1. The slot special has a label which is derived from the platform, hardware, or firmware.

Slot iou#0-pci#3
   This slot contains a Sun expansion chassis with an FRU identifier of BADF. This expansion chassis contains three PCI Express slots, pcie1, pcie2, and pcie3 with physical slot numbers 1, 2, and 3, respectively; and two PCI slots, pci1 and pci2, with physical slot numbers 1 and 2, respectively.

The following command shows a listing for a topology with both PCI Express and PCI attachment points in an I/O expansion chassis with connected hotpluggable and non-hotpluggable host slots:
EXAMPLE 3  Interpreting ApIds in a PCI Express Topology  (Continued)

example#  cfgadm -s cols=ap_id:info

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slot1</td>
<td>Location: Slot1</td>
</tr>
<tr>
<td>Slot2:iob4ffa56.pcie1</td>
<td>Location: Slot2/iob4ffa56.pcie1</td>
</tr>
<tr>
<td>Slot2:iob4ffa56.pcie2</td>
<td>Location: Slot2/iob4ffa56.pcie2</td>
</tr>
<tr>
<td>Slot5:iob3901.pci1</td>
<td>Location: Slot2/iob3901.pci1</td>
</tr>
<tr>
<td>Slot5:iob3901.pci2</td>
<td>Location: Slot2/iob3901.pci2</td>
</tr>
</tbody>
</table>

In this example, the host system only has one hotpluggable slot, Slot1. We can infer that Slot2 and Slot5 are not hotpluggable slots because they do not appear as attachment points themselves in cfgadm. However, Slot2 and Slot5 each contains a third party expansion chassis with hotpluggable slots.

The following command shows a listing for a topology with attachment points that are lacking in certain device properties:

example#  cfgadm -s cols=ap_id:info

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>px_pci7.pcie0</td>
<td>Location: px_pci7.pcie0</td>
</tr>
<tr>
<td>px_pci11.pcie0</td>
<td>Location: px_pci11.pcie0</td>
</tr>
<tr>
<td>px_pci11.pcie0:iob.pcie1</td>
<td>Location: px_pci11.pcie0/iob.pcie1</td>
</tr>
<tr>
<td>px_pci11.pcie0:iob.pcie2</td>
<td>Location: px_pci11.pcie0/iob.pcie2</td>
</tr>
<tr>
<td>px_pci11.pcie0:iob.pcie3</td>
<td>Location: px_pci11.pcie0/iob.pcie3</td>
</tr>
</tbody>
</table>

In this example, the host system contains two hotpluggable slots, px_pci7.pcie0 and px_pci11.pcie0. In this case, it uses slot-id form (3) (the default form) for the base slot-path component in the absolute-slot-path, because the framework could not obtain enough information to produce other more descriptive forms of higher precedence.

Interpreting right-to-left, attachment point px_pci7.pcie0 represents a PCI Express slot with PCI device number 0 (which does not imply a physical slot number of the same number), bound to nexus driver px_pci, instance 7. Likewise, attachment point px_pci11.pcie0 represents a PCI Express slot with PCI device number 0 bound to driver instance 11 of px_pci.

Under px_pci11.pcie0 is a third-party expansion chassis without a serial-id and with three hotpluggable PCI Express slots.

The following command shows a listing for a topology with attachment point paths exceeding the ApId field length limit:

example#  cfgadm -s cols=ap_id:info

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>pcie4</td>
<td>Location: pcie4</td>
</tr>
<tr>
<td>pcie4:iobSUNW.pcie1</td>
<td>Location: pcie4/iobSUNW.pcie1</td>
</tr>
<tr>
<td>pcie4:iobSUNW.pcie2</td>
<td>Location: pcie4/iobSUNW.pcie2</td>
</tr>
</tbody>
</table>

System Administration Commands - Part 1 261
**EXAMPLE 3**  Interpreting ApIds in a PCI Express Topology  

(Continued)

iob8879c3f3.pci1  
Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci1

iob8879c3f3.pci2  
Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci2

iob8879c3f3.pci3  
Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci3

In this example, there is only one hotpluggable slot, pcie4 in the host. Connected under pcie4 is a Sun expansion chassis with FRU identifier SUNW. Nested under PCI Express slot pcie2 of that expansion chassis (ApId pcie4:iobSUNW.pcie2) lies another expansion chassis with three hotpluggable PCI slots.

Because the length of the absolute-slot-path form of:

```
pcie4/iobSUNW.pcie2/iob8879c3f3.pci1...3
```

...exceeds the ApId field length limit, and the leaf slot-path component is globally unique, ap_id form (2) is used, where the leaf slot-path component in the `absolute-slot-path` is used as the final ApId.

The following command shows a listing for a topology with attachment point paths exceeding the ApId field-length limit and lacking enough information to uniquely identify the leaf slot-id on its own (for example, missing the serial-id):

```
ex ample# cfgadm -s cols=ap_id:info
Ap_Id Information
pcie4 Location: pcie4
pcie4:iob4567812345678.pcie3 Location: pcie4/iob4567812345678.pcie3
px_pci20.pcie0 Location: pcie4/iob4567812345678.pcie3/iob.pcie1
px_pci21.pcie0 Location: pcie4/iob4567812345678.pcie3/iob.pcie2
```

In this example, there is only one hotpluggable slot, pcie4 in the host. Connected under pcie4 is a third-party expansion chassis with hexadecimal serial-id 4567812345678. Nested under the PCI Express slot pcie3 of that expansion chassis (ApId pcie4:iob4567812345678.pcie3), lies another third-party expansion chassis without a serial-id and with two hotpluggable PCI Express slots.

Because the length of the absolute-slot-path form of:

```
pcie4/iob4567812345678.pcie3/iob.pcie1...2
```

exceeds the ApId field length limit, and the leaf slot-path component is not globally unique, ap_id form (3) is used. ap_id form (2) is where slot-id form (3) (the default form) of the leaf slot-path component in the `absolute-slot-path` is used as the final ApId.
EXAMPLE 3 Interpreting ApIds in a PCI Express Topology   (Continued)

The default form or slot-id form (3) of the leaf component .../iob.pcie1 represents a PCI Express slot with device number 0, bound to driver instance 20 of px_pci. Likewise, the default form of the leaf component .../iob.pcie2 represents a PCI Express slot with device number 0, bound to driver instance 21 of px_pci.

Notes   The cfgadm_shp library is dependent on the hotplug service, which is managed by smf(5) under FMRI:

        svc:/system/hotplug:default

        The service must be enabled for the cfgadm_shp library to function properly. See hotplugd(1M) for details.
cfgadm_sysctrl(1M)

**Name**
cfgadm_sysctrl – EXX00 system board administration

**Synopsis**
```
/usr/sbin/cfgadm -c function [-f]
    [-o disable-at-boot | enable-at-boot] [-n | -y] sysctrl0:slot# ...
```

```
/usr/sbin/cfgadm -x quiesce-test sysctrl0:slot#
```

```
/usr/sbin/cfgadm -x insert-test | remove-test sysctrl0:slot# ...
```

```
/usr/sbin/cfgadm -x set-condition-test=# sysctrl0:slot# ...
```

```
/usr/sbin/cfgadm [-l]
    -o disable-at-boot | enable-at-boot sysctrl0:slot# ...
```

**Description**
The sysctrl hardware specific library `usr/platform/sun4u/lib/cfgadm/sysctrl.so.1` provides dynamic reconfiguration functionality for configuring and disconnecting system boards on E6X00, E5X00, E4X00, and E3X00 systems. You can insert both I/O and CPU boards into a slot on a running system that is configured for Solaris without rebooting. You can also disconnect and remove both types of boards from a running system without rebooting.

System slots appear as attachment points in the device tree, one attachment point for each actual slot in the system chassis. If a board is not in a slot, the receptacle state is empty. If a board is powered-off and ready to remove, the receptacle state is disconnected. If a board is powered-on and is connected to the system bus, the receptacle state is connected.

The occupant state is unconfigured when the receptacle state is empty or disconnected. The occupant state is either unconfigured or configured when the receptacle state is connected.

In the configured state the devices on a board are available for use by Solaris. In the unconfigured state, the devices on the board are not.

Inserting a board changes the receptacle state from empty to disconnected. Removing a board changes the receptacle state from disconnected to empty. Removing a board that is in the connected state crashes the operating system and can result in permanent damage to the system.

**Options**
Refer to `cfgadm(1M)` for a more complete description options.

The following options are supported:

- `-c function` Perform the state change function. Specify `function` as `connect`, `disconnect`, `configure` or `unconfigure`.

- `-o enable-at-boot` Change the occupant state to configure.

If the receptacle state is disconnected, the configure function first attempts to connect the receptacle. The configure function walks the OBP device tree created as
part of the connect function and creates the Solaris device tree nodes, attaching devices as required. For CPU/Memory boards, configure adds CPUs to the CPU list in the powered-off state. These are visible to the psrinfo(1M) and psradm(1M) commands. Two memory attachment points are published for CPU/memory boards. Use mount(1M) and ifconfig(1M) to use I/O devices on the new board. To use CPUs, use psradm -n to on-line the new processors. Use cfgadm_ac(1M) to test and configure the memory banks.

**connect**

Change the receptacle state to connected.

Changing the receptacle state requires that the system bus be frozen while the bus signals are connected and the board tested. The bus is frozen by running a quiesce operation which stops all process activity and suspends all drivers. Because the quiesce operation and the subsequent resume can be time consuming, and are not supported by all drivers, the -x quiesce -test is provided. While the system bus is frozen, the board being connected is tested by firmware. This operation takes a short time for I/O boards and a significant time for CPU/Memory boards due to CPU external cache testing. This does not provide memory testing. The user is prompted for confirmation before proceeding with the quiesce. Use the -y or -n option to override the prompt. The connect operation is refused if the board is marked as
disabled-at-boot, unless either the force flag, -f, or the enable at boot flag, -o enable-at-boot, is given. See -l.

disconnect

Change the receptacle state to disconnected.

If the occupant state is configure, the disconnect function first attempts to unconfigure the occupant. The disconnect operation does not require a quiesce operation and operates quickly. The board is powered-off ready for removal.

unconfigure

Change the occupant state to unconfigured.

Devices on the board are made invisible to Solaris during this process. The I/O devices on an I/O board are removed from the Solaris device tree. Any device that is still in use stops the unconfigure process and be reported as in use. The unconfigure operation must be retried after the device is made non-busy. For CPU/Memory boards, the memory must have been changed to the unconfigured state prior to issuing the board unconfigure operation. The CPUs on the board are off-lined, powered off and removed from the Solaris CPU list. CPUs that have processes bound to them cannot be off-lined. See psradm(1M), psrinfo(1M), pbind(1M), and p_online(2) for more information on off-lining CPUs.

-f

Force a block on connecting a board marked as disabled-at-boot in the non-volatile
disabled-board-list variable. See Platform Notes: Sun Enterprise 6x00/5x00/4x00/3x00 Systems

- l

List options. Supported as described in cfgadm(1M) cfgadm(1M).

The type field can be one of cpu/mem, mem, dual-sbus, sbus-upa, dual-pci, soc+sbus, soc+upa, disk or unknown.

The hardware-specific info field is set as follows:
[disabled at boot] [non-detachable] [100 MHz capable]

For sbus-upa and soc+upa type boards, the following additional information appears first: [single buffered ffb] [double buffered ffb] [no ffb installed] For disk type boards, the following additional information appears first: {target: # | no disk} {target: # | no disk}

- o disable-at-boot | enable-at-boot

Modify the state of the non—volatile disabled-board-list variable. Use this the - o option in conjunction with the - c function or - l option.

Use - o enable-at-boot with the - c connect to override a block on connecting a disabled-at-boot board.

- x insert-test | remove-test

Perform a test.

Specify remove-test to change the driver state for the specified slot from disconnected to empty without the need for physically removing the board during automated test sequences.

Specify insert-test to change the driver state of a slot made to appear empty using the remove-test command to the disconnected state as if it had been inserted.

- x quiesce-test sysctrl0:slot1

Perform a test.

Allows the quiesce operation required for board connect operations to be exercised. The execution of this test confirms that, with the current software and hardware configuration, it is possible to quiesce the
system. If a device or process cannot be quiesced, its name is printed in an error message. Any valid board attachment point can be used with this command, but since all systems have a slot1 the given form is recommended.

- x set-condition-test=#

Perform a test.

Allows the condition of a system board attachment point to be set for testing the policy logic for state change commands. The new setting is given as a number indicating one of the following condition values:

0 unknown
1 ok
2 failing
3 failed
4 unusable

Operands The following operand is supported:

sysctrl0:slot#

The attachment points for boards on EXX00 systems are published by instance 0 of the sysctrl driver (sysctrl0). The names of the attachment points are numbered from slot0 through slot15. Specify # as a number between 0 and 15, indicating the slot number. This form conforms to the logical ap_id specification given in cfgadm(1M). The corresponding physical ap_ids are listed in the FILES section.

Sun Enterprise 6x00, 5x00, 4x00 and 3x00 Systems Dynamic Reconfiguration User’s Guide
Platform Notes: Sun Enterprise 6x00/5x00/4x00/3x00 Systems

Notes Refer to the Sun Enterprise 6x00, 5x00, 4x00 and 3x00 Systems Dynamic Reconfiguration User’s Guide for additional details regarding dynamic reconfiguration of EXX00 system CPU/Memory boards.
The Universal Serial Bus (USB) hardware-specific library /usr/lib/cfgadm/usb.so.1 provides the functionality for administering USB devices via the `cfgadm(1M)` command. `cfgadm` operates on attachment points. For details regarding attachment points, refer to `cfgadm(1M)`.

For USB administration, the only attachment points supported are the ports of hubs attached to the USB bus.

Attachment points are named through attachment point IDs (`ap_ids`). The USB bus is hierarchical, so the `ap_ids` are as well. USB hubs have ports, numbered from 1 to `n`. All USB `ap_ids` consist of a string of the following form:

```
usbN/A[.B[.C[...]]]
```

where

- `N` is the `N`th USB host controller on the system,
- `A` is port `#A` on the (top) hub.
- `B` is port `#B` of the hub plugged into port `#A` of the hub above it.
- `C` is port `#C` of the hub plugged into port `#B` of the hub above it, and so forth.

For example, the first port on the root hub of USB controller 0 (the only controller), has a logical `ap_id`:

```
usb0/1
```

Similarly, the second port on the first external hub plugged into the first port on the root hub of the first USB controller has a logical `ap_id`:

```
usb0/1.2
```

For example, if the `ap_id` is `usb0/1.4.3.4`, it represents port 4 of the hub plugged into port 3 of the hub plugged into port 4 of the hub plugged into port 1 of the root hub of the first USB host controller on the system.

```
example# cfsadm -l

<table>
<thead>
<tr>
<th>Ap_Id</th>
<th>Type</th>
<th>Receptacle</th>
<th>Occupant</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>usb0/1</td>
<td>USB-hub</td>
<td>connected</td>
<td>configured</td>
<td>ok</td>
</tr>
<tr>
<td>usb0/2</td>
<td>unknown</td>
<td>empty</td>
<td>unconfigured</td>
<td>ok</td>
</tr>
</tbody>
</table>
```
USB2.0 chips have one EHCI host USB2.0 host controller and a number of companion USB 1.x host controllers (either OHCI or UHCI host controllers).

When a USB2.0 device has been plugged in, it shows up on the EHCI logical ports which might not have a 1 to 1 mapping to external physical port numbers on the system. When a USB1.x device is plugged in, the EHCI host controller reroutes the device to a companion host controller and the device shows up on the companion’s logical port number.

The mapping of logical port numbers to physical port numbers can get quite complicated. For example:

```
% cfgadm
```

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

In this example `usb0` is the onboard USB 1.x host controller. `usb1` and `usb2` are companion OHCI USB1.x host controllers and `usb3` is an EHCI USB2.0 host controller.

The following table shows the somewhat confusing routing for this USB2.0 chip:

<table>
<thead>
<tr>
<th>logical port number</th>
<th>physical port number</th>
</tr>
</thead>
<tbody>
<tr>
<td>usb1/1</td>
<td>internal port 1</td>
</tr>
<tr>
<td>usb1/2</td>
<td>external port 1</td>
</tr>
<tr>
<td>usb1/3</td>
<td>external port 3</td>
</tr>
</tbody>
</table>
Unfortunately, the exact routing can often only be determined by experimentation.

The receptacle states for attachment points at the USB port have the following meanings:

- **connected**: USB port is powered on and enabled. A USB device is plugged in to the port. The device is logically connected to the USB bus.
- **disconnected**: USB port is powered on and enabled. A USB device is plugged into the port. The device has been logically disconnected from the USB bus (using the `cfgadm -c disconnect` command).
- **empty**: USB port is powered on, but no device is plugged in to it.

The occupant states for devices at USB port attachment points at the USB port have the following meanings:

- **configured**: The USB device at the USB port is configured and usable by Solaris.
- **unconfigured**: The USB device at the USB port was explicitly off-lined using `cfgadm -c unconfigure`, or was not successfully configured for use with Solaris, for example, having no driver or a device problem.

The attachment point conditions are:

- **ok**: Normal state - ready for use.
- **failing**: Not used.
- **failed**: Not used.
- **unusable**: The user has physically removed a device while an application had the device open (there might be outstanding I/O). Users need to reinsert the same physical device and close the application properly before removing the device again. The port cannot configure other inserted devices until this is done.

If the original device cannot be reinserted into the port, see the *System Administration Guide: Basic Administration* for instructions for clearing this attachment point condition.

- **unknown**: Not used.
A USB device can be hotplugged or hotunplugged at any time, and the system detects the event and takes the appropriate action.

It is not necessary to transition a receptacle to the disconnected state before removing its device from the USB. However, it is not recommended to hot-remove devices currently in use (such as removable disks currently opened by volume manager (see `vold(1M)`)) or some other application.

**Options**  
`cfgadm` defines several types of operations. These operations include invoking configuration state changes (`-c`), invoking hardware-specific functions (`-x`), and obtaining configuration administration help messages (`-h`).

If any of these operations fail, the device and attachment point might not be in the expected state. Use the `cfgadm -l` command to display the device's current status.

All other options have the same meaning as defined in `cfgadm(1M)`.

The following options are supported:

- `-c function`  
The following generic commands are defined for the USB hardware specific library. The following configuration state change operations are supported:

  **configure**  
  If there is a USB device plugged into the port, this command attempts to configure it and set everything up so that it is usable by Solaris. This command does an implied `connect` (reverse of `disconnect`) if necessary. This command accomplishes nothing, and returns an error message, if the device at that port is already configured. After successful execution of this command, the device is ready for use under Solaris.

  **disconnect**  
  Performs an `unconfigure` on the `ap_id` (if it is not already unconfigured), and then transitions the receptacle to the disconnected state, even though a device is still plugged into the port. Issuing a `cfgadm -c configure`, or physically hotplugging the device, brings the device back to the connected receptacle state, and to the configured occupant state, assuming a driver can be found and there are no problems enumerating and configuring the device.

  **unconfigure**  
  Makes the device plugged into the port unusable by Solaris (offline it). If successful, `cfgadm` reports
this ap_id's occupant state as unconfigured. Issuing a configure to the ap_id (if successful) brings its occupant back to the configured (online) condition, as it physically hotplugging the device on the port.

- f Not supported.
- h ap_id USB specific help can be obtained by using the help option with any USB attachment point.
- l[v] The - l option works as described in cfgadm(1M). When paired with the - v option, the Information field contains the following USB-specific information:
  - Mfg: manufacturer string (iManufacturer)
  - Product: product string (iProduct)
  - NConfigs: total number of configurations the device supports (bNumConfigurations).
  - Config: current configuration setting in decimal (configuration index, not configuration value).
  - The configuration string descriptor for the current configuration (iConfiguration)

See the Universal Serial Bus specification for a description of these fields.

- o hardware_options Hardware options are only supported for the hardware-specific command, -x usb_config. See the description of that command below for an explanation of the options available.

- s listing_options Attachment points of class USB can be listed by using the select sub-option. See cfgadm(1M).

- x hardware_function The following hardware-specific functions are defined:
  - usb_config -o config=n This command requires the mandatory config value to be specified using the -o option.

Sets the USB configuration of a multi-configuration USB device at ap_id to configuration index n. The device is set to this configuration henceforth and this setting persists across reboots, hot-removes, and unconfigure/configure of the device.
Valid values of \( n \) range from 0 to \((N\text{configs} - 1)\). The device is reset by a disconnect followed by a configure. The configure causes the device to be configured to the new configuration setting.

If any of these steps fail, the configuration file and the device are restored to their previous state and an error message is issued.

**usb_reset**

Performs a software reset (re-enumeration) of the device. This is the equivalent of removing the device and inserting it back again. The port on the hub is power cycled if the hub supports power cycling of individual ports.

If the connected device is a hub, this function has the effect of resetting that hub and any devices down the tree of which it is the root.

If any of these steps fail, the device is restored to its previous state and an error message is issued.

State table: attachment points state versus commands:

**Valid states:**

- empty/unconfigured \( \rightarrow \) no device connected
- disconnected/unconfigured \( \rightarrow \) logically disconnected, unavailable, devinfo node removed, device physically connected
- connected/unconfigured \( \rightarrow \) logically connected, unavailable, devinfo node present
- connected/configured \( \rightarrow \) connected, available

The table below clarifies the state transitions resulting from actions or commands:
current state | operation | new state
--------------|------------|------------
empty/        |            |            
unconfigured:  |            |            
| device plugged in: | connected/configured or connected/unconfigured (if enumeration failed) | 
| device removed: | n/a | 
| cfgadm -c unconfigure: | empty/unconfigured | 
| cfgadm -c configure: | empty/unconfigured | 
| cfgadm -c disconnect: | empty/unconfigured (no-op and error) | 

disconnected/ |            |            
unconfigured:  |            |            
| device plugged in: | n/a | 
| device removed: | empty/unconfigured | 
| cfgadm -c unconfigure: | disconnected/unconfigured | 
| cfgadm -c configure: | connected/configured, or connected/unconfigured (if reenumeration failed) | 
| cfgadm -c disconnect: | disconnected/unconfigured | 

connected/unconfigured:
| device plugged in: | n/a | 
| device removed: | empty/unconfigured | 
| cfgadm -c unconfigure: | connected/unconfigured | 
| cfgadm -c configure: | connected/configured, or connected/unconfigured (if reenumeration failed) | 
| cfgadm -c disconnect: | disconnected/unconfigured | 

connected/configured:
| device plugged in: | n/a | 
| device removed: | empty/unconfigured or connected/configured, but with ap condition 'unusable' if device was open when removed | 
| cfgadm -c unconfigure: | connected/unconfigured | 
| cfgadm -c configure: | connected/configured | 
| cfgadm -c disconnect: | disconnected/unconfigured | 

**Examples**

**Example 1** Listing the Status of All USB Devices

The following command lists the status of all USB devices on the system:
EXAMPLE 1  Listing the Status of All USB Devices  (Continued)

```
# cfgadm
Ap_Id Type Receptacle Occupant Condition
usb0/1 USB-hub connected configured ok
usb0/2 unknown empty unconfigured ok
usb0/1.1 USB-storage connected configured ok
usb0/1.2 unknown empty unconfigured ok
usb0/1.3 unknown empty unconfigured ok
usb0/1.4 USB-device connected configured ok
```

Notice that cfgadm treats the USB-device device at ap_id usb0/1.4 as a single unit, since it cannot currently control individual interfaces.

EXAMPLE 2  Listing the Status of a Port with No Device Plugged In

The following command lists the status of a port with no device plugged in:

```
example# cfgadm -l usb0/1.3
```

```
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 unknown empty unconfigured ok
```

EXAMPLE 3  Listing the Status of the Same Port with a Device Plugged In

The following command lists the status of the same port after physically plugging in a device that configures without problems:

```
example# cfgadm -l usb0/1.3
```

```
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 USB-hub connected configured ok
```

EXAMPLE 4  Unconfiguring an Existing USB Device

The following command unconfigures the USB device attached to usb0/1.3, then displays the status of the ap_id:

```
example# cfgadm -c unconfigure usb0/1.3
```

```
Unconfigure the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
Continue (yes/no)?
```

```
Enter:
```

```
y
```

```
example# cfgadm -l usb0/1.3
```

```
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 unknown connected unconfigured ok
```
Unconfiguring and Logically Disconnecting an Existing USB Device

The following command unconfigures and logically disconnects a USB device attached to usb0/1.3:

```
example# cfgadm -c disconnect usb0/1.3
Disconnect the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?
```

```
Enter:
y
```

```
exmaple# cfgadm -l usb0/1.3
Ap_Id   Type  Receptacle  Occupant   Condition
usb0/1.3 unknown disconnected unconfigured ok
```

A disconnect implies that cfgadm does an unconfigure first. The receptacle status now shows disconnected, even though the device is still physically connected. In this case, a physical hotplug or using the `cfgadm -c configure` on the ap_id brings it back on-line.

Configuring a Previously Unconfigured USB Device

The following command configures a USB device that was previously attached to usb0/1.3:

```
example # cfgadm -yc configure usb0/1.3
example# cfgadm -l usb0/1.3
Ap_Id   Type  Receptacle  Occupant   Condition
usb0/1.3 unknown connected configured ok
```

Resetting a USB Device

The following command resets a USB device:

```
example# cfgadm -x usb_reset usb0/1.3
Reset the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?
```

```
Enter:
y
```

Displaying Detailed Information About a USB Device

The following command displays detailed information about a USB device. This device shows the following USB-specific information in the 'Information' field:

- Manufacturer string: Iomega
EXAMPLE 8  Displaying Detailed Information About a USB Device  

- Product string: USB Zip 250
- Number of configurations supported: 1
- Configuration currently active: 0
- Configuration string descriptor for configuration 0: Default

example# cfgadm -lv usb0/1.5
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
usb0/1.5 connected configured ok Mfg:"Io mega" Product:"USB Zip 250" NConfigs:1 Config:0 : Default

example# cfgadm -l -s "cols=ap_id:info" usb0/1.5
Ap_Id Information
usb0/1.5 Mfg:"Iomega" Product:"USB Zip 250" NConfigs:1 Config:0 : Default

EXAMPLE 9  Displaying Detailed Information About All USB Devices

The following command displays detailed information about all USB devices on the system:

example# cfgadm -l -s "select=class(usb),cols=ap_id:info" | grep Mfg

## Lines containing only an ap_id are empty ports. These can be filtered out. This example only lists USB ap_ids with connected devices, and information about those devices.

example# cfgadm -l -s "select=class(usb),cols=ap_id:info" | grep Mfg

System Administration Commands - Part 1  279
EXAMPLE 9  Displaying Detailed Information About All USB Devices  (Continued)

```
usb0/1.5  Mfg:"Iomega" Product:"USB Zip 250"
NConfigs:1 Config:0 : Default
usb0/1.6  Mfg:"SOLID YEAR" Product:"SOLID YEAR USB"
Config:0 <no cfg str descr>
```

EXAMPLE 10  Listing Information About a Multi-configuration USB Device

The following example lists information about a multi-configuration USB device.

Notice the NConfigs field: the configurations available for this device are 0, 1, and 2 (0 to (NConfigs-1)).

```
example# cfgadm -l -s "cols=ap_id:info" usb0/1.4
Ap_Id Information
usb0/1.4  Mfg:"Wizard" Product:"Modem/ISDN"
NConfigs:3 Config:1 V.90 Analog Modem
```

EXAMPLE 11  Setting the Current Configuration of a Multi-configuration USB Device

The following example sets the current configuration of a multi-configuration USB device:

```
example# cfgadm -o config=2 -x usb_config usb0/1.4
Setting the device: /devices/pci@1f,2000/usb@1/device@3
to USB configuration 2
This operation suspends activity on the USB device
Continue (yes/no)?
Enter:

y

USB configuration changed successfully.
```

The device path should be checked to ensure that the right instance of a device is being referred to, in the case where multiple devices of the exact same type are on the same bus. This information is available in the 'Information' field.

`cfgadm(1M), vold(1M), config_admin(3CFGADM), attributes(5), scsa2usb(7D), usba(7D)`

Universal Serial Bus 1.1 Specification (www.usb.org)

*System Administration Guide: Basic Administration*

Notes

`cfgadm(1M)` can not unconfigure, disconnect, reset, or change the configuration of any USB device currently opened by `vold(1M)` or any other application. These operations also fail on a hub if a device in its hierarchy is opened by an application. See `scsa2usb(7D)` for unconfiguring a USB mass-storage device that is being used by `vold(1M)`.

Only super-users can execute any functions on an attachment point. However, one need not be a super-user to list the attachment points.
Name  cfsadmin – administer disk space used for caching file systems with the Cache File-System (CacheFS)

Synopsis  cfsadmin -c [-o cacheFS-parameters] cache_directory
          cfsadmin -d {cache_ID | all} cache_directory
          cfsadmin -l cache_directory
          cfsadmin -s {mntpt1 ....} | all
          cfsadmin -u [-o cacheFS-parameters] cache_directory

Description  The cfsadmin command provides the following functions:

- cache creation
- deletion of cached file systems
- listing of cache contents and statistics
- resource parameter adjustment when the file system is unmounted.

You must always supply an option for cfsadmin. For each form of the command except -s, you must specify a cache directory, that is, the directory under which the cache is actually stored. A path name in the front file system identifies the cache directory. For the -s form of the command, you must specify a mount point.

You can specify a cache ID when you mount a file system with CacheFS, or you can let the system generate one for you. The -l option includes the cache ID in its listing of information. You must know the cache ID to delete a cached file system.

Options  The following options are supported:

- `cfsadmin -c [-o cacheFS-parameters] cache_directory`
  Create a cache under the directory specified by cache_directory. This directory must not exist prior to cache creation.

- `cfsadmin -d {cache_ID | all} cache_directory`
  Remove the file system whose cache ID you specify and release its resources, or remove all file systems in the cache by specifying all. After deleting a file system from the cache, you must run the fsck_cachefs(1M) command to correct the resource counts for the cache.

  As indicated by the syntax above, you must supply either a cache_ID or all, in addition to cache_directory.

- `cfsadmin -l cache_directory`
  List file systems stored in the specified cache, as well as statistics about them. Each cached
The filesystem is listed by cache ID. The statistics document resource utilization and cache resource parameters.

-s { mntpt1 ... | all }
Request a consistency check on the specified filesystem (or all cache's mounted filesystems). The -s option only works if the cache file system was mounted with demandconst enabled (see mount_cachefs(1M)). Each file in the specified cache file system is checked for consistency with its corresponding file in the back file system. Note that the consistency check is performed file by file as files are accessed. If no files are accessed, no checks are performed. Use of this option does not result in a sudden "storm" of consistency checks.

As indicated by the syntax above, you must supply one or more mount points, or all.

-u [ -o cacheFS-parameters ] cache_directory
Update resource parameters of the specified cache directory. Parameter values can only be increased. To decrease the values, you must remove the cache and recreate it. All filesystems in the cache directory must be unmounted when you use this option. Changes take effect the next time you mount any filesystem in the specified cache directory. The -u option with no -o option sets all parameters to their default values.

You can specify the following CacheFS resource parameters as arguments to the -o option. Separate multiple parameters with commas.

- **maxblocks=n**
  Maximum amount of storage space that CacheFS can use, expressed as a percentage of the total number of blocks in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the maxblocks parameter allows is available. The default is 90.

- **minblocks=n**
  Minimum amount of storage space, expressed as a percentage of the total number of blocks in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If
CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the minblocks parameter attempts to reserve is available. The default is 0.

**threshblocks=n** A percentage of the total blocks in the front file system beyond which CacheFS cannot claim resources once its block usage has reached the level specified by minblocks. The default is 85.

**maxfiles=n** Maximum number of files that CacheFS can use, expressed as a percentage of the total number of inodes in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the inodes the maxfiles parameter allows is available. The default is 90.

**minfiles=n** Minimum number of files, expressed as a percentage of the total number of inodes in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the inodes the minfiles parameter attempts to reserve is available. The default is 0.

**threshfiles=n** A percentage of the total inodes in the front file system beyond which CacheFS cannot claim inodes once its usage has reached the level specified by minfiles. The default is 85.

**maxfilesize=n** Largest file size, expressed in megabytes, that CacheFS is allowed to cache. The default is 3. You cannot decrease the block or inode allotment for a cache. To decrease the size of a cache, you must remove it and create it again with different parameters.

Currently maxfilesize is ignored by cachefs, therefore, setting it has no effect.

**Operands**

- **cache_directory** The directory under which the cache is actually stored.
- **mntpt1** The directory where the CacheFS is mounted.

**Usage**

See `largefile(5)` for the description of the behavior of cfsadmin when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

**Examples**

**EXAMPLE 1** Creating a Cache Directory

The following example creates a cache directory named /cache:

```
example# cfsadmin -c /cache
```
EXAMPLE 2  Creating a Cache
The following example creates a cache named /cache1 that can claim a maximum of 60 percent of the blocks in the front file system, can use 40 percent of the front file system blocks without interference by CacheFS internal control mechanisms, and has a threshold value of 50 percent. The threshold value indicates that after CacheFS reaches its guaranteed minimum, it cannot claim more space if 50 percent of the blocks in the front file system are already used.

example# cfsadmin -c -o maxblocks=60,minblocks=40,threshblocks=50 /cache1

EXAMPLE 3  Changing the maxfilesize Parameter
The following example changes the maxfilesize parameter for the cache directory /cache2 to 2 megabytes:

example# cfsadmin -u -o maxfilesize=2 /cache2

EXAMPLE 4  Listing the Contents of a Cache Directory
The following example lists the contents of a cache directory named /cache3 and provides statistics about resource utilization:

example# cfsadmin -l /cache3

EXAMPLE 5  Removing a Cached File System
The following example removes the cached file system with cache ID 23 from the cache directory /cache3 and frees its resources (the cache ID is part of the information returned by cfsadmin -l):

example# cfsadmin -d 23 /cache3

EXAMPLE 6  Removing All Cached File Systems
The following example removes all cached file systems from the cache directory /cache3:

example# cfsadmin -d all /cache3

EXAMPLE 7  Checking for Consistency in File Systems
The following example checks for consistency all file systems mounted with demandconst enabled. No errors are reported if no demandconst file systems were found.

example# cfsadmin -s all

Exit Status  The following exit values are returned:

0  Successful completion.
1  An error occurred.

Name chat – automated conversational exchange tool

Synopsis chat [options] script

Description The chat program implements a conversational text-based exchange between the computer and any serial device, including (but not limited to) a modem, an ISDN TA, and the remote peer itself, establishing a connection between the Point-To-Point Protocol daemon (pppd) and the remote pppd process.

Options The chat command supports the following options:

- `* <chat file>` Read the chat script from the chat file. This option is mutually exclusive with the chat script parameters. You must have read access to use the file. Multiple lines are permitted in the file. Use the space or horizontal tab characters to separate the strings.

- `t <timeout>` Set the timeout for the expected string to be received. If the string is not received within the time limit, the reply string is not sent. If specified, a 'subexpect' (alternate reply) string can be sent. Otherwise, if no alternate reply strings remain, the chat script fails.. A failed script will cause the chat program to terminate with a non-zero error code.

- `r <report file>` Set the file for output of the report strings. If you use the keyword REPORT, the resulting strings are written to this file. If the -r option is not used and you use the REPORT keyword, the stdout file is used for the report strings.

- `e` Start with the echo option turned on. You turn echo on or off at specific points in the chat script using the ECHO keyword. When echoing is enabled, all output from the modem is echoed to stdout.

- `E` Enables environment variable substitution within chat scripts using the standard $xxx syntax.

- `v` Request that the chat script execute in a verbose mode. The chat program logs the execution state of the chat script as well as all text received from the modem and output strings sent to the modem. The default is to log through syslog(3C) with facility local2; the logging method is alterable using the -S and -s options.

- `V` Request that the chat script be executed in a stderr verbose mode. The chat program logs all text received from the modem and output strings sent to the modem to stderr. stderr is usually the local console at the station running the chat or pppd program.

- `s` Use stderr. Log messages from -v and error messages are sent to stderr.
-S

Do not use syslog. By default, error messages are set to syslog. This option prevents log messages from -v and error messages from being sent to syslog.

-T <phonenumber>

Pass in an arbitrary string (usually a telephone number) that will be substituted for the \T substitution metacharacter in a send string.

-U <phonenumber 2>

Pass in a second string (usually a telephone number) that will be substituted for the \U substitution metacharacter in a send string. This is useful when dialing an ISDN terminal adapter that requires two numbers.

script

If the script is not specified in a file with the -f option, the script is included as parameters to the chat program.

The chat script defines communications. A script consists of one or more "expect-send" pairs of strings separated by spaces, with an optional "subexpect-subsend" string pair, separated by a dash (as in the following example:)

```
login: BREAK-login: ppp passwd: hello2u2
```

The example indicates that the chat program should expect the string "login:". If it fails to receive a login prompt within the time interval allotted, it sends a break sequence to the remote and then expects the string "login:". If the first "login:" is received, the break sequence is not generated.

Upon receiving the login prompt, the chat program sends the string "ppp" and then expects the prompt "passwd:". When the password prompt is received, it sends the password hello2u2.

A carriage return is normally sent following the reply string. It is not expected in the "expect" string unless it is specifically requested by using the \r character sequence.

The expect sequence should contain only what is needed to identify the received data. Because it's stored on a disk file, it should not contain variable information. Generally it is not acceptable to look for time strings, network identification strings, or other variable pieces of data as an expect string.

To correct for characters that are corrupted during the initial sequence, look for the string "login:" rather than "login:". The leading "T" character may be received in error, creating problems in finding the string. For this reason, scripts look for "login:" rather than "login:" and "passwd:" rather than "password:".

An example of a simple script follows:

```
login: ppp passwd: hello2u2
```
The example can be interpreted as: expect login:, send ppp, expect ...password:, send hello2u2.

When login to a remote peer is necessary, simple scripts are rare. At minimum, you should include sub-expect sequences in case the original string is not received. For example, consider the following script:

```
login:--login: ppp password: hello2u2
```

This script is more effective than the simple one used earlier. The string looks for the same login prompt; however, if one is not received, a single return sequence is sent and then the script looks for login: again. If line noise obscures the first login prompt, send the empty line to generate a login prompt again.

Comments

Comments can be embedded in the chat script. Comment lines are ignored by the chat program. A comment starts with the hash (“#”) character in column one. If a # character is expected as the first character of the expect sequence, quote the expect string. If you want to wait for a prompt that starts with a # character, write something like this:

```
# Now wait for the prompt and send logout string
#' # ' logout
```

Sending Data From A File

If the string to send begins with an at sign (“@”), the remainder of the string is interpreted as the name of the file that contains the string. If the last character of the data read is a newline, it is removed. The file can be a named pipe (or fifo) instead of a regular file. This enables chat to communicate with another program, for example, a program to prompt the user and receive a password typed in.

Abort

Many modems report the status of a call as a string. These status strings are often “CONNECTED” or “NO CARRIER” or “BUSY.” If the modem fails to connect to the remote, you can terminate the script. Abort strings may be specified in the script using the ABORT sequence. For example:

```
ABORT BUSY ABORT "NO CARRIER" "ATZ OK ATDT5551212 CONNECT"
```

This sequence expects nothing and sends the string ATZ. The expected response is the string OK. When OK is received, the string ATDT5551212 dials the telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the script is executed. When the modem finds a busy telephone, it sends the string BUSY, causing the string to match the abort character sequence. The script fails because it found a match to the abort string. If the NO CARRIER string is received, it aborts for the same reason.

Clr_Abort

The CLR_AbORT sequence clears previously set ABORT strings. ABORT strings are kept in an array of a pre-determined size; CLR_AbORT reclaims the space for cleared entries, enabling new strings to use that space.
The SAY string enables the script to send strings to a user at a terminal via standard error. If chat is being run by pppd and pppd is running as a daemon (detached from its controlling terminal), standard error is normally redirected to the /etc/ppp/connect-errors file.

SAY strings must be enclosed in single or double quotes. If carriage return and line feed are required for the output, you must explicitly add them to your string.

The SAY string can provide progress messages to users even with “ECHO OFF.” For example, add a line similar to the following to the script:

```
ABORT BUSY
ECHO OFF
SAY "Dialing your ISP...
" ATDT5551212
TIMEOUT 120
SAY "Waiting up to 2 minutes for connection ...
"
CONNECT "
SAY "Connected, now logging in ...
"
login: account
password: pass
$ \c
SAY "Logged in OK ...
"
```

This sequence hides script detail while presenting the SAY string to the user. In this case, you will see:

```
Dialing your ISP...
Waiting up to 2 minutes for connection...Connected, now logging in...
Logged in OK ...
```

REPORT is similar to the ABORT string. With REPORT, however, strings and all characters to the next control character (such as a carriage return), are written to the report file.

REPORT strings can be used to isolate a modem’s transmission rate from its CONNECT string and return the value to the chat user. Analysis of the REPORT string logic occurs in conjunction with other string processing, such as looking for the expect string. It’s possible to use the same string for a REPORT and ABORT sequence, but probably not useful.

Report strings may be specified in the script using the REPORT sequence. For example:

```
REPORT CONNECT
ABORT BUSY
ATDT5551212 CONNECT
login: account
```

The above sequence expects nothing, then sends the string ATDT5551212 to dial the telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the
script is executed. In addition, the program writes the string CONNECT to the report file (specified by -r) in addition to any characters that follow.

**Clr_Report**
CLR_REPORT clears previously set REPORT strings. REPORT strings are kept in an array of a pre-determined size; CLR_REPORT reclaims the space for cleared entries so that new strings can use that space.

**Echo**
ECHO determines if modem output is echoed to stderr. This option may be set with the -e option, but can also be controlled by the ECHO keyword. The "expect-send" pair ECHO ON enables echoing, and ECHO OFF disables it. With ECHO, you can select which parts of the conversation should be visible. In the following script:

```
ABORT 'BUSY'
ABORT 'NO CARRIER'
** AT&F
OK\r\n ATD1234567
 \n \c
ECHO ON
CONNECT \c
login: account
```

All output resulting from modem configuration and dialing is not visible, but output is echoed beginning with the CONNECT (or BUSY) message.

**Hangup**
The HANGUP option determines if a modem hangup is considered an error. HANGUP is useful for dialing systems that hang up and call your system back. HANGUP can be ON or OFF. When HANGUP is set to OFF and the modem hangs up (for example, following the first stage of logging in to a callback system), chat continues running the script (for example, waiting for the incoming call and second stage login prompt). When the incoming call is connected, use the HANGUP ON string to reinstall normal hang up signal behavior. An example of a simple script follows:

```
ABORT 'BUSY'
*** AT&F
OK\r\n ATD1234567
 \n \c
CONNECT \c
"Callback login:" call_back_ID
HANGUP OFF
ABORT "Bad Login"
"Callback Password:" Call_back_password
TIMEOUT 120
CONNECT \c
HANGUP ON
ABORT "NO CARRIER"
login:--BREAK--login: real_account
```
The initial timeout value is 45 seconds. Use the \(-t\) parameter to change the initial timeout value.

To change the timeout value for the next expect string, the following example can be used:

```
"AT&T
OK ATDT5551212
CONNECT \c
TIMEOUT 10
login:--login: username
TIMEOUT 5
password: hello2u2
```

The example changes the timeout to ten seconds when it expects the login prompt. The timeout is changed to five seconds when it looks for the password prompt.

Once changed, the timeout value remains in effect until it is changed again.

**EOT** The EOT special reply string instructs the chat program to send an EOT character to the remote. This is equivalent to using `^D`\c as the reply string. The EOT string normally indicates the end-of-file character sequence. A return character is not sent following the EOT. The EOT sequence can be embedded into the send string using the sequence `^D`.

**BREAK** The BREAK special reply string sends a break condition. The break is a special transmitter signal. Many UNIX systems handle break by cycling through available bit rates, and sending break is often needed when the remote system does not support autobaud. BREAK is equivalent to using `\K`\c as the reply string. You embed the break sequence into the send string using the `\K` sequence.

**Escape Sequences** Expect and reply strings can contain escape sequences. Reply strings accept all escape sequences, while expect strings accept most sequences. A list of escape sequences is presented below. Sequences that are not accepted by expect strings are indicated.

- `''` Expects or sends a null string. If you send a null string, chat sends the return character. If you expect a null string, chat proceeds to the reply string without waiting. This sequence can be a pair of apostrophes or quote mark characters.
- `\b` Represents a backspace character.
- `\c` Suppresses the newline at the end of the reply string. This is the only method to send a string without a trailing return character. This sequence must be at the end of the send string. For example, the sequence `hello\c` will simply send the characters h, e, l, o. (Not valid in expect.)
- `\d` Delay for one second. The program uses `sleep(1)` which delays to a maximum of one second. (Not valid in expect.)
- `\K` Insert a BREAK. (Not valid in expect.)
\n Send a newline or linefeed character.
\N Send a null character. The same sequence may be represented by \0. (Not valid in expect.)
\p Pause for 1/10th of a second. (Not valid in expect.)
\q Suppress writing the string to syslog. The string ?????? is written to the log in its place. (Not valid in expect.)
\r Send or expect a carriage return.
\s Represents a space character in the string. Can be used when it is not desirable to quote the strings which contains spaces. The sequence 'HI TIM' and HI\sTIM are the same.
\t Send or expect a tab character.
\T Send the phone number string as specified with the -T option. (Not valid in expect.)
\U Send the phone number 2 string as specified with the -U option. (Not valid in expect.)
\\ Send or expect a backslash character.
\ddd Collapse the octal digits (ddd) into a single ASCII character and send that character. (\000 is not valid in an expect string.)
^C Substitute the sequence with the control character represented by C. For example, the character DC1 (17) is shown as ^Q. (Some characters are not valid in expect.)

Environment Variables
Environment variables are available within chat scripts if the -E option is specified on the command line. The metacharacter $ introduces the name of the environment variable to substitute. If the substitution fails because the requested environment variable is not set, nothing is replaced for the variable.

Exit Status
The chat program terminates with the following completion codes:
0 Normal program termination. Indicates that the script was executed without error to normal conclusion.
1 One or more of the parameters are invalid or an expect string was too large for the internal buffers. Indicates that the program was not properly executed.
2 An error occurred during the execution of the program. This may be due to a read or write operation failing or chat receiving a signal such as SIGINT.
3 A timeout event occurred when there was an expect string without having a "-subsend" string. This indicates that you may not have programmed the script correctly for the condition or that an unexpected event occurred and the expected string could not be found.
The first string marked as an ABORT condition occurred.
The second string marked as an ABORT condition occurred.
The third string marked as an ABORT condition occurred.
The fourth string marked as an ABORT condition occurred.

The other termination codes are also strings marked as an ABORT condition.

To determine which event terminated the script, use the termination code. It is possible to decide if the string "BUSY" was received from the modem versus "NO DIALTONE." While the first event may be retried, the second probably will not succeed during a retry.

Additional information on chat scripts are available with UUCP documentation. The chat script format was taken from scripts used by the uucico program.
check-hostname(1M)

Name  check-hostname – check if sendmail can determine the system’s fully-qualified host name

Synopsis  /usr/sbin/check-hostname

Description  The check-hostname script is a migration aid for sendmail(1M). This script tries to determine the local host’s fully-qualified host name (FQHN) in a manner similar to sendmail(1M). If check-hostname is able to determine the FQHN of the local host, it reports success. Otherwise, check-hostname reports how to reconfigure the system so that the FQHN can be properly determined.

Files  /etc/hosts     Host name database
       /etc/nsswitch.conf     Name service switch configuration file
       /etc/resolv.conf     Configuration file for name server routines

See Also  domainname(1M), sendmail(1M), hosts(4), attributes(5)
check-permissions(1M)

Name  check-permissions – check permissions on mail rerouting files

Synopsis  /usr/sbin/check-permissions [login]

Description  The check-permissions script is intended as a migration aid for sendmail(1M). It checks the /etc/mail/sendmail.cf file for all configured alias files, and checks the alias files for :include: files. It also checks for certain .forward files. For each file that check-permissions checks, it verifies that none of the parent directories are group- or world-writable. If any directories are overly permissive, it is reported. Otherwise it reports that no unsafe directories were found.

As to which .forward files are checked, it depends on the arguments included on the command line. If no argument is given, the current user’s home directory is checked for the presence of a .forward file. If any arguments are given, they are assumed to be valid logins, and the home directory of each one is checked.

If the special argument ALL is given, the passwd entry in the /etc/nsswitch.conf file is checked, and all password entries that can be obtained through the switch file are checked. In large domains, this can be time-consuming.

Operands  The following operands are supported:

login Where login is a valid user name, checks the home directory for login.

ALL Checks the home directory of all users.

Files  /etc/mail/sendmail.cf Defines environment for sendmail

/etc/mail/aliases Ascii mail aliases file

chk_encodings(1M)

Name
chk_encodings – check the label encodings file syntax

Synopsis
/usr/sbin/chk_encodings [-a] [-c maxclass] [pathname]

Description
chk_encodings checks the syntax of the label-encodings file that is specified by pathname. With the -a option, chk_encodings also prints a semantic analysis of the label-encodings file that is specified by pathname. If pathname is not specified, chk_encodings checks and analyzes the /etc/security/tsol/label_encodings file.

If label-encodings file analysis was requested, whatever analysis can be provided is written to the standard output file even if errors were found.

Options
- a
Provide a semantic analysis of the label encodings file.

- c maxclass
Accept a maximum classification value of maxclass (default 255) in the label encodings file CLASSIFICATIONS section.

Exit Status
When successful, chk_encodings returns an exit status of 0 (true) and writes to the standard output file a confirmation that no errors were found in pathname. Otherwise, chk_encodings returns an exit status of nonzero (false) and writes an error diagnostic to the standard output file.

Files
/etc/security/tsol/label_encodings
The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

Attributes
See attributes(5) for descriptions of the following attributes:

label_encodings(4), attributes(5), labels(5)

“How to Analyze and Verify the label_encodings File” in Oracle Solaris Trusted Extensions Label Administration
Notes  The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.
**Name**

chroot – change root directory for a command

**Synopsis**

/usr/sbin/chroot newroot command

**Description**

The chroot utility causes command to be executed relative to newroot. The meaning of any initial slashes (/) in the path names is changed to newroot for command and any of its child processes. Upon execution, the initial working directory is newroot.

Notice that redirecting the output of command to a file,

```
chroot newroot command >x
```

will create the file x relative to the original root of command, not the new one.

The new root path name is always relative to the current root. Even if a chroot is currently in effect, the newroot argument is relative to the current root of the running process.

This command can be run only by the super-user.

**Return Values**

The exit status of chroot is the return value of command.

**Examples** **EXAMPLE 1** Using the chroot Utility

The chroot utility provides an easy way to extract tar files (see tar(1)) written with absolute filenames to a different location. It is necessary to copy the shared libraries used by tar (see ldd(1)) to the newroot filesystem.

```
example# mkdir /tmp/lib; cd /lib
example# cp ld.so.1 libc.so.1 libcmd.so.1 libdl.so.1 \ 
      libsec.so.1 /tmp/lib
example# cp /usr/bin/tar /tmp
example# dd if=/dev/rmt/0 | chroot /tmp tar xvf -
```

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**

cd(1), tar(1), chroot(2), ttynname(3C), attributes(5)

**Notes**

Exercise extreme caution when referencing device files in the new root file system.

References by routines such as ttynname(3C) to stdin, stdout, and stderr will find that the device associated with the file descriptor is unknown after chroot is run.
The `cimworkshop` command starts Sun WBEM CIM WorkShop, a graphical user interface that enables you to create, modify, and view the classes and instances that describe the managed resources on your system.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM class is a computer representation, or model, of a type of managed resource, such as a printer, disk drive, or CPU. A CIM instance is a particular managed resource that belongs to a particular class. Instances contain actual data. Objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

The CIM WorkShop application displays a Login dialog box. Context help is displayed on the left side of the CIM WorkShop dialog boxes. When you click on a field, the help content changes to describe the selected field.

By default, CIM WorkShop uses the RMI protocol to connect to the CIM Object Manager on the local host, in the default namespace, `root\cimv2`. You can select HTTP if you want to communicate to a CIM Object Manager using the standard XML/HTTP protocol from the Desktop Management Task Force. When a connection is established, all classes contained in the default namespace are displayed in the left side of the CIM WorkShop window.

The name of the current namespace is listed in the tool bar. All programming operations are performed within a namespace. Four namespaces are created in a root namespace during installation:

- **cimv2**: Contains the default CIM classes that represent managed resources on your system.
- **security**: Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.
- **system**: Contains properties for configuring the CIM Object Manager.
- **snmp**: Contains pre-defined SNMP-related classes and all SNMP MOF files that are compiled.

The `cimworkshop` application allows you to perform the following tasks:

- **Create, view, and change namespaces.**

  - Use the CIM WorkShop application to view all namespaces. A namespace is a directory-like structure that can store CIM classes and instances.
Create, delete, and view CIM classes. You cannot modify the unique attributes of the classes that make up the CIM and Solaris Schema. You can create a new instance or subclass of the class and modify the desired attributes in that instance or subclass.

Create, modify, delete, and view CIM instances. You can add instances to a class and modify its inherited properties or create new properties. You can also change the property values of a CIM instance.

Invoke methods. You can set input values for a parameter of a method and invoke the method.

When CIM WorkShop connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When you use CIM WorkShop to view CIM data, the WBEM system validates your login information on the current host. By default, a validated WBEM user is granted read access to the CIM Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

Read Only Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.

Read/Write Allows full read, write, and delete access to all CIM classes and instances.

Write Allows write and delete, but not read access to all CIM classes and instances.

None Allows no access to CIM classes and instances.

Usage The cimworkshop command is not a tool for a distributed environment. Rather, this command is used for local administration on the machine on which the CIM Object Manager is running.

Exit Status The cimworkshop utility terminates with exit status 0.

**clear_locks**

**Name**
clear_locks – clear locks held on behalf of an NFS client

**Synopsis**
/usr/sbin/clear_locks [-s] hostname

**Description**
The `clear_locks` command removes all file, record, and share locks created by the `hostname` and held on the current host, regardless of which process created or owns the locks.

This command can be run only by the super-user.

This command should only be used to repair the rare case of a client crashing and failing to clear held locks. Clearing locks held by an active client may cause applications to fail in an unexpected manner.

**Options**
- `-s` Remove all locks created by the current machine and held by the server `hostname`.

**Operands**
The following operands are supported:

  - `hostname` name of host server

**Exit Status**
0 Successful operation.
1 If not root.
2 Usage error.
3 If unable to contact server (RPC).

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

`fcntl(2), attributes(5)`
The `clinfo` command displays cluster configuration information about the node from which the command is executed.

Without arguments, `clinfo` returns an exit status of 0 if the node is configured and booted as part of a cluster. Otherwise, `clinfo` returns an exit status of 1.

**Options**

- `-h` Displays the highest node number allowed to be configured. This is different from the maximum number of nodes supported in a given cluster. The current highest configured node number can change immediately after the command returns since new nodes can be dynamically added to a running cluster.

  For example, `clinfo -h` might return 64, meaning that the highest number you can use to identify a node is 64. See the *Sun Cluster 3.0 System Administration Guide* for a description of utilities you can use to determine the number of nodes in a cluster.

- `-n` Prints the number of the node from which `clinfo` is executed.

**Exit Status**

The following exit values are returned:

- 0  Successful completion.
- 1  An error occurred.

This is usually because the node is not configured or booted as part of a cluster.

Name  clri, dcopy – clear inode

Synopsis  clri [-F FSType] [-V] special i-number
dcopy [-F FSType] [-V] special i-number

Description  clri writes zeros on the inodes with the decimal i-number on the file system stored on special. After clri, any blocks in the affected file show up as missing in an fsck(1M) of special.

Read and write permission is required on the specified file system device. The inode becomes allocatable.

The primary purpose of this routine is to remove a file that for some reason appears in no directory. If it is used to zap an inode that does appear in a directory, care should be taken to track down the entry and remove it. Otherwise, when the inode is reallocated to some new file, the old entry will still point to that file. At that point, removing the old entry will destroy the new file. The new entry will again point to an unallocated inode, so the whole cycle is likely to be repeated again and again.

dcopy is a symbolic link to clri.

Options  -F FSType  Specify the FSType on which to operate. The FSType should either be specified here or be determinable from /etc/vfstab by matching special with an entry in the table, or by consulting /etc/default/fs.

-V  Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option should be used to verify and validate the command line.

Usage  See largefile(5) for the description of the behavior of clri and dcopy when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files  /etc/default/fs  Default local file system type
       /etc/vfstab  List of default parameters for each file system

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  fsck(1M), vfstab(4), attributes(5), largefile(5)

Notes  This command might not be supported for all FSTypes.
Name  configCCR – configure Oracle Configuration Manager

Synopsis  /usr/lib/ocm/ccr/bin/configCCR

    configCCR [-a] [-d] [-C OracleSupportHubURL] [-s]
              [CSI-number [[MyOracleSupportID] [country]]]

    configCCR [-r] [-C OracleSupportHubURL] [-s]

    configCCR [-R response_file]

    configCCR -D [-v] [-T target_type [ -N target_name [ -P property_name ]]]

Description  The configCCR command is used to modify Oracle Configuration Manager (OCM) configuration information. This command enables you to modify the registration credentials after Oracle Configuration Manager has been installed. You can also use this command to switch between Connected and Disconnected modes, and to configure Diagnostic Checks properties.

Options  The following options are supported:

- a
  Run with instance data the directory defined by ORACLE_CONFIG_HOME.

- C URL
  Defines the Oracle Support Hub used to connect to Oracle.

- d
  Run is disconnected mode. In this mode data is not collected automatically.

- D [-v] [-T target_type [-N target_name [-P property_name]]]
  Configure missing diagnostic check properties.

- v
  Verifies that all target properties are properly configured and that no properties are missing.

- T target_type
  Provides the target type to be configured or verified.

- N target_name
  Provides the target name to be configured or verified. Must be used with - T.

- P property_name
  Provides the property name for the target to be configured or verified. Must be used with - N and - T.

- R file
  Reconfigures using the contents of the response file named file.
Removes the instance data in the directory defined by ORACLE_CONFIG_HOME. If not set the ./.ccr/hosts/hostname (where hostname is the current hostname) is removed with the associated crontab(1) entry.

Indicates that you accept the Oracle Configuration Manager License agreement.

Operands

CSI-number
Customer Support Identifier

MyOracleSupportID
My Oracle Support User Name

country
two-letter country code

Files

/usr/lib/ocm
Directory to store all OCM related files and data.

/usr/lib/ocm/ccr/config
Contains configuration files.

/usr/lib/ocm/ccr/log
Contains log files.

/usr/lib/ocm/ccr/state
Contains state files and collected data.

/usr/lib/ocm/ccr/state/review/targetMap.xml
Summaries of the data that was collected.

/usr/lib/ocm/ccr/state/review
Data that was uploaded to the server.

Oracle Configuration Manager Installation and Administration Guide
Name  
consadm -- select or display devices used as auxiliary console devices

Synopsis  
/usr/sbin/consadm
/usr/sbin/consadm [-a device . . .] [-p]
/usr/sbin/consadm [-d device . . .] [-p]
/usr/sbin/consadm [-p]

Description  
consadm selects the hardware device or devices to be used as auxiliary console devices, or displays the current device. Only superusers are allowed to make or display auxiliary console device selections.

Auxiliary console devices receive copies of console messages, and can be used as the console during single user mode. In particular, they receive kernel messages and messages directed to /dev/sysmsg. On Solaris x86 based systems they can also be used for interaction with the bootstrap.

By default, selecting a display device to be used as an auxiliary console device selects that device for the duration the system remains up. If the administrator needs the selection to persist across reboots the -p option can be specified.

consadm runs a daemon in the background, monitoring auxiliary console devices. Any devices that are disconnected (hang up, lose carrier) are removed from the auxiliary console device list, though not from the persistent list. While auxiliary console devices may have been removed from the device list receiving copies of console messages, those messages will always continue to be displayed by the default console device.

The daemon will not run if it finds there are not any auxiliary devices configured to monitor. Likewise, after the last auxiliary console is removed, the daemon will shut itself down. Therefore the daemon persists for only as long as auxiliary console devices remain active.

See eeprom(1M) for instructions on assigning an auxiliary console device as the system console.

Options  
The following options are supported:

- a device  
Adds device to the list of auxiliary console devices. Specify device as the path name to the device or devices to be added to the auxiliary console device list.

- d device  
Removes device from the list of auxiliary console devices. Specify device as the path name to the device or devices to be removed from the auxiliary console device list.

- p  
Prints the list of auxiliary consoles that will be auxiliary across reboots.

When invoked with the -a or -d options, tells the application to make the change persist across reboot.
Adding to the list of devices that will receive console messages
The following command adds /dev/term/a to the list of devices that will receive console messages.
example# consadm -a /dev/term/a

Removing from the list of devices that will receive console messages
The following command removes /dev/term/a from the list of devices that will receive console messages. This includes removal from the persistent list.
example# consadm -d -p /dev/term/a

Printing the list of devices selected as auxiliary console devices
The following command prints the name or names of the device or devices currently selected as auxiliary console devices.
example# consadm

See environ(5) for descriptions of the following environment variables that affect the execution of consadm: LC_CTYPE, LC_MESSAGES, and NLSPATH.

The following exit values are returned:
0 Successful completion.
>0 An error occurred.

See attributes(5) for descriptions of the following attributes:

<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Stability Level</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

Auxiliary console devices are not usable for kadb or firmware I/O, do not receive panic messages, and do not receive output directed to /dev/console.

The consadm service is managed by the service management facility, smf(5), under the service identifier:
svc:/system/consadm

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

See Also svc(1), eeprom(1M), svcadm(1M), syslogd(1M), kadb(1M), environ(5), attributes(5), smf(5), sysmsg(7D), console(7D)
conv_lp(1M)

**Name**  
conv_lp – convert LP configuration

**Synopsis**  
conv_lp [-d dir] [-f file]

**Description**  
conv_lp reads LP printer configuration information from a directory and converts it to an output file for use with print client software.

**Options**  
The following options are supported:

- **-d dir**  
The root (’/’) directory from which LP configuration information is read. The default is root (’/’).

- **-f file**  
The output file to which conv_lp writes the converted LP configuration information. The default is /etc/printers.conf.

**Examples**

**EXAMPLE 1**  
Converting LP Configuration Information from the Default Directory and File

The following example converts LP configuration information from directory root (/) to file /etc/printers.conf.

% conv_lp

**EXAMPLE 2**  
Converting LP Configuration Information From a Specified Directory and File

The following example converts LP configuration information from directory /export/root/client to file /export/root/client/etc/printers.conf.

% conv_lp -d /export/root/client -f /export/root/client/etc/printers.conf

**Exit Status**  
The following exit values are returned:

- **0**  
  Successful completion.

- **non-zero**  
  An error occurred.

**Files**  
/etc/printers.conf  
System printer configuration database.

**Attributes**

Name  conv_lpd – convert LPD configuration

Synopsis  conv_lpd [-c printers | -c printcap] [-n] file

Description  conv_lpd converts LPD printer configuration information from file to a printers.conf or a
printcap file (see printers.conf(4)). file specifies the name of the input file, and can be
either in printers.conf or printcap format. If file is in printers.conf format, it converts it
to a printcap file. If file is in printcap format, it converts it to a printers.conf file.

Options  The following options are supported:

- c printers | - c printcap  Specifies the type of output file produced by the conversion.
- c printers converts to a printers.conf file. - c printcap
converts to a printcap file. - c printers is the default.
- n  Preserves the namelist during the conversion.

Operands  The following operands are supported:

file  The file to be converted.

Examples  EXAMPLE 1  Converting a printcap file to a printers.conf file.
The following example converts a printcap file to a printers.conf file.
example% conv_lpd /etc/printcap

EXAMPLE 2  Converting a printcap file to a printers.conf file and preserving the namelist.
The following example converts a printcap file to a printers.conf file and preserves the
namelist.
example% conv_lpd -c printers -n /etc/printcap

EXAMPLE 3  Converting a printers.conf file to a printcap file and preserving the namelist.
The following example converts a printers.conf file to a printcap file and preserves the
namelist.
example% conv_lpd -c printcap -n /etc/printers.conf

Exit Status  The following exit values are returned:
0  Successful completion.
non-zero  An error occurred.

Files  /etc/printers.conf  System printer configuration database.
/etc/printcap  SunOS 4.x printer capability database.
Attributes  See attributes(5) for descriptions of the following attributes:

Name  coreadm – core file administration

Synopsis  coreadm [-g pattern] [-G content] [-i pattern] [-I content]
          [-d option]... [-e option]...
          coreadm [-p pattern] [-P content] [pid]...
          coreadm -u

Description  coreadm specifies the name and location of core files produced by abnormally-terminating processes. See core(4).

Only users who have the sys_admin privilege can execute the first form of the SYNOPSIS. This form configures system-wide core file options, including a global core file name pattern and a core file name pattern for the init(1M) process. All settings are saved in coreadm’s configuration file /etc/coreadm.conf to set at boot. See init(1M).

Nonprivileged users can execute the second form of the SYNOPSIS. This form specifies the file name pattern and core file content that the operating system uses to generate a per-process core file.

Only users who have the sys_admin privilege can execute the third form of the SYNOPSIS. This form updates all system-wide core file options, based on the contents of /etc/coreadm.conf. Normally, this option is used on reboot when starting svc:/system/coreadm:default.

A core file name pattern is a normal file system path name with embedded variables, specified with a leading % character. The variables are expanded from values that are effective when a core file is generated by the operating system. The possible embedded variables are as follows:

%d  Executable file directory name, up to a maximum of MAXPATHLEN characters
%f  Executable file name, up to a maximum of MAXCOMLEN characters
%g  Effective group-ID
%m  Machine name (uname -m)
%n  System node name (uname -n)
%p  Process-ID
%t  Decimal value of time(2)
%u  Effective user-ID
%z  Name of the zone in which process executed (zonename)
%%  Literal %

For example, the core file name pattern /var/core/core.%f.%p would result, for command foo with process-ID 1234, in the core file name /var/core/core.foo.1234.
A core file content description is specified using a series of tokens to identify parts of a process's binary image:

- **anon** Anonymous private mappings, including thread stacks that are not main thread stacks
- **ctf** CTF type information sections for loaded object files
- **data** Writable private file mappings
- **dism** DISM mappings
- **heap** Process heap
- **ism** ISM mappings
- **rodata** Read-only private file mappings
- **shanon** Anonymous shared mappings
- **shfile** Shared mappings that are backed by files
- **shm** System V shared memory
- **stack** Process stack
- **symtab** Symbol table sections for loaded object files
- **text** Readable and executable private file mappings

In addition, you can use the token **all** to indicate that core files should include all of these parts of the process's binary image. You can use the token **none** to indicate that no mappings are to be included. The **default** token indicates inclusion of the system default content (stack+heap+shm+ism+dism+text+data+rodata+anon+shanon+ctf). The /proc file system data structures are always present in core files regardless of the mapping content.

You can use **+** and **-** to concatenate tokens. For example, the core file content **default-ism** would produce a core file with the default set of mappings without any intimate shared memory mappings.

The **coreadm** command with no arguments reports the current system configuration, for example:

```
$ coreadm
  global core file pattern: /var/core/core.%f.%p
  global core file content: all
    init core file pattern: core
      init core file content: default
        global core dumps: enabled
        per-process core dumps: enabled
        global setid core dumps: enabled
```
per-process setid core dumps: disabled
  global core dump logging: disabled

The coreadm command with only a list of process-IDs reports each process's per-process core file name pattern, for example:

$ coreadm 278 5678
  278: core.%f.%p default
  5678: /home/george/cores/%f.%p.%t all-ism

Only the owner of a process or a user with the proc_owner privilege can interrogate a process in this manner.

When a process is dumping core, up to three core files can be produced: one in the per-process location, one in the system-wide global location, and, if the process was running in a local (non-global) zone, one in the global location for the zone in which that process was running. Each core file is generated according to the effective options for the corresponding location.

When generated, a global core file is created in mode 600 and owned by the superuser. Nonprivileged users cannot examine such files.

Ordinary per-process core files are created in mode 600 under the credentials of the process. The owner of the process can examine such files.

A process that is or ever has been setuid or setgid since its last exec(2) presents security issues that relate to dumping core. Similarly, a process that initially had superuser privileges and lost those privileges through setuid(2) also presents security issues that are related to dumping core. A process of either type can contain sensitive information in its address space to which the current nonprivileged owner of the process should not have access. If setid core files are enabled, they are created mode 600 and owned by the superuser.

Options

The following options are supported:

- **d option**... Disable the specified core file option. See the -e option for descriptions of possible options.

  Multiple -e and -d options can be specified on the command line. Only users with the sys_admin privilege can use this option.

- **e option**... Enable the specified core file option. Specify option as one of the following:
  
  - global
  - global-setid
  - log
  - process

  Allow core dumps that use global core pattern.
  
  Allow set-id core dumps that use global core pattern.
  
  Generate a syslog(3C) message when generation of a global core file is attempted.
  
  Allow core dumps that use per-process core pattern.
proc-setid  Allow set-id core dumps that use per-process core pattern.

Multiple -e and -d options can be specified on the command line. Only users with the sys_admin privilege can use this option.

- g pattern  Set the global core file name pattern to pattern. The pattern must start with a / and can contain any of the special % variables that are described in the DESCRIPTION.

Only users with the sys_admin privilege can use this option.

-G content  Set the global core file content to content. You must specify content by using the tokens that are described in the DESCRIPTION.

Only users with the sys_admin privilege can use this option.

-I pattern  Set the default per-process core file name to pattern. This changes the per-process pattern for any process whose per-process pattern is still set to the default. Processes that have had their per-process pattern set or are descended from a process that had its per-process pattern set (using the -p option) are unaffected. This default persists across reboot.

Only users with the sys_admin or proc_owner privilege can use this option.

-I content  Set the default per-process core file content to content. This changes the per-process content for any process whose per-process content is still set to the default. Processes that have had their per-process content set or are descended from a process that had its per-process content set (using the -P option) are unaffected. This default persists across reboot.

Only users with the sys_admin or proc_owner privileges can use this option.

-p pattern  Set the per-process core file name pattern to pattern for each of the specified process-IDs. The pattern can contain any of the special % variables described in the DESCRIPTION and need not begin with / . If the pattern does not begin with / , it is evaluated relative to the directory that is current when the process generates a core file.

A nonprivileged user can apply the -p option only to processes that are owned by that user. A user with the proc_owner privilege can apply the option to any process. The per-process core file name pattern is inherited by future child processes of the affected processes. See fork(2).

If no process-IDs are specified, the -p option sets the per-process core file name pattern to pattern on the parent process (usually the shell that ran coreadm).
Set the per-process core file content to `content` for each of the specified process-IDs. The content must be specified by using the tokens that are described in the DESCRIPTION.

A nonprivileged user can apply the `-p` option only to processes that are owned by that user. A user with the `proc_owner` privilege can apply the option to any process. The per-process core file name pattern is inherited by future child processes of the affected processes. See `fork(2)`.

If no process-IDs are specified, the `-P` option sets the per-process file content to `content` on the parent process (usually the shell that ran `coreadm`).

Update system-wide core file options from the contents of the configuration file `/etc/coreadm.conf`. If the configuration file is missing or contains invalid values, default values are substituted. Following the update, the configuration file is resynchronized with the system core file configuration.

Only users with the `sys_admin` privilege can use this option.

**Operands**
The following operands are supported:

- `pid` process-ID

**Examples**

**EXAMPLE 1** Setting the Core File Name Pattern
When executed from a user's `$HOME/.profile` or `$HOME/.login`, the following command sets the core file name pattern for all processes that are run during the login session:

```
example$ coreadm -p core.%f.%p
```

Note that since the process-ID is omitted, the per-process core file name pattern will be set in the shell that is currently running and is inherited by all child processes.

**EXAMPLE 2** Dumping a User's Files Into a Subdirectory
The following command dumps all of a user's core dumps into the `corefiles` subdirectory of the home directory, discriminated by the system node name. This command is useful for users who use many different machines but have a shared home directory.

```
example$ coreadm -p $HOME/corefiles/%n.%f.%p 1234
```

**EXAMPLE 3** Culling the Global Core File Repository
The following commands set up the system to produce core files in the global repository only if the executables were run from `/usr/bin` or `/usr/sbin`.

```
example# mkdir -p /var/cores/usr/bin
example# mkdir -p /var/cores/usr/sbin
example# coreadm -G all -g /var/cores/%d/%f.%p.%n
```
The following exit values are returned:

0  Successful completion.
1  A fatal error occurred while either obtaining or modifying the system core file configuration.
2  Invalid command-line options were specified.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  gc(1M), sv(1), init(1M), svcadm(1M), exec(2), fork(2), setuid(2), time(2), syslog(3C), core(4), attributes(5), smf(5)

Notes  In a local (non-global) zone, the global settings apply to processes running in that zone. In addition, the global zone's apply to processes run in any zone.

The term global settings refers to settings which are applied to the system or zone as a whole, and does not necessarily imply that the settings are to take effect in the global zone.

The coreadm service is managed by the service management facility, smf(5), under the service identifier:

    svc://system/coreadm:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
Name cpustat – monitor system behavior using CPU performance counters

Synopsis cpustat -c eventspec [-c eventspec]... [-p period] [-sntD] [interval [count]]

Description The cpustat utility allows CPU performance counters to be used to monitor the overall behavior of the CPUs in the system.

If interval is specified, cpustat samples activity every interval seconds, repeating forever. If a count is specified, the statistics are repeated count times. If neither are specified, an interval of five seconds is used, and there is no limit to the number of samples that are taken.

Options The following options are supported:

- c eventspec Specifies a set of events for the CPU performance counters to monitor. The syntax of these event specifications is:

[picn=]eventn[,attr[n][=val]][,[picn=]eventn
 [,attr[n][=val]],...,]

You can use the -h option to obtain a list of available events and attributes. This causes generation of the usage message. You can omit an explicit counter assignment, in which case cpustat attempts to choose a capable counter automatically.

Attribute values can be expressed in hexadecimal, octal, or decimal notation, in a format suitable for strtoll(3C). An attribute present in the event specification without an explicit value receives a default value of 1. An attribute without a corresponding counter number is applied to all counters in the specification.

The semantics of these event specifications can be determined by reading the CPU manufacturer's documentation for the events.

Multiple -c options can be specified, in which case the command cycles between the different event settings on each sample.

-D Enables debug mode.

-h Prints an extensive help message on how to use the utility and how to program the processor-dependent counters.

-p period Causes cpustat to cycle through the list of events every period seconds. The tool sleeps after each cycle until period seconds have elapsed since the first eventspec was measured.
When this option is present, the optional \textit{count} parameter specifies the number of total cycles to make (instead of the number of total samples to take). If \textit{period} is less than the number of \textit{eventspecs} times \textit{interval}, the tool acts as if period is 0.

\textbf{-s} Creates an idle soaker thread to spin while system-only \textit{eventspecs} are bound. One idle soaker thread is bound to each CPU in the current processor set. System-only \textit{eventspecs} contain both the \texttt{nouser} and the \texttt{sys} tokens and measure events that occur while the CPU is operating in privileged mode. This option prevents the kernel's idle loop from running and triggering system-mode events.

\textbf{-n} Omits all header output (useful if \texttt{cpustat} is the beginning of a pipeline).

\textbf{-t} Prints an additional column of processor cycle counts, if available on the current architecture.

\textbf{Usage} A closely related utility, \texttt{cputrack(1)}, can be used to monitor the behavior of individual applications with little or no interference from other activities on the system.

The \texttt{cpustat} utility must be run by the super-user, as there is an intrinsic conflict between the use of the CPU performance counters system-wide by \texttt{cpustat} and the use of the CPU performance counters to monitor an individual process (for example, by \texttt{cputrack}).

Once any instance of this utility has started, no further per-process or per-LWP use of the counters is allowed until the last instance of the utility terminates.

The times printed by the command correspond to the wallclock time when the hardware counters were actually sampled, instead of when the program told the kernel to sample them. The time is derived from the same timebase as \texttt{gethrtime(3C)}.

The processor cycle counts enabled by the -t option always apply to both user and system modes, regardless of the settings applied to the performance counter registers.

On some hardware platforms running in system mode using the “sys” token, the counters are implemented using 32-bit registers. While the kernel attempts to catch all overflows to synthesize 64-bit counters, because of hardware implementation restrictions, overflows can be lost unless the sampling interval is kept short enough. The events most prone to wrap are those that count processor clock cycles. If such an event is of interest, sampling should occur frequently so that less than 4 billion clock cycles can occur between samples.

The output of \texttt{cpustat} is designed to be readily parseable by \texttt{nawk(1)} and \texttt{perl(1)}, thereby allowing performance tools to be composed by embedding \texttt{cpustat} in scripts. Alternatively, tools can be constructed directly using the same APIs that \texttt{cpustat} is built upon using the facilities of \texttt{libcpc(3LIB)}. See \texttt{cpc(3CPC)}. 
The `cpustat` utility only monitors the CPUs that are accessible to it in the current processor set. Thus, several instances of the utility can be running on the CPUs in different processor sets. See `psrset(1M)` for more information about processor sets.

Because `cpustat` uses LWPs bound to CPUs, the utility might have to be terminated before the configuration of the relevant processor can be changed.

### Examples

**SPARC**  
**EXAMPLE 1  Measuring External Cache References and Misses**

The following example measures misses and references in the external cache. These occur while the processor is operating in user mode on an UltraSPARC machine.

```
example% cpustat -c EC_ref,EC_misses 1 3
```

```
time cpu event  pic0  pic1
 1.008 0 tick 69284 1647
 1.008 1 tick 43284 1175
 2.008 0 tick 179576 1834
 2.008 1 tick 202022 12046
 3.008 0 tick 93262 384
 3.008 1 tick 63649 1118
 3.008 2 total 651077 18204
```

**EXAMPLE 2  Measuring Branch Prediction Success on Pentium 4**

The following example measures branch mispredictions and total branch instructions in user and system mode on a Pentium 4 machine.

```
example% cpustat -c \pic12=branch_retired,\emask12=0x4,\pic14=branch_retired,\emask14=0xf,\sys 1 3
```

```
time cpu event  pic12  pic14
 1.010 1 tick 458 684
 1.010 0 tick 305 511
 2.010 0 tick 181 269
 2.010 1 tick 469 684
 3.010 0 tick 182 269
 3.010 1 tick 468 684
 3.010 2 total 2063 3101
```

**EXAMPLE 3  Counting Memory Accesses on Opteron**

The following example determines the number of memory accesses made through each memory controller on an Opteron, broken down by internal memory latency:
EXAMPLE 3  Counting Memory Accesses on Opteron  (Continued)

    cpustat -c \
    pic0=NB_mem_ctrlr_page_access,umask0=0x01, \n    pic1=NB_mem_ctrlr_page_access,umask1=0x02, \n    pic2=NB_mem_ctrlr_page_access,umask2=0x04,sys  \
    1

    time  cpu event  pic0  pic1  pic2
    1.003  0  tick  41976  53519  7720
    1.003  1  tick  5589   19402  731
    2.003  1  tick  6011  17005  658
    2.003  0  tick  43944  45473  7338
    3.003  1  tick  7105  20177  762
    3.003  0  tick  47045  48025  7119
    4.003  0  tick  43224  46296  6694
    4.003  1  tick  5366  19114  652

Warnings  By running the cpustat command, the super-user forcibly invalidates all existing
performance counter context. This can in turn cause all invocations of the cputrack
command, and other users of performance counter context, to exit prematurely with
unspecified errors.

If cpustat is invoked on a system that has CPU performance counters which are not
supported by Solaris, the following message appears:

    cpustat: cannot access performance counters - Operation not applicable

This error message implies that cpc_open() has failed and is documented in
    cpc_open(3CPC). Review this documentation for more information about the problem and
possible solutions.

If a short interval is requested, cpustat might not be able to keep up with the desired sample
rate. In this case, some samples might be dropped.

Notes When `cpustat` is run on a Pentium 4 with HyperThreading enabled, a CPC set is bound to only one logical CPU of each physical CPU. See `cpc_bind_cpu(3CPC)`.
cron – clock daemon

/susr/sbin/cron

cron starts a process that executes commands at specified dates and times. You can specify regularly scheduled commands to cron according to instructions found in crontab files in the directory /var/spool/cron/crontabs. Users can submit their own crontab file using the crontab(1) command. Commands which are to be executed only once can be submitted using the at(1) command.

cron only examines crontab or at command files during its own process initialization phase and when the crontab or at command is run. This reduces the overhead of checking for new or changed files at regularly scheduled intervals.

As cron never exits, it should be executed only once. This is done routinely by way of the svc:/system/cron:default service. The file /etc/cron.d/FIFO file is used as a lock file to prevent the execution of more than one instance of cron.

cron captures the output of the job's stdout and stderr streams, and, if it is not empty, mails the output to the user. If the job does not produce output, no mail is sent to the user. An exception is if the job is an at(1) job and the -m option was specified when the job was submitted.

cron and at jobs are not executed if your account is locked. Jobs and processes execute. The shadow(4) file defines which accounts are not locked and will have their jobs and processes executed.

The timezone of the cron daemon sets the system-wide timezone for cron entries. This, in turn, is by set by default system-wide using /etc/default/init.

If some form of daylight savings or summer/winter time is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.

To keep a log of all actions taken by cron, you must specify CRONLOG=YES in the /etc/default/cron file. If you specify CRONLOG=NO, no logging is done. Keeping the log is a user configurable option since cron usually creates huge log files.

You can specify the PATH for user cron jobs by using PATH= in /etc/default/cron. You can set the PATH for root cron jobs using SUPATH= in /etc/default/cron. Carefully consider the security implications of setting PATH and SUPATH.

Example /etc/default/cron file:

CRONLOG=YES
PATH=/usr/bin:/usr/ucb:

This example enables logging and sets the default PATH used by non-root jobs to /usr/bin:/usr/ucb:. Root jobs continue to use /usr/sbin:/usr/bin.
The cron log file is periodically rotated by logadm(1M).

**Files**
- `/etc/cron.d` Main cron directory
- `/etc/cron.d/FIFO` Lock file
- `/etc/default/cron` cron default settings file
- `/var/cron/log` cron history information
- `/var/spool/cron` Spool area
- `/etc/cron.d/queuedefs` Queue description file for at, batch, and cron
- `/etc/logadm.conf` Configuration file for logadm

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also** svcs(1), at(1), crontab(1), sh(1), logadm(1M), svcadm(1M), queuedefs(4), shadow(4), attributes(5), rbac(5), smf(5), smf_security(5)

**Notes** The cron service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/cron:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command. Most administrative actions may be delegated to users with the solaris.smf.manage.cron authorization (see rbac(5) and smf_security(5)).

**Diagnostics** A history of all actions taken by cron is stored in /var/cron/log and possibly in /var/cron/olog.
**Name**
cryptoadm – cryptographic framework administration

**Synopsis**
cryptoadm list [-mpv] [provider=provider-name] [mechanism=mechanism-list]
cryptoadm disable  
   provider=provider-name mechanism=mechanism-list | random | all  
cryptoadm enable  
   provider=provider-name mechanism=mechanism-list | random | all  
cryptoadm install provider=provider-name  
cryptoadm install provider=provider-name [mechanism=mechanism-list]  
cryptoadm uninstall provider=provider-name  
cryptoadm unload provider=provider-name  
cryptoadm disable fips-140  
cryptoadm enable fips-140  
cryptoadm list fips-140  
cryptoadm refresh  
cryptoadm start  
cryptoadm stop  
cryptoadm --help

**Description**
The cryptoadm utility displays cryptographic provider information for a system, configures the mechanism policy for each provider, and installs or uninstalls a cryptographic provider. The cryptographic framework supports three types of providers: a user-level provider (a PKCS11 shared library), a kernel software provider (a loadable kernel software module), and a kernel hardware provider (a cryptographic hardware device).

For kernel software providers, the cryptoadm utility provides the unload subcommand. This subcommand instructs the kernel to unload a kernel software providers.

For the cryptographic framework's metaslot, the cryptoadm utility provides subcommands to enable and disable the metaslot's features, list metaslot's configuration, specify alternate persistent object storage, and configure the metaslot's mechanism policy.

The cryptoadm utility provides subcommands to enable and disable FIPS-140 mode in the Cryptographic Framework. It also provides a list subcommand to display the current status of FIPS-140 mode.

Administrators will find it useful to use syslog facilities (see syslogd(1M) and logadm(1M)) to maintain the cryptographic subsystem. Logging can be especially useful under the following circumstances:
If kernel-level daemon is dead, all applications fail. You can learn this from syslog and use `svcadm(1M)` to restart the svc:/system/cryptosvc service.

If there are bad providers plugged into the framework, you can learn this from syslog and remove the bad providers from the framework.

With the exception of the subcommands or options listed below, the `cryptoadm` command needs to be run by a privileged user.

- subcommand list, any options
- subcommand --help

**Options**

The `cryptoadm` utility has the various combinations of subcommands and options shown below.

`cryptoadm list`
Display the list of installed providers.

`cryptoadm list metaslot`
Display the system-wide configuration for metaslot.

`cryptoadm list -m [ provider=provider-name | metaslot ]`
Display a list of mechanisms that can be used with the installed providers or metaslot. If a provider is specified, display the name of the specified provider and the mechanism list that can be used with that provider. If the metaslot keyword is specified, display the list of mechanisms that can be used with metaslot.

`cryptoadm list -p [ provider=provider-name | metaslot ]`
Display the mechanism policy (that is, which mechanisms are available and which are not) for the installed providers. Also display the provider feature policy or metaslot. If a provider is specified, display the name of the provider with the mechanism policy enforced on it only. If the metaslot keyword is specified, display the mechanism policy enforced on the metaslot.

`cryptoadm list -v provider=provider-name | metaslot`
Display details about the specified provider if a provider is specified. If the metaslot keyword is specified, display details about the metaslot.

- `v`
  For the various `list` subcommands described above (except for `list -p`), the `-v` (verbose) option provides details about providers, mechanisms and slots.

`cryptoadm disable provider=provider-name [ mechanism=mechanism-list | provider-feature ... | all ]`
Disable the mechanisms or provider features specified for the provider. See OPERANDS for a description of `mechanism`, `provider-feature`, and the `all` keyword.

`cryptoadm [ mechanism=mechanism-list ] [ auto-key-migrate ]`
Disable the metaslot feature in the cryptographic framework or disable some of metaslot’s features. If no operand is specified, this command disables the metaslot feature in the
cryptoadm enable provider=provider-name
    [ mechanism=mechanism-list | provider-feature ... | all ]
    Enable the mechanisms or provider features specified for the provider. See OPERANDS for a description of mechanism, provider-feature, and the all keyword.

cryptoadm enable metaslot [ mechanism=mechanism-list ]
    [ [ token=token-label ] [ slot=slot-description ] ]
    default-keystore ] | [ auto-key-migrate ]
    If no operand is specified, this command enables the metaslot feature in the cryptographic framework. If a list of mechanisms is specified, it enables only the list of specified mechanisms for metaslot. If token-label is specified, the specified token will be used as the persistent object store. If the slot-description is specified, the specified slot will be used as the persistent object store. If both the token-label and the slot-description are specified, the provider with the matching token label and slot description is used as the persistent object store. If the default-keystore keyword is specified, metaslot will use the default persistent object store. If the auto-key-migrate keyword is specified, sensitive token objects will automatically migrate to other slots as needed to complete certain crypto operations. See OPERANDS for a description of mechanism, token, slot, default-keystore, and auto-key-migrate.

cryptoadm install provider=provider-name
    Install a user-level provider into the system. The provider operand must be an absolute pathname of the corresponding shared library. If there are both 32-bit and 64-bit versions for a library, this command should be run once only with the path name containing $ISA. Note that $ISA is not a reference to an environment variable. Note also that $ISA must be quoted (with single quotes [for example, ’$ISA’]) or the $ must be escaped to keep it from being incorrectly expanded by the shell. The user-level framework expands $ISA to an empty string or an architecture-specific directory, for example, sparcv9.

    The preferred way of installing a user-level provider is to build a package for the provider. For more information, see the Solaris Security for Developer’s Guide.

cryptoadm install provider=provider-name
    mechanism=mechanism-list
    Install a kernel software provider into the system. The provider should contain the base name only. The mechanism-list operand specifies the complete list of mechanisms to be supported by this provider.

    The preferred way of installing a kernel software provider is to build a package for providers. For more information, see the Solaris Security for Developer’s Guide.
cryptoadm uninstall provider=provider-name
  Uninstall the specified provider and the associated mechanism policy from the system. This subcommand applies only to a user-level provider or a kernel software provider.

cryptoadm unload provider=provider-name
  Unload the kernel software module specified by provider.

cryptoadm disable fips-140
  Disable FIPS-140 mode in the Cryptographic Framework and for hardware providers.

cryptoadm enable fips-140
  Enable FIPS-140 mode in the Cryptographic Framework and for hardware providers. This subcommand does not disable the non-FIPS approved algorithms from the user-level pkcs11_softtoken library and the kernel software providers. It is the consumers of the framework that are responsible for using only FIPS-approved algorithms.

  Upon completion of this subcommand, a message is issued to inform the administrator that any plugins added that are not within the boundary might invalidate FIPS compliance and to check the Security Policies for those plugins.

  The system will require a reboot to perform Power-Up Self Tests that include a cryptographic algorithm test and a software integrity test.

cryptoadm list fips-140
  Display the current setting of FIPS-140 mode in the Cryptographic Framework and for hardware providers. The status of FIPS-140 mode is enabled or disabled. The default FIPS-140 mode is disabled.

cryptoadm refresh
cryptoadm start
cryptoadm stop
  Private interfaces for use by smf(5), these must not be used directly.

cryptoadm -help
  Display the command usage.

Operands

provider=provider-name
  A user-level provider (a PKCS11 shared library), a kernel software provider (a loadable kernel software module), or a kernel hardware provider (a cryptographic hardware device).

  A valid value of the provider operand is one entry from the output of a command of the form: cryptoadm list. A provider operand for a user-level provider is an absolute pathname of the corresponding shared library. A provider operand for a kernel software provider contains a base name only. A provider operand for a kernel hardware provider is in a “name/number” form.
mechanism=mechanism-list
A comma separated list of one or more PKCS #11 mechanisms. A process for implementing a cryptographic operation as defined in PKCS #11 specification. You can substitute all for mechanism-list, to specify all mechanisms on a provider. See the discussion of the all keyword, below.

provider-feature
A cryptographic framework feature for the given provider. Currently only random is accepted as a feature. For a user-level provider, disabling the random feature makes the PKCS #11 routines C_GenerateRandom and C_SeedRandom unavailable from the provider. For a kernel provider, disabling the random feature prevents /dev/random from gathering random numbers from the provider.

all
The keyword all can be used with with the disable and enable subcommands to operate on all provider features.

token=token-label
The label of a token in one of the providers in the cryptographic framework.

A valid value of the token operand is an item displayed under “Token Label” from the output of the command cryptoadm list -v.

slot=slot-description
The description of a slot in one of the providers in the cryptographic framework.

A valid value of the slot operand is an item displayed under “Description” from the output of the command cryptoadm list -v.

default-keystore
The keyword default-keystore is valid only for metaslot. Specify this keyword to set the persistent object store for metaslot back to using the default store.

auto-key-migrate
The keyword auto-key-migrate is valid only for metaslot. Specify this keyword to configure whether metaslot is allowed to move sensitive token objects from the token object slot to other slots for performing cryptographic operations.

The keyword all can be used in two ways with the disable and enable subcommands:

- You can substitute all for mechanism=mechanism-list and any other provider-features, as in:

# cryptoadm enable provider=dca/0 all

This command enables the mechanisms on the provider and any other provider-features, such as random.

- You can also use all as an argument to mechanism, as in:

# cryptoadm enable provider=des mechanism=all
...which enables all mechanisms on the provider, but enables no other provider–features, such as random.

**Examples**

**EXAMPLE 1** Display List of Providers Installed in System

The following command displays a list of all installed providers:

```
example% cryptoadm list
user-level providers:
/usr/lib/security/$ISA/pkcs11_kernel.so
/usr/lib/security/$ISA/pkcs11_softtoken.so
/opt/lib/libcryptoki.so.1
/opt/SUNWconn/lib/$ISA/libpkcs11.so.1

kernel software providers:
  des
  aes
  bfish
  sha1
  md5

kernel hardware providers:
  dca/0
```

**EXAMPLE 2** Display Mechanism List for md5 Provider

The following command is a variation of the list subcommand:

```
example% cryptoadm list -m provider=md5
md5: CKM_MD5,CKM_MD5_HMAC,CKM_MD5_HMAC_GENERAL
```

**EXAMPLE 3** Disable Specific Mechanisms for Kernel Software Provider

The following command disables mechanisms CKM_DES3_ECB and CKM_DES3_CBC for the kernel software provider des:

```
example# cryptoadm disable provider=des
```

**EXAMPLE 4** Display Mechanism Policy for a Provider

The following command displays the mechanism policy for the des provider:

```
example% cryptoadm list -p provider=des
des: All mechanisms are enabled, except CKM_DES3_ECB, CKM_DES3_CBC
```

**EXAMPLE 5** Enable Specific Mechanism for a Provider

The following command enables the CKM_DES3_ECB mechanism for the kernel software provider des:

```
example# cryptoadm enable provider=des mechanism=CKM_DES3_ECB
```
EXAMPLE 6  Install User-Level Provider
The following command installs a user-level provider:
example# cryptoadm install provider=/opt/lib/libcryptoki.so.1

EXAMPLE 7  Install User-Level Provider That Contains 32- and 64-bit Versions
The following command installs a user-level provider that contains both 32-bit and 64-bit versions:
example# cryptoadm install \
provider=/opt/SUNWconn/lib/'$ISA'/libpkcs11.so.1

EXAMPLE 8  Uninstall a Provider
The following command uninstalls the md5 provider:
example# cryptoadm uninstall provider=md5

EXAMPLE 9  Disable metaslot
The following command disables the metaslot feature in the cryptographic framework.
example# cryptoadm disable metaslot

EXAMPLE 10  Specify metaslot to Use Specified Token as Persistent Object Store
The following command specifies that metaslot use the Venus token as the persistent object store.
ex
example# cryptoadm enable metaslot token="SUNW,venus"

Exit Status  The following exit values are returned:
0        Successful completion.
>0       An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcs</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The start, stop, and refresh options are Private interfaces. All other options and the utility name are Committed.
If a hardware provider's policy was made explicitly (that is, some of its mechanisms were disabled) and the hardware provider has been detached, the policy of this hardware provider is still listed.

cryptoadm assumes that, minimally, a 32–bit shared object is delivered for each user-level provider. If both a 32–bit and 64–bit shared object are delivered, the two versions must provide the same functionality. The same mechanism policy applies to both.
The virtual console daemon, cvcd, is a server process that supports the network console provided on some platforms. The cvcd daemon accepts network console connections from a remote host (only one host at any given time). Console input is read from this connection and forwarded to cvc(7D) by way of cvcredir(7D).

Similarly, console output is read from cvcredir(7D) and forwarded across the network console connection. If cvcd dies, console traffic is automatically rerouted through an internal hardware interface.

The cvcd daemon normally starts at system boot time. Each domain supports only one cvcd process at a time.

**Caution** – On Sun Enterprise 10000 domains, cvcd uses a configuration file (/etc/ssphostname) to determine the name of the host from which network console connections are allowed. If the remote console host is renamed, you must edit the configuration file to reflect that change.

The cvcd daemon supports per-socket IP Security Architecture (IPsec) through the options described below. See ipsec(7P).

**Options**

The cvcd daemon supports the options listed below.

- `-a auth` Controls the IPsec Authentication Header (AH) algorithm. `auth` can be one of `none`, `md5`, or `sha1`.
- `-e encr` Controls the IPsec Encapsulating Security Payload (ESP) encryption algorithm. `encr` can be one of `none`, `des`, or `3des`.
- `-u esp_auth` Controls the IPsec Encapsulating Security Payload (ESP) authentication algorithm. `esp_auth` can be one of `none`, `md5`, or `sha1`.

**Operands**

The following operands are supported:

- `platform_name` The official Sun platform name used in packaging and code. For example, for Sun Fire 15K servers, the `platform_name` would be `SUNW,Sun-Fire-15000`.

**Examples**

**EXAMPLE 1** Setting an IPsec Option

The command below sets the value of the IPsec Authentication Header algorithm to `md5`. As a result of this command, cvcd will use the HMAC-MD5 authentication algorithm.

```bash
# svccfg -s svc:/system/cvc setprop cvc/ah_auth = "md5"
# svccfg -s svc:/system/cvc setprop cvc/esp_encr = "none"
# svccfg -s svc:/system/cvc setprop cvc/esp_auth = "none"
```
EXAMPLE 1 Setting an IPSec Option (Continued)

# svcadm refresh svc:/system/cvc

Sun Enterprise 10000 SSP Reference Manual
System Management Services (SMS) Reference Manual

Notes The cvcd service is managed by the service management facility, smf(5), under the fault management resource identifier (FMRI):

svc:/system/cvc

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M) or svccfg(1M). The service's status can be queried using the svcs(1) command.
The `datadm` utility maintains the DAT static registry file, `dat.conf`.

This administrative configuration program allows uDAPL service providers to add and remove themselves to the `dat.conf` file.

You can add or remove interface adapters that a service provider supports from a system after its installation. You can use `datadm` to update the `dat.conf` file to reflect the current state of the system. A new set of interface adapters for all the service providers currently installed is regenerated.

The following options are supported:

- `-a service_provider.conf` Enumerate each device entry in the `service_provider.conf` file into a list of interface adapters, that is, interfaces to external network that are available to uDAPL consumers.

- `-r service_provider.conf` Remove the list of interface adapters that corresponds to the device entry in the `service_provider.conf` file.

- `-u` Update the `dat.conf` to reflect the current state of the system with an up to date set of interface adapters for the service providers that are currently listed in the DAT static registry.

- `-v` Display the DAT static registry file, `dat.conf`.

**Examples**

**EXAMPLE 1** Enumerating a Device Entry

The following example enumerates a device entry in the `service_provider.conf` file into interface adapters in the `dat.conf` file.

Assume that SUNW has a service provider library that supports the device `tavor`. It has a `service_provider.conf` file installed in the directory `/usr/share/dat/SUNWudaplt.conf` with a single entry as follows:

```
driver_name=tavor u1.2 nonthreadsafe default\
   udapl_tavor.so.1 SUNW.1.0 ""
```

tavor is an Infiniband Host Channel Adapter with two ports. Both IB ports exist in a single IB partition, 0x8001. If an IP interface is plumbed to each port, there are two IPoIB device instances, ibd0 and ibd1:

```
# ls -l /dev/ibd*
/dev/ibd0 -> /devices/pci@1/pci15b3,5a44@0/ibport@1,8001,ipib:ibd0
/dev/ibd1 -> /devices/pci@1/pci15b3,5a44@0/ibport@2,8001,ipib:ibd1
```
EXAMPLE 1  Enumerating a Device Entry  (Continued)

Running the command, datadm -a /usr/share/dat/SUNWudaplt.conf appends two new entries (if they do not already exist) in the /etc/dat/dat.conf file:

ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 "" "driver_name=tavor"
ibd1 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 "" "driver_name=tavor"

EXAMPLE 2  Updating the dat.conf to Reflect the Current State of the System

A new IB partition, 0x8002 is added to the above example covering port 1 of the Host Channel Adapter. If a new IP interface is plumbed to port 1/partition 0x8002, there is a third IPoIB device instance: ibd2.

# ls -l /dev/ibd*
/dev/ibd0 -> /devices/pci@1/pci15b3,5a44@0/ibport@1,8001,ipib:ibd0
/dev/ibd1 -> /devices/pci@1/pci15b3,5a44@0/ibport@2,8001,ipib:ibd1
/dev/ibd2 -> /devices/pci@1/pci15b3,5a44@0/ibport@1,8002,ipib:ibd2

Running datadm -u command, updates the /etc/dat/dat.conf file with a new entry added reflecting the current state of the system.

datadm -v shows that there are now three entries in the /etc/dat/dat.conf file:

ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 "" "driver_name=tavor"
ibd1 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 "" "driver_name=tavor"
ibd2 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 "" "driver_name=tavor"

Files  /etc/dat/dat.conf   DAT static registry file

The Domain Configuration Server (DCS) is a daemon process that runs on Sun servers that support remote Dynamic Reconfiguration (DR) clients. It is started by the Service Management Facility (see smf(5)) when the first DR request is received from a client connecting to the network service sun-dr. After the DCS accepts a DR request, it uses the libcfgadm(3LIB) interface to execute the DR operation. After the operation is performed, the results are returned to the client.

The DCS listens on the network service labeled sun-dr. Its underlying protocol is TCP. It is invoked as a server program by the SMF using the TCP transport. The fault management resource identifier (FMRI) for DCS is:

svc:/platform/sun4u/dcs:default

If you disable this service, DR operations initiated from a remote host fail. There is no negative impact on the server.

Security for the DCS connection is provided differently based upon the architecture of the system. The SMF specifies the correct options when invoking the DCS daemon, based upon the current architecture. For all architectures, security is provided on a per-connection basis.

The DCS daemon has no security options that are applicable when used on a Sun Enterprise 10000 system. So there are no options applicable to that architecture.

The security options for Sun Fire high-end systems are based on IPsec options defined as SMF properties. These options include the -a auth, -e encr, and -u esp_auth options, and can be set using the svccfg(1M) command. These options must match the IPsec policies defined for DCS on the system controller. Refer to the kmd(1M) man page in the System Management Services (SMS) Reference Manual. The kmd(1M) man page is not part of the SunOS man page collection.

Security on SPARC Enterprise Servers is not configurable. The DCS daemon uses a platform-specific library to configure its security options when running on such systems. The -l option is provided by the SMF when invoking the DCS daemon on SPARC Enterprise Servers. No other security options to the DCS daemon should be used on SPARC Enterprise Servers.

Options

The following options are supported:

- **-a auth** Controls the IPsec Authentication Header (AH) algorithm. auth can be one of none, md5, or sha1.
- **-e encr** Controls the IPsec Encapsulating Security Payload (ESP) encryption algorithm. encr can be one of none, des, or 3des.
-l Enables the use of platform-specific security options on SPARC Enterprise Servers.

-s sessions Sets the number of active sessions that the DCS allows at any one time. When the limit is reached, the DCS stops accepting connections until active sessions complete the execution of their DR operation. If this option is not specified, a default value of 128 is used.

-u esp_auth Controls the IPsec Encapsulating Security Payload (ESP) authentication algorithm. esp_auth can be one of none, md5, or sha1.

Examples

**EXAMPLE 1 Setting an IPSec Option**

The following command sets the Authentication Header algorithm for the DCS daemon to use the HMAC-MD5 authentication algorithm. These settings are only applicable for using the DCS daemon on a Sun Fire high-end system.

```
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/ah_auth = "md5"
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/esp_encr = "none"
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/esp_auth = "none"
# svcadm refresh svc:/platform/sun4u/dcs
```

Errors The DCS uses *syslog*(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all of the DCS error messages to the /var/adm/messages log.

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdcsu, SUNWdcsr</td>
</tr>
<tr>

<td>Evolving</td>
</tr>
</tbody>
</table>

Notes The dcs service is managed by the service management facility, *smf*(5), under the fault management resource identifier (FMRI):

```
svc:/platform/sun4u/dcs:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using *svcadm*(1M). The service's status can be queried using the *svcs*(1) command.
**Name**

`dd` – convert and copy a file

**Synopsis**

```
/usr/bin/dd [operand=value]...
```

**Description**

The `dd` utility copies the specified input file to the specified output with possible conversions. The standard input and output are used by default. The input and output block sizes may be specified to take advantage of raw physical I/O. Sizes are specified in bytes; a number may end with k, b, or w to specify multiplication by 1024, 512, or 2, respectively. Numbers may also be separated by x to indicate multiplication.

The `dd` utility reads the input one block at a time, using the specified input block size. `dd` then processes the block of data actually returned, which could be smaller than the requested block size. `dd` applies any conversions that have been specified and writes the resulting data to the output in blocks of the specified output block size.

`cbs` is used only if `ascii`, `asciib`, `unblock`, `ebcdic`, `ebcdicb`, `ibm`, `ibmb`, or `block` conversion is specified. In the first two cases, `cbs` characters are copied into the conversion buffer, any specified character mapping is done, trailing blanks are trimmed, and a `NEWLINE` is added before sending the line to output. In the last three cases, characters up to `NEWLINE` are read into the conversion buffer and blanks are added to make up an output record of size `cbs`. ASCII files are presumed to contain `NEWLINE` characters. If `cbs` is unspecified or 0, the `ascii`, `asciib`, `ebcdic`, `ebcdicb`, `ibm`, and `ibmb` options convert the character set without changing the input file's block structure. The `unblock` and `block` options become a simple file copy.

After completion, `dd` reports the number of whole and partial input and output blocks.

**Operands**

The following operands are supported:

- `if=file`
  Specifies the input path. Standard input is the default.

- `of=file`
  Specifies the output path. Standard output is the default. If the `seek=expr` conversion is not also specified, the output file will be truncated before the copy begins, unless `conv=notrunc` is specified. If `seek=expr` is specified, but `conv=notrunc` is not, the effect of the copy will be to preserve the blocks in the output file over which `dd` seeks, but no other portion of the output file will be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file is shortened by the copy.)

- `ibs=n`
  Specifies the input block size in `n` bytes (default is 512).

- `obs=n`
  Specifies the output block size in `n` bytes (default is 512).

- `bs=n`
  Sets both input and output block sizes to `n` bytes, superseding `ibs` and `obs`. If no conversion other than `sync`, `noerror`, and `notrunc` is specified, each input block is copied to the output as a single block without aggregating short blocks.
cbs=n  Specifies the conversion block size for block and unblock in bytes by n (default is 0). If cbs= is omitted or given a value of 0, using block or unblock produces unspecified results.

This option is used only if ASCII or EBCDIC conversion is specified. For the ascii and asciiib operands, the input is handled as described for the unblock operand except that characters are converted to ASCII before the trailing SPACE characters are deleted. For the ebc dic, ebc dicb, ibm, and ibmb operands, the input is handled as described for the block operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing SPACE characters are added.

files=n  Copies and concatenates n input files before terminating (makes sense only where input is a magnetic tape or similar device).

skip=n  Skips n input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation reads the blocks or seeks past them. On non- seekable files, the blocks are read and the data is discarded.

iseek=n  Seeks n blocks from beginning of input file before copying (appropriate for disk files, where skip can be incredibly slow).

oseek=n  Seeks n blocks from beginning of output file before copying.

seek=n  Skips n blocks (using the specified output block size) from beginning of output file before copying. On non-seekable files, existing blocks are read and space from the current end-of-file to the specified offset, if any, is filled with null bytes. On seekable files, the implementation seeks to the specified offset or reads the blocks as described for non-seekable files.

count=n  Copies only n input blocks.

conv=value[, value...]  Where values are comma-separated symbols from the following list:

ascii  Converts EBCDIC to ASCII.

asciiib  Converts EBCDIC to ASCII using BSD-compatible character translations.

ebc dic  Converts ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINES, sets up a pipeline with dd conv=unblock beforehand.

ebc dicb  Converts ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length
ASCII records without NEWLINES, sets up a pipeline with dd conv=unblock beforehand.

ibm Slightly different map of ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINES, sets up a pipeline with dd conv=unblock beforehand.

ibmb Slightly different map of ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length ASCII records without NEWLINES, sets up a pipeline with dd conv=unblock beforehand.

The ascii (or asciiib), ebcdic (or ebcdicb), and ibm (or ibmb) values are mutually exclusive.

block Treats the input as a sequence of NEWLINE-terminated or EOF-terminated variable-length records independent of the input block boundaries. Each record is converted to a record with a fixed length specified by the conversion block size. Any NEWLINE character is removed from the input line. SPACE characters are appended to lines that are shorter than their conversion block size to fill the block. Lines that are longer than the conversion block size are truncated to the largest number of characters that will fit into that size. The number of truncated lines is reported.

unblock Converts fixed-length records to variable length. Reads a number of bytes equal to the conversion block size (or the number of bytes remaining in the input, if less than the conversion block size), delete all trailing SPACE characters, and append a NEWLINE character.

The block and unblock values are mutually exclusive.

case Maps upper-case characters specified by the LC_CTYPE keyword tolower to the corresponding lower-case character. Characters for which no mapping is specified are not modified by this conversion.

ucase Maps lower-case characters specified by the LC_CTYPE keyword toupper to the corresponding upper-case character. Characters for which no mapping is specified are not modified by this conversion.
The `lcase` and `ucase` symbols are mutually exclusive.

**swab**  
Swaps every pair of input bytes. If the current input record is an odd number of bytes, the last byte in the input record is ignored.

**noerror**  
Does not stop processing on an input error. When an input error occurs, a diagnostic message is written on standard error, followed by the current input and output block counts in the same format as used at completion. If the `sync` conversion is specified, the missing input is replaced with null bytes and processed normally. Otherwise, the input block will be omitted from the output.

**notrunc**  
Does not truncate the output file. Preserves blocks in the output file not explicitly written by this invocation of `dd`. (See also the preceding `of=file` operand.)

**sync**  
Pads every input block to the size of the `ibs=` buffer, appending null bytes. (If either `block` or `unblock` is also specified, appends SPACE characters, rather than null bytes.)

If operands other than `conv=` are specified more than once, the last specified `operand=value` is used.

For the `bs=`, `cbs=`, `ibs=`, and `obs=` operands, the application must supply an expression specifying a size in bytes. The expression, `expr`, can be:

1. a positive decimal number
2. a positive decimal number followed by `k`, specifying multiplication by 1024
3. a positive decimal number followed by `b`, specifying multiplication by 512
4. two or more positive decimal numbers (with or without `k` or `b`) separated by `x`, specifying the product of the indicated values.

All of the operands will be processed before any input is read.

**Usage**  
See `largefile(5)` for the description of the behavior of `dd` when encountering files greater than or equal to 2 Gbyte (\(2^{31}\) bytes).

**Examples**  

**EXAMPLE 1  Copying from one tape drive to another**

The following example copies from tape drive 0 to tape drive 1, using a common historical device naming convention.
Copying from one tape drive to another  (Continued)

example% dd if=/dev/rmt/0h of=/dev/rmt/1h

Stripping the first 10 bytes from standard input

The following example strips the first 10 bytes from standard input:

example% dd ibs=10 skip=1

Reading a tape into an ASCII file

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into
the ASCII file x:

example% dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcase

Using conv=sync to write to tape

The following example uses conv=sync when writing to a tape:

example% tar cvf - . | compress | dd obs=1024k of=/dev/rmt/0 conv=sync

See environ(5) for descriptions of the following environment variables that affect
the execution of dd: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

The following exit values are returned:

0   The input file was copied successfully.

>0   An error occurred.

If an input error is detected and the noerror conversion has not been specified, any partial
output block will be written to the output file, a diagnostic message will be written, and the
copy operation will be discontinued. If some other error is detected, a diagnostic message will
be written and the copy operation will be discontinued.

</tr>
</tbody>
</table>

See Also  cp(1), sed(1), tr(1), attributes(5), environ(5), largefile(5), standards(5)

Diagnostics  f+p records in(out) numbers of full and partial blocks read(written)
**Notes**  Do not use `dd` to copy files between file systems having different block sizes.

Using a blocked device to copy a file will result in extra nulls being added to the file to pad the final block to the block boundary.

When `dd` reads from a pipe, using the `ibs=X` and `obs=Y` operands, the output will always be blocked in chunks of size `Y`. When `bs=Z` is used, the output blocks will be whatever was available to be read from the pipe at the time.

When using `dd` to copy files to a tape device, the file size must be a multiple of the device sector size (for example, 512 Kbyte). To copy files of arbitrary size to a tape device, use `tar(1)` or `cpio(1)`.

For `SIGINT`, `dd` writes status information to standard error before exiting. It takes the standard action for all other signals.
Name  devattr – display device attributes

Synopsis  devattr [-v] device [attribute]...

Description  devattr displays the values for a device’s attributes. The display can be presented in two formats. Used without the -v option, only the attribute values are shown. Used with the -v option, the attributes are shown in an attribute=value format. When no attributes are given on the command line, all attributes for the specified device are displayed in alphabetical order by attribute name. If attributes are given on the command line, only those attributes are shown, displayed in command line order.

Options  The following options are supported:
- v  Specifies verbose format. Attribute values are displayed in an attribute=value format.

Operands  The following operands are supported:
attribute  Defines which attribute, or attributes, should be shown. Default is to show all attributes for a device. See the putdev(1M) manual page for a complete listing and description of available attributes.

device  Defines the device whose attributes should be displayed. Can be the pathname of the device or the device alias.

Exit Status  The following exit values are returned:
0  successful completion.
1  Command syntax was incorrect, invalid option was used, or an internal error occurred.
2  Device table could not be opened for reading.
3  Requested device could not be found in the device table.
4  Requested attribute was not defined for the specified device.

Name      devfree — release devices from exclusive use

Synopsis  devfree  key  [device]...

Description  devfree releases devices from exclusive use. Exclusive use is requested with the command devreserv.

When devfree is invoked with only the key argument, it releases all devices that have been reserved for that key. When called with key and device arguments, devfree releases the specified devices that have been reserved with that key.

Operands  The following operands are supported:

device   Defines device that this command will release from exclusive use. device can be the pathname of the device or the device alias.

key      Designates the unique key on which the device was reserved.

Exit Status  The following exit values are returned:

0       Successful completion.
1       Command syntax was incorrect, an invalid option was used, or an internal error occurred.
2       Device table or device reservation table could not be opened for reading.
3       Reservation release could not be completely fulfilled because one or more of the devices was not reserved or was not reserved on the specified key.

Files  /etc/device.tab

/etc/devlkfile

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  devreserv(1M), attributes(5)

Notes  The commands devreserv and devfree are used to manage the availability of devices on a system. These commands do not place any constraints on the access to the device. They serve only as a centralized bookkeeping point for those who wish to use them. Processes that do not use devreserv may concurrently use a device with a process that has reserved that device.
devfsadm(1M) maintains the /dev namespace. It replaces the previous suite of devfs administration tools including drvconfig(1M), disks(1M), tapes(1M), ports(1M), audlinks(1M), and devlinks(1M).

The default operation is to attempt to load every driver in the system and attach to all possible device instances. Next, devfsadm creates logical links to device nodes in /dev and /devices and loads the device policy.

devfsadmd(1M) is the daemon version of devfsadm(1M). The daemon is started during system startup and is responsible for handling both reconfiguration boot processing and updating /dev and /devices in response to dynamic reconfiguration event notifications from the kernel.

For compatibility purposes, drvconfig(1M), disks(1M), tapes(1M), ports(1M), audlinks(1M), and devlinks(1M) are implemented as links to devfsadm.

In addition to managing /dev, devfsadm also maintains the path_to_inst(4) database.

Options

The following options are supported:

- **-C** Cleanup mode. Prompt devfsadm to cleanup dangling /dev links that are not normally removed. If the -c option is also used, devfsadm only cleans up for the listed devices' classes.

- **-c device_class** Restrict operations to devices of class device_class. Solaris defines the following values for device_class: disk, tape, port, audio, and pseudo. This option might be specified more than once to specify multiple device classes.

- **-d driver_name** Configure only the devices for the named driver, driver_name.

- **-n** Do not attempt to load drivers or add new nodes to the kernel device tree.

- **-s** Suppress any changes to /dev. This is useful with the -v option for debugging.

- **-t table_file** Read an alternate devlink.tab file. devfsadm normally reads /etc/devlink.tab.

- **-r root_dir** Presume that the /dev directory trees are found under root_dir, not directly under root(/). No other use or assumptions are made about root_dir.

- **-v** Print changes to /dev in verbose mode.
Exit Status  The following exit values are returned:

0   Successful completion.
1   An error occurred.

Notes  This document does not constitute an API. The /devices directory might not exist or might have different contents or interpretations in a future release. The existence of this notice does not imply that any other documentation that lacks this notice constitutes an API.

devfsadm no longer manages the /devices name space. See devfs(7FS).

The device configuration service is managed by the service management facility, smf(5), under the service identifier, and can be used to start devfsadm during reconfiguration boot by:

svc:/system/device/local:default

Otherwise, devfsadm is started by:

svc:/system/sysevent:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
device_remap(1M)

**Name**

device_remap – administer the Solaris I/O remapping feature

**Synopsis**

```
/usr/platform/sun4v/sbin/device_remap [-v | -R dir]
```

**Description**

Certain multi-node sun4v platforms, such as T5440 and T5240 servers, have an integrated PCI topology that cause the I/O device paths to change in a CPU node failover condition. The device remapping script, `device_remap`, remaps the device paths in `/etc/path_to_inst` file and the symlinks under `/dev` to match the hardware.

**Options**

The following options are supported:

- `-v`
  - Displays the `/etc/path_to_inst` and `/dev` symlink changes.

- `-R dir`
  - Perform remapping on the `/etc/path_to_inst` and `/etc/path_to_inst` files in the root image at `dir`.

**Usage**

The primary function of `device_remap` is to remap the device paths in the `/etc/path_to_inst` file and the symlinks under `/dev` in a CPU node failover condition to match the hardware.

After adding CPU node(s) or removing CPU node(s), boot the system to the OBP prompt and use the following procedure:

1. Boot either the failsafe miniroot using: `boot -F failsafe`, or an install miniroot using `boot net -s` or similar command.
2. Mount the root disk as `/mnt`.
3. Change directory to the mounted root disk:
   ```
   # cd /mnt
   ```
4. Run `device_remap` script:
   ```
   # /mnt/usr/platform/sun4v/sbin/device_remap
   ```
5. Boot the system from disk.

All the error messages are self-explanatory, except for the error message “missing ioaliases node” which means the firmware on the system does not support device remapping.

**Examples**

**Example 1**

Displaying Changes Following Failover

The following command displays the path_to_inst and /dev changes following a CPU node failover.

```
# device_remap -v
```
EXAMPLE 2  Changing Directory Prior to Any Changes

The following command changes the directory on which the boot image is mounted prior to
making any changes.

```
# device_remap -R /newroot
```

devinfo (1M)

Name  devinfo – print device specific information

Synopsis  /usr/sbin/devinfo -i device
           /usr/sbin/devinfo -p device

Description  The devinfo command is used to print device specific information about disk devices on
              standard out. The command can only be used by the superuser.

Options  -i  Prints the following device information:
             ■ Device name
             ■ Software version (not supported and prints as 0)
             ■ Drive id number (not supported and prints as 0)
             ■ Device blocks per cylinder
             ■ Device bytes per block
             ■ Number of device partitions with a block size greater than zero

-p  Prints the following device partition information:
             ■ Device name
             ■ Device major and minor numbers (in hexadecimal)
             ■ Partition start block
             ■ Number of blocks allocated to the partition
             ■ Partition flag
             ■ Partition tag

This command is used by various other commands to obtain device specific information for
the making of file systems and determining partition information. If the device cannot be
opened, an error message is reported.

Operands  device  Device name.

Exit Status  0  Successful operation.
2  Operation failed.

Name  devlinks – adds /dev entries for miscellaneous devices and pseudo-devices

Synopsis  /usr/sbin/devlinks [-d] [-r rootdir] [-t table-file]

Description  devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of devlinks.

devlinks creates symbolic links from the /dev directory tree to the actual block- and character-special device nodes under the /devices directory tree. The links are created according to specifications found in the table-file (by default /etc/devlink.tab).

devlinks is called each time the system is reconfiguration-booted, and can only be run after drvconfig(1M) is run.

The table-file (normally /etc/devlink.tab) is an ASCII file, with one line per record. Comment lines, which must contain a hash character ('#') as their first character, are allowed. Each entry must contain at least two fields, but may contain three fields. Fields are separated by single TAB characters.

The fields are:

devfs-spec  Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.

The possible keywords are:

type  The devinfo device type. Possible values are specified in ddi_create_minor_node(9F)

name  The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':.' character.

addr[n]  The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':.' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the addr it specifies a match of a particular comma-separated subfield of the address field: addr1 matches the first subfield, addr2 matches the second, and so on. addr0 is the same as addr and matches the whole field.

minor[n]  The minor portion of a node name – the portion of the name after the ':.'. As with addr above, a number after the minor keyword specifies a subfield to match.
Of these four specifications, only the type specification must always be present.

**name**

Specification of the /dev links that correspond to the devinfo nodes. This field allows devlinks to determine matching /dev names for the /devices nodes it has found. The specification of this field uses escape-sequences to allow portions of the /devices name to be included in the /dev name, or to allow a counter to be used in creating node names. If a counter is used to create a name, the portion of the name before the counter must be specified absolutely, and all names in the /dev/-subdirectory that match (up to and including the counter) are considered to be subdevices of the same device. This means that they should all point to the same directory, name and address under the /devices/-tree.

The possible escape-sequences are:

- **\D** Substitute the device-name (name) portion of the corresponding devinfo node-name.
- **\An** Substitute the \(n\)th component of the address component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole address component.
- **\Mn** Substitute the \(n\)th sub-component of the minor component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole minor component.
- **\Nn** Substitute the value of a `counter` starting at \(n\). There can be only one counter for each dev-spec, and counter-values will be selected so they are as low as possible while not colliding with already-existing link names.

In a dev-spec the counter sequence should not be followed by a digit, either explicitly or as a result of another escape-sequence expansion. If this occurs, it would not be possible to correctly match already-existing links to their counter entries, since it would not be possible to unambiguously parse the already-existing /dev-name.

**extra-dev-link**

Optional specification of an extra /dev link that points to the initial /dev link (specified in field 2). This field may contain a counter escape-sequence (as described for the dev-spec field) but may not contain any of the other escape-sequences. It provides a way to specify an alias of a particular /dev name.
Options

The following options are supported:

- **d**
  Debugging mode – print out all devinfo nodes found, and indicate what links would be created, but do not do anything.

- **r rootdir**
  Use rootdir as the root of the /dev and /devices directories under which the device nodes and links are created. Changing the root directory does not change the location of the /etc/devlink.tab default table, nor is the root directory applied to the filename supplied to the -t option.

- **t table-file**
  Set the table file used by devlinks to specify the links that must be created. If this option is not given, /etc/devlink.tab is used. This option gives a way to instruct devlinks just to perform a particular piece of work, since just the links-types that devlinks is supposed to create can be specified in a command-file and fed to devlinks.

Errors

If devlinks finds an error in a line of the table-file it prints a warning message on its standard output and goes on to the next line in the table-file without performing any of the actions specified by the erroneous rule.

If it cannot create a link for some filesystem-related reason it prints an error-message and continues with the current rule.

If it cannot read necessary data it prints an error message and continues with the next table-file line.

Examples

**EXAMPLE 1** Using the /etc/devlink.tab Fields

The following are examples of the /etc/devlink.tab fields:

```
type=pseudo;name=win  win\M0
```
```
type=ddi_display  framebuffer/\M0  fb\N0
```

The first example states that all devices of type pseudo with a name component of win will be linked to /dev/win\x, where x is the minor component of the devinfo-name (this is always a single-digit number for the win driver).

The second example states that all devinfo nodes of type ddi_display will be linked to entries under the /dev/framebuffer directory, with names identical to the entire minor component of the /devices name. In addition an extra link will be created pointing from /dev/fbn to the entry under /dev/framebuffer. This entry will use a counter to end the name.

Files

- **/dev**
  entries for the miscellaneous devices for general use

Bugs  It is very easy to construct mutually-contradictory link specifications, or specifications that can never be matched. The program does not check for these conditions.
Name  devnm – device name

Synopsis  
/usr/sbin/devnm name [name]...

Description  The devnm command identifies the special file associated with the mounted file system where the argument name resides. One or more name can be specified.

Examples  

EXAMPLE 1  Using the devnm Command

Assuming that /usr is mounted on /dev/dsk/c0t3d0s6, the following command:

/usr/sbin/devnm /usr

produces:

/dev/dsk/c0t3d0s6 /usr

Files  
/dev/dsk/*
/etc/mnttab

**Name**  
devreserv – reserve devices for exclusive use

**Synopsis**  
devreserv [key [device-list]...]

**Description**  
devreserv reserves devices for exclusive use. When the device is no longer required, use devfree to release it.

devreserv reserves at most one device per device-list. Each list is searched in linear order until the first available device is found. If a device cannot be reserved from each list, the entire reservation fails.

When devreserv is invoked without arguments, it lists the devices that are currently reserved and shows to which key it was reserved. When devreserv is invoked with only the key argument, it lists the devices that are currently reserved to that key.

**Operands**  
The following operands are supported:

device-list  Defines a list of devices that devreserv will search to find an available device.
The list must be formatted as a single argument to the shell.

key  Designates a unique key on which the device will be reserved. The key must be a positive integer.

**Examples**  
**EXAMPLE 1**  Reserving a Floppy Disk and a Cartridge Tape

The following example reserves a floppy disk and a cartridge tape:

$ key=$$
$ echo "The current Process ID is equal to: $key"
    The Current Process ID is equal to: 10658
$ devreserv $key diskette1 ctape1

**EXAMPLE 2**  Listing All Devices Currently Reserved

The following example lists all devices currently reserved:

$ devreserv
    disk1   2423
    diskette1  10658
    ctape1   10658

**EXAMPLE 3**  Listing All Devices Currently Reserved to a Particular Key

The following example lists all devices currently reserved to a particular key:

$ devreserv $key
    diskette1
    ctape1
Exit Status  The following exit values are returned:

0   Successful completion.
1   Command syntax was incorrect, an invalid option used, or an internal error occurred.
2   Device table or device reservation table could not be opened for reading.
3   Device reservation request could not be fulfilled.

Files  /etc/device.tab
       /etc/devlkfile

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  devfree(1M), attributes(5)

Notes  The commands devreserv and devfree are used to manage the availability of devices on a system. Their use is on a participatory basis and they do not place any constraints on the actual access to the device. They serve as a centralized bookkeeping point for those who wish to use them. Devices which have been reserved cannot be used by processes which utilize the device reservation functions until the reservation has been canceled. However, processes that do not use device reservation may use a device that has been reserved since such a process would not have checked for its reservation status.
**df** utility displays the amount of disk space occupied by mounted or unmounted file systems, the amount of used and available space, and how much of the file system's total capacity has been used. The file system is specified by device, or by referring to a file or directory on the specified file system.

Used without operands or options, df reports on all mounted file systems.

df may not be supported for all FSTypes.

If df is run on a networked mount point that the automounter has not yet mounted, the file system size will be reported as zero. As soon as the automounter mounts the file system, the sizes will be reported correctly.

**Options**

The following options are supported for both /usr/bin/df and /usr/xpg4/bin/df:

- `-a`
  
  Reports on all file systems including ones whose entries in /etc/mnttab (see mnttab(4)) have the ignore option set.

- `-b`
  
  Prints the total number of kilobytes free.

- `-e`
  
  Prints only the number of files free.

- `-F FSType`
  
  Specifies the FSType on which to operate. The `-F` option is intended for use with unmounted file systems. The FSType should be specified here or be determinable from /etc/vfstab (see vfstab(4)) by matching the directory, block_device, or resource with an entry in the table, or by consulting /etc/default/fs. See default_fs(4).

- `-g`
  
  Prints the entire statvfs(2) structure. This option is used only for mounted file systems. It can not be used with the `-o` option. This option overrides the `-b`, `-e`, `-k`, `-n`, `-P`, and `-t` options.

- `-h`
  
  Like `-k`, except that sizes are in a more human readable format. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing
files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.

This option overrides the -b, -e, -g, -k, -n, -t, and -V options. This option only works on mounted filesystems and cannot be used together with -o option.

-k
Prints the allocation in kbytes. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. This option overrides the -b, -e, -n, and -t options.

-l
Reports on local file systems only. This option is used only for mounted file systems. It can not be used with the -o option.

-n
Prints only the FSType name. Invoked with no operands, this option prints a list of mounted file system types. This option is used only for mounted file systems. It can not be used with the -o option.

-o FSType-specific_options
Specifies FSType-specific options. These options are comma-separated, with no intervening spaces. See the manual page for the FSType-specific command for details.

-t
Prints full listings with totals. This option overrides the -b, -e, and -n options.

-V
Echoes the complete set of file system specific command lines, but does not execute them. The command line is generated by using the options and operands provided by the user and adding to them information derived from /etc/mnttab, /etc/vfstab, or /etc/default/fs. This option may be used to verify and validate the command line.

-Z
Displays mounts in all visible zones. By default, df only displays mounts located within the current zone. This option has no effect in a non-global zone.

The following option is supported for /usr/bin/df only:

-v
Like -k, except that sizes are displayed in multiples of the smallest block size supported by each specified file system.
The output consists of one line of information for each file system. This one line of information includes the following:

- the file system’s mount point
- the file system’s name
- the total number of blocks allocated to the file system
- the number of blocks allocated to existing files
- the number of blocks available for the creation of new files by unprivileged users
- the percentage of blocks in use by files

The following option is supported for /usr/xpg4/bin/df only:

- P
  Same as -h except in 512-byte units.

Operands
The df utility interprets operands according to the following precedence: block_device, directory, file, resource. The following operands are supported:

block_device
  Represents a block special device (for example, /dev/dsk/c1d0s7).

directory
  Represents a valid directory name. df reports on the file system that contains directory.

file
  Represents a valid file name. df reports on the file system that contains file.

resource
  Represents an NFS resource name.

Usage
See largefile(5) for the description of the behavior of df when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Examples

**EXAMPLE 1  Executing the df command**

The following example shows the df command and its output:

```
example% /usr/bin/df

/       (/dev/dsk/c0t0d0s0 ) : 287530 blocks 92028 files
/system/contract (ctfs ) :   0 blocks 2147483572 files
/system/object (objfs ) :   0 blocks 2147483511 files
/usr     (/dev/dsk/c0t0d0s6 ) : 1020214 blocks 268550 files
/proc     (/proc ) :   0 blocks 878 files
/dev/fd   (fd ) :   0 blocks 0 files
/etc/mnttab (mnttab ) :   0 blocks 0 files
/var/run (swap ) : 396016 blocks 9375 files
/tmp     (swap ) : 396016 blocks 9375 files
/opt     (/dev/dsk/c0t0d0s5 ) : 381552 blocks 96649 files
```

362 man pages section 1M: System Administration Commands • Last Revised 30 Nov 2009
EXAMPLE 1  Executing the df command  (Continued)

/export/home  (/dev/dsk/c0t0d0s7 ): 434364 blocks  108220 files

where the columns represent the mount point, device (or “filesystem”, according to df -k), free blocks, and free files, respectively. For contract file systems, /system/contract is the mount point, ctf s is the contract file system (used by SMF) with 0 free blocks and 2147483582(INTMAX-1) free files. For object file systems, /system/object is the mount point, objfs is the object file system (see objfs(7FS)) with 0 free blocks and 2147483511 free files.

EXAMPLE 2  Writing Portable Information About the /usr File System
The following example writes portable information about the /usr file system:

example% /usr/xpg4/bin/df -P /usr

EXAMPLE 3  Writing Portable Information About the /usr/src File System
Assuming that /usr/src is part of the /usr file system, the following example writes portable information:

example% /usr/xpg4/bin/df -P /usr/src

EXAMPLE 4  Using df to Display Inode Usage
The following example displays inode usage on all ufs file systems:

example% /usr/bin/df -F ufs -o i

Environment Variables

SYSV3

This variable is used to override the default behavior of df and provide compatibility with INTERACTIVE UNIX System and SCO UNIX installation scripts. As the SYSV3 variable is provided for compatibility purposes only, it should not be used in new scripts.

When set, any header which normally displays “files” will now display “nodes”. See environ(5) for descriptions of the following environment variables that affect the execution of df: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status

The following exit values are returned:

0  Successful completion.

>0  An error occurred.
Files  
/dev/dsk/*
   Disk devices

/etc/default/fs
   Default local file system type. Default values can be set for the following flags in
   /etc/default/fs. For example: LOCAL=ufs, where LOCAL is the default partition for a
   command if no FSType is specified.

/etc/mnttab
   Mount table

/etc/vfstab
   List of default parameters for each file system

Attributes  See attributes(5) for descriptions of the following attributes:

Notes  If UFS logging is enabled on a file system, the disk space used for the log is reflected in the df
       report. The log is allocated from free blocks on the file system, and it is sized approximately 1
       Mbyte per 1 Gbyte of file system, up to 256 Mbytes. The log size may be larger (up to a
       maximum of 512 Mbytes) depending on the number of cylinder groups present in the file
       system.
**Name**
dfmounts – display mounted resource information

**Synopsis**
dfmounts [-F FSType] [-h] [-o specific_options] [restriction]...  

**Description**
dfmounts shows the local resources shared through a distributed file system FSType along with a list of clients that have the resource mounted. If restriction is not specified, dfmounts shows file systems that are currently shared on any NFS server. specific_options as well as the availability and semantics of restriction are specific to particular distributed file system types.

If dfmounts is entered without arguments, remote resources currently mounted on the local system are displayed, regardless of file system type. However, the dfmounts command does not display the names of NFS Version 4 clients.

**dfmounts Output**
The output of dfmounts consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

```
resource server pathname clients ...
```

where:
- **resource** Specifies the resource name that must be given to the mount(1M) command.
- **server** Specifies the system from which the resource was mounted.
- **pathname** Specifies the path name that must be given to the share(1M) command.
- **clients** Is a comma-separated list of systems that have mounted the resource. Clients are listed in the form domain., domain.system, or system, depending on the file system type.

A field can be null. Each null field is indicated by a hyphen (−) unless the remainder of the fields on the line are also null, in which case the hyphen can be omitted.

Fields with whitespace are enclosed in quotation marks (" ").

**Options**
- **-F FSType** Specify filesystem type. Defaults to the first entry in /etc/dfs/fstypes. Note: currently the only valid FSType is nfs.
- **-h** Suppress header line in output.
- **-o specific_options** Specify options specific to the filesystem provided by the -F option. Note: currently no options are supported.

**Files**
/etc/dfs/fstypes file system types

**Name**

dfmounts_nfs – display mounted NFS resource information

**Synopsis**

dfmounts [-F nfs] [-h] [server]...

**Description**

dfmounts shows the local resources shared through NFS, along with the list of clients that have mounted the resource. The -F flag may be omitted if NFS is the only file system type listed in the file /etc/dfs/fstypes.

dfmounts without options, displays all remote resources mounted on the local system, regardless of file system type.

The output of dfmounts consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server pathname clients ...

where

resource Does not apply to NFS. Printed as a hyphen (-).
server Specifies the system from which the resource was mounted.
pathname Specifies the path name that must be given to the share(1M) command.
clients Is a comma-separated list of systems that have mounted the resource.

**Options**

- F nfs Specifies the nfs-FSType.
- h Suppress header line in output.
server Displays information about the resources mounted from each server, where server can be any system on the network. If no server is specified, the server is assumed to be the local system.

**Files**

/etc/dfs/fstypes

dfshares

Name
dfshares – list available resources from remote or local systems

Synopsis
dfshares [-F FSType] [-h] [-o specific_options] [server]...

Description
dfshares provides information about resources available to the host through a distributed file system of type FSType. specific_options as well as the semantics of server are specific to particular distributed file systems.

If dfshares is entered without arguments, all resources currently shared on the local system are displayed, regardless of file system type.

The output of dfshares consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server access transport

where

resource Specifies the resource name that must be given to the mount(1M) command.
server Specifies the name of the system that is making the resource available.
access Specifies the access permissions granted to the client systems, either ro (for read-only) or rw (for read/write). If dfshares cannot determine access permissions, a hyphen (−) is displayed.
transport Specifies the transport provider over which the resource is shared.

A field may be null. Each null field is indicated by a hyphen (−) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.

Options

- F FSType Specify filesystem type. Defaults to the first entry in /etc/dfs/fstypes.
- h Suppress header line in output.
- o specific_options Specify options specific to the filesystem provided by the -F option.

Files

/etc/dfs/fstypes

dfshares_nfs – list available NFS resources from remote systems

Synopsis

dfshares [-F nfs] [-h] [server]...

Description

dfshares provides information about resources available to the host through NFS. The -F flag may be omitted if NFS is the first file system type listed in the file /etc/dfs/fstypes.

The query may be restricted to the output of resources available from one or more servers.

dfshares without arguments displays all resources shared on the local system, regardless of file system type.

Specifying server displays information about the resources shared by each server. Server can be any system on the network. If no server is specified, then server is assumed to be the local system.

The output of dfshares consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server access transport

where

resource      Specifies the resource name that must be given to the mount(1M) command.
server       Specifies the system that is making the resource available.
access       Specifies the access permissions granted to the client systems; however, dfshares cannot determine this information for an NFS resource and populates the field with a hyphen (-).
transport    Specifies the transport provider over which the resource is shared; however, dfshares cannot determine this information for an NFS resource and populates the field with a hyphen (-).

A field may be null. Each null field is indicated by a hyphen (-) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.

Options

-F nfs       Specify the NFS file system type
-h           Suppress header line in output.

Files

/etc/dfs/fstypes

**df_ufs (1M)**

**Name**
df_ufs – report free disk space on ufs file systems

**Synopsis**
df `-F ufs [generic_options] [-o i] [directory | special]

**Description**
df displays the amount of disk space occupied by ufs file systems, the amount of used and available space, and how much of the file system’s total capacity has been used. The amount of space reported as used and available is less than the amount of space in the file system; this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this can be adjusted using tunefs(1M). When all the space on the file system except for this reserve is in use, only the superuser can allocate new files and data blocks to existing files. When the file system is overallocated in this way, df might report that the file system is more than 100% utilized. If neither directory nor special is specified, df displays information for all mounted ufs file systems.

**Options**
The following options are supported:

- **generic_options**
  Options supported by the generic df command. See df(1M) for a description of these options.

- **-o i**
  Specify ufs file system specific options. The available option is:

  - **1**
    Report the number of used and free inodes. This option can not be used with generic_options.

**Files**
/etc/mnttab list of file systems currently mounted

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcxu, SUNWxcu4</td>
</tr>
</tbody>
</table>

**See Also**
df(1M), fsck(1M), fstyp(1M), tunefs(1M), mnttab(4), attributes(5), ufs(7FS),

**Notes**
df calculates its results differently for mounted and unmounted file systems. For unmounted systems, the numbers reflect the 10% reservation. This reservation is not reflected in df output for mounted file systems. For this reason, the available space reported by the generic command can differ from the available space reported by this module.

If you suspect that you have exhausted contiguous fragments on your file system, you can use the fstyp(1M) utility with the `-v` option. In the fstyp output, look at the `nbfree` (number of blocks free) and `nffree` (number of fragments free) fields. On unmounted filesystems, you can use fsck(1M) and observe the last line of output, which reports, among other items, the number of fragments and the degree of fragmentation. See fsck(1M).
The dhcpagent daemon obtains configuration parameters for the client (local) machine's network interfaces from a DHCP server. These parameters may include a lease on an IP address, which gives the client machine use of the address for the period of the lease, which may be infinite. If the client wishes to use the IP address for a period longer than the lease, it must negotiate an extension using DHCP. For this reason, dhcpagent must run as a daemon, terminating only when the client machine powers down.

For IPv4, the dhcpagent daemon is controlled through ifconfig(1M) in much the same way that the init(1M) daemon is controlled by telinit(1M). dhcpagent can be invoked as a user process, albeit one requiring root privileges, but this is not necessary, as ifconfig(1M) will start it automatically.

For IPv6, the dhcpagent daemon is invoked automatically by in.ndpd(1M). It can also be controlled through ifconfig(1M), if necessary.

When invoked, dhcpagent enters a passive state while it awaits instructions from ifconfig(1M) or in.ndpd(1M). When it receives a command to configure an interface, it starts DHCP on the interface. Once DHCP is complete, dhcpagent can be queried for the values of the various network parameters. In addition, if DHCP was used to obtain a lease on an address for an interface, it configures the address for use. When a lease is obtained, it is automatically renewed as necessary. If the lease cannot be renewed, dhcpagent will unconfigure the address, and attempt to acquire a new address lease on the interface.

dhcpagent monitors system suspend/resume events and will validate any non-permanent leases with the DHCP server upon resume. Similarly, dhcpagent monitors link up/down events and will validate any non-permanent leases with the DHCP server when the downed link is brought back up.

For IPv4, if the configured interface is found to be unplumbed, marked down, or to have a different IP address, subnet mask, or broadcast address from those obtained from DHCP, the interface is abandoned by DHCP control.

For IPv6, dhcpagent automatically plumbs and unplumbs logical interfaces as necessary for the IPv6 addresses supplied by the server. The IPv6 prefix length (netmask) is not set by the DHCPv6 protocol, but is instead set by in.ndpd(1M) using prefix information obtained by Router Advertisements. If any of the logical interfaces created by dhcpagent is unplumbed, marked down, or configured with a different IP address, it will be abandoned by DHCP control. If the link-local interface is unplumbed, then all addresses configured by DHCP on that physical interface will be removed.
In addition to DHCP, dhcpagent also supports BOOTP (IPv4 only). See RFC 951, Bootstrap Protocol. Configuration parameters obtained from a BOOTP server are treated identically to those received from a DHCP server, except that the IP address received from a BOOTP server always has an infinite lease.

DHCP also acts as a mechanism to configure other information needed by the client, for example, the domain name and addresses of routers. Aside from the IP address, and for IPv4 alone, the netmask, broadcast address, and default router, the agent does not directly configure the workstation, but instead acts as a database which may be interrogated by other programs, and in particular by dhcpinfo(1).

On clients with a single interface, this is quite straightforward. Clients with multiple interfaces may present difficulties, as it is possible that some information arriving on different interfaces may need to be merged, or may be inconsistent. Furthermore, the configuration of the interfaces is asynchronous, so requests may arrive while some or all of the interfaces are still unconfigured. To handle these cases, one interface may be designated as primary, which makes it the authoritative source for the values of DHCP parameters in the case where no specific interface is requested. See dhcpinfo(1) and ifconfig(1M) for details.

For IPv4, the dhcpagent daemon can be configured to request a particular host name. See the REQUEST_HOSTNAME description in the FILES section. When first configuring a client to request a host name, you must perform the following steps as root to ensure that the full DHCP negotiation takes place:

# pkill dhcpagent
# rm /etc/dhcp/interface.dhc
# reboot

All DHCP packets sent by dhcpagent include a vendor class identifier (RFC 2132, option code 60; RFC 3315, option code 16). This identifier is the same as the platform name returned by the uname -i command, except:

- Any commas in the platform name are changed to periods.
- If the name does not start with a stock symbol and a comma, it is automatically prefixed with SUNW.

Messages The dhcpagent daemon writes information and error messages in five categories:

critical

Critical messages indicate severe conditions that prevent proper operation.

ersors

Error messages are important, sometimes unrecoverable events due to resource exhaustion and other unexpected failure of system calls; ignoring errors may lead to degraded functionality.

warnings

Warnings indicate less severe problems, and in most cases, describe unusual or incorrect datagrams received from servers, or requests for service that cannot be provided.
Informational messages provide key pieces of information that can be useful to debugging a DHCP configuration at a site. Informational messages are generally controlled by the \(-v\) option. However, certain critical pieces of information, such as the IP address obtained, are always provided.

Debugging messages, which may be generated at two different levels of verbosity, are chiefly of benefit to persons having access to source code, but may be useful as well in debugging difficult DHCP configuration problems. Debugging messages are only generated when using the \(-d\) option.

When \(\text{dhcpagent}\) is run without the \(-f\) option, all messages are sent to the system logger \(\text{syslog(3C)}\) at the appropriate matching priority and with a facility identifier \(\text{LOG_DAEMON}\). When \(\text{dhcpagent}\) is run with the \(-f\) option, all messages are directed to standard error.

If an executable (binary or script) is placed at \(/\text{etc/dhcp/eventhook}\), the \(\text{dhcpagent}\) daemon will automatically run that program when any of the following events occur:

**BOUND** and **BOUND6**
These events occur during interface configuration. The event program is invoked when \(\text{dhcpagent}\) receives the DHCPv4 ACK or DHCPv6 Reply message from the DHCP server for the lease request of an address, indicating successful initial configuration of the interface. (See also the **INFORM** and **INFORM6** events, which occur when configuration parameters are obtained without address leases.)

**EXTEND** and **EXTEND6**
These events occur during lease extension. The event program is invoked just after \(\text{dhcpagent}\) receives the DHCPv4 ACK or DHCPv6 Reply from the DHCP server for the DHCPv4 REQUEST (renew) message or the DHCPv6 Renew or Rebind message.

Note that with DHCPv6, the server might choose to remove some addresses, add new address leases, and ignore (allow to expire) still other addresses in a given Reply message. The EXTEND6 event occurs when a Reply is received that leaves one or more address leases still valid, even if the Reply message does not extend the lease for any address. The event program is invoked just before any addresses are removed, but just after any new addresses are added. Those to be removed will be marked with the \(\text{IFF_DEPRECATED}\) flag.

**EXPIRE** and **EXPIRE6**
These events occur during lease expiration. For DHCPv4, the event program is invoked just before the leased address is removed from an interface and the interface is marked as **down**. For DHCPv6, the event program is invoked just before the last remaining leased addresses are removed from the interface.

**DROP** and **DROP6**
These events occur during the period when an interface is dropped. The event program is invoked just before the interface is removed from DHCP control. If the interface has been
abandoned due the user unplumbing the interface, then this event will occur after the user's action has taken place. The interface might not be present.

**INFORM and INFORM6**

These events occur when an interface acquires new or updated configuration information from a DHCP server by means of the DHCPv4 INFORM or the DHCPv6 Information-Request message. These messages are sent using an `ifconfig(1M) dhcp inform` command or when the DHCPv6 Router Advertisement 0 (letter 0) bit is set and the M bit is not set. Thus, these events occur when the DHCP client does not obtain an IP address lease from the server, and instead obtains only configuration parameters.

**LOSS6**

This event occurs during lease expiration when one or more valid leases still remain. The event program is invoked just before expired addresses are removed. Those being removed will be marked with the `IFF_DEPRECATED` flag.

Note that this event is not associated with the receipt of the Reply message, which occurs only when one or more valid leases remain, and occurs only with DHCPv6. If all leases have expired, then the EXPIRE6 event occurs instead.

**RELEASE and RELEASE6**

This event occurs during the period when a leased address is released. The event program is invoked just before `dhcpagent` relinquishes the address on an interface and sends the DHCPv4 RELEASE or DHCPv6 Release packet to the DHCP server.

The system does not provide a default event program. The file `/etc/dhcp/eventhook` is expected to be owned by root and have a mode of 755.

The event program will be passed two arguments, the interface name and the event name, respectively. For DHCPv6, the interface name is the name of the physical interface.

The event program can use the `dhcpinfo(1)` utility to fetch additional information about the interface. While the event program is invoked on every event defined above, it can ignore those events in which it is not interested. The event program runs with the same privileges and environment as `dhcpagent` itself, except that `stdin`, `stdout`, and `stderr` are redirected to `/dev/null`. Note that this means that the event program runs with root privileges.

If an invocation of the event program does not exit after 55 seconds, it is sent a SIGTERM signal. If does not exit within the next three seconds, it is terminated by a SIGKILL signal.

See EXAMPLES for an example event program.

**Options**

The following options are supported:

```
-a
```

Adopt a configured IPv4 interface. This option is for use with diskless DHCP clients. In the case of diskless DHCP, DHCP has already been performed on the network interface.
providing the operating system image prior to running dhcpagent. This option instructs
the agent to take over control of the interface. It is intended primarily for use in boot
scripts.

The effect of this option depends on whether the interface is being adopted.

If the interface is being adopted, the following conditions apply:

dhcpagent uses the client id specified in /chosen:<client_id>, as published by the PROM
or as specified on a boot(1M) command line. If this value is not present, the client id is
undefined. The DHCP server then determines what to use as a client id. It is an error
condition if the interface is an Infiniband interface and the PROM value is not present.

If the interface is not being adopted:

dhcpagent uses the value stored in /etc/default/dhcpagent. If this value is not present,
the client id is undefined. If the interface is Infiniband and there is no value in
/etc/default/dhcpagent, a client id is generated as described by the draft document on
DHCP over Infiniband, available at:

http://www.ietf.org

-d n
Set debug level to n. Two levels of debugging are currently available, 1 and 2; the latter is
more verbose.

-f
Run in the foreground instead of as a daemon process. When this option is used, messages
are sent to standard error instead of to syslog(3C).

-v
Provide verbose output useful for debugging site configuration problems.

Examples

EXAMPLE 1  Example Event Program

The following script is stored in the file /etc/dhcp/eventhook, owned by root with a mode of
755. It is invoked upon the occurrence of the events listed in the file.

#!/bin/sh

( 
  echo "Interface name: "$1
  echo "Event: "$2
  case $2 in
    "BOUND")
      echo "Address acquired from server 
      /sbin/dhcpinfo -i $1 ServerID"
    ;;
    "BOUND6")
  esac
)
EXAMPLE 1  Example Event Program  (Continued)

    echo "Addresses acquired from server " \
          '/sbin/dhcpinfo -v6 -i $1 ServerID'
    ;;
    "EXTEND")
    echo "Lease extended for " \
          'sbin/dhcpinfo -i $1 LeaseTime" seconds" \
    ;;
    "EXTEND6")
    echo "New lease information obtained on $i"
    ;;
    "EXPIRE" | "DROP" | "RELEASE")
    ;;

    esac
) > /var/run/dhcp_eventhook_output 2>&1

Note the redirection of stdout and stderr to a file.

Files  /etc/dhcp/if.dhc
       /etc/dhcp/if.dh6
       Contains the configuration for interface. The mere existence of this file does not imply that
       the configuration is correct, since the lease might have expired. On start-up, dhcpagent
       confirms the validity of the address using REQUEST (for DHCPv4) or Confirm
       (DHCPv6).

       /etc/dhcp/duid
       /etc/dhcp/iaid
       Contains persistent storage for DUID (DHCP Unique Identifier) and IAID (Identity
       Association Identifier) values. The format of these files is undocumented, and applications
       should not read from or write to them.

       /etc/default/dhcpagent
       Contains default values for tunable parameters. All values may be qualified with the
       interface they apply to by prepending the interface name and a period (".") to the interface
       parameter name. The parameters include: the interface parameter name.

       To configure IPv6 parameters, place the string .v6 between the interface name (if any) and
       the parameter name. For example, to set the global IPv6 parameter request list, use
       .v6.PARAM_REQUEST_LIST. To set the CLIENT_ID (DUID) on hme0, use hme0.v6.CLIENT_ID.

       The parameters include:

       RELEASE_ON_SIGTERM
       Indicates that a RELEASE rather than a DROP should be performed on managed interfaces
       when the agent terminates. Release causes the client to discard the lease, and the server
       to make the address available again. Drop causes the client to record the lease in
       /etc/dhcp/interface.dhc or /etc/dhcp/interface.dh6 for later use.
OFFER_WAIT
Indicates how long to wait between checking for valid OFFERs after sending a DISCOVER.
For DHCPv6, sets the time to wait between checking for valid Advertisements after
sending a Solicit.

CLIENT_ID
Indicates the value that should be used to uniquely identify the client to the server. This
value can take one of three basic forms:

decimal, data . . . 
0xHHHHH . . . 
"string . . . "

The first form is an RFC 3315 DUID. This is legal for both IPv4 DHCP and DHCPv6.
For IPv4, an RFC 4361 Client ID is constructed from this value. In this first form, the
format of data... depends on the decimal value. The following formats are defined for
this first form:

1, hwtype, time, lla
Type 1, DUID-LLT. The hwtype value is an integer in the range 0-65535, and
indicates the type of hardware. The time value is the number of seconds since
midnight, January 1st, 2000 UTC, and can be omitted to use the current system time.
The lla value is either a colon-separated MAC address or the name of a physical
interface. If the name of an interface is used, the hwtype value can be omitted. For
example: 1, , , hme0

2, enterprise, hex...
Type 2, DUID-EN. The enterprise value is an integer in the range 0-4294967295 and
represents the SMI Enterprise number for an organization. The hex string is an
even-length sequence of hexadecimal digits.

3, hwtype, lla
Type 3, DUID-LL. This is the same as DUID-LLT (type 1), except that a time stamp is
not used.

*, hex
Any other type value (0 or 4-65535) can be used with an even-length hexadecimal
string.

The second and third forms of CLIENT_ID are legal for IPv4 only. These both represent
raw Client ID (without RFC 4361), in hex, or NVT ASCII string format. Thus, Sun and
0x53756E are equivalent.

PARAM_REQUEST_LIST
Specifies a list of comma-separated integer values of options for which the client would
like values.
REQUEST_HOSTNAME

Indicatestheclientrequeststhedhcpservertomaptoclient'sleasedIPv4addressto
thehostnameassociatedwiththenetworkinterfacethatperformedhcpprotontheclient.
Thehostnamemustbespecifiedinthe/etc/hostname.interfacefilefortherelevant
interfaceonolineoftheform

inet hostname

wherehostnameisthehostnamerequested.

ThisoptionworkswithDHCPv4only.

/etc/dhcp/eventhook

System Administration Guide: IP Services

Lemon, T. and B. Sommerfeld. RFC 4361, Node-specific Client Identifiers for Dynamic Host
Configuration Protocol Version Four (DHCPv4). Nominum and Sun Microsystems. February
2006.

Notes  The dhcpagent daemon can be used on IPv4 logical interfaces, just as with physical interfaces.
When used on a logical interface, the daemon automatically constructs a Client ID value based
on the DUID and IAI values, according to RFC 4361. The /etc/default/dhcpclient
CLIENT_ID value, if any, overrides this automatic identifier.

As with physical IPv4 interfaces, the /etc/hostname.hme0:1 and /etc/dhcp.hme0:1 files
must also be created in order for hme0:1 to be automatically plumbed and configured at boot.
In addition, unlike physical IPv4 interfaces, dhcpagent does not add or remove default routes
associated with logical interfaces.
With DHCPv6, the link-local interface must be configured using /etc/hostname6. hme0 in order for DHCPv6 to run on hme0 at boot time. The logical interfaces for each address are plumbed by dhcpagent automatically.
**Name**
dhcpconfig - DHCP service configuration utility

**Synopsis**
dhcpconfig -D -r resource -p path [-u uninterpreted]
            [-l lease_length] [-n ] [-d DNS_domain]
            [-a DNS_server_addresses] [-h hosts_resource]
            [-y hosts_domain]
dhcpconfig -R server_addresses

dhcpconfig -U [-f] [-x] [-h]
dhcpconfig -N network_address [-m subnet_mask] [-b]
            [-t router_addresses] [-y NIS-domain]
            [-a NIS_server_addresses] [-g]
dhcpconfig -C -r resource -p path [-f] [-k]
            [-u uninterpreted]
dhcpconfig -X filename [-m macro_list] [-o option_list]
            [-a network_addresses] [-f] [-x] [-g]
dhcpconfig -I filename [-f] [-g]
dhcpconfig -P [parameter=value],...
dhcpconfig -S [-f] [-e | -d | -r | -q]

**Description**
The dhcpconfig command is used to configure and manage the Dynamic Host Configuration Protocol (DHCP) service or BOOTP relay services. It is intended for use by experienced Solaris system administrators and is designed for ease of use in scripts. The dhcpmgr utility is recommended for less experienced administrators or those preferring a graphical utility to configure and manage the DHCP service or BOOTP relay service.

The dhcpconfig command can be run by root, or by other users assigned to the DHCP Management profile. See rbac(5) and user_attr(4).

dhcpconfig requires one of the following function flags: -D, -R, -U, -N, -C, -X, -I, -P or -S.

The dhcpconfig menu driven mode is supported in Solaris 8 and previous versions of Solaris.

dhcpconfig scans various configuration files on your Solaris machine for information it can use to assign values to options contained in macros it adds to the dhcptab configuration table. The following table lists information dhcpconfig needs, the source used, and how the information is used:

<table>
<thead>
<tr>
<th>Information</th>
<th>Source</th>
<th>Where Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timezone</td>
<td>System date, timezone settings</td>
<td>Locale macro</td>
</tr>
<tr>
<td>DNS parameters</td>
<td>nsswitch.conf,/etc/resolv.conf</td>
<td>Server macro</td>
</tr>
</tbody>
</table>
NIS parameters System domainname, nsswitch.conf, NIS
Subnetmask Network interface, netmasks table in nameservice

If you have not set these parameters on your server machine, you should do so before configuring the DHCP server with `dhcpconfig`. Note that if you specify options with the `dhcpconfig -D` command line, the values you supply override the values obtained from the system files.

**Options** The following options are supported:

- `-C` Convert to using a new data store, recreating the DHCP data tables in a format appropriate to the new data store, and setting up the DHCP server to use the new data store.

  The following sub-options are required:

  `-p path_to_data` The paths for SUNW files and SUNWbin files must be absolute UNIX pathnames. The path for SUNWnisplus must be a fully specified NIS+ directory (including the trailing period.) See `dhcp_modules(5)`.

  `-r data_resource` New data store resource. One of the following must be specified: SUNW files, SUNWbin files, or SUNWnisplus. See `dhcp_modules(5)`.

  The following sub-options are optional:

  `-f` Do not prompt for confirmation. If `-f` is not used, a warning and confirmation prompt are issued before the conversion starts.

  `-k` Keep the old DHCP data tables after successful conversion. If any problem occurs during conversion, tables are not deleted even if `-k` sub-option is not specified.

  `-u uninterpreted` Data which is ignored by `dhcpconfig`, but passed on to the datastore for interpretation. The private layer provides for module-specific configuration information through the use of the RESOURCE_CONFIG keyword. Uninterpreted data is stored within RESOURCE_CONFIG keyword of `dhcpsvc.conf(4)`. The `-u` sub-option is not used with the SUNW files, SUNWbin files, and
Configure the DHCP service.

The following sub-options are required:

- **-D**  
  Configure the DHCP service.

- **-r data_resource**  
  One of the following must be specified:
  SUNWfiles, SUNWbinfiles, or SUNWnisplus. Other data stores may be available. See dhcp_modules(5).

- **-p path**  
  The paths for SUNWfiles and SUNWbinfiles must be absolute UNIX pathnames. The path for SUNWnisplus must be a fully specified NIS+ directory (including the trailing period). See dhcp_modules(5).

The following sub-options are optional:

- **-a DNS_servers**  
  IP addresses of DNS servers, separated with commas.

- **-d DNS_domain**  
  DNS domain name.

- **-h hosts_resource**  
  Resource in which to place hosts data. Usually, the name service in use on the server. Valid values are nisplus, files, or dns.

- **-l seconds**  
  Lease length used for addresses not having a specified lease length, in seconds.

- **-n**  
  Non-negotiable leases

- **-y hosts_domain**  
  DNS or NIS+ domain name to be used for hosts data. Valid only if dns or nisplus is specified for -h sub-option.

- **-u uninterpreted**  
  Data which is ignored by dhcpconfig, but passed on to the datastore for interpretation. The private layer provides for module-specific configuration information through the use of the RESOURCE_CONFIG keyword. Uninterpreted data is stored within RESOURCE_CONFIG keyword of dhcpsvc.conf(4). The -u sub-option is not used with the SUNWfiles, SUNWbinfiles, and SUNWnisplus data stores. See dhcp_modules(5).

- **-I filename**  
  Import data from filename, containing data previously exported from a Solaris DHCP server. Note that after importing, you may have to edit
macros to specify the correct domain names, and edit network tables to change the owning server of addresses in imported networks. Use dhtadm and pntadm to do this.

The following sub-options are supported:

- **-f** Replace any conflicting data with the data being imported.
- **-g** Signal the daemon to reload the dhcptab once the import has been completed.

- **-N net_address** Configure an additional network for DHCP service.

The following sub-options are supported:

- **-a NIS_server_addresses** List of IP addresses of NIS servers.
- **-b** Network is a point-to-point (PPP) network, therefore no broadcast address should be configured. If -b is not used, the network is assumed to be a LAN, and the broadcast address is determined using the network address and subnet mask.
- **-g** Signal the daemon to reload the dhcptab.
- **-m xxx.xxx.xxx.xxx** Subnet mask for the network; if -m is not used, subnet mask is obtained from netmasks.
- **-t router_addresses** List of router IP addresses; if not specified, router discovery flag is set.
- **-y NIS_domain_name** If NIS is used on this network, specify the NIS domain name.

- **-P** Configure the DHCP service parameters. Each parameter and value are specified by the following pattern:

  parameter[=value], . . .

Where parameter and value are:

- **parameter** One of the DHCP service parameters listed in dhcpsvc.conf(4). If the corresponding value is not specified, the current parameter value is displayed. If parameter is not specified, all parameters and current values are displayed.
value Optional string to set the servers parameter to if the value is acceptable. If the value is missing or is empty (""), the parameter and its current value are deleted.

After a parameter has changed the DHCP server requires re-starting before you can use new parameter values.

-R server_addresses Configure the BOOTP relay service. BOOTP or DHCP requests are forwarded to the list of servers specified.

server_addresses is a comma separated list of hostnames and/or IP addresses.

-S Control the DHCP service.

The following sub-options are supported:

- d Disable and stop the DHCP service.
- e Enable and start the DHCP service.
- q Display the state of the DHCP service. The state is encoded into the exit status.
  0 DHCP service disabled and stopped
  1 DHCP service enabled and stopped
  2 DHCP service disabled and running
  3 DHCP service enabled and running
- r Enable and restart the DHCP service.

-U Unconfigure the DHCP service or BOOTP relay service.

The following sub-options are supported:

- f Do not prompt for confirmation. If -f is not used, a warning and confirmation prompt is issued.
- h Delete hosts entries from nameservice.
- x Delete the dhcp.tab and network tables.

-X filename Export data from the DHCP data tables, saving to filename, to move the data to another Solaris DHCP server.

The following sub-options are optional:

- a networks_to_export List of networks whose addresses should be exported, or the keyword ALL to specify all networks. If -a is not specified, no networks are exported.
-g  Signal the daemon to reload the dhcp.tab after the export has been completed.

-m macros_to_export  List of macros to export, or the keyword ALL to specify all macros. If -m is not specified, no macros are exported.

-o options_to_export  List of options to export, or the keyword ALL to specify all options. If -o is not specified, no options are exported.

-x  Delete the data from this server after it is exported. If -x is not specified you are in effect copying the data.

Examples

Example 1  Configuring DHCP Service with Binary Files Data Store
The following command configures DHCP service, using the binary files data store, in the DNS domain acme.eng, with a lease time of 28800 seconds (8 hours),

```
example# dhcpconfig -D -r SUNWbinfiles -p /var/dhcp -l 28800\n            -d acme.eng -a 120.30.33.4 -h dns -y acme.eng
```

Example 2  Configuring BOOTP Relay Agent
The following command configures the DHCP daemon as a BOOTP relay agent, which forwards BOOTP and DHCP requests to the servers having the IP addresses 120.30.33.7 and 120.30.42.132:

```
example# dhcpconfig -R 120.30.33.7,120.30.42.132
```

Example 3  Unconfiguring DHCP Service
The following command unconfigures the DHCP service, with confirmation, and deletes the DHCP data tables and host table entries:

```
example# dhcpconfig -U -x -h
```

Example 4  Configuring a Network for DHCP Service
The following command configures an additional LAN network for DHCP service, specifying that clients should use router discovery and providing the NIS domain name and NIS server address:

```
example# dhcpconfig -N 120.30.171.0 -y east.acme.eng.com\n            -a 120.30.33.4
```

Example 5  Converting to SUNWnisplus Data Store
The following command converts a DHCP server from using a text or binary files data store to a NIS+ data store, deleting the old data store’s DHCP tables:
EXAMPLE 5 Converting to SUNWnisplus Data Store (Continued)

example# dhcpconfig -C -r SUNWnisplus -p whatever.com.

EXAMPLE 6 Exporting a Network, Macros, and Options from a DHCP Server

The following command exports one network (120.30.171.0) and its addresses, the macro 120.30.171.0, and the options motd and PSptr from a DHCP server, saves the exported data in file /export/var/120301710_data, and deletes the exported data from the server.

example# dhcpconfig -X /var/dhcp/120301710_export -a 120.30.171.0 -m 120.30.171.0 -o motd,PSptr

EXAMPLE 7 Importing Data on a DHCP Server

The following command imports DHCP data from a file, /net/golduck/export/var/120301710_data, containing data previously exported from a Solaris DHCP server, overwrites any conflicting data on the importing server, and signals the daemon to reload the dhcptab once the import is completed:

example# dhcpconfig -I /net/golduck/export/var/120301710_data -f -g

EXAMPLE 8 Setting DHCP Server Parameters

The following command sets the number of minutes that the DHCP server waits before timing out when updating DNS information on DHCP clients to five minutes.

example# example# dhcpconfig -P UPDATE_TIMEOUT=5

EXAMPLE 9 Re-starting the DHCP server

The following command stops and re-starts the DHCP server.

example# example# dhcpconfig -S -r

DHCP server stopped
DHCP server started

System Administration Guide: IP Services
dhcpmgr – graphical interface for managing DHCP service

/usr/sadm/admin/bin/dhcpmgr

dhcpmgr is a graphical user interface which enables you to manage the Dynamic Host Configuration Protocol (DHCP) service on the local system. It performs the functions of the dhcpconfig, dhtadm, and pntadm command line utilities. You must be root to use dhcpmgr. The dhcpmgr Help, available from the Help menu, contains detailed information about using the tool.

You can perform the following tasks using dhcpmgr:

- **Configure DHCP service**: Use dhcpmgr to configure the DHCP daemon as a DHCP server, and select the data store to use for storing network configuration tables.
- **Configure BOOTP relay service**: Use dhcpmgr to configure the DHCP daemon as a BOOTP relay.
- **Manage DHCP or BOOTP relay service**: Use dhcpmgr to start, stop, enable, disable or unconfigure the DHCP service or BOOTP relay service, or change DHCP server parameters.
- **Manage DHCP addresses**: Use dhcpmgr to add, modify, or delete IP addresses leased by the DHCP service.
- **Manage DHCP macros**: Use dhcpmgr to add, modify or delete macros used to supply configuration parameters to DHCP clients.
- **Manage DHCP options**: Use dhcpmgr to add, modify or delete options used to define parameters deliverable through DHCP.
- **Convert to a new DHCP data store**: Use dhcpmgr to configure the DHCP server to use a different data store, and convert the DHCP data to the format used by the new data store.
- **Move DHCP data to another server**: Use dhcpmgr to export data from one Solaris DHCP server and import data onto another Solaris DHCP server.

The following exit values are returned:

- 0: Successful completion.
- non-zero: An error occurred.

dhtadm  \[-R \[-r \text{ resource}\] \[-p \text{ path}\] \[-u \text{ uninterpreted}\] \[-g\]\]  
dhtadm  \[-B \[-v\] \[-g\]\]  

**Description**  
dhtadm manages the Dynamic Host Configuration Protocol (DHCP) service configuration table, dhcptab. You can use it to add, delete, or modify DHCP configuration macros or options or view the table. For a description of the table format, see [dhcptab](4).

The dhtadm command can be run by root, or by other users assigned to the DHCP Management profile. See [rbac](5) and [user_attr](4).

After you make changes with dhtadm, you should issue a SIGHUP to the DHCP server, causing it to read the dhcptab and pick up the changes. Do this using the \[-g\] option.

**Options**  
One of the following function flags must be specified with the dhtadm command: \[-A\], \[-B\], \[-C\], \[-D\], \[-M\], \[-P\] or \[-R\].

The following options are supported:

- **\[-A\]**  
  Add a symbol or macro definition to the dhcptab table.

  The following sub-options are required:
-d definition  Specify a macro or symbol definition.

definition must be enclosed in single quotation marks. For macros, use the form
-d ' :symbol=value;symbol=value;'.
Enclose a value that contains colons in double quotation marks. For symbols, the
definition is a series of fields that define a symbol's characteristics. The fields are
separated by commas. Use the form -d 'context,code,type,granularity,maximum'.
See dhcptab(4) for information about these fields.

-m macro_name  Specify the name of the macro to be added.

The -d option must be used with the -m option. The -s option cannot be used with
the -m option.

-s symbol_name  Specify the name of the symbol to be added.

The -d option must be used with the -s option. The -m option cannot be used with
the -s option.

-B  Batch process dhtadm commands. dhtadm reads from the specified
file or from standard input a series of dhtadm commands and
execute them within the same process. Processing many dhtadm
commands using this method is much faster than running an
executable batchfile itself. Batch mode is recommended for using
dhtadm in scripts.

The following sub-option is optional:

-v  Display commands to standard output as they are
processed.

-C  Create the DHCP service configuration table, dhcptab.

-D  Delete a symbol or macro definition.

The following sub-options are required:

-m macro_name  Delete the specified macro.

-s symbol_name  Delete the specified symbol.
Signal the DHCP daemon to reload the dhcptab after successful completion of the operation.

Modify an existing symbol or macro definition.

The following sub-options are required:

- **d definition** Specify a macro or symbol definition to modify.

  The definition must be enclosed in single quotation marks. For macros, use the form `-d ':symbol=value:symbol=value:'`. Enclose a value that contains colons in double quotation marks. For symbols, the definition is a series of fields that define a symbol's characteristics. The fields are separated by commas. Use the form `-d 'context, code, type, granularity, maximum'`. See `dhcptab(4)` for information about these fields.

- **e** This sub-option uses the `symbol=value` argument. Use it to edit a symbol/value pair within a macro. To add a symbol which does not have an associate value, enter:

  `symbol= NULL_VALUE`

  To delete a symbol definition from a macro, enter:

  `symbol=`

- **m** This sub-option uses the `macro_name` argument. The `-n`, `-d`, or `-e` sub-options are legal companions for this sub-option.

- **n** This sub-option uses the `new_name` argument and modifies the name of the object specified by the `-m` or `-s` sub-option. It is not limited to macros. Use it to specify a new macro name or symbol name.

- **s** This sub-option uses the `symbol_name` argument. Use it to specify a symbol. The `-d` sub-option is a legal companion.
-p path
 Override the dhcpsvc.conf configuration value for PATH= with path. See dhcpsvc.conf(4) for more details regarding path. See dhcp_modules(5) for information regarding data storage modules for the DHCP service.

-P
 Print (display) the dhcptab table.

-r data_store_resource
 Override the dhcpsvc.conf(4) configuration value for RESOURCE= with the data_store_resource specified. See dhcpsvc.conf(4) for more details on resource type. See Solaris DHCP Service Developer's Guide for more information about adding support for other data stores. See dhcp_modules(5) for information regarding data storage modules for the DHCP service.

-R
 Remove the dhcptab table.

-u uninterpreted
 Data which is ignored by dhtadm, but passed to currently configured public module, to be interpreted by the data store. The private layer provides for module-specific configuration information through the use of the RESOURCE_CONFIG keyword. Uninterpreted data is stored within RESOURCE_CONFIG keyword of dhcpsvc.conf(4). See dhcp_modules(5) for information regarding data storage modules for the DHCP service.

Examples

**EXAMPLE 1** Creating the DHCP Service Configuration Table

The following command creates the DHCP service configuration table, dhcptab:

```
# dhtadm -C
```

**EXAMPLE 2** Adding a Symbol Definition

The following command adds a Vendor option symbol definition for a new symbol called MySym to the dhcptab table in the SUNWfiles resource in the /var/mydhcp directory:

```
# dhtadm -A -s MySym
   -d 'Vendor=SUNW.PCW.LAN,20,IP,1,0'
   -r SUNWfiles -p /var/mydhcp
```

**EXAMPLE 3** Adding a Macro Definition

The following command adds the aruba macro definition to the dhcptab table. Note that symbol/value pairs are bracketed with colons (:).

```
# dhtadm -A -m aruba \n   -d ':Timeserv=10.0.0.10 10.0.0.11:DNServ=10.0.0.1:'
```
EXAMPLE 4  Modifying a Macro Definition
The following command modifies the `Locale` macro definition, setting the value of the `UTCOffst` symbol to 18000 seconds. Note that any macro definition which includes the definition of the `Locale` macro inherits this change.

```
# dhtadm -M -m Locale -e 'UTCOffst=18000'
```

EXAMPLE 5  Deleting a Symbol
The following command deletes the `Timeserv` symbol from the `aruba` macro. Any macro definition which includes the definition of the `aruba` macro inherits this change.

```
# dhtadm -M -m aruba -e 'Timeserv='
```

EXAMPLE 6  Adding a Symbol to a Macro
The following command adds the `Hostname` symbol to the `aruba` macro. Note that the `Hostname` symbol takes no value, and thus requires the special value `_NULL_VALUE_`. Note also that any macro definition which includes the definition of the `aruba` macro inherits this change.

```
# dhtadm -M -m aruba -e 'Hostname=_NULL_VALUE_ '
```

EXAMPLE 7  Renaming a Macro
The following command renames the `Locale` macro to `MyLocale`. Note that any `Include` statements in macro definitions which include the `Locale` macro also need to be changed.

```
# dhtadm -M -m Locale -n MyLocale
```

EXAMPLE 8  Deleting a Symbol Definition
The following command deletes the `MySym` symbol definition. Note that any macro definitions which use `MySym` symbol needs to be modified.

```
# dhtadm -D -s MySym
```

EXAMPLE 9  Removing a dhcptab
The following command removes the `dhcptab` table in the NIS+ directory specified.

```
```

EXAMPLE 10  Printing a dhcptab
The following command prints to standard output the contents of the `dhcptab` that is located in the data store and path indicated in the `dhcpsvc.conf` file.

```
# dhtadm -P
EXAMPLE 11  Executing dhtadm in Batch Mode
The following command runs a series of dhtadm commands contained in a batch file and
signals the daemon to reload the dhcptab once the commands have been executed:

# dhtadm -B addmacros -g

Exit Status  0  Successful completion.
1  Object already exists.
2  Object does not exist.
3  Non-critical error.
4  Critical error.

Files  /etc/inet/dhcpsvc.conf

Name dig – DNS lookup utility

Synopsis dig [@server] [-b address] [-c class] [-f filename]
       [-k filename] [-m] [-p port#] [-q name] [-t type] [-x addr]
       [-y [hmac:]name:key] [-4] [-6] [name] [type] [class] [queryopt]...

dig [-h]
dig [global-queryopt...] [query...]...

Description The dig utility (domain information groper) is a flexible tool for interrogating DNS name servers. It performs DNS lookups and displays the answers that are returned from the name server(s) that were queried. Most DNS administrators use dig to troubleshoot DNS problems because of its flexibility, ease of use and clarity of output. Other lookup tools tend to have less functionality than dig.

Although dig is normally used with command-line arguments, it also has a batch mode of operation for reading lookup requests from a file. A brief summary of its command-line arguments and options is printed when the -h option is specified. Unlike earlier versions, the BIND 9 implementation of dig allows multiple lookups to be issued from the command line.

Unless it is told to query a specific name server, dig tries each of the servers listed in /etc/resolv.conf.

When no command line arguments or options are given, dig performs an NS query for "." (the root).

It is possible to set per-user defaults for dig with $HOME/.digrc. This file is read and any options in it are applied before the command line arguments.

The IN and CH class names overlap with the IN and CH top level domains names. Either use the -t and -c options to specify the type and class, or use "IN." and "CH." when looking up these top level domains.

Simple Usage The following is a typical invocation of dig:

dig @server name type

where:

server The name or IP address of the name server to query. This can be an IPv4 address in dotted-decimal notation or an IPv6 address in colon-delimited notation. When the supplied server argument is a hostname, dig resolves that name before querying that name server. If no server argument is provided, dig consults /etc/resolv.conf and queries the name servers listed there. The reply from the name server that responds is displayed.

name The name of the resource record that is to be looked up.
type
Indicates what type of query is required (ANY, A, MX, SIG, among others.) type can be any valid query type. If no type argument is supplied, dig performs a lookup for an A record.

Options
The following options are supported:

- **4**
  Use only IPv4 transport. By default both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

- **6**
  Use only IPv6 transport. By default both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

- **b address**
  Set the source IP address of the query to address. This must be a valid address on one of the host's network interfaces or 0.0.0.0 or ::. An optional port may be specified by appending: #<port>

- **c class**
  Override the default query class (IN for internet). The class argument is any valid class, such as HS for Hesiod records or CH for CHAOSNET records.

- **f filename**
  Operate in batch mode by reading a list of lookup requests to process from the file filename. The file contains a number of queries, one per line. Each entry in the file should be organized in the same way they would be presented as queries to dig using the command-line interface.

- **h**
  Print a brief summary of command-line arguments and options.

- **k filename**
  Specify a transaction signature (TSIG) key file to sign the DNS queries sent by dig and their responses using TSIGs.

- **m**
  Enable memory usage debugging.

- **p port#**
  Query a non-standard port number. The port# argument is the port number that dig sends its queries instead of the standard DNS port number 53. This option tests a name server that has been configured to listen for queries on a non-standard port number.

- **q name**
  Sets the query name to name. This can be useful in that the query name can be easily distinguished from other arguments.
-t type
Set the query type to type, which can be any valid query type supported in BIND9. The
default query type "A", unless the -x option is supplied to indicate a reverse lookup. A zone
transfer can be requested by specifying a type of AXFR. When an incremental zone transfer
(IXFR) is required, type is set to ixfr=N. The incremental zone transfer will contain the
changes made to the zone since the serial number in the zone's SOA record was N.

-x addr
Simplify reverse lookups (mapping addresses to names). The addr argument is an IPv4
address in dotted-decimal notation, or a colon-delimited IPv6 address. When this option is
used, there is no need to provide the name, class and type arguments. The dig utility
automatically performs a lookup for a name like 11.12.13.10.in-addr.arpa and sets the
query type and class to PTR and IN, respectively. By default, IPv6 addresses are looked up
using nibble format under the IP6.ARPA domain. To use the older RFC1886 method using
the IP6.INT domain, specify the -i option. Bit string labels (RFC 2874) are now
experimental and are not attempted.

-y [hmac:]name:key
Specify a transaction signature (TSIG) key on the command line. This is done to sign the
DNS queries sent by dig, as well as their responses. You can also specify the TSIG key itself
on the command line using the -y option. The optional hmac is the type of TSIG; the
default is HMAC-MD5. The name argument is the name of the TSIG key and the key argument
is the actual key. The key is a base-64 encoded string, typically generated by
dnssec-keygen(1M).

Caution should be taken when using the -y option on multi-user systems, since the key can
be visible in the output from ps(1) or in the shell's history file. When using TSIG
authentication with dig, the name server that is queried needs to know the key and
algorithm that is being used. In BIND, this is done by providing appropriate key and
server statements in named.conf.

Query Options
The dig utility provides a number of query options which affect the way in which lookups are
made and the results displayed. Some of these set or reset flag bits in the query header, some
determine which sections of the answer get printed, and others determine the timeout and
retry strategies.

Each query option is identified by a keyword preceded by a plus sign (+). Some keywords set
or reset an option. These may be preceded by the string no to negate the meaning of that
keyword. Other keywords assign values to options like the timeout interval. They have the
form +keyword=value. The query options are:

+tcp
Use [do not use] TCP when querying name servers. The default behaviour is to use UDP
unless an AXFR or IXFR query is requested, in which case a TCP connection is used.
+[no]vc
Use [do not use] TCP when querying name servers. This alternate syntax to +[no]tcp is provided for backwards compatibility. The “vc” stands for “virtual circuit”.

+[no]ignore
Ignore truncation in UDP responses instead of retrying with TCP. By default, TCP retries are performed.

+domain=somename
Set the search list to contain the single domain somename, as if specified in a domain directive in /etc/resolv.conf, and enable search list processing as if the +search option were given.

+[no]search
Use [do not use] the search list defined by the searchlist or domain directive in resolv.conf (if any). The search list is not used by default.

+[no]showsearch
Perform [do not perform] a search showing intermediate results.

+[no]defname
Deprecated, treated as a synonym for +[no]search.

+[no]aaonly
Sets the aa flag in the query.

+[no]aaflag
A synonym for +[no]aaonly.

+[no]adflag
Set [do not set] the AD (authentic data) bit in the query. This requests that the server return, regardless of whether all of the answer and authority sections have all been validated as secure according to the security policy of the server. A setting of AD=1 indicates that all records have been validated as secure and the answer is not from an OPT-OUT range. AD=0 indicates that some part of the answer is insecure or not validated.

+[no]cdflag
Set [do not set] the CD (checking disabled) bit in the query. This requests the server to not perform DNSSEC validation of responses.

+[no]cl
Display [do not display] the CLASS when printing the record.

+[no]ttlid
Display [do not display] the TTL when printing the record.

+[no]recurse
Toggle the setting of the RD (recursion desired) bit in the query. This bit is set by default, which means dig normally sends recursive queries. Recursion is automatically disabled when the +nssearch or +trace query options are used.
+[no]nssearch
When this option is set, dig attempts to find the authoritative name servers for the zone containing the name being looked up and display the SOA record that each name server has for the zone.

+[no]trace
Toggle tracing of the delegation path from the root name servers for the name being looked up. Tracing is disabled by default. When tracing is enabled, dig makes iterative queries to resolve the name being looked up. It will follow referrals from the root servers, showing the answer from each server that was used to resolve the lookup.

+[no]cmd
Toggle the printing of the initial comment in the output identifying the version of dig and the query options that have been applied. This comment is printed by default.

+[no]short
Provide a terse answer. The default is to print the answer in a verbose form.

+[no]identify
Show [or do not show] the IP address and port number that supplied the answer when the +short option is enabled. If short form answers are requested, the default is not to show the source address and port number of the server that provided the answer.

+[no]comments
Toggle the display of comment lines in the output. The default is to print comments.

+[no]stats
Toggle the printing of statistics: when the query was made, the size of the reply and so on. The default behaviour is to print the query statistics.

+[no]qr
Print [do not print] the query as it is sent. By default, the query is not printed.

+[no]question
Print [do not print] the question section of a query when an answer is returned. The default is to print the question section as a comment.

+[no]answer
Display [do not display] the answer section of a reply. The default is to display it.

+[no]authority
Display [do not display] the authority section of a reply. The default is to display it.

+[no]additional
Display [do not display] the additional section of a reply. The default is to display it.

+[no]all
Set or clear all display flags.
+time=T
Sets the timeout for a query to T seconds. The default time out is 5 seconds. An attempt to
set T to less than 1 will result in a query timeout of 1 second being applied.

+tries=T
Sets the maximum number of UDP attempts to T. The default number is 3 (1 initial
attempt followed by 2 retries). If T is less than or equal to zero, the number of retries is
silently rounded up to 1.

+retry=T
Sets the number of UDP retries to T. The default is 2.

+ndots=D
Set the number of dots that have to appear in name to D for it to be considered absolute.
The default value is that defined using the ndots statement in /etc/resolv.conf, or 1 if no
ndots statement is present. Names with fewer dots are interpreted as relative names and
will be searched for in the domains listed in the search or domain directive in
/etc/resolv.conf.

+bufsize=B
Set the UDP message buffer size advertised using EDNS0 to B bytes. The maximum and
minimum sizes of this buffer are 65535 and 0 respectively. Values outside this range are
rounded up or down appropriately.

+edns=#
Specify the EDNS version with which to query. Valid values are 0 to 255. Setting the EDNS
version causes a EDNS query to be sent. +noedns clears the remembered EDNS version.

+[no]multiline
Print records like the SOA records in a verbose multi-line format with human-readable
comments. The default is to print each record on a single line, to facilitate machine parsing
of the dig output.

+[no]fail
Do not try the next server if you receive a SERVFAIL. The default is to not try the next server
which is the reverse of normal stub resolver behavior.

+[no]besteffort
Attempt to display the contents of messages which are malformed. The default is to not
display malformed answers.

+[no]dnssec
Request DNSSEC records be sent by setting the DNSSEC OK bit (DO) in the OPT record in
the additional section of the query.

+[no]sigchase
Chase DNSSEC signature chains. Requires dig be compiled with -DDIG_SIGCHASE.
+trusted-key=####
  Specifies a file containing trusted keys to be used with +sigchase. Each DNSKEY record must
  be on its own line.

  If not specified dig will look for /etc/trusted-key.key then trusted-key.key in the
  current directory.

  Requires dig be compiled with -DDIG_SIGCHASE.

+[no]topdown
  When chasing DNSSEC signature chains, perform a top-down validation. Requires dig be
  compiled with -DDIG_SIGCHASE.

+[no]nsid
  Include an EDNS name server ID request when sending a query.

**Multiple Queries**

The BIND 9 implementation of dig supports specifying multiple queries on the command
line (in addition to supporting the -f batch file option). Each of those queries can be supplied
with its own set of flags, options and query options.

In this case, each query argument represent an individual query in the command-line syntax
described above. Each consists of any of the standard options and flags, the name to be looked
up, an optional query type, and class and any query options that should be applied to that
query.

A global set of query options, which should be applied to all queries, can also be supplied.
These global query options must precede the first tuple of name, class, type, options, flags, and
query options supplied on the command line. Any global query options (except the +{no}cmd
option) can be overridden by a query-specific set of query options. For example:

```bash
dig +qr www.isc.org any -x 127.0.0.1 isc.org ns +noqr
```

...shows how dig could be used from the command line to make three lookups: an ANY query
for www.isc.org, a reverse lookup of 127.0.0.1 and a query for the NS records of isc.org. A
global query option of +qr is applied, so that dig shows the initial query it made for each
lookup. The final query has a local query option of +noqr which means that dig will not print
the initial query when it looks up the NS records for isc.org.

**Files**

/etc/resolv.conf
  Resolver configuration file

${HOME}/.digrc
  User-defined configuration file

**Attributes**

RFC 1035

See the BIND 9 Administrator's Reference Manual. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Bugs  
There are probably too many query options.

Notes  
nslookup(1M) and dig now report "Not Implemented" as NOTIMP rather than NOTIMPL. This will have impact on scripts that are looking for NOTIMPL.
Name directoryserver – front end for the Directory Server (DS)

Synopsis 

`/usr/sbin/directoryserver`

`/usr/sbin/directoryserver help [subcommand]

Description The directoryserver command is a comprehensive, front end to the utility programs provided by the Solaris Directory Server (DS).

Options for the directoryserver command itself must appear before the subcommand. Arguments for a subcommand must appear after the subcommand. Subcommands have specific arguments. See SUBCOMMANDS.

Subcommands The following subcommands are supported:

account-inactivate args

Inactivates and locks an entry or group of entries.

The account-inactivate subcommand supports the following arguments:

[-D rootdn] Directory Server userDN with root permissions, such as Directory Manager.

[-h host] Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.

-I DN Entry DN or role DN to activate.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-j file</code></td>
<td>Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.</td>
</tr>
<tr>
<td><code>-w password</code></td>
<td>Password associated with the user DN. Supplying the password on the command line is visible using the <code>/bin/ps</code> command. This is considered insecure. Use with extreme caution. The value `- can be used in place the password. The program prompts the user for a password to be entered from the terminal.</td>
</tr>
</tbody>
</table>

**account-activate args**

Activates an entry or group of entries.

The `account-activate` subcommand supports the following arguments:

- `-D rootdn` Directory Server user DN with root permissions, such as Directory Manager.
- `-h host` Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.
- `-I DN` Entry DN or role DN to activate.
- `-j file` Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.
Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.

Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.

The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

Provides account status information to establish whether an entry or group of entries is inactivated or not.

The `account-status` subcommand supports the following arguments:

- `-D rootdn` Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.

- `-h host` Entry DN or role DN whose status is required.

- `-j file` Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.

- `-p port` Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.

- `-w password` Password associated with the rootDN. Supplying the password on the command line is visible using the
The value `-` can be used in place of the password. The program prompts the user for a password to be entered from the terminal.

**admin_ip args**
Change the IP address of the administrative server in the configuration.

The `admin_ip` subcommand supports the following arguments:

- `dir_mg_DN` Directory Manager's DN.
- `dir_mg_password` Directory Manager's password.
- `old_ip` Old IP.
- `new_ip` New IP.
- `port_#` Port number.

**bak2db backup_directory**
Restore the database from the most recent archived backup.

Specify `backup_directory` as the backup directory.

**bak2db-task args**
Restore the data to the database.

The `bak2db-task` subcommand supports the following arguments:

- `-a directory` Directory where the backup files are stored. By default it is under `/var/ds5/slapd-serverID/bak`
- `-D rootDN` User DN with root permissions, such as Directory Manager. The default is the DN of the directory manager which is read from the `nsslapd-root` attribute under `cn=config`.

/bin/ps command. This is considered insecure. Use with extreme caution.
- j file  Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.

This is considered insecure. Use with extreme caution.

[- t database_type]  Database type. The only possible database type is dbm.

[- v]  Verbose mode.

-w password  Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.

The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

db2bak-task args  Back up the contents of the database. It creates an entry in the directory that launches this dynamic task. An entry is generated based upon the values provided for each option.

The db2bak-task subcommand supports the following arguments:

[- a directory]  Directory where the backup files are stored. By default it is under /var/ds5/slapd-serverID/bak. The backup file is named according to the year-month-day-hour format (YYYY_MM_DD_hhmmss).

-D rootDN  User DN with root permissions, such as Directory
Manager. The default is the DN of the directory manager which is read from the \texttt{nsslapd-root} attribute under \texttt{cn=config}.

\texttt{-j file} \quad Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.

This is considered insecure. Use with extreme caution.

\texttt{-t database_type} \quad Database type. The only possible database type is \texttt{ldbm}.

\texttt{[-v]} \quad Verbose mode.

\texttt{-w password} \quad Password associated with the user DN. Supplying the password on the command line is visible using the \texttt{/bin/ps} command. This is considered insecure. Use with extreme caution.

The value \texttt{-} can be used in place the password. The program prompts the user for a password to be entered from the terminal.

db2bak [\texttt{backup_directory}] \quad Create a backup of the current database contents. The server must be stopped to run this subcommand.

The default is \texttt{/var/ds5/slapd-serverID/bak}. The backup file is named according to the year-month-day-hour format \texttt{(YYYY-MM-DD_hhmmss)}.

db2index-text \texttt{args} \quad Create and generate the new set of indexes to be maintained following the modification of indexing entries in the \texttt{cn=config} configuration file.

The \texttt{db2index-text} subcommand supports the following arguments:
-D rootdn User DN with root permissions, such as Directory Manager.

-j file Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.

-n backend_instance Instance to be indexed.

[-t attributeName] Name of the attribute to be indexed. If omitted, all indexes defined for that instance are generated.

[-v] Verbose mode.

-w password Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.

The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

db2ldif-task args Exports the contents of the database to LDIF. It creates an entry in the directory that launches this dynamic task. The entry is generated based upon the values you provide for each option. To run this subcommand the server must be running and either -n backend_instance or -s include suffix is required.

The db2ldif-task subcommand supports the following arguments:

[-a outputfile] File name of the output LDIF file.
-C  Only the main db file is used.

-0 rootDN  User DN with root permissions, such as Directory Manager.

-j file  Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.

[-M]  Output LDIF is stored in multiple files.

[-m]  Minimal base64 encoding.

{-n backend_instance}*  Instance to be exported.

[-N]  Minimal base64 encoding.

[-o]  Output LDIF to be stored in one file by default with each instance stored in instance_file name.

[-r]  Export replica.

[-s]includesuffix)*  Suffix(es) to be included or to specify the subtrees to be included if -n has been used.

[-u]  Request that the unique ID is not exported.

[-U]  Request that the output LDIF is not folded.

-w password  Password associated with the user DN. Supplying the password on the command line is visible
using the /bin/ps command. This is considered insecure. Use with extreme caution.

The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

[-x excludesuffix]* Suffixes to be excluded.
[-1] Delete, for reasons of backward compatibility the first line of the LDIF file that gives the version of the LDIF standard.

db2ldif args

Export the contents of the database to LDIF. You must specify either the -n or the -s option or both.

The db2ldif subcommand supports the following options:

[-a outputfile] Filename of the output LDIF file.
[-C] Only use the main db file.
[-m] Minimal base64 encoding.
[-M] Use of several files for storing the output LDIF with each instance stored in instance_file name (where file name is the file name specified for -a option).

[-n baclemd_instance]* Instance to be exported.
[-N] Specify that the entry IDs are not to be included in the LDIF output. The entry IDs are necessary
only if the `db2ldif` output is to be used as input to `db2index -text`.

[ -r ] Export replica.

[ -s includesuffix]* Suffixes to be included or to specify the subtrees to be included if -n has been used.

[[-x excludesuffix]* Suffixes to be excluded.

[ -u ] Request that the unique id is not exported.

[ -U ] Request that the output LDIF is not folded.

[ -l ] Delete, for reasons of backward compatibility, the first line of the LDIF file which gives the version of the LDIF standard.

help [subcommand] Display directoryserver usage message or subcommand specific usage message.

idsktune args Provide an easy and reliable way of checking the patch levels and kernel parameter settings for your system. You must install the Directory Server before you can run idsktune. It gathers information about the operating system, kernel, and TCP stack to make tuning recommendations.

The idsktune subcommand supports the following arguments:

[ -c ] Client-specific tuning: the output only includes tuning recommendations for running a directory client application.

[ -D ] Debug mode: the output includes the commands it runs internally, preceded by DEBUG heading.

[ -i installdir ] The install directory.
[-q] Quiet mode. Output only includes tuning recommendations. OS version statements are omitted.

[-v] Version. Gives the build date identifying the version of the toll.

keyupg args
Upgrade the key from Lite to normal (only one way).

The keyupg subcommand supports the following arguments:

- k key The key to be upgraded.
- f key_file_path The key file path.

ldif2db-task args
Import data to the directory. It create an entry in the directory that launches this dynamic task. The entry is generated based upon the values you provide for each option. The server must be running when you run this subcommand.

The ldif2db-task subcommand supports the following arguments:

- c Request that only the core db is created without attribute indexes.
- D rootDN User DN with root permissions, such as Directory Manager.
- g string Generation of a unique ID. Enter none for no unique ID to be generated and deterministic for the generated unique ID to be name-based. Generates a time-based unique ID by default.

If you use the deterministic generation to have a name-based unique ID, you can also
specify the namespace you want the server to use as follows:

- `g deterministic namespace_id`

where `namespace_id` is a string of characters in the following format:

00-xxxxxxxx-xxxxxxxx-xxxxxxxx-xxxxxxxx

Use this option if you want to import the same LDIF file into two different directory servers, and you want the contents of both directories to have the same set of unique IDs. If unique IDs already exist in the LDIF file you are importing, then the existing IDs are imported to the server regardless of the options you have specified.

[-G namespace_id] Generate a namespace ID as a name-based unique ID. This is the same as specifying `-g deterministic`.

{-i filename}* File name of the input LDIF files. When you import multiple files, they are imported in the order in which you specify them on the command line.

-j file Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.

-n backend_instance Instance to be imported.
[-0] Request that only the core db is created without attribute indexes.

[-s includesuffix] Suffixes to be included. This argument can also be used to specify the subtrees to be included with -n.

-w password Password associated with the user DN. Supplying the password on the command line is visible using the /bin/ps command. This is considered insecure. Use with extreme caution.

   The value - can be used in place the password. The program prompts the user for a password to be entered from the terminal.

[[-x excludesuffix]]

[-v] Verbose mode.

ldif args Format LDIF files, and create base 64 encoded attribute values. With Base 64 Encoding you can represent binary data, such as a JPEG image, in LDIF by using base 64 encoding. You identify base 64 encoded data by using the :: symbol. The ldif subcommand takes any input and formats it with the correct line continuation and appropriate attribute information. The subcommand also senses whether the input requires base 64 encoding.

   The ldif subcommand supports the following arguments

[-b] Interpret the entire input as a single binary value. If -b is not present, each line is considered to be a separate input value.

[attrtype] If -b is specified, the output is attrtype:: <base 64 encoded
value.

ldif2db args

Import the data to the directory. To run this subcommand the server must be stopped. Note that ldif2db supports LDIF version 1 specifications. You can load an attribute using the URL specifier notation, for example:

jpegphoto:file:///tmp/myphoto.jpg

[-c] Merge chunk size.

[-g string] Generation of a unique ID. Type none for no unique ID to be generated and deterministic for the generated unique ID to be name-based. By default a time-based unique ID is generated.

If you use the deterministic generation to have a name-based unique ID, you can also specify the namespace you want the server to use as follows:

-g deterministic namespace_id

where namespace_id is a string of characters in the following format:

00-xxxxxxxx-xxxxxxxx-xxxxxxxx-xxxxxxxx

Use this option if you want to import the same LDIF file into two different directory servers, and you want the contents of both directories to have the same set of unique IDs. If unique IDs already exist in the LDIF file you are importing, then the existing IDs are imported to the server regardless of the options you have specified.
Generate a namespace ID as a name-based unique ID. This is the same as specifying the -g deterministic option.

File name of the input LDIF file(s). When you import multiple files, they are imported in the order in which you specify them on the command line.

Instance to be imported.

Request that only the core db is created without attribute indexes.

Suffixes to be included or to specify the subtrees to be included if -n has been used.

Suffixes to be excluded

Perform an import operation over LDAP to the Directory Server. To run this subcommand the server must be running.

The ldif2ldap subcommand supports the following arguments:

- User DN with root permissions, such as Directory Manager.
- Password associated with the user DN.
- File name of the file to be imported. When you import multiple files, they are imported in the order in which you specify them on the command line.

Start SNMP master agent. The Config and INIT files are in /usr/iplanet/ds5/plugins/snmp/magt. For more information, see the iPlanet Directory Server 5.1 Administrator's Guide.

The magt subcommand supports the following options:
The CONFIG file defines the community and the manager that master agent works with. Specify the manager value as a valid system name or an IP address.

The INIT file is a nonvolatile file that contains information from the MIB-II system group, including system location and contact information. If INIT doesn’t already exist, starting the master agent for the first time creates it. An invalid manager name in the CONFIG file causes the master agent start-up to fail.

Retrieves performance monitoring information using the ldapsearch command-line utility.

Combine multiple LDIF files into a single authoritative set of entries. Typically each LDIF file is from a master server cooperating in a multi master replication agreement. [e.g. masters that refuse to sync up for whatever reason]. Optionally, it can generate LDIF change files that could be applied to original to bring it up to date with authoritative. At least two input files must be specified.

The mmldif subcommand supports the following arguments:

- \[-c inputfile ...\] Write a change file (.delta) for each input file. Specify inputfile as the input LDIF files.
- \[-D\] Print debugging information.
- \[-o out.ldif\] Write authoritative data to this file.

Convert one language encoding to another. For example, convert a native language to UTF-8 format.

The nativetoascii subcommand supports the following options:

- \[-d Encodings Directory\] Path to the
directory which contains the conv directory

[-i input_filename -o output_filename] The input file name and output file name.

-\l List supported encodings

-\r Replace existing files.

-\s suffix Suffix to be mapped to the backend.

-\s SourceEncoding Source Encoding of input stream.

-\t TargetEncoding Target Encoding of output stream.

-\v Verbose output.

pwdhash args Print the encrypted form of a password using one of the server’s encryption algorithms. If a user cannot log in, you can use this script to compare the user’s password to the password stored in the directory.

The pwdhash subcommand supports the following arguments:
The available schemes are SSHA, SHA, CRYPT and CLEARE. It generates the encrypted passwords according to scheme's algorithm. The -c specifies the encrypted password to be compared with. The result of comparison is either OK or doesn't match.

-D instance-dir

The instance directory.

[-H]

The passwords are hex-encoded.

password ...

The clear passwords to generate encrypted form from or to be compared with.

restart

Restarts the directory server.

When the -s option is not specified, restarts all instances of servers. When the -s option is specified, restarts the server specified by -s.

restart-admin

Restarts the administration server.

restoreconfig

Restores the most recently saved Administration Server configuration information to the NetscapeRoot partition under /var/ds5/slapd-serverID/confbak.

sagt -c CONFIG

Start proxy SNMP agent. For more information, see the *iPlanet Directory Server 5.1 Administrator's Guide*.

The sagt subcommand supports the following options:
-c configfile The CONFIG file includes the port that the SNMP daemon listens to. It also needs to include the MIB trees and traps that the proxy SNMP agent forwards. Edit the CONFIG file located in /usr/iplanet/ds5/plugins/snmp/sagt.

saveconfig Saves the administration server configuration information to the /var/ds5/slapd-serverID/confbak directory.

setup [-f configuration_file] Configures an instance of the directory server or administration server. Creates a basic configuration for the directory server and the administrative server that is used to manage the directory.

The setup subcommand has two modes of operation. You can invoke it with a curses-based interaction to gather input. Alternatively, you can provide input in a configuration file using the -f option.

The setup subcommand supports the following option:

-f configuration_file

Specifies the configuration file for silent installation.

start Starts the directory server. When the -s option is not specified, starts servers of all instances. When the -s option is specified, starts the server instance specified by -s.

start-admin Starts the directory server.

When the -s option is not specified, restarts all instances of servers. When the -s option is specified, restarts the server specified by -s.

startconsole Starts the directory console.

stop Stops the directory server.

When the -s option is not specified, restarts all instances of servers. When the -s option is specified, restarts the server specified by -s.

stop-admin Stop the administration server.
suffix2instance [-s suffix]  Map a suffix to a backend name.

Specify -s suffix as the suffix to be mapped to the backend.

uninstall  Uninstalls the directory server and the administration server.

This subcommand stops servers of all instances and removes all the changes created by setup.

vlvindex args  Create virtual list view (VLV) indexes, known in the Directory Server Console as Browsing Indexes. The server must be stopped beforehand.

The vlvindex subcommand supports the following arguments:

-\(d\) debug_level  Specify the debug level to use during index creation. Debug levels are defined in nsslapd-errorlog-level (error Log Level). See the iPlanet Directory Server 5.1 Configuration, Command, and File Reference.

-\(n\) backend_instance  Name of the database containing the entries to index.

-\(s\) suffix  Name of the suffix containing the entries to index.

-\(T\) VLVTag  Name of the database containing the entries to index.

**Options**  Options for the directoryserver command itself must appear before the subcommand argument.

The following options are supported:

-\(s\) server-instance  The server instance name. Specify the directory server instance to process the command against. For some of the listed subcommands the server instance is optional and for other sub
commands it is a required option.

**Examples**

**EXAMPLE 1** Starting All Instances of the Directory Servers

The following command starts all the instances of the directory servers:

```bash
example% directoryserver start
```

**EXAMPLE 2** Starting the Instances of myhost of the Directory Server

The following command starts the instances myhost of the directory server.

```bash
example% directoryserver -s myhost start
```

**EXAMPLE 3** Running the Monitor Tool and Outputting the Current Status

The following command runs the monitor tool and output the current status of the ephesus directory instance.

```bash
example% directoryserver -s ephesus monitor
```

**EXAMPLE 4** Running the idsktune Tool and Outputting Performance Tuning Information

The following command runs the idsktune tool and outputs performance tuning information:

```bash
example% directoryserver idsktune
```

**Exit Status**

The following exit values are returned:

- 0 Success. 
- non-zero An error occurred.

*iPlanet Directory Server 5.1 Administrator's Guide*

*iPlanet Directory Server 5.1 Configuration, Command, and File Reference*
The `diskinfo` command enables a system administrator or suitably privileged user to view the relationship between disk paths and bays (also known as "slots") for devices that are enumerated by `libtopo`. These are typically JBODs and direct-attached devices in blade systems.

There are three modes of operation: disk, enclosure, and chassis. Both the disk and enclosure modes require that the user specify a Solaris device name to identify which part of a machine's configuration to report information about. The chassis method requires that the user specify a Chassis Serial Number (CSN). Both the enclosure and chassis modes then allow limiting the output to devices in specific bays of the enclosure.

Various other options can also be specified, to report different levels of detail about the selected devices. This detail might include:
- the list of physical paths to the device
- SCSI Inquiry information
- the silkscreen label
- devid information

Options

One of the following four mutually-exclusive options must be specified:

- `-a`
  - Probe and report on all attached enclosures.

- `-d disk`
  - Report which enclosure, subchassis, and bay a specific disk is housed in. The disk name is specified using the cXtYdZ notation or the silkscreen label as reported by `libtopo`.

- `-e enclosure`
  - Limit output to bays and disks in a specific enclosure. The enclosure name is specified as `/dev/es/sesN` when using the `ses(7D)` driver, or `/dev/scsi/ses/cXtY` when using the `sgen(7D)` driver.

- `-C CSN`
  - Limit output to bays and disks in an enclosure with the specified Chassis Serial Number (CSN). For direct-attached HBAs, this can be a synthetic CSN, composed of the system serial number, then a physical or logical designation, then an instance number. For example: `YB09F7-physical-hba-0` or `YB09F7-logical-hba-2`.

In conjunction with the preceding options, the following options can also be specified:

- `-B label`
  - Limits information to the bay that matches label. This option also requires specifying a CSN (-C) or enclosure path (-e).
- b j
Limit the reported information to this specific bay number in the specified enclosure. This option is valid only with the - e or - C options.

**Caution** – This option might significantly slow down the response from the utility if the enclosure contains a large number of elements, especially subchassis. If the specified enclosure or CSN has subchassis elements, then the - c argument must also be specified with this option.

- c i
For enclosures that utilize subchassis elements, limit the reported information to the specified subchassis. This option is valid only with the - e or - C options.

**Caution** – This option might significantly slow down the response from the utility.

- h
Displays a brief usage message.

- L
Toggle the Identification LED for the specified disk, or for the specified bay in the enclosure. See NOTES below.

- p
Display physical path mapping for the specified disk. This option is not valid with the - e or - a operating modes.

- v
Display all available information for the device. All identified paths to the device and target port identifiers will be listed, along with the device devid and SCSI INQUIRY-reported serial number. This option is valid with all the operating modes of - a, - C, - d and - e.

**Examples**

In some of the following examples, example output wraps in an 80-character-wide display.

**EXAMPLE 1** Determining Which Bay
The following command determines which bay a specific disk resides in.

```
# /usr/sbin/diskinfo -d c0t5000C5000B2330F7d0
```

**EXAMPLE 2** Reporting Disks in an Enclosure
The following command reports all the disks within an enclosure.

```
Enclosure path: /dev/scsi ses/c11t50016360000AA5FDd0
Chassis Serial Number: 08480AJ001

The SCSI Storage Interfaces committee website, http://www.t10.org

SCSI Primary Commands-4, SPC4; SCSI Enclosure Services-2; SES2, Serial Attached SCSI-2, SAS2
The enumeration libraries that /usr/sbin/diskinfo depends on require that enclosures behave in a standards-compliant (SPC4 and SES2) fashion. Enclosures that do not respond appropriately might not report slots or disk nodes to FMA correctly. Specifically, diskinfo requires that enclosures support SES diagnostic page 0xa (Additional Element Status) and set the Element Index Present (EIP) bit to 1. Enclosures that do not meet this criteria are not enumerable and will not be properly visible with FMA or /usr/sbin/diskinfo.

LED support is not included in the initial integration of this utility.
disks – creates /dev entries for hard disks attached to the system

**Synopsis**  
/usr/sbin/disks [-C] [-r rootdir]

**Description**  
`devfsadm(1M)` is now the preferred command for `/dev` and should be used instead of `disks`. `disks` creates symbolic links in the `/dev/dsk` and `/dev/rdsk` directories pointing to the actual disk device special files under the `/devices` directory tree. It performs the following steps:

1. `disks` searches the kernel device tree to see what hard disks are attached to the system. It notes the `/devices` pathnames for the slices on the drive and determines the physical component of the corresponding `/dev/dsk` or `/dev/rdsk` name.

2. The `/dev/dsk` and `/dev/rdsk` directories are checked for disk entries – that is, symbolic links with names of the form `cN[tN]dNsN`, or `cN[tN]dNpN`, where `N` represents a decimal number. `cN` is the logical controller number, an arbitrary number assigned by this program to designate a particular disk controller. The first controller found on the first occasion this program is run on a system, is assigned number 0. `tN` is the bus-address number of a subsidiary controller attached to a peripheral bus such as SCSI or IPI (the target number for SCSI, and the facility number for IPI controllers). `dNsN` is the number of the disk attached to the controller. `sN` is the slice number on the disk. `pN` is the FDISK partition number used by `fdisk(1M)` (x86 Only)

3. If only some of the disk entries are found in `/dev/dsk` for a disk that has been found under the `/devices` directory tree, `disks` creates the missing symbolic links. If none of the entries for a particular disk are found in `/dev/dsk`, `disks` checks to see if any entries exist for other disks attached to the same controller, and if so, creates new entries using the same controller number as used for other disks on the same controller. If no other `/dev/dsk` entries are found for slices of disks belonging to the same physical controller as the current disk, `disks` assigns the lowest-unused controller number and creates entries for the disk slices using this newly-assigned controller number.

`disks` is run automatically each time a reconfiguration-boot is performed or when `add_drv(1M)` is executed. When invoking `disks(1M)` manually, first run `drvconfig(1M)` to ensure `/devices` is consistent with the current device configuration.

**Notice to Driver Writers**  
`disks` considers all devices with a node type of `DDI_NT_BLOCK`, `DDI_NT_BLOCK_CHAN`, `DDI_NT_CD`, `DDI_NT_BLOCK_WWN` or `DDI_NT_CD_CHAN` to be disk devices. `disks(1M)` requires the minor name of disk devices obey the following format conventions.

The minor name for block interfaces consists of a single lowercase ASCII character, a through u. The minor name for character (raw) interfaces consists of a single lowercase ASCII character, a through u, followed by , raw.

`disks` translates a through p to s0 through s15, while it translates q through u to p0 through p4. SPARC drivers should only use the first 8 slices: a through h, while x86 drivers can use a through u, with q through u corresponding to `fdisk(1M)` partitions. q represents the entire disk, while r, s, t, and u represent up to 4 additional partitions.
To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using a node type: DDI_NT_BLOCK, DDI_NT_BLOCK_CHAN, DDI_NT_CD, or DDI_NT_CD_CHAN when calling ddi_create_minor_node(9F).

### Options

The following options are supported:

- **-C**
  Causes disks to remove any invalid links after adding any new entries to /dev/dsk and /dev/rdsk. Invalid links are links which refer to non-existent disk nodes that have been removed, powered off, or are otherwise inaccessible.

- **-r rootdir**
  Causes disks to presume that the /dev/dsk, /dev/rdsk and /devices directory trees are found under rootdir, not directly under /.

### Errors

If disks finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the /dev directory, since it cannot determine which of the two alternative logical-to-physical mappings is correct. The links should be manually corrected or removed before another reconfiguration-boot is performed.

### Examples

#### EXAMPLE 1 Creating Block and Character Minor Devices

The following example demonstrates creating the block and character minor devices from within the xkdisk driver’s attach(9E) function.

```c
#include <sys/dkio.h>

/*
 * Create the minor number by combining the instance number
 * with the slice number.
 */
#define MINOR_NUM(i, s) ((i) << 4 | (s))

int xkdiskattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, slice;
    char name[8];

    /* other stuff in attach... */

    instance = ddi_get_instance(dip);
    for (slice = 0; slice < V_NUMPAR; slice++) {
        /* create block device interface */
        sprintf(name, "%c", slice + 'a');
        ddi_create_minor_node(dip, name, S_IFBLK,
                               MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);
    }
}
```

man pages section 1M: System Administration Commands • Last Revised 7 Nov 2002
/*
 * create the raw (character) device interface
 */
sprintf(name, "%c,raw", slice + 'a');
ddi_create_minor_node(dip, name, S_IFCHR,
    MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);

Installing the xkdisk disk driver on a Sun Fire 4800, with the driver controlling a SCSI disk
(target 3 attached to an isp(7D) SCSI HBA) and performing a reconfiguration-boot (causing
disks to be run) creates the following special files in /devices.

```bash
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isptwo@4/
brw-r----- 1 root sys 32, 16 Aug 29 00:02 xkdisk@3,0:a
crw-r----- 1 root sys 32, 16 Aug 29 00:02 xkdisk@3,0:a,raw
brw-r----- 1 root sys 32, 17 Aug 29 00:02 xkdisk@3,0:b
brw-r----- 1 root sys 32, 17 Aug 29 00:02 xkdisk@3,0:b,raw
brw-r----- 1 root sys 32, 18 Aug 29 00:02 xkdisk@3,0:c
crw-r----- 1 root sys 32, 18 Aug 29 00:02 xkdisk@3,0:c,raw
brw-r----- 1 root sys 32, 19 Aug 29 00:02 xkdisk@3,0:d
brw-r----- 1 root sys 32, 19 Aug 29 00:02 xkdisk@3,0:d,raw
brw-r----- 1 root sys 32, 20 Aug 29 00:02 xkdisk@3,0:e
crw-r----- 1 root sys 32, 20 Aug 29 00:02 xkdisk@3,0:e,raw
brw-r----- 1 root sys 32, 21 Aug 29 00:02 xkdisk@3,0:f
brw-r----- 1 root sys 32, 21 Aug 29 00:02 xkdisk@3,0:f,raw
brw-r----- 1 root sys 32, 22 Aug 29 00:02 xkdisk@3,0:g
brw-r----- 1 root sys 32, 22 Aug 29 00:02 xkdisk@3,0:g,raw
brw-r----- 1 root sys 32, 23 Aug 29 00:02 xkdisk@3,0:h
crw-r----- 1 root sys 32, 23 Aug 29 00:02 xkdisk@3,0:h,raw
```

/dev/dsk will contain the disk entries to the block device nodes in /devices

```bash
# ls -l /dev/dsk
/dev/dsk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a
/dev/dsk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b
/dev/dsk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c
/dev/dsk/c0t3d0s3 -> ../../devices/[...]/xkdisk@3,0:d
/dev/dsk/c0t3d0s4 -> ../../devices/[...]/xkdisk@3,0:e
/dev/dsk/c0t3d0s5 -> ../../devices/[...]/xkdisk@3,0:f
/dev/dsk/c0t3d0s6 -> ../../devices/[...]/xkdisk@3,0:g
/dev/dsk/c0t3d0s7 -> ../../devices/[...]/xkdisk@3,0:h
```

and /dev/rdsk will contain the disk entries for the character device nodes in /devices
EXAMPLE 1  Creating Block and Character Minor Devices  (Continued)

# ls -1 /dev/rdsk
/dev/rdsk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a,raw
/dev/rdsk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b,raw
/dev/rdsk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c,raw
/dev/rdsk/c0t3d0s3 -> ../../devices/[...]/xkdisk@3,0:d,raw
/dev/rdsk/c0t3d0s4 -> ../../devices/[...]/xkdisk@3,0:e,raw
/dev/rdsk/c0t3d0s5 -> ../../devices/[...]/xkdisk@3,0:f,raw
/dev/rdsk/c0t3d0s6 -> ../../devices/[...]/xkdisk@3,0:g,raw
/dev/rdsk/c0t3d0s7 -> ../../devices/[...]/xkdisk@3,0:h,raw

Writing Device Drivers

Bugs  disks silently ignores malformed minor device names.
**Name**
diskscan – perform surface analysis

**Synopsis**
diskscan [-W] [-n] [-y] raw_device

**Description**
diskscan is used by the system administrator to perform surface analysis on a portion of a hard disk. The disk portion may be a raw partition or slice; it is identified using its raw device name. By default, the specified portion of the disk is read (non-destructive) and errors reported on standard error. In addition, a progress report is printed on standard out. The list of bad blocks should be saved in a file and later fed into addbadsec(1M), which will remap them.

**Options**
The following options are supported:

- **-n** Causes diskscan to suppress linefeeds when printing progress information on standard out.
- **-W** Causes diskscan to perform write and read surface analysis. This type of surface analysis is destructive and should be invoked with caution.
- **-y** Causes diskscan to suppress the warning regarding destruction of existing data that is issued when -W is used.

**Operands**
The following operands are supported:

- **raw_device** The address of the disk drive (see FILES).

**Files**
The raw device should be /dev/rdsk/c?[t?]d?[ps]? or /dev/rdsk/g?[t?]l?[ps]? or /dev/rdsk/r?[t?]s?[ps]? or /dev/rdsk/t?[t?]t?[ps]?. See disks(1M) for an explanation of SCSI and IDE device naming conventions.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>

<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**
addbadsec(1M), disks(1M), fdisk(1M), fmthard(1M), format(1M), attributes(5)

**Notes**
The format(1M) utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the diskscan, addbadsec(1M), fdisk(1M), and fmthard(1M) commands available for x86. To format an IDE disk, use the DOS format utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris format(1M) utility.
The `dispadmin` command displays or changes process scheduler parameters while the system is running.

dispadmin does limited checking on the values supplied in file to verify that they are within their required bounds. The checking, however, does not attempt to analyze the effect that the new values have on the performance of the system. Inappropriate values can have a negative effect on system performance. (See System Administration Guide: Basic Administration)

The following options are supported:

- **-c class** Specifies the class whose parameters are to be displayed or changed. Valid class values are: RT for the real-time class, TS for the time-sharing class, IA for the inter-active class, FSS for the fair-share class, and FX for the fixed-priority class. The time-sharing and inter-active classes share the same scheduler, so changes to the scheduling parameters of one will change those of the other.

- **-d [class]** Sets or displays the name of the default scheduling class to be used on reboot when starting svc:/system/scheduler:default. If class name is not specified, the name and description of the current default scheduling class is displayed. If class name is specified and is a valid scheduling class name, then it is saved in dispadmin's private configuration file /etc/dispadmin.conf. Only super-users can set the default scheduling class.

- **-g** Gets the parameters for the specified class and writes them to the standard output. Parameters for the real-time class are described in rt_dptbl(4). Parameters for the time-sharing and inter-active classes are described in ts_dptbl(4). Parameters for the fair-share class are described in FSS(7). Parameters for the fixed-priority class are described in fx_dptbl(4).

The -g and -s options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.

- **-l** Lists the scheduler classes currently configured in the system.

- **-r res** When using the -g option you may also use the -r option to specify a resolution to be used for outputting the time quantum values. If no resolution is specified, time quantum values are in milliseconds. If res is specified it must be a positive integer between 1 and 1000000000 inclusive, and the resolution used is the reciprocal of res in seconds. For example, a res value of 10 yields time quantum values expressed in tenths of a second; a res value of 1000000 yields time quantum values expressed in microseconds. If the time quantum cannot be
expressed as an integer in the specified resolution, it is rounded up to the next integral multiple of the specified resolution.

- **s file**  
Sets scheduler parameters for the specified class using the values in file. These values overwrite the current values in memory—they become the parameters that control scheduling of processes in the specified class. The values in file must be in the format output by the -g option. Moreover, the values must describe a table that is the same size (has same number of priority levels) as the table being overwritten. Super-user privileges are required in order to use the -s option.

Specify time quantum values for scheduling classes in system clock ticks, and not in constant-time units. Time quantum values are based on the value of the kernel’s hz variable. If kernel variable hires_tick is set to 1 to get higher resolution clock behavior, the actual time quanta will be reduced by the order of 10.

The -g and -s options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.

**Examples**

**EXAMPLE 1**  
Retrieving the Current Scheduler Parameters for the real-time class

The following command retrieves the current scheduler parameters for the real-time class from kernel memory and writes them to the standard output. Time quantum values are in microseconds.

```
dispadmin -c RT -g -r 1000000
```

**EXAMPLE 2**  
Overwriting the Current Scheduler Parameters for the Real-time Class

The following command overwrites the current scheduler parameters for the real-time class with the values specified in rt.config.

```
dispadmin -c RT -s rt.config
```

**EXAMPLE 3**  
Retrieving the Current Scheduler Parameters for the Time-sharing Class

The following command retrieves the current scheduler parameters for the time-sharing class from kernel memory and writes them to the standard output. Time quantum values are in nanoseconds.

```
dispadmin -c TS -g -r 1000000000
```

**EXAMPLE 4**  
Overwriting the Current Scheduler Parameters for the Time-sharing Class

The following command overwrites the current scheduler parameters for the time-sharing class with the values specified in ts.config.

```
dispadmin -c TS -s ts.config
```
dispadmin(1M)

System Administration Guide: Basic Administration Programming Interfaces Guide

Diagnostics  dispadmin prints an appropriate diagnostic message if it fails to overwrite the current scheduler parameters due to lack of required permissions or a problem with the specified input file.

Notes  The default scheduling class setting facility is managed by the service management facility, smf(5), under the service identifier:

svc:/system/scheduler:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Note that disabling the service while it is running will not change anything. The service’s status can be queried using the svcs(1) command.
dladm – configure data-link interfaces

**Synopsis**

dladm show-link [-s [-i interval]] [-p] [name]
dladm show-dev [-s [-i interval]] [-p] [dev]
dladm delete-aggr [-t] [-R root-dir] key
dladm add-aggr [-t] [-R root-dir] -d dev [-d dev] ... key
dladm remove-aggr [-t] [-R root-dir] -d dev [-d dev] ... key
dladm show-aggr [-L] [-s [-i interval]] [-p] [key]
dladm set-linkprop [-t] [-R root-dir] -p prop=value[, ...] name
dladm reset-linkprop [-t] [-R root-dir] [-p prop, ...] name
dladm show-linkprop [-cP] [-p prop, ...] [name]
dladm -?

**Description**

The `dladm` command is used to configure data-links. A configured data-link is represented in the system as a STREAMS DLPI (v2) interface which may be plumbed under protocol stacks such as TCP/IP. Each data-link relies on either a single network device or an aggregation of devices to send packets to or receive packets from a network.

The `dladm` command operates on the following kinds of objects:

- **link**
  - Data-links, identified by a name. A name is a maximum of 30 characters. The first character must be alphabetic, the last numeric.

- **aggr**
  - Aggregations of network devices, identified by a key.

- **dev**
  - Network devices, identified by concatenation of a driver name and an instance number.

The behavior of the linkprop subcommands depends on the type of link and underlying device, currently only one linkprop, “zone” is supported.

Some devices do not support configurable data-links or aggregations. The fixed data-links provided by such devices can be viewed using `dladm`, but can not be configured.

**SUBCOMMANDS**

The following subcommands are supported:
show-link
Show configuration information for all data-links or the specified data-link. By default, the system is configured to have one data-link for each known network device.

show-dev
Shows information for all devices or the specified device.

create-aggr
Creates an aggregation using the given key value from as many dev objects as are specified. A data-link is created by default, and is given a name which is the concatenation of “aggr” and the key value of the aggregation.

delete-aggr
Deletes the specified aggregation.

add-aggr
Adds as many dev objects as are specified to the given aggregation.

remove-aggr
Removes as many dev objects as are specified from the given aggregation.

modify-aggr
Modifies the parameters of the given aggregation.

show-aggr
Shows configuration information for all aggregations or the specified aggregation.

set-linkprop
Sets the values of one or more properties on the link specified by name. The list of properties and their possible values depend on the link type, the network device driver, and networking hardware, but can be retrieved using show-linkprop.

reset-linkprop
Resets one or more properties to their values on the link specified by name. If no properties are specified, all properties are reset.

show-linkprop
Show the current values of one or more properties, either for all data-links or for the specified link name. If no properties are specified, all available link properties are displayed.

Options
The following options are supported:

-k key
--key=key
The key of an aggregation. This must be an integer value between 1 and 999.

-d dev
--dev=dev
A device specifier. This must be a concatenation of the name and instance of the driver bound to the device.
-P policy
  --policy=policy
  Specifies the port selection policy to use for load spreading of outbound traffic. The policy specifies which dev object is used to send packets. A policy consists of a list of one or more layers specifiers separated by commas. A layer specifier is one of the following:

  L2
  Select outbound device according to source and destination MAC addresses of the packet.

  L3
  Select outbound device according to source and destination IP addresses of the packet.

  L4
  Select outbound device according to the upper layer protocol information contained in the packet. For TCP and UDP, this includes source and destination ports. For IPsec, this includes the SPI (Security Parameters Index.)

In the absence of a policy specification, dladm uses the default, L4.

As an example of use of the Lnum identifiers, to use upper layer protocol information, specify the following policy:

  -P L4

Note that, as the default, specification of L4 is superfluous.

To use the source and destination MAC addresses as well as the source and destination IP addresses, the following policy can be used:

  -P L2, L3

-\ mode
  --lacp-mode=mode
  Specifies whether LACP should be used and, if used, the mode in which it should operate. Legal values are off, active or passive.

-\ time
  --lacp-timer=time
  Specifies the LACP timer value. The legal values are short or long.

-\ address
  --unicast=address
  Specifies a fixed unicast address to be used for the aggregation. If this option is not specified then an address is automatically chosen from the set of addresses of the component devices.

-\ lacp
  Specifies whether detailed LACP information should be displayed.
-s
--statistics
Used with the show-link, show-aggr, or show-dev subcommands to show the statistics of
data-links, aggregations or devices, respectively.

-i interval
--interval=interval
Used with the -s option to specify an interval, in seconds, at which statistics should be
displayed. If this option is not specified, statistics will only be displayed once.

-t
--temporary
Specifies that the change is temporary. Temporary changes last until the next reboot.

-R root-dir
--root-dir=root-dir
Specifies an alternate root directory where dladm applies changes. This can be useful in
JumpStart scripts, where the root directory of the system being modified is mounted
elsewhere.

-p
--parseable
Specifies that configuration information should be displayed in parseable format.

-?
--help
Displays help information. (Stops interpretation of subsequent arguments).

The following link properties listed below are supported. Note that these properties can be
modified only temporarily through dladm, and thus the -t option must be specified. See the
NOTES section for instructions on how to make property values persistent.

zone
Specifies the zone to which the link belongs. Possible values consist of any exclusive-IP
zone currently running on the system. By default, the zone binding is as per zonecfg(1M).

tagmode
This link property controls the conditions in which 802.1Q VLAN tags will be inserted in
packets being transmitted on the link. Two mode values can be assigned to this property:

normal
Insert a VLAN tag in outgoing packets under the following conditions:
  ■ The packet belongs to a VLAN.
  ■ The user requested priority tagging.

vlanonly
Insert a VLAN tag only when the outgoing packet belongs to a VLAN. If a tag is being
inserted in this mode and the user has also requested a non-zero priority, the priority is
honored and included in the VLAN tag.
The default value is `vlanonly`.

### Examples

**EXAMPLE 1  Configuring an Aggregation**

To configure a data-link over an aggregation of devices `bge0` and `bge1` with key 1, enter the following command:

```
# dladm create-aggr -d bge0 -d bge1 1
```

### Attributes

</tr>
</tbody>
</table>
```

### See Also

`ifconfig(1M)`, `zonecfg(1M)`, `attributes(5)`, `smf(5)`, `dlpi(7P)`

### Notes

There are two ways to make values for link properties persistent across reboots:

- Using `rc` scripts.
- Writing a transient `smf(5)` service.

The second method, using `smf(5)`, is preferred.

To use the `rc` feature, perform steps such as the following:

1. Create a shell script, with permissions 744.
2. Store the script in `/etc/rc3.d`.
3. Inside the script, enter a command such as the following:

   ```
   /usr/sbin/dladm set-linkprop -t -p tagmode=vlanonly ce1
   ```

   In this example, it is the value for the `tagmode` property that is being made persistent. The interface `ce1` is also particular to this example. Your interface name might be different.

See `/etc/rc3.d /README` for further guidance.
The second, preferred means of making values persistent is to use the smf(5) facility. To do so, perform steps such as the following:

1. Compose a manifest file. The following is an example of such a file:

```xml
<service_bundle type='manifest' name='apply_linkprop'>
  <service name='network/apply_linkprop' type='service' version='1'>
    <instance name='default' enabled='true'>
      <dependency name='dlmgmtd' grouping='require_all' restart_ov='none' type='service'>
        <service_fmri value='svc:/network/datalink-management:default'/> 
      </dependency>
      <exec_method type='method' name='stop' exec=':true' timeout_seconds='3'/>
      <property_group name='startd' type='framework'>
        <propval name='duration' type='astring' value='transient'/> 
      </property_group>
    </instance>
    <stability value='Evolving' />
  </service>
</service_bundle>
```

Store this file in /lib/svc/manifest/network/.

2. Create a shell script in /lib/svc/method that contains:

```bash
/usr/sbin/dladm set-linkprop -t tagmode=vlanonly ce1
```

The property, tagmode, and interface name, ce1, are examples. Use the names appropriate for your system.

Any additional properties you want to make persistent should be added, as separate commands, to the preceding shell script. There is no need to create an additional manifest file.
**Name**  
dmesg – collect system diagnostic messages to form error log

**Synopsis**  
/usr/bin/dmesg  
/usr/sbin/dmesg

**Description**  
dmesg is made obsolete by syslogd(1M) for maintenance of the system error log.

dmesg looks in a system buffer for recently printed diagnostic messages and prints them on the standard output.

**Attributes**

The `dmi_cmd` utility provides the ability to:

- Obtain version information about the DMI Service Provider
- Set the configuration to describe the language required by the management application
- Obtain configuration information describing the current language in use for the session
- Install components into the database
- List components in a system to determine what is installed
- Delete an existing component from the database
- Install group schemas to an existing component in the database
- List class names for all groups in a component
- List the groups within a component
- Delete a group from a component
- Install a language schema for an existing component in the database
- List the set of language mappings installed for a specified component
- Delete a specific language mapping for a component
- List the properties for one or more attributes in a group

Note that this command is Obsolete.

**Options** The following options are supported:

- `-a attrId` Specify an attribute by its ID (positive integer). The default value is 0.
- `-AL` List the attributes for the specified component.
- `-c complId` Specify a component by its ID (positive integer). The default value is 0.
- `-CD` Delete the specified component.
- `-CI mif-file` Install the component described in the `mif-file`.
- `-CL` List component information.
- `-d` Display descriptions.
- `-g groupId` Specify a group by its ID (positive integer). The default value is 0.
- `-GD` Delete a group for the specified component.
- `-GI schema-file` Install the group schema specified in `schema-file`.
- `-GL` List the groups for the specified component.
- `-GM` List the class names for the specified component.
- `-h` Help. Print the command line usage.
- `-l language-string` Specify a language mapping.
- `-m max-count` Specify the maximum number of components to display.
- `-ND` Delete a language mapping for the specified component.
- `-NI schema-file` Install the language schema specified in `schema-file`.
- `-NL` List the language mappings for a specified component.
- `-p` Display the pragma string.
- `-r req-mode` Specify the request mode. The valid values are:

  1. DMI_UNIQUE - access the specified item (or table row).
  2. DMI_FIRST - access the first item.
  3. DMI_NEXT - access the next item.
The default request mode is `DMI_UNIQUE`.

- `-s hostname` Specify the host machine on which `dmispd` is running. The default host is the local host.

- `-V` Version. Prints version information about the DMI Service Provider.

- `-W config-file` Set the configuration specified in `config-file` to `dmispd`.

- `-X` Retrieve configuration information describing the current language in use.

**Exit Status**
The following error values are returned:

- `0` Successful completion.

- `-1` An error occurred.

**Attributes**

Name  dmiget – DMI command line retrieval utility

Synopsis  dmiget  -c compId [-a attrId] [-g groupId] [-s hostname]
          dmiget  -h

Description  The dmiget utility retrieves the table information of a specific component in the DMI Service Provider.

Options  The following options are supported:

- -a attrId  Display the attribute information for the component specified with the -c argument.
- -c compId  Display all the table information for the specified component.
- -g groupId  Display all the attribute information in the group specified with groupId for the component specified with the -c argument.
- -h  Help. Print the command line usage.
- -s hostname  Specify the host machine on which dmispd is running. The default host is the local host.

Exit Status  The following error values are returned:

0  Successful completion.
-1  An error occurred.

Name  dminfo – report information about a device entry in a device maps file

Synopsis  dminfo [-v] [-a] [-f pathname]
          dminfo [-v] [-a] [-f pathname] -n dev-name...
          dminfo [-v] [-a] [-f pathname] -d dev-path...
          dminfo [-v] [-a] [-f pathname] -t dev-type...
          dminfo [-v] [-f pathname] -u dm-entry

Description  dminfo reports and updates information about the device_maps(4) file.

Options  The following options are supported

   -a  Succeed if any of the requested entries are found. If used with -v, all entries
        that match the requested case(s) are printed.

   -d dev-path  Search by dev-path. Search device_maps(4) for a device special pathname in
                the device_list field matching the dev-path argument. This option cannot be
                used with -n, -t or -u.

   -f pathname  Use a device_maps file with pathname instead of
                /etc/security/device_maps.

   -n dev-name  Search by dev-name. Search device_maps(4) for a device_name field
                matching dev-name. This option cannot be used with -d, -t or -u.

   -t dev-type  Search by dev-type. Search device_maps(4) for a device_type field matching
                the given dev-type. This option cannot be used with -d, -n or -u.

   -u dm-entry  Update the device_maps(4) file. This option is provided to add entries to the
                device_maps(4) file. The dm-entry must be a complete device_maps(4) file
                entry. The dm-entry has fields, as in the device_maps file. It uses the colon
                (:) as a field separator, and white space as the device_list subfield separators.
                The dm-entry is not made if any fields are missing, or if the dm-entry would
                be a duplicate. The default device maps file can be updated only by the super
                user.

   -v  Verbose. Print the requested entry or entries, one line per entry, on the
        standard output. If no entries are specified, all are printed.

Exit Status  0  Successful completion.
        1  Request failed.
        2  Incorrect syntax.

Files  /etc/security/device_maps

Notes  The functionality described in this man page is available only if the Solaris Auditing feature has been enabled. See bsmconv(1M) for more information.
**Name**
dmispd – Sun Solstice Enterprise DMI Service Provider

**Synopsis**
```
/usr/lib/dmi/dmispd [-h] [-c config-dir] [-d debug-level]
```

**Description**
The DMI Service Provider, dmispd, is the core of the DMI solution. Management applications and Component instrumentations communicate with each other through the Service Provider. The Service Provider coordinates and arbitrates requests from the management application to the specified component instrumentations. The Service Provider handles runtime management of the Component Interface (CI) and the Management Interface (MI), including component installation, registration at the MI and CI level, request serialization and synchronization, event handling for CI, and general flow control and housekeeping.

The Service Provider is invoked from a start-up script at boot time only if contents of the DMI Service Provider configuration file `/etc/dmi/conf/dmispd.conf` are non-trivial.

**Options**
The following options are supported:

- `-c config-dir`
  Specify the full path of the directory containing the `dmispd.conf` configuration file. The default directory is `/etc/dmi/conf`.

- `-d debug-level`
  Debug. Levels from 0 to 5 are supported, giving various levels of debug information. The default is 0, meaning no debug information is given.

  If this option is omitted, then `dmispd` is run as a daemon process.

- `-h`
  Help. Print the command line usage.

**Exit Status**
The following error values are returned:

- `0` Successful completion.
- `1` An error occurred.

**Files**
`/etc/dmi/conf/dmispd.conf` DMI Service Provider configuration file

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

### Name

dnssec-dsfromkey – DNSSEC DS RR generation tool

### Synopsis

### Description

**dnssec-dsfromkey**

The following options are supported:

- **-1**
  Use SHA-1 as the digest algorithm. The default is to use both SHA-1 and SHA-256.

- **-2**
  Use SHA-256 as the digest algorithm.

- **-a algorithm**
  Select the digest algorithm. The value of `algorithm` must be one of SHA-1 (SHA1) or SHA-256 (SHA256). These values are case-insensitive.

- **-v level**
  Sets the debugging level.

- **-s**
  Keyset mode: in place of the keyfile name, the argument is the DNS domain name of a keyset file. The `-c` and `-d` options have meaning only in this mode.

- **-c class**
  Specifies the DNS class (default is IN); useful only in the keyset mode.

- **-d directory**
  Look for keyset files in directory as the directory; ignored when not in the keyset mode.

### Examples

To build the SHA-256 DS RR from the `Kexample.com.+003+26160` keyfile name, use a command such as the following:

```
# dnssec-dsfromkey -2 Kexample.com.+003+26160
```

This command would produce output similar to the following:

```
example.com. IN DS 26160 5 2 3A1EADA7A74B8D0BA6726B0C227AA85A8B8B02B2004F41A868A54F0 C5EA0B94
```

### Files

The keyfile can be designated by the key identification `Knnnn.+aaa+iiiiii`, or the full file name `Knnnn.+aaa+iiiiii.key`, as generated by `dnssec-keygen(1M)`.

The keyset file name is built from the directory, the string `keyset-` and the `dnsname`.

RFC 3658, RFC 4509

See the BIND 9 Administrator’s Reference Manual. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Caution  A keyfile error can produce a “file not found” message, even if the file exists.
Name
dnssec-keyfromlabel – DNSSEC key generation tool

Synopsis
dnssec-keyfromlabel -a algorithm -l label [-c class] [-f flag] [-k]

[-n nametype] [-p protocol] [-t type] [-v level] name

Description
dnssec-keyfromlabel retrieves keys with a specified label from a crypto hardware device and
builds key files for DNSSEC (Secure DNS), as defined in RFC 2535 and RFC 4034.

Options
The following options are supported:

-a algorithm
Selects the cryptographic algorithm. The value of algorithm must be one of RSAMD5 (RSA)
or RSASHA1, DSA, NSEC3RSAHA1, NSEC3DSA, or DH (Diffie-Hellman). These values are
case-insensitive.

Note that for DNSSEC, RSASHA1 is a mandatory-to-implement algorithm, and DSA is
recommended. Note also that DH automatically sets the -k flag.

-l label
Specifies the label of keys in the crypto hardware (PKCS#11) device.

-n nametype
Specifies the owner type of the key. The value of nametype must either be ZONE (for a
DNSSEC zone key (KEY/DNSKEY)), HOST or ENTITY (for a key associated with a host (KEY)),
USER (for a key associated with a user (KEY)), or OTHER (DNSKEY). These values are
case-insensitive.

-c class
Indicates that the DNS record containing the key should have the specified class. If not
specified, class IN is used.

-f flag
Set the specified flag in the flag field of the KEY/DNSKEY record. The only recognized flag is
KSK (Key Signing Key) DNSKEY.

-h
Displays a short summary of the options and arguments to dnssec-keyfromlabel.

-k
Generate KEY records rather than DNSKEY records.

-p protocol
Sets the protocol value for the generated key. The protocol is a number between 0 and 255.
The default is 3 (DNSSEC). Other possible values for this argument are listed in RFC 2535
and its successors.

-t type
Indicates the use of the key. type must be one of AUTHCONF, NOAUTHCONF, NOAUTH, or NOCONF.
The default is AUTHCONF. AUTH refers to the ability to authenticate data, and CONF the ability
to encrypt data.
-v level
Sets the debugging level.

**Generated Key Files**

When `dnssec-keyfromlabel` completes successfully, it displays a string of the form `Knnnn.+aaa+iiiii` to the standard output. This is an identification string for the key files it has generated, which translates as follows:

- `nnnn` is the key name.
- `aaa` is the numeric representation of the algorithm.
- `iiiii` is the key identifier (or footprint).

`dnssec-keyfromlabel` creates two files, with names based on the displayed string. `Knnnn.+aaa+iiiii.key` contains the public key, and `Knnnn.+aaa+iiiii.private` contains the private key.

The first file contains a DNS KEY record that can be inserted into a zone file (directly or with an `$INCLUDE` statement).

The second file contains algorithm-specific fields. For obvious security reasons, this file does not have general read permission.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

RFC 2539, RFC 2845, RFC 4033

See the BIND 9 Administrator’s Reference Manual. As of the date of publication of this man page, this document is available at [https://www.isc.org/software/bind/documentation](https://www.isc.org/software/bind/documentation).
**Name**  
dnssec-keygen − DNSSEC key generation tool

**Synopsis**  
dnssec-keygen -a algorithm -b keysize -n nametype [ -ehk ]  
[ -c class ] [ -f flag ] [ -g generator ] [ -p protocol ]  
[ -r randomdev ] [ -s strength ] [ -t type ] [ -v level ] name

**Description**  
The dnssec-keygen utility generates keys for DNSSEC (Secure DNS), as defined in RFC 2535 and RFC 4034. It can also generate keys for use with TSIG (Transaction Signatures), as defined in RFC 2845.

The following options are supported:

- **-a algorithm**  
  Select the cryptographic algorithm. The value of algorithm must be one of RSAMD5 (RSA) or RSASHA1, DSA, NSEC3RSASHA1, NSEC3DSA, DH (Diffie-Hellman), or HMAC-MD5. These values are case insensitive.

  For DNSSEC, RSASHA1 is a mandatory-to-implement algorithm and DSA is recommended. For TSIG, HMAC-MD5 is mandatory.

  **Note** − HMAC-MD5 and DH automatically set the -k flag.

- **-b keysize**  
  Specify the number of bits in the key. The choice of key size depends on the algorithm used. RSAMD5 and RSASHA1 keys must be between 512 and 2048 bits. Diffie-Hellman keys must be between 128 and 4096 bits. DSA keys must be between 512 and 1024 bits and an exact multiple of 64. HMAC-MD5 keys must be between 1 and 512 bits.

- **-c class**  
  Indicate that the DNS record containing the key should have the specified class. If not specified, class IN is used.

- **-e**  
  Use a large exponent if generating an RSAMD5 or RSASHA1 key.

- **-f flag**  
  Set the specified flag in the flag field of the KEY/DNSKEY record. The only recognized flag is KSK (Key Signing Key) DNSKEY.

- **-g generator**  
  Use this generator if generating a Diffie Hellman key. Allowed values are 2 and 5. If no generator is specified, a known prime from RFC 2539 will be used if possible; otherwise the default is 2.

- **-h**  
  Print a short summary of the options and arguments to dnssec-keygen.

- **-k**  
  Generate KEY records rather than DNSKEY records.
-n nametype
   Specify the owner type of the key. The value of nametype must either be ZONE for a
   DNSSEC zone key (KEY/DNSKEY)), HOST or ENTITY (for a key associated with a host
   (KEY)), USER (for a key associated with a user(KEY)), or OTHER (DNSKEY). These values
   are case insensitive. Defaults to ZONE for DNSKEY generation.

-p protocol
   Set the protocol value for the generated key. The protocol argument is a number between 0
   and 255. The default is 3 (DNSSEC) Other possible values for this argument are listed in
   RFC 2535 and its successors.

-r randomdev
   Specify the source of randomness. If the operating system does not provide a /dev/random
   or equivalent device, the default source of randomness is keyboard input. randomdev
   specifies the name of a character device or file containing random data to be used instead of
   the default. The special value "keyboard" indicates that keyboard input should be used.

-s strength
   Specify the strength value of the key. The strength argument is a number between 0 and 15,
   and currently has no defined purpose in DNSSEC.

-t type
   Indicate the use of the key. type must be one of AUTHCONF, NOAUTHCONF, NOAUTH, or NOCONF.
   The default is AUTHCONF. AUTH refers to the ability to authenticate data, and CONF the ability
   to encrypt data.

-v level
   Set the debugging level.

Generated Keys
When dnssec-keygen completes successfully, it prints a string of the form Knmnn.++aaa+iiii
   to the standard output. This is an identification string for the key it has generated.

- nnnn is the key name.
- aaa is the numeric representation of the algorithm.
- iiili is the key identifier (or footprint).

The dnssec-keygen utility creates two files, with names based on the printed string.

- Knmnn.++aaa+iiii.key contains the public key.
- Knmnn.++aaa+iiii.private contains the private key.

The .key file contains a DNS KEY record that can be inserted into a zone file (directly or with a
$INCLUDE statement).

The .private file contains algorithm specific fields. For obvious security reasons, this file does
not have general read permission.

Both .key and .private files are generated for symmetric encryption algorithm such as
HMAC-MD5, even though the public and private key are equivalent.
**Examples**

**EXAMPLE 1** Generating a 768-bit DSA Key

To generate a 768-bit DSA key for the domain example.com, the following command would be issued:

dnssec-keygen -a DSA -b 768 -n ZONE example.com

The command would print a string of the form:

Kexample.com.+003+26160

The following files would be created:

Kexample.com.+003+26160.key
Kexample.com.+003+26160.private

*RFC 2539, RFC 2845, RFC 4033*

See the BIND 9 Administrator’s Reference Manual. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.
The `dnssec-signzone` utility signs a zone. It generates NSEC and RRSIG records and produces a signed version of the zone. The security status of delegations from the signed zone (that is, whether the child zones are secure or not) is determined by the presence or absence of a keyset file for each child zone.

### Options

The following options are supported:

- **-A**
  When generating an NSEC3 chain, set the OPTOUT flag on all NSEC3 records and do not generate NSEC3 records for insecure delegations.

- **-a**
  Verify all generated signatures.

- **-c class**
  Specify the DNS class of the zone.

- **-d directory**
  Look for keyset files in directory.

- **-e end-time**
  Specify the date and time when the generated RRSIG records expire. As with `start-time`, an absolute time is indicated in `YYYYMMDDHHMMSS` notation. A time relative to the start time is indicated with `+N`, which is `N` seconds from the start time. A time relative to the current time is indicated with `now+N`. If no `end-time` is specified, 30 days from the start time is used as a default.

- **-f output-file**
  The name of the output file containing the signed zone. The default is to append `.signed` to the input file name.

- **-g**
  Generate DS records for child zones from keyset files. Existing DS records will be removed.

- **-H iterations**
  When generating a NSEC3 chain use the number of iterations specified by `iterations`. The default is 100.

- **-h**
  Prints a short summary of the options and arguments to `dnssec-signzone()`.
-I input-format
   The format of the input zone file. Possible formats are text (default) and raw. This option
   is primarily intended for dynamic signed zones so that the dumped zone file in a non-text
   format containing updates can be signed directly. The use of this option serves no purpose
   for non-dynamic zones.

- i interval
   Specify the cycle interval as an offset from the current time (in seconds). When a previously
   signed zone is passed as input, records could be resigned. If an RRSIG record expires after
   the cycle interval, it is retained. Otherwise, it is considered to be expiring soon and will be
   replaced.

   The default cycle interval is one quarter of the difference between the signature end and
   start times. If neither end-time or start-time are specified, dnssec-signzone generates
   signatures that are valid for 30 days, with a cycle interval of 7.5 days. Any existing RRSIG
   records due to expire in less than 7.5 days would be replaced.

-j jitter
   When signing a zone with a fixed signature lifetime, all RRSIG records issued at the time of
   signing expire simultaneously. If the zone is incrementally signed, that is, a
   previously-signed zone is passed as input to the signer, all expired signatures have to be
   regenerated at about the same time. The jitter option specifies a jitter window that will be
   used to randomize the signature-expire time, thus spreading incremental signature
   regeneration over time.

   Signature lifetime jitter also benefits, to some extent, validators and servers by spreading
   out cache expiration. That is, if large numbers of RRSIGs from all caches do not expire at the
   same time, there will be less congestion than if all validators needed to refetch at almost the
   same time.

-k key
   Treat specified key as a key-signing key, ignoring any key flags. This option can be specified
   multiple times.

-l domain
   Generate a DLV set in addition to the key (DNSKEY) and DS sets. The domain is appended
   to the name of the records.

-N soa-serial-format
   The SOA serial number format of the signed zone. Possible formats are keep (default),
   increment and unixtime, described as follows.

   keep
      Do not modify the SOA serial number.

   increment
      Increment the SOA serial number using RFC 1982 arithmetic.
unixtime
  Set the SOA serial number to the number of seconds since epoch.

-n nthreads
  Specifies the number of threads to use. By default, one thread is started for each detected CPU.

-O output_format
  The format of the output file containing the signed zone. Possible formats are text (default) and raw.

-o origin
  Specify the zone origin. If not specified, the name of the zone file is assumed to be the origin.

-p
  Use pseudo-random data when signing the zone. This is faster, but less secure, than using real random data. This option may be useful when signing large zones or when the entropy source is limited.

-r randomdev
  Specifies the source of randomness. If the operating system does not provide a /dev/random or equivalent device, the default source of randomness is keyboard input. randomdev specifies the name of a character device or file containing random data to be used instead of the default /dev/random. The special value keyboard indicates that keyboard input should be used.

-s start-time
  Specify the date and time when the generated RRSIG records become valid. This can be either an absolute or relative time. An absolute start time is indicated by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +N, which is N seconds from the current time. If no start-time is specified, the current time minus one hour (to allow for clock skew) is used.

-t
  Print statistics at completion.

-v level
  Set the debugging level.

-z
  Ignore KSK flag on key when determining what to sign.

-3 salt
  Generate a NSEC3 chain with the specified hex-encoded salt. A dash (-) can be used to indicate that no salt is to be used when generating the NSEC3 chain.
The following operands are supported:

zonefile
   The file containing the zone to be signed.

key
   Specify which keys should be used to sign the zone. If no keys are specified, then the zone
   will be examined for DNSKEY records at the zone apex. If these are found and there are
   matching private keys in the current directory, these will be used for signing.

Examples

Example 1  Signing a Zone with a DSA Key

The following command signs the example.com zone with the DSA key generated in the
example in the dnssec-keygen(1M) manual page (Kexample.com.+003+17247). The zone’s
keys must be in the master file (db.example.com). This invocation looks for keyset files in the
current directory, so that DS records can be generated from them (-g).

% dnssec-signzone -g -o example.com db.example.com \
   Kexample.com.+003+17247
db.example.com.signed
%

In the above example, dnssec-signzone creates the file db.example.com.signed. This file
should be referenced in a zone statement in a named.conf file.

Example 2  Re-signing a Previously Signed Zone

The following commands re-sign a previously signed zone with default parameters. The
private keys are assumed to be in the current directory.

% cp db.example.com.signed db.example.com
% dnssec-signzone -o example.com db.example.com \
   db.example.com.signed
%

page, this document is available at https://www.isc.org/software/bind/documentation.
domainname(1M)

Name  domainname – set or display name of the current domain

Synopsis  domainname [name-of-domain]

Description  Without an argument, domainname displays the name of the current domain name used in 
RPC exchanges, usually referred to as the NIS or NIS+ domain name. This name typically 
comprises a group of hosts or passwd entries under the same administration. The 
domainname command is used by various components of Solaris to resolve names for entries 
such as are found in passwd, hosts and aliases. By default, naming services such as NIS and 
NIS+ use domainname to resolve names.

With appropriate privileges (root or an equivalent role [see rbac(5)]), you can set the name of 
the domain by specifying the name as an argument to the domainname command.

The domain name for various naming services can also be set by other means. For example, 
ypinit can be used to specify a different domain for all NIS calls. The domain name of the 
machine is usually set during boot time through the domainname command by the 
svc:/system/identity:domain service. If the new domain name is not saved in the 
/etc/defaultdomain file, the machine reverts to the old domain after it reboots.

The sendmail(1M) daemon, as shipped with Solaris, and the sendmail implementation 
provided by sendmail.org (formerly referred to as "Berkeley 8.x sendmail") both attempt to 
determine a local host's fully qualified host name at startup and both pursue follow-up actions 
if the initial search fails. It is in these follow-up actions that the two implementations differ.

Both implementations use a standard Solaris or Unix system call to determine its fully 
qualified host name at startup, following the name service priorities specified in 
nsswitch.conf(4). To this point, the Solaris and sendmail.org versions behave identically.

If the request for a fully qualified host name fails, the sendmail.org sendmail sleeps for 60 
seconds, tries again, and, upon continuing failure, resorts to a short name. The Solaris version 
of sendmail makes the same initial request, but then, following initial failure, calls 
domainname. If successful, the sleep is avoided.

On a Solaris machine, if you run the sendmail.org version of sendmail, you get the startup 
behavior (omitting the domainname call) described above. If you run the Solaris sendmail, the 
domainname call is made if needed.

If the Solaris sendmail cannot determine the fully qualified host name, use 
check-hostname(1M) as a troubleshooting aid. This script can offer guidance as to 
appropriate corrective action.

Files  /etc/defaultdomain

/etc/nsswitch.conf
### Attributes

### Notes

The domainname service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/identity:domain

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
drd(1M)

Name  drd – Logical Domain Dynamic Reconfiguration daemon

Synopsis /usr/lib/ldoms/drd

Description  The drd daemon is part of the framework that enables the addition and removal of resources from a Logical Domain. This framework is collectively called Dynamic Reconfiguration (DR).

  drd is responsible for various aspects of DR on a Logical Domain and must be enabled to ensure proper DR functionality. It is started at boot time and has no configuration options.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWldomu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Unstable</td>
</tr>
</tbody>
</table>

See Also  svc(1), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Errors  drd uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all the drd error messages to the /var/adm/messages log.

Notes  The drd service is managed by the service management facility, smf(5), under the service identifier:

  svc:/platform/sun4v/drd:default

  Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
drvconfig(1M)

**Name**
drvconfig – apply permission and ownership changes to devices

**Synopsis**
drvconfig [-bn] [-a alias_name] [-c class_name]
[-i drivername] [-m major_num] [-r root_dir]

**Description**
devfsadm(1M) is now the preferred command and should be used instead of drvconfig.

The default operation of drvconfig is to apply permission and ownership changes to devices. Normally, this command is run automatically after a new driver has been installed (with add_drv(1M)) and the system has been rebooted.

**Options**
The following options are supported:

- **-a alias_name**
  Add the name alias_name to the list of aliases that this driver is known by. This option, if used, must be used with the -m major_num, the -b and the -i drivername options.

- **-b**
  Add a new major number to name binding into the kernel’s internal name_to_major tables. This option is not normally used directly, but is used by other utilities such as add_drv(1M). Use of the -b option requires that -i and -m be used also. No /devices entries are created.

- **-c class_name**
  The driver being added to the system exports the class class_name. This option is not normally used directly, but is used by other utilities. It is only effective when used with the -b option.

- **-i drivername**
  Only configure the devices for the named driver. The following options are used by the implementation of add_drv(1M) and rem_drv(1M), and may not be supported in future versions of Solaris:

- **-m major_num**
  Specify the major number major_num for this driver to add to the kernel’s name_to_major binding tables.

- **-n**
  Do not try to load and attach any drivers, or if the -i option is given, do not try to attach the driver named drivername.

- **-r root_dir**
  Perform operations under root_dir, rather than directly under root.

**Exit Status**
0  Successful completion.
non-zero  An error occurred.

**Files**

- /devices  Device nodes directory
- /etc/minor_perm  Minor mode permissions
- /etc/name_to_major  Major number binding
- /etc/driver_classes  Driver class binding file

**Name**

dsvclockd – DHCP service lock daemon

**Synopsis**

/usr/lib/inet/dsvclockd [-d 1 | 2] [-f ] [-v]

**Description**

The `dsvclockd` daemon is a lock manager that works in conjunction with the Dynamic Host Configuration Protocol (DHCP) Data Service Library (`libdhcpsvc`). It provides shared or exclusive access to the `dhcp_network(4)` and `dhcptab(4)` tables. This service is used by the `SUNWbinfiles` and `SUNWfiles` DHCP data store modules. See `dhcp_modules(5)`.

dsvclockd is started on demand by `libdhcpsvc`. The `dsvclockd` daemon should be started manually only if command line options need to be specified.

**Options**

The following options are supported:

- `-d 1 | 2` Set debug level. Two levels of debugging are currently available, 1 and 2. Level 2 is more verbose.
- `-f` Run in the foreground instead of as a daemon process. When this option is used, messages are sent to standard error instead of to `syslog(3C)`.
- `-v` Provide verbose output.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>

**Name**
dtrace – DTrace dynamic tracing compiler and tracing utility

**Synopsis**

```bash
dtrace [-32 | -64] [-aACeFGHhlqSvVwZ] [-b bufsz] [-c cmd]
       [-D name [=value]] [-I path] [-L path] [-o output]
       [-s script] [-U name] [-X a | c | s | t] [-p pid]
       [-P provider {{predicate} action}]
       [-m [provider:] module {{predicate} action}]
       [-f [provider:] module: function {{predicate} action}]
       [-n [provider:] module: function: name {{predicate} action}]
       [-i probe-id {{predicate} action}]
```

**Description**

DTrace is a comprehensive dynamic tracing framework for the Solaris Operating System. DTrace provides a powerful infrastructure that permits administrators, developers, and service personnel to concisely answer arbitrary questions about the behavior of the operating system and user programs.

The Solaris Dynamic Tracing Guide describes how to use DTrace to observe, debug, and tune system behavior. Refer to this book for a detailed description of DTrace features, including the bundled DTrace observability tools, instrumentation providers, and the D programming language.

The dtrace command provides a generic interface to the essential services provided by the DTrace facility, including:

- Options that list the set of probes and providers currently published by DTrace
- Options that enable probes directly using any of the probe description specifiers (provider, module, function, name)
- Options that run the D compiler and compile one or more D program files or programs written directly on the command line
- Options that generate anonymous tracing programs
- Options that generate program stability reports
- Options that modify DTrace tracing and buffering behavior and enable additional D compiler features

You can use dtrace to create D scripts by using it in a `#!` declaration to create an interpreter file. You can also use dtrace to attempt to compile D programs and determine their properties without actually enabling tracing using the `-e` option. See OPTIONS. See the Solaris Dynamic Tracing Guide for detailed examples of how to use the dtrace utility to perform these tasks.

**Options**

The arguments accepted by the `-P`, `-m`, `-f`, `-n`, and `-i` options can include an optional D language predicate enclosed in slashes `//` and optional D language action statement list enclosed in braces `{}`. D program code specified on the command line must be appropriately quoted to avoid interpretation of meta-characters by the shell.

The following options are supported:
The D compiler produces programs using the native data model of the operating system kernel. You can use the `isainfo -b` command to determine the current operating system data model. If the `-32` option is specified, `dtrace` forces the D compiler to compile a D program using the 32-bit data model. If the `-64` option is specified, `dtrace` forces the D compiler to compile a D program using the 64-bit data model. These options are typically not required as `dtrace` selects the native data model as the default. The data model affects the sizes of integer types and other language properties. D programs compiled for either data model can be executed on both 32-bit and 64-bit kernels. The `-32` and `-64` options also determine the ELF file format (ELF32 or ELF64) produced by the `-G` option.

Claim anonymous tracing state and display the traced data. You can combine the `-a` option with the `-e` option to force `dtrace` to exit immediately after consuming the anonymous tracing state rather than continuing to wait for new data. See the Solaris Dynamic Tracing Guide for more information about anonymous tracing.

Generate `driver.conf(4)` directives for anonymous tracing. This option constructs a set of `dtrace(7D)` configuration file directives to enable the specified probes for anonymous tracing and then exits. By default, `dtrace` attempts to store the directives to the file `/kernel/drv/dtrace.conf`. You can modify this behavior if you use the `-o` option to specify an alternate output file.

Set principal trace buffer size (`bufsz`). The trace buffer size can include any of the size suffixes k, m, g, or t. If the buffer space cannot be allocated, `dtrace` attempts to reduce the buffer size or exit depending on the setting of the `bufsize` property.

Run the specified command `cmd` and exit upon its completion. If more than one `-c` option is present on the command line, `dtrace` exits when all commands have exited, reporting the exit status for each child process as it terminates. The process-ID of the first command is made available to any D programs specified on the command line or using the `-s` option through the `$target` macro variable. Refer to the Solaris Dynamic Tracing Guide for more information on macro variables.

Run the C preprocessor `cpp(1)` over D programs before compiling them. You can pass options to the C preprocessor using the `-D`, `-U`, `-I`, and `-H` options. You can select the degree of C standard conformance if you use the `-X` option. For a description of the set of tokens defined by the D compiler when invoking the C preprocessor, see `-X`.

Define name when invoking `cpp(1)` (enabled using the `-C` option). If you specify the equals sign (=) and additional value, the name is assigned the corresponding value. This option passes the `-D` option to each `cpp` invocation.
- e
Exit after compiling any requests and consuming anonymous tracing state (-a option) but prior to enabling any probes. You can combine this option with the -a option to print anonymous tracing data and exit. You can also combine this option with D compiler options. This combination verifies that the programs compile without actually executing them and enabling the corresponding instrumentation.

- f [ [provider:]module:]function[ [predicate] action]
Specify function name to trace or list (-l option). The corresponding argument can include any of the probe description forms provider:module:function, module:function, or function. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than function are specified in the description, all probes with the corresponding function are matched. The -f argument can be suffixed with an optional D probe clause. You can specify more than one -f option on the command line at a time.

- F
Coalesce trace output by identifying function entry and return. Function entry probe reports are indented and their output is prefixed with ->. Function return probe reports are unindented and their output is prefixed with <-. System call entry probe reports are indented and their output is prefixed with =>. System call return probe reports are unindented and their output is prefixed with <=.

- G
Generate an ELF file containing an embedded DTrace program. The DTrace probes specified in the program are saved inside of a relocatable ELF object which can be linked into another program. If the -o option is present, the ELF file is saved using the pathname specified as the argument for this operand. If the -o option is not present and the DTrace program is contained with a file whose name is filename.d, then the ELF file is saved using the name filename.o. Otherwise the ELF file is saved using the name d.out.

- H
Print the pathnames of included files when invoking cpp(1) (enabled using the -C option). This option passes the -H option to each cpp invocation, causing it to display the list of pathnames, one for each line, to stderr.

- h
Generate a header file containing macros that correspond to probes in the specified provider definitions. This option should be used to generate a header file that is included by other source files for later use with the -o option. If the -o option is present, the header file is saved using the pathname specified as the argument for that option. If the -o option is not present and the DTrace program is contained with a file whose name is filename.d, then the header file is saved using the name filename.h.

- i probe-id[ [predicate] action]
Specify probe identifier (probe-id) to trace or list (-l option). You can specify probe IDs using decimal integers as shown by dtrace -l. The -i argument can be suffixed with an optional D probe clause. You can specify more than one -i option at a time.
-I path
Add the specified directory path to the search path for #include files when invoking cpp(1) (enabled using the -C option). This option passes the -I option to each cpp invocation. The specified path is inserted into the search path ahead of the default directory list.

-L path
Add the specified directory path to the search path for DTrace libraries. DTrace libraries are used to contain common definitions that can be used when writing D programs. The specified path is added after the default library search path.

-1
List probes instead of enabling them. If the -l option is specified, dtrace produces a report of the probes matching the descriptions given using the -P, -m, -f, -n, -i, and -s options. If none of these options are specified, this option lists all probes.

-m [[provider:] module: [[predicate] action]]
Specify module name to trace or list (-l option). The corresponding argument can include any of the probe description forms provider:module or module. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than module are specified in the description, all probes with a corresponding module are matched. The -m argument can be suffixed with an optional D probe clause. More than one -m option can be specified on the command line at a time.

-n [[[[provider:] module:] function:] name [[predicate] action]]
Specify probe name to trace or list (-l option). The corresponding argument can include any of the probe description forms provider:module:function:name, module:function:name, function:name, or name. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than name are specified in the description, all probes with a corresponding name are matched. The -n argument can be suffixed with an optional D probe clause. More than one -n option can be specified on the command line at a time.

-o output
Specify the output file for the -A, -G, -h, and -l options, or for the traced data itself. If the -A option is present and -o is not present, the default output file is /kernel/drv/dtrace.conf. If the -G option is present and the -s option’s argument is of the form filename.d and -o is not present, the default output file is filename.o. Otherwise the default output file is d.out.

-p pid
Grab the specified process-ID pid, cache its symbol tables, and exit upon its completion. If more than one -p option is present on the command line, dtrace exits when all commands have exited, reporting the exit status for each process as it terminates. The first process-ID is made available to any D programs specified on the command line or using the -s option through the $target macro variable. Refer to the Solaris Dynamic Tracing Guide for more information on macro variables.
-P provider [ {predicate} action]
Specify provider name to trace or list ( -l option). The remaining probe description fields module, function, and name are left blank and match any probes regardless of the values in those fields. The -P argument can be suffixed with an optional D probe clause. You can specify more than one -P option on the command line at a time.

-q
Set quiet mode. dtrace suppresses messages such as the number of probes matched by the specified options and D programs and does not print column headers, the CPU ID, the probe ID, or insert newlines into the output. Only data traced and formatted by D program statements such as trace() and printf() is displayed to stdout.

-s
Compile the specified D program source file. If the -e option is present, the program is compiled but instrumentation is not enabled. If the -l option is present, the program is compiled and the set of probes matched by it is listed, but instrumentation is not enabled. If none of -e, -l, -G, or -A are present, the instrumentation specified by the D program is enabled and tracing begins.

-S
Show D compiler intermediate code. The D compiler produces a report of the intermediate code generated for each D program to stderr.

-U name
Undefine the specified name when invoking cpp(1) (enabled using the -C option). This option passes the -U option to each cpp invocation.

-v
Set verbose mode. If the -v option is specified, dtrace produces a program stability report showing the minimum interface stability and dependency level for the specified D programs. DTrace stability levels are explained in further detail in the Solaris Dynamic Tracing Guide.

-V
Report the highest D programming interface version supported by dtrace. The version information is printed to stdout and the dtrace command exits. Refer to the Solaris Dynamic Tracing Guide for more information about DTrace versioning features.

-w
Permit destructive actions in D programs specified using the -s, -P, -m, -f, -n, or -i options. If the -w option is not specified, dtrace does not permit the compilation or enabling of a D program that contains destructive actions.

-x arg [=val]
Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the Solaris Dynamic Tracing Guide. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).
Specify the degree of conformance to the ISO C standard that should be selected when invoking `cpp(1)` (enabled using the `-C` option). The `-X` option argument affects the value and presence of the `__STDC__` macro depending upon the value of the argument letter.

The `-X` option supports the following arguments:

- `a` Default. ISO C plus K&R compatibility extensions, with semantic changes required by ISO C. This is the default mode if `-X` is not specified. The predefined macro `__STDC__` has a value of 0 when `cpp` is invoked in conjunction with the `-Xa` option.

- `c` Conformance. Strictly conformant ISO C, without K&R C compatibility extensions. The predefined macro `__STDC__` has a value of 1 when `cpp` is invoked in conjunction with the `-Xc` option.

- `s` K&R C only. The macro `__STDC__` is not defined when `cpp` is invoked in conjunction with the `-Xs` option.

- `t` Transition. ISO C plus K&R C compatibility extensions, without semantic changes required by ISO C. The predefined macro `__STDC__` has a value of 0 when `cpp` is invoked in conjunction with the `-Xt` option.

As the `-X` option only affects how the D compiler invokes the C preprocessor, the `-Xa` and `-Xt` options are equivalent from the perspective of D and both are provided only to ease re-use of settings from a C build environment.

Regardless of the `-X` mode, the following additional C preprocessor definitions are always specified and valid in all modes:

- `__sun`
- `__unix`
- `__SVR4`
- `__sparc` (on SPARC systems only)
- `__sparcv9` (on SPARC systems only when 64-bit programs are compiled)
- `__i386` (on x86 systems only when 32-bit programs are compiled)
- `__amd64` (on x86 systems only when 64-bit programs are compiled)
- `__’uname -s’ ’uname -r’` (for example, `__SunOS_5_10`)
- `__SUNW_D=1`
- `__SUNW_D_VERSION=0xMMmmmuuu`

Where `MM` is the major release value in hexadecimal, `mmm` is the minor release value in hexadecimal, and `uuu` is the micro release value in hexadecimal. Refer to the Solaris Dynamic Tracing Guide for more information about DTrace versioning.
-Z
Permit probe descriptions that match zero probes. If the -Z option is not specified, dtrace reports an error and exits if any probe descriptions specified in D program files (-s option) or on the command line (-P, -m, -f, -n, or -i options) contain descriptions that do not match any known probes.

**Operands**
You can specify zero or more additional arguments on the dtrace command line to define a set of macro variables ($1, $2, and so forth). The additional arguments can be used in D programs specified using the -s option or on the command line. The use of macro variables is described further in the Solaris Dynamic Tracing Guide.

**Exit Status**
The following exit values are returned:

0 Successful completion.

For D program requests, an exit status of 0 indicates that programs were successfully compiled, probes were successfully enabled, or anonymous state was successfully retrieved. dtrace returns 0 even if the specified tracing requests encountered errors or drops.

1 An error occurred.

For D program requests, an exit status of 1 indicates that program compilation failed or that the specified request could not be satisfied.

2 Invalid command line options or arguments were specified.

**See Also**
cpp(1), isainfo(1), ssh(1), libdtrace(3LIB), driver.conf(4), attributes(5), dtrace(7D)

**Solaris Dynamic Tracing Guide**

**Usage**
When using the -p flag, dtrace stops the target processes while it is inspecting them and reporting results. A process can do nothing while it is stopped. This means that, if, for example, the X server is inspected by dtrace running in a window under the X server’s control, the whole window system can become deadlocked, because the proc tool would be attempting to display its results to a window that cannot be refreshed. In such a case, logging in from another system using ssh(1) and killing the offending proc tool clears the deadlock.
dumpadm(1M)

Name
dumpadm – configure operating system crash dump

Synopsis
/usr/sbin/dumpadm [-nuy] [-c content-type] [-d dump-device]
   [-m mink | minm | min%] [-s savecore-dir]
   [-r root-dir] [-z on | off]

Description
The dumpadm program is an administrative command that manages the configuration of the operating system crash dump facility. A crash dump is a disk copy of the physical memory of the computer at the time of a fatal system error. When a fatal operating system error occurs, a message describing the error is printed to the console. The operating system then generates a crash dump by writing the contents of physical memory to a predetermined dump device, which is typically a local disk partition. The dump device can be configured by way of dumpadm. Once the crash dump has been written to the dump device, the system will reboot.

Fatal operating system errors can be caused by bugs in the operating system, its associated device drivers and loadable modules, or by faulty hardware. Whatever the cause, the crash dump itself provides invaluable information to your support engineer to aid in diagnosing the problem. As such, it is vital that the crash dump be retrieved and given to your support provider. Following an operating system crash, the savecore(1M) utility is executed automatically during boot to retrieve the crash dump from the dump device and write it to your file system in compressed form, to a file name vmdump.X, where X is an integer identifying the dump. Afterwards, savecore(1M) can be invoked on the same or another system to expand the compressed crash dump to a pair of files named unix.X and vmcore.X. The directory in which the crash dump is saved on reboot can be configured using dumpadm.

For systems with a UFS root file system, the default dump device is configured to be an appropriate swap partition. Swap partitions are disk partitions reserved as virtual memory backing store for the operating system. Thus, no permanent information resides in swap to be overwritten by the dump. See swap(1M). For systems with a ZFS root file system, dedicated ZFS volumes are used for swap and dump areas. For further information about setting up a dump area with ZFS, see the ZFS Administration Guide. To view the current dump configuration, use the dumpadm command with no arguments:

example# dumpadm

   Dump content: kernel pages
   Dump device: /dev/dsk/c0t0d0s1 (swap)
   Savecore directory: /var/crash/saturn
   Savecore enabled: yes
   Save compressed: yes

When no options are specified, dumpadm displays the current crash dump configuration. The example above shows the set of default values: the dump content is set to kernel memory pages only, the dump device is a swap disk partition, the directory for savecore files is set to /var/crash/hostname, savecore is set to run automatically on reboot and save the crash dump in a compressed format. 
When one or more options are specified, `dumpadm` verifies that your changes are valid, and if so, reconfigures the crash dump parameters and displays the resulting configuration. You must be root to view or change dump parameters.

**Options** The following options are supported:

- `-c content-type`
  Modify the dump configuration so that the crash dump consists of the specified dump content. The content should be one of the following:
  
  * `kernel`
    Kernel memory pages only.
  
  * `all`
    All memory pages.

- `-d dump-device`
  Modify the dump configuration to use the specified dump device. The dump device may one of the following:

  * `dump-device`
    A specific dump device specified as an absolute pathname, such as `/dev/dsk/cNtNdNsN` when the system is running a UFS root file system. Or, specify a ZFS volume, such as `/dev/zvol/dsk/rpool/dump`, when the system is running a ZFS root file system.

  * `swap`
    If the special token `swap` is specified as the dump device, `dumpadm` examines the active swap entries and selects the most appropriate entry to configure as the dump device. See `swap(1M)`. Refer to the NOTES below for details of the algorithm used to select an appropriate swap entry. When the system is first installed with a UFS root file system, `dumpadm` uses the value for `swap` to determine the initial dump device setting. A given ZFS volume cannot be configured for both the swap area and the dump device.

- `-m mink | minm | min%`
  Create a `minfree` file in the current savecore directory indicating that savecore should maintain at least the specified amount of free space in the file system where the savecore directory is located. The `min` argument can be one of the following:

  * `k`
    A positive integer suffixed with the unit `k` specifying kilobytes.

  * `m`
    A positive integer suffixed with the unit `m` specifying megabytes.
A % symbol, indicating that the minfree value should be computed as the specified percentage of the total current size of the file system containing the savecore directory.

The savecore command will consult the minfree file, if present, prior to writing the dump files. If the size of these files would decrease the amount of free disk space below the minfree threshold, no dump files are written and an error message is logged. The administrator should immediately clean up the savecore directory to provide adequate free space, and re-execute the savecore command manually. The administrator can also specify an alternate directory on the savecore command-line.

-n
Modify the dump configuration to not run savecore automatically on reboot. This is not the recommended system configuration; if the dump device is a swap partition, the dump data will be overwritten as the system begins to swap. If savecore is not executed shortly after boot, crash dump retrieval may not be possible.

-r root-dir
Specify an alternate root directory relative to which dumpadm should create files. If no -r argument is specified, the default root directory / is used.

-s savecore-dir
Modify the dump configuration to use the specified directory to save files written by savecore. The directory should be an absolute path and exist on the system. If upon reboot the directory does not exist, it will be created prior to the execution of savecore. See the NOTES section below for a discussion of security issues relating to access to the savecore directory. The default savecore directory is /var/crash/hostname where hostname is the output of the -n option to the uname(1) command.

-u
Forcibly update the kernel dump configuration based on the contents of /etc/dumpadm.conf. Normally this option is used only on reboot when starting svc:/system/dumpadm:default, when the dumpadm settings from the previous boot must be restored. Your dump configuration is saved in the configuration file for this purpose. If the configuration file is missing or contains invalid values for any dump properties, the default values are substituted. Following the update, the configuration file is resynchronized with the kernel dump configuration.

-y
Modify the dump configuration to automatically run savecore on reboot. This is the default for this dump setting.

-z on | off
Modify the dump configuration to control the operation of savecore on reboot. The options are on, to enable saving core files in a compressed format, and off, to automatically uncompress the crash dump file. The default is on, because crash dump files can be very large and require less file system space if saved in a compressed format.
EXAMPLE 1  Reconfiguring The Dump Device To A Dedicated Dump Device:
The following command reconfigures the dump device to a dedicated dump device:

```bash
example# dumpadm -d /dev/dsk/c0t2d0s2
```

Dump content: kernel pages
Dump device: /dev/dsk/c0t2d0s2 (dedicated)
Savecore directory: /var/crash/saturn
Savecore enabled: yes
Save compressed: yes

The following exit values are returned:

0  Dump configuration is valid and the specified modifications, if any, were made successfully.
1  A fatal error occurred in either obtaining or modifying the dump configuration.
2  Invalid command line options were specified.

Files  
/dev/dump
   Dump device.

/etc/dumpadm.conf
   Contains configuration parameters for dumpadm. Modifiable only through that command.

savecore-directory/minfree
   Contains minimum amount of free space for savecore-directory. See savecore(1M).

</tr>
</tbody>
</table>

See Also  
svcs(1), uname(1), savecore(1M), svcadm(1M), swap(1M), attributes(5), smf(5)

Notes  The system crash dump service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/dumpadm:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svc(1) command.
When the special swap token is specified as the argument to `dumpadm -d` the utility will attempt to configure the most appropriate swap device as the dump device. `dumpadm` configures the largest swap block device as the dump device; if no block devices are available for swap, the largest swap entry is configured as the dump device. If no swap entries are present, or none can be configured as the dump device, a warning message will be displayed. While local and remote swap files can be configured as the dump device, this is not recommended.

In the event that the dump device is also a swap device, and the swap device is deleted by the administrator using the `swap -d` command, the `swap` command will automatically invoke `dumpadm -d swap` in order to attempt to configure another appropriate swap device as the dump device. If no swap devices remain or none can be configured as the dump device, the crash dump will be disabled and a warning message will be displayed. Similarly, if the crash dump is disabled and the administrator adds a new swap device using the `swap -a` command, `dumpadm -d swap` will be invoked to re-enable the crash dump using the new swap device.

Once `dumpadm -d swap` has been issued, the new dump device is stored in the configuration file for subsequent reboots. If a larger or more appropriate swap device is added by the administrator, the dump device is not changed; the administrator must re-execute `dumpadm -d swap` to reselect the most appropriate device from the new list of swap devices.

If the `dumpadm -m` option is used to create a `minfree` file based on a percentage of the total size of the file system containing the `savecore` directory, this value is not automatically recomputed if the file system subsequently changes size. In this case, the administrator must re-execute `dumpadm -m` to recomputate the `minfree` value. If no such file exists in the `savecore` directory, `savecore` will default to a free space threshold of one megabyte. If no free space threshold is desired, a `minfree` file containing size 0 can be created.

If, upon reboot, the specified `savecore` directory is not present, it will be created prior to the execution of `savecore` with permissions 0700 (read, write, execute by owner only) and owner `root`. It is recommended that alternate `savecore` directories also be created with similar permissions, as the operating system crash dump files themselves may contain secure information.
editmap(1M)

Name  editmap – query and edit single records in database maps for sendmail

Synopsis  editmap  -C  file  [-N]  [-f]  [-q | -u | -x]  maptype  mapname  key
  ["value"]...

Description  The editmap command queries or edits one record in a database maps used by the keyed map lookups in sendmail(1M). Arguments are passed on the command line and output (for queries) is directed to standard output.

Depending on how it is compiled, editmap handles up to three different database formats, selected using the maptype parameter. See OPERANDS.

If the TrustedUser option is set in the sendmail configuration file and editmap is invoked as root, the generated files are owned by the specified TrustedUser.

Options  The following options are supported:

  -C  file  Use the specified sendmail configuration file (file) to look up the TrustedUser option.

  -f  Disable the folding of all upper case letters in the key to lower case. Normally, all upper case letters in the key are folded to upper case. This is intended to mesh with the -f flag in the $K line in sendmail.cf. The value is never case folded.

  -N  Include the null byte that terminates strings in the map (for alias maps).

  -q  Query the map for the specified key. If found, print value to standard output and exit with 0. If not found then print an error message to stdout and exit with EX_UNAVAILABLE.

  -u  Update the record for key with value or inserts a new record if one doesn’t exist. Exits with 0 on success or EX_IOERR on failure.

  -x  Delete the specific key from the map. Exit with 0 on success or EX_IOERR on failure.

Operands  The following operands are supported:

  key  The left hand side of a record.

  Each record is of the form:

  key  value

  key and value are separated by white space.

  mapname  File name of the database map being created.

  maptype  Specifies the database format. The following maptype parameters are available:

    dbm  Specifies DBM format maps.

    btree  Specifies B-Tree format maps.
hash  Specifies hash format maps.

value  The right hand side of a record.

Each record is of the form:

key  value

key and value are separated by white space.

edquota(1M)

Name edquota – edit user quotas for ufs file system

Synopsis edquota [-p proto_user] username...
               edquota -t

Description edquota is a quota editor. One or more users may be specified on the command line. For each user a temporary file is created with an ASCII representation of the current disk quotas for that user for each mounted ufs file system that has a quotas file, and an editor is then invoked on the file. The quotas may then be modified, new quotas added, etc. Upon leaving the editor, edquota reads the temporary file and modifies the binary quota files to reflect the changes made.

The editor invoked is vi(1) unless the EDITOR environment variable specifies otherwise.

Only the super-user may edit quotas. In order for quotas to be established on a file system, the root directory of the file system must contain a file, owned by root, called quotas. (See quota(1M).)

proto_user and username can be numeric, corresponding to the UID of a user. Unassigned UIDs may be specified; unassigned names may not. In this way, default quotas can be established for users who are later assigned a UID.

If no options are specified, the temporary file created will have one or more lines of the format, where a block is considered to be a 1024 byte (1K) block:

\[fs mount_point blocks (soft = number, \backslash
hard = number ) inodes (soft = number, \backslash
hard = number)\]

The number fields may be modified to reflect desired values.

Options The following options are supported:

- \[p\] Duplicate the quotas of the proto_user specified for each username specified. This is the normal mechanism used to initialize quotas for groups of users.

- \[t\] Edit the soft time limits for each file system. If the time limits are zero, the default time limits in /usr/include/sys/fs/ufs_quota.h are used. The temporary file created will have one or more lines of the form

\[fs mount_point blocks time limit = number tmunit, files time limit = number tmunit\]

\(tmunit\) may be one of “month”, “week”, “day”, “hour”, “min” or “sec”; characters appended to these keywords are ignored, so you may write “months” or “minutes” if you prefer. The number and tmunit fields may be modified to set desired values. Time limits are printed in the greatest possible time unit such that the value is greater than or equal to one. If “default” is printed after the tmunit, this indicates that the value shown is zero (the default).
Usage

See `largefile(5)` for the description of the behavior of edquota when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

Files

quotas  
quota file at the file system root
/etc/mnttab  

table of mounted file systems

Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also

Notes

All UIDs can be assigned quotas.
**Name**
eeprom – EEPROM display and load utility

**Synopsis**
/usr/sbin/eeprom [-] [-f device] [parameter=value]

**Description**
eeprom displays or changes the values of parameters in the EEPROM. It processes parameters in the order given. When processing a parameter accompanied by a value, eeprom makes the indicated alteration to the EEPROM; otherwise, it displays the parameter’s value. When given no parameter specifiers, eeprom displays the values of all EEPROM parameters. A ‘−’ (hyphen) flag specifies that parameters and values are to be read from the standard input (one parameter or parameter=value per line).

Only the super-user may alter the EEPROM contents.

eeprom verifies the EEPROM checksums and complains if they are incorrect.

*platform-name* is the name of the platform implementation and can be found using the -i option of *uname*(1).

**SPARC**
SPARC based systems implement firmware password protection with eeprom, using the security-mode, security-password and security-#badlogins properties.

**x86**
EEPROM storage is simulated using a file residing in the platform-specific boot area. The /boot/solaris/bootenv.rc file simulates EEPROM storage.

Because x86 based systems typically implement password protection in the system BIOS, there is no support for password protection in the eeprom program. While it is possible to set the security-mode, security-password and security-#badlogins properties on x86 based systems, these properties have no special meaning or behavior on x86 based systems.

**Options**
- -f device
  Use device as the EEPROM device.

**Operands**
|x86 Only| acpi-user-options
---|---
A configuration variable that controls the use of Advanced Configuration and Power Interface (ACPI), a power management specification. The acceptable values for this variable depend on the release of the Solaris operating system you are using.

For all releases of Solaris 10 and Solaris 11, a value of of 0x0 means that there will be an attempt to use ACPI if it is available on the system. A value of 0x2 disables the use of ACPI.

For the Solaris 10 1/06 release, a value of 0x8 means that there will be an attempt to use ACPI in a mode compatible with previous releases of Solaris 10 if it is available on the system. The default for Solaris 10 1/06 is 0x8.

For releases of Solaris 10 after the 1/06 release and for Solaris 11, the default is 0x0.

Most users can safely accept the default value, which enables ACPI if available. If issues related to the use of ACPI are suspected on releases of Solaris after Solaris 1/06, it is suggested to first try a value of 0x8 and then, if you do not obtain satisfactory results, 0x02.
**console**

Specifies the console device. Possible values are ttya, ttyb, and text. In text mode, console output goes to the frame buffer and input comes from the keyboard. When this property is not present, the console device falls back to the device specified by `input-device` and `output-device`. When neither the console property or the `input-device` and `output-device` property pair are present, the console defaults to the frame buffer and keyboard.

Not all OpenBoot systems support all parameters. Defaults vary depending on the system and the PROM revision. See the output in the “Default Value” column of the `printenv` command, as entered at the `ok` (OpenBoot) prompt, to determine the default for your system.

**auto-boot?**

If true, boots automatically after power-on or reset. Defaults to true. On x86, this parameter is controlled by the grub menu file. See `installgrub(1M)`.

**ansi-terminal?**

Configuration variable used to control the behavior of the terminal emulator. The value false makes the terminal emulator stop interpreting ANSI escape sequences; instead, echoes them to the output device. Defaults to true.

**boot-args**

Holds a string of arguments that are passed to the boot subsystem. For example, you can use `boot-args=’- install dhcp’` to request a customer jumpstart installation. See `boot(1M)`, `kadbf(1M)` and `kernel(1M)`.

**boot-command**

Command executed if `auto-boot?` is true. Defaults to `boot`.

**boot-device**

Device from which to boot. `boot-device` may contain 0 or more device specifiers separated by spaces. Each device specifier may be either a prom device alias or a prom device path. The boot prom will attempt to open each successive device specifier in the list beginning with the first device specifier. The first device specifier that opens successfully will be used as the device to boot from. Defaults to `disk net`.

**boot-file**

File to boot (an empty string lets the secondary booter choose default). Defaults to empty string.

**boot-from**

Boot device and file (OpenBoot PROM version 1.x only). Defaults to `vmunix`.

**boot-from-diag**

Diagnostic boot device and file (OpenBoot PROM version 1.x only). Defaults to `le( )unix`.
boot-ncpus
  Configuration variable that controls the number of processors with which the system
  should boot. By default, the system boots with maximum supported number of processors.

comX-noprobe
  Where X is the number of the serial port, prevents device probe on serial port X.

diag-device
  Diagnostic boot source device. Defaults to net.

diag-file
  File from which to boot in diagnostic mode. Defaults to empty string.

diag-level
  Diagnostics level. Values include off, min, max and menus. There may be additional
  platform-specific values. When set to off, POST is not called. If POST is called, the value is
  made available as an argument to, and is interpreted by POST. Defaults to
  platform-dependent.

diag-switch?
  If true, run in diagnostic mode. Defaults to false on most desktop systems, true on most
  servers.

e-error-reset-recovery
  Recover after an error reset trap. Defaults to platform-specific setting.

  On platforms supporting this variable, it replaces the watchdog-reboot?,
  watchdog-sync?, redmode-reboot?, redmode-sync?, sir-sync?, and xir-sync?
  parameters.

  The options are:

  none
    Print a message describing the reset trap and go to OpenBoot PROM’s user interface,
    aka OK prompt.

  sync
    Invoke OpenBoot PROM’s sync word after the reset trap. Some platforms may treat this
    as none after an externally initiated reset (XIR) trap.

  boot
    Reboot after the reset trap. Some platforms may treat this as none after an XIR trap.

e-code-debug?
  If true, include name parameter for plug-in device FCodes. Defaults to false.

e-hardware-revision
  System version information.

e-input-device
  Input device used at power-on (usually keyboard, ttya, or ttyb). Defaults to keyboard.
keyboard-click?
  If true, enable keyboard click. Defaults to false.

keyboard-layout
  A string that specifies the layout name for non-self-identifying keyboards (type 7c). Invoke kbd -s to obtain a list of acceptable layout names. See kbd(1).

keymap
  Keymap for custom keyboard.

last-hardware-update
  System update information.

load-base
  Default load address for client programs. Default value is 16384.

local-mac-address?
  If true, network drivers use their own MAC address, not the system's. Defaults to false.

mfg-mode
  Manufacturing mode argument for POST. Possible values include off or chamber. The value is passed as an argument to POST. Defaults to off.

mfg-switch?
  If true, repeat system self-tests until interrupted with STOP-A. Defaults to false.

nvramrc
  Contents of NVRAMRC. Defaults to empty.

network-boot-arguments
  Arguments to be used by the PROM for network booting. Defaults to an empty string. network-boot-arguments can be used to specify the boot protocol (RARP/DHCP) to be used and a range of system knowledge to be used in the process.

  The syntax for arguments supported for network booting is:

  [protocol, ] [key=value , ]*

  All arguments are optional and can appear in any order. Commas are required unless the argument is at the end of the list. If specified, an argument takes precedence over any default values, or, if booting using DHCP, over configuration information provided by a DHCP server for those parameters.

  protocol, above, specifies the address discovery protocol to be used.

  Configuration parameters, listed below, are specified as key=value attribute pairs.

  tftp-server
    IP address of the TFTP server

  file
    file to download using TFTP or URL for WAN boot
host-ip
   IP address of the client (in dotted-decimal notation)

router-ip
   IP address of the default router (in dotted-decimal notation)

subnet-mask
   subnet mask (in dotted-decimal notation)

client-id
   DHCP client identifier

hostname
   hostname to use in DHCP transactions

http-proxy
   HTTP proxy server specification (IPADDR[:PORT])

tftp-retries
   maximum number of TFTP retries

dhcp-retries
   maximum number of DHCP retries

If no parameters are specified (that is, network-boot-arguments is an empty string), the PROM will use the platform-specific default address discovery protocol.

Absence of the protocol parameter when other configuration parameters are specified implies manual configuration.

Manual configuration requires that the client be provided with all the information necessary for boot. If using manual configuration, information required by the PROM to load the second-stage boot program must be provided in network-boot-arguments while information required for the second-stage boot program can be specified either as arguments to the boot program or by means of the boot program's interactive command interpreter.

Information required by the PROM when using manual configuration includes the booting client's IP address, name of the boot file, and the address of the server providing the boot file image. Depending on network configuration, it might be required that the subnet mask and address of the default router to use also be specified.

oem-banner
   Custom OEM banner (enabled by setting oem-banner? to true). Defaults to empty string.

oem-banner?
   If true, use custom OEM banner. Defaults to false.

oem-logo
   Byte array custom OEM logo (enabled by setting oem-logo? to true). Displayed in hexadecimal.
oem-logo?
  If true, use custom OEM logo (else, use Sun logo). Defaults to false.

pci-mem64?
  If true, the OpenBoot PROM allocates 64-bit PCI memory addresses to a PCI device that can support 64-bit addresses.

  This variable is available on SPARC platforms only and is optional. Some versions of SunOS do not support PCI MEM64 addresses and will fail in unexpected ways if the OpenBoot PROM allocates PCI MEM64 addresses.

  The default value is system-dependent. If the variable exists, the default value is appropriate to the lowest version of the SunOS that shipped with a specific platform.

output-device
  Output device used at power-on (usually screen, ttya, or ttyb). Defaults to screen.

redmode-reboot?
  Specify true to reboot after a redmode reset trap. Defaults to true. (Sun Enterprise 10000 only.)

redmode-sync?
  Specify true to invoke OpenBoot PROM's sync word after a redmode reset trap. Defaults to false. (Sun Enterprise 10000 only.)

rootpath
  Specifies the root device of the operating system.

sbus-probe-list
  Designate which SBus slots are probed and in what order. Defaults to 0123.

screen-#columns
  Number of on-screen columns (characters/line). Defaults to 80.

screen-#rows
  Number of on-screen rows (lines). Defaults to 34.

scsi-initiator-id
  SCSI bus address of host adapter, range 0-7. Defaults to 7.

sd-targets
  Map SCSI disk units (OpenBoot PROM version 1.x only). Defaults to 31204567, which means that unit 0 maps to target 3, unit 1 maps to target 1, and so on.

security-#badlogins
  Number of incorrect security password attempts. This property has no special meaning or behavior on x86 based systems.
security-mode
Firmware security level (options: none, command, or full). If set to command or full, system will prompt for PROM security password. Defaults to none. This property has no special meaning or behavior on x86 based systems.

security-password
Firmware security password (never displayed). Can be set only when security-mode is set to command or full. This property has no special meaning or behavior on x86 based systems.

```
example# eeprom security-password=
Changing PROM password:
New password:
Retype new password:
```

selftest-#megs
Megabytes of RAM to test. Ignored if diag-switch? is true. Defaults to 1.

sir-sync?
Specify true to invoke OpenBoot PROM's sync word after a software-initiated reset (SIR) trap. Defaults to false. (Sun Enterprise 10000 only.)

skip-vme-loopback?
If true, POST does not do VMEbus loopback tests. Defaults to false.

st-targets
Map SCSI tape units (OpenBoot PROM version 1.x only). Defaults to 45670123, which means that unit 0 maps to target 4, unit 1 maps to target 5, and so on.

sunmon-compat?
If true, display Restricted Monitor prompt (>). Defaults to false.

testarea
One-byte scratch field, available for read/write test. Defaults to 0.

tpe-link-test?
Enable 10baseT link test for built-in twisted pair Ethernet. Defaults to true.

ttya-mode
TTYA (baud rate, #bits, parity, #stop, handshake). Defaults to 9600, 8, n, 1, -. Fields, in left-to-right order, are:

Baud rate:
110, 300, 1200, 4800, 9600 . . .

Data bits:
5, 6, 7, 8

Parity:
n(none), e(even), o(odd), m(mark), s(space)
Stop bits:
  1, 1.5, 2

Handshake:
  −(none), h(hardware:rts/cts), s(software:xon/xoff)

ttyb-mode
  TTYB (baud rate, #bits, parity, #stop, handshake). Defaults to 9600, 8, n, 1, −.

Fields, in left-to-right order, are:
  Baud rate:
  110, 300, 1200, 4800, 9600 . . .
  Data bits:
  5, 6, 7, 8
  Stop bits:
  1, 1.5, 2
  Parity:
  n(none), e(even), o(odd), m(mark), s(space)
  Handshake:
  −(none), h(hardware:rts/cts), s(software:xon/xoff)

ttya-ignore-cd
  If true, operating system ignores carrier-detect on TTYA. Defaults to true.

ttyb-ignore-cd
  If true, operating system ignores carrier-detect on TTYB. Defaults to true.

ttya-rts-dtr-off
  If true, operating system does not assert DTR and RTS on TTYA. Defaults to false.

ttyb-rts-dtr-off
  If true, operating system does not assert DTR and RTS on TTYB. Defaults to false.

use-nvramrc?
  If true, execute commands in NVRAMRC during system start-up. Defaults to false.

verbosity
  Controls the level of verbosity of PROM messages. Can be one of debug, max, normal, min, or none. Defaults to normal.

version2?
  If true, hybrid (1.x/2.x) PROM comes up in version 2.x. Defaults to true.

watchdog-reboot?
  If true, reboot after watchdog reset. Defaults to false.
**watchdog-sync?**
Specify true to invoke OpenBoot PROM’s sync word after a watchdog reset trap. Defaults to false. (Sun Enterprise 10000 only.)

**xir-sync?**
Specify true to invoke OpenBoot PROM’s sync word after an XIR trap. Defaults to false. (Sun Enterprise 10000 only.)

### Examples

**EXAMPLE 1** Changing the Number of Megabytes of RAM.

The following example demonstrates the method for changing from one to two the number of megabytes of RAM that the system will test.

```
example# eeprom selftest-#megs
selftest-#megs=1
```

```
example# eeprom selftest-#megs=2
```

```
example# eeprom selftest-#megs
selftest-#megs=2
```

**EXAMPLE 2** Setting the auto-boot? Parameter to true.

The following example demonstrates the method for setting the auto-boot? parameter to true.

```
example# eeprom auto-boot?=true
```

When the eeprom command is executed in user mode, the parameters with a trailing question mark (?) need to be enclosed in double quotation marks (" ") to prevent the shell from interpreting the question mark. Preceding the question mark with an escape character (\) will also prevent the shell from interpreting the question mark.

```
example% eeprom "auto-boot?=true"
```

**EXAMPLE 3** Using network-boot-arguments

To use DHCP as the boot protocol and a hostname of abcd.example.com for network booting, set these values in network-boot-arguments as:

```
example# eeprom network-boot-arguments="dhcp,hostname=abcd.example.com"
```

...then boot using the command:

```
ok boot net
```

Note that network boot arguments specified from the PROM command line cause the contents of network-boot-arguments to be ignored. For example, with network-boot-arguments set as shown above, the boot command:

```
ok boot net:dhcp
```
EXAMPLE 3 Using network-boot-arguments  (Continued)

...causes DHCP to be used, but the hostname specified in network-boot-arguments will not be used during network boot.

EXAMPLE 4 Setting System Console to Auxiliary Device

The command below assigns the device /dev/term/a as the system console device. You would make such an assignment prior to using tip(1) to establish a tip connection to a host.

On a SPARC machine:

```
# eeprom output-device=/dev/term/a
```

On an x86 machine:

```
# eeprom console=ttya
```

On a SPARC machine, the preceding command would be sufficient for assigning the console to an auxiliary device. For an x86 machine, you might, in addition, need to set the characteristics of the serial line, for which you would have to consult the BIOS documentation for that machine. Also, on some x86 machines, you might use a device other than device a, as shown above. For example, you could set console to ttyb if the second serial port is present.

Files

- `/boot/solaris/bootenv.rc`
  - File storing eeprom values on x86 machines.
- `/dev/openprom`
  - Device file
- `/usr/platform/platform-name/sbin/eeprom`
  - Platform-specific version of eeprom. Use `uname -i` to obtain `platform-name`.

*OpenBoot 3.x Command Reference Manual*

*ONC+ Developer's Guide*
efdaemon – embedded FCode interpreter daemon

### Synopsis
/usr/lib/efcode/sparcv9/efdaemon [-d]

### Description
efdaemon, the embedded FCode interpreter daemon, invokes the embedded FCode interpreter when the daemon receives an interpretation request. A new session of the interpreter is started for each unique request by invoking the script /usr/lib/efcode/efcode.

efdaemon is used on selected platforms as part of the processing of some dynamic reconfiguration events.

### Options
The following option is supported:

- `-d`
  Set debug output. Log debug messages as LOG_DEBUG level messages by using syslog(). See syslog(3C).

### Files
/dev/fcode
- FCode interpreter pseudo device, which is a portal for receipt of FCode interpretation requests

/usr/lib/efcode/efcode
- Shell script that invokes the embedded FCode interpreter

/usr/lib/efcode/interpreter
- Embedded FCode interpreter

### Notes
The efdaemon service is managed by the service management facility, smf(5), under the service identifier:

svc:/platform/sun4u/efdaemon:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
The `embedded_su` command allows an application to prompt the user for security credentials and execute a program as another user or role (see `rbac(5)` for information on role-based access control). The default `username` is `root` (super user).

`embedded_su` is identical to `su(1M)`, except that the user interaction is packaged in a form suitable for another program to interpret and display. Typically, `embedded_su` would be used to allow a graphical program to prompt for the super user password and execute a command as the super user, without requiring that the requesting program be run as the super user.

`embedded_su` implements a simple protocol over standard input, standard output, and standard error. This protocol consists of three phases, roughly corresponding to PAM initialization, the PAM dialog, and PAM completion.

**Phase 1: Initialization**

After starting `embedded_su`, the application must send an initialization block on `embedded_su`'s standard input. This block is a text block, as described under "Text Blocks". There are currently no initialization parameters defined; the application should send an empty block by sending a line consisting solely of a period (.)..

**Phase 2: Conversation**

`embedded_su` then emits zero or more conversation blocks on its standard output. Each conversation block may require zero or more responses.

A conversation block starts with a line consisting of the word `CONV`, followed by whitespace, followed by the number of messages in the conversation block as a decimal integer. The number of messages may be followed by whitespace and additional data. This data, if present, must be ignored.

Each message consists of a line containing a header followed by a text block, as described under "Text Blocks". A single newline is appended to each message, allowing the message to end with a line that does not end with a newline.

A message header line consists of a PAM message style name, as described in `pam_start(3PAM)`. The message header values are:

- `PAM_PROMPT_ECHO_OFF`: The application is to prompt the user for a value, with echoing disabled.
- `PAM_PROMPT_ECHO_ON`: The application is to prompt the user for a value, with echoing enabled.
- `PAM_ERROR_MSG`: The application is to display the message in a form appropriate for displaying an error.
The application is to display the message in a form appropriate for general information.

The PAM message style may be followed by whitespace and additional data. This data, if present, must be ignored.

After writing all of the messages in the conversation block, if any of them were PAM_PROMPT_ECHO_OFF or PAM_PROMPT_ECHO_ON, embedded_su waits for the response values. It expects the response values one per line, in the order the messages were given.

**Phase 3: Completion**

After zero or more conversation blocks, embedded_su emits a result block instead of a conversation block.

Upon success, embedded_su emits a single line containing the word "SUCCESS". The word SUCCESS may be followed by whitespace and additional data. This data, if present, must be ignored.

Upon failure, embedded_su emits a single line containing the word "ERROR", followed by a text block as described under "Text Blocks". The text block gives an error message. The word ERROR may be followed by whitespace and additional data. This data, if present, must be ignored.

**Text Blocks**

Initialization blocks, message blocks, and error blocks are all text blocks. These are blocks of text that are terminated by a line containing a single period (.). Lines in the block that begin with a "," have an extra "," prepended to them.

All messages are localized to the current locale; no further localization is required.

**SECURITY**

embedded_su uses pam(3PAM) for authentication, account management, and session management. Its primary function is to export the PAM conversation mechanism to an unprivileged program. Like su(1M), the PAM configuration policy can be used to control embedded_su. The PAM service name used is "embedded_su".

embedded_su is almost exactly equivalent to su(1M) for security purposes. The only exception is that it is slightly easier to use embedded_su in writing a malicious program that might trick a user into providing secret data. For those sites needing maximum security, potentially at the expense of application functionality, the EXAMPLES section shows how to disable embedded_su.

**Examples**

In the following examples, left angle brackets (<<<) indicate a line written by embedded_su and read by the invoking application. Right angle brackets (>>>) indicate a line written by the application and read by embedded_su.
EXAMPLE 1  Executing a command with the Correct Password
The following example shows an attempt to execute “somecommand” as “someuser”, with the correct password supplied:

```
/usr/lib/embedded_su someuser -c somecommand
>>>.
<<<CONV 1
<<<PAM_PROMPT_ECHO_OFF
<<<Password:
<<.,
>>>[ correct password ]
<<<SUCCESS
[ somecommand executes ]
```
EXAMPLE 3  Message Examples  (Continued)

A pam_message structure with msg_style equal to PAM_ERROR_MESSAGE and msg equal to "aaa\nbbb" produces:

```
PAM_ERROR_MESSAGE
aaa
bbb
```

A pam_message structure with msg_style equal to PAM_TEXT_INFO and msg equal to "" produces:

```
PAM_TEXT_INFO

```

A pam_message structure with msg_style equal to PAM_TEXT_INFO and msg equal to NULL produces:

```
PAM_TEXT_INFO

```

EXAMPLE 4  Disabling embedded_su

To disable embedded_su, add a line to the /etc/pam.conf file similar to:

```
edded_su auth requisite pam_deny.so.1
```

emCCR – configure data collection for OCM

**Synopsis**

```
/usr/lib/ocm/ccr/bin/emCCR [automatic_update on|off]
  [clear -diagnostic[=SR=n[,FILE=path] [-c completed] [-f force]]
  [[-annotation="annotation string"] collect]
  [enable_diagchecks | disable_diagchecks]
  [enable_target | disable_target] [getupdates] [help] [hold]
  [register] [resume] [set collection_interval="string"] [start]
  [status [-diagnostic[=SR=n[,FILE=path]]]] [stop]
  [[-register] [-verbose] test]
  [update_components [ [-silent] -staged_dir="dir" ] -distribution="name"]
  [upload -diagnostic=SR=n,FILE=path [-restart] [-force]]
```

**Description**

The emCCR utility is used to configure the collection of data for the Oracle Configuration Manager (OCM). emCCR is implemented as a set of subcommands, with options to those subcommands.

**Sub-commands**

The following options are supported:

- **emCCR automatic_update [on|off]**
  
  Enable or disable the automatic retrieval of new software updates from automatic collections. By default, automatic updates are enabled.

- **emCCR clear -diagnostic**

  Clears all diagnostic upload files.

  **clear -diagnostic=SR=x-y**
  
  Clears all uploads for a particular service request. The SR number must be in the format x-y where:
  
  x represents one digit
  
  y represents multiple digits

  **clear -diagnostic=SR=x-y,FILE=path**
  
  Clears a particular upload. *path* must include the full path to the diagnostic package, such as `/scratch/test/support_info.zip`.

- **clear -diagnostic -completed**

  Clears completed uploads only.

- **clear -diagnostic=SR=x-y,FILE=path -completed**

  Clears completed uploads for a particular service request. If *FILE=path* is added, only the upload for that instance is cleared.

- **clear -diagnostic -force**

  Clears all uploads even if there are errors.
clear -diagnostic=SR=x-y,FILE=path -force
   Clears all uploads for a particular service request. If FILE=path is added, only the upload for that instance is cleared.

emCCR collect
   In connected mode, this command will perform an immediate discovery, collection, and uploading of configuration data. In disconnected mode, this command will perform a manual discovery and collection of configuration data. The data is stored in:

   ...
   /ccr/state/upload/ocmconfig.jar
-annotation="string"
   Adds a note, consisting of "string", to the data collected.

emCCR [enable_diagchecks | disable_diagchecks]
   Use this command to enable or disable all diagnostic checks collections.

emCCR [enable_target | disable_target]
   Use this command to enable or disable the collection of configuration information for targets discovered by the Oracle Configuration Manager. When you enter this command, the list of targets that can be enabled or disabled is displayed. Enter the number for the target that is to be enabled or disabled. If you press Return without entering a target number no enabling or disabling occurs.

emCCR getupdates
   Use this command to retrieve any new software updates from the content server and deploy these updates.

emCCR help
   Use this command to list the available options.

emCCR hold
   Use this command to put Oracle Configuration Manager on hold. When in hold, configuration data will not be automatically collected and uploaded to the Oracle repository. You can manually collect and upload the information with the collect command. To restart the collection of data, use the resume command.

emCCR register
   Use this command to reregister any information that has changed.

emCCR resume
   Use this command to resume the automatic collection and uploading of the configuration data.

emCCR set collection_interval="string"
   Use this command to define the schedule to collect configuration data. By default the collection is daily at the time the collector was first configured. The data can be collected daily, weekly, monthly or the time of collection can be changed as defined by string where:

   FREQ=DAILY[:BYHOUR=0-23][:BYMINUTE=0 to 59]
   Selects daily collections. You can optionally set the hour and minute to do the collection.
FREQ=WEEKLY\;BYDAY=MON to SUN \;BYHOUR=0-23][\;BYMINUTE=0 to 59]  
Selects weekly collections. You can optionally set the day, hour and minute to do the collection.

FREQ=MONTHLY\;BYMONTHDAY=1 to 31 \;BYHOUR=0-23][\;BYMINUTE=0 to 59]  
Selects monthly collections. You can optionally set the date, hour and minute to do the collection.

[\;BYHOUR=0-23][\;BYMINUTE=0 to 59]  
Selects a new time to collect the data. The frequency will not be changed.

emCCR start  
Use this command to start the scheduler.

emCCR status [-diagnostic]  

status  
Reports the status of the collector.

status -diagnostic  
Reports the status of all diagnostics uploads.

status -diagnostic=SR=x-y  
Reports all uploads for a particular service request. The SR number must be in the format $x-y$ where:

\begin{itemize}
  \item $x$ represents one digit
  \item $y$ represents multiple digits
\end{itemize}

status -diagnostic=SR=x-y,FILE=path  
Reports a particular upload. $path$ must include the full path to the diagnostic file.

emCCR stop  
Use this command to stop the scheduler.

emCCR [-register] [-verbose] test  
Use this command to test the connection to the server at Oracle, where:

- register  
Specifies that the client will be registered during the test.

- verbose  
Selects to display detailed information about the connection process.

emCCR update_components  
Use this command to deploy any updates to the Oracle Configuration Manager client and to deploy the Diagnostic Check package.

[-silent] -staged_dir="dir"  
Specifies the directory in which the Oracle Configuration Manager packages have been staged.

- silent  
Specifies that no output be displayed to screen.

[-silent] -distribution="path"  
Specifies the path to the Oracle Configuration Manager Kit to be used for deployment.
-silent  Specifies that no output be displayed to screen.

dmCCR upload -diagnostic

upload -diagnostic=SR=x-y,FILE=path

Uploads diagnostic information for a particular instance. The SR number must be in the format x-y where:

x  represents one digit
y  represents multiple digits

The path must include the full path to the diagnostic file.

upload -diagnostic=SR=x-y,FILE=path -restart

Continues the upload for a particular service request. If FILE=path is added, only the upload for that instance is done.

upload -diagnostic=SR=x-y,FILE=path -force

Restarts the upload for a particular service request. If FILE=path is added, only the upload for that instance is done.

Files  
/usr/lib/ocm
Directory to store all OCM related files and data.

/usr/lib/ocm/ccr/config
Contains configuration files.

/usr/lib/ocm/ccr/log
Contains log files.

/usr/lib/ocm/ccr/state
Contains state files and collected data.

/usr/lib/ocm/ccr/state/review/targetMap.xml
Summaries of the data that was collected.

/usr/lib/ocm/ccr/state/review
Data that was uploaded to the server.

Oracle Configuration Manager Installation and Administration Guide
The `emocmrsp` command creates a response file that can be used to configure the Oracle Configuration Manager (OCM). This utility walks you through the interrogation phase of an installation and records your responses to the prompts. The information is recorded in an OCM private format response file. By default, the response file is created in the current directory with the filename `ocm.rsp`.

**Options**

The following options are supported:

- `-help`
  Displays usage information.

- `-no_banner`
  Indicates that the banner for the response utility is not to be displayed.

- `-output file`
  Creates a response file with the specified name. By default, the response file is created in your current working directory with the name `ocm.rsp`.

- `-repeater URL`
  Defines the URL of the Oracle Support Hub.

- `-verbose file`
  Displays the contents of the specified response file.

- `-verify file`
  Verifies that the contents of the specified response file are valid.

**Operands**

- `CSI-number`  
  Customer Support Identifier

- `MyOracleSupportID`  
  My Oracle Support User Name

**Files**

- `/usr/lib/ocm`
  Directory to store all OCM related files and data.

- `/usr/lib/ocm/ocm`  
  Contains configuration files.

- `/usr/lib/ocm/ocm/ocm`  
  Contains log files.

- `/usr/lib/ocm/ocm/state`  
  Contains state files and collected data.
Summaries of the data that was collected.

Data that was uploaded to the server.

Oracle Configuration Manager Installation and Administration Guide
SMTP’s ETRN command allows an SMTP client and server to interact, giving the server an opportunity to start the processing of its queues for messages to go to a given host. This is meant to be used in start-up conditions, as well as for mail nodes that have transient connections to their service providers.

The `etrn` utility initiates an SMTP session with the host `server-host` and sends one or more ETRN commands as follows: If no `client-hosts` are specified, `etrn` looks up every host name for which `sendmail(1M)` accepts email and, for each name, sends an ETRN command with that name as the argument. If any `client-hosts` are specified, `etrn` uses each of these as arguments for successive ETRN commands.

### Options

- `-b` System boot special case. Make sure localhost is accepting SMTP connections before initiating the SMTP session with server-host.

  This option is useful because it prevents race conditions between `sendmail(1M)` accepting connections and `server-host` attempting to deliver queued mail. This check is performed automatically if no `client-hosts` are specified.

- `-v` The normal mode of operation for `etrn` is to do all of its work silently. The `-v` option makes it verbose, which causes `etrn` to display its conversations with the remote SMTP server.

### Environment Variables

No environment variables are used. However, at system start-up, `svc:/network/smtp:sendmail` reads `/etc/default/sendmail`. In this file, if the variable `ETRN_HOSTS` is set, `svc:/network/smtp:sendmail` parses this variable and invokes `etrn` appropriately. `ETRN_HOSTS` should be of the form:

```
"s1:c1.1,c1.2 s2:c2.1 s3:c3.1,c3.2,c3.3"
```

That is, white-space separated groups of `server:client` where `client` can be one or more comma-separated names. The `:client` part is optional. `server` is the name of the server to prod; a mail queue run is requested for each `client` name. This is comparable to running:

```
/usr/lib/sendmail -qR client
```

on the host `server`.

### Examples

**Example 1** Using `etrn`

Inserting the line:

```
ETRN_HOSTS="s1.domain.com:clnt.domain.com s2.domain.com:clnt.domain.com"
```
EXAMPLE 1  Using etrn  (Continued)

Using etrn in /etc/default/sendmail results in svc:/network/smtp:sendmail invoking etrn such
that ETRN commands are sent to both s1.domain.com and s2.domain.com, with both having
cnt.domain.com as the ETRN argument.

The line:

ETRN_HOSTS="server.domain.com:client1.domain.com,client2.domain.com"

results in two ETRN commands being sent to server.domain.com, one with the argument
client1.domain.com, the other with the argument client2.domain.com.

The line:

ETRN_HOSTS="server1.domain.com server2.domain.com"

results in set of a ETRN commands being sent to both server1.domain.com and
server2.domain.com; each set contains one ETRN command for each host name for which
sendmail(1M) accepts email, with that host name as the argument.

Files  
/etc/mail/sendmail.cf  sendmail configuration file
/etc/default/sendmail  Variables used by svc:/network/smtp:sendmail

RFC 1985

Notes  Not all SMTP servers support ETRN.
Name  fbconfig – Frame Buffer configuration utility

Synopsis  fbconfig [-list | -gui | -help]
          fbconfig [-dev device_filename] [-prconf] [-propt]
              [-res \?]
          fbconfig [-dev device_filename] [-res resolution-specification]
              device_specific_options

Description  fbconfig is the generic command line interface to query and configure frame buffer attributes.

The following form of fbconfig is the interface for the device independent operations performed by fbconfig:

          fbconfig [-list | -gui | -help]

The following form of fbconfig is the interface for configuring a frame buffer:

          fbconfig [-dev device_filename] [-prconf] [-propt]
              [-res]

If the -dev option is omitted, the default frame buffer (/dev/fb or /dev/fb0) is assumed. In the absence of specific options, the response will depend upon the device specific configuration program and how it responds to no options.

Options  The following options are supported:

-dev device_filename  Specify the FFB special file. The default is /dev/fbs/ffb0.

-gui  Invoke the Graphical User Interface (GUI). The GUI is available if the SUNWdcm package is installed. All other arguments are ignored.

          The GUI can configure devices (as an alternative to the fbconfig command line) and can update the Xservers file without directly editing the file. The GUI allows the user that is logged in on the graphics device or devices to configure which graphics displays the window system should use, their screen layout (where they appear on the user’s desktop), and screen properties (X attributes).

          In addition, the GUI allows advanced users to create a new video format (resolution) that some graphics devices can select from fbconfig command line or from the device-dependent portion of the GUI. The GUI’s online help explains all options and features.

-help  Print the fbconfig command usage summary. This is the default option.
-list

Print the list of installed frame buffers and associated device specific configuration routines.

<table>
<thead>
<tr>
<th>Device Filename</th>
<th>Specific Config Program</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/fbs/ffb0</td>
<td>SUNWffb_config</td>
</tr>
<tr>
<td>/dev/fbs/ffb1</td>
<td>SUNWffb_config</td>
</tr>
<tr>
<td>/dev/fbs/m640</td>
<td>SUNWm64_config</td>
</tr>
<tr>
<td>/dev/fbs/cgsix0</td>
<td>not configurable</td>
</tr>
</tbody>
</table>

-prconf

Print the current hardware configuration.

-propt

Print the current software configuration.

-res

Print the current hardware resolution.

Operands

The following operands are supported:

device_specific_options   device_specific_options are specified in the format shown by the -help output, or the corresponding device-specific man page.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWfbc</td>
</tr>
</tbody>
</table>

See Also

SUNWgfb_config(1M), SUNWifb_config(1M), SUNWpfb_config(1M), SUNWzulu_config(1M), afbconfig(1M), fbconfig(1M), m64config(1M), pgxconfig(1M), attributes(5)

Limitations

Because of limitations in the m64 kernel driver and related software, fbconfig (with the -prconf option) is unable to distinguish between a current depth of 24 or 8+24. The -propt option returns the depth specified in the OWconfig file, which will be in effect following the next restart of the window system. The xwininfo utility, usually shipped in the package containing frame buffer software (such as SUNWxwp11), reports current depth of a specified window.
**fcinfo(1M)**

**Name**
fcinfo – Fibre Channel HBA Port Command Line Interface

**Synopsis**
finfo hba-port [-l] [HBA_port_WWN]...
finfo remote-port [-ls] [-p HBA_port_WWN] [REMOTE_port_WWN]...
finfo logical-unit l u [-v] [OS device_path]
finfo [-V]
finfo [-?]  

**Description**
finfo is a command line interface that collects administrative information on fibre channel host bus adapter (HBA) ports on a host. It also collects data on any fibre channel targets that may be connected to those ports in a Storage Area Network (SAN).

**SUBCOMMANDS**
The following subcommands are supported:

- **hba-port**
  
  Lists information for the HBA port referenced by the specified HBA_port_WWN. If HBA_port_WWN is not specified, all fibre channel HBA ports on the host will be listed.

- **remote-port**
  
  Lists the remote-port information for those remote ports that are specified. If no REMOTE_port_WWN is specified, all remote ports that are visible through HBA_port_WWN are listed.

- **logical-unit | lu**
  
  Lists the logical unit referenced by the specified device_path. If device_path is not specified, all fibre channel logical units will be listed.

**Options**
The following options are supported:

- **-l, --linkstat**
  
  Lists the link error statistics information for the port referenced by the specified HBA_port_WWN or REMOTE_port_WWN.

- **-p HBA_port_WWN, --port HBA_port_WWN**
  
  Retrieve remote port information from the HBA_port_WWN of the local HBA port on the host. The -p option can only be used with the remote-port subcommand and is a mandatory option.

- **-s, --scsi-target**
  
  Lists the SCSI target information for all remote ports the user has asked for. The -p, -port option must always be specified and must be a valid HBA port on the host. This HBA port will be used as the initiator for which to retrieve the SCSI level target information. Note that
this will only function on remote port fibre channel World-Wide Names that support an FC4 type of SCSI.

-\texttt{v}, \texttt{--verbose} When used with the \texttt{logical-unit} subcommand, the \texttt{-v} displays additional information for the logical unit, including SCSI vendor and product information and device type as well as the FC World-Wide names for the local and remote fibre channel ports to which this device is attached.

-\texttt{V}, \texttt{--version} Prints the version information.

-\texttt{?}, \texttt{--help} Prints the usage information.

\textbf{Examples} \hfill \textbf{EXAMPLE 1} Listing all HBA ports

The following command lists all fibre channel HBA ports on the host:

\begin{verbatim}
# fcinfo hba-port
\end{verbatim}

EXAMPLE 3  Listing all remote ports

The following command lists all remote ports that are visible through the given HBA port:

# fcinfo remote-port -p 210100e08b274cb5

Remote Port WWN: 50020f230000b4af
  Active FC4 Types: SCSI
  SCSI Target: yes
  Node WWN: 50020f200000b4af
EXAMPLE 3  Listing all remote ports  (Continued)

Remote Port WWN: 210000e08b07daa6
  Active FC4 Types: SCSI
  SCSI Target: no
  Node WWN: 200000e08b07daa6
Remote Port WWN: 20030003ba27c788
  Active FC4 Types: SCSI
  SCSI Target: yes
  Node WWN: 1000003ba27c788
Remote Port WWN: 210000e08b096a60
  Active FC4 Types: SCSI,IP
  SCSI Target: no
  Node WWN: 200000e08b096a60

EXAMPLE 4  Listing remote ports and link statistics

The following command lists information for the remote ports and the link statistics for those ports:

```bash
# fcinfo remote-port -l -p 210100e08b272ab5
```

Remote Port WWN: 210100e08b296a60
  Active FC4 Types: SCSI,IP
  SCSI Target: no
  Node WWN: 200100e08b296a60
  Link Error Statistics:
    Link Failure Count: 0

**EXAMPLE 7**  Listing the Logical Unit

The following command lists the logical unit:

```
# fcinfo logical-unit
```

```
/dev/rdsk/c0t600C0FF000000000036223AE73EB705d0s2
/dev/rdsk/c0t600C0FF0000000000362272539E5B03d0s2
/dev/rmt/0n
```

**EXAMPLE 8**  Displaying Additional Information for the Logical Unit

The following command displays additional information about the logical unit using the `-v` option for device `/dev/rmt/0n`:

```
# fcinfo lu -v /dev/rmt/0n
```

```
OS Device Name: /dev/rmt/0n
  HBA Port WWN: 210000e07c030b91
    Remote Port WWN: 21010003b7830a6
  LUN: 0
  Vendor: STK
  Product: 9940A
  Device Type: Tape device
```

The following command displays additional information about the logical unit using the `-v` option for device `/dev/rdsk/c0t600C0FF000000000036223AE73EB705d0s2`:

```
# fcinfo logical-unit -v \
/dev/rdsk/c0t600C0FF000000000036223AE73EB705d0s2
```

```
OS Device Name: /dev/rdsk/c0t600C0FF000000000036223AE73EB705d0s2

**Error Messages**  
Errors that can occur in addition to the errors normally associated with system administration commands:

- `HBA_port_WWN`: not found
- `REMOTE_port_WWN`: not found
fdetach(1M)

Name    fdetach – detach a name from a STREAMS-based file descriptor

Synopsis  fdetach path

Description  The fdetach command detaches a STREAMS-based file descriptor from a name in the file system. Use the path operand to specify the path name of the object in the file system name space, which was previously attached. See fattach(3C).

The user must be the owner of the file or a user with the appropriate privileges. All subsequent operations on path will operate on the underlying file system entry and not on the STREAMS file. The permissions and status of the entry are restored to the state they were in before the STREAMS file was attached to the entry.

Operands  The following operands are supported:

  path     Specifies the path name of the object in the file system name space, which was previously attached.

STREAMS Programming Guide
This command is used to do the following:

- Create and modify an fdisk partition table on x86 systems
- Create and modify an fdisk partition table on removable media on SPARC or x86 systems
- Install the master boot record that is put in the first sector of the fixed disk on x86 systems only

This table is used by the first-stage bootstrap (or firmware) to identify parts of the disk reserved for different operating systems, and to identify the partition containing the second-stage bootstrap (the active Solaris partition). The rdevice argument must be used to specify the raw device associated with the fixed disk, for example, /dev/rdsk/c0t0d0p0.

The program can operate in three different modes. The first is interactive mode. In interactive mode, the program displays the partition table as it exists on the disk, and then presents a menu allowing the user to modify the table. The menu, questions, warnings, and error messages are intended to be self-explanatory.

In interactive mode, if there is no partition table on the disk, the user is given the options of creating a default partitioning or specifying the initial table values. The default partitioning allocates the entire disk for the Solaris system and makes the Solaris system partition active. In either case, when the initial table is created, fdisk also writes out the first-stage bootstrap (x86 only) code along with the partition table. In this mode (x86 only), when creating an entry for a non-EFI partition on a disk that is larger than 2 TB (terabytes), fdisk warns that the maximum size of the partition is 2 TB. Under these conditions percentages displayed by fdisk are based on 2 TB.

The second mode of operation is used for automated entry addition, entry deletion, or replacement of the entire fdisk table. This mode can add or delete an entry described on the command line. In this mode the entire fdisk table can be read in from a file replacing the original table. fdisk can also be used to create this file. There is a command line option that will cause fdisk to replace any fdisk table with the default of the whole disk for the Solaris system.

The third mode of operation is used for disk diagnostics. In this mode, a section of the disk can be filled with a user specified pattern, and mode sections of the disk can also be read or written.
When `fdisk` creates a partition, the space is allocated in the `fdisk` partition table, but the allocated disk space is not initialized. `newfs(1M)` is required to create and write file system metadata to the new partition, and `format(1M)` is required to write the VTOC or EFI/GPT metadata.

**Menu Options**

The menu options for interactive mode given by the `fdisk` program are:

**Create a partition**

This option allows the user to create a new partition. The maximum number of partitions is 4. The program will ask for the type of the partition (SOLARIS, MS-DOS, UNIX, or other). It will then ask for the size of the partition as a percentage of the disk. The user may also enter the letter c at this point, in which case the program will ask for the starting cylinder number and size of the partition in cylinders. If a c is not entered, the program will determine the starting cylinder number where the partition will fit. In either case, if the partition would overlap an existing partition or will not fit, a message is displayed and the program returns to the original menu.

**Change Active (Boot from) partition**

This option allows the user to specify the partition where the first-stage bootstrap will look for the second-stage bootstrap, otherwise known as the active partition.

**Delete a partition**

This option allows the user to delete a previously created partition. Note that this will destroy all data in that partition.

**Change between Solaris and Solaris2 Partition IDs**

This option allows the user to switch between the current `fdisk` operating system partition identifier and the previous one. This does not affect any data in the disk partition and is provided for compatibility with older software.

Use the following options to include your modifications to the partition table at this time or to cancel the session without modifying the table:

**Exit**

This option writes the new version of the table created during this session with `fdisk` out to the fixed disk, and exits the program.

**Cancel**

This option exits without modifying the partition table.

**Options**

The following options apply to `fdisk`:

  Add a partition as described by the argument (see the `-F` option below for the format). Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

- `b master_boot`

  Specify the file `master_boot` as the master boot program. The default master boot program is `/usr/lib/fs/ufs/mboot`.
-B
Default to one Solaris partition that uses the whole disk. On an x86 machine, if the disk is larger than 2 TB (terabytes), the default size of the Solaris partition will be limited to 2 TB.

-d
Turn on verbose debug mode. This will cause fdisk to print its state on stderr as it is used. The output from this option should not be used with -F.

Delete a partition as described by the argument (see the -F option below for the format). Note that the argument must be an exact match or the entry will not be deleted! Use of this option will zero out the VTOC on the Solaris partition if the fdisk table changes.

-E
Create an EFI partition that uses the entire disk.

-F fdisk_file
Use fdisk file fdisk_file to initialize table. Use of this option will zero out the VTOC on the Solaris partition if the fdisk table changes.

The fdisk_file contains up to four specification lines. Each line is delimited by a new-line character (\n). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, are separated by “white space” or colons, and have the following format:

id act bhead bsect bcyl ehead esect ecyl rsect numsect

where the entries have the following values:

id
This is the type of partition and the correct numeric values may be found in fdisk.h.

act
This is the active partition flag; 0 means not active and 128 means active.

bhead
This is the head where the partition starts. If this is set to 0, fdisk will correctly fill this in from other information.

bsect
This is the sector where the partition starts. If this is set to 0, fdisk will correctly fill this in from other information.

bcyl
This is the cylinder where the partition starts. If this is set to 0, fdisk will correctly fill this in from other information.

ehead
This is the head where the partition ends. If this is set to 0, fdisk will correctly fill this in from other information.

esect
This is the sector where the partition ends. If this is set to 0, fdisk will correctly fill this in from other information.

ecyl
This is the cylinder where the partition ends. If this is set to 0, fdisk will correctly fill this in from other information.
### fdisk(1M)

- **rsect**
  The relative sector from the beginning of the disk where the partition starts. This must be specified and can be used by `fdisk` to fill in other fields.

- **numsect**
  The size in sectors of this disk partition. This must be specified and can be used by `fdisk` to fill in other fields.

- **-g**
  Get the label geometry for disk and display on stdout (see the `-S` option for the format).

- **-G**
  Get the physical geometry for disk and display on stdout (see the `-S` option for the format).

- **-h**
  Issue verbose message; message will list all options and supply an explanation for each.

- **-I**
  Forgo device checks. This is used to generate a file image of what would go on a disk without using the device. Note that you must use `-S` with this option (see above).

- **-n**
  Don’t update `fdisk` table unless explicitly specified by another option. If no other options are used, `-n` will only write the master boot record to the disk. In addition, note that `fdisk` will not come up in interactive mode if the `-n` option is specified.

- **-o offset**
  Block offset from start of disk. This option is used for `-P`, `-r`, and `-w`. Zero is assumed when this option is not used.

- **-P fill_patt**
  Fill disk with pattern `fill_patt`. `fill_patt` can be decimal or hex and is used as number for constant long word pattern. If `fill_patt` is #, then pattern is block # for each block. Pattern is put in each block as long words and fills each block (see `-o` and `-s`).

- **-r**
  Read from disk and write to stdout. See `-o` and `-s`, which specify the starting point and size of the operation.

- **-R**
  Treat disk as read-only. This is for testing purposes.

- **-s size**
  Number of blocks to perform operation on (see `-o`).

- **-S geom_file**
  Set the label geometry to the content of the `geom_file`. The `geom_file` contains one specification line. Each line is delimited by a new-line character (`\n`). If the first character of a line is an asterisk (`*`), the line is treated as a comment. Each line is composed of entries that are position-dependent, are separated by white space, and have the following format:

  ```
  pcy1 ncyl acyl bcy1 nheads nsectors sectsiz
  ```

  where the entries have the following values:
fdisk(1M)

- cyl
  This is the number of physical cylinders for the drive.

ncyl
  This is the number of usable cylinders for the drive.

acyl
  This is the number of alt cylinders for the drive.

bcyl
  This is the number of offset cylinders for the drive (should be zero).

nheads
  The number of heads for this drive.

nsectors
  The number of sectors per track.

sectsiz
  The size in bytes of a sector.

-t
  Adjust incorrect slice table entries so that they will not cross partition table boundaries.

-T
  Remove incorrect slice table entries that span partition table boundaries.

-v
  Output the HBA (virtual) geometry dimensions. This option must be used in conjunction with the -W flag. This option will work for platforms which support virtual geometry. (x86 only)

-w
  Write to disk and read from stdin. See -o and -s, which specify the starting point and size of the operation.

-W
  Output the disk table to stdout.

-W fdisk_file
  Create an fdisk file fdisk_file from disk table. This can be used with the -F option below.

Diagnostics
Most messages will be self-explanatory. The following may appear immediately after starting the program:

Files
/dev/rdsk/c0t0d0p0 Raw device associated with the fixed disk.
/usr/lib/fs/ufs/mboot Default master boot program.

See Also
uname(1), fmthard(1M), format(1M), newfs(1M), prtvtoc(1M), attributes(5)
Fdisk: cannot open <device>
   This indicates that the device name argument is not valid.

Fdisk: unable to get device parameters for device <device>
   This indicates a problem with the configuration of the fixed disk, or an error in the fixed
disk driver.

Fdisk: error reading partition table
   This indicates that some error occurred when trying initially to read the fixed disk. This
could be a problem with the fixed disk controller or driver, or with the configuration of the
fixed disk.

Fdisk: error writing boot record
   This indicates that some error occurred when trying to write the new partition table out to
the fixed disk. This could be a problem with the fixed disk controller, the disk itself, the
driver, or the configuration of the fixed disk.
Name  ff – list file names and statistics for a file system

Synopsis  ff [-F FSType] [-V] [generic_options] [-o specific_options] special...

Description  ff prints the pathnames and inode numbers of files in the file system which resides on the special device special. Other information about the files may be printed using options described below. Selection criteria may be used to instruct ff to only print information for certain files. If no selection criteria are specified, information for all files considered will be printed (the default); the -i option may be used to limit files to those whose inodes are specified.

Output is sorted in ascending inode number order. The default line produced by ff is:

path-name  i-number

The maximum information the command will provide is:

path-name  i-number  size  uid

Options  -F  Specify the FSType on which to operate. The FSType should either be specified here or be determinable from /etc/vfstab by matching the special with an entry in the table, or by consulting /etc/default/fs.

-V  Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.

generic_options  Options that are supported by most FSType-specific modules of the command. The following options are available:

- I  Do not print the i-node number after each path name.

- l  Generate a supplementary list of all path names for multiply-linked files.

- p prefix  The specified prefix will be added to each generated path name. The default is '.' (dot).

- s  Print the file size, in bytes, after each path name.

- u  Print the owner's login name after each path name.

- a - n  Select if the file has been accessed in n days.

- m - n  Select if the file has been written or created in n days.

- c - n  Select if file's status has been changed in n days.

- n file  Select if the file has been modified more recently than the argument file.
-i i-node-list  Generate names for only those i-nodes specified in
i-node-list. i-node-list is a list of numbers separated by
commas (with no intervening spaces).

-o  Specify FSType-specific options in a comma separated (without spaces)
list of suboptions and keyword-attribute pairs for interpretation by the
FSType-specific module of the command.

Operands  special  A special device.

Usage  See largefile(5) for the description of the behavior of \( \texttt{ff} \) when encountering files greater than or equal to 2 Gbyte (\( 2^{31} \) bytes).

Files  /etc/default/fs  default local file system type. Default values can be set for the following
flags in /etc/default/fs. For example: LOCAL=ufs

   LOCAL  The default partition for a command if no FSType is
   specified.

   /etc/vfstab  list of default parameters for each file system

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also find(1), ncheck(1M), stat(2), vfstab(4), attributes(5), largefile(5) Manual pages for the
FSType-specific modules of \( \texttt{ff} \).

Notes  This command may not be supported for all FSTypes.

The -a, -m, and -c flags examine the st_atime, st_mtime, and st_ctime fields of the stat
structure respectively. (See \( \texttt{stat}(2) \).)
ffbconfig(1M)

**Name**
ffbconfig, SUNWffb_config – configure the FFB Graphics Accelerator

**Synopsis**
```
/usr/sbin/ffbconfig [-dev device-filename]
[-res video-mode [now | try] [noconfirm | nocheck]]
[-file | machine | system]
[-deflinear | true | false]
[-defoverlay | true | false]
[-linearorder | first | last]
[-overlayorder | first | last]
[-expvis | enable | disable]
[-sov | enable | disable] [-maxwids n]
[-extovl | enable | disable]
[-g gamma-correction-value]
[-gfile gamma-correction-file] [-propt] [-prconf]
[-defaults]
```

```
/usr/sbin/ffbconfig [-propt] [-prconf]
/usr/sbin/ffbconfig [-help] [-res ?]
```

**Description**
ffbconfig configures the FFB Graphics Accelerator and some of the X11 window system defaults for FFB.

The first form of `ffbconfig` stores the specified options in the OWconfig file. These options will be used to initialize the FFB device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms of `ffbconfig`, which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options do not update the OWconfig file. Additionally, for the third form all other options are ignored.

Options may be specified for only one FFB device at a time. Specifying options for multiple FFB devices requires multiple invocations of `ffbconfig`.

Only FFB-specific options can be specified through `ffbconfig`. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the `openwin` command line. See the *OpenWindows Desktop Reference Manual* for details.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. The `-file` option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the `/usr/openwin` directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the `ffbconfig` program, which is owned by the root user, always runs with setuid root permission.
Options

-dev device-filename
   Specifies the FFB special file. The default is /dev/fbs/ffb0.

-file machine|system
   Specifies which OpenWin config file to update. If machine is specified, the machine-specific OpenWin config file in the /etc/openwin directory tree is updated. If system is specified, the global OpenWin config file in the /usr/openwin directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is machine.

-res video-mode [now | try [noconfirm | nocheck]]
   Specifies the video mode used to drive the monitor connected to the specified FFB device.

video-mode has the format of widthxheightxrate where width is the screen width in pixels, height is the screen height in pixels, and rate is the vertical frequency of the screen refresh.

The s suffix, as in 960x680x112s and 960x680x108s, indicates stereo video modes. The i suffix, as in 640x480x60i and 768x575x50i, indicates interlaced video timing. If absent, non-interlaced timing will be used.

-res (the third form in the SYNOPSIS) also accepts formats with @ (at sign) in front of the refresh rate instead of x. 1280x1024@76 is an example of this format.

Some video-modes are supported only on certain revisions of FFB. Also, some video-modes, supported by FFB, may not be supported by the monitor. The list of video-modes supported by the FFB device and the monitor can be obtained by running ffbconfig with the -res? option.

The following table lists all possible video modes supported on FFB:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1024x768x60</td>
<td></td>
</tr>
<tr>
<td>1024x768x70</td>
<td></td>
</tr>
<tr>
<td>1024x768x75</td>
<td></td>
</tr>
<tr>
<td>1024x768x77</td>
<td></td>
</tr>
<tr>
<td>1024x800x84</td>
<td></td>
</tr>
<tr>
<td>1152x900x66</td>
<td></td>
</tr>
<tr>
<td>1152x900x76</td>
<td></td>
</tr>
<tr>
<td>1280x800x76</td>
<td></td>
</tr>
<tr>
<td>1280x1024x60</td>
<td></td>
</tr>
<tr>
<td>1280x1024x67</td>
<td></td>
</tr>
</tbody>
</table>
Symbolic names

For convenience, some video modes have symbolic names defined for them. Instead of the form \textit{widthxheightxrate}, one of these names may be supplied as the argument to \texttt{-res}. The meaning of the symbolic name \texttt{none} is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

\begin{tabular}{|l|l|}
\hline
Name & Corresponding Video Mode \\
\hline
svga & 1024x768x60 \\
1152 & 1152x900x76 \\
1280 & 1280x1024x76 \\
stereo & 960x680x112s \\
ntsc & 640x480x60i \\
pal & 768x575x50i \\
\textbf{none} & (video mode currently programmed in device) \\
\hline
\end{tabular}

The \texttt{-res} option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.
now
Specifies that the FFB device will be immediately programmed to display this video mode, in addition to updating the video mode in the OWconfig file. This option is useful for changing the video mode before starting the window system.

It is inadvisable to use this suboption with ffbconfig while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run ffbconfig with the now suboption, first bring the window system down. If the now suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won’t change until the window system is exited and re-entered. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

noconfirm
Instructs ffbconfig to bypass confirmation and warning messages and to program the requested video mode anyway.

Using the -res option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of ffbconfig is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. This option is useful when ffbconfig is being run from a shell script.

nocheck
Suspends normal error checking based on the monitor sense code. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the FFB device. Note: Use of this option implies noconfirm as well.

try
Programs the specified video mode on a trial basis. The user will be asked to confirm the video mode by typing y within 10 seconds. The user may also terminate the trial before 10 seconds are up by typing any character. Any character other than y or RETURN is considered a no and the previous video mode will be restored and ffbconfig will not change the video mode in the OWconfig file and other options specified will still take effect. If a RETURN is pressed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with ffbconfig while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run fconfig with the try sub-option, the window system should be brought down first.
FFB possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

`-deflinear true | false`  
FFB sets the default visual to the linear visual that satisfies other specified default visual selection options. Specifically, the default visual selection options are those set by the `Xsun (1) defdepth` and `defclass` options. See OpenWindows Desktop Reference Manual for details.

`-deflinear false` (or if there is no linear visual that satisfies the other default visual selection options) sets the default visual to the non-linear visual as the default.

This option cannot be used when the `-defoverlay` option is present, because FFB does not possess a linear overlay visual.

`-defoverlay true | false`  
FFB provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the FFB visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. This visual has 256 `maxwids` of opaque color values. See `-maxwids` in OPTIONS.

If `-defoverlay` is true, the overlay visual will be made the default visual. If `-defoverlay` is false, the nonoverlay visual that satisfies the other default visual selection options, such as `defdepth` and `defclass`, will be chosen as the default visual. See the OpenWindows Desktop Reference Manual for details.

Whenever `-defoverlay` true is used, the default depth and class chosen on the openwin command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as false. This option cannot be used when the `-deflinear` option is present, because FFB doesn't possess a linear overlay visual.

`-linearorder first | last`  
If first, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the FFB screen. If last, the nonlinear visuals will come before the linear ones.

`-overlayorder first | last`  
If true, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the FFB screen. If false, the non-overlay visual will come before the overlay one.

`-expvis enable | disable`  
If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor and so forth) can be found in the screen visual list.
-sov enable | disable
Advertises the root window's SERVER_OVERLAY_VISUALS property. SOV visuals will be exported and their transparent types, values and layers can be retrieved through this property. If -sov disable is specified, the SERVER_OVERLAY_VISUALS property will not be defined. SOV visuals will not be exported.

-maxwids n
Specifies the maximum number of FFB X channel pixel values that are reserved for use as window sIDs (WIDs). The remainder of the pixel values in overlay colormaps are used for normal X11 opaque color pixels. The reserved WIDs are allocated on a first-come first-serve basis by 3D graphics windows (such as XGL), MBX windows, and windows that have a non-default visual. The X channel codes 0 to (255-n) will be opaque color pixels. The X channel codes (255-n+1) to 255 will be reserved for use as WIDs. Legal values on FFB, FFB2 are: 1, 2, 4, 8, 16, and 32. Legal values on FFB2+ are: 1, 2, 4, 8, 16, 32, and 64.

-extovl enable | disable
This option is available only on FFB2+. If enabled, extended overlay is available. The overlay visuals will have 256 opaque colors. The SOV visuals will have 255 opaque colors and 1 transparent color. This option enables hardware supported transparency which provides better performance for windows using the SOV visuals.

-g gamma-correction value
This option is available only on FFB2+. This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by xsolarisGetVisualGamma(3). See xsolarisGetVisualGamma(3) for a description of that function.

This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

-gfile gamma-correction file
This option is available only on FFB2+. This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. This file should provide 256 triplet values, each in hexadecimal format and separated by at least 1 space. Following is an example of this file:

```
0x80 0x80 0x80
0x81 0x81 0x81
0x82 0x82 0x82
...
...
0xff 0xff 0xff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note, when gamma correction is being done using user specified table, the
gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

- defaults
  Resets all option values to their default values.

- propt
  Prints the current values of all FFB options in the OWconfig file specified by the -file option for the device specified by the -dev option. Prints the values of options as they will be in the OWconfig file after the call to ffbconfig completes. The following is a typical display using the -propt option:

  --- OpenWindows Configuration for /dev/fbs/ffb0 ---
  OWconfig: machine
  Video Mode: NONE
  Default Visual: Non-Linear Normal Visual
  Visual Ordering: Linear Visuals are last
  Overlay Visuals are last
  OpenGL Visuals: disabled
  SOV: disabled
  Allocated WIDs: 32

- prconf
  Prints the FFB hardware configuration. The following is a typical display using the -prconf option:

  --- Hardware Configuration for /dev/fbs/ffb0 ---
  Type: double-buffered FFB2 with Z-buffer
  Board: rev x
  PROM Information: @(x)ffb2.fth x.x xx/xx/xx
  FBC: version x
  DAC: Brooktree 9068, version x
  3DRAM: Mitsubishi 1309, version x
  EDID Data: Available - EDID version 1 revision x
  Monitor Sense ID: 4 (Sun 37x29cm RGB color monitor)
  Monitor possible resolutions: 1024x768x60, 1024x768x70, 1024x768x75, 1152x900x66, 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680x112s, 640x480x60
  Current resolution setting: 1280x1024x76

- help
  Prints a list of the ffbconfig command line options, along with a brief explanation of each.

**Defaults**

For a given invocation of ffbconfig command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if an FFB option has never been specified via ffbconfig, a default value is used. The option defaults are listed in the following table:
The default for the `res` option of none means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, 6X) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default FFB video mode.

**Examples**

**Example 1** Changing The Monitor Type

The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

```bash
example% /usr/sbin/ffbconfig -res 1280x1024x76
```

ff_ufs(1M)

Name  ff_ufs – list file names and statistics for a ufs file system

Synopsis  ff -F ufs [generic_options] [-o a,m,s] special...

Description  ff prints the pathnames and inode numbers of files in the file system which resides on the special device special.

See ff(1M) for information regarding the ff command. See OPTIONS for information regarding the ufs-specific options.

Options  The following options are supported:

   -o   Specify ufs file system specific options. The following options available are:

   a   Print the '.' and '..' directory entries.

   m   Print mode information. This option must be specified in conjunction with the -i i-node-list option (see ff(1M)).

   s   Print only special files and files with set-user-ID mode.

Name  fiocompress – file compression utility

Synopsis  /sbin/fiocompress -c [-m] [-b block_size] input_file output_file

/sbin/fiocompress -d input_file output_file

Description  The fiocompress utility is a file compression tool that works together with the dcfs(7FS) file system to perform per-file compression. You can use fiocompress to decompress a compressed file or mark a compressed file as compressed, causing automatic decompression on read. The primary use of fiocompress is to compress files in the boot archive.

Note that this utility is not a Committed interface. See attributes(5).

Options  The following options are supported:

- b block_size
  Specify a block size for compression. The default block size is 8192.

- c
  Compress the specified file.

- d
  Decompress the specified file.

- m
  Mark the compressed file for automatic decompression on read. Can be used only in conjunction with -c.

Exit Status  0

The command completed successfully.

-1

The command exited due to an error.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Interface Stability</td>
<td>Private</td>
</tr>
</tbody>
</table>

See Also  boot(1M), bootadm(1M), dcfs(7FS), ufs(7FS), attributes(5)

Notes  This compression/decompression utility works only with files stored in a UFS file system.

There is no obvious way to determine whether a given file is compressed, other than copying the file and comparing the number of disk blocks of the copy against the original.
The **flar** command is used to administer flash archives. A flash archive is an easily transportable version of a reference configuration of the Solaris operating environment, plus optional other software. Such an archive is used for the rapid installation of Solaris on large numbers of machines. You can create a flash archive using either `flar` with the `create` subcommand or the `flar create (1M)` command. See `flash_archive (4)`.

In flash terminology, a system on which an archive is created is called a *master*. The system image stored in the archive is deployed to systems that are called *clones*.

A flash archive can be created on a system that is running a UFS root file system or a ZFS root file system. A flash archive of a ZFS rooted system contains the ZFS send stream of the entire dataset hierarchy under root dataset and additional send streams for other datasets outside `rpool/ROOT` except for the swap and dump volumes and any excluded datasets.

ZFS send stream flash archive images *cannot* be used to install zones. You must create a flash archive with an explicit `cpio` or `pax` archive when the system has a ZFS root. To create the flash archive, use the `-L archiver` option, described below, specifying `cpio` or `pax` as the method to archive the files.

There are two types of flash archives: full and differential. Both are created with the `create` subcommand. A full archive contains all the files that are in a system image. A differential archive contains only differences between two system images. Installation of a differential archive is faster and consumes fewer resources than installation of a full archive.

In creating a differential archive, you compare two system images. A system image can be any of:

- a Live Upgrade boot environment, mounted on some directory using `lumount (1M)` (see `live_upgrade (5)`)
- a clone system mounted over NFS with root permissions
- a full flash archive expanded into some local directory
To explain the creation of a differential flash archive, the following terminology is used:

old  The image prior to upgrade or other modification. This is likely the image as it was installed on clone systems.

new  The old image, plus possible additions or changes and minus possible deletions. This is likely the image you want to duplicate on clone systems.

The flar command compares old and new, creating a differential archive as follows:

- files on new that are not in old are added to the archive;
- files of the same name that are different between old and new are taken from new and added to the archive;
- files that are in old and not in new are put in list of files to be deleted when the differential archive is installed on clone systems.

When creating a differential flash archive, the currently running image is, by default, the new image and a second image, specified with the -A option, is the old image. You can use the -R option to designate an image other than the currently running system as the new image. These options are described below.

Note that differential flash archives are not supported for a ZFS root filesystem.

You can run flar create in multi- or single-user mode. You can also use the command when the master system is booted from the first Solaris software CD or from a Solaris net image. Archive creation should be performed when the master system is in as stable a state as possible.

Following creation of a flash archive, you can use JumpStart to clone the archive on multiple systems. You can install a flash archive of a ZFS root pool by using JumpStart, the luupgrade(1M) command, or by selecting this option from the interactive text installation method.

Subcommands

The flar command includes subcommands for creating, combining, splitting, and providing information about archives. A subcommands is the first argument in a flar command line. These subcommands are as follows:

create  Create a new flash archive, of a name you specify with the -n argument, based on the currently running system. Use the -A option (described below) to create a differential flash archive.

combine  Combine the individual sections that make up an archive into the archive. If dir is specified (see -d option below), the sections will be gathered from dir; otherwise, they will be gathered from the current directory. Each section is assumed to be in a separate file, the names of which are the section names. At a minimum, the archive cookie (cookie), archive identification (identification), and archive files (archive) sections must be present. If archive is a directory, its contents are
archived using files_archived_method (cpio and pax) prior to inclusion in the archive. If so specified in the identification section, the contents are compressed.

Note that no validation is performed on any of the sections. In particular, no fields in the identification section are validated or updated. See flash_archive(4) for a description of the archive sections.

info Extract information on an archive. This subcommand is analogous to pkginfo.

split Split an archive into one file for each section of the archive. Each section is copied into a separate file in dir, if dir is specified (see -d option below), or the current directory if it is not. The files resulting from the split are named after the sections. The archive cookie is stored in a file named cookie. If section is specified (see -u option below), only the named section is copied.

The create subcommand requires root privileges.

The options for each subcommand are described below.

Options The options for the create subcommand are below. Many of these options supply values for keywords in the identification section of a file containing a flash archive. See flash_archive(4) for a description of these keywords.

-a author author is used to provide an author name for the archive identification section of the new flash archive. If you do not specify -a, no author name is included in the identification section.

-A system_image Create a differential flash archive by comparing a new system image (see DESCRIPTION) with the image specified by the system_image argument. By default, the new system image is the currently running system. You can change the default with the -R option, described below. system_image is a directory containing an image. It can be accessible through UFS, NFS, or lumount(1M).

The rules for inclusion and exclusion of files in a differential archive are described in DESCRIPTION. You can modify the effect of these rules with the use of the -x, -X, -y, and -z options, described below.

This option is not supported when creating a flash archive of a ZFS root pool.

-c Compress the archive using compress(1)

-D dataset Exclude specified datasets from the flash archive. This option can be used multiple times to exclude multiple datasets.
Use the contents of `filelist` as a list of files to include in the archive. The files are included in addition to the normal file list, unless `-F` is specified (see below). If `filelist` is `-`, the list is taken from standard input. `filelist` can include directories. If a directory is listed, all files and subdirectories under that directory are included.

This option is not supported when creating a flash archive of a ZFS root pool.

The description to be included in the archive as the value of the `content_description` archive identification key. This option is incompatible with `-E`.

The description to be used as the value of the archive identification `content_description` key is retrieved from the file `descr_file`. This option is incompatible with `-e`.

Include only files in the list specified by `-f`. This option makes `-f filelist` an absolute list, rather than a list that is appended to the normal file list.

This option is not supported when creating a flash archive of a ZFS root pool.

Do not generate hash identifier.

Ignore integrity check. To prevent you from excluding important system files from an archive, `flar` runs an integrity check. This check examines all files registered in a system package database and stops archive creation if any of them are excluded. Use this option to override this integrity check.

This option is not supported when creating a flash archive of a ZFS root pool.

By default, the value for the `creation_date` field in the identification section is generated automatically, based on the current system time and date. If you specify the `-i` option, `date` is used instead. `date` is in the format `YYYYMMDDhhmmss`, so that, for example:

```
20060905031000
```

...stands for 3:10 AM on September 5, 2006.

By default, the value for the `files_archived_method` field in the identification section is `pax(1)`. If you specify `-L`, the archiver (`cpio(1)` and `pax`) is used instead.
-m master
By default, the value for the creation_master field in the identification section is the name of the system on which you run flar create, as reported by uname -n. If you specify -m, master is used instead.

-M
Used only when you are creating a differential flash archive. When creating a differential archive, flar creates a long list of the files in the system that remain the same, are changed, and are to be deleted on clone systems. This list is stored in the manifest section of the archive (see flash_archive(4)). When the differential archive is deployed, the flash software uses this list to perform a file-by-file check, ensuring the integrity of the clone system. Use of this option to avoid such a check and saves the space used by the manifest section in a differential archive. However, you must weigh the savings in time and disk space against the loss of an integrity check upon deployment. Because of this loss, use of this option is not recommended.

This option is not supported when creating a flash archive of a ZFS root pool.

-n name
name is supplied as the value of the content_name keyword. See flash_archive(4).

The -n name option, with name argument, is required for the create subcommand.

-R root
Create the archive from the file system tree rooted at root. If you do not specify this option, flar creates an archive from a file system rooted at /. When creating a differential flash archive, the system image specified by -R replaces the currently running system as the new image. See DESCRIPTION.

Note - The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-S
Skip the disk space check and do not write archive size data to the archive. Without -S, flar builds a compressed archive in memory before writing the archive to disk, to ensure you have sufficient disk space. Use -S to skip this step. The result of the use of -S is a significant decrease in the time it takes to create an archive.

-T type
Content type included in the archive as the value of the content_type archive identification key. If you do not specify -T, the content_type keyword is not included.
-u key=value...
Include the user-defined keyword(s) and values in the archive identification section. See flash_archive(4).

-u section...
Include the user-defined section located in the file section in the archive. section must be a blank-separated list of section names as described in flash_archive(4).

-x exclude ...
Exclude the file or directory exclude from the archive. Note that the exclude file or directory is assumed to be relative to the alternate root specified using -R. If the parent directory of the file exclude is included with the -y option (see -y include), then only the specific file or directory specified by exclude is excluded. Conversely, if the parent directory of an included file is specified for exclusion, then only the file include is included. For example, if you specify:

-x /a -y /a/b
all of /a except for /a/b is excluded. If you specify:

-y /a -x /a/b
all of /a except for /a/b is included.

This option is not supported when creating a flash archive of a ZFS root pool.

-y include ...
Include the file or directory include in the archive. Note that the exclude file or directory is assumed to be relative to the alternate root specified using -R. See the description of the -x option, above, for a description of the interaction of the -x and -y options.

This option is not supported when creating a flash archive of a ZFS root pool.

-X filelist ...
Use the contents of filelist as a list of files to exclude from the archive. If filelist is -, the list is taken from standard input.

This option is not supported when creating a flash archive of a ZFS root pool.

-z filelist ...
filelist is a list of files prefixed with a plus (+) or minus (-). A plus indicates that a file should be included in the archive; the minus indicates exclusion. If filelist is -, the list is taken from standard input.

This option is not supported when creating a flash archive of a ZFS root pool.

The options for flar info subcommand are as follows:
Only the value of the keyword *keyword* is returned.

List all files in the archive. Does not process content from any sections other than the *archive* section.

The following are *flar info* options used with tape archives:

- **-b blocksize** The block size to be used when creating the archive. If not specified, a default block size of 64K is used.

- **-p posn** Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is examined.

- **-t** The archive to be analyzed is located on a tape device. The path to the device is specified by *archive* (see OPERANDS).

The options for *flar split* and *combine* (split and combine archives) subcommands are as follows:

- **-d dir** Retrieve sections from *dir*, rather than from the current directory.

- **-f** (Used with *split* only.) Extract the *archive* section into directory called *archive*, rather than placing it in a file of the same name as the section.

- **-S section** (Used with *split* only.) Extract only the section named *section* from the archive.

- **-u section...** Appends *section* to the list of sections to be included. The default list includes the *cookie*, *identification*, and *archive* sections. *section* can be a single section name or a space-separated list of section names.

The following options are used with tape archives (with both *split* and *combine*):

- **-b blocksize** The block size to be used when creating the archive. If not specified, a default block size of 64K is used.

- **-p posn** Used only with -t. Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is used.

- **-t** Create an archive on or read an archive from a tape device. The *archive* operand (see OPERANDS) is assumed to be the name of the tape device.

**Operands** The following operand is supported:

- **archive** Path to tape device if the -t option was used. Otherwise, the complete path name of a flash archive. By convention, a file containing a flash archive has a file extension of .flar.
**Examples**

**EXAMPLE 1** Creating a Flash Archive

The command below creates a flash archive named pogoS9 and stores it in `/export/home/archives/s9fcs.flar`. The currently running system is the basis for the new archive.

```
# flar create -n pogoS9 /export/home/archives/s9fcs.flar
```

**EXAMPLE 2** Creating Differential Flash Archives

The command below creates a differential flash archive.

```
# flar create -n diff_pogoS9 -A /images 
/export/home/archives/diff_s9fcs.flar
```

In the following example the *old* system image is accessed through `lumount`.

```
# lumount s9BE /test
# flar create -n diff_pogoS9 -A /test 
   /export/home/archives/diff_s9fcs.flar
```

The following example shows the use of the `-R` option to specify a new system image other than the currently running system.

```
# flar create -n diff_pogoS9 -R /test 
   -A /images /export/home/archives/diff_s9fcs.flar
```

Note the caveat on the use of the `-R` option in the description of that option, above.

**Exit Status**

The following exit values are returned for the `create`, `split`, and `combine` subcommands:

- **0** Successful completion.
- **>0** An error occurred.

The following exit values are returned for the `info` subcommand:

- **0** Successful completion.
- **1** Command failed. If the `-k` option is used and the requested keyword is not found, `flar` returns 2.

See Also  cpio(1), pax(1), flarcreate(1M), luupgrade(1M), flash_archive(4), attributes(5)
The `flarcreate` command creates a flash archive from a master system. A master system is one that contains a reference configuration, which is a particular configuration of the Solaris operating environment, plus optional other software. A flash archive is an easily transportable version of the reference configuration.

In flash terminology, a system on which an archive is created is called a master. The system image stored in the archive is deployed to systems that are called clones.

A flash archive can be created on a system that is running a UFS root file system or a ZFS root file system. A flash archive of a ZFS rooted system contains the ZFS send stream of the entire dataset hierarchy under root dataset and additional send streams for other datasets outside rpool/ROOT except for the swap and dump volumes and any excluded datasets.

ZFS send stream flash archive images cannot be used to install zones. You must create a flash archive with an explicit `cpio` or `pax` archive when the system has a ZFS root. To create the flash archive, use the `-L archiver` option, described below, specifying `cpio` or `pax` as the method to archive the files.

There are two types of flash archives: full and differential. A full archive contains all the files that are in a system image. A differential archive contains only differences between two system images. Installation of a differential archive is faster and consumes fewer resources than installation of a full archive.

In creating a differential archive, you compare two system images. A system image can be any of:
- a Live Upgrade boot environment, mounted on some directory using `lumount(1M)` (see `live_upgrade(5)`)
- a clone system mounted over NFS with root permissions
- a full flash archive expanded into some local directory

To explain the creation of a differential flash archive, the following terminology is used:

**old**

The image prior to upgrade or other modification. This is likely the image as it was installed on clone systems.
The old image, plus possible additions or changes and minus possible deletions. This is likely the image you want to duplicate on clone systems.

The flarc create command compares old and new, creating a differential archive as follows:
- files on new that are not in old are added to the archive;
- files of the same name that are different between old and new are taken from new and added to the archive;
- files that are in old and not in new are put in list of files to be deleted when the differential archive is installed on clone systems.

When creating a differential flash archive, the currently running image is, by default, the new image and a second image, specified with the -A option, is the old image. You can use the -R option to designate an image other than the currently running system as the new image. These options are described below.

Note that differential flash archives are not supported for a ZFS root file system.

Following creation of a flash archive, you can use JumpStart to clone the archive on multiple systems. Using JumpStart to install one or more systems is the only installation method available for installing a flash archive of a ZFS root pool.

You can run flarc create in multi- or single-user mode. You can also use the command when the master system is booted from the first Solaris software CD or from a Solaris net image.

Archive creation should be performed when the master system is in as stable a state as possible. Following archive creation, use the flarc(1M) command to administer a flash archive.

See flash_archive(4) for a description of the flash archive.

The flarc create command requires root privileges.

**Options**
The flarc create command has one required argument:

- name
  Specifies the name of the flash archive. name is supplied as the value of the content_name keyword. See flash_archive(4).

The flarc create command has the following general options:

- system_image
  Create a differential flash archive by comparing a new system image (see DESCRIPTION) with the image specified by the system_image argument. By default, the new system image is the currently running system. You can change the default with the -R option, described below. system_image is a directory containing an image. It can be accessible through UFS, NFS, or lumount(1M).
The rules for inclusion and exclusion of files in a differential archive are described in DESCRIPTION. You can modify the effect of these rules with the use of the -x, -X, -y, and -z options, described below.

This option is not supported when creating a flash archive of a ZFS root pool.

- c
  Compress the archive using compress(1)

- D dataset
  Exclude specified datasets from the flash archive. This option can be used multiple times to exclude multiple datasets.

- f filelist
  Use the contents of filelist as a list of files to include in the archive. The files are included in addition to the normal file list, unless -F is specified (see below). If filelist is -, the list is taken from standard input. filelist can include directories. If a directory is listed, all files and subdirectories under that directory are included.

This option is not supported when creating a flash archive of a ZFS root pool.

- F
  Include only files in the list specified by -f. This option makes -f filelist an absolute list, rather than a list that is appended to the normal file list.

This option is not supported when creating a flash archive of a ZFS root pool.

- H
  Do not generate hash identifier.

- I
  Ignore integrity check. To prevent you from excluding important system files from an archive, flarcreate runs an integrity check. This check examines all files registered in a system package database and stops archive creation if any of them are excluded. Use this option to override this integrity check.

This option is not supported when creating a flash archive of a ZFS root pool.

- L archiver
  By default, the value for the files_archived_method field in the identification section is pax(1). If you specify -L, the archiver (cpio(1) and pax) is used instead.

- M
  Used only when you are creating a differential flash archive. When creating a differential archive, flarcreate creates a long list of the files in the system that remain the same, are changed, and are to be deleted on clone systems. This list is stored in the manifest section of the archive (see flash_archive(4)). When the differential archive is deployed, the flash software uses this list to perform a file-by-file check, ensuring the integrity of the clone system. Use of this option to avoids such a check and saves the space used by the manifest
section in a differential archive. However, you must weigh the savings in time and disk space against the loss of an integrity check upon deployment. Because of this loss, use of this option is not recommended.

This option is not supported when creating a flash archive of a ZFS root pool.

-R root
Create the archive from the file system tree rooted at root. If you do not specify this option, flarcreate creates an archive from a file system rooted at /. 

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-S
Skip the disk space check and do not write archive size data to the archive. Without -S, flarcreate builds a compressed archive in memory before writing the archive to disk, to determine the size of the archive. This size information is written to the header of the archive in the files_archived_size field and is used during archive deployment on the client to ensure enough disk space is available on the client. Use -S to skip this step. The result of the use of -S is a significant decrease in the time it takes to create an archive.

-U key=value...
Include the user-defined keyword(s) and values in the archive identification section.

-x exclude...
Exclude the file or directory exclude from the archive. Note that the exclude file or directory is assumed to be relative to the alternate root specified using -R. If the parent directory of the file exclude is included with the -y option (see -y include), then only the specific file or directory specified by exclude is excluded. Conversely, if the parent directory of an included file is specified for exclusion, then only the file include is included. For example, if you specify:

-x /a -y /a/b

all of /a except for /a/b is excluded. If you specify:

-y /a -x /a/b

all of /a except for /a/b is included.

This option is not supported when creating a flash archive of a ZFS root pool.

-X filelist...
Use the contents of filelist as a list of files to exclude from the archive. If filelist is –, the list is taken from standard input.

This option is not supported when creating a flash archive of a ZFS root pool.
-y include...
Include the file or directory include in the archive. Note that the include file or directory is assumed to be relative to the alternate root specified using -R. See the description of the -x option, above, for a description of the interaction of the -x and -y options.

This option is not supported when creating a flash archive of a ZFS root pool.

-z filelist...
filelist is a list of files prefixed with a plus (+) or minus (-). A plus indicates that a file should be included in the archive; the minus indicates exclusion. If filelist is –, the list is taken from standard input.

This option is not supported when creating a flash archive of a ZFS root pool.

Use the following option with user-defined sections.

-u section...
Include the user-defined section located in the file section in the archive. section must be a blank-separated list of section names as described in flash_archive(4).

Use the following options with tape archives.

-b blocksize
The block size to be used when creating the archive. If not specified, a default block size of 64K is used.

-p posn
Used only with -t. Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is used.

-t
Create an archive on a tape device. The archive operand (see OPERANDS) is assumed to be the name of the tape device.

The following options are used for archive identification.

-a author
author is used to provide an author name for the archive identification section. If you do not specify -a, no author name is included in the identification section.

-e descr
The description to be included in the archive as the value of the content_description archive identification key. This option is incompatible with -E.

-E descr_file
The description to be used as the value of the archive identification content_description key is retrieved from the file descr_file. This option is incompatible with -e.
-1 date
  By default, the value for the creation_date field in the identification section is generated automatically, based on the current system time and date. If you specify the -1 option, date is used instead. date is in the format YYYYMMDDhhmmss, so that, for example:

  20060905031000

  ...stands for 3:10 AM on September 5, 2006.

-m master
  By default, the value for the creation_master field in the identification section is the name of the system on which you run flarcreate, as reported by uname -n. If you specify -m, master is used instead.

-T type
  Content type included in the archive as the value of the content_type archive identification key. If you do not specify -T, the content_type keyword is not included.

Operands
The following operand is supported:

archive
  Path to tape device if the -t option was used. Otherwise, the complete path name of a flash archive. By convention, a file containing a flash archive has a file extension of .flar.

Examples
EXAMPLE 1
Install a Master System with a ZFS Root
The following command installs a master system with a ZFS root and creates a flash archive.

  # flarcreate -n flar_archive_name flar_location

Exit Status
The following exit values are returned:

0
  Successful completion.

>0
  An error occurred.

**Name**
fmadm – fault management configuration tool

**Synopsis**
fmadm [-q] [subcommand [arguments]]

**Description**
The `fmadm` utility can be used by administrators and service personnel to view and modify system configuration parameters maintained by the Solaris Fault Manager, `fmd(1M)`. `fmd` receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

`fmadm` can be used to:

- view the set of diagnosis engines and agents that are currently participating in fault management,
- view the list of system components that have been diagnosed as faulty, and
- perform administrative tasks related to these entities.

The Fault Manager attempts to automate as many activities as possible, so use of `fmadm` is typically not required. When the Fault Manager needs help from a human administrator, service repair technician, or Sun, it produces a message indicating its needs. It also refers you to a knowledge article on Sun's web site, [http://www.sun.com/msg/](http://www.sun.com/msg/). The web site might ask you to use `fmadm` or one of the other fault management utilities to gather more information or perform additional tasks. The documentation for `fmd(1M)`, `fmdump(1M)`, and `fmstat(1M)` describe more about tools to observe fault management activities.

The `fmadm` utility requires the user to possess the `SYS_CONFIG` privilege. Refer to the *System Administration Guide: Security Services* for more information about how to configure Solaris privileges. The `fmadm load` subcommand requires that the user possess all privileges.

**SUBCOMMANDS**
`fmadm` accepts the following subcommands. Some of the subcommands accept or require additional options and operands:

`fmadm acquit fmr | label [uuid]`
Notify the Fault Manager that the specified resource is not to be considered to be a suspect in the fault event identified by `uuid`, or if no UUID is specified, then in any fault or faults that have been detected. The `fmadm acquit` subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

`fmadm acquit uuid`
Notify the Fault Manager that the fault event identified by `uuid` can be safely ignored. The `fmadm acquit` subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable any previously faulted resources.
fmadm config
Display the configuration of the Fault Manager itself, including the module name, version, and description of each component module. Fault Manager modules provide services such as automated diagnosis, self-healing, and messaging for hardware and software present on the system.

fmadm faulty [-afgiprsv] [-n max] [-u uid]
Display status information for resources that the Fault Manager currently believes to be faulty.

The following options are supported:

- **a**  Display all faults. By default, the `fmadm faulty` command only lists output for resources that are currently present and faulty. If you specify the `-a` option, all resource information cached by the Fault Manager is listed, including faults which have been automatically corrected or where no recovery action is needed. The listing includes information for resources that might no longer be present in the system.

- **f**  Display faulty fru's (Field replaceable units).

- **g**  Group together faults which have the same fru, class and fault message.

- **i**  Display persistent cache identifier for each resource in the Fault Manager.

- **n max**  If faults or resources are grouped together with the `-a` or `-g` options, limit the output to `max` entries.

- **p**  Pipe output through pager with form feed between each fault.

- **r**  Display Fault Management Resource with their Identifier (FMRI) and their fault management state.

- **s**  Display 1 line fault summary for each fault event.

- **u uid**  Only display fault with given uid.

- **v**  Display full output.

The percentage certainty is displayed if a fault has multiple suspects, either of different classes or on different fru's. If more than one resource is on the same fru and it is not 100% certain that the fault is associated with the fru, the maximum percentage certainty of the possible suspects on the fru is displayed.

The Fault Manager associates the following states with every resource for which telemetry information has been received:

- **ok**  The resource is present and in use and has no known problems so far as the Fault Manager is concerned.
<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unknown</td>
<td>The resource is not present or not usable but has no known problems. This might indicate the resource has been disabled or deconfigured by an administrator. Consult appropriate management tools for more information.</td>
</tr>
<tr>
<td>faulted</td>
<td>The resource is present but is not usable because one or more problems have been diagnosed by the Fault Manager. The resource has been disabled to prevent further damage to the system.</td>
</tr>
<tr>
<td>degraded</td>
<td>The resource is present and usable, but one or more problems have been diagnosed in the resource by the Fault Manager. If all affected resources are in the same state, this is reflected in the message at the end of the list. Otherwise the state is given after each affected resource.</td>
</tr>
</tbody>
</table>

**fmadm flush fmri**
Flush the information cached by the Fault Manager for the specified resource, named by its FMRI. This subcommand should only be used when indicated by a documented Sun repair procedure. Typically, the use of this command is not necessary as the Fault Manager keeps its cache up-to-date automatically. If a faulty resource is flushed from the cache, administrators might need to apply additional commands to enable the specified resource.

**fmadm load path**
Load the specified Fault Manager module. *path* must be an absolute path and must refer to a module present in one of the defined directories for modules. Typically, the use of this command is not necessary as the Fault Manager loads modules automatically when Solaris initially boots or as needed.

**fmadm unload module**
Unload the specified Fault Manager module. Specify *module* using the basename listed in the `fmadm config` output. Typically, the use of this command is not necessary as the Fault Manager loads and unloads modules automatically based on the system configuration.

**fmadm repaired fmri | label**
Notify the Fault Manager that a repair procedure has been carried out on the specified resource. The `fmadm repaired` subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.
fmadm replaced 

`fmadm replaced fnri | label`
Notify the Fault Manager that the specified resource has been replaced. This command should be used in those cases where the Fault Manager is unable to automatically detect the replacement. The `fmadm replaced` subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

fmadm reset [-s serd] module
Reset the specified Fault Manager module or module subcomponent. If the `-s` option is present, the specified Soft Error Rate Discrimination (SERD) engine is reset within the module. If the `-s` option is not present, the entire module is reset and all persistent state associated with the module is deleted. The `fmadm reset` subcommand should only be used at the direction of a documented Sun repair procedure. The use of this command is typically not necessary as the Fault Manager manages its modules automatically.

fmadm rotate errlog | fltlog
The rotate subcommand is a helper command for `logadm(1M)`, so that `logadm` can rotate live log files correctly. It is not intended to be invoked directly. Use one of the following commands to cause the appropriate log file to be rotated, if the current one is not zero in size:

```
# logadm -p now -s 1b /var/fm/fmd/errlog
# logadm -p now -s 1b /var/fm/fmd/fltlog
```

Options
The following options are supported:

- `-q` Set quiet mode. `fmadm` does not produce messages indicating the result of successful operations to standard output.

Operands
The following operands are supported:

- `cmd` The name of a subcommand listed in `SUBCOMMANDS`.
- `args` One or more options or arguments appropriate for the selected `subcommand`, as described in `SUBCOMMANDS`.

Exit Status
The following exit values are returned:

- `0` Successful completion.
- `1` An error occurred. Errors include a failure to communicate with `fmd` or insufficient privileges to perform the requested operation.
- `2` Invalid command-line options were specified.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>

*System Administration Guide: Security Services*

http://www.sun.com/msg/
**Name**
fmd – fault manager daemon

**Synopsis**
```
```

**Description**
fmd is a daemon that runs in the background on each Solaris system. fmd receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components. When appropriate, the fault manager also sends a message to the syslogd(1M) service to notify an administrator that a problem has been detected. The message directs administrators to a knowledge article on Sun’s web site, http://www.sun.com/msg/, which explains more about the problem impact and appropriate responses.

Each problem diagnosed by the fault manager is assigned a Universal Unique Identifier (UUID). The UUID uniquely identifies this particular problem across any set of systems. The fmdump(1M) utility can be used to view the list of problems diagnosed by the fault manager, along with their UUIDs and knowledge article message identifiers. The fmadm(1M) utility can be used to view the resources on the system believed to be faulty. The fmstat(1M) utility can be used to report statistics kept by the fault manager. The fault manager is started automatically when Solaris boots, so it is not necessary to use the fmd command directly. Sun’s web site explains more about what capabilities are currently available for the fault manager on Solaris.

**Options**
The following options are supported

- `-f file`
  Read the specified configuration file prior to searching for any of the default fault manager configuration files.

- `-o opt=value`
  Set the specified fault manager option to the specified value. Fault manager options are currently a Private interface; see attributes(5) for information about Private interfaces.

- `-R dir`
  Use the specified root directory for all pathnames evaluated by the fault manager, instead of the default root (/).

- `-V`
  Print the fault manager’s version to stdout and exit.

**Exit Status**
The following exit values are returned:

- `0`
  Successful completion

- `1`
  An error occurred which prevented the fault manager from initializing, such as failure to open the telemetry transport.

- `2`
  Invalid command-line options were specified.

**Files**
```
/etc/fm/fmd Fault manager configuration directory
/usr/lib/fm/fmd Fault manager library directory
/var/fm/fmd Fault manager log directory
```
Attributes  See attributes(5) for descriptions of the following attributes:

<table>

See Also  svcs(1), fmadm(1M), fmdump(1M), fmstat(1M), syslogd(1M), attributes(5), smf(5)

Notes  The Fault Manager is managed by the service management facility, smf(5), under the service identifier:

svc:/system/fmd:default

The service’s status can be queried using the svcs(1) command. Administrators should not disable the Fault Manager service.
The `fmdump` utility can be used to display the contents of any of the log files associated with the Solaris Fault Manager, `fmd(1M)`. The Fault Manager runs in the background on each Solaris system. It receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

The Fault Manager maintains two sets of log files for use by administrators and service personnel:

- **error log**: A log which records error telemetry, the symptoms of problems detected by the system.
- **fault log**: A log which records fault diagnosis information, the problems believed to explain these symptoms.

By default, `fmdump` displays the contents of the fault log, which records the result of each diagnosis made by the fault manager or one of its component modules.

An example of a default `fmdump` display follows:

```
# fmdump
TIME    UUID                SUNW-MSG-ID
Dec 28 13:01:27.3919 bf36f0ea-9e47-42b5-fc6f-c0d979c4c8f4 FMD-8000-11
Dec 28 13:01:49.3765 3a186292-3402-40ff-b5ae-810601be337d FMD-8000-11
Dec 28 13:02:59.4448 58107381-1985-48a4-b56f-91d8a617ad83 FMD-8000-0W
...```

Each problem recorded in the fault log is identified by:

- The time of its diagnosis
- A Universal Unique Identifier (UUID) that can be used to uniquely identify this particular problem across any set of systems
- A message identifier that can be used to access a corresponding knowledge article located at Sun’s web site, [http://www.sun.com/msg/](http://www.sun.com/msg/)

If a problem requires action by a human administrator or service technician or affects system behavior, the Fault Manager also issues a human-readable message to `syslogd(1M)`. This message provides a summary of the problem and a reference to the knowledge article on the Sun web site, [http://www.sun.com/msg/](http://www.sun.com/msg/).
You can use the -v and -V options to expand the display from a single-line summary to increased levels of detail for each event recorded in the log. The -c, -t, -T, and -u options can be used to filter the output by selecting only those events that match the specified class, range of times, or uuid.

If more than one filter option is present on the command-line, the options combine to display only those events that are selected by the logical AND of the options. If more than one instance of the same filter option is present on the command-line, the like options combine to display any events selected by the logical OR of the options. For example, the command:

```
# fmdump -u uuid1 -u uuid2 -t 02Dec03
```

selects events whose attributes are (uuid1 OR uuid2) AND (time on or after 02Dec03).

### Options

The following options are supported:

- **-c class**
  Select events that match the specified class. The class argument can use the glob pattern matching syntax described in sh(1). The class represents a hierarchical classification string indicating the type of telemetry event. More information about Sun's telemetry protocol is available at Sun's web site, [http://www.sun.com/msg/](http://www.sun.com/msg/).

- **-e**
  Display events from the fault management error log instead of the fault log. This option is shorthand for specifying the pathname of the error log file.

  The error log file contains private telemetry information used by Sun’s automated diagnosis software. This information is recorded to facilitate post-mortem analysis of problems and event replay, and should not be parsed or relied upon for the development of scripts and other tools. See attributes(5) for information about Sun’s rules for private interfaces.

- **-f**
  Follow the growth of the log file by waiting for additional data. fmdump enters an infinite loop where it will sleep for a second, attempt to read and format new data from the log file, and then go back to sleep. This loop can be terminated at any time by sending an interrupt (Control-C).

- **-m**
  Print the localized diagnosis message associated with each entry in the fault log.

- **-n name[.name][=value]**
  Select fault log or error log events, depending on the -e option, that have properties with a matching name (and optionally a matching value). For string properties the value can be a regular expression match. Regular expression syntax is described in the EXTENDED REGULAR EXPRESSIONS section of the regex(5) manual page. Be careful when using the characters:
  
  ```
  $ * { ^ | ( ) \ 
  ```
...or a regular expression, because these are meaningful to the shell. It is safest to enclose any of these in single quotes. For numeric properties, the value can be octal, hex, or decimal.

-R dir
Use the specified root directory for the log files accessed by fmdump, instead of the default root (/).

-t time
Select events that occurred at or after the specified time. The time can be specified using any of the following forms:

\texttt{mm/dd/yy hh:mm:ss}
Month, day, year, hour in 24-hour format, minute, and second. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

\texttt{mm/dd/yy hh:mm}
Month, day, year, hour in 24-hour format, and minute. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

\texttt{mm/dd/yy}
12:00:00AM on the specified month, day, and year.

\texttt{ddMonyy hh:mm:ss}
Day, month name, year, hour in 24-hour format, minute, and second. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

\texttt{ddMonyy hh:mm}
Day, month name, year, hour in 24-hour format, and minute. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

\texttt{Mon dd hh:mm:ss}
Month, day, hour in 24-hour format, minute, and second of the current year.

\texttt{yyyy-mm-dd [T hh:mm[:ss]]}
Year, month, day, and optional hour in 24-hour format, minute, and second. The second, or hour, minute, and second, can be optionally omitted.

\texttt{ddMonyy}
12:00:00AM on the specified day, month name, and year.

\texttt{hh:mm:ss}
Hour in 24-hour format, minute, and second of the current day.

\texttt{hh:mm}
Hour in 24-hour format and minute of the current day.
Tns | Tnsec
T nanoseconds ago where T is an integer value specified in base 10.

Tus | Tusec
T microseconds ago where T is an integer value specified in base 10.

Tms | Tmsec
T milliseconds ago where T is an integer value specified in base 10.

Ts | Tsec
T seconds ago where T is an integer value specified in base 10.

Tm | Tmin
T minutes ago where T is an integer value specified in base 10.

Th | Thour
T hours ago where T is an integer value specified in base 10.

Td | Tday
T days ago where T is an integer value specified in base 10.

You can append a decimal fraction of the form \( \cdot \, n \) to any \(-t\) option argument to indicate a fractional number of seconds beyond the specified time.

\(-t\) \textit{time}
Select events that occurred at or before the specified time. \textit{time} can be specified using any of the time formats described for the \(-t\) option.

\(-u\) \textit{uuid}
Select fault diagnosis events that exactly match the specified \textit{uuid}. Each diagnosis is associated with a Universal Unique Identifier (UUID) for identification purposes. The \(-u\) option can be combined with other options such as \(-v\) to show all of the details associated with a particular diagnosis.

If the \(-e\) option and \(-u\) option are both present, the error events that are cross-referenced by the specified diagnosis are displayed.

\(-v\)
Display verbose event detail. The event display is enlarged to show additional common members of the selected events.

\(-V\)
Display very verbose event detail. The event display is enlarged to show every member of the name-value pair list associated with each event. In addition, for fault logs, the event display includes a list of cross-references to the corresponding errors that were associated with the diagnosis.

\textbf{Operands} \ The following operands are supported:

\textit{file}\hfill Specifies an alternate log file to display instead of the system fault log. The \texttt{fmdump} utility determines the type of the specified log automatically and produces appropriate
EXAMPLE 1  Retrieving Given Class from fmd Log

Use any of the following commands to retrieve information about a specified class from the fmd log. The complete class name is ereport.io.ddi.context.

```
# fmdump -Ve -c 'ereport.io.ddi.context'
# fmdump -Ve -c 'ereport.*.context'
# fmdump -Ve -n 'class=ereport.io.ddi.context'
# fmdump -Ve -n 'class=ereport.*.context'
```

Any of the preceding commands produces the following output:

```
nvlist version: 0
  class = ereport.io.ddi.context
  ena = 0x1b03a15ecf00001
  detector = (embedded nvlist)
  nvlist version: 0
    version = 0x0
    scheme = dev
    device-path = /
  (end detector)

__ttl = 0x1
__tod = 0x470706b0 0x3a1da690
```

EXAMPLE 2  Retrieving Specific Detector Device Path from fmd Log

The following command retrieves a detector device path from the fmd log.

```
# fmdump -Ve -n 'detector.device-path=.*disk@1,0$'
Oct 06 2007 12:04:28.065660760 ereport.io.scsi.disk.rqs
```

```
nvlist version: 0
  class = ereport.io.scsi.disk.rqs
  ena = 0x453ff3732400401
  detector = (embedded nvlist)
  nvlist version: 0
    version = 0x0
    scheme = dev
    device-path = /pci@0,0/pci1000,3060@3/disk@1,0
  (end detector)

__ttl = 0x1
__tod = 0x470706b0 0x3a1da690
```

Exit Status  The following exit values are returned:

```
0  Successful completion. All records in the log file were examined successfully.
```

fmdump(1M)
A fatal error occurred. This prevented any log file data from being examined, such as failure to open the specified file.

Invalid command-line options were specified.

The log file was opened successfully, but one or more log file records were not displayed, either due to an I/O error or because the records themselves were malformed. fmdump issues a warning message for each record that could not be displayed, and then continues on and attempts to display other records.

System Administration Guide: Security Services

http://www.sun.com/msg/

Notes

Fault logs contain references to records stored in error logs that can be displayed using fmdump -V to understand the errors that were used in the diagnosis of a particular fault. These links are preserved if an error log is renamed as part of log rotation. They can be broken by removing an error log file, or by moving it to another filesystem directory. fmdump can not display error information for such broken links. It continues to display any and all information present in the fault log.
The `fmstat` utility can be used by administrators and service personnel to report statistics associated with the Solaris Fault Manager, `fmd(1M)` and its associated set of modules. The Fault Manager runs in the background on each Solaris system. It receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

You can use `fmstat` to view statistics for diagnosis engines and agents that are currently participating in fault management. The documentation for `fmd(1M)`, `fmadm(1M)`, and `fmdump(1M)` describes more about tools to observe fault management activities.

If the `-m` option is present or the `-t` option is present, `fmstat` reports any statistics kept by the specified fault management module. The module list can be obtained using `fmadm config`.

If the `-m` option is not present, `fmstat` reports the following statistics for each of its client modules:

- **module**
  The name of the fault management module, as reported by `fmadm config`.
- **ev_recv**
  The number of telemetry events received by the module.
- **ev_acpt**
  The number of events accepted by the module as relevant to a diagnosis.
- **wait**
  The average number of telemetry events waiting to be examined by the module.
- **svc_t**
  The average service time for telemetry events received by the module, in milliseconds.
- **%w**
  The percentage of time that there were telemetry events waiting to be examined by the module.
- **%b**
  The percentage of time that the module was busy processing telemetry events.
- **open**
  The number of active cases (open problem investigations) owned by the module.
- **solve**
  The total number of cases solved by this module since it was loaded.
- **memsz**
  The amount of dynamic memory currently allocated by this module.
- **bufsz**
  The amount of persistent buffer space currently allocated by this module.

The `fmstat` utility requires the user to posses the SYS_CONFIG privilege. Refer to the *System Administration Guide: Security Services* for more information about how to configure Solaris privileges.

**Options**

The following options are supported:
Print all statistics for a module, including those kept on its behalf by `fmd`. If the `-a` option is not present, only those statistics kept by the module are reported. If the `-a` option is used without the `-m module`, a set of global statistics associated with `fmd` are displayed.

Print a report on the statistics associated with the specified fault management module, instead of the default statistics report. Modules can publish an arbitrary set of statistics to help Sun service the fault management software itself. The module statistics constitute a Private interface. See `attributes(5)` for information on Sun's rules for Private interfaces. Scripts should not be written that depend upon the values of fault management module statistics as they can change without notice.

Print a report on Soft Error Rate Discrimination (SERD) engines associated with the module instead of the default module statistics report. A SERD engine is a construct used by fault management software to determine if a statistical threshold measured as $N$ events in some time $T$ has been exceeded. The `-s` option can only be used in combination with the `-m` option.

Print a report on the statistics associated with each fault management event transport. Each fault management module can provide the implementation of one or more event transports.

Print a table of the authority information associated with each fault management event transport. If the `-m` option is present, only transports associated with the specified module are displayed.

Omit statistics with a zero value from the report associated with the specified fault management module. The `-z` option can only be used in combination with the `-m` option.

The following operands are supported:

- `count` Print only count reports, and then exit.
- `interval` Print a new report every `interval` seconds.

If no `interval` and no `count` are specified, a single report is printed and `fmstat` exits. If an `interval` is specified but no `count` is specified, `fmstat` prints reports every `interval` seconds indefinitely until the command is interrupted.

The following exit values are returned:

- 0 Successful completion.
- 1 A fatal error occurred. A fatal error could be the failure to communicate with `fmd(1M)`. It could also be that insufficient privileges were available to perform the requested operation.
Invalid command-line options were specified.

*System Administration Guide: Security Services*
**Name**  
fmthard – populate label on hard disks

**Synopsis**

<table>
<thead>
<tr>
<th>SPARC</th>
<th>fmthard -d data</th>
<th>-n volume_name</th>
<th>-s datafile [-i] /dev/rdsk/c? [t?] d?s2</th>
</tr>
</thead>
<tbody>
<tr>
<td>x86</td>
<td>fmthard -d data</td>
<td>-n volume_name</td>
<td>-s datafile [-i] /dev/rdsk/c? [t?] d?s2</td>
</tr>
</tbody>
</table>

**Description**  
The `fmthard` command updates the VTOC (Volume Table of Contents) on hard disks and, on x86 systems, adds boot information to the Solaris `fdisk` partition. One or more of the options `-s datafile`, `-d data`, or `-n volume_name` must be used to request modifications to the disk label. To print disk label contents, see `prtvtoc(1M)`. The `/dev/rdsk/c? [t?] d?s2` file must be the character special file of the device where the new label is to be installed. On x86 systems, `fdisk(1M)` must be run on the drive before `fmthard`.

If you are using an x86 system, note that the term “partition” in this page refers to slices within the x86 `fdisk` partition on x86 machines. Do not confuse the partitions created by `fmthard` with the partitions created by `fdisk`.

**Options**  
The following options are supported:

- `-d data`  
The `data` argument of this option is a string representing the information for a particular partition in the current VTOC. The string must be of the format `part:tag:flag:start:size` where `part` is the partition number, `tag` is the ID TAG of the partition, `flag` is the set of permission flags, `start` is the starting sector number of the partition, and `size` is the number of sectors in the partition. See the description of the `datafile` below for more information on these fields.

- `-i`  
This option allows the command to create the desired VTOC table, but prints the information to standard output instead of modifying the VTOC on the disk.

- `-n volume_name`  
This option is used to give the disk a `volume_name` up to 8 characters long.

- `-s datafile`  
This option is used to populate the VTOC according to a `datafile` created by the user. If the `datafile` is – (a hyphen), `fmthard` reads from standard input. The `datafile` format is described below. This option causes all of the disk partition timestamp fields to be set to zero.

Every VTOC generated by `fmthard` will also have partition 2, by convention, that corresponds to the whole disk. If the input in `datafile` does not specify an entry for partition 2, a default partition 2 entry will be created automatically in VTOC with the tag V_BACKUP and size equal to the full size of the disk.
The datafile contains one specification line for each partition, starting with partition 0. Each line is delimited by a new-line character (\n). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, separated by white space and having the following format:

```
partition tag flag starting_sector size_in_sectors
```

where the entries have the following values:

**partition**
The partition number. Currently, for Solaris SPARC, a disk can have up to 8 partitions, 0–7. Even though the partition field has 4 bits, only 3 bits are currently used. For x86, all 4 bits are used to allow slices 0–15. Each Solaris fdisk partition can have up to 16 slices.

**tag**
The partition tag: a decimal number. The following are reserved codes: 0 (V_UNASSIGNED), 1 (V_BOOT), 2 (V_ROOT), 3 (V_SWAP), 4 (V_USR), 5 (V_BACKUP), 6 (V_STANDARD), 7 (V_VAR), and 8 (V_HOME).

**flag**
The flag allows a partition to be flagged as unmountable or read only, the masks being: V_UNMNT 0x01, and V_RONLY 0x10. For mountable partitions use 0x00.

**starting_sector**
The sector number (decimal) on which the partition starts.

**size_in_sectors**
The number (decimal) of sectors occupied by the partition.

You can save the output of a prtvtoc command to a file, edit the file, and use it as the datafile argument to the -s option.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**
uname(1), format(1M), prtvtoc(1M), attributes(5)

**x86 Only**
fdisk(1M), installgrub(1M)

**Notes**
Special care should be exercised when overwriting an existing VTOC, as incorrect entries could result in current data being inaccessible. As a precaution, save the old VTOC.

For disks under two terabytes, fmthard cannot write a VTOC on an unlabeled disk. Use format(1M) for this purpose.
**Name**
format – disk partitioning and maintenance utility

**Synopsis**
format [-f command-file] [-l log-file] [-x data-file]
[-d disk-name] [-t disk-type] [-p partition-name]
[-s] [-m] [-M] [-e] [disk-list]

**Description**
format enables you to format, label, repair, and analyze disks on your system. Unlike previous disk maintenance programs, format runs under SunOS. Because there are limitations to what can be done to the system disk while the system is running, format is also supported within the memory-resident system environment. For most applications, however, running format under SunOS is the more convenient approach.

format first uses the disk list defined in data-file if the -x option is used. format then checks for the FORMAT_PATH environment variable, a colon-separated list of filenames and/or directories. In the case of a directory, format searches for a file named format.dat in that directory; a filename should be an absolute pathname, and is used without change. format adds all disk and partition definitions in each specified file to the working set. Multiple identical definitions are silently ignored. If FORMAT_PATH is not set, the path defaults to /etc/format.dat.

disk-list is a list of disks in the form c?t?d? or /dev/rdsk/c?t?d?s?. With the latter form, shell wildcard specifications are supported. For example, specifying /dev/rdsk/c2* causes format to work on all drives connected to controller c2 only. If no disk-list is specified, format lists all the disks present in the system that can be administered by format.

Removable media devices are listed only when users execute format in expert mode (option -e). This feature is provided for backward compatibility. Use rmformat(1) for rewritable removable media devices.

**Options**
The following options are supported:

- **-d disk-name**
  Specify which disk should be made current upon entry into the program. The disk is specified by its logical name (for instance, -d c0t1d0). This can also be accomplished by specifying a single disk in the disk list.

- **-e**
  Enable SCSI expert menu. Note this option is not recommended for casual use.

- **-f command-file**
  Take command input from command-file rather than the standard input. The file must contain commands that appear just as they would if they had been entered from the keyboard. With this option, format does not issue continue? prompts; there is no need to specify y(es) or n(no) answers in the command-file. In non-interactive mode, format does not initially expect the input of a disk selection number. The user must specify the current working disk with the -d disk-name option when format is invoked, or specify disk and the disk selection number in the command-file.
format(1M)

- \ log-file Log a transcript of the format session to the indicated log-file, including the standard input, the standard output and the standard error.
- m Enable extended messages. Provides more detailed information in the event of an error.
- M Enable extended and diagnostic messages. Provides extensive information on the state of a SCSI device's mode pages, during formatting.
- p partition-name Specify the partition table for the disk which is current upon entry into the program. The table is specified by its name as defined in the data file. This option can be used only if a disk is being made current, and its type is either specified or available from the disk label.
- s Silent. Suppress all of the standard output. Error messages are still displayed. This is generally used in conjunction with the -f option.
- t disk-type Specify the type of disk which is current upon entry into the program. A disk's type is specified by name in the data file. This option can only be used if a disk is being made current as described above.
- x data-file Use the list of disks contained in data-file.

Usage When you invoke format with no options or with the -e, -l, -m, -M, or -s options, the program displays a numbered list of available disks and prompts you to specify a disk by list number. If the machine has more than 10 disks, press SPACE to see the next screenful of disks.

You can specify a disk by list number even if the disk is not displayed in the current screenful. For example, if the current screen shows disks 11-20, you can enter 25 to specify the twenty-fifth disk on the list. If you enter a number for a disk that is not currently displayed, format prompts you to verify your selection. If you enter a number from the displayed list, format silently accepts your selection.

After you specify a disk, format displays its main menu. This menu enables you to perform the following tasks:

analyze Run read, write, compare tests, and data purge. The data purge function implements the National Computer Security Center Guide to Understanding Data Remnance (NCSC-TG-025 version 2) Overwriting Algorithm. See NOTES.
backup Search for backup labels.
cache Enable, disable, and query the state of the write cache and read cache. This menu item only appears when format is invoked with the -e option, and is only supported on SCSI devices.
current Display the device name, the disk geometry, and the pathname to the disk device.
defect Retrieve and print defect lists. This option is supported only on SCSI devices. IDE disks perform automatic defect management. Upon using the defect option on an IDE disk, you receive the message:

Controller does not support defect management
or disk supports automatic defect management.

disk Choose the disk that will be used in subsequent operations (known as the current disk.)

fdisk Run the fdisk(1M) program to create a fdisk partition for Solaris software (x86 based systems only).

format Format and verify the current disk. This option is supported only on SCSI devices. IDE disks are pre-formatted by the manufacturer. Upon using the format option on an IDE disk, you receive the message:

Cannot format this drive. Please use your manufacturer-supplied formatting utility.

inquiry Display the vendor, product name, and revision level of the current drive.

label Write a new label to the current disk.

partition Create and modify slices.

quit Exit the format menu.

repair Repair a specific block on the disk.

save Save new disk and slice information.

type Select (define) a disk type.

verify Read and display labels. Print information such as the number of cylinders, alternate cylinders, heads, sectors, and the partition table.

volname Label the disk with a new eight character volume name.

Environment Variables

| FORMAT_PATH | a colon-separated list of filenames and/or directories of disk and partition definitions. If a directory is specified, format searches for the file format.dat in that directory. |

Files

| /etc/format.dat | default data file |

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
When the format function is selected to format the Maxtor 207MB disk, the following message displays:

Mode sense page(4) reports rpm value as 0, adjusting it to 3600

This is a drive bug that may also occur with older third party drives. The above message is not an error; the drive will still function correctly.

Cylinder 0 contains the partition table (disk label), which can be overwritten if used in a raw disk partition by third party software.

format supports writing EFI-compliant disk labels in order to support disks or LUNs with capacities greater than one terabyte. However, care should be exercised since many software components, such as filesystems and volume managers, are still restricted to capacities of one terabyte or less. See the System Administration Guide: Basic Administration for additional information.

By default, on an unlabeled disk, EFI labels will be written on disks larger than 2 TB. When format is invoked with the -e option, on writing the label, the label type can be chosen. Booting is not currently supported on a disk with an EFI label.

Notes format provides a help facility you can use whenever format is expecting input. You can request help about what information is expected by simply entering a question mark (?) and format prints a brief description of what type of input is needed. If you enter a ? at the menu prompt, a list of available commands is displayed.

For SCSI disks, formatting is done with both Primary and Grown defects list by default. However, if only Primary list is extracted in defect menu before formatting, formatting will be done with Primary list only.

Changing the state of the caches is only supported on SCSI devices, and not all SCSI devices support changing or saving the state of the caches.

Name  fpsd – Fp-scrubber daemon

Synopsis  /usr/lib/fps/fpsd

Description  fpsd is a user-level daemon that periodically runs non-intrusive tests to validate proper functioning of FPU (Floating Point Unit) hardware in the system. A fault management action is initiated by means of fmd(1M), in case an error is detected by the test.

Exit Status  The following exit values are returned:

0
  Successful completion.

non-zero
  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWfsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Uncommitted</td>
</tr>
</tbody>
</table>

See Also  svcs(1), fmd(1M), svcadm(1M), svccfg(1M), attributes(5), smf(5)

Notes   The fpsd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/fpsd:default

You can use svccfg(1M) to change the default fpsd behavior:

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| config/exclude_cpus  | astring| comma delimited list of CPU IDs to be excluded from proactive testing.

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Disabling the service can increase system's vulnerability to silent data corruption, if a fault were to develop in an FPU within the system.
fruadm – prints and updates customer data associated with FRUs

Synopsis
/usr/platform/sun4u/sbin/fruadm
/usr/platform/sun4u/sbin/fruadm -l
/usr/platform/sun4u/sbin/fruadm [-r] path [text]

Description
fruadm prints or sets the customer data for Field-Replaceable Units (FRUs).

Without arguments, fruadm prints the paths of all FRU ID-capable FRUs (containers) in the system, along with the contents of the customer data record, if present, for each such FRU; for FRUs without customer data, fruadm prints only the container's path.

Only a privileged user can create or update data in containers. The privileges required to perform these write operations are hardware dependent. Typically, a default system configuration restricts write operations to the superuser or to the platform-administrator user.

Options
The following options are supported:
-  l  List the system’s frutree paths.
-  r  Recursively display or update the data for all containers rooted at the argument path.

Operands
The following operands are supported:

path  A full or partial system frutree path for or under which to print or set the customer data. The first field of each line of output of fruadm -l gives the valid full frutree paths for the system.

Paths can include shell meta-characters; such paths should be quoted appropriately for the user's shell. For partial paths, the first matching full path is selected for display or update. Without the - r option, the path must be that of a container; with the - r option, all containers (if any) under path will be selected.

text  Up to 80 characters of text set as the customer data. If the text contains white space or shell metacharacters, it should be quoted appropriately for the user’s shell.

Examples
EXAMPLE 1  Displaying All Customer Data
The following example prints all customer data available from FRUs on the system. For containers with no customer data, only the containers' paths will be listed.

    example% fruadm

EXAMPLE 2  Displaying Customer Data For a Single FRU
The following command prints the customer data, if present, for the specified FRU:

    example% fruadm /frutree/chassis/system-board
EXAMPLE 3  Displaying Customer Data For a Single FRU
The following command prints the customer data, if present, for the first mem-module found:
example% fruadm mem-module

EXAMPLE 4  Setting Customer Data
The following example sets the customer data for a FRU:
example# fruadm system-board 'Asset Tag 123456'

EXAMPLE 5  Setting Customer Data
The following command sets the customer data for all FRUs under chassis:
example# fruadm -r /frutree/chassis "Property of XYZ, Inc."

Exit Status  The following exit values are returned:
0    Successful completion.
>0   An error occurred.

**Name**
fsck – check and repair file systems

**Synopsis**
fsck [ -F FSType ] [-m] [-V] [ special ]...

fsck [ -F FSType] [ -n | N | y | Y ] [-V] [-o FSType-specific-options]
[ special ]...

**Description**
fsck audits and interactively repairs inconsistent file system conditions. If the file system is inconsistent the default action for each correction is to wait for the user to respond yes or no. If the user does not have write permission fsck defaults to a no action. Some corrective actions will result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

*FSType-specific-options* are options specified in a comma-separated (with no intervening spaces) list of options or keyword ATTRIBUTE pairs for interpretation by the *FSType*-specific module of the command.

*special* represents the character special device on which the file system resides, for example, /dev/rdsk/c1t0d0s7. Note: the character special device, not the block special device, should be used. fsck will not work if the block device is mounted.

If no *special* device is specified fsck checks the file systems listed in /etc/vfstab. Those entries in /etc/vfstab which have a character special device entry in the fsckdev field and have a non-zero numeric entry in the fsckpass field will be checked. Specifying *-F FSType* limits the file systems to be checked to those of the type indicated.

If *special* is specified, but *-F* is not, the file system type will be determined by looking for a matching entry in /etc/vfstab. If no entry is found, the default local file system type specified in /etc/default/fs will be used.

If a file system type supports parallel checking, for example, ufs, some file systems eligible for checking may be checked in parallel. Consult the file system-specific man page (for example, *fsck_ufs*(1M)) for more information.

**Options**
The following generic options are supported:

- *F FSType*
  Specify the file system type on which to operate.

- *m*
  Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:
  
  ufs fsck: sanity check: /dev/rdsk/c0t3d0s1 okay

- *n | -N*
  Assume a no response to all questions asked by fsck; do not open the file system for writing.
-V
Echo the expanded command line but do not execute the command. This option may
be used to verify and to validate the command line.

-y | Y
Assume a yes response to all questions asked by fsck.

-o specific-options
These specific-options can be any combination of the following separated by commas (with
no intervening spaces).

b=n
Use block n as the super block for the file system. Block 32 is always one of the alternate
super blocks. Determine the location of other super blocks by running newfs(1M) with
the -Nv options specified.

c
If the file system is in the old (static table) format, convert it to the new (dynamic table)
format. If the file system is in the new format, convert it to the old format provided the
old format can support the file system configuration. In interactive mode, fsck will list
the direction the conversion is to be made and ask whether the conversion should be
done. If a negative answer is given, no further operations are done on the file system. In
preen mode, the direction of the conversion is listed and done if possible without user
interaction. Conversion in preen mode is best used when all the file systems are being
converted at once. The format of a file system can be determined from the first line of
output from fstyp(1M). Note: the c option is seldom used and is included only for
compatibility with pre-4.1 releases. There is no guarantee that this option will be
included in future releases.

f
Force checking of file systems regardless of the state of their super block clean flag.

p
Check and fix the file system non-interactively ("preen"). Exit immediately if there is a
problem requiring intervention. This option is required to enable parallel file system
checking.

w
Check writable file systems only.

Exit Status

</tr>
</tbody>
</table>
37  a signal was caught during processing
39  uncorrectable errors detected - terminate immediately
40  for root, same as 0.

Usage The fsck command is large file aware for UFS file systems, per the largefile(5) man page.

Files /etc/default/fs
default local file system type. Default values can be set for the following flags in
/etc/default/fs. For example: LOCAL=ufs.

LOCAL
The default partition for a command if no FSType is specified.

/etc/vfstab
list of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also cli(1M), fsck_cachefs(1M), fsck_ufs(1M), fsdb_ufs(1M), fsirand(1M), fstyp(1M),
mkfs(1M), mkfs_ufs(1M), mountall(1M), newfs(1M), reboot(1M), vfstab(4),
attributes(5), largefile(5), ufs(7FS)

Warnings The operating system buffers filesystem data. Running fsck on a mounted filesystem can cause the operating system’s buffers to become out of date with respect to the disk. For this reason, the file system should be unmounted when fsck is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after fsck is run. Quite often, however, this will not be sufficient. A panic will probably occur if running fsck on a file system modifies the file system.

Notes This command may not be supported for all FSTypes.

Starting with Solaris 9, fsck manages extended attribute data on the disk. (See fsattr(5) for a description of extended file attributes.) A filesystem with extended attributes can be mounted on versions of Solaris that are not attribute-aware (versions prior to Solaris 9), but the attributes will not be accessible and fsck will strip them from the files and place them in lost+found. Once the attributes have been stripped, the file system is completely stable on versions of Solaris that are not attribute-aware, but would be considered corrupted on attribute-aware versions. In the latter circumstance, run the attribute-aware fsck to stabilize the file system before using it in an attribute-aware environment.
Name  
fsck_cachefs — check integrity of data cached with CacheFS

Synopsis  
fsck -F cachefs [-m] [-o noclean] cache_directory

Description  
The CacheFS version of the fsck command checks the integrity of a cache directory. This utility corrects any CacheFS problems it finds by default. There is no interactive mode. The most likely invocation of fsck for CacheFS file systems is at boot time from an entry in the /etc/vfstab file. See vfstab(4).

Options  
The following options are supported:
- \texttt{\texttt{-m}} \quad \text{Check, but do not repair.}
- \texttt{\texttt{-o noclean}} \quad \text{Force a check on the cache even if there is no reason to suspect there is a problem.}

Examples  
\textbf{EXAMPLE 1}  
Using \texttt{fsck_cachefs} to Force a Check on the Cache Directory

The following example forces a check on the cache directory /cache3:
exemle\% fsck -F cachefs -o noclean /cache3

cfsadmin(1M), fsck(1M), mount_cachefs(1M), vfstab(4), attributes(5)
The `fsck` utility audits and interactively repairs inconsistent conditions on file systems. `special` represents the character special device on which the file system resides, for example `/dev/rdiskette`. The character special device, not the block special device, should be used.

In the case of correcting serious inconsistencies, by default, `fsck` asks for confirmation before making a repair and waits for the operator to respond either `yes` or `no`. If the operator does not have write permission on the file system, `fsck` defaults to a `-n` (no corrections) action. See `fsck(1M)`.

Repairing some file system inconsistencies may result in loss of data. The amount and severity of data loss may be determined from the diagnostic output.

When executed with the verify option (`-o v`), `fsck` automatically scans the entire file system to verify that all of its allocation units are accessible. If it finds any units inaccessible, it updates the file allocation table (FAT) appropriately. It also updates any affected directory entries to reflect the problem. This directory update includes truncating the file at the point in its allocation chain where the file data is no longer accessible. Any remaining accessible allocation units become orphaned.

Orphaned chains of accessible allocation units are, with the operator's concurrence, linked back into the file system as files in the root directory. These files are assigned names of the form `fileNNNN.chk`, where the `N`s are digits in the integral range from `0` through `9`.

After successfully scanning and correcting any errors in the file system, `fsck` displays a summary of information about the file system. This summary includes the size of the file system in bytes, the number of bytes used in directories and individual files, and the number of available allocation units remaining in the file system.

The following generic options are supported:

- `-m` Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, `fsck` displays a message such as:

  `pcfs fsck: sanity check: /dev/rdiskette okay`

- `-n | -N` Assume a no response to all questions asked by `fsck`; do not open the file system for writing.

- `-V` Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line.
Assume a yes response to all questions asked by `fsck`.

Specify `pcfs` file system specific options in a comma-separated list, in any combination, with no intervening spaces.

Verify all allocation units are accessible prior to correcting inconsistencies in the metadata.

Check and fix the file system non-interactively (preen). Exit immediately if there is a problem requiring intervention.

Check writable file systems only.

The device which contains the `pcfs`. The device name for a diskette is specified as `/dev/rdiskette0` for the first diskette drive, or `/dev/rdiskette1` for a second diskette drive. A hard disk device or high-capacity removable device name much be qualified with a suffix to indicate the proper `FDISK` partition.

For example, in the names: `/dev/rdsk/c0t0d0p0:c` and `/dev/rdsk/c0t4d0s2:c`, the `:c` suffix indicates the first partition on the disk contains the `pcfs`.

The operating system buffers file system data. Running `fsck` on a mounted file system can cause the operating system’s buffers to become out of date with respect to the disk. For this reason, the file system should be unmounted when `fsck` is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after `fsck` is run. Quite often, however, this is not sufficient. A panic will probably occur if running `fsck` on a file system modifies the file system.

`fsck_udfs` – file system consistency check and interactive repair

**Synopsis**  
`fsck -F udfs [generic_options] [special ...]`

`fsck -F udfs [generic_options] [-o specific_options] [special ...]`

**Description**  
`fsck` audits and interactively repairs inconsistent conditions on file systems. A file system to be checked can be specified by giving the name of the block or character special device or by giving the name of its mount point if a matching entry exists in `/etc/vfstab`.

`special` represents the character special device, for example, `/dev/rdsk/c0t2d0s0`, on which the file system resides. The character special device, not the block special device should be used. `fsck` does not work on a mounted block device.

If no special device is specified, all `udfs` file systems specified in the `vfstab` file with a `fsckdev` entry are checked. If the `-p (preen)` option is specified, `udfs` file systems with an `fsckpass` number greater than 1 are checked in parallel. See `fsck(1M)`.

In the case of correcting serious inconsistencies, by default, `fsck` asks for confirmation before making a repair and waits for the operator to respond with either `yes` or `no`. If the operator does not have write permission on the file system, `fsck` defaults to the `-n (no corrections)` option. See `fsck(1M)`.

Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

`fsck` automatically corrects innocuous inconsistencies. It displays a message for each corrected inconsistency that identifies the nature of the correction which took place on the file system. After successfully correcting a file system, `fsck` prints the number of files on that file system and the number of used and free blocks.

Inconsistencies checked are as follows:

- Blocks claimed by more than one file or the free list
- Blocks claimed by a file or the free list outside the range of the file system
- Incorrect link counts in file entries
- Incorrect directory sizes
- Bad file entry format
- Blocks not accounted for anywhere
- Directory checks, file pointing to unallocated file entry and absence of a parent directory entry
- Descriptor checks, more blocks for files than there are in the file system
- Bad free block list format
- Total free block count incorrect
Options  The following options are supported:

generic_options  The following generic_options are supported:

-m  Check but do not repair. This option checks to be sure that the file system is suitable for mounting, and returns the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:

  udfs fsck: sanity check: /dev/rdsk/c0t2d0s0 okay

-n | -N  Assume a no response to all questions asked by fsck; do not open the file system for writing.

-V  Echo the expanded command line, but do not execute the command. This option can be used to verify and to validate the command line.

-y | -Y  Assume a yes response to all questions asked by fsck.

-o specific_options  Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following specific_options are available:

f  Force checking of file systems regardless of the state of their logical volume integrity state.

p  Check and fix the file system non-interactively (preen). Exit immediately if there is a problem that requires intervention. This option is required to enable parallel file system checking.

w  Check writable file systems only.

Files  /etc/vtstab  List of default parameters for each file system.

</tr>
</tbody>
</table>

See Also  fsck(1M), fsdb_udfs(1M), fstyp(1M), mkfs(1M), mkfs_udfs(1M), mountall(1M), reboot(1M), vsfstat(4), attributes(5)

Warnings  The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, use fsck only when the file system is unmounted. If this is not possible, take care that the system is quiescent and that it is rebooted immediately after running fsck. A panic will probably occur if running fsck on a file system that modifies the file system while it is mounted.
If an unmount of the file system is not done before the system is shut down, the file system might become corrupted. In this case, a file system check needs to be completed before the next mount operation.

**Diagnostics**

- **not writable**
  - You cannot write to the device.

- **Currently Mounted on**
  - The device is already mounted and cannot run `fsck`.

- **FILE SYSTEM WAS MODIFIED**
  - File system has been modified to bring it to a consistent state.

- **Can’t read allocation extent**
  - Cannot read the block containing allocation extent.

- **Bad tag on alloc extent**
  - Invalid tag detected when expecting an allocation extent.

- **Volume sequence tag error**
  - Invalid tag detected in the volume sequence.

- **Space bitmap tag error**
  - Invalid tag detected in the space bitmap.

**UNEXPECTED INCONSISTENCY; RUN fsck MANUALLY**

- Use `fsck` in interactive mode.
**fsck_ufs(1M)**

**Name**
fsck_ufs – file system consistency check and interactive repair

**Synopsis**

```
fsck -F ufs [generic-options] [special]...
```

```
fsck -F ufs [generic-options] [-o specific-options] [special]...
```

**Description**
The `fsck` utility audits and interactively repairs inconsistent conditions on file systems. A file system to be checked may be specified by giving the name of the block or character `special` device or by giving the name of its mount point if a matching entry exists in `/etc/vfstab`.

The `special` parameter represents the character special device, for example, `/dev/rdsk/c1t0d0s7`, on which the file system resides. The character special device, not the block special device should be used. The `fsck` utility will not work if the block device is mounted, unless the file system is error-locked.

If no `special` device is specified, all `ufs` file systems specified in the `vfstab` with a `fsckdev` entry will be checked. If the `-p` ("preen") option is specified, `ufs` file systems with an `fsckpass` number greater than 1 are checked in parallel. See `fsck(1M)`.

In the case of correcting serious inconsistencies, by default, `fsck` asks for confirmation before making a repair and waits for the operator to respond either `yes` or `no`. If the operator does not have write permission on the file system, `fsck` will default to a `-n` (no corrections) action. See `fsck(1M)`.

Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

The `fsck` utility automatically corrects innocuous inconsistencies such as unreferenced inodes, too-large link counts in inodes, missing blocks in the free list, blocks appearing in the free list and also in files, or incorrect counts in the super block. It displays a message for each inconsistency corrected that identifies the nature of the correction on the file system which took place. After successfully correcting a file system, `fsck` prints the number of files on that file system, the number of used and free blocks, and the percentage of fragmentation.

Inconsistencies checked include:

- Blocks claimed by more than one inode or the free list.
- Blocks claimed by an inode or the free list outside the range of the file system.
- Incorrect link counts.
- Incorrect directory sizes.
- Bad inode format.
- Blocks not accounted for anywhere.
- Directory checks, file pointing to unallocated inode, inode number out of range, and absence of ‘.’ and ‘..’ as the first two entries in each directory.
- Super Block checks: more blocks for inodes than there are in the file system.
Bad free block list format.
Total free block and/or free inode count incorrect.

Orphaned files and directories (allocated but unreferenced) are, with the operator's concurrence, reconnected by placing them in the lost+found directory. The name assigned is the inode number. If the lost+found directory does not exist, it is created. If there is insufficient space in the lost+found directory, its size is increased.

An attempt to mount a ufs file system with the -o no large files option will fail if the file system has ever contained a large file (a file whose size is greater than or equal to 2 Gbyte). Invoking fsck resets the file system state if no large files are present in the file system. A successful mount of the file system after invoking fsck indicates the absence of large files in the file system. An unsuccessful mount attempt indicates the presence of at least one large file. See mount_ufs(1M).

Options

The generic-options consist of the following options:

- **-m**  Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:

  ufs fsck: sanity check: /dev/rdsk/c0t3d0s1 okay

- **-n | N**  Assume a no response to all questions asked by fsck; do not open the file system for writing.

- **-V**  Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line.

- **-v**  Enables verbose output. Might not be supported by all filesystem-specific fsck implementations.

- **-y | Y**  Assume a yes response to all questions asked by fsck.

See generic fsck(1M) for the details for specifying special.

- **-o specific-options**  Specify ufs file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces).

  - **b=n**  Use block n as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running newfs(1M) with the -Nv options specified.

  - **f**  Force checking of file systems regardless of the state of their super block clean flag.
Check and fix the file system non-interactively ("preen"). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.

Check writable file systems only.

Warnings  The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be unmounted when fsck is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after fsck is run. Quite often, however, this will not be sufficient. A panic will probably occur if running fsck on a file system modifies the file system.

Notes  It is usually faster to check the character special device than the block special device.

Running fsck on file systems larger than 2 Gb fails if the user chooses to use the block interface to the device:

```
fsck /dev/dsk/c?t?d?s?
```

rather than the raw (character special) device:

```
fsck /dev/rdsk/c?t?d?s?
```
**fsdb(1M)**

**Name**  
fsdb – file system debugger

**Synopsis**  
fsdb [-F FSType] [-V] [-o FSType-specific options] special

**Description**  
fsdb is a file system debugger that allows for the manual repair of a file system after a crash. special is a special device used to indicate the file system to be debugged. fsdb is intended for experienced users only. FSType is the file system type to be debugged. Since different FSTypes have different structures and hence different debugging capabilities, the manual pages for the FSType-specific fsdb should be consulted for a more detailed description of the debugging capabilities.

**Options**  
- F Specify the FSType on which to operate. The FSType should either be specified here or be determinable from /etc/vfstab by matching the special with an entry in the table, or by consulting /etc/default/fs.
- V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.
- o Specify FSType-specific options.

**Usage**  
See largefile(5) for the description of the behavior of fsdb when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

**Files**  
/etc/default/fs  
default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

- LOCAL: The default partition for a command if no FSType is specified.

/etc/vfstab  
list of default parameters for each file system

**Attributes**

**Notes**  
This command may not be supported for all FSTypes.
The `fsdb_udfs` command is an interactive tool that can be used to patch up a damaged udfs file system. `fsdb_udfs` has conversions to translate block and i-numbers into their corresponding disk addresses. Mnemonic offsets to access different parts of an inode are also included. Mnemonic offsets greatly simplify the process of correcting control block entries or descending the file system tree.

`fsdb` contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking `fsdb` with the `-o` option or by using the `o` command.

`fsdb` reads one block at a time, and therefore works with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. In order to modify any portion of the disk, `fsdb` must be invoked with the `-w` option.

Wherever possible, adb-like syntax has been adopted to promote the use of `fsdb` through familiarity.

**Options**

The following options are supported:

- `-o specific_option` Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following specific options are supported:
  - `o` Overwrite some error conditions.
  - `p=string` Set prompt to `string`.
  - `w` Open for write.
  - `?` Display usage.

**Usage**

Numbers are considered hexadecimal by default. The user has control over how data is to be displayed or accepted. The `base` command displays or sets the input and output base. Once set, all input defaults to this base and all output displays in this base. The base can be overriden temporarily for input by preceding hexadecimal numbers by 0x, preceding decimal numbers with a 0t, or octal numbers with a 0. Hexadecimal numbers beginning with a -f or A -F must be preceded with a 0x to distinguish them from commands.

Disk addressing by `fsdb` is at the byte level. However, `fsdb` offers many commands to convert a desired inode, directory entry, block, and so forth, to a byte address. After the address has been calculated, `fsdb` records the result in the current address (dot).

Several global values are maintained by `fsdb`:

- Current base (referred to as base)
- Current address (referred to as dot)
Current inode (referred to as inode)
Current count (referred to as count)
Current type (referred to as type)

Most commands use the preset value of dot in their execution. For example,

`> 2:inode`

first sets the value of dot (.) to 2, colon (:), signifies the start of a command, and the `inode` command sets inode to 2. A count is specified after a comma (,). Once set, count remains at this value until a new command is encountered that resets the value back to 1 (the default).

So, if

`> 2000,400/X`

is entered, 400 hex longs are listed from 2000, and when completed, the value of dot is `2000 + 400 * sizeof(long)`. If a RETURN is then entered, the output routine uses the current values of dot, count, and type and displays 400 more hex longs. An asterisk (*) causes the entire block to be displayed. An example showing several commands and the use of RETURN would be:

`> 2:ino; 0:dir?d`

or

`> 2:ino; 0:db:block?d`

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, subsequently entering a RETURN, plus (+), or minus (-) advances to subsequent entries. Notice that

`> 2:inode; :ls`

or

`> :ls /

is again synonymous.

The following symbols are recognized by `fsdb`:

**RETURN**  Update the value of dot by the current value of type and display using the current value of count.

**#**       Update the value of dot by specifying a numeric expression. Specify numeric expressions using addition, subtraction, multiplication, and division operators (+, -, *, and %). Numeric expressions are evaluated from left to right and can use parentheses. After evaluation, the value of dot is updated.
count

Update the count indicator. The global value of count is updated to count. The value of count remains until a new command is run. A count specifier of * attempts to show a block's worth of information. The default for count is 1.

? f

Display in structured style with format specifier f. See Formatted Output.

/ f

Display in unstructured style with format specifier f. See Formatted Output.

. Display the value of dot.

+ e

Increment the value of dot by the expression e. The amount actually incremented is dependent on the size of type: dot = dot + e * sizeof(type) The default for e is 1.

- e

Decrement the value of dot by the expression e. See +.

* e

Multiply the value of dot by the expression e. Multiplication and division don’t use type. In the above calculation of dot, consider the sizeof(type) to be 1.

% e

Divide the value of dot by the expression e. See *.

< name

Restore an address saved in register name. name must be a single letter or digit.

> name

Save an address in register name. name must be a single letter or digit.

= f

Display indicator. If f is a legitimate format specifier (see Formatted Output), then the value of dot is displayed using format specifier f. Otherwise, assignment is assumed. See = [s] [e].

= [s] [e]

Change the value of dot using an assignment indicator. The address pointed to by dot has its contents changed to the value of the expression e or to the ASCII representation of the quoted (" string s. This can be useful for changing directory names or ASCII file information.

=+ e

Change the value of dot using an incremental assignment. The address pointed to by dot has its contents incremented by expression e.

=- e

Change the value of dot using a decremental assignment. Decrement the contents of the address pointed to by dot by expression e.

A command must be prefixed by a colon (:). Only enough letters of the command to uniquely distinguish it are needed. Multiple commands can be entered on one line by separating them by a SPACE, TAB, or semicolon (;).

To view a potentially unmounted disk in a reasonable manner, fsdb supports the cd, pwd, ls, and find commands. The functionality of each of these commands basically matches that of its UNIX counterpart. See cd(1), pwd(1), ls(1), and find(1) for details. The *, ., ?, and - wildcard characters are also supported.

The following commands are supported:

System Administration Commands - Part 1
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base[=b]</td>
<td>Display or set the base. All input and output is governed by the current base. Without the = b, displays the current base. Otherwise, sets the current base to b. Base is interpreted using the old value of base, so to ensure correctness use the 0, 0t, or 0x prefix when changing the base. The default for base is hexadecimal.</td>
</tr>
<tr>
<td>block</td>
<td>Convert the value of dot to a block address.</td>
</tr>
<tr>
<td>cd [dir]</td>
<td>Change the current directory to directory dir. The current values of inode and dot are also updated. If dir is not specified, changes directories to inode 2, root (/).</td>
</tr>
<tr>
<td>directory</td>
<td>If the current inode is a directory, converts the value of dot to a directory slot offset in that directory, and dot now points to this entry.</td>
</tr>
<tr>
<td>file</td>
<td>Set the value of dot as a relative block count from the beginning of the file. The value of dot is updated to the first byte of this block.</td>
</tr>
<tr>
<td>find dir [-name n]</td>
<td>Find files by name or i-number. Recursively searches directory dir and below for file names whose i-number matches n or whose name matches pattern n. Only one of the two options (-name or -inum) can be used at one time. The find -print is not necessary or accepted.</td>
</tr>
<tr>
<td>fill=p</td>
<td>Fill an area of disk with pattern p. The area of disk is delimited by dot and count.</td>
</tr>
<tr>
<td>inode</td>
<td>Convert the value of dot to an inode address. If successful, the current value of inode is updated as well as the value of dot. As a convenient shorthand, if :inode appears at the beginning of the line, the value of dot is set to the current inode and that inode is displayed in inode format.</td>
</tr>
<tr>
<td>ls [-R] [-l] pat1 pat2...</td>
<td>List directories or files. If no file is specified, the current directory is assumed. Either or both of the options can be used (but, if used, must be specified before the filename specifiers). Wild card characters are available and multiple arguments are acceptable. The long listing shows only the i-number and the name; use the inode command with ?i to get more information.</td>
</tr>
<tr>
<td>override</td>
<td>Toggle the value of override. Some error conditions might be overridden if override is toggled to on.</td>
</tr>
<tr>
<td>prompt “p”</td>
<td>Change the fsdb prompt to p. p must be enclosed in quotes.</td>
</tr>
</tbody>
</table>
pwd
  Display the current working directory.

quit
  Quit fsdb.

tag
  Convert the value of dot and if this is a valid tag, print the
  volume structure according to the tag.

!
  Escape to the shell.

Inode Commands

In addition to the above commands, several other commands deal with inode fields and
operate directly on the current inode (they still require the colon (:)). They can be used to more
easily display or change the particular fields. The value of dot is only used by the :db and :ib
commands. Upon completion of the command, the value of dot is changed so that it points to
that particular field. For example,

> :ln=+1

increments the link count of the current inode and sets the value of dot to the address of the
link count field.

The following inode commands are supported:

  at         Access time
  bs         Block size
  ct         Creation time
  gid        Group id
  ln         Link number
  mt         Modification time
  md         Mode
  maj        Major device number
  min        Minor device number
  nm         This command actually operates on the directory name field. Once poised at the
desired directory entry (using the directory command), this command allows you
to change or display the directory name. For example,

  > 7:dir:nn="foo"

gets the 7th directory entry of the current inode and changes its name to foo.
Directory names cannot be made larger than the field allows. If an attempt is made to
make a directory name larger than the field allows, the string is truncated to fit and a
warning message is displayed.

sz
  File size
Formatted output comes in two styles and many format types. The two styles of formatted output are: structured and unstructured. Structured output is used to display inodes, directories, and so forth. Unstructured output displays raw data.

Format specifiers are preceded by the slash (/) or question mark (?) character. *type* is updated as necessary upon completion.

The following format specifiers are preceded by the ? character:

- **i** Display as inodes in the current base.
- **d** Display as directories in the current base.

The following format specifiers are preceded by the / character:

- **b** Display as bytes in the current base.
- **c** Display as characters.
- **o** Display as octal shorts or longs.
- **d** Display as decimal shorts or longs.
- **x** Display as hexadecimal shorts or longs.

**Examples**

**EXAMPLE 1** Using *fsdb* as a calculator for complex arithmetic

The following command displays 2010 in decimal format, and is an example of using *fsdb* as a calculator for complex arithmetic.

```bash
> 2000+400%(20+20)=D
```

**EXAMPLE 2** Using *fsdb* to display an i-number in idode fomat

The following command displays the i-number 386 in inode format. 386 becomes the current inode.

```bash
> 386:ino?i
```

**EXAMPLE 3** Using *fsdb* to change the link count

The following command changes the link count for the current inode to 4.

```bash
> :ln=4
```
EXAMPLE 4  Using fsdb to increment the link count
The following command increments the link count by 1.
> :ln=+1

EXAMPLE 5  Using fsdb to display the creation time as a hexadecimal long
The following command displays the creation time as a hexadecimal long.
> :ct=X

EXAMPLE 6  Using fsdb to display the modification time in time format
The following command displays the modification time in time format.
> :mt=t

EXAMPLE 7  Using fsdb to display in ASCII
The following command displays, in ASCII, block 0 of the file associated with the current inode.
> 0:file/c

EXAMPLE 8  Using fsdb to display the directory entries for the root inode
The following command displays the first block’s directory entries for the root inode of this file system. This command stops prematurely if the EOF is reached.
> 2:ino,*?d

EXAMPLE 9  Using fsdb to change the current inode
The following command changes the current inode to that associated with the 5th directory entry (numbered from 0) of the current inode. The first logical block of the file is then displayed in ASCII.
> 5:dir:inode; 0:file,*/c

EXAMPLE 10  Using fsdb to change the i-number
The following command changes the i-number for the 7th directory slot in the root directory to 3.
> 2:inode; 7:dir=3

EXAMPLE 11  Using fsdb to change the name field
The following command changes the name field in the directory slot to name.
> 7:dir:nm="name"
**EXAMPLE 12** Using fsdb to display the a block
The following command displays the 3rd block of the current inode as directory entries.

**EXAMPLE 13** Using fsdb to set the contents of address
The following command sets the contents of address 2050 to 0xffffffff. 0xffffffff can be truncated, depending on the current type.

> 2050=0xffffffff

**EXAMPLE 14** Using fsdb to place an ASCII string at an address
The following command places the ASCII string this is some text at address 1c92434.

> 1c92434="this is some text"

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

The `fsdb_ufs` command is an interactive tool that can be used to patch up a damaged UFS file system. It has conversions to translate block and i-numbers into their corresponding disk addresses. Also included are mnemonic offsets to access different parts of an inode. These greatly simplify the process of correcting control block entries or descending the file system tree.

`fsdb` contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking `fsdb` with the `-o` option or by the use of the `o` command.

`fsdb` reads a block at a time and will therefore work with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. Note that in order to modify any portion of the disk, `fsdb` must be invoked with the `w` option.

Wherever possible, adb-like syntax was adopted to promote the use of `fsdb` through familiarity.

### Options
The following option is supported:

- `-o` Specify UFS file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces). The options available are:
  - `?` Display usage
  - `o` Override some error conditions
  - `p='string'` set prompt to string
  - `w` open for write

### Usage
Numbers are considered hexadecimal by default. However, the user has control over how data is to be displayed or accepted. The `base` command will display or set the input/output base. Once set, all input will default to this base and all output will be shown in this base. The base can be overridden temporarily for input by preceding hexadecimal numbers with `0x`, preceding decimal numbers with `0t`, or octal numbers with `0`. Hexadecimal numbers beginning with a-f or A-F must be preceded with `0x` to distinguish them from commands.

Disk addressing by `fsdb` is at the byte level. However, `fsdb` offers many commands to convert a desired inode, directory entry, block, superblock and so forth to a byte address. Once the address has been calculated, `fsdb` will record the result in dot (.).

Several global values are maintained by `fsdb`:

- the current base (referred to as `base`),
the current address (referred to as dot),
the current inode (referred to as inode),
the current count (referred to as count),
and the current type (referred to as type).

Most commands use the preset value of dot in their execution. For example,

> 2:inode

will first set the value of dot to 2, ':', will alert the start of a command, and the inode command will set inode to 2. A count is specified after a ',', Once set, count will remain at this value until a new command is encountered which will then reset the value back to 1 (the default). So, if

> 2000, 400/X

is typed, 400 hex longs are listed from 2000, and when completed, the value of dot will be 2000 + 400 * sizeof (long). If a RETURN is then typed, the output routine will use the current values of dot, count, and type and display 400 more hex longs. A '*' will cause the entire block to be displayed.

End of fragment, block and file are maintained by fsdb. When displaying data as fragments or blocks, an error message will be displayed when the end of fragment or block is reached. When displaying data using the db, 1b, directory, or file commands an error message is displayed if the end of file is reached. This is mainly needed to avoid passing the end of a directory or file and getting unknown and unwanted results.

An example showing several commands and the use of RETURN would be:

> 2:ino; 0:dir?d

or

> 2:ino; 0:db:block?d

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, any subsequent RETURN (or +, -) will advance to subsequent entries.

Note that

> 2:inode; :ls

or

> :ls /

is again synonymous.

Expressions

The symbols recognized by fsdb are:

RETURN update the value of dot by the current value of type and display using the current value of count.
numeric expressions may be composed of +, -, *, and % operators (evaluated left to right) and may use parentheses. Once evaluated, the value of dot is updated.

count indicator. The global value of count will be updated to count. The value of count will remain until a new command is run. A count specifier of '*' will attempt to show a block's worth of information. The default for count is 1.

display in structured style with format specifier f. See Formatted Output.

display in unstructured style with format specifier f See Formatted Output.

the value of dot.

increment the value of dot by the expression e. The amount actually incremented is dependent on the size of type:

\[
\text{dot} = \text{dot} + e \times \text{sizeof (type)}
\]

The default for e is 1.

decrement the value of dot by the expression e. See +.

multiply the value of dot by the expression e. Multiplication and division don't use type. In the above calculation of dot, consider the sizeof (type) to be 1.

divide the value of dot by the expression e. See *.

restore an address saved in register name. name must be a single letter or digit.

save an address in register name. name must be a single letter or digit.

display indicator. If f is a legitimate format specifier, then the value of dot is displayed using the format specifier f. See Formatted Output. Otherwise, assignment is assumed See =.

assignment indicator. The address pointed to by dot has its contents changed to the value of the expression e or to the ASCII representation of the quoted ('\') string s. This may be useful for changing directory names or ASCII file information.

incremental assignment. The address pointed to by dot has its contents incremented by expression e.

decremental assignment. The address pointed to by dot has its contents decremented by expression e.

A command must be prefixed by a ':' character. Only enough letters of the command to uniquely distinguish it are needed. Multiple commands may be entered on one line by separating them by a SPACE, TAB or ':'.

Commands

#
In order to view a potentially unmounted disk in a reasonable manner, fsdb offers the cd, pwd, ls and find commands. The functionality of these commands substantially matches those of its UNIX counterparts. See individual commands for details. The ‘*’, ‘?’, and ‘[-]’ wild card characters are available.

**base=b**

Display or set base. As stated above, all input and output is governed by the current base. If the =b is omitted, the current base is displayed. Otherwise, the current base is set to b. Note that this is interpreted using the old value of base, so to ensure correctness use the '0', '0t', or '0x' prefix when changing the base. The default for base is hexadecimal.

**block**

Convert the value of dot to a block address.

**cd dir**

Change the current directory to directory dir. The current values of inode and dot are also updated. If no dir is specified, then change directories to inode 2 ("/").

**cg**

Convert the value of dot to a cylinder group.

**directory**

If the current inode is a directory, then the value of dot is converted to a directory slot offset in that directory and dot now points to this entry.

**file**

The value of dot is taken as a relative block count from the beginning of the file. The value of dot is updated to the first byte of this block.

**find dir [ -name n ] [ -inum i ]**

Find files by name or i-number. find recursively searches directory dir and below for filenames whose i-number matches i or whose name matches pattern n. Note that only one of the two options (-name or -inum) may be used at one time. Also, the -print is not needed or accepted.

**fill=p**

Fill an area of disk with pattern p. The area of disk is delimited by dot and count.

**fragment**

Convert the value of dot to a fragment address. The only difference between the fragment command and the block command is the amount that is able to be displayed.

**inode**

Convert the value of dot to an inode address. If successful, the current value of inode will be updated as well as the value of dot. As a convenient shorthand, if 'inode' appears at the beginning of the line, the value of dot is set to the current inode and that inode is displayed in inode format.

**log_chk**

Run through the valid log entries without printing any information and verify the layout.
log_delta

count the number of deltas into the log, using the value of dot as an offset into the log. No checking is done to make sure that offset is within the head/tail offsets.

log_head

display the header information about the file system logging. This shows the block allocation for the log and the data structures on the disk.

log_otodb

return the physical disk block number, using the value of dot as an offset into the log.

log_show

display all deltas between the beginning of the log (BOL) and the end of the log (EOL).

ls

[ -R ] [ -l ] pat1 pat2 ... list directories or files. If no file is specified, the current directory is assumed. Either or both of the options may be used (but, if used, must be specified before the filename specifiers). Also, as stated above, wild card characters are available and multiple arguments may be given. The long listing shows only the i-number and the name; use the inode command with '?i' to get more information.

override

toggle the value of override. Some error conditions may be overridden if override is toggled on.

prompt p

change the fsdb prompt to p. p must be surrounded by ('')s.

pwd

display the current working directory.

quit

quit fsdb.

sb

the value of dot is taken as a cylinder group number and then converted to the address of the superblock in that cylinder group. As a shorthand, 'sb' at the beginning of a line will set the value of dot to the superblock and display it in superblock format.

shadow

if the current inode is a shadow inode, then the value of dot is set to the beginning of the shadow inode data.

! escape to shell

Inode Commands

In addition to the above commands, there are several commands that deal with inode fields and operate directly on the current inode (they still require the ':'). They may be used to more easily display or change the particular fields. The value of dot is only used by the ':sb' and ':ib' commands. Upon completion of the command, the value of dot is changed to point to that particular field. For example,
would increment the link count of the current inode and set the value of dot to the address of the link count field.

at  access time.
bs  block size.
ct  creation time.
db  use the current value of dot as a direct block index, where direct blocks number from 0 - 11. In order to display the block itself, you need to 'pipe' this result into the block or fragment command. For example,

```
> 1:db:block,20/X
```

would get the contents of data block field 1 from the inode and convert it to a block address. 20 longs are then displayed in hexadecimal. See FormattedOutput.

gid  group id.
ib  use the current value of dot as an indirect block index where indirect blocks number from 0 - 2. This will only get the indirect block itself (the block containing the pointers to the actual blocks). Use the file command and start at block 12 to get to the actual blocks.
ln  link count.
mt  modification time.
md  mode.
maj  major device number.
min  minor device number.
nm  although listed here, this command actually operates on the directory name field. Once poised at the desired directory entry (using the directory command), this command will allow you to change or display the directory name. For example,

```
> 7:dir:nm="foo"
```

will get the 7th directory entry of the current inode and change its name to foo. Note that names cannot be made larger than the field is set up for. If an attempt is made, the string is truncated to fit and a warning message to this effect is displayed.

si  shadow inode.
sz  file size.
uid  user id.
There are two styles and many format types. The two styles are structured and unstructured. Structured output is used to display inodes, directories, superblocks and the like. Unstructured displays raw data. The following shows the different ways of displaying:

```
?  c  display as cylinder groups
    i  display as inodes
    d  display as directories
    s  display as superblocks
    S  display as shadow inode data
```

The formatspecifier immediately follows the '/' or '?' character. The values displayed by '/b' and all '?' formats are displayed in the current base. Also, type is appropriately updated upon completion.

**Examples**

**EXAMPLE 1  Displaying in Decimal**

The following command displays 2010 in decimal (use of fsdb as a calculator for complex arithmetic):

```
> 2000+400%(20+20)=D
```

**EXAMPLE 2  Displaying an i-number in Inode Format**

The following command displays i-number 386 in an inode format. This now becomes the current inode:

```
> 386:ino?i
```

**EXAMPLE 3  Changing the Link Count**

The following command changes the link count for the current inode to 4:

```
> :ln=4
```
EXAMPLE 4  Incrementing the Link Count
The following command increments the link count by 1:
> :ln+=1

EXAMPLE 5  Displaying the Creation Time
The following command displays the creation time as a hexadecimal long:
> :ct=X

EXAMPLE 6  Displaying the Modification Time
The following command displays the modification time in time format:
> :mt=t

EXAMPLE 7  Displaying in ASCII
The following command displays in ASCII, block zero of the file associated with the current inode:
> 0:file/c

EXAMPLE 8  Displaying the First Block's Worth of Directory Entries
The following command displays the first block’s worth of directory entries for the root inode of this file system. It will stop prematurely if the EOF is reached:
> 2:ino,*/d

EXAMPLE 9  Displaying Changes to the Current Inode
The following command displays changes to the current inode to that associated with the 5th directory entry (numbered from zero) of the current inode. The first logical block of the file is then displayed in ASCII:
> 5:dir(inode; 0:file,*/c

EXAMPLE 10  Displaying the Superblock
The following command displays the superblock of this file system:
> :sb

EXAMPLE 11  Displaying the Cylinder Group
The following command displays cylinder group information and summary for cylinder group 1:
> 1:cg?c
EXAMPLE 12  Changing the i-number
The following command changes the i-number for the seventh directory slot in the root directory to $3$:

> 2:inode; 7:dir=3

EXAMPLE 13  Displaying as Directory Entries
The following command displays the third block of the current inode as directory entries:

> 2:db:block,*?d

EXAMPLE 14  Changing the Name Field
The following command changes the name field in the directory slot to *name*:

> 7:dir:,&="name"

EXAMPLE 15  Getting and Filling Elements
The following command gets fragment $3c3$ and fill $20$ type elements with $0x20$:

> 3c3:fragment,20:fill=0x20

EXAMPLE 16  Setting the Contents of an Address
The following command sets the contents of address $2050$ to $0xffffffff$. $0xffffffff$ may be truncated depending on the current type:

> 2050=0xffff

EXAMPLE 17  Placing ASCII
The following command places the ASCII for the string at $1c92434$:

> 1c92434="this is some text"

EXAMPLE 18  Displaying Shadow Inode Data
The following command displays all of the shadow inode data in the shadow inode associated with the root inode of this file system:

> 2:ino:si:ino;0:shadow,*?S

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
See Also  clri(1M), fsck_ufs(1M), dir_ufs(4), attributes(5), ufs(7FS)

Warnings  Since fsdb reads the disk raw, extreme caution is advised in determining its availability of fsdb on the system. Suggested permissions are 600 and owned by bin.

Notes  The old command line syntax for clearing i-nodes using the ufs-specific '-z i-number' option is still supported by the new debugger, though it is obsolete and will be removed in a future release. Use of this flag will result in correct operation, but an error message will be printed warning of the impending obsolescence of this option to the command. The equivalent functionality is available using the more flexible clri(1M) command.
Name  fsirand – install random inode generation numbers

Synopsis  fsirand [-p] special

Description  fsirand installs random inode generation numbers on all the inodes on device special, and also installs a file system ID in the superblock. This helps increase the security of file systems exported by NFS.

fsirand must be used only on an unmounted file system that has been checked with fsck(1M). The only exception is that it can be used on the root file system in single-user mode, if the system is immediately re-booted afterwards.

Options  -p  Print out the generation numbers for all the inodes, but do not change the generation numbers.

Usage  See largefile(5) for the description of the behavior of fsirand when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  fsck(1M), attributes(5), largefile(5)
The `fssnap` command creates a stable, read-only snapshot of a file system when given either an active mount point or a special device containing a mounted file system, as in the first form of the synopsis. A snapshot is a temporary image of a file system intended for backup operations.

While the snapshot file system is stable and consistent, an application updating files when the snapshot is created might leave these files in an internally inconsistent, truncated, or otherwise unusable state. In such a case, the snapshot will contain these partially written or corrupted files. It is a good idea to ensure active applications are suspended or checkpointed and their associated files are also consistent during snapshot creation.

File access times are not updated while the snapshot is being created.

A path to the virtual device that contains this snapshot is printed to standard output when a snapshot is created.

The following options are supported:

- `-d` Deletes the snapshot associated with the given file system.
- `-F FSType` Specifies the file system type to be used. The FSType should either be specified here or be determined by matching the block special device with an entry in the `/etc/vfstab` table, or by consulting `/etc/default/fs`.
- `-i` Displays the state of any given FSType snapshot. If a mount-point or device is not given, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default. The format and meaning of this information is file-system dependent. See the FSType-specific `fssnap` man page for details.
- `-o special_options` See the FSType-specific man page for `fssnap`.
- `-V` Echoes the complete command line, but does not execute the command.

The following operands are supported:

- `/mount/point` The directory where the file system resides.
Examples  See FSType-specific man pages for examples.

Exit Status  The following exit values are returned:
               0   Successful completion.
               >0  An error occurred.

Files  /etc/vfstab      Specifies file system type.
        /etc/default/fs   Specifies the default local file system type.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  fssnap_ufs(1M), attributes(5)

Notes  This command might not be supported for all FSTypes.
fssnap_ufs(1M)

Name
fssnap_ufs – create a temporary snapshot of a UFS file system

Synopsis
fssnap -d [-F ufs] [-V] /mount/point | dev
fssnap -i [-F ufs] [-V] [-o specific-options] /mount/point | dev

Description
The fssnap command queries, creates, or deletes a temporary snapshot of a UFS file system. A snapshot is a point-in-time image of a file system that provides a stable and unchanging device interface for backups.

When creating a file system snapshot, you must specify the file system to be captured and the backing-store file. The backing-store file(s) are where the snapshot subsystem saves old file system data before it is overwritten. Beyond the first backing-store file, fssnap automatically creates additional backing-store files on an as-needed basis.

The number and size of the backing store files varies with the amount of activity in the file system. The destination path must have enough free space to hold the backing-store file(s). This location must be different from the file system that is being captured in a snapshot. The backing-store file(s) can reside on any type of file system, including another UFS file system or an NFS–mounted file system.

Options
The following options are supported:

-d
   Deletes the snapshot associated with the given file system.

-i
   Displays the state of one or all UFS snapshots. If a mount-point or device is not specified, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default.

Use the -o options with the -i option to specify what snapshot information is displayed. Since this feature is provided primarily for use in scripts and on the command line, no labels are displayed for the data. Sizes are all in bytes, and the output is not internationalized or localized. The information is displayed on one line per option.

Unrecognized options display a single ? on the line. One line per option guarantees that there are the same number of lines as options specified and there is a one-to-one correspondence between an output line and an option.

The following -o options display specific information for a given snapshot. See the EXAMPLES section for examples of how to use these options.

snapnumber
   Display the snapshot number.

blockdevname
   Display the block device path.
rawdevname
  Display the raw device path.

mountpoint
  Display the mount point of the master file system.

state
  Display the state of the snapshot device.

backing-store
  Display the location of the first backing-store file for this snapshot. If there are multiple
  backing-store files, subsequent files have the same name as the first file, with the suffixes
  .2, .3, and so forth.

backing-store-len
  Display the sum of the sizes of the backing-store files.

maxsize
  Display the maxsize value specified for the backing-store file(s).

createtime
  Display the time that the snapshot was created.

chunksize
  Display the copy-on-write granularity.

-o specific-options
Without -d or -i, the default action is to create a snapshot. Specify the following options
when creating a snapshot. All of these options are discretionary, except for the
backing-store file, which is required.

backing-store=path
  Uses path in the creation of the backing-store file(s). path must not reside on the file
  system that is being captured in a snapshot and must not be the name of an existing file.
  If path is a directory, then a backing-store file is created within it using a name that is
  generated automatically. If path is not a directory and does not already exist, then a
  backing-store file with that name is created. If more than one backing-store file is
  required, fssnap creates subsequent files automatically. The second and subsequent
  files have the same name as the first file, with suffixes of .2, .3, and so forth.

  This option can be abbreviated as bf=path or bs=path.

unlink
  Unlinks the backing-store file after the snapshot is created. This option specifies that the
  backing-store file does not need to be removed manually when the snapshot is deleted.
  This might make administration more difficult since the file is not visible in the file
  system. If this option is not specified, the backing-store files should be removed
  manually after the snapshot is deleted.
chunksize=n [k,m,g]
  Uses n for the chunk size. Chunk size is the granularity of the data that is sent to the
  backing store.

Specify chunksize in the following units: k for kilobytes, m for megabytes, or g for
gigabytes. By default, chunk size is four times the block size of the file system (typically
32k).

maxsize=n[k,m,g]
  Does not allow the sum of the sizes of the backing-store file(s) to exceed n, where n is the
  unit specified. The snapshot is deleted automatically when the sum of the sizes of the
  backing-store file(s) exceeds maxsize.

Specify maxsize in the following units: k for kilobytes, m for megabytes, or g for
gigabytes.

raw
  Displays to standard output the name of the raw device instead of the block device when
  a snapshot is created. The block device is printed by default (when raw is not specified).
  This option makes it easier to embed fssnap commands in the command line for
  commands that require the raw device instead. Both devices are always created. This
  option affects only the output.

Operands

The following operands are supported:

  mount-point
    The directory where the file system resides.

  special
    The physical device for the file system, such as /dev/dsk/c0t0d0s7.

Examples

  EXAMPLE 1  Creating a Snapshot of a File System

  The following example creates a snapshot of a file system. The block special device created for
  the snapshot is /dev/fssnap/0.

  # fssnap -F ufs -o backing-store=/var/tmp /export/home
     /dev/fssnap/0

  EXAMPLE 2  Backing Up a File System Snapshot Without Having To Unmount the File System

  The following example backs up a file system snapshot without having to unmount the file
  system. Since ufsdump requires the path to a raw device, the raw option is used. The
  /export/home file system snapshot is removed in the second command.

  # ufsdump 0uf /dev/rmt/0 'fssnap -F ufs
       -o raw,bs=/export/snap /export/home'
    <output from ufsdump>
  # fssnap -F ufs -d /export/home
EXAMPLE 3  Backing Up a File System
When backing up a file system, do not let the backing-store file(s) exceed 400 Mbytes. The second command removes the /export/home file system snapshot.

```bash
# ufsdump 0uf /dev/rmt/0 'fssnap -F ufs
-o maxsize=400M,backing-store=/export/snap,raw
/export/home'
# fssnap -F ufs -d /export/home
```

EXAMPLE 4  Performing an Incremental Dump of a Snapshot
The following example uses ufsdump to back up a snapshot of /var. Note the use of the N option to ufsdump, which writes the name of the device being dumped, rather than the name of the snapshot device, to /etc/dumpdates file. See ufsdump(1M) for details on the N flag.

```bash
# ufsdump lfNu /dev/rmt/0 /dev/rdsk/c0t3d0s2 'fssnap -F ufs
-o raw,bs=/export/scratch,unlink /var'
```

EXAMPLE 5  Finding Out What Snapshots Currently Exist
The following command displays the currently existing snapshots.

```bash
# fssnap -i
0 /src
1 /export/home
<output continues>
```

EXAMPLE 6  Mounting a File System Snapshot
The following example creates a file system snapshot. After you create a file system snapshot, mount it on /tmp/mount for temporary read-only access.

```bash
# fssnap -F ufs -o backing-store=/nfs/server/scratch /export/home
/dev/fssnap/1
# mkdir /tmp/mount
# mount -F ufs -o ro /dev/fssnap/1 /tmp/mount
```

EXAMPLE 7  Creating a File System Snapshot and Unlinking the Backing-store File
The following example creates a file system snapshot and unlinks the backing-store file. After creating a file system snapshot and unlinking the backing-store file, check the state of the snapshot.

```bash
# fssnap -o bs=/scratch,unlink /src
/dev/fssnap/0
# fssnap -i /src
Snapshot number : 0
Block Device : /dev/fssnap/0
Raw Device : /dev/rfssnap/0
Mount point : /src
Device state : active
```
EXAMPLE 7  Creating a File System Snapshot and Unlinking the Backing-store File  

Backinɡ store path : /scratch/snapshoṭ2 <UNLINKED>
Backinɡ store size : 192 KB
Maximum backing store size : Unlimited
Snapshot create time : Sat May 06 10:55:11 2000
Copy-on-write granularity : 32 KB

EXAMPLE 8  Displaying the Size and Location of the Backing-store File(s) and the Creation Time for the Snapshot

The following example displays the size of the backing-store file(s) in bytes, the location of the backing store, and the creation time for the snapshot of the /test file system.

# fssnap -i -o backing-store-len,backing-store,createtime /test
196608
/snapshot2
Sat May 6 10:55:11 2000

Note that if there are multiple backing-store files stored in /snapshot2, they will have names of the form file (for the first file), file.1, file.2, and so forth.

Exit Status  The following exit values are returned:

0
  Successful completion.

>0
  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

The script-readable output mode is a stable interface that can be added to, but will not change. All other interfaces are subject to change.

See Also  xntpd(1M), mlock(3C), attributes(5)

Notes  The fssnap device files should be treated like a regular disk block or character device.

The association between a file system and the snapshot is lost when the snapshot is deleted or the system reboots. Snapshot persistence across reboots is not currently supported.

To avoid unnecessary performance impacts, perform the snapshot and system backup when the system is least active.
It is not possible to perform a snapshot of a file system if any of the following conditions are true:

- The file system is in use by system accounting
- The file system contains a local swap file
- The file system is used as backing store by an application that uses `mlock(3C)` to lock its pages. Typically, these are real time applications, such as `xntpd(1M)`.

These conditions result in `fssnap` being unable to write lock the file system prior to performing the snapshot.
**Name**
fsstat – report file system statistics

**Synopsis**
fsstat [-a|f|i|n|v] [-T | u|d] {-F | {fstype|path}...}

**Description**

fsstat reports kernel file operation activity by the file system type (*fstype*) or by the path name, which is converted to a mount point. The first set of lines of output reports all activity since:

- The file system module was loaded (in the case of *fstype*)
- The file system was mounted (in the case of mount point)

Statistics are gathered at the file system independent layer at both the *fstype* and the mount point levels. However, not all file system types are represented in the gathering of statistics. (See the NOTES section of this man page.)

The output of fsstat is dependent on the mode (option) requested. All statistic fields are displayed using “smart numbers” which automatically scale the units in a human readable form that fits in a maximum of 5 characters. For example:

100 is displayed as 100
2048 is displayed as 2K
3000000 is displayed as 2.86M

The unit modifiers are: K (Kbyte), M (Mbyte), G (Gbyte), T (terabyte), P (petabyte), and E (exabyte).

During the execution of fsstat, the state of the system can change. If relevant, a state change message is included in the fsstat output in one of the following forms:

<<mount point no longer available: {path}>>
<<file system module no longer loaded: {fstype}>>

After the state change messages are displayed, fsstat continues to display the statistics as directed. If all of the *fstypes* and mount points that fsstat was reporting on are no longer available, then fsstat exits.

The user is required to specify the -F option (all available file system types) or a list of one or more *fstypes* and/or mount points.

The default report shows general file system activity. This display combines similar operations into general categories as follows:

- **new file** Number of creation operations for file system objects (for example, files, directories, symlinks, etc.)
- **name remov** Number of name removal operations
- **name chng** Number of name change operations
attr get  Number of object attribute retrieval operations
attr set  Number of object attribute change operations
lookup ops  Number of object lookup operations
rddir ops  Number of read directory operations
read ops  Number of data read operations
read bytes  Bytes transferred by data read operations
write ops  Number of data write operations
write bytes  Bytes transferred by data write operations

The entity being reported on (fstype or mount point) is displayed in the last column.

Options  The following options are supported:

- a  Report the activity for kernel attribute operations. The following statistics are reported:
  getattrib  Number of file attribute retrieval calls
  setattr  Number of file attribute modification calls
  getsec  Number of file security attribute retrieval calls
  setsec  Number of file security attribute modification calls

  The entity being reported on (fstype or mount point) is displayed in the last column.

- f  Report the full activity for all kernel file operations. Each file operation is listed in the left column. The following statistics are reported for each operation:
  #ops  Number of calls for this operation
  bytes  Average transfer size in bytes (only applies to read, write, readdir)

  The entity being reported on (fstype or mount point) is displayed in the first row.

- i  Reports the activity for kernel I/O operations. The following statistics are reported:
  read ops  Number of data read calls
  read bytes  Number of bytes read
  write ops  Number of data write calls
  write bytes  Number of bytes written
  rddir ops  Number of read directory calls
applname

rddir bytes  Number of bytes read by reading directories
rwlock ops  Number of internal file system lock operations
rwulock ops  Number of internal file system unlock operations

The entity being reported on (fstype or mount point) is displayed in the last column.

-n
Reports the activity for kernel naming operations. The following statistics are reported:
lookup    Number of file name retrieval calls
creat     Number of file creation calls
remov     Number of file remove calls
link      Number of link calls
renam     Number of file renaming calls
mkdir     Number of directory creation calls
rmdir     Number of directory removal calls
rddir     Number of directory read calls
symlink   Number of symlink creation calls
rdlink    Number of symlink read calls

The entity being reported on (fstype or mount point) is displayed in the last column.

-v
Reports the activity for calls to the virtual memory operations. The following statistics are reported.
map       Number of calls mapping a file
addmap    Number of calls setting additional mapping to a mapped file
delmap    Number of calls deleting mapping to a file
getpag    Number of calls retrieving a page of data from a file
putpag    Number of calls writing a page of data to a file
pagio     Number of calls to transfer pages in file system swap files

The entity being reported on (fstype or mount point) is displayed in the last column.

-F
Report on all available file system types.
-T u|d  Display a time stamp.
  Specify u for a printed representation of the internal representation of time (see time(2)) Specify d for the standard date format. (See date(1)). The time stamp is only used when an interval is set.

**Operands**
The following operands are supported:

- count  Display only count reports.
- fstype  Explicitly specify the file system type(s) to be reported. The file system module must be loaded.
- interval  Report once each interval seconds.
- path  Specify the path(s) of the mount point(s) to be reported. If path is not a mount point, the mount point containing path will be determined and displayed in the output.

If no interval and no count are specified, a single report is printed and fsstat exits. If an interval is specified but no count is specified, fsstat prints reports every interval seconds indefinitely until the command is interrupted.

**Examples**

**EXAMPLE 1**  Displaying General Activity
The following example shows general activity for all file system types.

```
$ fsstat -F
```

System Administration Commands - Part 1 627
EXAMPLE 2  Displaying Naming Activity  (Continued)

EXAMPLE 3  Displaying Attribute Activity

The following example shows the attribute activity for the FS type ufs and the mounted file systems "/" and "/export/home" every three seconds for every third iteration:

```
# fsstat -a ufs / /export/home 3 3
getattr   setattr  getsec  setsec
  378K  91.9K   11.8K   0   ufs

EXAMPLE 4  Displaying File Operation Statistics

The following example shows the statistics for each file operation for "/" (using the -f option):

```
$ fsstat -f /
Mountpoint: /
operation  #ops   bytes
  open      8.54K
  close     9.8K
    read    43.6K   65.9M
    write   1.57K   2.99M
    ioctl   2.06K
    setfl    4
  getattr   40.3K
  setattr    38
  access    9.19K
  lookup    203K
  create    595
  remove    56
    link     0
  rename     9
  mkdir     19
  rmdir     0
  readdir   2.02K   2.27M
  symlink    4
```

**EXAMPLE 4**  Displaying File Operation Statistics

**Environment Variables**  

See environ(5) for descriptions of the following environment variables that affect the execution of fsstat: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, LC_TIME, and NLSPATH.

**Exit Status**  

The following exit values are returned:

0  Successful completion.
1  A fatal error occurred. A fatal error could be a failed system call or another internal error.
2  Invalid command-line options were specified.

**Attributes**  

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>CSI</td>
<td>Enabled</td>
</tr>
</tbody>
</table>
The command-line options are Unstable. The human-readable output is not considered an interface.

See Also date(1), time(2), attributes(5)

Notes All display options (-a, -f, -i, -n, -v) are mutually exclusive. Entering more than one of these options will result in an error.

The fstype and path operands must appear after the option, but before the interval or count on the command line. For example, "fsstat -fstype interval". Preference is given to fstype so that if a user wishes to see the statistics for a directory that has the same name as an fstype (for example, ufs), then the path must be specified unambiguously (for example, ./ufs). Similarly, in order to define a file with a numeric name (for example, "10") from an interval or count operand, the name should be prefixed accordingly (for example, ./10).

When an interval is used, headers repeat after more than 12 lines of statistics have been displayed and the set of lines to be displayed in the current interval have completed.

Statistics are not displayed for all pseudo-filesystems. The output displayed with the -F option shows which of the loaded filesystem types are supported.

Unbundled file systems may not be recognized by fsstat.

The command-line options are classified as Unstable and could change. The output is not considered to be an interface. The construction of higher level software tools depend on either the command-line options or the output of fsstat is not recommended.
fstyp(1M)

Name  fstyp – determine file system type

Synopsis  fstyp  [-v]  special

Description  fstyp allows the user to determine the file system type of unmounted file systems using heuristic programs.

An fstyp module for each file system type to be checked is executed; each of these modules applies an appropriate heuristic to determine whether the supplied special file is of the type for which it checks. If it is, the program prints on standard output the usual file system identifier for that type (for example, “ufs”) and exits with a return code of 0; if none of the modules succeed, the error message unknown_fstyp (no matches) is returned and the exit status is 1. If more than one module succeeds, the error message unknown_fstyp (multiple matches) is returned and the exit status is 2.

This command is unreliable and its results should not be used to make any decisions about subsequent use of a storage device or disk partition.

Options  -v  Produce verbose output. This is usually information about the file systems superblock and varies across different FSTypes. See ufs(7FS), mkfs_ufs(1M), and tunefs(1M) for details.

Usage  See largefile(5) for the description of the behavior of fstyp when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  mkfs_ufs(1M), tunefs(1M), attributes(5), largefile(5), hsfs(7FS), ufs(7FS), pcfs(7FS)

Notes  The use of heuristics implies that the result of fstyp is not guaranteed to be accurate.

This command is unreliable and its results should not be used to make any decisions about subsequent use of a storage device or disk partition.
The `ftpaddhost` script is executed by the super user to set up virtual FTP hosts. The `ftpaddhost` command configures the virtual host `hostname` under directory `root_dir`. The value of `hostname` can be an IP address or the name of a host.

The `ftpaddhost` script supports the following options:

- `-b` Create a banner for the virtual host. This option is useful to confirm that the virtual host is working.

- `-c` Configure complete virtual hosting. This option allows each virtual host to have its own version of the `ftpaccess`, `ftpconversion`, `ftpgroups`, `ftphosts`, and `ftpusers` files. The master version of each of these configuration files is copied from the `/etc/ftpd` directory and placed in the `/etc/ftpd/virtual-ftpd/hostname` directory. If the `/etc/ftputers` file exists it is appended to the virtual `ftpusers` file. If a virtual host lacks its own version of a configuration file, the master version is used.

- `-l` Configure limited virtual hosting. This option allows a small number of parameters to be configured differently for a virtual host. See the `virtual` keyword on the `ftpaccess(4)` manual page.

- `-x xferlog` Create a log file entry such that the transfer logs for the virtual host are written to the specified file. An absolute path must be specified for the `xferlog` file.

The following operands are supported:

- `hostname` The host name or IP address of the virtual server.
- `root_dir` The absolute pathname of the directory under which the virtual server is set up.

The following exit values are returned:

- 0 Successful completion
- 1 Improper usage of the command
- 2 Command failed

The configuration files directory for the virtual host `hostname` is `/etc/ftpd/virtual-ftpd/hostname`.

ftpconfig – set up anonymous FTP

Synopsis  ftpconfig [ftpdir]
            ftpconfig -d ftpdir

Description The ftpconfig script is executed by the super user to set up anonymous FTP. Anonymous FTP allows users to remotely log on to the FTP server by specifying the user name ftp or anonymous and the user's email address as password. The anonymous users are logged on to the FTP Server and given access to a restricted file area with its own file system root. See chroot(2). The FTP area has its own minimal system files.

This command will copy and set up all the components needed to operate an anonymous FTP server, including creating the ftp user account, creating device nodes, copying /usr/lib files, and copying timezone data. The passwd and group files set up have been stripped down to prevent malicious users from finding login names on the server. The anonymous file area will be placed under ftpdir. If the ftp user account already exists, then the current FTP area is used, and the system files in it are updated. All other files are left untouched. This command should be run to update the anonymous FTP area's configuration whenever a system patch is installed, or the system is upgraded.

Options  -d Create a new or update an existing ftpdir without creating or updating the ftp user account. Use this option when creating guest FTP user accounts.

Operands The following operands are supported:

ftpdir The absolute pathname of the directory under which the anonymous FTP area is set up.

Exit Status The following exit values are returned:

0 Successful completion
1 Improper usage of the command
2 Command failed

Name ftprestart – restart previously shutdown FTP Servers

Synopsis ftprestart [-V]

Description Use the ftprestart command to restart an FTP Server previously shut down by means of ftpshut(1M). The ftprestart command reads the shutdown capability from the ftpaccess(4) file to determine the path of the shutdown message files. It then reenables the FTP Server by removing any shutdown message files in the anonymous and virtual FTP Server area, as well as the system wide shutdown message file.

Options The ftprestart command supports the following options:

- V Display program copyright and version information, then terminate.

Examples Example 1 Sample Output from ftprestart

The following example shows sample output from the ftprestart command:

example% ftprestart
ftprestart: /export/home/ftp/etc/ftpd/shutdown.msg removed.
ftprestart: /export/home/virtual1/etc/ftpd/shutdown.msg removed.
ftprestart: /etc/ftpd/shutdown.msg removed.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /etc/ftpd/ftpaccess

/etc/ftpd/ftpservers

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWftpU</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>External</td>
</tr>
</tbody>
</table>

See Also ftpshut(1M), in.ftpd(1M), ftpaccess(4), ftpservers(4), attributes(5)
The **ftpshut** command provides an automated shutdown procedure that the superuser can use to notify FTP users when the FTP Server is shutting down.

Ten minutes before shutdown, or immediately if the value of *time* is less than ten minutes, any new FTP Server connections will be disabled. You may adjust the shutdown of new FTP Server connections by means of the `-l` option.

Five minutes before shutdown, or immediately if the value of *time* is less than five minutes, all current FTP connections will be disconnected. You may adjust the shutdown of current FTP connections by means of the `-d` option.

The **ftpshut** command creates shutdown message files that the FTP Server uses to determine when to shutdown. Separate shutdown message files are created in the anonymous and virtual host FTP Server areas, in addition to the system wide shutdown message file. Once the shutdown occurs, the server continues to refuse connections until the appropriate shutdown message file is removed. This normally is done by using the **ftprestart(1M)** command. The location of the shutdown message file is specified by the shutdown capability in the **ftpaccess** file.

The following magic cookies are available:

- `%s` The time system is going to shut down.
- `%r` The time new connections will be denied.
- `%d` The time current connections will be dropped.
- `%C` The current working directory.
- `%E` The maintainer’s email address as defined in the **ftpaccess** file.
- `%F` The free space in the partition of CWD, in kilobytes.
- `%L` The local host name.
- `%M` The maximum allowed number of users in this class.
- `%N` The current number of users in this class.
- `%R` The remote host name.
- `%T` The local time (form Thu Nov 15 17:12:42 1990).
- `%U` The username given at login time.
The `ftpshut` command supports the following options:

- `-V` Display program copyright and version information, then terminate.
- `-d min` The time ahead of shutdown, in minutes, that existing connections will be disconnected upon completion of their current or next (if idle) FTP request.
- `-l min` The time ahead of shutdown, in minutes, that new connections will be refused.
- `-v` Verbose. Output the pathname of the shutdown message files created.

The `ftpshut` command supports the following operands:

- `time` The time at which `ftpshut` will bring the FTP Servers down. `time` can have a value of `now`, which indicates an immediate shutdown. Alternatively, `time` can specify a future time in one of two formats: `+number` or `HHMM`. The first form brings the FTP Server down in `number` minutes. The second brings the FTP Server down at the time of day indicated, using a 24-hour clock format. When using the absolute time format, you can only specify times between now and 23:59.

- `warning-message` The message to display that warns of the imminent shutdown. The `warning-message` will be formatted at 70 characters wide. `ftpshut` knows the actual string length of the magic cookies. If no warning-message is supplied, the default message “System shutdown at %s” is used.

The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

Files

- `/etc/ftpd/ftpaccess`
- `/etc/ftpd/ftpservers`

fuser(1M)

Name  fuser – identify users of files and devices

Synopsis  

```
/usr/sbin/fuser [-c | -d | -f] [-nu] [-k | -s sig] files
[ [- -c | -d | -f] [-nu] [-k | -s sig] files ...]
```

Description  The fuser utility displays the process IDs of the processes that are using the files specified as arguments.

Each process ID is followed by a letter code. These letter codes are interpreted as follows. If the process is using the file as

- c  Indicates that the process is using the file as its current directory.
- m  Indicates that the process is using a file mapped with mmap(2). See mmap(2) for details.
- n  Indicates that the process is holding a non-blocking mandatory lock on the file.
- o  Indicates that the process is using the file as an open file.
- r  Indicates that the process is using the file as its root directory.
- t  Indicates that the process is using the file as its text file.
- y  Indicates that the process is using the file as its controlling terminal.

For block special devices with mounted file systems, all processes using any file on that device are listed. For all types of files (text files, executables, directories, devices, and so forth), only the processes using that file are reported.

For all types of devices, fuser also displays any known kernel consumers that have the device open. Kernel consumers are displayed in one of the following formats:

- `[module_name]`
- `[module_name, dev_path=path]`
- `[module_name, dev=(major, minor)]`
- `[module_name, dev=(major, minor), dev_path=path]`

If more than one group of files are specified, the options may be respecified for each additional group of files. A lone dash cancels the options currently in force.

The process IDs are printed as a single line on the standard output, separated by spaces and terminated with a single new line. All other output is written on standard error.

Any user can run fuser, but only the superuser can terminate another user’s process.

Options  The following options are supported:

- `-c`  Reports on files that are mount points for file systems, and any files within that mounted file system.
Report device usage information for all minor nodes bound to the same device node as the specified minor node. This option does not report file usage for files within a mounted file system.

- f
Prints a report for the named file, not for files within a mounted file system.

- k
Sends the SIGKILL signal to each process. Since this option spawns kills for each process, the kill messages may not show up immediately (see kill(2)). No signals will be sent to kernel file consumers.

- n
Lists only processes with non-blocking mandatory locks on a file.

- s sig
Sends a signal to each process. The sig option argument specifies one of the symbolic names defined in the <signal.h> header, or a decimal integer signal number. If sig is a symbolic name, it is recognized in a case-independent fashion, without the SIG prefix. The -k option is equivalent to -s KILL or -s 9. No signals will be sent to kernel file consumers.

- u
Displays the user login name in parentheses following the process ID.

**Examples**

**EXAMPLE 1 Reporting on the Mount Point and Files**
The following example reports on the mount point and files within the mounted file system.

example% fuser -c /export/foo

**EXAMPLE 2 Restricting Output when Reporting on the Mount Point and Files**
The following example reports on the mount point and files within the mounted file system, but the output is restricted to processes that hold non-blocking mandatory locks.

example% fuser -cn /export/foo

**EXAMPLE 3 Sending SIGTERM to Processes Holding a Non-blocking Mandatory Lock**
The following command sends SIGTERM to any processes that hold a non-blocking mandatory lock on file /export/foo/my_file.

example% fuser -fn -s term /export/foo/my_file

**Environment Variables**
See environ(5) for descriptions of the following environment variables that affect the execution of fuser: LANG, LC_ALL LC_CTYPE, LC_MESSAGES, and NLSPATH.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Standard</td>
</tr>
</tbody>
</table>
Because `fuser` works with a snapshot of the system image, it may miss processes that begin using a file while `fuser` is running. Also, processes reported as using a file may have stopped using it while `fuser` was running. These factors should discourage the use of the `-k` option.

See Also `ps(1), mount(1M), kill(2), mmap(2), signal(3C), attributes(5), environ(5), standards(5)`

Notes Because `fuser` works with a snapshot of the system image, it may miss processes that begin using a file while `fuser` is running. Also, processes reported as using a file may have stopped using it while `fuser` was running. These factors should discourage the use of the `-k` option.
fwflash – firmware query and update utility

**Synopsis**

```
/usr/sbin/fwflash  [-l  [-c device_class | ALL ]]
          |  [-v]  |  [-h]
fwflash  [-f file | -r file]
          |  [-y]  |  [-d dev_spec]
```

**Description**

The fwflash command writes a binary image file to flash devices of an HBA or HCA device. It also provides the ability to read firmware to a file if supported by the device. Because changing the firmware in a device can have significant impact on the stability of a system, only users with the privilege ALL are allowed to execute this command. Users authorized to run fwflash can be granted the “Firmware Flash Update” Rights Profile.

The first form of the command, above, provides information about devices. It lists all devices currently available on the system and supported by fwflash for firmware upgrade. You can filter the list operation, to display only specified classes of devices. The second form of the command provides the operations to read or write the firmware images to specific devices.

**Options**

The following options are supported:

- **-c device_class**

  An optional parameter, valid only when used with the -l option. This option causes the command to list only devices of a specific class type. Currently supported classes are IB or ALL. If -c is not specified for the -l option, the class defaults to ALL.

- **-d dev_spec**

  The dev_spec is an identifier of the device that the user wants to modify with the -f or -r operation. dev_spec can be either the absolute path name as displayed in the -l listing or as the device number from the same listing. If the device cannot be found, the command fails.

- **-f file**

  Specify the path to a binary firmware file you want to write to the device. fwflash will verify that the file is a valid firmware binary for the dev_spec specified. If it is not, the command fails with an appropriate error message.

- **-h**

  List the command line help for fwflash.

- **-l**

  List the devices on a system available for firmware upgrade and display information specific to each device or device class.

  For InfiniBand (IB) devices, the list operation displays the guids (Globally Unique Identifier) currently set for the HCA, as well as the current firmware revision installed. There are four separate guids on the HCA; two of them can be set with the same value.

- **-r file**

  Specify the path to a file to create when reading the firmware from the device. The -f and -r options are mutually exclusive.
-V
  Output fwflash version information and exit.

-y
  Valid during an -f or -r operation, causes fwflash not to prompt for confirmation during operation and operate non-interactively.

Examples

**EXAMPLE 1** Entering Command Without Arguments

The following command shows fwflash when the command is entered without arguments.

```
example# fwflash
Usage: fwflash [-l [-c <device_class> | ALL]] | [-v] | [-h]
        [-f <file> | -r <file>] [-y] [-d <dev_spec>]
```

**EXAMPLE 2** Listing Devices Available to Flash

The following command lists the devices available to be flashed.

```
example# fwflash -l
List of available devices:
Device[0], /devices/pci@0,0/pci8086,3595@2/pci8086,32a@0,2/pci15b3,5a46@c/pci15b3,5a44@0:devctl
  Class [IB]
  GUID: System Image - 0002c901081e33b3
  Node - 0000000000003446
  Port 1 - 0002c901081e33b1
  Port 2 - 0002c901081e33b2
  Firmware revision: 3.3.0002
  No HW information available

Device[1], /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
  Class [IB]
  GUID: System Image - 0002c9010a99e3b3
  Node - 0002c9010a99e3b0
  Port 1 - 0002c9010a99e3b1
  Port 2 - 0002c9010a99e3b2
  Firmware revision: 4.8.00c8
  Product : MTLP25208-CF256T (Lion cub)
  PSID : MT_00B0000001
```

**EXAMPLE 3** Flash Upgrading an IB HCA Device

The following command flash upgrades an IB HCA device.

```
example# fwflash -f ./version.3.2.0000 -d 0
About to update firmware on:
 /devices/pci@1d,700000/pci@1/pci15b3,5a44@0:devctl
Continue (Y/N): Y
Updating . . . . . . . . . . . . .
```

642 man pages section 1M: System Administration Commands • Last Revised 12 Jun 2007
EXEMPLARY 3  Flash Upgrading an IB HCA Device  (Continued)

Done. New image will be active after the system is rebooted.

Note that you are prompted before the upgrading proceeds.

The following command adds the -y option to the preceding command.

```bash
example# fwflash -y -f ./version.3.2.0000 -d 0
```

About to update firmware on:
```
/devices/pci@1d,700000/pci@1/pci15b3,5a44@0:devctl
```

Updating . . . . . . .

Done. New image will be active after the system is rebooted.

EXEMPLARY 4  Reading Device Firmware to File

The command shown below reads the device firmware to a file. The command uses the -y option so that read occurs without prompting.

```bash
example# fwflash -y -r /firmware.bin -d 1
```

About to read firmware on:
```
/devices/pci@0,0/pci8086,3596@3/pci15b3,6278@0:devctl
to filename: /firmware.bin
```

Reading ...

Done.

**Return Values**  The `fwflash` command returns the following values:

0  Success

1  Failure

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWfwflash</td>
</tr>
</tbody>
</table>

**See Also** attributes(5), tavor(7D)

**Notes**  The `fwflash` command supports IB class HCA cards containing either the AMD or the Intel parallel flash parts. The `tavor(7D)` HCA driver is required.
fwtmp(1M)

Name    fwtmp, wtmpfix – manipulate connect accounting records

Synopsis  /usr/lib/acct/fwtmp [-ic]
           /usr/lib/acct/wtmpfix [file]...

Description  fwtmp reads from the standard input and writes to the standard output, converting binary records of the type found in /var/adm/wtmpx to formatted ASCII records. The ASCII version is useful when it is necessary to edit bad records.

wtmpfix examines the standard input or named files in utmpx format, corrects the time/date stamps to make the entries consistent, and writes to the standard output. A hyphen (−) can be used in place of file to indicate the standard input. If time/date corrections are not performed, acctcon(1M) will fault when it encounters certain date-change records.

Each time the date is set, a pair of date change records are written to /var/adm/wtmpx. The first record is the old date denoted by the string "old time" placed in the line field and the flag OLD_TIME placed in the type field of the utmpx structure. The second record specifies the new date and is denoted by the string new time placed in the line field and the flag NEW_TIME placed in the type field. wtmpfix uses these records to synchronize all time stamps in the file.

In addition to correcting time/date stamps, wtmpfix will check the validity of the name field to ensure that it consists solely of alphanumeric characters or spaces. If it encounters a name that is considered invalid, it will change the login name to INVALID and write a diagnostic to the standard error. In this way, wtmpfix reduces the chance that acctcon will fail when processing connect accounting records.

Options  -ic    Denotes that input is in ASCII form, and output is to be written in binary form.

Files    /var/adm/wtmpx    history of user access and administration information

System Administration Guide: Basic Administration
getdev - lists devices based on criteria

Synopsis
getdev [-ae] [criteria] . . . [device] . . .

Description
getdev generates a list of devices that match certain criteria. The criteria includes a list of attributes (given in expressions) and a list of devices. If no criteria are given, all devices are included in the list.

Devices must satisfy at least one of the criteria in the list unless the -a option is used. Then, only those devices which match all of the criteria in a list will be included.

Devices which are defined on the command line and which match the criteria are included in the generated list. However, if the -e option is used, the list becomes a set of devices to be excluded from the list. See OPTIONS and OPERANDS.

Options
The following options are supported:

- a  Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.

- e  Specifies that the list of devices which follows on the command line should be excluded from the list generated by this command. Without the -e the named devices are included in the generated list. The flag has no effect if no devices are defined.

Operands
The following operands are supported:

criteria  Defines the criteria that a device must match to be included in the generated list. criteria is specified by expressions.

There are four possible expression types which the criteria specified in the criteria argument may follow:

 attribute=value  Selects all devices whose attribute attribute is defined and is equal to value.

 attribute ! =value  Selects all devices whose attribute attribute is defined and does not equal value.

 attribute :*  Selects all devices which have the attribute attribute defined.

 attribute !:*  Selects all devices which do not have the attribute attribute defined.

See the putdev(1M) manual page for a complete listing and description of available attributes.

device  Defines the devices which should be included in the generated list. This can be the pathname of the device or the device alias.
Exit Status  The following exit values are returned:

0  Successful completion.
1  Command syntax was incorrect, invalid option was used, or an internal error occurred.
2  Device table could not be opened for reading.

Files  /etc/device.tab

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**Name**
getdevpolicy – inspect the system’s device policy

**Synopsis**
/usr/sbin/getdevpolicy [device...]

**Description**
Without arguments, getdevpolicy outputs the device policy in effect to standard output.

With arguments, each argument is treated as a pathname to a device and the device policy in effect for that specific device is printed preceded by the supplied pathname.

**Usage**
The device policy adds access restrictions over and above the file permissions.

**Exit Status**
The following exit values are returned:

0   Successful completion.
non-zero   An error occurred.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td></td>
</tr>
</tbody>
</table>

The invocation is evolving. The output is unstable.

add_drv(1M), rem_drv(1M), update_drv(1M), attributes(5), privileges(5), devfs(7FS)
getdgrp(1M)

Name  getdgrp – lists device groups which contain devices that match criteria

Synopsis  /usr/sbin/getdgrp [-ael] [criteria]... [dgroup]...

Description  getdgrp generates a list of device groups that contain devices matching the given criteria. The criteria is given in the form of expressions.

Options  The following options are supported:

- -a  Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.

- -e  Specifies that the list of device groups on the command line should be excluded from the list generated by this command. Without the -e option the named device groups are included in the generated list. The flag has no effect if no devices are defined.

- -l  Specifies that all device groups (subject to the -e option and the dgroup list) should be listed even if they contain no valid device members. This option has no effect if criteria is specified on the command line.

Operands  The following operands are supported:

criteria  Defines criteria that a device must match before a device group to which it belongs can be included in the generated list. Specify criteria as an expression or a list of expressions which a device must meet for its group to be included in the list generated by getdgrp. If no criteria are given, all device groups are included in the list.

Devices must satisfy at least one of the criteria in the list. However, the -a option can be used to define that a "logical and" operation should be performed. Then, only those groups containing devices which match all of the criteria in a list will be included.

There are four possible expressions types which the criteria specified in the criteria argument may follow:

attribute=value  Selects all device groups with a member whose attribute attribute is defined and is equal to value.

attribute!=value  Selects all device groups with a member whose attribute attribute is defined and does not equal value.

attribute:*  Selects all device groups with a member which has the attribute attribute defined.

attribute!:*  Selects all device groups with a member which does not have the attribute attribute defined.

See putdev(1M) for a complete listing and description of available attributes.
dgroup

Defines a set of device groups which should be included in or excluded from the generated list. Device groups that are defined and which contain devices matching the criteria are included.

If the -e option is used, this list defines a set of device groups to be excluded. When the -e option is used and criteria is also defined, the generated list will include device groups containing devices which match the criteria and are not in the command line list.

Exit Status

The following exit values are returned:

0  Successful completion of the task.
1  Command syntax was incorrect, invalid option was used, or an internal error occurred.
2  Device table or device group table could not be opened for reading.

Files

/etc/device.tab
/etc/dgroup.tab

getent – get entries from administrative database

**Synopsis**

```
getent database [key]...
```

**Description**

`getent` gets a list of entries from the administrative database specified by `database`. The information generally comes from one or more of the sources that are specified for the `database` in `/etc/nsswitch.conf`.

`database` is the name of the database to be examined. This can be `passwd`, `group`, `hosts`, `ipnodes`, `services`, `protocols`, `ethers`, `project`, `networks`, or `netmasks`. For each of these databases, `getent` uses the appropriate library routines described in `getpwnam(3C)`, `getgrnam(3C)`, `gethostbyaddr(3NSL)`, `gethostbyname(3NSL)`, `getipnodebyaddr(3SOCKET)`, `getipnodebyname(3SOCKET)`, `getservbyname(3SOCKET)`, `getprotobyname(3SOCKET)`, `ethers(3SOCKET)`, `getprojbyname(3PROJECT)` and `getnetbyname(3SOCKET)`, respectively.

Each `key` must be in a format appropriate for searching on the respective database. For example, it can be a `username` or `numeric-uid` for `passwd`; `hostname` or `IP address` for `hosts`; or `service`, `service/protocol`, `port`, or `port/proto` for `services`.

`getent` prints out the database entries that match each of the supplied keys, one per line, in the format of the matching administrative file: `passwd(4)`, `group(4)`, `project(4)`, `hosts(4)`, `services(4)`, `protocols(4)`, `ethers(3SOCKET)`, `networks(4)`, or `netmasks(4)`. If no key is given, all entries returned by the corresponding enumeration library routine, for example, `getpwent()` or `gethostent()`, are printed. Enumeration is not supported on `ipnodes`.

**Key Interpretation for passwd and group Databases**

When `getent` is invoked with database set to `passwd`, each key value is processed as follows:

- If the key value consists only of numeric characters, `getent` assumes that the key value is a numeric user ID and searches the user database for a matching user ID.

- If the user ID is not found in the user database or if the key value contains any non-numeric characters, `getent` assumes the key value is a user name and searches the user database for a matching user name.

Similarly, when `getent` is invoked with database set to `group`, each key value is processed as follows:

- If the key value consists only of numeric characters, `getent` assumes that the key value is a numeric group ID and searches the group database for a matching group ID.

- If the group ID is not found in the group database or if the key value contains any non-numeric characters, `getent` assumes the key value is a group name and searches the group database for a matching group name.

**Exit Status**

The following exit values are returned:

- **0**  Successful completion.
- **1**  Command syntax was incorrect, an invalid option was used, or an internal error occurred.
At least one of the specified entry names was not found in the database.

There is no support for enumeration on this database.

**Files**
- `/etc/nsswitch.conf` name service switch configuration file
- `/etc/passwd` password file
- `/etc/group` group file
- `/etc/inet/hosts` IPv4 and IPv6 host name database
- `/etc/services` Internet services and aliases
- `/etc/project` project file
- `/etc/protocols` protocol name database
- `/etc/ethers` Ethernet address to hostname database or domain
- `/etc/networks` network name database
- `/etc/netmasks` network mask database

**Attributes**

gettable(1M)

Name  gettable – get DoD Internet format host table from a host

Synopsis  /usr/sbin/gettable host

Description  gettable is a simple program used to obtain the DoD Internet host table from a “hostname” server. The specified host is queried for the table. The table is placed in the file hosts.txt.

gettable operates by opening a TCP connection to the port indicated in the service specification for “hostname”. A request is then made for all names and the resultant information is placed in the output file.

gettable is best used in conjunction with the htable(1M) program which converts the DoD Internet host table format to that used by the network library lookup routines.

</table>

Notes  Should allow requests for only part of the database.
getty(1M)

Name
getty – set terminal type, modes, speed, and line discipline

Synopsis
/usr/lib/saf/ttymon [-h] [-t timeout] line
   [speed [type [linedisc]]]

/usr/lib/saf/ttymon -c file

Description
getty sets terminal type, modes, speed, and line discipline. getty is a symbolic link to /usr/lib/saf/ttymon. It is included for compatibility with previous releases for the few applications that still call getty directly.

getty can only be executed by the super-user, (a process with the user ID root). Initially getty prints the login prompt, waits for the user's login name, and then invokes the login command. getty attempts to adapt the system to the terminal speed by using the options and arguments specified on the command line.

Without optional arguments, getty specifies the following: The speed of the interface is set to 300 baud, either parity is allowed, NEWLINE characters are converted to carriage return-line feed, and tab expansion is performed on the standard output. getty types the login prompt before reading the user's name a character at a time. If a null character (or framing error) is received, it is assumed to be the result of the user pressing the BREAK key. This will cause getty to attempt the next speed in the series. The series that getty tries is determined by what it finds in /etc/ttydefs.

Options
The following options are supported:

- h
  If the -h flag is not set, a hangup will be forced by setting the speed to zero before setting the speed to the default or a specified speed.

- t timeout
  Specifies that getty should exit if the open on the line succeeds and no one types anything in timeout seconds.

- c file
  The -c option is no longer supported. Instead use /usr/sbin/sttydefs -l to list the contents of the /etc/ttydefs file and perform a validity check on the file.

Operands
The following operands are supported:

line
  The name of a TTY line in /dev to which getty is to attach itself. getty uses this string as the name of a file in the /dev directory to open for reading and writing.

speed
  The speed argument is a label to a speed and TTY definition in the file /etc/ttydefs. This definition tells getty at what speed to run initially, what the initial TTY settings are, and what speed to try next, (should the user press the BREAK key to indicate that the speed is inappropriate). The default speed is 300 baud.

type and linedisc
  These options are obsolete and will be ignored.
Files /etc/ttydefs

Name  getvol – verifies device accessibility

Synopsis  
/usr/bin/getvol -n [-l label] device
/usr/bin/getvol [-f | -F] [-ow] [-l label | -x label] device

Description  getvol verifies that the specified device is accessible and that a volume of the appropriate medium has been inserted. The command is interactive and displays instructional prompts, describes errors, and shows required label information.

Options  The following options are supported:

-\( n \)  Runs the command in non-interactive mode. The volume is assumed to be inserted upon command invocation.
-\( l \) label  Specifies that the label label must exist on the inserted volume (can be overridden by the -o option).
-\( f \)  Formats the volume after insertion, using the format command defined for this device in the device table.
-\( F \)  Formats the volume after insertion and places a file system on the device. Also uses the format command defined for this device in the device table.
-\( o \)  Allows the administrator to override a label check.
-\( w \)  Allows administrator to write a new label on the device. User is prompted to supply the label text. This option is ineffective if the -n option is enabled.
-\( x \) label  Specifies that the label label must exist on the device. This option should be used in place of the -l option when the label can only be verified by visual means. Use of the option causes a message to be displayed asking the administrator to visually verify that the label is indeed label.

Operands  The following operands are supported:

device  Specifies the device to be verified for accessibility.

Exit Status  The following exit values are returned:

0  Successful completion.
1  Command syntax was incorrect, invalid option was used, or an internal error occurred.
3  Device table could not be opened for reading.

Files  /etc/device.tab

Attributes  See attributes(5) for descriptions of the following attributes:
This command uses the device table to determine the characteristics of the device when performing the volume label checking.

See Also attributes(5)

Notes This command uses the device table to determine the characteristics of the device when performing the volume label checking.
**Name**
gkadmin – Kerberos principals and policies administration GUI

**Synopsis**
/usr/sbin/gkadmin

**Description**
gkadmin is an interactive graphical user interface (GUI) that enables you to maintain Kerberos principals and policies. gkadmin provides much the same functionality as the kadmin(1M) command.

gkadmin does not support the management of keytabs. You must use kadmin for keytabs management. gkadmin uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network.

When gkadmin is invoked, the login window is populated with default values. For the principal name, gkadmin determines your user name from the USER environment variable. It appends /admin to the name (username/admin) to create a default user instance in the same manner as kadmin. It also selects appropriate defaults for realm and master KDC (admin_server) from the /etc/krb5/krb5.conf file.

You can change these defaults on the login window. When you enter your password, a session is started with kadmind. Operations performed are subject to permissions that are granted or denied to the chosen user instance by the Kerberos ACL file. See kadm5.acl(4).

After the session is started, a tabbed folder is displayed that contains a principal list and a policy list. The functionality is mainly the same as kadmin, with addition, deletion, and modification of principal and policy data available.

**Files**
/etc/krb5/krb5.conf

Kerberos configuration information on a Kerberos client. Used to search for default realm and master KDC (admin_server), including a port number for the master KDC.
$HOME/.gkadmin

Default parameters used to initialize new principals created during the session.

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWkdcu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

**See Also**

kpasswd(1), kadmin(1M), kadmind(1M), kadmin.local(1M), kdb5_util(1M), kadm5.acl(4), kdc.conf(4), krb5.conf(4), attributes(5), kerberos(5)

**Diagnostics**

The gkadmin interface is currently incompatible with the MIT kadmin daemon interface, so you cannot use this interface to administer an MIT-based Kerberos database. However, clients running the Solaris implementation of Kerberos can still use an MIT-based KDC.
The `groupadd` command creates a new group definition on the system by adding the appropriate entry to the `/etc/group` file.

**Options**

- `-g gid` Assigns the group id `gid` for the new group. This group id must be a non-negative decimal integer below `MAXUID` as defined in `/usr/include/sys/param.h`. The group ID defaults to the next available (unique) number above the highest number currently assigned. For example, if groups 100, 105, and 200 are assigned as groups, the next default group number is 201. (Group IDs from 0–99 are reserved by SunOS for future applications.)

- `-o` Allows the `gid` to be duplicated (non-unique).

**Operands**

- `group` A string consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message is written if the string exceeds `MAXGLEN-1`, which is usually eight characters. The `group` field must contain at least one character; it accepts lower case or numeric characters or a combination of both, and must not contain a colon (`:`) or NEWLINE.

**Exit Status**

- `0` Successful completion.
- `2` Invalid command syntax. A usage message for the `groupadd` command is displayed.
- `3` An invalid argument was provided to an option.
- `4` The `gid` is not unique (when `-o` option is not used).
- `9` The `group` is not unique.
- `10` The `/etc/group` file cannot be updated.

**Files**

- `/etc/group`
- `/usr/include/userdefs.h`

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
See Also  users(1B), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), useradd(1M), userdel(1M), usermod(1M), group(4), attributes(5)

Notes  groupadd only adds a group definition to the local system. If a network name service such as NIS or NIS+ is being used to supplement the local /etc/group file with additional entries, groupadd cannot change information supplied by the network name service. However, groupadd verifies the uniqueness of group name and group ID against the external name service.
groupdel – delete a group definition from the system

/usr/sbin/groupdel

description

The groupdel utility deletes a group definition from the system. It deletes the appropriate entry from the /etc/group file.

operands

group An existing group name to be deleted.

exit status

The following exit values are returned:

0 Success.

2 Invalid command syntax. A usage message for the groupdel command is displayed.

6 group does not exist.

10 Cannot update the /etc/group file.

files

/etc/group system file containing group definitions

attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

see also

users(1B), groupadd(1M), groupmod(1M), logins(1M), useradd(1M), userdel(1M), usermod(1M), attributes(5)

notes

The groupdel utility only deletes a group definition that is in the local /etc/group file. If a network nameservice such as NIS or NIS+ is being used to supplement the local /etc/group file with additional entries, groupdel cannot change information supplied by the network nameservice.
**groupmod**– modify a group definition on the system

**Synopsis**

```
/usr/sbin/groupmod [-g gid [-o]] [-n name] group
```

**Description**
The `groupmod` command modifies the definition of the specified group by modifying the appropriate entry in the `/etc/group` file.

**Options**
The following options are supported:

- `-g gid` Specify the new group ID for the group. This group ID must be a non-negative decimal integer less than `MAXUID`, as defined in `<param.h>`. The group ID defaults to the next available (unique) number above 99. (Group IDs from 0-99 are reserved by SunOS for future applications.)

- `-n name` Specify the new name for the group. The `name` argument is a string of no more than eight bytes consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept group fields that do not meet these requirements. The `name` argument must contain at least one character and must not include a colon (:) or NEWLINE (`\n`).

- `-o` Allow the `gid` to be duplicated (non-unique).

**Operands**
The following operands are supported:

- `group` An existing group name to be modified.

**Exit Status**
The `groupmod` utility exits with one of the following values:

- `0` Success.
- `2` Invalid command syntax. A usage message for the `groupmod` command is displayed.
- `3` An invalid argument was provided to an option.
- `4` `gid` is not unique (when the `-o` option is not used).
- `6` `group` does not exist.
- `9` `name` already exists as a group name.
- `10` Cannot update the `/etc/group` file.

**Files**

- `/etc/group` group file

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
See Also  users(1B), groupadd(1M), groupdel(1M), logins(1M), useradd(1M), userdel(1M), usermod(1M), group(4), attributes(5)

Notes  The groupmod utility only modifies group definitions in the /etc/group file. If a network name service such as NIS or NIS+ is being used to supplement the local /etc/group file with additional entries, groupmod cannot change information supplied by the network name service. The groupmod utility will, however, verify the uniqueness of group name and group ID against the external name service.
**Name**
growfs – non-destructively expand a UFS file system

**Synopsis**
```
/usr/sbin/growfs [-M mount-point] [newfs-options] [raw-device]
```

**Description**
growfs non-destructively expands a mounted or unmounted UNIX file system (UFS) to the size of the file system's slice(s).

Typically, disk space is expanded by first adding a slice to a metadevice, then running the growfs command. When adding space to a mirror, you expand each submirror before expanding the file system.

growfs will "write-lock" (see `lockfs(1M)`) a mounted file system when expanding. The length of time the file system is write-locked can be shortened by expanding the file system in stages. For instance, to expand a 1 Gbyte file system to 2 Gbytes, the file system can be grown in 16 Mbyte stages using the -s option to specify the total size of the new file system at each stage. The argument for -s is the number of sectors, and must be a multiple of the cylinder size.

Note: The file system cannot be grown if a cylinder size of less than 2 is specified. Refer to the `newfs(1M)` man page for information on the options available when growing a file system.

growfs displays the same information as `mkfs` during the expansion of the file system.

If `growfs` is aborted, recover any lost free space by unmounting the file system and running the `fsck` command, or run the `growfs` command again.

**Note:** If `growfs` is aborted and the file system is used before `fsck` is run on it, UFS metadata might be left in an incomplete state, with the result that the file system would be corrupted. In such a circumstance, you would have to restore the file system from backups.

**Options**
Root privileges are required for all of the following options.

- `-M mount-point` The file system to be expanded is mounted on `mount-point`. File system locking (`lockfs`) will be used.

- `newfs-options` The options are documented in the `newfs` man page.

- `raw-device` Specifies the name of a raw metadevice or raw special device, residing in `/dev/md/rdsk`, or `/dev/rdsk`, respectively, including the disk slice, where you want the file system to be grown.

**Examples**

**EXAMPLE 1** Expanding nonmetadevice slice for `/export` file system

The following example expands a nonmetadevice slice for the `/export` file system. In this example, the existing slice, `/dev/dsk/c1t0d0s3`, is converted to a metadevice so additional slices can be concatenated.

```
# metainit -f d8 2 1 c1t0d0s3 1 c2t0d0s3
# umount /export
```
EXAMPLE 2  Associate /export with new metadevice

Edit the /etc/vfstab file to change the entry for /export to the newly defined metadevice, d8.

```
# mount /export
# growfs -M /export /dev/md/rdsk/d8
```

The first example starts by running the metainit command with the -f option to force the creation of a new concatenated metadevice d8, which consists of the existing slice /dev/dsk/c1t0d0s3 and a new slice /dev/dsk/c2t0d0s3. Next, the file system on /export must be unmounted. The /etc/vfstab file is edited to change the entry for /export to the newly defined metadevice name, rather than the slice name. After the file system is remounted, the growfs command is run to expand the file system. The file system will span the entire metadevice when growfs completes. The -M option enables the growfs command to expand a mounted file system. During the expansion, write access for /export is suspended until growfs unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

EXAMPLE 3  Dynamic Expansion of /export file system

The following example picks up from the previous one. Here, the /export file system mounted on metadevice d8 is dynamically expanded.

```
# metattach d8 c0t1d0s2
# growfs -M /export /dev/md/rdsk/d8
```

This example begins by using the metattach command to dynamically concatenate a new slice, /dev/dsk/c0t1d0s2, to the end of an existing metadevice, d8. Next, the growfs command specifies that the mount-point is /export and that it is to be expanded onto the raw metadevice /dev/md/rdsk/d8. The file system will span the entire metadevice when growfs completes. During the expansion, write access for /export is suspended until growfs unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

EXAMPLE 4  Expanding mounted file system to existing mirror

The following example expands a mounted file system /files, to an existing mirror, d80, which contains two submirrors, d9 and d10.

```
# metattach d9 c0t2d0s5
# metattach d10 c0t3d0s5
# growfs -M /files /dev/md/rdsk/d80
```

In this example, the metattach command dynamically concatenates the new slices to each submirror. The metattach command must be run for each submirror. The mirror will automatically grow when the last submirror is dynamically concatenated. The mirror will grow to the size of the smallest submirror. The growfs command then expands the file system. The growfs command specifies that the mount-point is /files and that it is to be expanded.
EXAMPLE 4 Expanding mounted file system to existing mirror  (Continued)

onto the raw metadevice /dev/md/rdsn/d80. The file system will span the entire mirror when
the growfs command completes. During the expansion, write access for the file system is
suspended until growfs unlocks the file system. Read access is not affected, though access
times are not kept when the lock is in effect.

Exit Status  The following exit values are returned:

0     Successful completion.
>0     An error occurred.

Solaris Volume Manager Administration Guide

Limitations  Only UFS file systems (either mounted or unmounted) can be expanded using the growfs
command. Once a file system is expanded, it cannot be decreased in size. The following
conditions prevent you from expanding file systems: When acct is activated and the
accounting file is on the target device. When C2 security is activated and the logging file is on
the target file system. When there is a local swap file in the target file system. When the file
system is root (/), /usr, or swap.
The `gsscred` utility is used to create and maintain a mapping between a security principal name and a local UNIX `uid`. The format of the user name is assumed to be `GSS_C_NT_USER_NAME`. You can use the `-o` option to specify the object identifier of the name type. The OID must be specified in dot-separated notation, for example: `1.2.3.45464.3.1`

The `gsscred` table is used on server machines to lookup the `uid` of incoming clients connected using RPCSEC_GSS.

When adding users, if no `user` name is specified, an entry is created in the table for each user from the `passwd` table. If no `comment` is specified, the `gsscred` utility inserts a comment that specifies the user name as an ASCII string and the GSS-API security mechanism that applies to it. The security mechanism will be in string representation as defined in the `/etc/gss/mech` file.

The parameters are interpreted the same way by the `gsscred` utility to delete users as they are to create users. At least one of the following options must be specified: `-n`, `-u`, or `-m`. If no security mechanism is specified, then all entries will be deleted for the user identified by either the `uid` or `user` name. If only the security mechanism is specified, then all `user` entries for that security mechanism will be deleted.

Again, the parameters are interpreted the same way by the `gsscred` utility to search for users as they are to create users. If no options are specified, then the entire table is returned. If the `user` name or `uid` is specified, then all entries for that `user` are returned. If a security mechanism is specified, then all `user` entries for that security mechanism are returned.

### Options

- **-a**
  Add a table entry.
- **-c comment**
  Insert comment about this table entry.
- **-l**
  Search table for entry.
- **-m mech**
  Specify the mechanism for which this name is to be translated.
- **-n user**
  Specify the optional principal name.
- **-o oid**
  Specify the OID indicating the name type of the user.
- **-r**
  Remove the entry from the table.
- **-u uid**
  Specify the `uid` for the `user` if the `user` is not local.
Examples

EXAMPLE 1 Creating a gsscred Table for the Kerberos v5 Security Mechanism

The following shows how to create a gsscred table for the kerberos v5 security mechanism. gsscred obtains user names and uid's from the passwd table to populate the table.

example% gsscred -m kerberos_v5 -a

EXAMPLE 2 Adding an Entry for root/host1 for the Kerberos v5 Security Mechanism

The following shows how to add an entry for root/host1 with a specified uid of 0 for the kerberos v5 security mechanism.

example% gsscred -m kerberos_v5 -n root/host1 -u 0 -a

EXAMPLE 3 Listing All User Mappings for the Kerberos v5 Security Mechanism

The following lists all user mappings for the kerberos v5 security mechanism.

example% gsscred -m kerberos_v5 -l

EXAMPLE 4 Listing All Mappings for All Security Mechanisms for a Specified User

The following lists all mappings for all security mechanisms for the user bsimpson.

example% gsscred -n bsimpson -l

Exit Status

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Notes

Some GSS mechanisms, such as kerberos_v5, provide their own authenticated-name-to-local-name (uid) mapping and thus do not usually have to be mapped using gsscred. See gsscred.conf(4) for more information.
**Name**  
gssd – generates and validates GSS-API tokens for kernel RPC.

**Synopsis**  
/usr/lib/gss/gssd

**Description**  
gssd is the user mode daemon that operates between the kernel rpc and the Generic Security Service Application Program Interface (GSS-API) to generate and validate GSS-API security tokens. In addition, gssd maps the GSS-API principal names to the local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. gssd is invoked by the Internet daemon inetd(1M) the first time that the kernel RPC requests GSS-API services.

**Exit Status**  
The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion.</td>
</tr>
<tr>
<td>&gt;0</td>

**RFC 2078**

**Notes**  
The following signal has the specified effect when sent to the server process using the kill(1) command:

SIGHUP  
gssd rereads the gsscred.conf(4) options.

When one of the mechanisms being used is Kerberos, then the gssd process must be restarted after adding or changing the resolv.conf(4) file.

The gssd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/gss:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
halt (1M)

**Name**  
halt, poweroff – stop the processor

**Synopsis**  
/usr/sbin/halt [-dlncy]
/usr/sbin/poweroff [-dlncy]

**Description**  
The `halt` and `poweroff` utilities write any pending information to the disks and then stop the processor. The `poweroff` utility has the machine remove power, if possible.

The `halt` and `poweroff` utilities normally log the system shutdown to the system log daemon, `syslogd(1M)`, and place a shutdown record in the login accounting file `/var/adm/wtmpx`. These actions are inhibited if the `-n` or `-q` options are present.

**Options**  
The following options are supported:

- `-d` Force a system crash dump before rebooting. See `dumpadm(1M)` for information on configuring system crash dumps.
- `-l` Suppress sending a message to the system log daemon, `syslogd(1M)`, about who executed `halt`.
- `-n` Prevent the `sync(1M)` before stopping.
- `-q` Quick halt. No graceful shutdown is attempted.
- `-y` Halt the system, even from a dialup terminal.

**Files**  
`/var/adm/wtmpx` History of user access and administration information.

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**  
dumpadm(1M), init(1M), reboot(1M), shutdown(1M), sync(1M), syslogd(1M), init(1M), attributes(5), smf(5)

**Notes**  
The `halt` and `poweroff` utilities do not cleanly shutdown `smf(5)` services. Execute the scripts in `/etc/rcnum.d` or execute shutdown actions in `init(1M)`. To ensure a complete shutdown of system services, use `shutdown(1M)` or `init(1M)` to reboot a Solaris system.
**Name**
hextoalabel – convert an internal text label to its human readable equivalent

**Synopsis**
/usr/sbin/hextoalabel [internal-text-sensitivity-label]
/usr/sbin/hextoalabel -c [internal-text-clearance]

**Description**
hextoalabel converts an internal text label into its human readable equivalent and writes the result to the standard output file. This internal form is often hexadecimal. If no option is supplied, the label is assumed to be a sensitivity label.

If no internal text label is specified, the label is read from the standard input file. The expected use of this command is emergency repair of labels that are stored in internal databases.

**Options**
- **-c** Identifies the internal text label as a clearance.

**Exit Status**
The following exit values are returned:

0 On success.
1 On failure, and writes diagnostics to the standard error file.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWtsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The command output is Committed for systems with the same label_encodings file. The command invocation is Committed for systems that implement the DIA MAC policy.

**Files**
/etc/security/tsol/label_encodings

The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

“How to Obtain a Readable Label From Its Hexadecimal Form” in Oracle Solaris Trusted Extensions Administrator's Procedures

**Notes**
The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.
**host(1M)**

**Name**  
host – DNS lookup utility

**Synopsis**  
```bash  
host [ -aCdilmrsTvww ] [ -c class ] [ -N ndots ] [ -R number ]  
[ -t type ] [ -W wait ] [ -4 | -6 ] name [ server ]  
```

**Description**  
The `host` utility performs simple DNS lookups. It is normally used to convert names to IP addresses and IP addresses to names. When no arguments or options are given, `host` prints a short summary of its command line arguments and options.

The `name` argument is the domain name that is to be looked up. It can also be a dotted-decimal IPv4 address or a colon-delimited IPv6 address, in which case `host` by default performs a reverse lookup for that address. The optional `server` argument is either the name or IP address of the name server that `host` should query instead of the server or servers listed in `/etc/resolv.conf`.

**Options**  
The following options are supported:

- **-4**  
  Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options `-4` and `-6` are mutually exclusive.

- **-6**  
  Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options `-4` and `-6` are mutually exclusive.

- **-a**  
  Equivalent to setting the `-v` option and asking `host` to make a query of type `ANY`.

- **-c class**  
  Make a DNS query of class `class`. This can be used to lookup Hesiod or Chaosnet class resource records. The default class is IN (Internet).

- **-C**  
  Attempt to display the SOA records for zone `name` from all the listed authoritative name servers for that zone. The list of name servers is defined by the NS records that are found for the zone.

- **-d**  
  Generate verbose output. This option is equivalent to `-v`. These two options are provided for backward compatibility. In previous versions, the `-d` option switched on debugging traces and `-v` enabled verbose output.

- **-1**  
  Specifies that reverse lookups of IPv6 addresses should use the IP6.INT domain as defined in RFC 1886. The default is to use RFC 3152 domain IP6.ARPA.
-l
List mode. This option makes `host` perform a zone transfer for zone `name`, displaying the
NS, PTR and address records (A/AAAA). If combined with -a, all records will be displayed.
The argument is provided for compatibility with previous implementations. Options -la is
equivalent to making a query of type AXFR.

-m
Sets the memory usage debugging flags: record, usage, and trace.

-N ndots
Set the number of dots that have to be in `name` for it to be considered absolute. The default
value is that defined using the ndots statement in `/etc/resolv.conf`, or 1 if no ndots
statement is present. Names with fewer dots are interpreted as relative names and will be
searched for in the domains listed in the search or domain directive in `/etc/resolv.conf`.

-r
Make a non-recursive query. Setting this option clears the RD (recursion desired) bit in the
query made by `host`. The name server receiving the query does not attempt to resolve
name. The -r option enables `host` to mimic the behaviour of a name server by making
non-recursive queries and expecting to receive answers to those queries that are usually
referrals to other name servers.

-R number
Change the number of UDP retries for a lookup. The number argument indicates how
many times `host` will repeat a query that does not get answered. The default number of
retries is 1. If number is negative or zero, the number of retries will default to 1.

-s
Specifies that the host not send the query to the next name server if any server responds
with a SERVFAIL response, which is the reverse of normal stub resolver behavior.

-t type
Select the query type. The type argument can be any recognised query type: CNAME, NS, SOA,
SIG, KEY, and AXFR, among others. When no query type is specified, `host` automatically
selects an appropriate query type. By default it looks for A, AAAA, and MX records, but if
the -C option is specified, queries are made for SOA records. If name is a dotted-decimal
IPv4 address or colon-delimited IPv6 address, `host` queries for PTR records.

If a query type of IXFR is chosen the starting serial number can be specified by appending
an equal followed by the starting serial number (for example: -t IXFR=12345678).

-T
Use a TCP connection when querying the name server. TCP is automatically selected for
queries that require it, such as zone transfer (AXFR) requests. By default `host` uses UDP
when making queries.

-v
Generate verbose output. This option is equivalent to -d.
Wait forever for a reply. The time to wait for a response will be set to the number of seconds given by the hardware’s maximum value for an integer quantity.

-W wait
Wait for wait seconds for a reply. If wait is less than one, the wait interval is set to one second.

Files
/etc/resolv.conf
Resolver configuration file

hostconfig – configure a system’s host parameters

**Synopsis**

```
    [-i interface] [-f hostname]
```

**Description**
The `hostconfig` program uses a network protocol to acquire a machine’s host parameters and set these parameters on the system.

The program selects which protocol to use based on the argument to the required `-p` flag. Different protocols may set different host parameters. Currently, only one protocol (bootparams) is defined.

**Options**
The following options are supported:

- `-d` Enable debug output.
- `-f hostname` Run the protocol as if this machine were named `hostname`.
- `-h` Echo the received hostname to stdout, rather than setting hostname using the system name directly.
- `-i interface` Use only the named network interface to run the protocol.
- `-n` Run the network protocol, but do not set the acquired parameters into the system.
- `-p protocol` Run `hostconfig` using `protocol`. Currently, only one protocol (bootparams) is available. This option is required.

Specifying the `-p bootparams` option uses the `whoami` call of the RPC bootparams protocol. This sets the system’s hostname, domainname, and default IP router parameters.

- `-v` Enable verbose output.

**Examples**

**EXAMPLE 1** Configuring Host Parameters with Verbose Output

The following command configures a machine’s host parameters using the `whoami` call of the RPC bootparams protocol with a verbose output.

```
example# hostconfig -p bootparams -v
```

**EXAMPLE 2** Displaying Host Parameters

The following command displays the parameters that would be set using the `whoami` call of the RPC bootparams protocol.

```
example# hostconfig -p bootparams -n -v
```
EXAMPLE 3  Configuring Host Parameters Less the System Name
The following command configures a machine's host parameters, less the system name, using
the whoami call of the RPC bootparams protocol.
example# hostconfig='hostconfig -p bootparams -h'

### Name
hotplug – configure hotplug connectors and ports

### Synopsis

```plaintext
hotplug list [-l] [-v] [path [connection]]
hotplug online path port
hotplug offline [-f] [-q] path port
hotplug enable path connector
hotplug disable [-f] [-q] path connector
hotplug poweron path connector
hotplug poweroff [-f] [-q] path connector
hotplug set -o options path connector
hotplug get -o options path connector
hotplug -?
```

### Description
The `hotplug` command is used to manage hotplug connections. A connection can be a connector or port. A hotplug connector is a representation of a physical point in the system where components can be inserted or removed. A hotplug port is a representation of a logical point in the system device tree where the connection of a device to the system is managed.

The `hotplug` command only supports hotplug operations on hotplug connectors for PCI Express buses and PCI buses that implement the Standard PCI Hotplug feature. Hotplug ports on PCI Express and PCI buses in systems with PCI Express fabrics are also supported. Additional buses may be supported in the future.

The `hotplug` command operates on the following kinds of objects:

- **path**
  Hotplug connectors and ports are integrated into the Solaris device tree. The names of connectors and ports are unique relative only to their bus controller. A device path is required to uniquely reference a connector or port.

- **connector**
  If a hardware component supports being physically inserted or removed, then a hotplug connector represents the location where this action may occur. When a connector exists, it has a hierarchy of ports and device nodes that depend upon it.

- **port**
  All device nodes can be virtually hotplugged, even if their hardware does not support physical hotplugging. A hotplug port exists between a device node and its parent node in the system device tree. It represents the location where the device node and its dependents can be managed.

- **connection**
  A hotplug connection is a generic term to refer to either a hotplug connector or a hotplug port.
Hotplug connectors and ports are managed according to a state model. The `hotplug` command can list information about the hotplug connections in a system, or it can initiate change of state operations on specific hotplug connections.

Hotplug connectors can be in the following states:
- **empty**: A component is not physically inserted in the connector.
- **present**: A component is physically inserted in the connector, but the component is powered off. The component is not in use.
- **powered**: A component is physically inserted in the connector, and the component is powered on. The component is disabled and is not in use.
- **enabled**: A component is physically inserted in the connector. The component is powered on and has been probed and tested. The component is enabled and devices that represent its functions can be used.

Hotplug ports can be in the following states:
- **port-empty**: No device exists for the hotplug port.
- **port-present**: A device exists for the hotplug port, but the device has not been probed and it has no attached device driver. The device is not in use.
- **offline**: A device exists for the hotplug port, and the device has been probed. A device driver is not attached, and the device is not in use.
- **online**: A device exists for the hotplug port, and its device driver is fully attached. The device is in use.
- **maintenance**: A device exists for the hotplug port, and its device driver is fully attached. The device is in use, but not fully operational. A maintenance or fault management operation is affecting the device.

The `hotplug` command can also access bus private properties for each hotplug connector. The current values of bus private properties can be displayed. New values for each bus private property can be set directly.
Sub-commands  The following subcommands are supported:

list
Show information for hotplug connectors, ports, and their associated devices. Hotplug connectors and hotplug ports are integrated into the Solaris device tree hierarchy. The list subcommand therefore displays the hierarchy of device nodes with additional information included to show the locations of hotplug connectors and hotplug ports. The names of hotplug connectors are enclosed in square brackets, and the names of hotplug ports are enclosed in angled brackets. The current state of each hotplug connection is displayed next to its name.

online
Change the state of a hotplug port to the online state.

offline
Change the state of a hotplug port to the offline state.

enable
Change the state of a hotplug connector to the enabled state. All of the hotplug connector's dependent ports will be automatically probed and initialized into the online state.

disable
Change the state of a hotplug connector from the enabled state to the powered state. All dependent ports that are in the online state will first be transitioned to the port-present state.

poweron
Change the state of a hotplug connector from the present state to the powered state.

poweroff
Change the state of a hotplug connector from the powered or enabled state to the present state. All dependent ports that are in the online state will first be transitioned to the port-present state, and will then be removed.

set
Set bus-specific properties for a hotplug connector. The specified option string is a bus specific string of name and value pairs, as could be parsed by getsubopt(3C). The names and values will be passed directly to the bus controller that manages the specified hotplug connector to perform a bus-specific function.

get
Display the current values of bus specific properties for a hotplug connector. The specified option string is a bus specific string of named properties, as could be parsed by getsubopt(3C). The names will be passed directly to the bus controller to specify which properties should be returned. The current values of each named property will then be displayed.
Options  The following options are supported:

- `list-path`  
  Show full paths to connections and device nodes. By default, the `list` subcommand shows hotplug connectors, ports, and devices in the format of a tree. This option enables the display of full paths to each connection and device node.

- `verbose`  
  Show verbose usage details. By default, the `list` subcommand shows only hotplug connectors, ports, and devices. This option enables the display of more detailed information about how the devices are currently consumed. Examples include mounted filesystems or plumbed network interfaces associated with individual devices.

  Note that the `verbose` option does not display information for disks under ZFS control.

- `force`  
  Force the operation. Some change state operations that impact resources currently in use will fail with a warning. A forced operation will attempt to ignore these warnings and proceed.

  This option should be used with extreme caution.

- `query`  
  Query the operation. Instead of actually performing a change state operation, perform a test to predict if the operation would succeed or fail. If it would fail, show the error messages that would be expected if the operation had really been attempted.

  It is not possible to predict every failure. An operation that succeeds during a query could still fail for another reason when actually attempted.

  This option will not actually change the state of the system.

- `options`, `options`  
  Specify bus-specific properties for a `set` or `get` command. The options string conforms to the `getsubopt(3C)` syntax convention.

  For the `get` subcommand, there are two special options that can be used. The special options value of `help` will display all supported properties and their possible values. The special options value of `all` will display the current value of all supported properties.

  For the `set` subcommand, there is one special option that can be used. The special options value of `help` will display all supported properties which can be set and their possible values.

  See “Notes” section for the properties supported by bus controllers.

- `help`  
  Display a brief help message on proper use of the command.
**Examples**

**EXAMPLE 1**  Showing All Hotplug Connections

The following command shows all hotplug connections:

```
# hotplug list -v
pci@0,0
  <pci.2,1> (ONLINE)
  pci108e,534a@2,1
    [pci30] (EMPTY)
  <pci.e,0> (ONLINE)
  pci10de,5d@e
    <pci.b,0> (ONLINE)
    display@b
    [NEM0] (ENABLED)
    <pci.a,0> (ONLINE)
    pci108e,534a@a,0
      { Network interface nge0 }
      { nge0: hosts IP addresses: 10.0.0.1 }
  <pci.a,1> (MAINTENANCE)
  pci108e,534a@a,0
    [NEM1] (EMPTY)
  <pci.c,0> (OFFLINE)
  pci108e,534a@4
```

To show the full paths of hotplug connections and devices, enter the following command:

```
# hotplug list -l
 pci@0,0 <pci.2,1> (ONLINE)
 /pci@0,0/pci108e,534a@2,1 [pci30] (EMPTY)
 /pci@0,0/pci.e,0> (ONLINE)
 /pci@0,0/pci10de,5d@e <pci.b,0> (ONLINE)
 /pci@0,0/pci10de,5d@e/display@b
 /pci@0,0/pci10de,5d@e [NEM0] (ENABLED)
 /pci@0,0/pci10de,5d@e <pci.a,0> (ONLINE)
 /pci@0,0/pci10de,5d@e/pci108e,534a@a,0
 /pci@0,0/pci10de,5d@e <pci.a,1> (MAINTENANCE)
 /pci@0,0/pci10de,5d@e/pci108e,534a@a,0
 /pci@0,0/pci10de,5d@e [NEM1] (EMPTY)
 /pci@0,0/pci.c,0> (OFFLINE)
 /pci@0,0/pci108e,534a@4
```

**EXAMPLE 2**  Reporting Failure During State Change Operation

If a change of state operation fails, an explanation is displayed to describe the failure. An attempt to offline a hotplug port with dependent devices that are currently in use by the system might fail as follows:

```
# hotplug offline /pci@0,0/pci10de,5d@e pci.a,0
ERROR: devices or resources are busy.
pci108e,534a@a,0:
```
EXAMPLE 2  Reporting Failure During State Change Operation  (Continued)

   { Network interface nge0 }
   { nge0: hosts IP addresses: 10.0.0.1 }
   { Plumbed IP Address }

EXAMPLE 3  Displaying Bus-Specific Properties and Values

The following command displays all supported bus-specific properties and their possible values:

```
# hotplug get -o help /pci@0,0 pci.2,1
power_led=<on|off|blink>
fault_led=<on|off|blink>
active_led=<on|off|blink>
attn_led=<on|off|blink>
card_type=<type description>
board_type=<type description>
```

EXAMPLE 4  Displaying Bus-Specific Options

The following command displays the card type and the current state of the Power LED of a PCI hotplug connector:

```
# hotplug get -o card_type,power_led /pci@0,0 pci.2,1
card_type=fibre
power_led=on
```

EXAMPLE 5  Setting a Bus-Specific Property

The following command turns on the attention LED of a PCI hotplug connector:

```
# hotplug set -o attn_led=on /pci@0,0 pci.2,1
```

**Exit Status**

0

  Successful completion.

1

  Invalid command line options were specified.

2

  The specified path or connection does not exist.

3

  A fatal error occurred. One or more error messages are displayed on standard error.

4

  The hotplug service is not available.
Attributes

Diagnostics

The following error message is displayed on systems that do not have any supported I/O buses:

ERROR: there are no connections to display.  
(See hotplug(1m) for more information.)

If this error message is seen, note that the system might still have other I/O devices that support hotplugging, through the cfgadm(1M) command instead of hotplug.

Notes

The hotplug service (FMRI svc:/system/hotplug) must be enabled as a prerequisite for using the hotplug command. The service is disabled by default. See hotplugd(1M).

The authorization solaris.hotplug.modify must be granted in order to perform change-of-state operations. Alternatively, the rights profile “Hotplug Management” can be granted, which includes that authorization.

Verbose usage information is gathered from the RCM framework. Its format and content is subject to change.

The following bus specific properties are supported in PCI bus controllers:

- power_led | fault_led | attn_led | active_led  
  States of a specific LED of a slot. The value could be on, off, or blink.

  They can all be used with get subcommand, but only property attn_led can be used with set subcommand.

- card_type | board_type  
  Type of a card or board of a slot.

  They can all be used with get subcommand, but neither can be used with set subcommand.
The hotplug daemon, `hotplugd`, provides user-level services for the management of hotplug connections. It is a system daemon started by the Service Management Facility (see `smf(5)`). Its fault management resource identifier (FMRI) is:

```
svc:/system/hotplug:default
```

Note that `hotplugd` is a Consolidation Private interface. See `attributes(5)`.

The `hotplug(1M)` command and any other client program that uses the private `libhotplug` library to query information about hotplug connections or initiate hotplug commands depends upon this daemon. The hotplug daemon is a door server which services requests from all `libhotplug` clients. The door interface is private.

Client applications use the private `libhotplug` interface to administer hotplug connections. `libhotplug` uses the door interface to administer hotplug connections through the hotplug daemon service. The hotplug daemon acts as a central location to serialize all hotplug operations and coordinate activities with all other parts of the system.

The following option is supported:

```
-d, --debug
```

Run the daemon in standalone debug mode. Messages will be displayed on the controlling terminal instead of to syslog. And increased verbosity will be enabled to display more details about the internal operations of the daemon.

### Examples

**EXAMPLE 1** Enabling the Hotplug Service

The following command enables the hotplug service:

```
# svcadm enable svc:/system/hotplug:default
```

**EXAMPLE 2** Disabling the Hotplug Service

The following command disables the hotplug service:

```
# svcadm disable svc:/system/hotplug:default
```

### Errors

The hotplug daemon uses `syslog(3C)` to report status and error messages. All of the messages are logged with the `LOG_DAEMON` facility. Error messages are logged with the `LOG_ERR` and `LOG_NOTICE` priorities, and informational messages are logged with the `LOG_INFO` priority. The default entries in the `/etc/syslog.conf` file log all of the hotplug daemon error messages to the `/var/adm/messages.log`.

### Files

- `/var/run/hotplugd_door`
  Hotplug daemon door
- `/var/run/hotplugd_pid`
  Hotplug daemon lock file
/usr/lib/hotplugd
Hotplug daemon binary

Notes  The hotplugd service is managed by the service management facility, smf(5), under the fault management resource identifier (FMRI):
	svc:/system/hotplug:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command. To administer the service, the authorization solaris.smf.manage.hotplug must be granted. Alternatively, the rights profile "Hotplug Management" can be granted.

The hotplug service must be enabled for the hotplug(1M) command and any other libhotplug client applications to function properly.
htable(1M)

Name  htable – convert DoD Internet format host table

Synopsis  /usr/sbin/htable filename

Description  htable converts a host table in the format specified by RFC 952 to the format used by the network library routines. Three files are created as a result of running htable: hosts, networks, and gateways. The hosts file is used by the gethostbyname(3NSL) routines in mapping host names to addresses. The networks file is used by the getnetbyname(3SOCKET) routines in mapping network names to numbers. The gateways file is used by the routing daemon to identify "passive" Internet gateways.

If any of the files localhosts, localnetworks, or localgateways are present in the current directory, the file's contents is prepended to the output file without interpretation. This allows sites to maintain local aliases and entries which are not normally present in the master database.

htable is best used in conjunction with the gettable(1M) program which retrieves the DoD Internet host table from a host.

Files  localhosts
localnetworks
localgateways

Notes  htable does not properly calculate the gateways file.
ickey – install a client key for WAN boot

**Synopsis**  
/usr/lib/inet/wanboot/ickey [-d] [-o type=3des]  
/usr/lib/inet/wanboot/ickey [-d] [-o type=aes]  
/usr/lib/inet/wanboot/ickey [-d] [-o type=sha1]

**Description**  
The `ickey` command is used to install WAN boot keys on a running UNIX system so that they can be used the next time the system is installed. You can store three different types of keys: 3DES and AES for encryption and an HMAC SHA-1 key for hashed verification.

`ickey` reads the key from standard input using `getpass(3C)` so that it does not appear on the command line. When installing keys on a remote system, you must take proper precautions to ensure that any keying materials are kept confidential. At a minimum, use `ssh(1)` to prevent interception of data in transit.

Keys are expected to be presented as strings of hexadecimal digits; they can (but need not) be preceded by a `0x` or `0X`.

The `ickey` command has a single option, described below. An argument of the type `-o type=keytype` is required.

**Options**  
The `ickey` command the following option.

- `-d` Delete the key specified by the `keytype` argument.

**Exit Status**  
On success, `ickey` exits with status `0`; if a problem occurs, a diagnostic message is printed and `ickey` exits with non-zero status.

**Files**  
/dev/openprom  
WAN boot key storage driver

**Name**

id – return user identity

**Synopsis**

```
/usr/bin/id [-p] [user]
/usr/bin/id -a [-p] [user]
/usr/xpg4/bin/id [-p] [user]
/usr/xpg4/bin/id -G [-n] [user]
/usr/xpg4/bin/id -g [-nr] [user]
/usr/xpg4/bin/id -u [-nr] [user]
```

**Description**

If no `user` operand is provided, the `id` utility writes the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both are written. If multiple groups are supported by the underlying system, `/usr/xpg4/bin/id` also writes the supplementary group affiliations of the invoking process.

If a `user` operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user are written. In this case, effective IDs are assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, `/usr/xpg4/bin/id` writes them in the same manner as the supplementary groups described in the preceding paragraph.

**Formats**

The following formats are used when the `LC_MESSAGES` locale category specifies the "C" locale. In other locales, the strings uid, gid, euid, egid, and groups may be replaced with more appropriate strings corresponding to the locale.

```
"uid=%u(%) gid=%u(%)\n" <real user ID>, <user-name>,
<real group ID>, <group-name>
```

If the effective and real user IDs do not match, the following are inserted immediately before the \n character in the previous format:

```
* euid=%u(%)"
```

with the following arguments added at the end of the argument list:

<effective user ID>, <effective user-name>

If the effective and real group IDs do not match, the following is inserted directly before the \n character in the format string (and after any addition resulting from the effective and real user IDs not matching):

```
* egid=%u(%)"
```

with the following arguments added at the end of the argument list:

<effective group-ID>, <effective groupname>

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first is added directly before the NEWLINE character in the format string:
with the following arguments added at the end of the argument list:

<supplementary group ID>, <supplementary group name>

and the necessary number of the following added after that for any remaining supplementary group IDs:

*,%u(%s)

and the necessary number of the following arguments added at the end of the argument list:

<supplementary group ID>, <supplementary group name>

If any of the userID, groupID, effectiveuserID, effectivegroupID or supplementary/multiple groupIDs cannot be mapped by the system into printable user or group names, the corresponding (%) and name argument is omitted from the corresponding format string.

When any of the options are specified, the output format is as described under OPTIONS.

**Options** The following option is supported by both /usr/bin/id and /usr/xpg4/bin/id. For /usr/xpg4/bin/id, -p is invalid if specified with any of the -G, -g, or -u options.

- **p** Reports additionally the current project membership of the invoking process. The project is reported using the format:

"projid=%u(%s)"

which is inserted prior to the \n character of the default format described in the Formats section. The arguments

<project ID>,<project name>

are appended to the end of the argument list. If the project ID cannot be mapped by the system into a printable project name, the corresponding (%) and name argument is omitted from the corresponding format string.

**/usr/bin/id** The following option is supported for /usr/bin/id only:

- **a** Reports user name, user ID and all the groups to which the user belongs.

**/usr/xpg/bin/id** The following options are supported for /usr/xpg/bin/id only:

- **G** Outputs all different group IDs (effective, real and supplementary) only, using the format "%u\n". If there is more than one distinct group affiliation, output each such affiliation, using the format "%u", before the NEWLINE character is output.

- **g** Outputs only the effective group ID, using the format "%u\n".

- **n** Outputs the name in the format "%s" instead of the numeric ID using the format "%u".

- **r** Outputs the real ID instead of the effective ID.
-u Outputs only the effective user ID, using the format "%u\n".

**Operands**
The following operand is supported:

*user* The user (login) name for which information is to be written.

**Environment Variables**
See `environ(5)` for descriptions of the following environment variables that affect the execution of id: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status**
The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Attributes**

**Notes**
Output produced by the -G option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups.
idsconfig(1M)

Name  idsconfig – prepare an iPlanet Directory Server (iDS) to be populated with data and serve LDAP clients

Synopsis  
/usr/lib/ldap/idsconfig [-v] [-i input_configfile] [-o output_configfile]

Description  Use the idsconfig tool to set up an iPlanet Directory Server (iDS). You can specify the input configuration file with the -i option on the command line. Alternatively, the tool will prompt the user for configuration information. The input configuration file is created by idsconfig with the -o option on a previous run.

The first time a server is set up, the user is prompted for all the required information. Future installations on that machine can use the configuration file previously generated by idsconfig using the -o option.

The output configuration file contains the directory administrator's password in clear text. Thus, if you are creating an output configuration file, take appropriate security precautions.

You should back up the directory server's configuration and data prior to running this command.

Options  The following options are supported:

- -i input_configfile  Specify the file name for idsconfig to use as a configuration file. This file will be read by idsconfig, and the values in the file will be used to configure the server. Do not manually edit input_configfile. The input_configfile is only partially validated, as idsconfig assumes that the file was created by a previous invocation of the command.

- -o output_configfile  Create a configuration file.

- -v  Verbose output.

Operands  The following operands are supported:

input_configfile  Name of configuration file for idsconfig to use.

output_configfile  Configuration file created by idsconfig.

Examples  EXAMPLE 1  Prompting the User for Input

In the following example, the user is prompted for information to set up iDS.

eample# idsconfig

EXAMPLE 2  Creating an Output Configuration File

In the following example, the user is prompted for information to set up iDS, and an output configuration file, config.1, is created when completed.

eample# idsconfig -o config.1
EXAMPLE 3  Setting up iDS Using the Specified Configuration File

In the following example, iDS is set up by using the values specified in the configuration file, config.1. The verbose mode is specified, so detailed information will print to the screen.

eexample# idsconfig -v -i config.1

Exit Status  The following exit values are returned:
0   Successful completion.
>0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

</table>

See Also  ldap(1), ldapadd(1), ldapdelete(1), ldaplist(1), ldapmodify(1), ldapmodrdn(1),
ldapsearch(1), ldap_cachemgr(1M), ldapaddent(1M), ldapclient(1M), suninstall(1M),
resolv.conf(4), attributes(5)
The command `ifconfig` is used to assign an address to a network interface and to configure network interface parameters. The `ifconfig` command must be used at boot time to define the network address of each interface present on a machine; it may also be used at a later time to redefine an interface’s address or other operating parameters. If no option is specified, `ifconfig` displays the current configuration for a network interface. If an address family is specified, `ifconfig` reports only the details specific to that address family. Only privileged users may modify the configuration of a network interface. Options appearing within braces ({ }) indicate that one of the options must be specified.

### DHCP Configuration
The forms of `ifconfig` that use the `auto-dhcp` or `dhcp` arguments are used to control the Dynamic Host Configuration Protocol (“DHCP”) configuration of the interface. In this mode, `ifconfig` is used to control operation of `dhcppagent(1M)`, the DHCP client daemon. Once an interface is placed under DHCP control by using the `start` operand, `ifconfig` should not, in normal operation, be used to modify the address or characteristics of the interface. If the address of an interface under DHCP is changed, `dhcppagent` will remove the interface from its control.

### Options
The following options are supported:

- **`addif address`**
  Create the next unused logical interface on the specified physical interface. If the physical interface is part of a multipathing group, the logical interface can be added to a different physical interface in the same group.
all-zones
Make the interface available to every shared-IP zone on the system. The appropriate zone
to which to deliver data is determined using the tnzonecfg database. This option is
available only if the system is configured with the Solaris Trusted Extensions feature.

The tnzonecfg database is described in the tnzonecfg(4) man page, which is part of the

anycast
Marks the logical interface as an anycast address by setting the ANYCAST flag. See
"INTERFACE FLAGS," below, for more information on anycast.

-anycast
Marks the logical interface as not an anycast address by clearing the ANYCAST flag.

arp
Enable the use of the Address Resolution Protocol ("ARP") in mapping between network
level addresses and link level addresses (default). This is currently implemented for
mapping between IPv4 addresses and MAC addresses.

-arp
Disable the use of the ARP on a physical interface.

auth_algs authentication algorithm
For a tunnel, enable IPsec AH with the authentication algorithm specified. The algorithm
can be either a number or an algorithm name, including any to express no preference in
algorithm. All IPsec tunnel properties must be specified on the same command line. To
disable tunnel security, specify an auth_algs of none.

It is now preferable to use the ipsecconf(1M) command when configuring a tunnel's
security properties. If ipsecconf was used to set a tunnel's security properties, this
keyword will not affect the tunnel.

auto-dhcp
Use DHCP to automatically acquire an address for this interface. This option has a
completely equivalent alias called dhcp.

For IPv6, the interface specified must be the zeroth logical interface (the physical interface
name), which has the link-local address.

primary
Defines the interface as the primary. The interface is defined as the preferred one for the
delivery of client-wide configuration data. Only one interface can be the primary at any
given time. If another interface is subsequently selected as the primary, it replaces the
previous one. Nominating an interface as the primary one will not have much
significance once the client workstation has booted, as many applications will already
have started and been configured with data read from the previous primary interface.
wait seconds
The `ifconfig` command will wait until the operation either completes or for the
interval specified, whichever is the sooner. If no wait interval is given, and the operation
is one that cannot complete immediately, `ifconfig` will wait 30 seconds for the
requested operation to complete. The symbolic value `forever` may be used as well, with
obvious meaning.

drop
Remove the specified interface from DHCP control without notifying the DHCP server,
and record the current lease for later use. Additionally, for IPv4, set the IP address to
zero and mark the interface as “down.” For IPv6, unplug all logical interfaces plumbed
by `dhcpagent`.

extend
Attempt to extend the lease on the interface’s IP address. This is not required, as the
agent will automatically extend the lease well before it expires.

inform
Obtain network configuration parameters from DHCP without obtaining a lease on IP
addresses. This is useful in situations where an IP address is obtained through
mechanisms other than DHCP.

ping
Check whether the interface given is under DHCP control, which means that the
interface is managed by the DHCP agent and is working properly. An exit status of 0
means success.

release
Relinquish the IP addresses on the interface by notifying the server and discard the
current lease. For IPv4, mark the interface as “down.” For IPv6, all logical interfaces
plumbed by `dhcpagent` are unplumbed.

start
Start DHCP on the interface.

status
Display the DHCP configuration status of the interface.

auto-revarp
Use the Reverse Address Resolution Protocol (RARP) to automatically acquire an address
for this interface. This will fail if the interface does not support RARP; for example, IPoIB
(IP over InfiniBand), and on IPv6 interfaces.

broadcast address
For IPv4 only. Specify the address to use to represent broadcasts to the network. The
default broadcast address is the address with a host part of all 1’s. A “+” (plus sign) given for
the broadcast value causes the broadcast address to be reset to a default appropriate for the
(possibly new) address and netmask. The arguments of `ifconfig` are interpreted left to
right. Therefore

System Administration Commands - Part 1
example% ifconfig -a netmask + broadcast +

and

example% ifconfig -a broadcast + netmask +

may result in different values being assigned for the broadcast addresses of the interfaces.

deprecated
Marks the logical interface as deprecated. An address associated with a deprecated interface will not be used as source address for outbound packets unless either there are no other addresses available on the interface or the application has bound to this address explicitly. The status display shows DEPRECATED as part of flags. See INTERFACE FLAGS for information on the flags supported by ifconfig.

-preprecated
Marks a logical interface as not deprecated. An address associated with such an interface could be used as a source address for outbound packets.

preferred
Marks the logical interface as preferred. This option is only valid for IPv6 addresses. Addresses assigned to preferred logical interfaces are preferred as source addresses over all other addresses configured on the system, unless the address is of an inappropriate scope relative to the destination address. Preferred addresses are used as source addresses regardless of which physical interface they are assigned to. For example, you can configure a preferred source address on the loopback interface and advertise reachability of this address by using a routing protocol.

-preferred
Marks the logical interface as not preferred.

destination dest_address
Set the destination address for a point-to-point interface.

dhcp
This option is an alias for option auto-dhcp

down
Mark a logical interface as “down”. (That is, turn off the IFF_UP bit.) When a logical interface is marked “down,” the system does not attempt to use the address assigned to that interface as a source address for outbound packets and will not recognize inbound packets destined to that address as being addressed to this host. Additionally, when all logical interfaces on a given physical interface are “down,” the physical interface itself is disabled.

When a logical interface is down, all routes that specify that interface as the output (using the -ifp option in the route(1M) command or RTA_IFP in a route(7P) socket) are removed from the forwarding table. Routes marked with RTF_STATIC are returned to the table if the interface is brought back up, while routes not marked with RTF_STATIC are simply deleted.
When all logical interfaces that could possibly be used to reach a particular gateway address are brought down (specified without the interface option as in the previous paragraph), the affected gateway routes are treated as though they had the RTF\_BLACKHOLE flag set. All matching packets are discarded because the gateway is unreachable.

**encaplimit** \( n \)

Set the tunnel encapsulation limit for the interface to \( n \). This option applies to IPv4–in-IPv6 and IPv6–in-IPv6 tunnels only. The tunnel encapsulation limit controls how many more tunnels a packet may enter before it leaves any tunnels, that is, the tunnel nesting level.

**-encaplimit**

Disable generation of the tunnel encapsulation limit. This option applies only to IPv4–in-IPv6 and IPv6–in-IPv6 tunnels.

**encr\_auth\_algs** *authentication algorithm*

For a tunnel, enable IPsec ESP with the authentication algorithm specified. It can be either a number or an algorithm name, including any or none, to indicate no algorithm preference. If an ESP encryption algorithm is specified but the authentication algorithm is not, the default value for the ESP authentication algorithm will be any.

It is now preferable to use the `ipsecconf(1M)` command when configuring a tunnel’s security properties. If `ipsecconf` was used to set a tunnel’s security properties, this keyword will not affect the tunnel.

**encr\_algs** *encryption algorithm*

For a tunnel, enable IPsec ESP with the encryption algorithm specified. It can be either a number or an algorithm name. Note that all IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify the value of `encr\_algs` as `none`. If an ESP authentication algorithm is specified, but the encryption algorithm is not, the default value for the ESP encryption will be `null`.

It is now preferable to use the `ipsecconf(1M)` command when configuring a tunnel’s security properties. If `ipsecconf` was used to set a tunnel’s security properties, this keyword will not affect the tunnel.

**ether** \([\text{address}]\)

If no address is given and the user is root or has sufficient privileges to open the underlying device, then display the current Ethernet address information.

Otherwise, if the user is root or has sufficient privileges, set the Ethernet address of the interfaces to `address`. The address is an Ethernet address represented as `x:x:x:x:x:x` where `x` is a hexadecimal number between 0 and FF. Similarly, for the IPoIB (IP over InfiniBand) interfaces, the address will be 20 bytes of colon-separated hex numbers between 0 and FF.

Some, though not all, Ethernet interface cards have their own addresses. To use cards that do not have their own addresses, refer to section 3.2.3(4) of the IEEE 802.3 specification for
a definition of the locally administered address space. The use of multipathing groups should be restricted to those cards with their own addresses (see MULTIPATHING GROUPS).

-failover
Mark the logical interface as a non-failover interface. Addresses assigned to non-failover logical interfaces will not failover when the interface fails. Status display shows NOFAILOVER as part of flags.

-failover
Mark the logical interface as a failover interface. An address assigned to such an interface will failover when the interface fails. Status display does not show NOFAILOVER as part of flags.

group [ name | """]
Insert the logical interface in the multipathing group specified by name. To delete an interface from a group, use a null string """. When invoked on the logical interface with id zero, the status display shows the group name.

-index n
Change the interface index for the interface. The value of n must be an interface index (if_index) that is not used on another interface. if_index will be a non-zero positive number that uniquely identifies the network interface on the system.

-metric n
Set the routing metric of the interface to n; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable. Metrics are counted as addition hops to the destination network or host.

-modinsert mod_name@pos
Insert a module with name mod_name to the stream of the device at position pos. The position is relative to the stream head. Position 0 means directly under stream head.

Based upon the example in the modlist option, use the following command to insert a module with name ipqos under the ip module and above the firewall module:

example% ifconfig eri0 modinsert ipqos@2

A subsequent listing of all the modules in the stream of the device follows:

eexample% ifconfig eri0 modlist
0 arp
1 ip
2 ipqos
3 firewall
4 eri

-modlist
List all the modules in the stream of the device.

The following example lists all the modules in the stream of the device:
modremove mod_name@pos
Remove a module with name mod_name from the stream of the device at position pos. The position is relative to the stream head.

Based upon the example in the modinsert option, use the following command to remove the firewall module from the stream after inserting the ipqos module:

```
example% ifconfig eri0 modremove firewall@3
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig eri0 modlist
0 arp
1 ip
2 ipqos
3 eri
```

Note that the core IP stack modules, for example, ip and tun modules, cannot be removed.

mtu n
Set the maximum transmission unit of the interface to n. For many types of networks, the mtu has an upper limit, for example, 1500 for Ethernet. This option sets the FIXEDMTU flag on the affected interface.

netmask mask
For IPv4 only. Specify how much of the address to reserve for subdividing networks into subnetworks. The mask includes the network part of the local address and the subnet part, which is taken from the host field of the address. The mask contains 1’s for the bit positions in the 32-bit address which are to be used for the network and subnet parts, and 0’s for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion. The mask can be specified in one of four ways:

1. with a single hexadecimal number with a leading 0x,
2. with a dot-notation address,
3. with a “+” (plus sign) address, or
4. with a pseudo host name/pseudo network name found in the network database

If a “+” (plus sign) is given for the netmask value, the mask is looked up in the netmasks(4) database. This lookup finds the longest matching netmask in the database by starting with the interface’s IPv4 address as the key and iteratively masking off more and more low order
bits of the address. This iterative lookup ensures that the netmasks(4) database can be used to specify the netmasks when variable length subnets are used within a network number.

If a pseudo host name/pseudo network name is supplied as the netmask value, netmask data may be located in the hosts or networks database. Names are looked up by first using gethostbyname(3NSL). If not found there, the names are looked up in getnetbyname(3SOCKET). These interfaces may in turn use nsswitch.conf(4) to determine what data store(s) to use to fetch the actual value.

For both inet and inet6, the same information conveyed by mask can be specified as a prefix_length attached to the address parameter.

nud
   Enables the neighbor unreachability detection mechanism on a point-to-point physical interface.

-nud
   Disables the neighbor unreachability detection mechanism on a point-to-point physical interface.

plumb
   Open the device associated with the physical interface name and set up the streams needed for IP to use the device. When used with a logical interface name, this command is used to create a specific named logical interface. An interface must be separately plumbed for use by IPv4 and IPv6. The address_family parameter controls whether the ifconfig command applies to IPv4 or IPv6.

   Before an interface has been plumbed, the interface will not show up in the output of the ifconfig -a command.

private
   Tells the in. routed routing daemon that a specified logical interface should not be advertised.

-‐‐private
   Specify unadvertised interfaces.

removeif address
   Remove the logical interface on the physical interface specified that matches the address specified. When the interface is part of a multipathing group, the logical interface will be removed from the physical interface in the group that holds the address.

router
   Enable IP forwarding on the interface. When enabled, the interface is marked ROUTER, and IP packets can be forwarded to and from the interface.
- router
  Disable IP forwarding on the interface. IP packets are not forwarded to and from the interface.

set
Set the address, prefix_length or both, for a logical interface.

standby
Marks the physical interface as a standby interface. If the interface is marked STANDBY and is part of the multipathing group, the interface will not be selected to send out packets unless some other interface in the group has failed and the network access has been failed over to this standby interface.

The status display shows "STANDBY, INACTIVE” indicating that that the interface is a standby and is also inactive. IFF_INACTIVE will be cleared when some other interface belonging to the same multipathing group fails over to this interface. Once a failback happens, the status display will return to INACTIVE.

- standby
  Turns off standby on this interface.

subnet
Set the subnet address for an interface.

td
Set the destination address of a tunnel. The address should not be the same as the dest_address of the tunnel, because no packets leave the system over such a tunnel.

thoplimit n
Set the hop limit for a tunnel interface. The hop limit value is used as the TTL in the IPv4 header for the IPv6--in-IPv4 and IPv4--in-IPv6 tunnels. For IPv6--in-IPv6 and IPv4--in-IPv6 tunnels, the hop limit value is used as the hop limit in the IPv6 header.

token address/prefix_length
Set the IPv6 token of an interface to be used for address autoconfiguration.

example% ifconfig eri0 inet6 token ::1/64

trailers
This flag previously caused a nonstandard encapsulation of IPv4 packets on certain link levels. Drivers supplied with this release no longer use this flag. It is provided for compatibility, but is ignored.

-trailers
Disable the use of a "trailer” link level encapsulation.

ts
Set the source address of a tunnel. This is the source address on an outer encapsulating IP header. It must be an address of another interface already configured using ifconfig.
unplumb
Close the device associated with this physical interface name and any streams that ifconfig set up for IP to use the device. When used with a logical interface name, the logical interface is removed from the system. After this command is executed, the device name will no longer appear in the output of ifconfig -a.

up
Mark a logical interface “up”. This happens automatically when assigning the first address to a logical interface. The up option enables an interface after an ifconfig down, which reinitializes the hardware.

usesrc [ name | none ]
Specify a physical interface to be used for source address selection. If the keyword none is used, then any previous selection is cleared.

When an application does not choose a non-zero source address using bind(3SOCKET), the system will select an appropriate source address based on the outbound interface and the address selection rules (see ipaddrsel(1M)).

When usesrc is specified and the specified interface is selected in the forwarding table for output, the system looks first to the specified physical interface and its associated logical interfaces when selecting a source address. If no usable address is listed in the forwarding table, the ordinary selection rules apply. For example, if you enter:

# ifconfig eri0 usesrc vni0
...and vni0 has address 10.0.0.1 assigned to it, the system will prefer 10.0.0.1 as the source address for any packets originated by local connections that are sent through eri0. Further examples are provided in the EXAMPLES section.

While you can specify any physical interface (or even loopback), be aware that you can also specify the virtual IP interface (see vni(7d)). The virtual IP interface is not associated with any physical hardware and is thus immune to hardware failures. You can specify any number of physical interfaces to use the source address hosted on a single virtual interface. This simplifies the configuration of routing-based multipathing. If one of the physical interfaces were to fail, communication would continue through one of the remaining, functioning physical interfaces. This scenario assumes that the reachability of the address hosted on the virtual interface is advertised in some manner, for example, through a routing protocol.

Because the ifconfig preferred option is applied to all interfaces, it is coarser-grained than the usesrc option. It will be overridden by usesrc and setsrc (route subcommand), in that order.

The use of the usesrc option is mutually exclusive of the IP multipathing ifconfig options, group and standby. That is, if an interface is already part of a IP multipathing
group or specified as a standby interface, then it cannot be specified with a usesrc option, and vice-versa. For more details on IP multipathing, see in.mpathd(1M) and the System Administration Guide: IP Services.

xmit
Enable a logical interface to transmit packets. This is the default behavior when the logical interface is up.

-xmit
Disable transmission of packets on an interface. The interface will continue to receive packets.

zone zonename
Place the logical interface in zone zonename. The named zone must be active in the kernel in the ready or running state. The interface is unplumbed when the zone is halted or rebooted. The zone must be configure to be an shared-IP zone. zonecfg(1M) is used to assign network interface names to exclusive-IP zones.

-zone
Place IP interface in the global zone. This is the default.

Operands
The interface operand, as well as address parameters that affect it, are described below.

interface
A string of one of the following forms:

- name physical-unit, for example, er10 or ce1
- name physical-unit: logical-unit, for example, er10:1
- i.p. tunN or i6p. tunN, for tunnels

If the interface name starts with a dash (-), it is interpreted as a set of options which specify a set of interfaces. In such a case, -a must be part of the options and any of the additional options below can be added in any order. If one of these interface names is given, the commands following it are applied to all of the interfaces that match.

-a
Apply the command to all interfaces of the specified address family. If no address family is supplied, either on the command line or by means of /etc/default/inet_type, then all address families will be selected.

-d
Apply the commands to all “down” interfaces in the system.

-D
Apply the commands to all interfaces not under DHCP (Dynamic Host Configuration Protocol) control.

-u
Apply the commands to all “up” interfaces in the system.
-Z
  Apply the commands to all interfaces in the user's zone.

-4
  Apply the commands to all IPv4 interfaces.

-6
  Apply the commands to all IPv6 interfaces.

_address_family_
  The address family is specified by the _address_family_ parameter. The _ifconfig_ command currently supports the following families: _inet_ and _inet6_. If no address family is specified, the default is _inet_.

_ifconfig_ honors the DEFAULT_IP setting in the /etc/default/inet_type file when it displays interface information. If DEFAULT_IP is set to IP_VERSION4, then _ifconfig_ will omit information that relates to IPv6 interfaces. However, when you explicitly specify an address family (_inet_ or _inet6_) on the _ifconfig_ command line, the command line overrides the DEFAULT_IP settings.

_address_
  For the IPv4 family (_inet_), the _address_ is either a host name present in the host name data base (see `hosts(4)`)) or in the Network Information Service (NIS) map _hosts_, or an IPv4 address expressed in the Internet standard "dot notation".

  For the IPv6 family (_inet6_), the _address_ is either a host name present in the host name data base (see `hosts(4)`)) or in the Network Information Service (NIS) map _ipnode_, or an IPv6 address expressed in the Internet standard colon-separated hexadecimal format represented as `x:x:x:x:x:x:x:x` where `x` is a hexadecimal number between 0 and FFFF.

_prefix_length_
  For the IPv4 and IPv6 families (_inet_ and _inet6_), the _prefix_length_ is a number between 0 and the number of bits in the address. For _inet_, the number of bits in the address is 32; for _inet6_, the number of bits in the address is 128. The _prefix_length_ denotes the number of leading set bits in the netmask.

_dest_address_
  If the _dest_address_ parameter is supplied in addition to the _address_ parameter, it specifies the address of the correspondent on the other end of a point-to-point link.

_tunnel_dest_address_
  An address that is or will be reachable through an interface other than the tunnel being configured. This tells the tunnel where to send the tunneled packets. This address must not be the same as the interface destination address being configured.

_tunnel_src_address_
  An address that is attached to an already configured interface that has been configured "up" with _ifconfig_.

-2
  Apply the commands to all interfaces in the user's zone.

-4
  Apply the commands to all IPv4 interfaces.

-6
  Apply the commands to all IPv6 interfaces.

_address_family_
  The address family is specified by the _address_family_ parameter. The _ifconfig_ command currently supports the following families: _inet_ and _inet6_. If no address family is specified, the default is _inet_.

_ifconfig_ honors the DEFAULT_IP setting in the /etc/default/inet_type file when it displays interface information. If DEFAULT_IP is set to IP_VERSION4, then _ifconfig_ will omit information that relates to IPv6 interfaces. However, when you explicitly specify an address family (_inet_ or _inet6_) on the _ifconfig_ command line, the command line overrides the DEFAULT_IP settings.

_address_
  For the IPv4 family (_inet_), the _address_ is either a host name present in the host name data base (see `hosts(4)`)) or in the Network Information Service (NIS) map _hosts_, or an IPv4 address expressed in the Internet standard "dot notation".

  For the IPv6 family (_inet6_), the _address_ is either a host name present in the host name data base (see `hosts(4)`)) or in the Network Information Service (NIS) map _ipnode_, or an IPv6 address expressed in the Internet standard colon-separated hexadecimal format represented as `x:x:x:x:x:x:x:x` where `x` is a hexadecimal number between 0 and FFFF.

_prefix_length_
  For the IPv4 and IPv6 families (_inet_ and _inet6_), the _prefix_length_ is a number between 0 and the number of bits in the address. For _inet_, the number of bits in the address is 32; for _inet6_, the number of bits in the address is 128. The _prefix_length_ denotes the number of leading set bits in the netmask.

_dest_address_
  If the _dest_address_ parameter is supplied in addition to the _address_ parameter, it specifies the address of the correspondent on the other end of a point-to-point link.

_tunnel_dest_address_
  An address that is or will be reachable through an interface other than the tunnel being configured. This tells the tunnel where to send the tunneled packets. This address must not be the same as the interface destination address being configured.

_tunnel_src_address_
  An address that is attached to an already configured interface that has been configured "up" with _ifconfig_.

-2
  Apply the commands to all interfaces in the user's zone.

-4
  Apply the commands to all IPv4 interfaces.

-6
  Apply the commands to all IPv6 interfaces.
**Interface Flags**

The `ifconfig` command supports the following interface flags. The term “address” in this context refers to a logical interface, for example, `eri0:0`, while “interface” refers to the physical interface, for example, `eri0`.

**ADDRCONF**

The address is from stateless addr conf. The stateless mechanism allows a host to generate its own address using a combination of information advertised by routers and locally available information. Routers advertise prefixes that identify the subnet associated with the link, while the host generates an “interface identifier” that uniquely identifies an interface in a subnet. In the absence of information from routers, a host can generate link-local addresses. This flag is specific to IPv6.

**ANYCAST**

Indicates an anycast address. An anycast address identifies the nearest member of a group of systems that provides a particular type of service. An anycast address is assigned to a group of systems. Packets are delivered to the nearest group member identified by the anycast address instead of being delivered to all members of the group.

**BROADCAST**

This broadcast address is valid. This flag and POINTTOPOINT are mutually exclusive.

**CoS**

This interface supports some form of Class of Service (CoS) marking. An example is the 802.1D user priority marking supported on VLAN interfaces.

Note that this flag is only set on interfaces over VLAN links and over Ethernet links that have their `dladm(1M)` tagmode link property set to normal.

**DEPRECATED**

This address is deprecated. This address will not be used as a source address for outbound packets unless there are no other addresses on this interface or an application has explicitly bound to this address. An IPv6 deprecated address will eventually be deleted when not used, whereas an IPv4 deprecated address is often used with IP network multipathing IPv4 test addresses, which are determined by the setting of the NOFAILOVER flag. Further, the DEPRECATED flag is part of the standard mechanism for renumbering in IPv6.

**DHCP**

DHCP is used to manage this address.

**DUPLICATE**

The logical interface has been disabled because the IP address configured on the interface is a duplicate. Some other node on the network is using this address. If the address was configured by DHCP or is temporary, the system will choose another automatically, if possible. Otherwise, the system will attempt to recover this address periodically and the interface will recover when the conflict has been removed from the network. Changing the address or netmask, or setting the logical interface to `up` will restart duplicate detection. Setting the interface to `down` terminates recovery and removes the DUPLICATE flag.
The interface has failed. New addresses cannot be created on this interface. If this interface is part of an IP network multipathing group, a failover will occur to another interface in the group, if possible.

**FIXEDMTU**

The MTU has been set using the `-mtu` option. This flag is read-only. Interfaces that have this flag set have a fixed MTU value that is unaffected by dynamic MTU changes that can occur when drivers notify IP of link MTU changes.

**INACTIVE**

Indicates that the interface is not currently being used for regular traffic by the system. New addresses cannot be created on this interface. The flag is set automatically on standby interfaces. It can also be set when the system detects that a failed interface has been repaired and `FAILBACK=no` is configured in `/etc/default/mpathd`. The flag is cleared when the interface fails or when a failover to that interface occurs.

**LOOPBACK**

Indicates that this is the loopback interface.

**MIP**

Indicates that mobile IP controls this interface.

**MULTI_BCAST**

Indicates that the broadcast address is used for multicast on this interface.

**MULTICAST**

The interface supports multicast. IP assumes that any interface that supports hardware broadcast, or that is a point-to-point link, will support multicast.

**NOARP**

There is no address resolution protocol (ARP) for this interface that corresponds to all interfaces for a device without a broadcast address. This flag is specific to IPv4.

**NOFAILOVER**

This address will not failover if the interface fails. IP network multipathing test addresses must be marked `nofailover`.

**NOLOCAL**

The interface has no address, just an on-link subnet.

**NUD**

`NUD` is disabled on this interface. `NUD` (neighbor unreachability detection) is used by a node to track the reachability state of its neighbors, to which the node actively sends packets, and to perform any recovery if a neighbor is detected to be unreachable. This flag is specific to IPv6.

**NORTEXCH**

The interface does not exchange routing information. For RIP-2, routing packets are not sent over this interface. Additionally, messages that appear to come over this interface
receive no response. The subnet or address of this interface is not included in advertisements over other interfaces to other routers.

NOXMIT
Indicates that the address does not transmit packets. RIP-2 also does not advertise this address.

OFFLINE
Indicates that the interface has been offline. New addresses cannot be created on this interface. Interfaces in an IP network multipathing group are offline prior to removal and replacement using dynamic reconfiguration.

POINTOPOINT
Indicates that the address is a point-to-point link. This flag and BROADCAST are mutually exclusive.

PREFERRED
This address is a preferred IPv6 source address. This address will be used as a source address for IPv6 communication with all IPv6 destinations, unless another address on the system is of more appropriate scope. The DEPRECATED flag takes precedence over the PREFERRED flag.

PRIVATE
Indicates that this address is not advertised. For RIP-2, this interface is used to send advertisements. However, neither the subnet nor this address are included in advertisements to other routers.

ROUTER
Indicates that IP packets can be forwarded to and from the interface.

RUNNING
Indicates that the required resources for an interface are allocated. For some interfaces this also indicates that the link is up.

STANDBY
Indicates that this is a standby interface to be used on failures. Only interfaces in an IP network multipathing group should be designated as standby interfaces. If this interface is part of a IP network multipathing group, the interface will not be selected to send out packets unless some other interface in the group fails over to it.

TEMPORARY
Indicates that this is a temporary IPv6 address as defined in RFC 3041.

UNNUMBERED
This flag is set when the local IP address on the link matches the local address of some other link in the system.

UP
Indicates that the interface is up, that is, all the routing entries and the like for this interface have been set up.
VIRTUAL
Indicates that the physical interface has no underlying hardware. It is not possible to transmit or receive packets through a virtual interface. These interfaces are useful for configuring local addresses that can be used on multiple interfaces. (See also the -usesrc option.)

XRESOLV
Indicates that the interface uses an IPv6 external resolver.

**Logical Interfaces**
Solaris TCP/IP allows multiple logical interfaces to be associated with a physical network interface. This allows a single machine to be assigned multiple IP addresses, even though it may have only one network interface. Physical network interfaces have names of the form `driver-name physical-unit-number`, while logical interfaces have names of the form `driver-name physical-unit-number:logical-unit-number`. A physical interface is configured into the system using the `plumb` command. For example:

```
example% ifconfig eri0 plumb
```

Once a physical interface has been “plumbed”, logical interfaces associated with the physical interface can be configured by separate `-plumb` or `-addif` options to the `ifconfig` command.

```
example% ifconfig eri0:1 plumb
```

allocates a specific logical interface associated with the physical interface eri0. The command

```
example% ifconfig eri0 addif 192.168.200.1/24 up
```

allocates the next available logical unit number on the eri0 physical interface and assigns an address and prefix length.

A logical interface can be configured with parameters (`address`, `prefix_length`, and so on) different from the physical interface with which it is associated. Logical interfaces that are associated with the same physical interface can be given different parameters as well. Each logical interface must be associated with an existing and “up” physical interface. So, for example, the logical interface eri0:1 can only be configured after the physical interface eri0 has been plumbed.

To delete a logical interface, use the `-unplumb` or `-removeif` options. For example,

```
example% ifconfig eri0:1 down unplumb
```

will delete the logical interface eri0:1.

**Multipathing Groups**
Physical interfaces that share the same IP broadcast domain can be collected into a multipathing group using the `group` keyword. Interfaces assigned to the same multipathing group are treated as equivalent and outgoing traffic is spread across the interfaces on a per-IP-destination basis. In addition, individual interfaces in a multipathing group are monitored for failures; the addresses associated with failed interfaces are automatically transferred to other functioning interfaces within the group.
For more details on IP multipathing, see `in.mpathd(1M)` and the *System Administration Guide: IP Services*. See `netstat(1M)` for per-IP-destination information.

**Configuring IPv6 Interfaces**

When an IPv6 physical interface is plumbed and configured “up” with `ifconfig`, it is automatically assigned an IPv6 link-local address for which the last 64 bits are calculated from the MAC address of the interface.

```bash
eexample% ifconfig eri0 inet6 plumb up
```

The following example shows that the link-local address has a prefix of `fe80::/10`.

```bash
eexample% ifconfig eri0 inet6
ce0:   flags=2000841<UP,RUNNING,MULTICAST,IPv6>
       mtu 1500 index 2
       inet6  fe80::a00:20ff:fe8e:f3ad/10
```

Link-local addresses are only used for communication on the local subnet and are not visible to other subnets.

If an advertising IPv6 router exists on the link advertising prefixes, then the newly plumbed IPv6 interface will autoconfigure logical interface(s) depending on the prefix advertisements. For example, for the prefix advertisement `2001:0db8:3c4d:55::/64`, the autoconfigured interface will look like:

```bash
eri0:2:   flags=2080841<UP,RUNNING,MULTICAST,ADDRCONF,IPv6>
       mtu 1500 index 2
       inet6  2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64
```

Even if there are no prefix advertisements on the link, you can still assign global addresses manually, for example:

```bash
eexample% ifconfig eri0 inet6 addif \
   2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64 up
```

To configure boot-time defaults for the interface eri0, place the following entry in the `/etc/hostname6.eri0` file:

```bash
addif 2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64 up
```

**Configuring IPv6/IPv4 tunnels**

An IPv6 over IPv4 tunnel interface can send and receive IPv6 packets encapsulated in an IPv4 packet. Create tunnels at both ends pointing to each other. IPv6 over IPv4 tunnels require the tunnel source and tunnel destination IPv4 and IPv6 addresses. Solaris 8 supports both automatic and configured tunnels. For automatic tunnels, an IPv4-compatible IPv6 address is used. The following demonstrates auto-tunnel configuration:

```bash
eexample% ifconfig ip.atun0 inet6 plumb
eexample% ifconfig ip.atun0 inet6 tsrc IPv4-address \
   ::IPv4-address/96 up
```

where IPv4-address is the IPv4 address of the interface through which the tunnel traffic will flow, and IPv4-address, ::<IPv4-address>, is the corresponding IPv4-compatible IPv6 address.
The following is an example of a configured tunnel:

```
example% ifconfig ip.tun0 inet6 plumb tsrc my-ipv4-address \
    tdst peer-ipv4-address up
```

This creates a configured tunnel between `my-ipv4-address` and `peer-ipv4-address` with corresponding link-local addresses. For tunnels with global or site-local addresses, the logical tunnel interfaces need to be configured in the following form:

```
example% ifconfig ip.tun0 inet6 addif my-v6-address peer-v6-address up
```

For example,

```
example% ifconfig ip.tun0 inet6 plumb tsrc 109.146.85.57 \
    tdst 109.146.85.212 up
example% ifconfig ip.tun0 inet6 addif 2::45 2::46 up
```

To show all IPv6 interfaces that are up and configured:

```
example% ifconfig -au6
ip.tun0: flags=2200851<UP,POINTOPOINT,RUNNING,MULTICAST,NONUD,IPv6> 
    mtu 1480 index 3
    inet tunnel src 109.146.85.57 tunnel dst 109.146.85.212
    tunnel security settings --> use 'ipseconf -ln -i ip.tun1'
    tunnel hop limit 60
    inet6 fe80::6d92:5539/10 --> fe80::6d92:55d4
ip.tun0:1: flags=2200851<UP,POINTOPOINT,RUNNING,MULTICAST,NONUD,IPv6> 
    mtu 1480 index 3
    inet6 2::45/128 --> 2::46
```

In the output above, note the line that begins with "tunnel security settings". The content of this line varies according to whether and how you have set your security settings. See "Display of Tunnel Security Settings," below.

An IPv4 over IPv6 tunnel interface can send and receive IPv4 packets encapsulated in an IPv6 packet. Create tunnels at both ends pointing to each other. IPv4 over IPv6 tunnels require the tunnel source and tunnel destination IPv6 and IPv4 addresses. The following demonstrates auto-tunnel configuration:

```
example% ifconfig ip6.tun0 inet plumb tsrc my-ipv6-address \
    tdst peer-ipv6-address my-ipv4-address \
    peer-ipv4-address up
```

This creates a configured tunnel between `my-ipv6-address` and `peer-ipv6-address` with `my-ipv4-address` and `peer-ipv4-address` as the endpoints of the point-to-point interface, for example:

```
example% ifconfig ip6.tun0 inet plumb tsrc fe80::1 tdst fe80::2 \
    10.0.0.208 10.0.0.210 up
```

To show all IPv4 interfaces that are up and configured:
example% ifconfig -au4
lo0: flags=1000849<UP,LOOPBACK,RUNNING,MULTICAST,IPv4> mtu 8232 index 1
    inet 127.0.0.1 netmask ff000000
eri0: flags=1004843<UP,BROADCAST,RUNNING,MULTICAST,DHCP,IPv4> mtu 1500 \ 
    index 2
    inet 172.17.128.208 netmask ffffff00 broadcast 172.17.128.255
ip6.tun0: flags=10008d1<UP,POINTOPOINT,RUNNING,NOARP,MULTICAST,IPv4> \ 
    index 3
    inet6 tunnel src fe80::1 tunnel dst fe80::2
    tunnel security settings --> use ‘ipsecconf -ln -i ip.tun1’
    tunnel hop limit 60 tunnel encapsulation limit 4
    inet 10.0.0.208 --> 10.0.0.210 netmask ff000000

In the output above, note the line that begins with “tunnel security settings”. The content of this line varies according to whether and how you have set your security settings. See “Display of Tunnel Security Settings,” below.

Display of Tunnel Security Settings

The ifconfig output for tunneled interfaces indicates security settings, if present, for a tunnel. The content of the line showing your settings differs depending on how you have made your settings:

- If you set your security policy using the ifconfig -auth_algs, -encr_algs, and -encr_auth_algs options and do not use ipsecconf(1M), ifconfig displays your settings for each of these options.
- If you set your security policy using ipsecconf(1M) with the tunnel keyword (the preferred method), ifconfig displays:

  tunnel security settings --> use ‘ipsecconf -ln -i ip.tun1’

...in effect, hiding your settings from those without privileges to view them.

If you do not set security policy, using either ifconfig or ipsecconf, there is no tunnel security setting displayed.

Examples

EXAMPLE 1 Using the ifconfig Command

If your workstation is not attached to an Ethernet, the network interface, for example, eri0, should be marked “down” as follows:

example% ifconfig eri0 down

EXAMPLE 2 Printing Addressing Information

To print out the addressing information for each interface, use the following command:

example% ifconfig -a
**EXAMPLE 3**  Resetting the Broadcast Address

To reset each interface's broadcast address after the netmasks have been correctly set, use the next command:

```
example% ifconfig -a broadcast +
```

**EXAMPLE 4**  Changing the Ethernet Address

To change the Ethernet address for interface ce0, use the following command:

```
example% ifconfig ce0 ether aa:1:2:3:4:5
```

**EXAMPLE 5**  Configuring an IP-in-IP Tunnel

To configure an IP-in-IP tunnel, first plumb it with the following command:

```
example% ifconfig ip.tun0 plumb
```

Then configure it as a point-to-point interface, supplying the tunnel source and the tunnel destination:

```
example% ifconfig ip.tun0 myaddr mydestaddr tsrc another_myaddr \
        tdst a_dest_addr up
```

Use `ipsecconf(1M)`, as described above, to configure tunnel security properties.

**EXAMPLE 6**  Configuring 6to4 Tunnels

To configure 6to4 tunnels, use the following commands:

```
example% ifconfig ip.6to4tun0 inet6 plumb
example% ifconfig ip.6to4tun0 inet6 tsrc IPv4-address 6to4-address/64 up
```

`IPv4-address` denotes the address of the encapsulating interface. `6to4-address` denotes the address of the local IPv6 address of form `2002:IPv4-address:SUBNET-ID:HOSTID`.

The long form should be used to resolve any potential conflicts that might arise if the system administrator utilizes an addressing plan where the values for SUBNET-ID or HOSTID are reserved for something else.

After the interface is plumbed, a 6to4 tunnel can be configured as follows:

```
example% ifconfig ip.6to4tun0 inet6 tsrc IPv4-address up
```

This short form sets the address. It uses the convention:

```
2002:IPv4-address::1
```

The SUBNET-ID is 0, and the HOSTID is 1.
EXAMPLE 7  Configuring IP Forwarding on an Interface

To enable IP forwarding on a single interface, use the following command:

example% ifconfig eri0 router

To disable IP forwarding on a single interface, use the following command:

example% ifconfig eri0 -router

EXAMPLE 8  Configuring Source Address Selection Using a Virtual Interface

The following command configures source address selection such that every packet that is locally generated with no bound source address and going out on qfe2 prefers a source address hosted on vni0.

example% ifconfig qfe2 usesrc vni0

The ifconfig -a output for the qfe2 and vni0 interfaces displays as follows:

```
qfe2:  flags=1100843<UP,BROADCAST,RUNNING,MULTICAST,ROUTER,IPv4>  mtu 1500  index 4
       usesrc vni0
       inet 1.2.3.4 netmask ffffff00 broadcast 1.2.3.255
       ether 0:3:ba:17:4b:e1
vni0:  flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
       mtu 0  index 5
       srcof qfe2
       inet 3.4.5.6 netmask fffffff
```

Observe, above, the usesrc and srcof keywords in the ifconfig output. These keywords also appear on the logical instances of the physical interface, even though this is a per-physical interface parameter. There is no srcof keyword in ifconfig for configuring interfaces. This information is determined automatically from the set of interfaces that have usesrc set on them.

The following command, using the none keyword, undoes the effect of the preceding ifconfig usesrc command.

```
example% ifconfig qfe2 usesrc none
```

Following this command, ifconfig -a output displays as follows:

```
qfe2:  flags=1100843<UP,BROADCAST,RUNNING,MULTICAST,ROUTER,IPv4>  mtu 1500  index 4
       inet 1.2.3.4 netmask ffffff00 broadcast 1.2.3.255
       ether 0:3:ba:17:4b:e1
vni0:  flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
       mtu 0  index 5
       inet 3.4.5.6 netmask fffffff
```

Note the absence of the usesrc and srcof keywords in the output above.
EXAMPLE 9  Configuring Source Address Selection for an IPv6 Address

The following command configures source address selection for an IPv6 address, selecting a
source address hosted on vni0.

example% ifconfig qfe1 inet6 usesrc vni0

Following this command, ifconfig -a output displays as follows:

qfe1: flags=2000841<UP,RUNNING,MULTICAST,IPv6> mtu 1500 index 3
     usesrc vni0
     inet6 fe80::203:baff:fe17:4be0/10
     ether 0:3:ba:17:4b:e0
vni0: flags=2002210041<UP,RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
     index 5
     srcof qfe1
     inet6 fe80::203:baff:fe17:4444/128
vni0:1: flags=2002210040<UP,RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
     index 5
     srcof qfe1
     inet6 fec0::203:baff:fe17:4444/128
vni0:2: flags=2002210040<UP,RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
     index 5
     srcof qfe1
     inet6 2000::203:baff:fe17:4444/128

Depending on the scope of the destination of the packet going out on qfe1, the appropriately
scoped source address is selected from vni0 and its aliases.

EXAMPLE 10  Using Source Address Selection with Shared-IP Zones

The following is an example of how the usesrc feature can be used with the zones(5) facility
in Solaris. The following commands are invoked in the global zone:

example% ifconfig hme0 usesrc vni0
example% ifconfig eri0 usesrc vni0
example% ifconfig qfe0 usesrc vni0

Following the preceding commands, the ifconfig -a output for the virtual interfaces would
display as:

vni0: flags=20011001<UP, RUNNING, NOARP, NOXMIT, ROUTER, IPv4, VIRTUAL>
     mtu 0 index 23
     srcof hme0 eri0 qfe0
     inet 10.0.0.1 netmask fffffff0
vni0:1: flags=20011001<UP, RUNNING, NOARP, NOXMIT, ROUTER, IPv4, VIRTUAL> mtu 0
     index 23
     zone test1
     srcof hme0 eri0 qfe0
     inet 10.0.0.2 netmask fffffff0

714  man pages section 1M: System Administration Commands  •  Last Revised 2 Jun 2009
EXAMPLE 10   Using Source Address Selection with Shared-IP Zones   (Continued)

vni0:2:
   flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
   index 23
   zone test2
   srcof hme0 eri0 qfe0
   inet 10.0.0.3 netmask ffffffff
vni0:3:
   flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
   index 23
   zone test3
   srcof hme0 eri0 qfe0
   inet 10.0.0.4 netmask ffffffff

There is one virtual interface alias per zone (test1, test2, and test3). A source address from the virtual interface alias in the same zone is selected. The virtual interface aliases were created using zonecfg(1M) as follows:

example% zonecfg -z test1
zonecfg:test1> add net
zonecfg:test1:net> set physical=vni0
zonecfg:test1:net> set address=10.0.0.2

The test2 and test3 zone interfaces and addresses are created in the same way.

EXAMPLE 11   Turning Off DHCPv6

The following example shows how to disable automatic use of DHCPv6 on all interfaces, and immediately shut down DHCPv6 on the interface named hme0. See in.ndpd(1M) and ndpd.conf(4) for more information on the automatic DHCPv6 configuration mechanism.

example% echo ifdefault StatefulAddrConf false >> /etc/inet/ndpd.conf
example% pkill -HUP -x in.ndpd
example% ifconfig hme0 dhcp release

Files
/etc/netmasks
   Netmask data.

/etc/default/inet_type
   Default Internet protocol type.

System Administration Guide: IP Services

Diagnosics ifconfig sends messages that indicate if:
- the specified interface does not exist
- the requested address is unknown
- the user is not privileged and tried to alter an interface's configuration

Notes Do not select the names broadcast, down, private, trailers, up or other possible option names when you choose host names. If you choose any one of these names as host names, it can cause unusual problems that are extremely difficult to diagnose.
### Name
if_mpadm – change operational status of interfaces within a multipathing group

### Synopsis
```
/usr/sbin/if_mpadm -d interface_name
/usr/sbin/if_mpadm -r interface_name
```

### Description
Use the `if_mpadm` utility to change the operational status of interfaces that are part of an IP multipathing group. If the interface is operational, you can use `if_mpadm -d` to detach or off-line the interface. If the interface is off-lined, use `if_mpadm -r` to revert it to its original state.

When a network interface is off-lined, all network access fails over to a different interface in the IP multipathing group. Any addresses that do not failover are brought down. Network access includes unicast, broadcast, and multicast for IPv4 and unicast and multicast for IPv6. Addresses marked with `IFF_NOFAILOVER` do not failover. They are marked down. After an interface is off-lined, the system will not use the interface for any outbound or inbound traffic, and the interface can be safely removed from the system without any loss of network access.

The `if_mpadm` utility can be applied only to interfaces that are part of an IP multipathing group.

### Options
The `if_mpadm` utility supports the following options:

- `-d interface_name` Detach or off-line the interface specified by `interface_name`.
- `-r interface_name` Reattach or undo the previous detach or off-line operation on the interface specified by `interface_name`. Unless the `-d` option was used to detach or off-line the interface, this option will fail.

### Examples
**EXAMPLE 1** Detaching an Interface

Use the following command to off-line or detach the interface. All network access will failover from hme0 to other interfaces in the same IP multipathing group. If no other interfaces are in the same group, the operation will fail.

```
example% if_mpadm -d hme0
```

**EXAMPLE 2** Reattaching an Off-line Interface

Use the following command to undo the previous operation. Network access will failback to hme0.

```
example% if_mpadm -r hme0
```

ifconfig(1M), in.mpathd(1M), attributes(5)

Diagnostics  
off-line failed as there is no other functional interface available in the multipathing group for failing over the network access.

Description: This message means that other interfaces in the group are failed over already or the multipathing configuration was not suitable for completing a failover.

off-line cannot be undone because multipathing configuration is not consistent across all the interfaces in the group.

Description: This message means that some interfaces in the IP multipathing group are not configured consistently with other interfaces in the group, for example, one of the interfaces in the group does not have an IFF_NOFAILOVER address.
**Name**  
ifparse – parse ifconfig command line

**Synopsis**  
/sbin/ifparse [-fs] addr_family commands

**Description**  
Use the ifparse command to parse the *ifconfig(1M)* command line options and output substrings, one per line, as appropriate. If no options are specified, ifparse returns the entire ifconfig command line as a series of substrings, one per line.

**Options**  
The ifparse command supports the following options:

- `-f` Lists only substrings of the ifconfig command line that are relevant to IP network multipath failover
- `-s` Lists only substrings of the ifconfig command line that are not relevant to IP network multipath failover

**Operands**  
The ifparse command does not support the *interface* operand of the ifconfig command.

**Examples**

**EXAMPLE 1**  
Parsing Command Line Options Relevant to Failover  
The following example shows the use of the ifparse command to parse the command line options relevant to IP network multipath failover:

```
example# ifparse -f inet 1.2.3.4 up group one addif 1.2.3.5 -failover up set 1.2.3.4 up
```

**EXAMPLE 2**  
Parsing Command Line Options That Are Not Relevant to Failover  
The following example shows the use of the ifparse command to parse the command line options that are not relevant to IP network multipath failover:

```
example# ifparse -s inet 1.2.3.4 up group one addif 1.2.3.5 -failover up group one addif 1.2.3.5 -failover up
```

**EXAMPLE 3**  
Parsing the Command Line For All Options  
The following example shows the use of the ifparse command to parse the command line for all ifconfig options:

```
example# ifparse inet 1.2.3.4 up group one addif 1.2.3.5 -failover up group one set 1.2.3.4 up addif 1.2.3.5 -failover up
```

**Attributes**  
See *attributes(5)* for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsr</td>
</tr>
</tbody>
</table>
ifparse(1M)

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stability Level</td>
<td>Obsolete</td>
</tr>
</tbody>
</table>

See Also  ifconfig(1M), attributes(5)

Diagnostics usage: -fs <addr_family> <commands>
  Description: This message indicates an invalid command line.

  ifparse: Not enough space
  Description: This message indicates insufficient memory.

  ifparse: dhcp not supported for inet6
  Description: DHCP operations are not supported for the inet6 address family.

  ifparse: Operation <operation> not supported for <addr_family>
  Description: Most operations cannot be used with all address families. For example, the broadcast operation is not supported on the inet6 address family.

  ifparse: no argument for <operation>
  Description: Some operations, for example broadcast, require an argument.

Notes  The ifparse command is classified as an obsolete interface. It will likely be removed in a future release. You should not develop applications that depend upon this interface.
ikeadm(1M)

**Name**
ikeadm – manipulate Internet Key Exchange (IKE) parameters and state

**Synopsis**
ikeadm [-np]
ikeadm [-np] get [debug | priv | stats | defaults]
ikeadm [-np] set [debug | priv] [level] [file]
ikeadm [-np] [get | del] [pl | rule | preshared] [id]
ikeadm [-np] add [rule | preshared] { description }
ikeadm [-np] token [login | logout] PKCS#11_Token_Object
ikeadm [-np] [read | write] [rule | preshared | certcache] file
ikeadm [-np] [dump | pls | rule | preshared]
ikeadm [-np] flush [pl | certcache]
ikeadm help
    [get | set | add | del | read | write | dump | flush | token]

**Description**
The ikeadm utility retrieves information from and manipulates the configuration of the Internet Key Exchange (IKE) protocol daemon, `in.iked(1M)`.

ikeadm supports a set of operations, which may be performed on one or more of the supported object types. When invoked without arguments, ikeadm enters interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached.

Because ikeadm manipulates sensitive keying information, you must be superuser to use this command. Additionally, some of the commands available require that the daemon be running in a privileged mode, which is established when the daemon is started.

For details on how to use this command securely see Security.

**Options**
The following options are supported:

- **-n**
  Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.

- **-p**
  Paranoid. Do not print any keying material, even if saving Security Associations. Instead of an actual hexadecimal digit, print an `X` when this flag is turned on.

**Usage**

**Commands**
The following commands are supported:

- **add**
  Add the specified object. This option can be used to add a new policy rule or a new preshared key to the current (running) in.iked configuration. When adding a new
preshared key, the command cannot be invoked from the command line, as it will contain keying material. The rule or key being added is specified using appropriate id-value pairs as described in the ID FORMATS section.

del
Delete a specific object or objects from in.iked's current configuration. This operation is available for IKE (Phase 1) SAs, policy rules, and preshared keys. The object to be deleted is specified as described in the ID FORMATS.

dump
Display all objects of the specified type known to in.iked. This option can be used to display all Phase 1 SAs, policy rules, preshared keys, or the certificate cache. A large amount of output may be generated by this command.

flush
Remove all IKE (Phase 1) SAs or cached certificates from in.iked.

Note that flushing the cert cache will also (as a side-effect) update IKE with any new certificates added or removed.

get
Lookup and display the specified object. May be used to view the current debug or privilege level, global statistics and default values for the daemon, or a specific IKE (Phase 1) SA, policy rule, or preshared key. The latter three object types require that identifying information be passed in; the appropriate specification for each object type is described below.

help
Print a brief summary of commands, or, when followed by a command, prints information about that command.

read
Update the current in.iked configuration by reading the policy rules or preshared keys from either the default location or from the file specified.

set
Adjust the current debug or privilege level. If the debug level is being modified, an output file may optionally be specified; the output file must be specified if the daemon is running in the background and is not currently printing to a file. When changing the privilege level, adjustments may only be made to lower the access level; it cannot be increased using ikeadm.

write
Write the current in.iked policy rule set or preshared key set to the specified file. A destination file must be specified. This command should not be used to overwrite the existing configuration files.
Log into a PKCS#11 token object and grant access to keying material or log out and invalidate access to keying material.

token can be run as a normal user with the following authorizations:

- token login: solaris.network.ipsec.ike.token.login
- token logout: solaris.network.ipsec.ike.token.logout

Object Types: **debug**

Specifies the daemon's debug level. This determines the amount and type of output provided by the daemon about its operations. The debug level is actually a bitmask, with individual bits enabling different types of information.

<table>
<thead>
<tr>
<th>Description</th>
<th>Flag</th>
<th>Nickname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate management</td>
<td>0x0001</td>
<td>cert</td>
</tr>
<tr>
<td>Key management</td>
<td>0x0002</td>
<td>key</td>
</tr>
<tr>
<td>Operational</td>
<td>0x0004</td>
<td>op</td>
</tr>
<tr>

<tr>
<td>Config file processing</td>
<td>0x0200</td>
<td>config</td>
</tr>
<tr>
<td>All debug flags</td>
<td>0x3ff</td>
<td>all</td>
</tr>
</tbody>
</table>

When specifying the debug level, either a number (decimal or hexadecimal) or a string of nicknames may be given. For example, 88, 0x58, and phase1+phase2+policy are all equivalent, and will turn on debug for phase 1 sa creation, phase 2 sa creation, and policy management. A string of nicknames may also be used to remove certain types of information; all-op has the effect of turning on all debug except for operational messages; it is equivalent to the numbers 1019 or 0x3fb.

Object Types: **priv**

Specifies the daemon's access privilege level. The possible values are:

<table>
<thead>
<tr>
<th>Description</th>
<th>Level</th>
<th>Nickname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base level</td>
<td>0</td>
<td>base</td>
</tr>
<tr>
<td>Access to preshared key info</td>
<td>1</td>
<td>modkeys</td>
</tr>
<tr>
<td>Access to keying material</td>
<td>2</td>
<td>keymat</td>
</tr>
</tbody>
</table>
By default, `in.ike` is started at the base level. A command-line option can be used to start the daemon at a higher level. `ikeadm` can be used to lower the level, but it cannot be used to raise the level.

Either the numerical level or the nickname may be used to specify the target privilege level.

In order to get, add, delete, dump, read, or write preshared keys, the privilege level must at least give access to preshared key information. However, when viewing preshared keys (either using the get or dump command), the key itself will only be available if the privilege level gives access to keying material. This is also the case when viewing Phase 1 SAs.

**stats**

Global statistics from the daemon, covering both successful and failed Phase 1 SA creation.

Reported statistics include:

- Count of current P1 SAs which the local entity initiated
- Count of current P1 SAs where the local entity was the responder
- Count of all P1 SAs which the local entity initiated since boot
- Count of all P1 SAs where the local entity was the responder since boot
- Count of all attempted P1 SAs since boot, where the local entity was the initiator; includes failed attempts
- Count of all attempted P1 SAs since boot, where the local entity was the responder; includes failed attempts
- Count of all failed attempts to initiate a P1 SA, where the failure occurred because the peer did not respond
- Count of all failed attempts to initiate a P1 SA, where the peer responded
- Count of all failed P1 SAs where the peer was the initiator
- Whether a PKCS#11 library is in use, and if applicable, the PKCS#11 library that is loaded. See Example 11.

**defaults**

Display default values used by the `in.ike` daemon. Some values can be overridden in the daemon configuration file (see `ike.config(4)`); for these values, the token name is displayed in the `get defaults` output. The output will reflect where a configuration token has changed the default.

Default values might be ignored in the event a peer system makes a valid alternative proposal or they can be overridden by per-rule values established in `ike.config`. In such instances, a `get defaults` command continues to display the default values, not the values used to override the defaults.

**p1**

An IKE Phase 1 SA. A `p1` object is identified by an IP address pair or a cookie pair; identification formats are described below.
rule
An IKE policy rule, defining the acceptable security characteristics for Phase 1 SAs between specified local and remote identities. A rule is identified by its label; identification formats are described below.

preshared
A preshared key, including the local and remote identification and applicable IKE mode. A preshared key is identified by an IP address pair or an identity pair; identification formats are described below.

**Id Formats**
Commands like add, del, and get require that additional information be specified on the command line. In the case of the delete and get commands, all that is required is to minimally identify a given object; for the add command, the full object must be specified.

Minimal identification is accomplished in most cases by a pair of values. For IP addresses, the local addr and then the remote addr are specified, either in dot-notation for IPv4 addresses, colon-separated hexadecimal format for IPv6 addresses, or a host name present in the host name database. If a host name is given that expands to more than one address, the requested operation will be performed multiple times, once for each possible combination of addresses.

Identity pairs are made up of a local type-value pair, followed by the remote type-value pair. Valid types are:
- prefix
  An address prefix.
- fqdn
  A fully-qualified domain name.
- domain
  Domain name, synonym for fqdn.
- user_fqdn
  User identity of the form user@fqdn.
- mailbox
  Synonym for user_fqdn.

A cookie pair is made up of the two cookies assigned to a Phase 1 Security Association (SA) when it is created; first is the initiator’s, followed by the responder’s. A cookie is a 64-bit number.

Finally, a label (which is used to identify a policy rule) is a character string assigned to the rule when it is created.

Formatting a rule or preshared key for the add command follows the format rules for the in.iked configuration files. Both are made up of a series of id-value pairs, contained in curly braces ({ and }). See ike.config(4) and ike.preshared(4) for details on the formatting of rules and preshared keys.
The `ikeadm` command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPSec traffic is compromised. The following issues should be taken into account when using the `ikeadm` command.

- **Is the TTY going over a network (interactive mode)?**
  If it is, then the security of the keying material is the security of the network path for this TTY's traffic. Using `ikeadm` over a clear-text telnet or rlogin session is risky. Even local windows may be vulnerable to attacks where a concealed program that reads window events is present.

- **Is the file accessed over the network or readable to the world (read/write commands)?**
  A network-mounted file can be sniffed by an adversary as it is being read. A world-readable file with keying material in it is also risky.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

Security weaknesses often lie in misapplication of tools, not the tools themselves. It is recommended that administrators are cautious when using the `ikeadm` command. The safest mode of operation is probably on a console, or other hard-connected TTY.

For additional information regarding this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C*.

### Examples

**EXAMPLE 1** Emptying out all Phase 1 Security Associations

The following command empties out all Phase 1 Security Associations:

```
example# ikeadm flush p1
```

**EXAMPLE 2** Displaying all Phase 1 Security Associations

The following command displays all Phase 1 Security Associations:

```
example# ikeadm dump p1
```

**EXAMPLE 3** Deleting a Specific Phase 1 Security Association

The following command deletes the specified Phase 1 Security Associations:

```
example# ikeadm del p1 local_ip remote_ip
```

**EXAMPLE 4** Adding a Rule From a File

The following command adds a rule from a file:

```
example# ikeadm add rule rule_file
```

**EXAMPLE 5** Adding a Preshared Key

The following command adds a preshared key:
**EXAMPLE 5** Adding a Preshared Key (Continued)

```
ikeadm>
ikeadm> add preshared { localidtype ip localid local_ip
remoteidtype ip remoteid remote_ip ike_mode main
key 1234567890abcdef1234567890abcdef }
```

**EXAMPLE 6** Saving All Preshared Keys to a File

The following command saves all preshared keys to a file:

```
ikeadm write preshared target_file
```

**EXAMPLE 7** Viewing a Particular Rule

The following command views a particular rule:

```
ikeadm get rule rule_label
```

**EXAMPLE 8** Reading in New Rules from ike.config

The following command reads in new rules from the ike.config file:

```
ikeadm read rules
```

**EXAMPLE 9** Lowering the Privilege Level

The following command lowers the privilege level:

```
ikeadm set priv base
```

**EXAMPLE 10** Viewing the Debug Level

The following command shows the current debug level

```
ikeadm get debug
```

**EXAMPLE 11** Using stats to Verify Hardware Accelerator

The following example shows how stats may include an optional line at the end to indicate if IKE is using a PKCS#11 library to accelerate public-key operations, if applicable.

```
ikeadm get stats
Phase 1 SA counts:
Current: initiator: 0 responder: 0
Total: initiator: 21 responder: 27
Attempted: initiator: 21 responder: 27
Failed: initiator: 0 responder: 0

initiator fails include 0 time-out(s)
PKCS#11 library linked in from /opt/SUNWconn/lib/libpkcs11.so
```

ikeadm(1M)
EXAMPLE 12  Displaying the Certificate Cache
The following command shows the certificate cache and the status of associated private keys, if applicable:

```
example# ikeadm dump certcache
```

EXAMPLE 13  Logging into a PKCS#11 Token
The following command shows logging into a PKCS#11 token object and unlocking private keys:

```
example# ikeadm token login "Sun Metaslot"
Enter PIN for PKCS#11 token:
ikeadm: PKCS#11 operation successful
```

Exit Status  The following exit values are returned:
0             Successful completion.
non-zero      An error occurred. Writes an appropriate error message to standard error.

Notes  As in.iked can run only in the global zone and exclusive-IP zones, this command is not useful in shared-IP zones.
ikecert – manipulates the machine's on-filesystem public-key certificate databases

**Synopsis**
ikecert certlocal
[-a | -e | -h | -k | -l | -r | -U | -C | -L]
[-p] -T PKCS#11 token identifier
[option_specific_arguments]...

ikecert certdb [-a | -e | -h | -l | -r | -U | -C | -L]
[-p] -T PKCS#11 token identifier
[option_specific_arguments]...

ikecert certrldb [-a | -e | -h | -l | -r]
[option_specific_arguments]...

ikecert tokens

**Description**
The `ikecert` command manipulates the machine's on-filesystem public-key certificate databases. See the "Files" section, below.

`ikecert` has three subcommands, one for each of the three major repositories, plus one for listing available hardware tokens:

- `certlocal` deals with the private-key repository,
- `certdb` deals with the public-key repository, and:
- `certrldb` deals with the certificate revocation list (CRL) repository.
- `tokens` shows the available PKCS#11 tokens for a given PKCS#11 library.

The only supported PKCS#11 library and hardware is the Sun Cryptographic Accelerator 4000.

**Options**
Except for `tokens`, each subcommand requires one option, possibly followed by one or more option-specific arguments.

The `tokens` subcommand lists all available tokens in the PKCS#11 library specified in `/etc/inet/ike/config`.

The following options are supported:

- `-a`

  **certlocal**
  When specified with the `certlocal` subcommand, this option installs (adds) a private key into the Internet Key Exchange (IKE) local ID database. The key data is read from standard input, and is in either Solaris-only format or unencrypted PKCS#8 DER format. Key format is automatically
detected. PKCS#8 key files in PEM format and files in password protected, encrypted format are not recognized, but can be converted appropriately using tools available in OpenSSL.

This option cannot be used with PKCS#11 hardware objects when the corresponding public certificate is not already present in the IKE database. When importing both a public certificate and a private key, the public portion must be imported first using the certdb subcommand.

certdb

When specified with the certdb subcommand, this option reads a certificate from standard input and adds it to the IKE certificate database. The certificate must be a X.509 certificate in PEM Base64 or ASN.1 BER encoding. The certificate adopts the name of its identity.

This option can import a certificate into a PKCS#11 hardware key store one of two ways: Either a matching public key object and an existing private key object were created using the certlocal -kc option, or if a PKCS#11 token is explicitly specified using the -T option.

certrldb

When specified with the certrldb subcommand, this option installs (adds) a CRL into the IKE database. The CRL reads from standard input.
-e [-f pkcs8] slot

certlocal
When specified with the certlocal subcommand, this option extracts a private key from the IKE local ID database. The key data are written to standard output. The slot specifies which private key to extract. Private keys are only extracted in binary/ber format.

Use this option with extreme caution. See the “Security” section, below.

This option will not work with PKCS#11 hardware objects.

When used in conjunction with "-f pkcs8", the private key is extracted in unencrypted PKCS#8 format.

-e [-f output-format] certspec

certdb
When specified with the certdb subcommand, this option extracts a certificate from the IKE certificate database which matches the certspec and writes it to standard output. The output-format option specifies the encoding format. Valid options are PEM and BER. This extracts the first matching identity. The default output format is PEM.

certrldb
When specified with the certrldb subcommand, this option extracts a CRL from the IKE database. The key data are written to standard output. The certspec specifies which CRL that is extracted. The first one that matches in the database is extracted. See NOTES, below, for details on certspec.
-kc -m keysize -t keytype -D dname -A altname [...] [-S validity start_time] [-F validity end_time] [-T PKCS#11 token identifier]

certlocal
When specified with the certlocal subcommand, this option generates an IKE public/private key pair and adds it into the local ID database. It also generates a certificate request and sends that to standard output. For details on the above options see Notes for details on the dname argument and see ALTERNATIVE NAMES for details on the altname argument(s) to this command.

If -T is specified, the hardware token will generate the pair of keys.

If -p is specified with -T, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with ikeadm(1M) once in.iked(1M) is running.

-ks -m keysize -t keytype -D dname -A altname [...] [-S validity start_time] [-F validity end_time] [-f output-format] [[-p] -T PKCS#11 token identifier]

certlocal
When specified with the certlocal subcommand, generates a public/private key pair and adds it into the local ID database. This option also generates a self-signed certificate and installs it into the certificate database. See NOTES, below, for details on the dname and altname arguments to this command.
If -T is specified, the hardware token will generate the pair of keys, and the self-signed certificate will also be stored in the hardware.

```
-l [-v] [slot]
```

certlocal
When specified with the certlocal subcommand, this option lists private keys in the local ID database. The -v option switches output to a verbose mode where the entire certificate is printed.

*Use the -v option with extreme caution.* See the “Security” section, below. The -v option will not work with PKCS#11 hardware objects.

```
-l [-v] [certspec]
```

certdb
When specified with the certdb subcommand, this option lists certificates in the IKE certificate database matching the certspec, if any pattern is given. The list displays the identity string of the certificates, as well as, the private key if in the key database. The -v switches the output to a verbose mode where the entire certificate is printed.

If the matching certificate is on a hardware token, the token ID is also listed.

certrldb
When specified with the certrldb subcommand, this option lists the CRLs in the IKE database along with any certificates that reside in the database and match the Issuer Name. certspec can be used to
specify to list a specific CRL. The -v option switches the output to a verbose mode where the entire certificate is printed. See NOTES, below, for details on certspec patterns.

- r slot

certlocal
When specified with the certlocal subcommand, deletes the local ID in the specified slot. If there is a corresponding public key, it is not be deleted. If this slot is deemed as "corrupted" or otherwise unrecognizable, it is deleted as well.

If this is invoked on a PKCS#11 hardware object, it will also delete the PKCS#11 public key and private key objects. If the public key object was already deleted by certdb -r, that is not a problem.

- r certspec

certdb
Removes certificates from the IKE certificate database. Certificates matching the specified certificate pattern are deleted. Any private keys in the certlocal database corresponding to these certificates are not deleted. This removes the first matching identity.

If the pattern specifies a slot and the slot is deemed as "corrupted" or otherwise unrecognizable, it is deleted as well.

If this is invoked on a PKCS#11 hardware object, it will also delete the certificate and the PKCS#11 public key object. If the public key...
object was already deleted by `certlocal -r`, that is not a problem.

**certrldb**
When specified with the `certrldb` subcommand, this option deletes the CRL with the given `certspec`.

**-U slot**

**certlocal**
When specified with the `certlocal` subcommand and the `-T` flag, this option unlinks a PKCS#11 private key object from the IKE database. There will be no attempt to access the hardware keystore or to validate or remove the on-token private key object. The object is simply disassociated from the IKE database.

**certdb**
When specified with the `certdb` subcommand and the `-T` flag, this option unlinks a PKCS#11 certificate object from the IKE database. There will be no attempt to access the hardware keystore or to validate or remove the on-token certificate or public key objects. The objects are simply disassociated from the IKE database.

**-C certspec**

**certlocal**
When specified with the `certlocal` subcommand, this option copies both the private key and its corresponding certificate and the public key from the on-disk keystore to the hardware keystore specified by its PKCS#11 token. This subcommand attempts
to create each of these components, even if one part fails. In all cases, the original on-disk private key and public certificate are still retained and must be deleted separately. Some hardware keystores, such as FIPS-140 compliant devices, may not support migration of private key objects in this manner.

certdb
When specified with the certdb subcommand, this option copies the certificate matching the given certspec and corresponding public key from the on-disk keystore to the hardware keystore specified by its PKCS#11 token. The original public certificate is still retained and must be deleted separately, if desired.

If -p is specified, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with ikeadm(1M) once in.iked(1M) is running.

-L pattern
certlocal
When specified with the certlocal subcommand, this option links an existing on-token private key object to the IKE database. The object itself remains on the token. This option simply lets the IKE infrastructure know that the object exists, as if it had been originally created on-token with the Solaris IKE utilities.

certdb
When specified with the certdb subcommand, this option links an
existing on-token certificate object to the IKE database. The object itself remains on the token. This option simply lets the IKE infrastructure know that the object exists, as if it had been originally created on-token with the Solaris IKE utilities.

If -p is specified, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with `ikeadm(1M)` once `in.iked(1M)` is running.

**Parameters** The following parameters are supported:

certspec

Specifies the pattern matching of certificate specifications. Valid certspects are the Subject Name, Issuer Name, and Subject Alternative Names.

These can be specified as certificates that match the given certspect values and that do not match other certspect values. To signify a certspect value that is not supposed to be present in a certificate, place an `!` in front of the tag.

Valid certspects are:

```!
<Subject Names>
SUBJECT=<Subject Names>
ISSUER=<Issuer Names>
SLOT=<Slot Number in the certificate database>
```

Example:

```
ISSUER=C=US, O=SUN !IP=1.2.3.4 DNS=example.com
```

Valid arguments to the alternative names are as follows:

```
IP=<IPv4 address>
DNS=<Domain Name Server address>
EMAIL=<email (RFC 822) address>
URI=<Uniform Resource Indicator value>
DN=<LDAP Directory Name value>
RID=<Registered Identifier value>
```

Valid Slot numbers can be specified without the keyword tag. Alternative name can also be issued with keyword tags.
Subject Alternative Names the certificate. The argument that follows the -A option should be in the form of tag=value. Valid tags are IP, DNS, EMAIL, URI, DN, and RID (See example below).

X.509 distinguished name for the certificate subject. It typically has the form of: C=country, O=organization, OU=organizational unit, CN=common name. Valid tags are: C, O, OU, and CN.

Encoding output format. pem for PEM Base64 or ber for ASN.1 BER. If -f is not specified, pem is assumed.

Finish certificate validity time. If the -F flag is not specified, the validity end time is calculated at four years from the validity start time. See NOTES for an explanation for the validity date and time syntax.

Key size. It can be 512, 1024, 2048, 3072, or 4096. Use the following command to determine the key sizes supported by the Solaris Cryptographic Framework:

% cryptoadm list -vm

The mechanisms displayed by the preceding command are described in pkcs11_softtoken(5). If your system has hardware acceleration, the mechanisms supported by the hardware will be listed in a separate section for each provider.

Mechanisms can be any of:

CKM_RSA_PKCS_KEY_PAIR_GEN
CKM_DSA_KEY_PAIR_GEN
CKM_DH_PKCS_KEY_PAIR_GEN

Note – Some hardware does not support all key sizes. For example, the Sun Cryptographic Accelerator 4000’s keystore (when using the -T option, below), supports only up to 2048-bit keys for RSA and 1024-bit keys for DSA.

Start certificate validity time. If the -S flag is not specified, the current date and time is used for the validity start time. See NOTES, below, for an explanation for the validity date and time syntax.

Key type. It can be rsa-sha1, rsa-md5, or dsa-sha1.

PKCS#11 token identifier for hardware key storage. This specifies a hardware device instance in conformance to the PKCS#11 standard. A PKCS#11 library must be specified in /etc/inet/ike/config. (See ike.config(4).)
A token identifier is a 32-character space-filled string. If the token given is less than 32 characters long, it will be automatically padded with spaces.

If there is more than one PKCS#11 library on a system, keep in mind that only one can be specified at a time in /etc/inet/ike/config. There can be multiple tokens (each with individual key storage) for a single PKCS#11 library instance.

**Security**

This command can save private keys of a public-private key pair into a file. Any exposure of a private key may lead to compromise if the key is somehow obtained by an adversary.

The PKCS#11 hardware object functionality can address some of the shortcomings of on-disk private keys. Because IKE is a system service, user intervention at boot is not desirable. The token's PIN, however, is still needed. The PIN for the PKCS#11 token, therefore, is stored where normally the on-disk cryptographic keys would reside. This design decision is deemed acceptable because, with a hardware key store, possession of the key is still unavailable, only use of the key is an issue if the host is compromised. Beyond the PIN, the security of ikecert then reduces to the security of the PKCS#11 implementation. The PKCS#11 implementation should be scrutinized also.

**Examples**

**EXAMPLE 1** Generating a Self-Signed Certificate

The following is an example of a self-signed certificate:

```bash
example# ikecert certlocal -ks -m 512 -t rsa-md5 -D "C=US, O=SUN" -A IP=1.2.3.4
Generating, please wait...
Certificate generated.
Certificate added to database.

-----END X509 CERTIFICATE-----
```

**EXAMPLE 2** Generating a CA Request

Generating a CA request appears the same as the self-signed certificate. The only differences between the two is the option `-c` instead of `-s`, and the certificate data is a CA request.

```bash
example# ikecert certlocal -kc -m 512 -t rsa-md5 \
-D "C=US, O=SUN" -A IP=1.2.3.4
```

System Administration Commands - Part 1 739
EXAMPLE 3  A CA Request Using a Hardware Key Store

The following example illustrates the specification of a token using the -T option.

date#  # ikecert certlocal -kc -m 1024 -t rsa-md5 -T vca0-keystore \
          -D "C=US, O=SUN" -A IP=1.2.3.4

Exit Status  The following exit values are returned:

  0  Successful completion.

  non-zero  An error occurred. Writes an appropriate error message to standard error.

Files  /etc/inet/secret/ike.privatekeys/*
   Private keys. A private key must have a matching public-key certificate with the same
   filename in /etc/inet/ike/publickeys/.

   /etc/inet/ike/publickeys/*
   Public-key certificates. The names are only important with regard to matching private key
   names.

   /etc/inet/ike/crls/*
   Public key certificate revocation lists.

   /etc/inet/ike/config
   Consulted for the pathname of a PKCS#11 library.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>

<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also  ikeadm(1M), in.iked(1M), getdate(3C), ike.config(4), attributes(5),
          pkcs11_softtoken(5)

RSA Labs, PKCS#11 v2.11: *Cryptographic Token Interface Standards*, November 2001.

Notes  The following is the validity date and time syntax when the -F or -S flags are used:

For relative dates, the syntax is as follows:

  {+, -} [Ns] [Nm] [Nh] [Nd] [Nm] [Nw] [NM] [Ny]

where:
N
  represents an integer
s
  represents seconds
m
  represents minutes
h
  represents hours
d
  represents days
w
  represents weeks
M
  represents months
y
  represents years

These parameters can be given in any order. For example, “+3d12h” is three and a half days from now, and “-3y2M” is three years and 2 months ago.

All parameters with fixed values can be added up in absolute seconds. Months and years, which have variable numbers of seconds, are calculated using calendar time. Months and years, which are not of fixed length, are defined such that adding a year or month means the same day next year or month. For instance, if it is Jan 26, 2005 and the certificate should expire 3 years and 1 month from today, the expiration (end validity time) date will be Feb 26, 2008. Overflows are dealt with accordingly. For example, one month from Jan 31, 2005 is March 3, 2005, since February has only 28 days.

For absolute dates, the syntax of the date formats included in the file /etc/datemsk are accepted (See getdate(3C) for details). Any date string prepended with a “+” or “-” is treated as a time relative to the current time, while others are treated as absolute dates. Sanity checking is also done to ensure that the end validity date is greater than the start validity date. For example, the following command would create a certificate with start date 1 day and 2 hours ago and an end date of Jan 22nd, 2007 at 12:00:00 local time.

```
# ikecert certlocal -ks -t rsa-shal -m 1024 \
  -D "CN=mycert, O=Sun, C=US" \ 
  -S -1d2h -F "01/22/2007 12:00:00"
```

As in.iked(1M) can run only in the global zone and exclusive-IP zones, this command is not useful in shared-IP zones.
**imqadmin**

**Name**
imqadmin – launch the Message Queue administration console

**Synopsis**
/usr/bin/imqadmin [-javahome path]
/usr/bin/imqadmin -h
/usr/bin/imqadmin -v

**Description**
imqadmin launches the graphical user interface application that performs most Message Queue administration tasks. These tasks include managing broker instances (including physical destinations) and administered objects.

**Options**
The following options are supported:
- **-h**
  Display usage help. The application is not launched.
- **-javahome path**
  Specify a path to an alternate Java 2 compatible runtime.
- **-v**
  Display version information.

**Environment Variables**
The following environment variables affect the execution of this command:
- **IMQ_JAVAHOME**
  Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se.

**Exit Status**
The following exit values are returned:
- **0** Successful completion.
- **>0** An error occurred.

**Files**
$HOME/.imq/admin/brokerlist.properties
Contains user settings, a list of broker instances being managed.

$HOME/.imq/admin/objectstorelist.properties
Contains user settings, a list of object stores being managed.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWiq</td>
</tr>
</tbody>

*Sun Java System Message Queue Administrator’s Guide*
Name  imqbrokerd – start a Message Queue broker instance

Synopsis  /usr/bin/imqbrokerd [option...]

               /usr/bin/imqbrokerd -h

Description  imqbrokerd starts an instance of the Message Queue broker. The Message Queue broker is the
              main component of a Message Queue message server. The broker performs reliable delivery of
              messages to and from Java Message Service (JMS) clients.

              imqbrokerd uses command line options to specify broker configuration properties.

Options  The following options are supported:

    -backup fileName  Back up a Master Broker's configuration change
                     record to fileName. This option only applies to
                     broker clusters.

    -cluster brokerList  Specify the list of broker instances which are
                        connected in a cluster. This list is merged with the
                        list in the imq.cluster.brokerlist property. This
                        option only applies to broker clusters.

                        brokerList is a comma-separated list of broker
                        instances, each specified by hostName:port (the
                        host on which the broker instance is running and
                        the port number it is using). If you don't specify a
                        value for hostName, localhost is used. If you don't
                        specify a value for port, the value of 7676 is used.
                        For example: host1:8899, host2:7878.

    -dbpassword password  Specify the password for a plugged-in
                            JDBC-compliant database used as a Message
                            Queue data store.

    -dbuser userName  Specify the user name for a plugged-in
                      JDBC-compliant data store.

    -Dproperty=value  Set the specified broker configuration property to
                      the value. The system does not validate either the
                      configuration property or value. Therefore,
                      spelling, formatting, and case is important.
                      Message Queue cannot set incorrect values passed
                      using the -D option.

    -force  Perform action without user confirmation. This
            option only applies when you use the -remove
            instance option, which normally requires
            confirmation.
-h
  Display usage help. Execute nothing else on the command line.

-javahome path
  Specify the path to an alternate Java 2-compatible Java Development
  Kit (JDK) or Java Runtime Environment (JRE) The default is to use the
  runtime bundled with the operating system.

-ldappassword password
  Specify the password for accessing an LDAP user repository when using an
  LDAP server (as opposed to a built-in flat-file repository) to authenticate
  users of a Message Queue message server.

-license [name]
  Specify the license to load, if different from the default for your Message
  Queue product edition. If you don't specify a license name, this lists all
  licenses installed on the system. Depending on the installed Message Queue
  edition, the values for name are pe (Platform Edition-basic features),
  try (Platform Edition-90-day trial enterprise features),
  and unl (Enterprise Edition).

-loglevel level
  Specify the logging level. Valid values for level are NONE, ERROR,
  WARNING, or INFO. The default value is INFO.

-metrics int
  Report metrics at a specific interval. Specify int as the number of
  seconds.

-name brokerName
  Specify the instance name of this broker and use the corresponding
  instance configuration file. If you do not specify a broker name, the
  name of the file is set to imqbroker. If you run more than one
  instance of a broker on the same host, each must have a unique name.

-passfile filename
  Specify the name of the file from which to read the passwords for the
  SSL keystore, LDAP user repository, or JDBC-compliant database.

-password keypassword
  Specify the password for the SSL certificate
  keystore.

-port number
  Specify the broker's Port Mapper port number. By default, this is set to
  7676. To run two instances of a broker on the same server, each broker's Port
Mapper must have a different port number. JMS clients connect to the broker instance using this port number.

- **remove instance**  
  Remove the broker instance. Delete the instance configuration file, log files, data store, and other files and directories associated with the broker instance. This option requires user confirmation unless you also specify the `-force` option.

- **reset store|messages|durables|props**  
  Reset the data store (or a subset of the store) or resets the configuration properties of the broker instance when the broker instance is started. The action depends on the argument provided.

  - `store`  
    Clear all persistent data in the data store, including messages, durable subscriptions, and transaction information store.

  - `messages`  
    Clear all persistent messages durable.

  - `durables`  
    Clear all durable subscriptions.

  - `props`  
    Clear all configuration information in the `config.props` instance configuration file. All properties assume default values.

- **restore filename**  
  Replace the Master Broker's configuration change record with the specified backup file. This file must have been previously created using the `-backup` option. This option only applies to broker clusters.

- **shared**  
  Specify that the jms connection service be implemented using the shared threadpool model, in which threads are shared among connections to increase the number of connections supported by a broker instance.

- **silent**  
  Turn off logging to the console.

- **tty**  
  Display all messages be to the console. WARNING and ERROR level messages are displayed on the console by default.
-upgrade-store-nobackup Specify that an earlier, incompatible version Message Queue data store is automatically removed when migrating to Message Queue 3.5 format.

If you do not use this option, you must manually delete the earlier data store. This applies to both built-in (flat-file) persistence and plugged-in (JDBC-compliant) persistence. Migration of the earlier data store to a Message Queue 3.5 data store takes place the first time you start a Message Queue 3.5 broker instance on an earlier version data store.

-version Display the version number of the installed product.

-vmargs are [[arg]...] Specify arguments to pass to the Java VM. Separate arguments with spaces. If you want to pass more than one argument or if an argument contains a space, use enclosing quotation marks. For example:

```
imqbrokerd -tty -vmargs "-Xmx128m -Xincgc"
```
/var/imq/instances/brokerName/props/config.properties
Broker instance configuration file.

Sun Java System Message Queue Administrator's Guide
Name  
imqcmd – manage Message Queue brokers

Synopsis  
/usr/bin/imqcmd subcommand argument [option...]
/usr/bin/imqcmd [-h | -H]
/usr/bin/imqcmd -v

Description  
imqcmd manages the Message Queue broker, including resources such as connection services, physical destinations, durable subscriptions, and transactions. The utility provides a number of subcommands for managing these resources.

imqcmd supports many subcommands. Basic connection and authentication is required for the execution of every imqcmd subcommand. Use the -secure option to specify secure connections. Subcommands and their corresponding arguments and options follow the imqcmd command on the command line. See USAGE and OPTIONS.

Options  
The following options are supported:

- **b**  
  **hostName:port**  
  Specify the name of the host on which the broker instance is running and the port number it is using.

  The default value is localhost:7676. If you do not specify the -b option, imqcmd uses the default.

  To specify port only, use: -b:7878. This is equivalent to -b localhost:7878

  To specify name only, use: -b somehost. This is equivalent to -b somehost:7676.

- **c**  
  **clientID**  
  Specify the ID of the durable subscriber to a topic.

- **d**  
  **topicName**  
  Specify the name of the topic.

  Use this option with the list dur and destroy dur subcommands.

- **f**  
  Perform action without user confirmation.

  Use this option with any subcommand.

- **h**  
  Display usage help. Execute nothing else on the command line.

- **H**  
  Display usage help, attribute list, and examples. Execute nothing else on the command line.

- **int**  
  **interval**  
  Specify the interval, in seconds, at which the metrics bkr, metrics dst, and metrics svc subcommands display metrics output.

  Use this option with the metrics subcommand.

- **javahome**  
  Specify an alternate Java 2 compatible runtime to use.
-m metricType Specify the type of metric information to display.

Use this option with the metrics bkr, metrics dst, and metrics svc subcommands. The value of metricType depends on whether the metrics are generated for a destination, a service, or a broker.

Use one of the following values to specify metricType:

ttl Total of messages in and out of the broker (default)

rts Provides the same information as ttl, but specifies the number of messages per second

cxn Connections, virtual memory heap, threads

The following command displays connection, VM heap, and threads metric information for the default broker instance (localhost:7676) every five seconds:

```
imqcmd metrics bkr -m cxn -int 5
```

msp numSamples Specify the number of samples the metrics bkr, metrics dst, and metrics svc subcommands display in the metrics output.

-n argumentName Specify the name of the subcommand argument. Depending on the subcommand, this might be the name of a service, a physical destination, a durable subscription, or a transaction ID.

-o attribute=value Specify the value of an attribute. Depending on the subcommand argument, this might be the attribute of a broker, service, or destination.

-p password Specify the administrator password.

This option is deprecated. Use the -passfile option instead.

-passfile Specify the administrator password.

-pst pauseType Specify whether producers, consumers, or both are paused when pausing a destination.

Use this option with the pause dst subcommand. Use one of the following values:

CONSUMERS Pause delivery of messages to consumers.

PRODUCERS Pause delivery of messages from producers.

ALL Pause delivery of messages to consumers and from producers.
If the -pst option is not specified, pauses both consumers and producers (the equivalent of -pst ALL).

- **rtm timeout** Specify the timeout period in seconds of an `imqcmd` subcommand. The default value is 10.

- **rtr numRetries** Specify the number of retries attempted after an `imqcmd` subcommand times out.

  The default value is 5.

- **s** Silent mode. No output is displayed.

  Use this option with any subcommand.

- **secure** Specify a secure administration connection to the broker instance. You must first configure the broker to enable a secure connection service.

  Use this option whenever you want a secure communication with the broker.

- **svn serviceName** Specify the service for which the connections are listed.

  Use this option with the `list cxn` subcommand.

- **t destinationType** Specify the type of a destination: t (topic) or q (queue).

- **tmp** Include temporary destinations when listing destinations using the `list dst` subcommand.

- **u name** Specify the administrator user name.

  If you omit this value, you are prompted for it.

- **v** Display version information. Execute nothing else on the command line.

**Usage**

The following subcommands and associated arguments and options are supported:

```
compact dst [-t type -n destName]  
Commit the flat-file data store for the destination of the specified type and name. If no type and name are specified, all destinations are compacted. Destinations must be paused before they can be compacted.

commit txn -n transaction_id  
Commit the specified transaction
```
create dst -t destinationType -n destName [-o attribute=value] [-o attribute=value1]...
Create a destination of the specified type, with the specified name, and the specified
attributes. Destination names must contain only alphanumeric characters (no spaces) and
can begin with an alphabetic character or the underscore character (_).

destroy dst -t destinationType -n destName
Destroy the destination of the specified type and name.

destroy dur -n subscrName -c client_id
Destroy the specified durable subscription for the specified Client Identifier.

list cxn [-svn serviceName] [-b hostName:port]
List all connections of the specified service name on the default broker or on a broker at the
specified host and port. If the service name is not specified, all connections are listed.

list dst [-tmp]
List all destinations, with option of listing temporary destinations as well.

list dur -d destination
List all durable subscriptions for the specified destination.

list svc
List all connection services on the broker instance.

list txn
List all transactions, being tracked by the broker.

metrics bkr [-m metricType] [-i int interval] [-m sp numSamples]
Display broker metrics for the broker instance.

Use the -m option to specify the type of metric to display. Use one of the following values to
specify metricType:

ttl Specifies the total of messages in and out of the broker (default).

rts Provides the same information as ttl, but specifies the number of messages per
second.

cxn Connections, virtual memory heap, threads.

Use the -i int option to specify the interval (in seconds) at which to display the metrics. The
default is 5 seconds.

Use the -m sp option to specify the number of samples displayed in the output. A value of -1
means an unlimited number. The default value is -1.

metrics dst -t type -n destName [-m metricType] [-i int interval] [-m sp numSamples]
Displays metrics information for the destination of the specified type and name.

Use the -m option to specify the type of metrics to display. Use one of the following values
to specify metricType:
```plaintext

imqcmd(1M)

### Metrics

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ttl</td>
<td>Specifies the number of messages flowing in and out of the broker and residing in memory.</td>
</tr>
<tr>
<td>rts</td>
<td>Provides the same information as ttl, but specifies the number of messages per second.</td>
</tr>
<tr>
<td>con</td>
<td>Displays consumer related metrics.</td>
</tr>
<tr>
<td>dsk</td>
<td>Displays disk usage metrics.</td>
</tr>
</tbody>
</table>

Use the `--int` option to specify the interval (in seconds) at which to display the metrics. The default is 5 seconds.

Use the `--msp` option to specify the number of samples displayed in the output. A value of -1 means an unlimited number. The default value is 5.

```metrics

metrics svc [-n serviceName] [-m metricType] [-int interval] [-msp numSamples]

```

List metrics for the specified service on the broker instance. Use the `--m` option to specify the type of metric to display. Use one of the following values to specify `metricType`:

- **ttl**: Total of messages in and out of the broker (default)
- **rts**: Provides the same information as `ttl`, but specifies the number of messages per second
- **cxn**: Connections, virtual memory heap, threads

Use the `--int` option to specify the interval (in seconds) at which to display the metrics. The default is 5 seconds.

Use the `--msp` option to specify the number of samples displayed in the output. A value of -1 means an unlimited number. The default value is -1.

```pause

pause bkr
  Pause the broker instance.

pause dst [-t type -n destName] [-p t pauseType]
  Pause the delivery of messages to consumers (`-p t CONSUMERS`), or from producers (`-p t PRODUCERS`), or both (`-p t ALL`), for the destination of the specified type and name. If no destination type or name are specified, all destinations are paused.

pause svc -n serviceName
  Pause the specified service running on the broker instance. You cannot pause the administrative service.

purge dst -t destinationType -n destName
  Purge messages at the destination with the specified type and name.

purge dur -n subscrName -c client_id
  Purge all messages for the specified client identifier.
```
query bkr
    List the current settings of properties of the broker instance. Show the list of running brokers (in a multi-broker cluster) that are connected to the specified broker.

query dst -t destinationType -n destName
    List information about the destination of the specified type and name.

query svc -n serviceName
    Display information about the specified service running on the broker instance.

query txn -n transaction_id
    List information about the specified transaction.

reload cls
    Forces all the brokers in a cluster to reload the imq.cluster.brokerlist property and update cluster information. This subcommand only applies to broker clusters.

restart bkr
    Shut down and restart the broker instance. This command restarts the broker using the options specified when the broker was first started. If you want different options to be in effect, you must shut down the broker and then start it again, specifying the options you want.

resume bkr
    Resume the broker instance.

resume dst [-t type] [-n(destName)]
    Resumes the delivery of messages for the paused destination of the specified type and name. If no destination type and name are specified, all destinations are resumed.

resume svc -n serviceName
    Resume the specified service running on the broker instance.

rollback txn -n transaction_id
    Roll back the specified transaction.

shutdown bkr
    Shut down the broker instance.

update bkr -o attribute=value [-o attribute=value]...
    Change the specified attributes for the broker instance.

update dst -t destinationType -n destName -o attribute=value [-o attribute=value1]...
    Update the value of the specified attributes at the specified destination.

update svc -n serviceName -o attribute=value [-o attribute=value1]...
    Update the specified attribute of the specified service running on the broker instance.

Attribute Value Pairs
You can specify attributes with the create and update subcommands. Applicable attributes depend on the subcommand arguments.

The following attributes are supported:
Queue (dst):

maxTotalMsgBytes Value: Integer (maximum total size of messages, in bytes)
Default: 0 (unlimited)

maxBytesPerMsg Value: Integer (maximum size of a single message, in bytes)
Default: 0 (unlimited)

maxNumMsgs Value: Integer (maximum total number of messages)
Default: 0 (unlimited)

consumerFlowLimit Value: Integer (Initial number of queued messages sent to active consumers before load-balancing starts. A value of -1 means an unlimited number.)
Default: 1000

isLocalOnly Value: Boolean (destination limited to delivering messages to local consumers only) Default: false

limitBehavior Value: Specify how broker responds when memory-limit is reached. Use one of the following values:
- FLOW_CONTROL Slows down producers
- REMOVE_OLDEST Purges oldest messages
- REJECT_NEWEST Rejects the newest messages
Default: REJECT_NEWEST

localDeliveryPreferred Value: Boolean (Specify messages be delivered to remote consumers only if there are no consumers on the local broker. Requires that the destination not be restricted to local-only delivery (isLocalOnly = false))
Default: false

maxNumActiveConsumers Value: Integer (maximum number of active consumers in load-balanced delivery). A value of -1 means an unlimited number.
Default: 1

maxNumBackupConsumers Value: Integer (maximum number of backup consumers in load-balanced delivery). A value of -1 means an unlimited number.
Default: 0
maxNumProducers | Value: (maximum total number of producers) A value of -1 means an unlimited number.
| Default: -1

useDMQ | Specify whether a destination’s dead messages are discarded or put on the dead message queue.
| Default: true

**Topic (dst):**

c consumerFlowLimit | Value: Integer Maximum number of messages delivered to a consumer in a single batch. A value of -1 means an unlimited number.
| Default: 1000

isLocalOnly | Value: Boolean (destination limited to delivering messages to local consumers only)
| Default: false

limitBehavior | Value: Specify how broker responds when memory-limit is reached. Use one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLOW_CONTROL</td>
<td>Slows down producers</td>
</tr>
<tr>
<td>REMOVE_OLEST</td>
<td>Purges the oldest messages</td>
</tr>
<tr>
<td>REJECT_NEWEST</td>
<td>Rejects the newest messages</td>
</tr>
</tbody>
</table>

| Default: REJECT_NEWEST

maxBytesPerMsg | Value: Integer (maximum size of a single message, in bytes)
| Default: 0 (unlimited)

maxNumMsgs | Value: Integer (maximum total number of messages) A value of -1 means an unlimited number.
| Default: -1

maxNumProducers | Value: (maximum total number of producers)
| Default: 0 (unlimited)

maxTotalMsgBytes | Value: Integer (maximum total size of messages, in bytes) A value of -1 means an unlimited number.
| Default: -1
### useDMQ

Specify whether a destination's dead messages are discarded or put on the dead message queue.

**Default:** `true`

### Broker (bkr):

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Description</th>
</tr>
</thead>
</table>
| imq.autocreate.destination.useDMQ | Value: Boolean. Set the `useDMQ` attribute to `true` to enable all autocreated physical destinations on a broker to use the dead message queue. Set the `useDMQ` attribute to `false` to disable all autocreated physical destinations on a broker from using the dead message queue.  
**Default:** `true`
| imq.autocreate.queue | Value: Boolean  
**Default:** `true`
| imq.autocreate.queue.maxNumActiveConsumers | Value: Integer (maximum number of consumers that can be active in load-balanced delivery from an autocreated queue destination) A value of `-1` means an unlimited number.  
**Default:** `1`
| imq.autocreate.queue.maxNumBackupConsumers | Value: Integer (maximum number of backup consumers that can take the place of active consumers) A value of `-1` means an unlimited number.  
**Default:** `0`
| imq.autocreate.topic | Value: Boolean  
**Default:** `true`
| imq.cluster.url | Value: String (location of cluster configuration file)  
**Default:** `none`
| imq.log.file.rolloverbytes | Value: Integer (maximum size of a log file, in bytes)
**imq.log.file.rolloversecs**

Value: Integer (maximum age of a log file, in seconds)

Default: 0 (no rollover based on size)

**imq.log.level**

Value: String (NONE, ERROR, WARNING, INFO)

Default: INFO

**imq.message.max_size**

Value: Integer (maximum size of a single message, in bytes)

Default: 70m

**imq.portmapper.port**

Value: Integer

Default: 7676

**imq.system.max_count**

Value: Integer (maximum total number of messages)

Default: 0 (no limit)

**imq.system.max_size**

Value: Integer (maximum total size of messages, in bytes)

Default: 0 (no limit)

**Service (svc):**

**maxThreads**

Value: Integer (maximum threads assigned)

Default: Depends on service

**minThreads**

Value: Integer (minimum threads assigned)

Default: Depends on service

**port**

Value: Integer

Default: 0 (dynamically allocated)

**Examples**

**EXAMPLE 1  Shutting Down a Broker**

The following command shuts down a broker for hostname myserver on port 7676:

```
mqcmd shutdown bkr -b myserver:7676
```
EXAMPLE 2  Restarting a Broker
The following command restarts a broker for hostname myserver:

    imqcmd restart bkr -b myserver

EXAMPLE 3  Pausing a Service
The following command pauses a broker for hostname localhost on port 7676, with a serviceName of jms:

    imqcmd pause svc -n jms -b :7676

EXAMPLE 4  Resuming a Service
The following command resumes a service for hostname localhost on port 7676, with a serviceName of jms:

    imqcmd resume svc -n jms -b myserver:7676

EXAMPLE 5  Creating a Queue Destination
The following command creates a queue destination for hostname myserver on port 7676, with a destName of myFQ, a queueDeliveryPolicy of Failover, and a maxBytesPerMsg of 10000:

    imqcmd create dst -n myFQ -t q -o "queueDeliveryPolicy=f" -o "maxBytesPerMsg=10000" -b myserver:7676

EXAMPLE 6  Purging a Queue Destination
The following command purges a queue destination for hostname myserver on port 7676, with a destName of myFQ:

    imqcmd purge dst -n myFQ -t q -b myserver:7676

EXAMPLE 7  Listing Destinations on a Broker
The following command lists destinations for hostname myserver on port 7676:

    imqcmd list dst -b myserver:7676

EXAMPLE 8  Updating a Portmapper Port
The following command updates a portmapper port on hostname myserver from port 7676 to 7878:

    imqcmd update bkr -o "imq.portmapper.port=7878"

EXAMPLE 9  Updating the Maximum Number of Messages in the Queue
The following command updates the maximum number of messages in the queue to 2000 for myserver on port 8080 with a destName of TestQueue:

    imqcmd update dst -b myserver:8080 -n TestQueue -t q -o "maxNumMsgs=2000"
EXAMPLE 10  Updating the Maximum Threads
The following command updates the maximum threads jms connection service to 200 for hostname localhost on port 7676:

```
imqcmd update svc -n jms -o "minThreads=200"
```

EXAMPLE 11  Listing Durable Subscriptions
The following command lists durable subscriptions for a topic with hostname localhost on port 7676 with a destName of myTopic:

```
imqcmd list dur -d myTopic
```

EXAMPLE 12  Destroying Durable Subscriptions
The following command destroys subscriptions for hostname localhost on port 7676 with a dursubName of myDurSub and a client_ID of 111.222.333.444:

```
imqcmd destroy dur -n myDurSub -c "111.222.333.444"
```

EXAMPLE 13  Listing All Transactions
The following command lists all transactions on a broker with hostname localhost on port 7676:

```
imqcmd list txn
```

EXAMPLE 14  Displaying Information About a Transaction
The following command displays information about a transaction with hostname localhost on port 7676, and a transactionID of 1234567890

```
imqcmd query txn -n 1234567890
```

EXAMPLE 15  Committing a Transaction
The following command commits a transaction with hostname localhost on port 7676, and a transactionID of 1234567890:

```
imqcmd commit txn -n 1234567890
```

Environment Variables
The following environment variables affect the execution of this command:

- `IMQ_JAVAHOME` Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to `/usr/j2se`.

Exit Status
The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

Sun Java System Message Queue Administrator’s Guide
**Name**
imqdbmgr – manage a plugged-in JDBC-compliant Message Queue data store

**Synopsis**
/usr/bin/imqdbmgr subcommand argument [ option...]
/usr/bin/imqdbmgr -h | -help
/usr/bin/imqdbmgr -v | -version

**Description**
The imqdbmgr utility creates and manages a Java Database Connectivity (JDBC) compliant database used for Message Queue persistent storage.

The database can be either embedded or external. To use a JDBC-compliant database (and the imdbmgr utility), you need to first set a number of JDBC-related properties in the broker instance configuration file. See the Sun Java System Message Queue Administrator's Guide for additional information.

imqdbmgr supports four management subcommands. These subcommands, and their corresponding arguments and options follow the imqdbmgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:
create Create a Message Queue database schema.
delete Delete Message Queue database tables in the current data store.
recreate Delete Message Queue database tables and recreate Message Queue database schema in the current data store.
reset Reset the database table lock to allow other processes to access database tables.

The imqdbmgr subcommands support the following arguments:
all Indicates the subcommand applies to the data store, as well as the database tables.
lck Indicates the subcommand applies to the database table lock.
oldtbl Indicates the subcommand applies to an older version of the database tables.
tbl Indicates the subcommand applies to the database tables only.

**Options**
The following options are supported:
-b brokerName Specify the broker instance name and corresponding instance configuration properties. If this option is not specified, the default broker instance is assumed.

Use this option with the create, delete, recreate, or reset subcommands.

-D property=value Set system property property to value.
Use this option with the create, delete, recreate, or reset subcommands.

- h | - help Display usage help. Execute nothing else on the command line.

- p password Specify the database password.

Use this option with the create, delete, recreate, or reset subcommands.

- u userName Specify the database user name.

Use this option with the create, delete, recreate, or reset subcommands.

- v | - version Display version information. Execute nothing else on the command line.

Usage

The following subcommands and associated arguments are supported:

create all Create a new embedded data store and Message Queue database schema for a specified or default broker instance.

create tbl [-u userName] [-p password] Create Message Queue database schema in an existing data store for a specified or default broker instance.

delete tbl [-u userName] [-p password] Delete Message Queue database tables in the current data store for a specified or default broker instance.

delete oldtbl [-u userName] [-p password] Delete the earlier version of Message Queue database tables. Used after the data store has been automatically migrated to the current version of Message Queue.

recreate tbl [-u userName] [-p password] Delete Message Queue database tables and recreate Message Queue database schema in the current data store for a specified or default broker instance.

reset lck Reset the database table lock to allow other processes to access database tables.

Environment Variables

The following environment variables affect the execution of this command:

IMQ_JAVAHOME Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se.
Exit Status  The following exit values are returned:

0  Successful completion.
>0  An error occurred.

Files  
/var/imq/instances/brokerName/dbstore  Recommended directory in which to create an embedded database.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWiqu</td>
</tr>
</tbody>
</table>

See Also  
imqadmin(1M), imqbrokerd(1M), imqcmd(1M), imqusermgr(1M), imqkeytool(1M), imqobjmgr(1M), attributes(5)

Sun Java System Message Queue Administrator's Guide
The `imqkeytool` utility generates a self-signed certificate for secure communication. The certificate can be used by a broker instance to establish a secure connection with a client, or by a Message Queue-supplied HTTPS servlet to establish a secure connection with a broker instance. An HTTPS servlet is an SSL-enabled variant of the HyperText Transfer Protocol that establishes a secure connection with a broker instance.

Without an option, `imqkeytool` generates a self-signed certificate for a broker instance.

`imqkeytool` uses command line options to specify whether the certificate is used by a broker instance or by a servlet.

**Options**

The following options are supported:

- **-broker**
  - Generate a self-signed certificate for the broker and places it in the Message Queue keystore. All broker instances running on a system must use the same certificate.

- **-h**
  - Display usage help. Do not execute anything else on the command line.

- **-servlet keystore_location**
  - Generate a self-signed certificate for an HTTPS servlet and places it in `keystore_location`.

  `keystore_location` refers to the location of the keystore. You should move this keystore to a location where it is accessible and readable by the Message Queue HTTPS servlet to establish a secure connection with a broker.

**Environment Variables**

The following environment variables affect the execution of this command:

- **IMQ_JAVAHOME**
  - Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to `/usr/j2se`.

**Exit Status**

The following exit values are returned:

- **0**
  - Successful completion.

- **>0**
  - An error occurred.

**Files**

- **/etc/imq/keystore**
  - Contains Message Queue keystore in which `imqkeytool` stores a self-signed certificate for brokers.

Sun Java System Message Queue Administrator's Guide
Name  imqobjmgr – manage Message Queue administered objects

Synopsis  /usr/bin/imqobjmgr subcommand [[option]...]
          /usr/bin/imqobjmgr -i fileName
          /usr/bin/imqobjmgr -h | [-H] | -help | -Help
          /usr/bin/imqobjmgr -v

Description  imqobjmgr manages Message Queue administered objects in an object store accessible using JNDI. Administered objects allow JMS clients to be provider-independent by insulating them from provider-specific naming and configuration formats.

imqobjmgr supports five management subcommands. These subcommands, and their corresponding options follow the imqobjmgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:
add      Add a new administered object
delete   Delete an administered object
list     Display a list of administered objects
query    Display information about administered objects
update   Update administered objects

You can use the -i option to specify the name of an input file that uses Java property file syntax to represent all or part of any imqobjmgr subcommand clause. The -f, -s, and -pre options can be used with any imqobjmgr subcommand.

Options  The following options are supported:
- f      Perform action without user confirmation.
-h | -help  Display usage help. Execute nothing else on the command line.
-H | -Help  Display usage help, attribute list, and examples. Execute nothing else on the command line.
-i fileName  Specify the name of an input file containing all or part of the subcommand clause, specifying object type, lookup name, object attributes, object store attributes, or other options. Use this option for repetitive information, such as object store attributes.
-j attribute=value  Specify attributes necessary to identify and access a JNDI object store.
-javahome  Specify an alternate Java 2 compatible runtime to use. imqobjmgr uses the runtime bundled with the operating system by default.
-\ lookupName  Specify the JNDI lookup name of an administered object. This name must be unique in the object store’s context.
-o attribute=value  Specify the attributes of an administered object.
-pre  Run command in preview mode. Preview mode indicates what will be done without performing the command.
-r read-only_state  Specify if an administered object is a read-only object. A value of true indicates the administered object is a read-only object. JMS clients cannot modify the attributes of read-only administered objects. The read-only state is set to false by default.
-s  Silent mode. No output is displayed.
-t type  Specify the type of an administered object:
q = queue
t = topic
cf = ConnectionFactory
qcf = queueConnectionFactory
tcf = topicConnectionFactory
xcf = XA ConnectionFactory (distributed transactions)
qxcf = XA queueConnectionFactory (distributed transactions)
txcf = XA topicConnectionFactory (distributed transactions)
e = SOAP endpoint (used to support SOAP messaging)
-v  Display version information. Execute nothing else on the command line.

Usage
This section provides information on subcommands, options, and attribute value pairs.
The following subcommands and corresponding options are supported:
add -t type -\ lookupName [-o attribute=value]... -j attribute=value...
Add a new administered object of the specified type, lookup name, and object attributes to an object store.
delete -t type -\ lookupName -j attribute=value...
Delete an administered object, of the specified type and lookup name from an object store.
list [-t type] -j attribute=value...
Display a list of administered objects of a specified type, or all administered objects, in an object store.
query -\ lookupName -j attribute=value...
Display information about an administered object of a specified lookup name in an object store.
update -l lookupName [-o attribute=value]... -j attribute=value...
Update the specified attribute values of an administered object of the specified lookup name in an object store.

Attribute Value Pairs
The following attribute value pairs are supported for the specified administered object types:

Type = ConnectionFactories: ConnectionFactory, TopicConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XATopicConnectionFactory, and XAQueueConnectionFactory

imqAckOnAcknowledge
Value: String (true, false, not specified)
Default: not specified

imqAckOnProduce
Value: String (true, false, not specified)
Default: not specified

imqAckTimeout
Value: String (time in milliseconds)
Default: 0 (no timeout)

imqAddressList
Value: String
Default: not specified

imqAddressListBehavior
Value: String
Default: Priority

imqAddressListIterations
Value: Integer
Default: 1

imqBrokerHostName
Used if imqConnectionType is TCP or TLS. This attribute type is only supported in Message Queue 3.0.
Value: String
Default: localhost

imqBrokerHostPort
Used if imqConnectionType is TCP or TLS. This attribute type is only supported in Message Queue 3.0.
Value: Integer
Default: 7676

imqBrokerServicePort
Used if imqConnectionType is TCP or TLS. This attribute type is only supported in Message Queue 3.0.

Value: Integer
Default: 0

imqConfiguredClientId
Value: String (ID number)
Default: no ID specified

imqConnectionFlowCount
Value: Integer
Default: 100

imqConnectionFlowLimit
Value: Integer
Default: 1000

imqConnectionFlowLimitEnabled
Value: Boolean
Default: false

imqConnectionType
This attribute type is only supported in Message Queue 3.0.

Value: String (TCP, TLS, HTTP).
Default: TCP

imqConnectionURL
Used if imqConnectionType is HTTP. This attribute type is only supported in Message Queue 3.0.

Value: String
Default: http://localhost/imq/tunnel

imqConsumerFlowLimit
Value: Integer
Default: 1000
imqConsumerFlowThreshold
   Value: Integer
   Default: 50

imqDefaultPassword
   Value: String
   Default: guest

imqDefaultUsername
   Value: String
   Default: guest

imqDisableSetClientID
   Value: Boolean
   Default: false

imqJMSDeliveryMode
   Value: Integer (1=non-persistent, 2=persistent)
   Default: 2

imqJMSExpiration
   Value: Long (time in milliseconds)
   Default: 0 (does not expire)

imqJMSPriority
   Value: Integer (0 to 9)
   Default: 4

imqLoadMaxToServerSession
   Value: Boolean
   Default: true

imqOverrideJMSDeliveryMode
   Value: Boolean
   Default: false

imqOverrideJMSExpiration
   Value: Boolean
   Default: false

imqOverrideJMSHeadersToTemporaryDestinations
   Value: Boolean
   Default: false
imqOverrideJMSPriority
   Value: Boolean
   Default: false

imqQueueBrowserMaxMessagesPerRetrieve
   Value: Integer
   Default: 1000

imqBrowserRetrieveTimeout
   Value: Long (time in milliseconds)
   Default: 60,000

imqReconnectAttempts
   Value: Integer
   Default: 0

imqReconnectEnabled
   Value: Boolean
   Default: false

imqReconnectInterval
   Value: Long (time in milliseconds)
   Default: 3000

imqSetJMSXAppID
   Value: Boolean
   Default: false

imqSetJMSXConsumerTXID
   Value: Boolean
   Default: false

imqSetJMSXProducerTXID
   Value: Boolean
   Default: false

imqSetJMSXRcvTimestamp
   Value: Boolean
   Default: false

imqSetJMSXUserID
   Value: Boolean
   Default: false
imqSSLIsHostTrusted
Used if imqConnectionType is TLS. This attribute type is only supported in Message Queue 3.0.

Value: Boolean
Default: true

Type = Destinations: Topic and Queue
imqDestinationDescription Value: String
Default: no description

imqDestinationName Value: String
Default: Untitled_Destination_Object

Type = Endpoint (SOAP Endpoint)
imqEndpointDescription Value: String
Default: A description for the endpoint object

imqEndpointName Value: String
Default: Untitled_Endpoint_Object

imqSOAPEndpointList Value: String (one or more space-separated URLs)
Default: no url

Examples

EXAMPLE 1  Adding a Topic Administered Object to an Object Store

Where JNDI lookup name=myTopic and imqDestinationName=MyTestTopic, the following command adds to an LDAP server object store:

imqobjmgr add -t t -l "cn=myTopic"
-o "imqDestinationName=MyTestTopic"
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"

Where JNDI lookup name=myTopic and imqDestinationName=MyTestTopic, the following command adds to a file system object store:

imqobjmgr add -t -l "cn=myTopic"
-o "imqDestinationName=MyTestTopic"
-j "java.naming.factory.initial=com.sun.jndi.fscontext.ReffFSContextFactory"
-j "java.naming.provider.url=file:/home/foo/imq_admin_objects"
EXAMPLE 1  Adding a Topic Administered Object to an Object Store (Continued)

Where JNDI lookup name=myTopic and imqDestinationName=MyTestTopic, the following command adds to a file system object store, using an input file:

    imqobjmgr -i inputfile

The associated input file consists of the following:

```
  cmdtype=add
  obj.type=t
  obj.lookupName=cn=myTopic
  obj.attrs.imqDestinationName=MyTestTopic
  objstore.attrs.java.naming.factory.initial=com.sun.jndi.fscontext.RefFSContextFactory
  objstore.attrs.java.naming.provider.url=file:/home/foo/imq_admin_objects
```

EXAMPLE 2  Adding a QueueConnectionFactory Administered Object to an Object Store

Where JNDI lookup name=myQCF, read-only state=true, imqAddressList=mq://foohost:777/jms, the following command adds to an LDAP server object store:

```
imqobjmgr add -t qf -l "cn=myQCF" -r true
  -o "imqAddressList=mq://foohost:777/jms"
  -j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"
  -j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"
```

Where JNDI lookup name=myQCF, read-only state=true, imqAddressList=mq://foohost:777/jms, the following command adds to an LDAP server object store using an input file:

```
imqobjmgr -i inputfile
```

The associated input file consists of the following:

```
  cmdtype=add
  obj.type=qf
  obj.lookupName=cn=myQCF
  obj.readOnly=true
  obj.attrs.imqAddressList=mq://foohost:777/jms
  objstore.attrs.java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory
  objstore.attrs.java.naming.provider.url=ldap://mydomain.com:389/o=imq
```

Where JNDI lookup name=myQCF, read-only state=true, imqAddressList=mq://foohost:777/jms, the following command adds to an LDAP server object store, using both an input file and command options:
**EXAMPLE 2**  Adding a QueueConnectionFactory Administered Object to an Object Store (Continued)

imqobjmgr add -t qf -l "cn=myQCF"
-o "imqAddressList=mq://foohost:777/jms"
-i inputfile

The associated input file consists of the following:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>objstore.attrs.java.naming.factory.initial</td>
<td>com.sun.jndi.ldap.LdapCtxFactory</td>
</tr>
<tr>
<td>objstore.attrs.java.naming.provider.url</td>
<td>ldap://mydomain.com:389/o=imq</td>
</tr>
</tbody>
</table>

**EXAMPLE 3**  Deleting a Topic Administered Object from an Object Store

Where JNDI lookup name=myTopic and no confirmation is requested, the following command deletes from an LDAP server object store:

imqobjmgr delete -f -l "cn=myTopic"
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"

**EXAMPLE 4**  Querying Information About a Topic Administered Object

Where JNDI lookup name=myTopic, the following command queries from an LDAP server object store using simple authentication scheme:

imqobjmgr query -l "cn=myTopic"
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"
-j "java.naming.security.authentication=simple"
-j "java.naming.security.principal=uid=foo,ou=imqobjmgr,o=imq"
-j "java.naming.security.credentials=foo"

**Exit Status**  The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.

*Sun Java System Message Queue Administrator's Guide*
## Name
imqusermgr – command utility for managing a Message Queue user repository

## Synopsis
```
/usr/bin/imqusermgr subcommand [[option]...]
```
```
/usr/bin/imqusermgr -h
```
```
/usr/bin/imqusermgr -v
```

## Description
The `imqusermgr` utility manages a file-based user repository to authenticate and authorize users of a Message Queue message server.

`imqusermgr` provides subcommands for adding, deleting, updating, and listing user entries in the repository.

`imqusermgr` supports four management subcommands. These subcommands, and their corresponding options, follow the `imqusermgr` command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:

- **add** Add a new user and associated password to the repository.
- **delete** Delete a user from the repository.
- **list** Display information about users in the repository.
- **update** Update the password or state of a user in the repository.

## Options
The following options are supported:

- **-a active_state** Specify if user’s state is active or inactive. An inactive user cannot create connections to the Message Queue message server.

  Valid values for `active_state` are `true` or `false`. Specify `true` for active or `false` for inactive. The default is `true`.

  Use this option with the **update** subcommand.

- **-f** Perform action without user confirmation.

  Use this option with the **delete** and **update** subcommands.

- **-g group** Specify the group of the user.

  Valid values for group are `admin`, `user`, and `anonymous`.

  Use this option with the **add** subcommand.

- **-h** Display usage help. Execute nothing else on the command line.

- **-i brokerName** Specify the broker instance user repository to which the command applied.

  If you do not specify `brokerName`, the default `brokerName` is assumed.
Use this option with the add, delete, list, and update subcommands.

- p password  Specify user password.

Use this option with the add and update subcommands.

- s  Silent mode. Display no output

Use this option with the add, delete, and update subcommands.

- u userName  Specify user name.

userName cannot contain the following characters: asterisk (*), colon (:), NEWLINE, or RETURN.

Use this option with the add, delete, update and list subcommands.

- v  Display version information. Execute nothing else on the command line.

Usage  The following subcommands and corresponding options are supported:

add - u userName - p password [-g group] [- s] [- i brokerName]  
Add a new user and associated password to the repository, and optionally specify the user's group.

delete - u userName [- s] [- f] [- i brokerName]  
Delete a user from the repository.

list [- u userName] [- i brokerName]  
Display information about the specified user in the repository. If no user is specified, all users are displayed.

update - u userName - p password [- a state] [- s] [- f] [- i brokerName]  
update - u userName - a state [- p password] [- s] [- f] [- i brokerName]  
Update the password or state (or both) of a user.

Environment Variables  The following environment variables affect the execution of this command:

IMQ_JAVAHOME  Specify the Java 2 compatible runtime. When this environment variable is not set, it defaults to /usr/j2se.

Exit Status  The following exit values are returned:

0  Successful completion.

>0  An error occurred.

Files  /etc/imq/passwd  Flat-file user repository.

Sun Java System Message Queue Administrator's Guide
in.chargend – UDP or TCP character generator service daemon

**Synopsis**

```
FMRI svc:/internet/chargen:default
```

**Description**

FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See `fmd(1M)` and `smf(5)`.

The `in.chargend` service provides the server-side of the character-generator protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 19.

The `in.chargend` service is an `inetd(1M) smf(5)` delegated service. The `in.chargend` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

**TCP-based service**

Once a connection is established, the `in.chargend` generates a stream of data. Any data received is discarded. The server generates data until the client program terminates the connection. Note that the data flow is limited by TCP flow control mechanisms.

**UDP-based service**

The `in.chargend` listens for UDP datagrams. When a datagram is received, the server generates a UDP datagram in response containing a random number of ASCII characters (ranging from 0 to 512 characters). Any received data is ignored.

The `in.chargend` data consists of a pattern of 72 character lines containing the printable, 7–bit ASCII characters. Each line is terminated with a carriage return and a line feed character.

**Attributes**

RFC 864
in.comsat(1M)

**Name**  
in.comsat, comsat – biff server

**Synopsis**  
/usr/sbin/in.comsat

**Description**  
comsat is the server process which listens for reports of incoming mail and notifies users who have requested to be told when mail arrives. It is invoked as needed by inetd(1M), and times out if inactive for a few minutes.

comsat listens on a datagram port associated with the biff service specification (see services(4)) for one line messages of the form

*user*@*mailbox-* *offset*

If the *user* specified is logged in to the system and the associated terminal has the owner execute bit turned on (by a biff y), the *offset* is used as a seek offset into the appropriate mailbox file, and the first 7 lines or 560 characters of the message are printed on the user’s terminal. Lines which appear to be part of the message header other than the From, To, Date, or Subject lines are not printed when displaying the message.

**Files**  
/var/adm/utmpx user access and administration information

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWrcmds</td>
</tr>
</tbody>
</table>

**See Also**  
svcs(1), inetadm(1M), inetd(1M), svcadm(1M), services(4), attributes(5), smf(5)

**Notes**  
The message header filtering is prone to error.

The in.comsat service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/comsat:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
in.daytimed – UDP or TCP daytime protocol service daemon

Synopsis

FMRI svc:/internet/daytime:default

Description

FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See fmd(1M) and smf(5).

The in.daytimed service provides the server-side of the daytime protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 13.

The in.daytimed service is an inetd(1M) smf(5) delegated service. The in.daytimed service detects which transport is requested by examining the socket it is passed by the inetd daemon.

TCP-based service

Once a connection is established, the in.daytimed generates the current date and time in ctime(3C) format as 7-bit ASCII and sends it through the connection. The server then closes the connection. Any data received from the client side of the connection is discarded.

UDP-based service

The in.daytimed listens for UDP datagrams. When a datagram is received, the server generates the current date and time in ctime(3C) format as 7-bit ASCII and inserts it in a UDP datagram sent in response to the client's request. Any received data is ignored.

Attributes

RFC 867
**Name**
in.dhcpd – Dynamic Host Configuration Protocol server

**Synopsis**
```
/usr/lib/inet/in.dhcpd [-denv] [-h relay_hops] [-i interface, ...]
  [-l syslog_local_facility] [-b automatic | manual]
  [-o DHCP_offer_time] [-t dhcptab_rescan_interval]
```
```
/usr/lib/inet/in.dhcpd [-dv] [-h relay_hops] [-i interface, ...]
  [-l syslog_local_facility] -r IP_address | hostname, ...
```

**Description**
in.dhcpd is a daemon that responds to Dynamic Host Configuration Protocol (DHCP) requests and optionally to BOOTP protocol requests. The daemon forks a copy of itself that runs as a background process. It must be run as root. The daemon has two run modes, DHCP server (with optional BOOTP compatibility mode) and BOOTP relay agent mode.

The first line in the SYNOPSIS section illustrates the options available in the DHCP/BOOTP server mode. The second line in the SYNOPSIS section illustrates the options available when the daemon is run in BOOTP relay agent mode.

The DHCP and BOOTP protocols are used to provide configuration parameters to Internet hosts. Client machines are allocated their IP addresses as well as other host configuration parameters through this mechanism.

The DHCP/BOOTP daemon manages two types of DHCP data tables: the dhcptab configuration table and the DHCP network tables.

See [dhcptab(4)](manpage) regarding the dhcptab configuration table and [dhcp_network(4)](manpage) regarding the DHCP network tables.

The dhcptab contains macro definitions defined using a termcap-like syntax which permits network administrators to define groups of DHCP configuration parameters to be returned to clients. However, a DHCP/BOOTP server always returns hostname, network broadcast address, network subnet mask, and IP maximum transfer unit (MTU) if requested by a client attached to the same network as the server machine. If those options have not been explicitly configured in the dhcptab, in.dhcpd returns reasonable default values.

The dhcptab is read at startup, upon receipt of a SIGHUP signal, or periodically as specified by the -t option. A SIGHUP (sent using the command svcadm refresh network/dhcp-server) causes the DHCP/BOOTP daemon to reread the dhcptab within an interval from 0-60 seconds (depending on where the DHCP daemon is in its polling cycle). For busy servers, users should run svcadm restart network/dhcp-server to force the dhcptab to be reread.

The DHCP network tables contain mappings of client identifiers to IP addresses. These tables are named after the network they support and the datastore used to maintain them.

The DHCP network tables are consulted during runtime. A client request received from a network for which no DHCP network table exists is ignored.

This command may change in future releases of Solaris software. Scripts, programs, or procedures that use this command might need modification when upgrading to future Solaris software releases. The command line options provided with the in.dhcpd daemon are used...
only for the current session, and include only some of the server options you can set. The
\texttt{dhcpsvc.conf(4)} contains all the server default settings, and can be modified by using the
dhcpsvc utility. See \texttt{dhcpsvc.conf(4)} for more details.

**Options**  The following options are supported:

- \texttt{-b automatic | manual}  This option enables BOOTP compatibility mode, allowing
the DHCP server to respond to BOOTP clients. The option
argument specifies whether the DHCP server should
automatically allocate permanent lease IP addresses to
requesting BOOTP clients if the clients are not registered in
the DHCP network tables (\texttt{automatic}) or respond only to
BOOTP clients who have been manually registered in the
DHCP network tables (\texttt{manual}). This option only affects
DHCP server mode.

- \texttt{-d}  Debugging mode. The daemon remains as a foreground
process, and displays verbose messages as it processes
DHCP and/or BOOTP datagrams. Messages are displayed
on the current TTY. This option can be used in both
DHCP/BOOTP server mode and BOOTP relay agent mode.

- \texttt{-h relay_hops}  Specifies the maximum number of relay agent hops that can
occur before the daemon drops the DHCP/BOOTP
datagram. The default number of relay agent hops is 4. This
option affects both DHCP/BOOTP server mode and
BOOTP relay agent mode.

- \texttt{-I interface,...}  Selects the network interfaces that the daemon should
monitor for DHCP/BOOTP datagrams. The daemon
ignores DHCP/BOOTP datagrams on network interfaces
not specified in this list. This option is only useful on
machines that have multiple network interfaces. If this
option is not specified, then the daemon listens for
DHCP/BOOTP datagrams on all network interfaces. The
option argument consists of a comma-separated list of
interface names. It affects both DHCP/BOOTP server and
BOOTP relay agent run modes.

- \texttt{-l syslog_local_facility}  The presence of this option turns on transaction logging for
the DHCP server or BOOTP relay agent. The value specifies
the \texttt{syslog} local facility (an integer from 0 to 7 inclusive) the
DHCP daemon should use for tagging the transactions.
Using a facility separate from the \texttt{LOG_DAEMON} facility allows
the network administrator to capture these transactions
separately from other DHCP daemon events for such
purposes as generating transaction reports. See syslog(3C),
for details about local facilities. Transactions are logged
using a record with 9 space-separated fields as follows:

1. **Protocol:**
   - Relay mode: "BOOTP"
   - Server mode: "BOOTP" or "DHCP" based upon client
type.

2. **Type:**
   - Relay mode: "RELAY-CLNT", "RELAY-SRVR"
   - Server mode: "ASSIGN", "EXTEND", "RELEASE",
     "DECLINE", "INFORM", "NAK" "ICMP-ECHO."

3. **Transaction time:** absolute time in seconds (unix time)

4. **Lease time:**
   - Relay mode: **Always 0.**
   - Server mode: **0** for ICMP-ECHO events, absolute time in
     seconds (unix time) **otherwise**

5. **Source IP address:** Dotted Internet form
   - Relay mode: Relay interface IP on RELAY-CLNT,
     INADDR_ANY on RELAY-SRVR.
   - Server mode: Client IP.

6. **Destination IP address:** Dotted Internet form
   - Relay mode: Client IP on RELAY-CLNT, Server IP on
     RELAY-SRVR.
   - Server mode: Server IP.

7. **Client Identifier:** Hex representation (0-9, A-F)
   - Relay mode: MAC address
   - Server mode: BOOTP - MAC address; DHCP - client id

8. **Vendor Class identifier** (white space converted to
   periods (\)).
   - Relay mode: Always "N/A"
   - Server mode: Vendor class ID tokenized by
     converting white space characters
to periods (\)

9. **MAC address:** Hex representation (0-9, A-F)
### Relay and Server Mode

- **Relay mode:** MAC address
- **Server mode:** MAC address

The format of this record is subject to change between releases.

Transactions are logged to the console if daemon is in debug mode (`-d`).

Logging transactions impact daemon performance.

It is suggested that you periodically rotate the DHCP transaction log file to keep it from growing until it fills the filesystem. This can be done in a fashion similar to that used for the general system message log `/var/adm/messages` and is best accomplished using the facilities provided by `logadm(1M)`.

---

**-n**

Disable automatic duplicate IP address detection. When this option is specified, the DHCP server does not attempt to verify that an IP address it is about to offer a client is not in use. By default, the DHCP server pings an IP address before offering it to a DHCP/BOOTP client, to verify that the address is not in use by another machine.

**-o DHCP_offer_time**

Specifies the number of seconds the DHCP server should cache the offers it has extended to discovering DHCP clients. The default setting is 10 seconds. On slow network media, this value can be increased to compensate for slow network performance. This option affects only DHCP server mode.

**-r IP_address|hostname,...**

This option enables BOOTP relay agent mode. The option argument specifies a comma-separated list of IP addresses or hostnames of DHCP or BOOTP servers to which the relay agent is to forward BOOTP requests. When the daemon is started in this mode, any DHCP tables are ignored, and the daemon simply acts as a BOOTP relay agent.

A BOOTP relay agent listens to UDP port 68, and forwards BOOTP request packets received on this port to the destinations specified on the command line. It supports the `BROADCAST` flag described in RFC 1542. A BOOTP relay
agent can run on any machine that has knowledge of local routers, and thus does not have to be an Internet gateway machine.

Note that the proper entries must be made to the netmasks database so that the DHCP server being served by the BOOTP relay agents can identify the subnet mask of the foreign BOOTP/DHCP client’s network. See netmasks(4) for the format and use of this database.

-t dhcpd_rescan_interval

Specifies the interval in minutes that the DHCP server should use to schedule the automatic rereading of the dhcpd_rescan_interval information. Typically, you would use this option if the changes to the dhcpd_rescan_interval are relatively frequent. Once the contents of the dhcpd_rescan_interval have stabilized, you can turn off this option to avoid needless reinitialization of the server.

-v

Verbose mode. The daemon displays more messages than in the default mode. Note that verbose mode can reduce daemon efficiency due to the time taken to display messages. Messages are displayed to the current TTY if the debugging option is used; otherwise, messages are logged to the syslogd facility. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

Examples

**EXAMPLE 1**  Starting a DHCP Server in BOOTP Compatibility Mode

The following command starts a DHCP server in BOOTP compatibility mode, permitting the server to automatically allocate permanent IP addresses to BOOTP clients which are not registered in the server’s table; limits the server’s attention to incoming datagrams on network devices le2 and tr0; drops BOOTP packets whose hop count exceeds 2; configures the DHCP server to cache extended DHCP offers for 15 seconds; and schedules dhcpd_rescan_interval scans to occur every 10 minutes:

```
# in.dhcpd -i le2, tr0 -h 2 -o 15 -t 10 -b automatic
```

**EXAMPLE 2**  Starting the Daemon in BOOTP Relay Agent Mode

The following command starts the daemon in BOOTP relay agent mode, registering the hosts bladerunner and 10.0.0.5 as relay destinations, with debugging and verbose modes enabled, and drops BOOTP packets whose hop count exceeds 5:

```
# in.dhcpd -d -v -h 5 -r bladerunner, 10.0.0.5
```

System Administration Guide: IP Services

Droms, R., Interoperation Between DHCP and BOOTP, RFC 1534, Bucknell University, October 1993.

Notes

The in.dhcpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/dhcp-server

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
Name  in.discardd – UDP or TCP discard protocol service

Synopsis  in.discardd

FMRI  svc:/internet/discard:default

Description  FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See fmd(1M) and smf(5).

The in.discardd service provides the server-side of the discard protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports through port 9.

The in.discardd service is an inetd(1M) smf(5) delegated service. The in.discardd detects which transport is requested by examining the socket it is passed by the inetd daemon.

The discard service simply throws away any data it receives from the client.

TCP-based service  Once a connection is established, the in.discardd discards any data received. No response is generated. The connection remains open until the client terminates it.

UDP-based service  The in.discardd listens for UDP datagrams. When a datagram is received, the server discards it. No response is sent.

RFC 863
in.echod(1M)

**Name**  in.echod – UDP or TCP echo protocol service daemon

**Synopsis**  

```
FMRI svc:/internet/echo:default
```

**Description**  
FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See fmd(1M) and smf(5).

The in.echod service provides the server-side of the echo protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 7.

The in.echod service is an inetd(1M) smf(5) delegated service. The in.echod detects which transport is requested by examining the socket it is passed by the inetd daemon.

**TCP-based service**  
Once a connection is established, the in.echod echoes any data received from the client back to the client. The server echoes data until the client program terminates the connection.

**UDP-based service**  
The in.echod listens for UDP datagrams. When a datagram is received, the server creates a UDP datagram containing the data it received and sends it to the client.

RFC 862
inetadm – observe or configure inetd-controlled services

**Synopsis**

```
inetadm
inetadm -?
inetadm -p
inetadm -l {FMRI | pattern}
inetadm -e {FMRI | pattern}
inetadm -d {FMRI | pattern}
inetadm -m {FMRI | pattern}... {name=value}...
inetadm -M {name=value}...
```

**Description**

The `inetadm` utility provides the following capabilities for `inetd`-managed SMF services:

- Provides a list of all such services installed.
- Lists the services' properties and values.
- Allows enabling and disabling of services.
- Allows modification of the services' property values, as well as the default values provided by `inetd`.

See `smf(5)` for a description of an SMF service.

With no arguments, `inetadm` lists all services under `inetd(1M)` control, including such attributes as their current run state and whether or not they are enabled.

**Options**

For options taking one or more FMRI operands (see `smf(5)` for a description of an FMRI), if the operand specifies a service (instead of a service instance), and that service has only a single instance, `inetadm` operates on that instance.

If a service name is supplied and it contains more than one instances or a pattern is supplied and it matches more than one instance, a warning message is displayed and that operand is ignored.

For those options taking `name=value` parameters, a description of each of the possible names and the allowed values is found in the `inetd(1M)` man page.

The following options are supported:

```
-?
Display a usage message.

-p Lists all default inet service property values provided by inetd in the form of name=value pairs. If the value is of boolean type, it is listed as TRUE or FALSE.
```
- \{FMRI | pattern\}... List all properties for the specified service instances as *name*=*value* pairs. In addition, if the property value is inherited from the default value provided by *inetd*, the *name*=*value* pair is identified by the token (default). Property inheritance occurs when properties do not have a specified service instance default.

- e \{FMRI | pattern\}... Enable the specified service instances.

- d \{FMRI | pattern\}... Disable the specified service instances.

- m \{FMRI | pattern\}...{name=value}... Change the values of the specified properties of the identified service instances. Properties are specified as whitespace-separated *name*=*value* pairs. To remove an instance-specific value and accept the default value for a property, simply specify the property without a value, for example, *name=*.

- M \{name=value\}... Change the values of the specified *inetd* default properties. Properties are specified as whitespace-separated *name*=*value* pairs.

**Examples**

**EXAMPLE 1** Displaying Properties for a Service

The following command displays the properties for the *spray* service.

```
# inetadm -l network/rpc/spray:default
SCOPE   NAME=VALUE
   name="sprayd"
   endpoint_type="tli"
   proto="datagram_v"
   isrpc=TRUE
   rpc_low_version=1
   rpc_high_version=1
   wait=TRUE
   exec="/usr/lib/netsvc/spray/rpc.sprayd"
   user="root"
   default bind_addr=""
   default bind_fail_max=-1
   default bind_fail_interval=-1
   default max_con_rate=-1
   default max_copies=-1
   default con_rate_offline=-1
   default failrate_cnt=40
   default failrate_interval=60
   default inherit_env=TRUE
   default tcp_trace=FALSE
```
EXAMPLE 1  Displaying Properties for a Service  (Continued)

default tcp_wrappers=FALSE
default connection_backlog=10

EXAMPLE 2  Displaying Default Properties

The following command displays default properties.

```
# inetadm -p
NAME=VALUE
bind_addr=""
bind_fail_max=-1
bind_fail_interval=-1
max_con_rate=-1
max_copies=-1
con_rate_offline=-1
failrate_cnt=40
failrate_interval=60
inherit_env=TRUE
tcp_trace=FALSE
tcp_wrappers=FALSE
default connection_backlog=10
```

EXAMPLE 3  Changing Property Values for a Service

The following command changes rpcl_high_version to 3 and tcp_trace to TRUE for the spray service.

```
# inetadm -m network/rpc/spray:default \ 
  rpc_high_version=3 tcp_trace=TRUE
# inetadm -l network/rpc/spray:default
```

SCOPE     NAME=VALUE
name="sprayd"
endpoint_type="tli"
proto="datagram_v"
isrpc=TRUE
rpc_low_version=1
rpc_high_version=3
wait=TRUE
exec="/usr/lib/netsvc/spray/rpc.sprayd"
user="root"
default bind_addr=""
default bind_fail_max=-1
default bind_fail_interval=-1
default max_con_rate=-1
default max_copies=-1
default con_rate_offline=-1
default failrate_cnt=40
EXAMPLE 3  Changing Property Values for a Service  (Continued)

default  failrate_interval=60
default  inherit_env=TRUE
tcp_trace=TRUE
default  tcp_wrappers=FALSE
default  connection_backlog=10

Exit Status  The following exit values are returned:

0  Operation completed successfully.
1  A fatal error occurred. An accompanying error message will provide further information.
2  Invalid arguments were supplied, such as an ambiguous service FMRI or pattern.

inetconv – convert inetd.conf entries into smf service manifests, import them into smf repository

Synopsis
inetconv -?
inetconv [-f] [-n] [-i srcfile] [-o destdir]
inetconv -e [-n] [-i srcfile]

Description
The inetconv utility converts a file containing records of inetd.conf(4) into smf(5) service manifests, and then import those manifests into the smf repository. Once the inetd.conf file has been converted, the only way to change aspects of an inet service is to use the inetadm(1M) utility.

There is a one-to-one correspondence between a service line in the input file and the manifest generated. By default, the manifests are named using the following template:
<svcname>-<proto>.xml

The <svcname> token is replaced by the service's name and the <proto> token by the service's protocol. Any slash (/) characters that exist in the source line for the service name or protocol are replaced with underscores (_).

The service line is recorded as a property of the converted service.

During the conversion process, if a service line is found to be malformed or to be for an internal inetd service, no manifest is generated and that service line is skipped.

The input file is left untouched by the conversion process.

Options
The following options are supported:
- ? Display a usage message.
- e Enable smf services which are listed in the input file.
- f If a service manifest of the same name as the one to be generated is found in the destination directory, inetconv will overwrite that manifest if this option is specified. Otherwise, an error message is generated and the conversion of that service is not performed.
- i srcfile Permits the specification of an alternate input file srcfile. If this option is not specified, then the inetd.conf(4) file is used as input.
- n Turns off the auto-import of the manifests generated during the conversion process. Later, if you want to import a generated manifest into the smf(5) repository, you can do so through the use of the svccfg(1M) utility.

If the -e option is specified, the -n option only displays the smf services that would be enabled.
Permitsthespecificationofanalternatedestinationdirectory `destdir` for the generated manifests. If this option is not specified, then the manifests are placed in `/var/svc/manifest/network/rpc`, if the service is a RPC service, or `/var/svc/manifest/network` otherwise.

**Examples**

**EXAMPLE 1** Generating smf Manifests from `inetd.conf`

The following command generates `smf(5)` manifests from `inetd.conf(4)` and places them in `/var/tmp`, overwriting any preexisting manifests of the same name, and then imports them into the smf repository.

```
# inetconv -f -o /var/tmp
100232/10 -> /var/tmp/100232_10-rpc_udp.xml
Importing 100232_10-rpc_udp.xml ...Done
telnet -> /var/tmp/telnet-tcp6.xml
Importing telnet-tcp6.xml ...Done
```

**EXAMPLE 2** Generating Manifests from an Alternate Input File

The following command specifies a different input file and does not load the resulting manifests into the smf repository.

```
# inetconv -n -i /export/test/inet.svcs -o /var/tmp
100232/10 -> /var/tmp/100232_10-rpc_udp.xml
telnet -> /var/tmp/telnet-tcp6.xml
```

**Exit Status** The following exit values are returned:

- **0** Operation completed successfully (no errors).
- **1** Invalid options specified.
- **2** One or more service lines are malformed, and thus no manifest(s) were generated for them.
- **3** An error occurred importing one or more of the generated manifests.
- **4** A system error occurred.

**Files**

```
/var/svc/manifest/network/{rpc}/{<svcname>-.<proto>}.xml
```

default output manifest file name

inetd(1M)

**Name**

inetd – Solaris Management Facility delegated restarter for inet services

**Synopsis**

```
inetd [configuration-file] start | stop | refresh
svc:/network/inetd:default
```

**Description**

inetd is the delegated restarter for internet services for the Service Management Facility (SMF). Its basic responsibilities are to manage service states in response to administrative requests, system failures, and service failures; and, when appropriate, to listen for network requests for services.

Services are no longer managed by editing the inetd configuration file, `inetd.conf(4)`.

Instead, you use `inetconv(1M)` to convert the configuration file content into SMF format services, then manage these services using `inetadm(1M)` and `svcadm(1M)`. Once a service has been converted by `inetconv`, any changes to the legacy data in the `inetd` config file will not become effective. However, `inetd` does alert the administrator when it notices change in the configuration file. See the start description under the “inetd Methods” section for further information.

Also note that the current `inetd` cannot be run from outside the SMF. This means it cannot be run from the command line, as was supported by the previous `inetd`. If you attempt to do this, a message is sent to stderr displaying mappings between the options supported by the previous `inetd` to the SMF version of `inetd`.

`inetd` listens for connections on behalf of all services that are in either the online or degraded state. A service enters one of these states when the service is enabled by the user and `inetd` manages to listen on its behalf. A listen attempt can fail if another server (whether standalone or a third-party internet service) is already listening on the same port. When this occurs, `inetd` logs this condition and continues trying to bind to the port at configured intervals a configured number of times. See the property `bind_fail_max` under “Service Properties,” below, for more details.

The configuration of all `inetd`'s managed SMF services is read when it is started. It is reread when `inetd` is refreshed, which occurs in response to an SMF request, or when it receives a SIGHUP signal. See the refresh description under “inetd Methods” for the behavior on configuration refresh.

You can use the `inetadm(1M)` or `svccfg(1M)` utilities to make configuration changes to Internet services within the SMF repository. `inetadm` has the advantage over `svccfg` in that it provides an Internet/RPC service context.

**Service States**

As part of its service management duties, `inetd` implements a state machine for each of its managed services. The states in this machine are made up of the `smf(5)` set of states. The semantics of these states are as follows:

- uninitialized
  - `inetd` has yet to process this service.
online
   The service is handling new network requests and might have existing connections active.

degraded
   The service has entered this state because it was able to listen and process requests for
   some, but not all, of the protocols specified for the service, having exhausted its listen
   retries. Existing network connections might be active.

offline
   Connections might be active, but no new requests are being handled. This is a transient
   state. A service might be offline for any of the following reasons:
   
   - The service’s dependencies are unmet. When its dependencies become met the service’s
     state will be re-evaluated.
   
   - The service has exceeded its configured connection rate limit, \texttt{max\_con\_rate}. The
     service’s state is re-evaluated when its connection offline timer, \texttt{con\_rate\_offline},
     expires.
   
   - The service has reached its allowed number of active connections, \texttt{max\_copies}. The
     service’s state is re-evaluated when the number of active connections drops below
     \texttt{max\_copies}.
   
   - \texttt{inetd} failed to listen on behalf of the service on all its protocols. As mentioned above,
     \texttt{inetd} retries up to a configured maximum number of times, at configured
     intervals. The service’s state is re-evaluated when either a listen attempt is successful or
     the retry limit is reached.

disabled
   The service has been turned off by an administrator, is not accepting new connections, and
   has none active. Administrator intervention is required to exit this state.

maintenance
   A service is in this state because it is either malfunctioning and needs administrator
   attention or because an administrator has requested it.

   Events constituting malfunctioning include: \texttt{inetd}’s inability to listen on behalf on any of
   the service’s protocols before exceeding the service’s bind retry limit, non-start methods
   returning with non-success return values, and the service exceeding its failure rate.

   You request the maintenance state to perform maintenance on the service, such as applying
   a patch. No new requests are handled in this state, but existing connections might be active.
   Administrator intervention is required to exit this state.

Use \texttt{inetadm(1M)} to obtain the current state of a managed service.

Service Methods
   As part of certain state transitions \texttt{inetd} will execute, if supplied, one of a set of methods
   provided by the service. The set of supported methods are:
**inetd_start**
Executed to handle a request for an online or degraded service. Since there is no separate state to distinguish a service with active connections, this method is not executed as part of a state transition.

**inetd_offline**
Executed when a service is taken from the online or degraded state to the offline state. For a wait-type service that at the time of execution is performing its own listening, this method should result in it ceasing listening. This method will be executed before the disable method in the case an online/degraded service is disabled. This method is required to be implemented for a wait-type service.

**inetd_online**
Executed when a service transitions from the offline state to the online state. This method allows a service author to carry out some preparation prior to a service starting to handle requests.

**inetd_disable**
Executed when a service transitions from the offline state to the disabled state. It should result in any active connections for a service being terminated.

**inetd_refresh**
Executed when both of the following conditions are met:
- *inetd* is refreshed, by means of the framework or a SIGHUP, or a request comes in to refresh the service, and
- the service is currently in the online state and there are no configuration changes that would result in the service needing to be taken offline and brought back again.

The only compulsory method is the `inetd_start` method. In the absence of any of the others, `inetd` runs no method but behaves as if one was run successfully.

**Service Properties**
Configuration for SMF–managed services is stored in the SMF repository. The configuration is made up of the basic configuration of a service, the configuration for each of the service’s methods, and the default configuration applicable to all `inetd`-managed services.

For details on viewing and modifying the configuration of a service and the defaults, refer to `inetadm(1M)`.

The basic configuration of a service is stored in a property group named `inetd` in the service. The properties comprising the basic configuration are as follows:

**bind_addr**
The address of the network interface to which the service should be bound. An empty string value causes the service to accept connections on any network interface.
bind_fail_interval
   The time interval in seconds between a failed bind attempt and a retry. The values 0 and -1 specify that no retries are attempted and the first failure is handled the same as exceeding bind_fail_max.

bind_fail_max
   The maximum number of times inetd retries binding to a service's associated port before giving up. The value -1 specifies that no retry limit is imposed. If none of the service's protocols were bound to before any imposed limit is reached, the service goes to the maintenance state; otherwise, if not all of the protocols were bound to, the service goes to the degraded state.

con_rate_offline
   The time in seconds a service will remain offline if it exceeds its configured maximum connection rate, max_con_rate. The values 0 and -1 specify that connection rate limiting is disabled.

connection_backlog
   The backlog queue size. Represents a limit on the number of incoming client requests that can be queued at the listening endpoints for servers.

endpoint_type
   The type of the socket used by the service or the value tli to signify a TLI-based service. Valid socket type values are: stream, dgram, raw, seqpacket.

failrate_cnt
   The count portion of the service's failure rate limit. The failure rate limit applies to wait-type services and is reached when count instances of the service are started within a given time. Exceeding the rate results in the service being transitioned to the maintenance state. This is different from the behavior of the previous inetd, which continued to retry every 10 minutes, indefinitely. The failrate_cnt check accounts for badly behaving servers that fail before consuming the service request and which would otherwise be continually restarted, taxing system resources. Failure rate is equivalent to the -r option of the previous inetd. The values 0 and -1 specify that this feature is disabled.

failrate_interval
   The time portion in seconds of the service's failure rate. The values 0 and -1 specify that the failure rate limit feature is disabled.

inherit_env
   If true, pass inetd's environment on to the service's start method. Regardless of this setting, inetd will set the variables SMF_FMRI, SMF_METHOD, and SMF_RESTARTER in the start method's environment, as well as any environment variables set in the method context. These variables are described in smf_method(5).

isrpc
   If true, this is an RPC service.
max_con_rate

The maximum allowed connection rate, in connections per second, for a nowait-type service. The values 0 and -1 specify that that connection rate limiting is disabled.

max_copies

The maximum number of copies of a nowait service that can run concurrently. The values 0 and -1 specify that copies limiting is disabled.

name

Can be set to one of the following values:
- a service name understood by `getservbyname(3SOCKET)`;
- if `isrpc` is set to true, a service name understood by `getrpcbyname(3NSL)`;
- if `isrpc` is set to true, a valid RPC program number.

proto

In the case of socket-based services, this is a list of protocols supported by the service. Valid protocols are: tcp, tcp6, tcp6only, udp, udp6, and udp6only. In the case of TLI services, this is a list of netids recognized by `getnetconfigent(3NSL)` supported by the service, plus the values tcp6only and udp6only. RPC/TLI services also support nettypes in this list, and `inetd` first tries to interpret the list member as a nettype for these service types. The values tcp6only and udp6only are new to `inetd`; these values request that `inetd` listen only for and pass on true IPv6 requests (not IPv4 mapped ones). See “Configuring Protocols for Sockets-Based Services,” below.

rpc_low_version

Lowest supported RPC version. Required when `isrpc` is set to true.

rpc_high_version

Highest supported RPC version. Required when `isrpc` is set to true.

tcp_trace

If true, and this is a nowait-type service, `inetd` logs the client's IP address and TCP port number, along with the name of the service, for each incoming connection, using the syslog(3C) facility. `inetd` uses the syslog facility code daemon and notice priority level. See `syslog.conf(4)` for a description of syslog codes and severity levels. This logging is separate from the logging done by the TCP wrappers facility.

tcp_trace is equivalent to the previous `inetd`'s `-t` option (and the `/etc/default/inetd` property ENABLE_CONNECTION_LOGGING).

tcp_wrappers

If true, enable TCP wrappers access control. This applies only to services with endpoint_type set to streams and wait set to false. The syslog facility code daemon is used to log allowed connections (using the notice severity level) and denied traffic (using the warning severity level). See `syslog.conf(4)` for a description of syslog codes and severity levels. The stability level of the TCP wrappers facility and its configuration files is External. As the TCP wrappers facility is not controlled by Sun, intra-release incompatibilities are not uncommon. See `attributes(5)`.
For more information about configuring TCP wrappers, you can refer to the tcpd(1M) and hosts_access(4) man pages, which are delivered as part of the Solaris operating system at /usr/sfw/man. These pages are not part of the standard Solaris man pages, available at /usr/man.

tcp_wrappers is equivalent to the previous inetd's /etc/default/inetd property ENABLE_TCPWRAPPERS.

wait
If true this is a wait-type service, otherwise it is a nowait-type service. A wait-type service has the following characteristics:

- Its inetd_start method will take over listening duties on the service's bound endpoint when it is executed.
- inetd will wait for it to exit after it is executed before it resumes listening duties.

Datagram servers must be configured as being of type wait, as they are always invoked with the original datagram endpoint that will participate in delivering the service bound to the specified service. They do not have separate “listening” and “accepting” sockets.

Connection-oriented services, such as TCP stream services can be designed to be either of type wait or nowait.

A number of the basic properties are optional for a service. In their absence, their values are taken from the set of default values present in the defaults property group in the inetd service. These properties, with their seed values, are listed below. Note that these values are configurable through inetadm(1M).

bind_fail_interval -1
bind_fail_max -1
con_rate_offline -1
connection_backlog 10
failrate_count 40
failrate_time 60
inherit_env true
max_con_rate -1
max_copies -1
tcp_trace false
tcp_wrappers false

Each method specified for a service will have its configuration stored in the SMF repository, within a property group of the same name as the method. The set of properties allowable for these methods includes those specified for the services managed by svc.startd(1M). (See svc.startd(1M) for further details.) Additionally, for the inetd_start method, you can set the arg0 property.

The arg0 property allows external wrapper programs to be used with inetd services. Specifically, it allows the first argument, argv[0], of the service's start method to be something other than the path of the server program.
In the case where you want to use an external wrapper program and pass arguments to the service's daemon, the arguments should be incorporated as arguments to the wrapper program in the exec property. For example:

```
exec='/path/to/wrapper/program service_daemon_args'
arg0='/path/to/service/daemon'
```

In addition to the special method tokens mentioned in `smf_method(5)`, `inetd` also supports the `:kill_process` token for `wait`-type services. This results in behavior identical to that if the `:kill` token were supplied, except that the `kill` signal is sent only to the parent process of the `wait`-type service's `start` method, not to all members of its encompassing process contract (see `process(4)`).

When configuring `inetd` for a sockets-based service, you have the choice, depending on what is supported by the service, of the alternatives described under the `proto` property, above. The following are guidelines for which `proto` values to use:

- For a service that supports only IPv4: `tcp` and `udp`
- For a service that supports only IPv6: `tcp6only` and `udp6only`
- For a service that supports both IPv4 and IPv6:
  - Obsolete and not recommended: `tcp6` and `udp6`
  - Recommended: use two separate entries that differ only in the `proto` field. One entry has `tcp` and the other has `tcp6only`, or `udp` plus `udp6only`.

See EXAMPLES for an example of a configuration of a service that supports both IPv4 and IPv6.

**inetd Methods**

`inetd` provides the methods listed below for consumption by the master recaster, `svc.startd(1M)`.

- **start**
  - Causes `inetd` to start providing service. This results in `inetd` beginning to handle `smf` requests for its managed services and network requests for those services that are in either the `online` or `degraded` state.

  In addition, `inetd` also checks if the `inetd.conf(4)`–format configuration file it is monitoring has changed since the last `inetconv(1M)` conversion was carried out. If it has, then a message telling the administrator to re-run `inetconv` to effect the changes made is logged in `syslog`.

- **stop**
  - Causes `inetd` to stop providing service. At this point, `inetd` transitions each of its services that are not in either the `maintenance` or `disabled` states to the `offline` state, running any appropriate methods in the process.
refresh
Results in a refresh being performed for each of its managed services and the
inetd.conf format configuration file being checked for change, as in the start method.
When a service is refreshed, its behavior depends on its current state:
■ if it is in the maintenance or disabled states, no action is performed because the
configuration will be read and consumed when the service leaves the state;
■ if it is in the offline state, the configuration will be read and any changes consumed
immediately;
■ if it is in the online or degraded state and the configuration has changed such that a
re-binding is necessary to conform to it, then the service will be transitioned to the
offline state and back again, using the new configuration for the bind;
■ if it is in the online state and a re-binding is not necessary, then the inetd refresh
method of the service, if provided, will be run to allow online wait–type services to
consume any other changes.

Options
No options are supported.

Operands
configuration-file
Specifies an alternate location for the legacy service file (inetd.conf).
start|stop|refresh
Specifies which of inetd’s methods should be run.

Examples
EXAMPLE 1 Configuring a Service that Supports Both IPv4 and IPv6
The following commands illustrate the existence of services that support both IPv4 and IPv6
and assign proto properties to those services.
example# svcs -a | grep mysvc
online 15:48:29 svc:/network/mysvc:dgram4
online 15:48:29 svc:/network/mysvc:dgram6
online 15:51:47 svc:/network/mysvc:stream4
online 15:52:10 svc:/network/mysvc:stream6

# inetadm -M network/rpc/mysvc:dgram4 proto=udp
# inetadm -M network/rpc/mysvc:dgram6 proto=udp6only
# inetadm -M network/rpc/mysvc:stream4 proto=tcp
# inetadm -M network/rpc/mysvc:stream6 proto=tcp6only

See svcs(1) and inetadm(1M) for descriptions of those commands.

The `inetd` daemon performs the same function as, but is implemented significantly differently from, the daemon of the same name in Solaris 9 and prior Solaris operating system releases. In the current Solaris release, `inetd` is part of the Solaris Management Facility (see `smf(5)`) and will run only within that facility.

The `/etc/default/inetd` file has been deprecated. The functionality represented by the properties `ENABLE_CONNECTION_LOGGING` and `ENABLE_TCP_WRAPPERS` are now available as the `tcp_trace` and `tcp_wrappers` properties, respectively. These properties are described above, under "Service Properties".

**Name**  
in.fingerd, fingerd – remote user information server

**Synopsis**  
/usr/sbin/in.fingerd [-s]

**Description**  
fingerd implements the server side of the Name/Finger protocol, specified in RFC 742. The Name/Finger protocol provides a remote interface to programs which display information on system status and individual users. The protocol imposes little structure on the format of the exchange between client and server. The client provides a single command line to the finger server which returns a printable reply.

fingerd waits for connections on TCP port 79. Once connected, it reads a single command line terminated by RETURN-LINEFEED and passes the arguments to finger(1), prepended with -s. fingerd closes its connections as soon as the output is finished.

**Options**  
fingerd supports the following option.

- **s**  
  Enable secure mode. Deny forwarding of queries to other remote hosts.

**Files**  
/var/adm/utmpx  
User and accounting information.

/etc/passwd  
System password file.

/var/adm/lastlog  
Last login times.

$HOME/.plan  
User's plans.

$HOME/.project  
User's projects.

**Usage**  
fingerd and in.fingerd are IPv6–enabled. See ip6(7P).

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>service/network/network-servers</td>
</tr>
</tbody>
</table>

**See Also**  
finger(1), svcs(1), inetadm(1M), inetd(1M), svcadm(1M), attributes(5), smf(5), ip6(7P)

**Notes**  
Connecting directly to the server from a TIP or an equally narrow-minded TELNET-protocol user program can result in meaningless attempts at option negotiation being sent to the server, which foul up the command line interpretation. fingerd should be taught to filter out IAC’s and perhaps even respond negatively (IAC does not) to all option commands received.

The in.fingerd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/finger:default
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.
infocmp – compare or print out terminfo descriptions

Synopsis
[-s | d | i | l | c] [-v] [-V] [-1] [-w width]
[-A directory] [-B directory] [termname]...

Description
infocmp compares a binary terminfo entry with other terminfo entries, rewrites a terminfo description to take advantage of the use= terminfo field, or prints out a terminfo description from the binary file (term) in a variety of formats. It displays boolean fields first, then numeric fields, followed by the string fields. If no options are specified and zero, or one termname is specified, the -I option is assumed. If more than one termname is specified, the -d option is assumed.

Options
The -d, -c, and -n options can be used for comparisons. infocmp compares the terminfo description of the first terminal termname with each of the descriptions given by the entries for the other terminal’s termname. If a capability is defined for only one of the terminals, the value returned will depend on the type of the capability: F for boolean variables, −1 for integer variables, and NULL for string variables.

- d Produce a list of each capability that is different between two entries. This option is useful to show the difference between two entries, created by different people, for the same or similar terminals.

- c Produce a list of each capability that is common between two entries. Capabilities that are not set are ignored. This option can be used as a quick check to see if the -u option is worth using.

- n Produce a list of each capability that is in neither entry. If no termname is given, the environment variable TERM will be used for both of the termnames. This can be used as a quick check to see if anything was left out of a description.

The -I, -L, and -C options will produce a source listing for each terminal named.

- I Use the terminfo names.
- L Use the long C variable name listed in <term.h>.
- C Use the termcap names. The source produced by the -C option may be used directly as a termcap entry, but not all of the parameterized strings may be changed to the termcap format. infocmp will attempt to convert most of the parameterized information, but anything not converted will be plainly marked in the output and commented out. These should be edited by hand.

- r When using -C, put out all capabilities in termcap form.

If no termname is given, the environment variable TERM will be used for the terminal name.

All padding information for strings will be collected together and placed at the beginning of the string where termcap expects it. Mandatory padding (padding information with a trailing '/') will become optional.
All termcap variables no longer supported by terminfo, but are derivable from other terminfo variables, will be displayed. Not all terminfo capabilities will be translated; only those variables which were part of termcap will normally be displayed. Specifying the -r option will take off this restriction, allowing all capabilities to be displayed in termcap form.

Note that because padding is collected to the beginning of the capability, not all capabilities are displayed. Mandatory padding is not supported. Because termcap strings are not as flexible, it is not always possible to convert a terminfo string capability into an equivalent termcap format. A subsequent conversion of the termcap file back into terminfo format will not necessarily reproduce the original terminfo source.

Some common terminfo parameter sequences, their termcap equivalents, and some terminal types which commonly have such sequences, are:

```
  terminfo   termcap       Representative Terminals
  %p1%c     %,   adm
  %p1%d     %d   hp, ANSI standard, vt100
  %p1%'x'+%c %+x  concept
  %i        %i   ANSI standard, vt100
  %p1%'x'>%p1'y'>%;  %>xy  concept
  %p2 is printed before %p1   %r   hp

-u Produce a terminfo source description of the first terminal termname which is relative to the sum of the descriptions given by the entries for the other terminals' termnames. It does this by analyzing the differences between the first termname and the other termnames and producing a description with use= fields for the other terminals. In this manner, it is possible to retrofit generic terminfo entries into a terminal's description. Or, if two similar terminals exist, but were coded at different times, or by different people so that each description is a full description, using infocmp will show what can be done to change one description to be relative to the other.

A capability is displayed with an at-sign (@) if it no longer exists in the first termname, but one of the other termname entries contains a value for it. A capability's value is displayed if the value in the first termname is not found in any of the other termname entries, or if the first of the other termname entries that has this capability gives a different value for that capability.

The order of the other termname entries is significant. Since the terminfo compiler tic does a left-to-right scan of the capabilities, specifying two use= entries that contain differing entries for the same capabilities will produce different results, depending on the order in which the entries are given. infocmp will flag any such inconsistencies between the other termname entries as they are found.

Alternatively, specifying a capability after a use= entry that contains, it will cause the second specification to be ignored. Using infocmp to recreate a description can be a useful check to make sure that everything was specified correctly in the original source description.
Another error that does not cause incorrect compiled files, but will slow down the compilation
time, is specifying superfluous use= fields. infocmp will flag any superfluous use= fields.

- s          Sorts the fields within each type according to the argument below:
              
              d    Leave fields in the order that they are stored in the terminfo database.
              i    Sort by terminfo name.
              l    Sort by the long C variable name.
              c    Sort by the termcap name.

              If the -s option is not given, the fields are sorted alphabetically by the terminfo
              name within each type, except in the case of the -C or the -L options, which cause
              the sorting to be done by the termcap name or the long C variable name,
              respectively.

- v          Print out tracing information on standard error as the program runs.
- V          Print out the version of the program in use on standard error and exit.

-1           Print the fields one to a line. Otherwise, the fields are printed several to a line to a
              maximum width of 60 characters.

- w width    Changes the output to width characters.

The location of the compiled terminfo database is taken from the environment variable
TERMINFO. If the variable is not defined, or the terminal is not found in that location, the
system terminfo database, usually in /usr/share/lib/terminfo, is used. The options -A and
- B may be used to override this location.

- A directory Set TERMINFO for the first termname.
- B directory Set TERMINFO for the other termnames. With this, it is possible to compare
descriptions for a terminal with the same name located in two different
databases. This is useful for comparing descriptions for the same terminal
created by different people.

Files /usr/share/lib/terminfo/?/* Compiled terminal description database.

in.ftpd, ftpd – File Transfer Protocol Server

[-r rootdir] [-S] [-s] [-T maxtimeout] [-t timeout]

Description  in.ftpd is the Internet File Transfer Protocol (FTP) server process. The server may be invoked by the Internet daemon inetd(1M) each time a connection to the FTP service is made or run as a standalone server. See services(4).

Options  in.ftpd supports the following options:

-4  When running in standalone mode, listen for connections on an AF_INET type socket. The default is to listen on an AF_INET6 type socket.

-a  Enables use of the ftpaccess(4) file.

- A  Disables use of the ftpaccess(4) file. Use of ftpaccess is disabled by default.

-C  Non-anonymous users need local credentials (for example, to authenticate to remote fileservers). So they should be prompted for a password unless they forwarded credentials as part of authentication.

-d  Writes debugging information to syslogd(1M).

-i  Logs the names of all files received by the FTP Server to xferlog(4). You can override the -i option through use of the ftpaccess(4) file.

-I  Disables the use of AUTH and ident to determine the username on the client. See RFC 931. The FTP Server is built not to use AUTH and ident.

-K  Connections are only allowed for users who can authenticate through the ftp AUTH mechanism. (Anonymous ftp may also be allowed if it is configured.) ftpd will ask the user for a password if one is required.

-l  Logs each FTP session to syslogd(1M).

-L  Logs all commands sent to in.ftpd to syslogd(1M). When the -L option is used, command logging will be on by default, once the FTP Server is invoked. Because the FTP Server includes USER commands in those logged, if a user accidentally enters a password instead of the username, the password will be logged. You can override the -L option through use of the ftpaccess(4) file.

-o  Logs the names of all files transmitted by the FTP Server to xferlog(4). You can override the -o option through use of the ftpaccess(4) file.

-P dataport  The FTP Server determines the port number by looking in the services(4) file for an entry for the ftp-data service. If there is no entry,
the daemon uses the port just prior to the control connection port. Use the -P option to specify the data port number.

- `p ctrlport` When run in standalone mode, the FTP Server determines the control port number by looking in the `services(4)` file for an entry for the ftp service. Use the -p option to specify the control port number.

- `Q` Disables PID files. This disables user limits. Large, busy sites that do not want to impose limits on the number of concurrent users can use this option to disable PID files.

- `q` Uses PID files. The `limit` directive uses PID files to determine the number of current users in each access class. By default, PID files are used.

- `r rootdir` `chroot(2)` to `rootdir` upon loading. Use this option to improve system security. It limits the files that can be damaged should a break in occur through the daemon. This option is similar to anonymous FTP. Additional files are needed, which vary from system to system.

- `S` Places the daemon in standalone operation mode. The daemon runs in the background. This is useful for startup scripts that run during system initialization. See `init.d(4)`.

- `s` Places the daemon in standalone operation mode. The daemon runs in the foreground. This is useful when run from `/etc/inittab` by `init(1M)`.

- `T maxtimeout` Sets the maximum allowable timeout period to `maxtimeout` seconds. The default maximum timeout limit is 7200 second (two hours). You can override the -T option through use of the `ftpaccess(4)` file.

- `t timeout` Sets the inactivity timeout period to `timeout` seconds. The default timeout period is 900 seconds (15 minutes). You can override the -t option through use of the `ftpaccess(4)` file.

- `u umask` Sets the default `umask` to `umask`.

- `V` Displays copyright and version information, then terminate.

- `v` Writes debugging information to `syslogd(1M)`.

- `W` Does not record user `login` and `logout` in the `wtmpx(4)` file.

- `w` Records each user `login` and `logout` in the `wtmpx(4)` file. By default, logins and logouts are recorded.

- `X` Writes the output from the -i and -o options to the `syslogd(1M)` file instead of `xferlog(4)`. This allows the collection of output from several hosts on one central loghost. You can override the -X option through use of the `ftpaccess(4)` file.
The FTP Server currently supports the following FTP requests. Case is not distinguished.

- **ABOR**: Abort previous command.
- **ADAT**: Send an authentication protocol message.
- **ALLO**: Allocate storage (vacuously).
- **AUTH**: Specify an authentication protocol to be performed. Currently only “GSSAPI” is supported.
- **APPE**: Append to a file.
- **CCC**: Set the command channel protection mode to “Clear” (no protection). Not allowed if data channel is protected.
- **CDUP**: Change to parent of current working directory.
- **CWD**: Change working directory.
- **DELE**: Delete a file.
- **ENC**: Send a privacy and integrity protected command (given in argument).
- **EPRT**: Specify extended address for the transport connection.
- **EPSV**: Extended passive command request.
- **HELP**: Give help information.
- **LIST**: Give list files in a directory (`ls -lA`).
- **LPRT**: Specify long address for the transport connection.
- **LPSV**: Long passive command request.
- **MIC**: Send an integrity protected command (given in argument).
- **MKD**: Make a directory.
- **MDTM**: Show last time file modified.
- **MODE**: Specify data transfer mode.
- **NLST**: Give name list of files in directory (`ls`).
- **NOOP**: Do nothing.
- **PASS**: Specify password.
- **PASV**: Prepare for server-to-server transfer.
- **PBSZ**: Specify a protection buffer size.
- **PROT**: Specify a protection level under which to protect data transfers. Allowed arguments:
  - clear: No protection.
safe   Integrity protection
private Integrity and encryption protection

PORT   Specify data connection port.
PWD    Print the current working directory.
QUIT   Terminate session.
REST   Restart incomplete transfer.
RETR   Retrieve a file.
RMD    Remove a directory.
RNFR   Specify rename-from file name.
RNTO   Specify rename-to file name.
SITE   Use nonstandard commands.
SIZE   Return size of file.
STAT   Return status of server.
STOR   Store a file.
STOU   Store a file with a unique name.
STRU   Specify data transfer structure.
SYST   Show operating system type of server system.
TYPE   Specify data transfer type.
USER   Specify user name.
XCUP   Change to parent of current working directory. This request is deprecated.
XCWD   Change working directory. This request is deprecated.
XMKD   Make a directory. This request is deprecated.
XPWD   Print the current working directory. This request is deprecated.
XRMD   Remove a directory. This request is deprecated.

The following nonstandard or UNIX specific commands are supported by the SITE request:

ALIAS   List aliases.
CDPATH  List the search path used when changing directories.
CHECKMETHOD List or set the checksum method.
CHECKSUM Give the checksum of a file.
CHMOD  Change mode of a file. For example, SITE CHMOD 755 filename.
EXEC   Execute a program. For example, SITE EXEC program params
GPASS  Give special group access password. For example, SITE GPASS bar.
GROUP  Request special group access. For example, SITE GROUP foo.
GROUPS List supplementary group membership.
HELP   Give help information. For example, SITE HELP.
IDLE   Set idle-timer. For example, SITE IDLE 60.
UMASK  Change umask. For example, SITE UMASK 002.

The remaining FTP requests specified in RFC 959 are recognized, but not implemented.

The FTP server will abort an active file transfer only when the ABOR command is preceded by a Telnet "Interrupt Process" (IP) signal and a Telnet "Synch" signal in the command Telnet stream, as described in RFC 959. If a STAT command is received during a data transfer that has been preceded by a Telnet IP and Synch, transfer status will be returned.

in.ftpd interprets file names according to the “globbing” conventions used by csh(1). This allows users to utilize the metacharacters: * ? [ ] { } ~

in.ftpd authenticates users according to the following rules:

First, the user name must be in the password data base, the location of which is specified in nsswitch.conf(4). An encrypted password (an authentication token in PAM) must be present. A password must always be provided by the client before any file operations can be performed. For non-anonymous users, the PAM framework is used to verify that the correct password was entered. See SECURITY below.

Second, the user name must not appear in either the /etc/ftpusers or the /etc/ftpd/ftpusers file. Use of the /etc/ftpusers files is deprecated, although it is still supported.

Third, the users must have a standard shell returned by getusershell(3C).

Fourth, if the user name is anonymous or ftp, an anonymous ftp account must be present in the password file for user ftp. Use ftpconfig(1M) to create the anonymous ftp account and home directory tree.

Fifth, if the GSS-API is used to authenticate the user, then gss_auth_rules(5) determines user access without a password needed.

The FTP Server supports virtual hosting, which can be configured by using ftpaddhost(1M).

The FTP Server does not support sublogins.
General FTP Extensions

The FTP Server has certain extensions. If the user specifies a filename that does not exist with a
RETR (retrieve) command, the FTP Server looks for a conversion to change a file or directory
that does into the one requested. See ftpconversions(4).

By convention, anonymous users supply their email address when prompted for a password.
The FTP Server attempts to validate these email addresses. A user whose FTP client hangs on a
long reply, for example, a multiline response, should use a dash (-) as the first character of the
user’s password, as this disables the Server’s \reply() function.

The FTP Server can also log all file transmission and reception. See xferlog(4) for details of
the log file format.

The SITE EXEC command may be used to execute commands in the /bin/ftp-exec directory.
Take care that you understand the security implications before copying any command into
the /bin/ftp-exec directory. For example, do not copy in /bin/sh. This would enable the
user to execute other commands through the use of sh -c. If you have doubts about this
feature, do not create the /bin/ftp-exec directory.

Security

For non-anonymous users, in.ftpd uses pam(3PAM) for authentication, account
management, and session management, and can use Kerberos v5 for authentication.

The PAM configuration policy, listed through /etc/pam.conf, specifies the module to be used
for in.ftpd. Here is a partial pam.conf file with entries for the in.ftpd command using the
UNIX authentication, account management, and session management module.

```
ftp auth requisite pam_authtok_get.so.1
ftp auth required pam_dhkeys.so.1
ftp auth required pam_unix_auth.so.1
ftp account required pam_unix_roles.so.1
ftp account required pam_unix_projects.so.1
ftp account required pam_unix_account.so.1
ftp session required pam_unix_session.so.1
```

If there are no entries for the ftp service, then the entries for the “other” service will be used.
Unlike login, passwd, and other commands, the ftp protocol will only support a single
password. Using multiple modules will prevent in.ftpd from working properly.

To use Kerberos for authentication, a host/<FQDN> Kerberos principal must exist for each
Fully Qualified Domain Name associated with the in.ftpd server. Each of these
host/<FQDN> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on
the in.ftpd server. An example principal might be:

```
host/bigmachine.eng.example.com
```
See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a krb5.keytab file. See System Administration Guide: Security Services for a discussion of Kerberos authentication.

For anonymous users, who by convention supply their email address as a password, in.ftpd validates passwords according to the passwd-check capability in the ftpaccess file.

**Usage**
The in.ftpd command is IPv6–enabled. See ip6(7P).

**Files**
- `/etc/ftpd/ftpaccess`: FTP Server configuration file
- `/etc/ftpd/ftpconversions`: FTP Server conversions database
- `/etc/ftpd/ftpgroups`: FTP Server enhanced group access file
- `/etc/ftpd/ftphosts`: FTP Server individual user host access file
- `/etc/ftpd/ftpservers`: FTP Server virtual hosting configuration file.
- `/etc/ftpd/ftpusers`: File listing users for whom FTP login privileges are disallowed.
- `/etc/ftpd/ftpusers`: File listing users for whom FTP login privileges are disallowed. This use of this file is deprecated.
- `/var/log/xferlog`: FTP Server transfer log file
- `/var/run/ftp.pids-classname`: Extended database files that contain the history of user access and accounting information for the wtmpx database.

in.ftpd(1M)

System Administration Guide: Security Services

Diagnostics

in.ftpd logs various errors to syslogd(1M), with a facility code of daemon.

Notes

The anonymous FTP account is inherently dangerous and should be avoided when possible.

The FTP Server must perform certain tasks as the superuser, for example, the creation of sockets with privileged port numbers. It maintains an effective user ID of the logged in user, reverting to the superuser only when necessary.

The FTP Server no longer supports the /etc/default/ftpd file. Instead of using UMASK=nnn to set the umask, use the defumask capability in the ftpaccess file. The banner greeting text capability is also now set through the ftpaccess file by using the greeting text capability instead of by using BANNER="...". However, unlike the BANNER string, the greeting text string is not passed to the shell for evaluation. See ftpaccess(4).

The pam_unix(5) module is no longer supported. Similar functionality is provided by pam_auth tok_check(5), pam_auth tok_get(5), pam_auth tok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).

The in.ftpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/ftp

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
in.iked(1M)

Name
in.iked – daemon for the Internet Key Exchange (IKE)

Synopsis
/usr/lib/inet/in.iked [-d] [-f filename] [-p level]
/usr/lib/inet/in.iked -c [-f filename]

Description
in.iked performs automated key management for IPsec using the Internet Key Exchange (IKE) protocol.

in.iked implements the following:

- IKE authentication with either pre-shared keys, DSS signatures, RSA signatures, or RSA encryption.
- Diffie-Hellman key derivation using either 768, 1024, or 1536-bit public key moduli.
- Authentication protection with cipher choices of AES, DES, Blowfish, or 3DES, and hash choices of either HMAC-MD5 or HMAC-SHA-1. Encryption in in.iked is limited to the IKE authentication and key exchange. See ipsecesp(7P) for information regarding IPsec protection choices.

in.iked is managed by the following smf(5) service:

svc:/network/ipsec/ike

This service is delivered disabled because the configuration file needs to be created before the service can be enabled. See ike.config(4) for the format of this file.

See “Service Management Facility” for information on managing the smf(5) service.

in.iked listens for incoming IKE requests from the network and for requests for outbound traffic using the PF_KEY socket. See pf_key(7P).

in.iked has two support programs that are used for IKE administration and diagnosis: ikeadm(1M) and ikecert(1M).

The ikeadm(1M) command can read the /etc/inet/ike/config file as a rule, then pass the configuration information to the running in.iked daemon using a doors interface.

example# ikeadm read rule /etc/inet/ike/config

Refreshing the ike smf(5) service provided to manage the in.iked daemon sends a SIGHUP signal to the in.iked daemon, which will (re)read /etc/inet/ike/config and reload the certificate database.

The preceding two commands have the same effect, that is, to update the running IKE daemon with the latest configuration. See “Service Management Facility” for more details on managing the in.iked daemon.
The IKE daemon (*in.iked*) is managed by the service management facility, *smf*(5). The following group of services manage the components of IPsec:

- svc:/network/ipsec/ipsecalgs (See ipsecalgs(1M))
- svc:/network/ipsec/policy (See ipsecconf(1M))
- svc:/network/ipsec/manual-key (See ipseckey(1M))
- svc:/network/ipsec/ike (see ike.config(4))

The manual-key and ike services are delivered disabled because the system administrator must create configuration files for each service, as described in the respective man pages listed above.

The correct administrative procedure is to create the configuration file for each service, then enable each service using *svcadm*(1M).

The ike service has a dependency on the ipsecalgs and policy services. These services should be enabled before the ike service. Failure to do so results in the ike service entering maintenance mode.

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

```bash
eexample# svcadm refresh ike
```

The following properties are defined for the ike service:

- **config/admin privilege**
  Defines the level that *ikeadm*(1M) invocations can change or observe the running *in.iked*. The acceptable values for this property are the same as those for the -p option. See the description of -p in OPTIONS.

- **config/config_file**
  Defines the configuration file to use. The default value is /etc/inet/ike/config. See *ike.config*(4) for the format of this file. This property has the same effect as the -f flag. See the description of -f in OPTIONS.

- **config/debug_level**
  Defines the amount of debug output that is written to the debug_logfile file, described below. The default value for this is op or operator. This property controls the recording of information on events such as re-reading the configuration file. Acceptable value for debug_level are listed in the *ikeadm*(1M) man page. The value all is equivalent to the -d flag. See the description of -d in OPTIONS.

- **config/debug_logfile**
  Defines where debug output should be written. The messages written here are from debug code within *in.iked*. Startup error messages are recorded by the *smf*(5) framework and recorded in a service-specific log file. Use any of the following commands to examine the logfile property:
The values for these log file properties might be different, in which case both files should be inspected for errors.

config/ignore_errors
A boolean value that controls in.iked's behavior should the configuration file have syntax errors. The default value is false, which causes in.iked to enter maintenance mode if the configuration is invalid.

Setting this value to true causes the IKE service to stay online, but correct operation requires the administrator to configure the running daemon with ikeadm(1M). This option is provided for compatibility with previous releases.

These properties can be modified using svccfg(1M) by users who have been assigned the following authorization:
solaris.smf.value.ipsec

PKCS#11 token objects can be unlocked or locked by using ikeadm token login and ikeadm token logout, respectively. Availability of private keying material stored on these PKCS#11 token objects can be observed with: ikeadm dump certcache. The following authorizations allow users to log into and out of PKCS#11 token objects:
solaris.network.ipsec.ike.token.login	solaris.network.ipsec.ike.token.logout

See auths(1), ikeadm(1M), user_attr(4), rbac(5).

The service needs to be refreshed using svcadm(1M) before a new property value is effective. General, non-modifiable properties can be viewed with the svcprop(1) command.

# svccfg -s ipsec/ike setprop config/config_file = /new/config_file
# svcadm refresh ike

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:
solaris.smf.manage.ipsec

The service's status can be queried using the svcs(1) command.

The in.iked daemon is designed to be run under smf(5) management. While the in.iked command can be run from the command line, this is discouraged. If the in.iked command is to be run from the command line, the ike smf(5) service should be disabled first. See svcadm(1M).
Options

The following options are supported:

- **c**
  Check the syntax of a configuration file.

- **d**
  Use debug mode. The process stays attached to the controlling terminal and
  produces large amounts of debugging output. This option is deprecated. See
  “Service Management Facility” for more details.

- **f filename**
  Use `filename` instead of `/etc/inet/ike/config`. See `ike.config(4)` for the
  format of this file. This option is deprecated. See “Service Management
  Facility” for more details.

- **p level**
  Specify privilege level (`level`). This option sets how much `ikeadm(1M)`
  invocations can change or observe about the running `in.iked`

  Valid levels are:
  0 Base level
  1 Access to preshared key info
  2 Access to keying material

  If `-p` is not specified, `level` defaults to `0`.

  This option is deprecated. See “Service Management Facility” for more details.

Security

This program has sensitive private keying information in its image. Care should be taken with
any core dumps or system dumps of a running `in.iked` daemon, as these files contain
sensitive keying information. Use the `coreadm(1M)` command to limit any corefiles produced
by `in.iked`.

init(1M)

**Name**
init, telinit – process control initialization

**Synopsis**
/sbin/init 0123456-abcQqSs
/etc/telinit 0123456-abcQqSs

**Description**
init is the default primordial user process. (Options given to the kernel during boot may result in the invocation of an alternative primordial user process, as described on kernel(1M)). init initiates the core components of the service management facility, svc.configd(1M) and svc.startd(1M), and restarts these components if they fail. For backwards compatibility, init also starts and restarts general processes according to /etc/inittab, as described below.

The run levels and system booting descriptions given below are provided for compatibility purposes only, and otherwise made obsolete by the service management facility, smf(5).

**init Failure**
If init exits for any reason other than system shutdown, it will be restarted with process-ID 1.

**Run Level Defined**
At any given time, the system is in one of eight possible run levels. A run level is a software configuration under which only a selected group of processes exists. Processes spawned by init for each of these run levels are defined in /etc/inittab. init can be in one of eight run levels, 0–6 and S or s (S and s are identical). The run level changes when a privileged user runs /sbin/init.

**init and System Booting**
When the system is booted, init is invoked and the following occurs. First, it reads /etc/default/init to set environment variables. This is typically where TZ (time zone) and locale-related environments such as LANG or LC_CTYPE get set. (See the FILES section at the end of this page.) init then looks in /etc/inittab for the initdefault entry (see inittab(4)). If the initdefault entry:

- exists
  - init usually uses the run level specified in that entry as the initial run level to enter only if the options/milestone property has not been specified for svc.startd(1M).
- does not exist
  - The service management facility, smf(5), examines its configuration specified in svc.startd(1M), and enters the milestone specified by the options/milestone property.

The initdefault entry in /etc/inittab corresponds to the following run levels:

S or s
- init goes to the single-user state. In this state, the system console device (/dev/console) is opened for reading and writing and the command /sbin/su, (see su(1M)), is invoked. Use either init or telinit to change the run level of the system. Note that if the shell is terminated (using an end-of-file), init only re-initializes to the single-user state if /etc/inittab does not exist.

0–6
- init enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states.
If this is the first time since power up that `init` has entered a run level other than single-user state, `init` first scans `/etc/inittab` for boot and bootwait entries (see `inittab(4)`). These entries are performed before any other processing of `/etc/inittab` takes place, providing that the run level entered matches that of the entry. In this way any special initialization of the operating system, such as mounting file systems, can take place before users are allowed onto the system. `init` then scans `/etc/inittab` and executes all other entries that are to be processed for that run level.

To spawn each process in `/etc/inittab`, `init` reads each entry and for each entry that should be respawned, it forks a child process. After it has spawned all of the processes specified by `/etc/inittab`, `init` waits for one of its descendant processes to die, a powerfail signal, or a signal from another `init` or `telinit` process to change the system's run level. When one of these conditions occurs, `init` re-examines `/etc/inittab`.

`inittab` Additions

New entries can be added to `/etc/inittab` at any time; however, `init` still waits for one of the above three conditions to occur before re-examining `/etc/inittab`. To get around this, `init Q` or `init q` command wakes `init` to re-examine `/etc/inittab` immediately.

When `init` comes up at boot time and whenever the system changes from the single-user state to another run state, `init` sets the `ioctl(2)` states of the console to those modes saved in the file `/etc/ioctl.syscon`. `init` writes this file whenever the single-user state is entered.

Run Level Changes

When a run level change request is made, `init` or its designate sends the warning signal (SIGTERM) to all processes that are undefined in the target run level. A minimum interval of five seconds is observed before `init` or its designate forcibly terminates these processes by sending a kill signal (SIGKILL). Additionally, `init` informs `svc.startd(1M)` that the run level is changing. `svc.startd(1M)` then restricts the system to the set of services which the milestone corresponding to the run-level change depends on.

When `init` receives a signal telling it that a process it spawned has died, it records the fact and the reason it died in `/var/adm/utmpx` and `/var/adm/wtmpx` if it exists (see `who(1)`). A history of the processes spawned is kept in `/var/adm/wtmpx`.

If `init` receives a powerfail signal (SIGPWR) it scans `/etc/inittab` for special entries of the type powerfail and powerwait. These entries are invoked (if the run levels permit) before any further processing takes place. In this way `init` can perform various cleanup and recording functions during the powerdown of the operating system.

Environment Variables in `/etc/default/init`

You can set default values for environment variables, for such items as timezone and character formatting, in `/etc/default/init`. See the FILES section, below, for a list of these variables.

telinit

`telinit`, which is linked to `/sbin/init`, is used to direct the actions of `init`. It takes a one-character argument and signals `init` to take the appropriate action.
init(1M)

Security

init uses pam(3PAM) for session management. The PAM configuration policy, listed through
/etc/pam.conf, specifies the session management module to be used for init. Here is a
partial pam.conf file with entries for init using the UNIX session management module.

```
init session required pam_unix_session.so
```

If there are no entries for the init service, then the entries for the “other” service will be used.

Options

0

Go into firmware.

1

Put the system in system administrator mode. All local file systems are mounted. Only a
small set of essential kernel processes are left running. This mode is for administrative tasks
such as installing optional utility packages. All files are accessible and no users are logged in
on the system.

This request corresponds to a request for smf(5) to restrict the system milestone to
svc:/milestone/single-user:default.

2

Put the system in multi-user mode. All multi-user environment terminal processes and
daemons are spawned. This state is commonly referred to as the multi-user state.

This request corresponds to a request for smf(5) to restrict the system milestone to
svc:/milestone/multi-user:default.

3

Extend multi-user mode by making local resources available over the network.

This request corresponds to a request for smf(5) to restrict the system milestone to
svc:/milestone/multi-user-server:default.

4

Is available to be defined as an alternative multi-user environment configuration. It is not
necessary for system operation and is usually not used.

5

Shut the machine down so that it is safe to remove the power. Have the machine remove
power, if possible.

6

Stop the operating system and reboot to the state defined by the initdefault entry in
/etc/inittab.

The service svc:/system/boot-config:default is enabled by default. When the
config/fastreboot_default property is set to true, init 6 will bypass certain firmware
initialization and test steps, depending on the specific capabilities of the system.
### Process only those `etc/inittab` entries having the a, b, or c run level set. These are pseudo-states, which may be defined to run certain commands, but which do not cause the current run level to change.

### Q, q
Re-examine `etc/inittab`.

### S, s
Enter single-user mode. This is the only run level that doesn’t require the existence of a properly formatted `etc/inittab` file. If this file does not exist, then by default, the only legal run level that `init` can enter is the single-user mode. When in single-user mode, the filesystems required for basic system operation will be mounted. When the system comes down to single-user mode, these file systems will remain mounted (even if provided by a remote file server), and any other local filesystems will also be left mounted. During the transition down to single-user mode, all processes started by `init` or `init.d` scripts that should only be running in multi-user mode are killed. In addition, any process that has a `utmpx` entry will be killed. This last condition insures that all port monitors started by the SAC are killed and all services started by these port monitors, including `ttymon` login services, are killed.

This request corresponds to a request for `smf(5)` to restrict the system milestone to `svc:/milestone/single-user:default`.

### Files
- `/dev/console`
  - System console device.
- `/etc/default/init`
  - Contains environment variables and their default values. For example, for the timezone variable, `TZ`, you might specify `TZ=US/Pacific`. The variables are:

  **TZ**
  - Either specifies the timezone information (see `ctime(3C)` or the name of a timezone information file `/usr/share/lib/zoneinfo`.
  - Refer to the `TIMEZONE(4)` man page before changing this setting.

  **CMASK**
  - The mask (see `umask(1)`) that `init` uses and that every process inherits from the `init` process. If not set, `init` uses the mask it inherits from the kernel. Note that `init` always attempts to apply a `umask` of 022 before creating a file, regardless of the setting of `CMASK`.

  **LC_CTYPE**
  - Character characterization information

  **LC_MESSAGES**
  - Message translation

  **LC_MONETARY**
  - Monetary formatting information
LC_NUMERIC
   Numeric formatting information

LC_TIME
   Time formatting information

LC_ALL
   If set, all other LC_* environmental variables take on this value.

LANG
   If LC_ALL is not set, and any particular LC_* is also not set, the value of LANG is used for that particular environmental variable.

/etc/inittab
   Controls process dispatching by init.

/etc/ioctl.syscon
   ioctl states of the console, as saved by init when single-user state is entered.

/etc/svc/volatile/init.state
   init state necessary to recover from failure.

/var/adm/utmpx
   User access and administration information.

/var/adm/wtmpx
   History of user access and administration information.

/etc/initpipe
   A named pipe used for internal communication.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcs</td>
</tr>
</tbody>
</table>

See Also  login(1), sh(1), stty(1), who(1), kernel(1M), shutdown(1M), su(1M), svc.configd(1M), svc.statd(1M), ttymon(1M), ioctl(2), kill(2), ctime(3C), pam(3PAM), init.d(4), inittab(4), pam.conf(4), TIMEZONE(4), utmpx(4), attributes(5), pam_unix_session(5), smf(5), termio(7I)

Diagnostics  If init finds that it is respawning an entry from /etc/inittab more than ten times in two minutes, it assumes that there is an error in the command string in the entry and generates an error message on the system console. It then refuses to respawn this entry until either five minutes has elapsed or it receives a signal from a user-spawned init or telinit command. This prevents init from eating up system resources when someone makes a typographical error in the inittab file, or a program is removed that is referenced in /etc/inittab.
Notes  init and telinit can be run only by a privileged user.

The S or s state must not be used indiscriminately in /etc/inittab. When modifying this file, it is best to avoid adding this state to any line other than initdefault.

If a default state is not specified in the initdefault entry in /etc/inittab, state 6 is entered. Consequently, the system will loop by going to firmware and rebooting continuously.

If the utmpx file cannot be created when booting the system, the system will boot to state "S" regardless of the state specified in the initdefault entry in /etc/inittab. This can occur if the /var filesystem is not accessible.

When a system transitions down to the S or s state, the /etc/nologin file (see nologin(4)) is created. Upon subsequent transition to run level 2, this file is removed.

init uses /var/run/initpipe, a named pipe, for internal communication.

The pam_unix(5) module is no longer supported. Similar functionality is provided by pam_unix_session(5).
Name  init.sma – start and stop the snmpd daemon

Synopsis  /etc/init.d/init.sma start | stop | restart | status

Description  The init.sma utility is run automatically during installation and each time the system is rebooted. This utility manages the snmpd. See snmpd(1M).

Options  The following options are supported:

- start  Starts the snmpd daemon.
- stop   Stops the snmpd daemon.
- restart Stops then starts the snmpd daemon.
- status Reports the snmpd daemon’s status.

</table>

See Also  snmpd(1M), attributes(5)
init.wbem(1M)

Name  init.wbem – start and stop the CIM Boot Manager

Synopsis  svccfg svc:/application/management/wbem start | stop

Description  The `init.wbem` utility is run automatically during installation, each time the system is rebooted, and by means of the `svccfg(1M)` command. This method manipulates the CIM Object Manager (CIMOM) and the Solaris Management Console server, both of which run combined in a single process. `init.wbem` can be used to start, stop, or retrieve status from the server.

The CIM Object Manager manages CIM objects on a WBEM-enabled system. A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects are stored internally as Java classes.

When a WBEM client application accesses information about a CIM object, the CIM Object Manager contacts either the appropriate provider for that object or the CIM Object Manager Repository. Providers are classes that communicate with managed objects to access data.

When a WBEM client application requests data from a managed resource that is not available from the CIM Object Manager Repository, the CIM Object Manager forwards the request to the provider for that managed resource. The provider dynamically retrieves the information.

At startup, the CIM Object Manager performs the following functions:

- Listens for RMI connections on RMI port 5987 and for XML/HTTP connections on HTTP port 5988.
- Sets up a connection to the CIM Object Manager Repository.
- Waits for incoming requests.

During normal operations, the CIM Object Manager performs the following functions:

- Performs security checks to authenticate user login and authorization to access namespaces.
- Performs syntactical and semantic checking of CIM data operations to ensure that they comply with the latest CIM Specification.
- Routes requests to the appropriate provider or to the CIM Object Manager Repository.
- Delivers data from providers and from the CIM Object Manager Repository to WBEM client applications.

A WBEM client application contacts the CIM Object Manager to establish a connection when it needs to perform WBEM operations, such as creating a CIM class or updating a CIM instance. When a WBEM client application connects to a CIM Object Manager, it gets a reference to the CIM Object Manager, which it then uses to request services and operations.
The Solaris Management Console server is the back end to the front end console, \texttt{smc(1M)}. It provides tools for the console to download and performs common services for the console and its tools to use, such as authentication, authorization, logging, messaging, and persistence.

The \texttt{init.wbem} script is installed in the \texttt{/etc/init.d} directory.

The \texttt{init.wbem} function is implemented as a service management facility (SMF) method and is controlled by means of the \texttt{svcadm(1M)} command using the fault management resource identifier (FMRI) \texttt{svc:/application/management/wbem}.

The following options are supported through \texttt{svcadm(1M)}:

- **start**: Starts the CIMOM and Solaris Management Console server on the local host.
- **stop**: Stops the CIMOM and Solaris Management Console server on the local host.
- **status**: Gets the status of the CIMOM and Solaris Management Console server on the local host.

The SMF property \texttt{options/tcp_listen} is used to control whether CIMOM and the Solaris Management console server will respond to requests from remote systems.

The specification:

\[
\texttt{svc:/application/management/wbem/options/tcp\_listen = true}
\]

...allows remote access and \texttt{false} disallows remote access. \texttt{false} is the default value.

**Examples**

**EXAMPLE 1** Allowing Access to Remote Systems

The following commands enable CIMOM and the Solaris Management Console server to allow access from remote systems.

```
# svccfg -s \\
svc:/application/management/wbem setprop options/tcp\_listen = true \\
# svcadm refresh svc:/application/management/wbem
```

**Notes**

When the \texttt{init.wbem} script is invoked by SMF, it does not run the CIMOM and Solaris Management Console server directly. The server process is in Java and is too heavyweight to be run immediately at system boot time. Instead, three lightweight processes listen on three different ports that the CIMOM and the Solaris Management Console server normally use. This acts similarly to \texttt{inetd(1M)}.

Because Java programs cannot inherit file descriptors as other programs can, there is a small time period from when the first connection is made until the server is fully operational where client connections may be dropped. WBEM clients are immune to this, as they will retry until the server comes online. Solaris Management Console clients are not immune, and it may be necessary to manually reconnect, though this should not happen in the common case.

See Also  inetd(1M), mofcomp(1M), smc(1M), smcconf(1M), svccfg(1M), svcadm(1M), wbemadmin(1M), wbemlogviewer(1M), attributes(5), smf(5)
The `inityp2l` utility assists with creation of the NISLDAPmapping and ypserv files. See `NISLDAPmapping(4)` and `ypserv(4)`. `inityp2l` examines the NIS maps on a system, and through a dialogue with the user, determines which NIS to (and from) LDAP mappings are required. A NISLDAPmapping file is then created based on this information. The utility asks users about their LDAP server configuration and a ypserv file is created based on this information.

`FINITYP2L` utility handles mappings for standard NIS maps and the auto.* series of maps. If requested, it creates default mappings for custom maps, with each map entry represented as a single DIT string. `FINITYP2L` does not handle full custom mapping, but if requested, `FINITYP2L` will insert comments into the NISLDAPmapping file that indicate where these should be added.

To write to the NISLDAPmapping or ypserv files is potentially dangerous. `FINITYP2L` warns the user and asks for confirmation before:

1. it overwrites either file
2. it writes to the default NISLDAPmapping file location, if this file did not previously exist.

This is important because the existence of a file in this location causes NIS components to work NIS to LDAP (N2L) mode when next restarted, rather than to traditional NIS mode.

`FINITYP2L` assists with rapid creation of a simple N2L configuration files. It is not a general purpose tool for the management of these files. An advanced user who would like to maintain the files or use custom mappings should examine the output of `FINITYP2L` and customize it by using a standard text editor.

### Options

- `-c` Specify the name of the generated ypserv file. The default location is described in `Files`
- `-m` Specify the name of the generated NISLDAPmapping file. The default is described in `Files`.

### Files

- `/var/yp` The directory to be searched for candidate domains (`/var/yp/*`) and NIS maps (`/var/yp/*/`)
- `/var/yp/NISLDAPmapping` The default location for the generated NISLDAPmapping file
- `/etc/default/ypserv` The default location for the generated ypserv file

in.lpd – BSD print protocol adaptor

**Synopsis**

```
/usr/lib/print/in.lpd
```

**Description**

in.lpd implements the network listening service for the BSD print protocol specified in RFC 1179. The BSD print protocol provides a remote interface for systems to interact with a local spooling system. The protocol defines five standard requests from the client to the server:

- starting queue processing,
- transferring print jobs,
- retrieving terse status,
- retrieving verbose status, and
- canceling print jobs.

The in.lpd service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/lp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

in.lpd uses the `config/log_from_remote` property to allow or disallow remote access. The default value of this property, `localhost`, disallows remote access.

`inetd` waits for connections on TCP port 515. Upon receipt of a connect request, in.lpd is started to service the connection. Once the request has been filled, in.lpd closes the connection and exits.

### Examples

**EXAMPLE 1  Allowing Remote Access**

The following command allows remote access to in.lpd.

```
# inetadm -m svc:/application/print/rfc1179:default bind_addr=""
```

### Exit Status

The following exit values are returned:

- 0  
  Successful completion.
- non-zero  
  An error occurred.

**Files**

- `/etc/printers.conf`  
  System printer configuration database.
- `printers.conf.byname`  
  NIS version of `/etc/printers.conf`.
- `printers.org_dir`  
  NIS+ version of `/etc/printers.conf`.
- `/usr/lib/print/bsd-adaptor/bsd_*.so*`  
  Spooler translation modules.

in.mpathd -- daemon for network adapter (NIC) failure detection, recovery, automatic failover and failback

/in.mpathd

The in.mpathd daemon performs Network Interface Card (NIC) failure and repair detection. In the event of a NIC failure, it causes IP network access from the failed NIC to failover to a standby NIC, if available, or to any another operational NIC that has been configured as part of the same network multipathing group. Once the failed NIC is repaired, all network access is restored to the repaired NIC.

The in.mpathd daemon can detect NIC failure and repair through two methods: by monitoring the IFF_RUNNING flag for each NIC (link-based failure detection), and by sending and receiving ICMP echo requests and replies on each NIC (probe-based failure detection). Link-based failure detection requires no explicit configuration and thus is always enabled (provided the NIC driver supports the feature); probe-based failure detection must be enabled through the configuration of one or more test addresses (described below), but has the benefit of testing the entire NIC send and receive path.

If only link-based failure detection is enabled, then the health of the interface is determined solely from the state of the IFF_RUNNING flag. Otherwise, the interface is considered failed if either of the two methods indicate a failure, and repaired once both methods indicate the failure has been corrected. Not all interfaces in a group need to be configured with the same failure detection methods.

As mentioned above, in order to perform probe-based failure detection in.mpathd needs a special test address on each NIC for the purpose of sending and receiving probes on the NIC. Use the ifconfig command -failover option to configure these test addresses. See ifconfig(1M). The test address must belong to a subnet that is known to the hosts and routers on the link.

The in.mpathd daemon can detect NIC failure and repair by two methods, by sending and receiving ICMP echo requests and replies on each NIC, and by monitoring the IFF_RUNNING flag for each NIC. The link state on some models of NIC is indicated by the IFF_RUNNING flag, allowing for faster failure detection when the link goes down. The in.mpathd daemon considers a NIC to have failed if either of the above two methods indicates failure. A NIC is considered to be repaired only if both methods indicate the NIC is repaired.

The in.mpathd daemon sends the ICMP echo request probes to on-link routers. If no routers are available, it sends the probes to neighboring hosts. Thus, for network failure detection and repair, there must be at least one neighbor on each link that responds to ICMP echo request probes.

in.mpathd works on both IPv4 and IPv6. If IPv4 is plumbed on a NIC, an IPv4 test address is configured on the NIC, and the NIC is configured as part of a network multipathing group, then in.mpathd will start sending ICMP probes on the NIC using IPv4.
In the case of IPv6, the link-local address must be configured as the test address. The `in.mpathd` daemon will not accept a non-link-local address as a test address. If the NIC is part of a multipathing group, and the test address has been configured, then `in.mpathd` will probe the NIC for failures using IPv6.

Even if both the IPv4 and IPv6 protocol streams are plumbed, it is sufficient to configure only one of the two, that is, either an IPv4 test address or an IPv6 test address on a NIC. If only an IPv4 test address is configured, it probes using only ICMPv4. If only an IPv6 test address is configured, it probes using only ICMPv6. If both type test addresses are configured, it probes using both ICMPv4 and ICMPv6.

The `in.mpathd` daemon accesses three variable values in `/etc/default/mpathd`:

- `FAILURE_DETECTION_TIME`
- `FAILBACK`
- `TRACK_INTERFACES_ONLY_WITH_GROUPS`

The `FAILURE_DETECTION_TIME` variable specifies the NIC failure detection time for the ICMP echo request probe method of detecting NIC failure. The shorter the failure detection time, the greater the volume of probe traffic. The default value of `FAILURE_DETECTION_TIME` is 10 seconds. This means that NIC failure will be detected by `in.mpathd` within 10 seconds. NIC failures detected by the `IFF_RUNNING` flag being cleared are acted on as soon as the `in.mpathd` daemon notices the change in the flag. The NIC repair detection time cannot be configured; however, it is defined as double the value of `FAILURE_DETECTION_TIME`.

By default, `in.mpathd` does failure detection only on NICs that are configured as part of a multipathing group. You can set `TRACK_INTERFACES_ONLY_WITH_GROUPS` to `no` to enable failure detection by `in.mpathd` on all NICs, even if they are not part of a multipathing group. However, `in.mpathd` cannot do failover from a failed NIC if it is not part of a multipathing group.

The `in.mpathd` daemon will restore network traffic back to the previously failed NIC, after it has detected a NIC repair. To disable this, set the value of `FAILBACK` to `no` in `/etc/default/mpathd`.

### Files
`/etc/default/mpathd` contains default values used by the `in.mpathd` daemon.

*System Administration Guide: IP Services*
**Diagnostics**

Test address `address` is not unique; disabling probe based failure detection on `interface_name`  
**Description:** For `in.mpathd` to perform probe-based failure detection, each test address in the group must be unique. Since the IPv6 test address is a link-local address derived from the MAC address, each IP interface in the group must have a unique MAC address.

NIC `interface_name` of group `group_name` is not plumbed for IPv{4|6} and may affect failover capability  
**Description:** All NICs in a multipathing group must be homogeneously plumbed. For example, if a NIC is plumbed for IPv4, then all NICs in the group must be plumbed for IPv4. The streams modules pushed on all NICs must be identical.

No test address configured on interface `interface_name` disabling probe-based failure detection on it  
**Description:** In order for `in.mpathd` to perform probe-based failure detection on a NIC, it must be configured with a test address: IPv4, IPv6, or both.

The link has come up on `interface_name` more than 2 times in the last minute; disabling failback until it stabilizes.  
**Description:** In order to prevent interfaces with intermittent hardware, such as a bad cable, from causing repeated failovers and failbacks, `in.mpathd` does not failback to interfaces with frequently fluctuating link states.

Invalid failure detection `time` assuming default 10000  
**Description:** An invalid value was encountered for `FAILURE_DETECTION_TIME` in the `/etc/default/mpathd` file.

Too small failure detection time of `time` assuming minimum 100  
**Description:** The minimum value that can be specified for `FAILURE_DETECTION_TIME` is currently 100 milliseconds.

Invalid value for `FAILBACK` value  
**Description:** Valid values for the boolean variable `FAILBACK` are yes or no.

Invalid value for `TRACK_INTERFACES_ONLY_WITH_GROUPS` value  
**Description:** Valid values for the boolean variable `TRACK_INTERFACES_ONLY_WITH_GROUPS` are yes or no.

Cannot meet requested failure detection time of `time` ms on (inet{6} `interface_name`) new failure detection time for group `group_name` is `time` ms  
**Description:** The round trip time for ICMP probes is higher than necessary to maintain the current failure detection time. The network is probably congested or the probe targets are loaded. `in.mpathd` automatically increases the failure detection time to whatever it can achieve under these conditions.
Improved failure detection time \textit{time} ms on (inet[6] \textit{interface_name}) for group \textit{group_name}

\textbf{Description:} The round trip time for ICMP probes has now decreased and \texttt{in.mpathd} has lowered the failure detection time correspondingly.

NIC failure detected on \textit{interface_name}

\textbf{Description:} \texttt{in.mpathd} has detected NIC failure on \textit{interface_name}, and has set the \texttt{IFF_FAILED} flag on NIC \textit{interface_name}.

Successfully failed over from NIC \textit{interface_name1} to NIC \textit{interface_name2}

\textbf{Description:} \texttt{in.mpathd} has caused the network traffic to failover from NIC \textit{interface_name1} to NIC \textit{interface_name2}, which is part of the multipathing group.

NIC repair detected on \textit{interface_name}

\textbf{Description:} \texttt{in.mpathd} has detected that NIC \textit{interface_name} is repaired and operational. If the \texttt{IFF_FAILED} flag on the NIC was previously set, it will be reset.

Successfully failed back to NIC \textit{interface_name}

\textbf{Description:} \texttt{in.mpathd} has restored network traffic back to NIC \textit{interface_name}, which is now repaired and operational.

The link has gone down on \textit{interface_name}

\textbf{Description:} \texttt{in.mpathd} has detected that the \texttt{IFF_RUNNING} flag for NIC \textit{interface_name} has been cleared, indicating the link has gone down.

The link has come up on \textit{interface_name}

\textbf{Description:} \texttt{in.mpathd} has detected that the \texttt{IFF_RUNNING} flag for NIC \textit{interface_name} has been set, indicating the link has come up.
in.ndpd(1M)

**Name**
in.ndpd – daemon for IPv6 autoconfiguration

**Synopsis**
/usr/lib/inet/in.ndpd [-adt] [-f config_file]

**Description**
in.ndpd provides both the host and router autoconfiguration components of Neighbor Discovery for IPv6 and Stateless Address Autoconfiguration for IPv6. In particular, in.ndpd implements

- router discovery;
- prefix discovery;
- parameter discovery;
- address autoconfiguration; and
- privacy extensions for stateless address autoconfiguration.

Other aspects of Neighbor Discovery are implemented by ip6(7P), including:

- address resolution;
- neighbor unreachability detection; and
- redirect.

The duplicate address detection function is implemented by ifconfig(1M).

If the /etc/inet/ndpd.conf file does not exist or does not set the variable AdvSendAdvertisements to true for a network interface, then in.ndpd will make the node a host for that interface, that is, sending router solicitation messages and then using router advertisement messages it receives to autoconfigure the node. Note that in.ndpd only autoconfigures the addresses of global or site-local scope from the prefix advertisement.

If AdvSendAdvertisements is set to true for an interface, then in.ndpd will perform router functions on that interface, that is, sending router advertisement messages to autoconfigure the attached hosts, but not use any advertisements it receives for autoconfiguration. However, when sending advertisements, in.ndpd will use the advertisements it sends itself to autoconfigure its prefixes.

Stateless autoconfiguration requires no manual configuration of hosts, minimal (if any) configuration of routers, and no additional servers. The stateless mechanism enables a host to generate its own addresses and uses local information as well as non-local information that is advertised by routers to generate the addresses.

Temporary addresses that are autoconfigured for an interface can also be implemented. A temporary address token is enabled for one or more interfaces on a host. However, unlike standard, autoconfigured IPv6 addresses, a temporary address consists of the site prefix and a randomly generated 64 bit number. This random number becomes the interface ID segment of the IPv6 address. A link-local address is not generated with the temporary address as the interface ID.

Routers advertise all prefixes that have been assigned on the link. IPv6 hosts use Neighbor Discovery to obtain a subnet prefix from a local router. Hosts automatically create IPv6
addresses by combining the subnet prefix with an interface IDs that is generated from an interface's MAC address. In the absence of routers, a host can generate only link-local addresses. Link-local addresses can only be used for communication with nodes on the same link.

For information on how to enable IPv6 address autoconfiguration, see System Administration Guide: IP Services

**Options**

- **-a**  
  Turn off stateless address auto configuration. When set, the daemon does not autoconfigure any addresses and does not renumber any addresses. This option does the same thing as the following line in `ndpd.conf`:
  ```
  ifdefault StatelessAddrConf off
  ```
- **-d**  
  Turn on large amounts of debugging output on stdout. When set, the program runs in the foreground and stays attached to the controlling terminal.
- **-t config_file**  
  Use `config_file` for configuration information instead of the default `/etc/inet/ndpd.conf`.
- **-t**  
  Turn on tracing (printing) of all sent and received packets to stdout. When set, the program runs in the foreground and stays attached to the controlling terminal.

**Files**

`/etc/inet/ndpd.conf`  
Configuration file. This file is not necessary on a host, but it is required on a router to enable `in.ndpd` to advertise autoconfiguration information to the hosts.

Diagnostics  Receipt of a SIGHUP signal will make in.ndpd restart and reread /etc/inet/ndpd.conf.
in.rarpd(1M)

Name  in.rarpd, rarpd – DARPA Reverse Address Resolution Protocol server

Synopsis  

/usr/sbin/in.rarpd [-d] -a

/usr/sbin/in.rarpd [-d] device unit

Description  in.rarpd starts a daemon that responds to Reverse Address Resolution Protocol (RARP) requests. The daemon forks a copy of itself that runs in background. It must be run as root.

RARP is used by machines at boot time to discover their Internet Protocol (IP) address. The booting machine provides its Ethernet address in a RARP request message. Using the ethers and hosts databases, in.rarpd maps this Ethernet address into the corresponding IP address which it returns to the booting machine in an RARP reply message. The booting machine must be listed in both databases for in.rarpd to locate its IP address. in.rarpd issues no reply when it fails to locate an IP address.

in.rarpd uses the STREAMS-based Data Link Provider Interface (DLPI) message set to communicate directly with the datalink device driver.

Options  The following options are supported:
-a  Get the list of available network interfaces from IP using the SIOCGIFADDR ioctl and start a RARP daemon process on each interface returned.
-d  Print assorted debugging messages while executing.

Examples  

EXAMPLE 1  Starting An in.rarpd Daemon For Each Network Interface Name Returned From /dev/ip:

The following command starts an in.rarpd for each network interface name returned from /dev/ip:

example# /usr/sbin/in.rarpd -a

EXAMPLE 2  Starting An rarpd Daemon On The Device /dev/le With The Device Instance Number 0

The following command starts one in.rarpd on the device /dev/le with the device instance number 0.

example# /usr/sbin/in.rarpd le 0

Files  /etc/ethers  File or other source, as specified by nsswitch.conf(4).
/etc/hosts  File or other source, as specified by nsswitch.conf(4).
/tftpboot
/dev/ip
/dev/arp
Attributes  See attributes(5) for descriptions of the following attributes:

nsswitch.conf(4), attributes(5), smf(5), dlpi(7P)

Notes  The in.rarpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rarp

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service’s status can be queried using the svcvs(1) command.
**Name**
in.rdisc, rdisc – network router discovery daemon

**Synopsis**

```
/usr/sbin/in.rdisc  [-a] [-f] [-s] [send-address] [receive-address]
```

```
/usr/sbin/in.rdisc  -r [-p preference] [-T interval] [send-address] [receive-address]
```

**Description**
in.rdisc remains part of the software distribution of the Solaris Operating Environment. It is, however, not used by default. `in.routed(1M)` includes the functionality provided by in.rdisc. See `routeadm(1M)` for details of how to specify the IPV4 routing daemon.

in.rdisc implements the ICMP router discovery protocol. The first form of the command is used on hosts and the second form is used on routers.

in.rdisc can be invoked in either the first form (host mode) or second form (router mode).

On a host, in.rdisc populates the network routing tables with default routes. On a router, advertises the router to all the hosts.

in.rdisc is managed by the service management facility (SMF), by means of the service identifier:

```
svc:/network/routing/rdisc:default
```

**Host (First Form)**
On a host, in.rdisc listens on the ALL_HOSTS (224.0.0.1) multicast address for ROUTER_ADVERTISE messages from routers. The received messages are handled by first ignoring those listed router addresses with which the host does not share a network. Among the remaining addresses, the ones with the highest preference are selected as default routers and a default route is entered in the kernel routing table for each one of them.

Optionally, in.rdisc can avoid waiting for routers to announce themselves by sending out a few ROUTER_SOLICITATION messages to the ALL_ROUTERS (224.0.0.2) multicast address when it is started.

A timer is associated with each router address. The address will no longer be considered for inclusion in the routing tables if the timer expires before a new advertise message is received from the router. The address will also be excluded from consideration if the host receives an advertise message with the preference being maximally negative or with a lifetime of zero.

**Router (Second Form)**

When in.rdisc is started on a router, it uses the SIOCGIFCONF ioctl(2) to find the interfaces configured into the system and it starts listening on the ALL_ROUTERS multicast address on all the interfaces that support multicast. It sends out advertise messages to the ALL_HOSTS multicast address advertising all its IP addresses. A few initial advertise messages are sent out during the first 30 seconds and after that it will transmit advertise messages approximately every 600 seconds.

When in.rdisc receives a solicitation message, it sends an advertise message to the host that sent the solicitation message.
When `in.rdisc` is terminated by a signal, it sends out an `advertise` message with the preference being maximally negative.

**Options**

Supported options and equivalent SMF service properties are listed below. SMF service properties are set using a command of the form:

```
# routeadm -m rdisc:default key=value
```

- `-a` Accept all routers independent of the preference they have in their `advertise` messages. Normally, `in.rdisc` only accepts (and enters in the kernel routing tables) the router or routers with the highest preference. Use of this option is equivalent to setting the `accept_all` property to true.

- `-f` Run `in.rdisc` forever even if no routers are found. Normally, `in.rdisc` gives up if it has not received any `advertise` message after soliciting three times, in which case it exits with a non-zero exit code. If `-f` is not specified in the first form then `-s` must be specified. For SMF execution, this option is required.

- `-r` Act as a router, rather than a host. Use of this option is equivalent to setting the `act_as_router` property to true.

- `-s` Send three `solicitation` messages initially to quickly discover the routers when the system is booted. When `-s` is specified, `in.rdisc` exits with a non-zero exit code if it cannot find any routers. This can be overridden with the `-f` option. This option is not supported for the `rdisc` service.

- `-p preference` Set the preference transmitted in the `solicitation` messages. The default is zero. Use of this option is equivalent to setting the `preference` property.

- `-T interval` Set the interval between transmitting the `advertise` messages. The default time is 600 seconds. Use of this option is equivalent to setting the `transmit_interval` property.

The `send-address` and `receive-address` daemon options can be set by means of the `send_address` and `receive_address` properties.

**Attributes**

in.rexed(1M)

Name
in.rexed, rexedc – remote execution server

Synopsis
in.rexed

Description
in. rexed is the server for the rexec(3SOCKET) routine. The server provides remote execution facilities with authentication based on user names and passwords. It is invoked automatically as needed by inetd(1M), and then executes the following protocol:

1. The server reads characters from the socket up to a null (\0) byte. The resultant string is interpreted as an ASCII number, base 10.
2. If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the stderr. A second connection is then created to the specified port on the client’s machine.
3. A null terminated user name of at most 16 characters is retrieved on the initial socket.
4. A null terminated password of at most 16 characters is retrieved on the initial socket.
5. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system’s argument list.
6. rexedc then validates the user as is done at login time and, if the authentication was successful, changes to the user’s home directory, and establishes the user and group protections of the user. If any of these steps fail the connection is aborted and a diagnostic message is returned.
7. A null byte is returned on the connection associated with the stderr and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by rexedc.

Usage
in.rexed and rexedc are IPv6–enabled. See ip6(7P).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWrcmds</td>
</tr>
</tbody>
</table>

See Also
svcs(1), inetd(1M), inetadm(1M), svcadm(1M), rexec(3SOCKET), attributes(5), smf(5), ip6(7P)

Diagnostics
All diagnostic messages are returned on the connection associated with the stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 (0 is returned in step 7 above upon successful completion of all the steps prior to the command execution).

username too long
  The name is longer than 16 characters.

password too long
  The password is longer than 16 characters.
command too long  The command line passed exceeds the size of the argument list (as configured into the system).
Login incorrect.  No password file entry for the user name existed.
Password incorrect. The wrong password was supplied.
No remote directory. The chdir command to the home directory failed.
Try again.  A fork by the server failed.
/usr/bin/sh: ...  The user's login shell could not be started.

Notes  The in.rexecd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rexec:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
in.ripngd – network routing daemon for IPv6

Synopsis
[logfile]

Description
in.ripngd is the IPv6 equivalent of `in.routed(1M)`. It is invoked at boot time to manage
in.ripngd is managed by the service management facility (SMF), by means of the service
identifier:
svc:/network/routing/ripng:default

In normal operation, in.ripngd listens on the `udp(7P)` socket port 521 for routing
information packets. If the host is an internetwork router, it periodically supplies copies of its
routing tables to any directly connected hosts and networks.

When in.ripngd is started, it uses the SIOCGLIFCONF `ioctl(2)` to find those directly
connected IPv6 interfaces configured into the system and marked “up”; the software loopback
interface is ignored. If multiple interfaces are present, it is assumed the host will forward
packets between networks. in.ripngd then multicasts a request packet on each IPv6 interface
and enters a loop, listening for request and response packets from other hosts.

When a request packet is received, in.ripngd formulates a reply based on the information
maintained in its internal tables. The response packet contains a list of known routes. With
each route is a number specifying the number of bits in the prefix. The prefix is the number of
bits in the high order part of an address that indicate the subnet or network that the route
describes. Each route reported also has a “hop count” metric. A count of 16 or greater is
considered “infinity.” The metric associated with each route returned provides a metric
relative to the sender.

The request packets received by in.ripngd are used to update the routing tables if one of the
following conditions is satisfied:

- No routing table entry exists for the destination network or host, and the metric indicates
  the destination is “reachable”, that is, the hop count is not infinite.
- The source host of the packet is the same as the router in the existing routing table entry.
  That is, updated information is being received from the very internetwork router through
  which packets for the destination are being routed.
- The existing entry in the routing table has not been updated for a period of time, defined to
  be 90 seconds, and the route is at least as cost-effective as the current route.
- The new route describes a shorter route to the destination than the one currently stored in
  the routing tables; this is determined by comparing the metric of the new route against the
  one stored in the table.
When an update is applied, `in.ripngd` records the change in its internal tables and generates a response packet to all directly connected hosts and networks. To allow possible unstable situations to settle, `in.ripngd` waits a short period of time (no more than 30 seconds) before modifying the kernel's routing tables.

In addition to processing incoming packets, `in.ripngd` also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

`in.ripngd` supports the options listed below. Listed with the options are the equivalent SMF property values. These are set for the `ripng:default` service with a command of the form:

```
# routeadm -m ripng:default key=value
```

- `p n` Send and receive the routing packets from other routers using the UDP port number `n`. Use of this option is equivalent to setting the `udp_port` property.
- `-P` Do not use poison reverse. Use of this option is equivalent to setting the `poison_reverse` property to false.
- `-q` Do not supply routing information. Use of this option is equivalent to setting the `quiet_mode` property to true.
- `-s` Force `in.ripngd` to supply routing information whether it is acting as an internetwork router or not. Use of this option is equivalent to setting the `supply_routes` property to true.
- `-t` Print all packets sent or received to standard output. `in.ripngd` will not divorce itself from the controlling terminal. Accordingly, interrupts from the keyboard will kill the process. Not supported by the `ripng` service.
- `-v` Print all changes made to the routing tables to standard output with a timestamp. Use of this option is equivalent to setting the `verbose` property to true.

Any other argument supplied to this option is interpreted as the name of the file in which the actions of `in.ripngd`, as specified by this option or by `-t`, should be logged instead of being sent to standard output.

The logfile can be specified for the `ripng` service by means of the `log_file` property.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

Notes The kernel’s routing tables may not correspond to those of in.ripngd for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

in.ripngd currently does not support all of the functionality of in.routed(1M). Future releases may support more if appropriate.

in.ripngd initially obtains a routing table by examining the interfaces configured on a machine. It then sends a request on all directly connected networks for more routing information. in.ripngd does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, in.ripngd does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by means of the route(1M) command. Therefore, these types of changes should not be done while in.ripngd is running. Rather, shut down in.ripngd, make the changes required, and then restart in.ripngd.
in.rlogind is the server for the rlogin(1) program. The server provides a remote login facility with authentication based on Kerberos V5 or privileged port numbers.

in.rlogind is invoked by inetd(1M) when a remote login connection is established. When Kerberos V5 authentication is required (see option -k below), the authentication sequence is as follows:

- Check Kerberos V5 authentication.
- Check authorization according to the rules in krb5_auth_rules(5).
- Prompt for a password if any checks fail and /etc/pam.conf is configured to do so.

In order for Kerberos authentication to work, a host/<FQDN> Kerberos principal must exist for each Fully Qualified Domain Name associated with the in.rlogind server. Each of these host/<FQDN> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on the in.rlogind server. An example principal might be:

host/bigmachine.eng.example.com

See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a krb5.keytab file. See System Administration Guide: Security Services for a discussion of Kerberos authentication.

If Kerberos V5 authentication is not enabled, then the authentication procedure follows the standard rlogin protocol:

- The server checks the client’s source port. If the port is not in the range 512-1023, the server aborts the connection.
- The server checks the client’s source address. If an entry for the client exists in both /etc/hosts and /etc/hosts.equiv, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in /etc/hosts, the user is prompted for a password, regardless of whether or not an entry for the client is present in /etc/hosts.equiv. See hosts(4) and hosts.equiv(4).

Once the source port and address have been checked, in.rlogind allocates a pseudo-terminal and manipulates file descriptors so that the slave half of the pseudo-terminal becomes the stdin, stdout, and stderr for a login process. The login process is an instance of the login(1) program, invoked with the -r.

The login process then proceeds with the pam(3PAM) authentication process. See SECURITY below. If automatic authentication fails, it reprompts the user to login.
The parent of the login process manipulates the master side of the pseudo-terminal, operating as an intermediary between the login process and the client instance of the `rlogin` program. In normal operation, a packet protocol is invoked to provide Ctrl-S and Ctrl-Q type facilities and propagate interrupt signals to the remote programs. The login process propagates the client terminal's baud rate and terminal type, as found in the environment variable, `TERM`.

**Options**

The following options are supported:

- `-5` Same as `-k`, for backwards compatibility.
- `-c` Requires Kerberos V5 clients to present a cryptographic checksum of initial connection information like the name of the user that the client is trying to access in the initial authenticator. This checksum provides additional security by preventing an attacker from changing the initial connection information. This option is mutually exclusive with the `-i` option.
- `-e` Creates an encrypted session.
- `-E` Same as `-e`, for backwards compatibility.
- `-i` Ignores authenticator checksums if provided. This option ignores authenticator checksums presented by current Kerberos clients to protect initial connection information. Option `-i` is the opposite of option `-c`.
- `-k` Allows Kerberos V5 authentication with the `.k5login` access control file to be trusted. If this authentication system is used by the client and the authorization check is passed, then the user is allowed to log in.
- `-M realm` Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the `krb5.conf` file.
- `-p` Prompts for authentication only if other authentication checks fail.
- `-P` Prompts for a password in addition to other authentication methods.
- `-s tos` Sets the IP TOS option.
- `-S keytab` Sets the KRB5 keytab file to use. The `/etc/krb5/krb5.keytab` file is used by default.
- `-x` Same as `-e`, for backwards compatibility.
- `-X` Same as `-e`, for backwards compatibility.

**Usage**

`rlogind` and `in.rlogind` are IPv6–enabled. See `ip6(7P)`. IPv6 is not currently supported with Kerberos V5 authentication.

Typically, Kerberized `rlogin` service runs on port 543 (`klogin`) and Kerberized, encrypted `rlogin` service runs on port 2105 (`eklogin`). The corresponding FMRI entries are:

```
svc:/network/login:klogin (rlogin with kerberos)
svc:/network/login:eklogin (rlogin with kerberos and encryption)
```
Security  
in. rlogind uses pam(3PAM) for authentication, account management, and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in. rlogind. Here is a partial pam.conf file with entries for the rlogin command using the "rhosts" and UNIX authentication modules, and the UNIX account, session management, and password management modules.

```
rlogin authsufficient pam_rhosts_auth.so.1
rlogin authrequisite pam_authtok_get.so.1
rlogin authrequired pam_dhkeys.so.1
rlogin authrequired pam_unix_auth.so.1
rlogin accountrequired pam_unix_roles.so.1
rlogin accountrequired pam_unix_projects.so.1
rlogin accountrequired pam_unix_account.so.1
rlogin sessionrequired pam_unix_session.so.1
```

With this configuration, the server checks the client's source address. If an entry for the client exists in both /etc/hosts and /etc/hosts.equiv, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in /etc/hosts, the user is prompted for a password, regardless of whether or not an entry for the client is present in /etc/hosts.equiv. See hosts(4) and hosts.equiv(4).

When running a Kerberized rlogin service (with or without the encryption option), the pam service name that should be used is "krlogin".

If there are no entries for the rlogin service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords. Removing the pam_rhosts_auth.so.1 entry will disable the /etc/hosts.equiv and ~/.rhosts authentication protocol and the user would always be forced to type the password. The sufficient flag indicates that authentication through the pam_rhosts_auth.so.1 module is sufficient to authenticate the user. Only if this authentication fails is the next authentication module used.

Attributes  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

See Also: login(1), svc(1), rlogin(1), gkadmin(1M), in.rshd(1M), inetadm(1M), inetd(1M), kadm(1M), svcadm(1M), pam(3PAM), hosts(4), hosts.equiv(4), krb5.conf(4), pam.conf(4), attributes(5), environ(5), krb5_auth_rules(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), smf(5)

Diagnostics: All diagnostic messages are returned on the connection associated with the stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1.

Try again.
A fork by the server failed.

Notes: The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

The pam_unix(5) module is no longer supported. Similar functionality is provided by pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).

The in.rlogind service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/login:rlogin (rlogin)
svc:/network/login:klogin (rlogin with kerberos)
svc:/network/login:eklogin (rlogin with kerberos and encryption)

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
The daemon `in.routed`, often referred to as `routed`, is invoked at boot time to manage the network routing tables. It uses Routing Information Protocol, RIPv1 (RFC 1058), RIPv2 (RFC 2453), and Internet Router Discovery Protocol (RFC 1256) to maintain the kernel routing table. The RIPv1 protocol is based on the reference 4.3BSD daemon.

`in.routed` is managed by means of the service management facility (SMF), using the fault management resource identifier (FMRI):

```
svc:/network/routing/route:default
```

The daemon listens on a `udp` socket for the route service (see `services(4)`) for Routing Information Protocol packets. It also sends and receives multicast Router Discovery ICMP messages. If the host is a router, `in.routed` periodically supplies copies of its routing tables to any directly connected hosts and networks. It also advertises or solicits default routes using Router Discovery ICMP messages.

When started (or when a network interface is later turned on), `in.routed` uses an `AF_ROUTE` address family facility to find those directly connected interfaces configured into the system and marked “up”. It adds necessary routes for the interfaces to the kernel routing table. Soon after being first started, and provided there is at least one interface on which RIP has not been disabled, `in.routed` deletes all pre-existing non-static routes in the kernel table. Static routes in the kernel table are preserved and included in RIP responses if they have a valid RIP metric (see `route(1M)`).

If more than one interface is present (not counting the loopback interface), it is assumed that the host should forward packets among the connected networks. After transmitting a RIP request and Router Discovery Advertisements or Solicitations on a new interface, the daemon enters a loop, listening for RIP request and response and Router Discovery packets from other hosts.

When a request packet is received, `in.routed` formulates a reply based on the information maintained in its internal tables. The response packet generated contains a list of known routes, each marked with a “hop count” metric (a count of 16 or greater is considered “infinite”). Advertised metrics reflect the metric associated with an interface (see `ifconfig(1M)`), so setting the metric on an interface is an effective way to steer traffic.

Responses do not include routes with a first hop on the requesting network, to implement in part split-horizon. Requests from query programs such as `rtquery(1M)` are answered with the complete table.

The routing table maintained by the daemon includes space for several gateways for each destination to speed recovery from a failing router. RIP response packets received are used to
update the routing tables, provided they are from one of the several currently recognized gateways or advertise a better metric than at least one of the existing gateways.

When an update is applied, in.routed records the change in its own tables and updates the kernel routing table if the best route to the destination changes. The change in the kernel routing table is reflected in the next batch of response packets sent. If the next response is not scheduled for a while, a flash update response containing only recently changed routes is sent.

In addition to processing incoming packets, in.routed also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry’s metric is set to infinity and marked for deletion. Deletions are delayed until the route has been advertised with an infinite metric to insure the invalidation is propagated throughout the local internet. This is a form of poison reverse.

Routes in the kernel table that are added or changed as a result of ICMP Redirect messages are deleted after a while to minimize black-holes. When a TCP connection suffers a timeout, the kernel tells in.routed, which deletes all redirected routes through the gateway involved, advances the age of all RIP routes through the gateway to allow an alternate to be chosen, and advances of the age of any relevant Router Discovery Protocol default routes.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks. These RIP responses are sent to the broadcast address on nets that support broadcasting, to the destination address on point-to-point links, and to the router’s own address on other networks. If RIPv2 is enabled, multicast packets are sent on interfaces that support multicasting.

If no response is received on a remote interface, if there are errors while sending responses, or if there are more errors than input or output (see netstat(1M)), then the cable or some other part of the interface is assumed to be disconnected or broken, and routes are adjusted appropriately.

The Internet Router Discovery Protocol is handled similarly. When the daemon is supplying RIP routes, it also listens for Router Discovery Solicitations and sends Advertisements. When it is quiet and listening to other RIP routers, it sends Solicitations and listens for Advertisements. If it receives a good Advertisement and it is not multi-homed, it stops listening for broadcast or multicast RIP responses. It tracks several advertising routers to speed recovery when the currently chosen router dies. If all discovered routers disappear, the daemon resumes listening to RIP responses. It continues listening to RIP while using Router Discovery if multi-homed to ensure all interfaces are used.

The Router Discovery standard requires that advertisements have a default “lifetime” of 30 minutes. That means should something happen, a client can be without a good route for 30 minutes. It is a good idea to reduce the default to 45 seconds using -P rdisc_interval=45 on the command line or rdisc_interval=45 in the /etc/gateways file. See gateways(4).
While using Router Discovery (which happens by default when the system has a single network interface and a Router Discover Advertisement is received), there is a single default route and a variable number of redirected host routes in the kernel table. On a host with more than one network interface, this default route will be via only one of the interfaces. Thus, multi-homed hosts running with -q might need the no_rdisc argument described below.

To support "legacy" systems that can handle neither RIPv2 nor Router Discovery, you can use the pm_rdisc parameter in the /etc/gateways. See gateways(4).

By default, neither Router Discovery advertisements nor solicitations are sent over point-to-point links (for example, PPP). The Solaris OE uses a netmask of all ones (255.255.255.255) on point-to-point links.

in.routed supports the notion of "distant" passive or active gateways. When the daemon is started, it reads the file /etc/gateways to find such distant gateways that cannot be located using only information from a routing socket, to discover if some of the local gateways are passive, and to obtain other parameters. Gateways specified in this manner should be marked passive if they are not expected to exchange routing information, while gateways marked active should be willing to exchange RIP packets. Routes through passive gateways are installed in the kernel's routing tables once upon startup and are not included in transmitted RIP responses.

Distant active gateways are treated like network interfaces. RIP responses are sent to the distant active gateway. If no responses are received, the associated route is deleted from the kernel table and RIP responses are advertised via other interfaces. If the distant gateway resumes sending RIP responses, the associated route is restored.

Distant active gateways can be useful on media that do not support broadcasts or multicasts but otherwise act like classic shared media, such as some ATM networks. One can list all RIP routers reachable on the HIPPI or ATM network in /etc/gateways with a series of "host" lines. Note that it is usually desirable to use RIPv2 in such situations to avoid generating lists of inferred host routes.

Gateways marked external are also passive, but are not placed in the kernel routing table, nor are they included in routing updates. The function of external entries is to indicate that another routing process will install such a route if necessary, and that other routes to that destination should not be installed by in.routed. Such entries are required only when both routers might learn of routes to the same destination.

Options Listed below are available options. Any other argument supplied is interpreted as the name of a file in which the actions of in.routed should be logged. It is better to use -T (described below) instead of appending the name of the trace file to the command. Associated SMF properties for these options are described, and can be set by means of a command of the form:

# routeadm -m route:default name=value
-A
Do not ignore RIPv2 authentication if we do not care about RIPv2 authentication. This option is required for conformance with RFC 2453. However, it makes no sense and breaks using RIP as a discovery protocol to ignore all RIPv2 packets that carry authentication when this machine does not care about authentication. This option is equivalent to setting the `ignore_auth` property value to false.

-d
Do not run in the background. This option is meant for interactive use and is not usable under the SMF.

-F net[/mask][, metric]
Minimize routes in transmissions via interfaces with addresses that match net (network number)/mask (netmask), and synthesizes a default route to this machine with the metric. The intent is to reduce RIP traffic on slow, point-to-point links, such as PPP links, by replacing many large UDP packets of RIP information with a single, small packet containing a “fake” default route. If metric is absent, a value of 14 is assumed to limit the spread of the “fake” default route. This is a dangerous feature that, when used carelessly, can cause routing loops. Notice also that more than one interface can match the specified network number and mask. See also -g. Use of this option is equivalent to setting the `minimize_routes` property.

-g
Used on internetwork routers to offer a route to the “default” destination. It is equivalent to -F 0/0, 1 and is present mostly for historical reasons. A better choice is -P pm_rdisc on the command line or pm_rdisc in the /etc/gateways file. A larger metric will be used with the latter alternatives, reducing the spread of the potentially dangerous default route. The -g (or -P) option is typically used on a gateway to the Internet, or on a gateway that uses another routing protocol whose routes are not reported to other local routers. Note that because a metric of 1 is used, this feature is dangerous. Its use more often creates chaos with a routing loop than solves problems. Use of this option is equivalent to setting the `offer_default_route` property to true.

-h
Causes host or point-to-point routes not to be advertised, provided there is a network route going the same direction. That is a limited kind of aggregation. This option is useful on gateways to LANs that have other gateway machines connected with point-to-point links such as SLIP. Use of this option is equivalent to setting the `advertise_host_routes` property to false.

-m
Cause the machine to advertise a host or point-to-point route to its primary interface. It is useful on multi-homed machines such as NFS servers. This option should not be used except when the cost of the host routes it generates is justified by the popularity of the server. It is effective only when the machine is supplying routing information, because there is more than one interface. The -m option overrides the -q option to the limited extent
of advertising the host route. Use of this option is equivalent to setting the advertise_host_routes_primary property to true.

-n
Do not install routes in kernel. By default, routes are installed in the kernel. Use of this option is equivalent to setting the install_routes property to false.

-P params
Equivalent to adding the parameter line params to the /etc/gateways file. Can also be set by means of the parameters property.

-q
Opposite of the -s option. This is the default when only one interface is present. With this explicit option, the daemon is always in “quiet mode” for RIP and does not supply routing information to other computers. Use of this option is equivalent to setting the quiet_mode property to true.

-s
Force in.routed to supply routing information. This is the default if multiple network interfaces are present on which RIP or Router Discovery have not been disabled, and if the /dev/ip ndd variable ip_forwarding is set to 1. Use of this option is equivalent to setting the supply_routes property to true.

-S
If in.routed is not acting as an internetwork router, instead of entering the whole routing table in the kernel, it enters only a default route for each internetwork router. This reduces the memory requirements without losing any routing reliability. This option is provided for compatibility with the previous, RIPv1-only in.routed. Use of this option is generally discouraged. Use of this option is equivalent to setting the default_routes_only property to true.

-t
Runs in the foreground (as with -d) and logs the contents of the packets received (as with -zz). This is for compatibility with prior versions of Solaris and has no SMF equivalent.

-T tracefile
Increases the debugging level to at least 1 and causes debugging information to be appended to the trace file. Because of security concerns, do not to run in.routed routinely with tracing directed to a file. Use of this option is equivalent to setting the log_file property to trace file path.

-v
Enables debug. Similar to -z, except, where -z increments trace_level, -v sets trace_level to 1. Also, -v requires the -T option. Use of this option is equivalent to setting the debug property to true.

-V
Displays the version of the daemon.
-z

Increase the debugging level, which causes more information to be logged on the trace file specified with -T or stdout. The debugging level can be increased or decreased with the SIGUSR1 or SIGUSR2 signals or with the `rtquery(1M)` command.

*Routing Information Protocol, v1 (RFC 1058, June 1988)*

*ICMP Router Discovery Messages (RFC 1256, September 1991)*

**Notes**

In keeping with its intended design, this daemon deviates from RFC 2453 in two notable ways:

- By default, `in.routed` does not discard authenticated RIPv2 messages when RIP authentication is not configured. There is little to gain from dropping authenticated packets when RIPv1 listeners will gladly process them. Using the `-A` option causes `in.routed` to conform to the RFC in this case.

- Unauthenticated RIP requests are never discarded, even when RIP authentication is configured. Forwarding tables are not secret and can be inferred through other means such as test traffic. RIP is also the most common router-discovery protocol, and hosts need to send queries that will be answered.

`in.routed` does not always detect unidirectional failures in network interfaces, for example, when the output side fails.
**Name**  
in.rshd, rshd – remote shell server

**Synopsis**  
in.rshd [-kSeciU] [-s tos] [-S keytab] [-M realm]  
[-L env_var] host.port

**Description**  
in.rshd is the server for the `rsh(1)` program. The server provides remote execution facilities with authentication based on Kerberos V5 or privileged port numbers.

`in.rshd` is invoked by `inetd(1M)` each time a shell service is requested.

When Kerberos V5 authentication is required (this can be set with Kerberos-specific options listed below), the following protocol is initiated:

1. Check Kerberos V5 authentication.
2. Check authorization according to rules in `krb5_auth_rules(5)`.
3. A null byte is returned on the initial socket and the command line is passed to the normal login shell of the user. (The `PATH` variable is set to `/usr/bin`.) The shell inherits the network connections established by `in.rshd`.

In order for Kerberos authentication to work, a `host/<FQDN>` Kerberos principal must exist for each Fully Qualified Domain Name associated with the `in.rshd` server. Each of these `host/<FQDN>` principals must have a keytab entry in the `/etc/krb5/krb5.keytab` file on the `in.rshd` server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See `kadmin(1M)` or `gkadmin(1M)` for instructions on adding a principal to a `krb5.keytab` file. See *System Administration Guide: Security Services* for a discussion of Kerberos authentication.

If Kerberos V5 authentication is not enabled, then `in.rshd` executes the following protocol:

1. The server checks the client's source port. If the port is not in the range 512-1023, the server aborts the connection. The client's host address (in hex) and port number (in decimal) are the arguments passed to `in.rshd`.
2. The server reads characters from the socket up to a null (`\0`) byte. The resultant string is interpreted as an ASCII number, base 10.
3. If the number received in step 2 is non-zero, it is interpreted as the port number of a secondary stream to be used for the `stderr`. A second connection is then created to the specified port on the client's machine. The source port of this second connection is also in the range 512-1023.
4. A null-terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as the user identity on the client's machine.
5. A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as a user identity to use on the server's machine.
6. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system’s argument list.

7. `in.rshd` then validates the user according to the following steps. The remote user name is looked up in the password file and a `chdir` is performed to the user’s home directory. If the lookup fails, the connection is terminated. If the `chdir` fails, it does a `chdir` to `/ (root)`. If the user is not the superuser, (user ID 0), and if the pam_rhosts_auth PAM module is configured for authentication, the file `/etc/hosts.equiv` is consulted for a list of hosts considered “equivalent”. If the client’s host name is present in this file, the authentication is considered successful. See the SECURITY section below for a discussion of PAM authentication.

   If the lookup fails, or the user is the superuser, then the file `.rhosts` in the home directory of the remote user is checked for the machine name and identity of the user on the client’s machine. If this lookup fails, the connection is terminated.

8. A null byte is returned on the initial connection and the command line is passed to the normal login shell of the user. The `PATH` variable is set to `/usr/bin`. The shell inherits the network connections established by `in.rshd`.

### Options

The following options are supported:

- **-5** Same as `-k`, for backwards compatibility
- **-c** Requires Kerberos V5 clients to present a cryptographic checksum of initial connection information like the name of the user that the client is trying to access in the initial authenticator. This checksum provides additional security by preventing an attacker from changing the initial connection information. This option is mutually exclusive with the `-i` option.
- **-e** Requires the client to encrypt the connection.
- **-i** Ignores authenticator checksums if provided. This option ignores authenticator checksums presented by current Kerberos clients to protect initial connection information. Option `-i` is the opposite of option `-c`.
- **-k** Allows Kerberos V5 authentication with the `.k5login` access control file to be trusted. If this authentication system is used by the client and the authorization check is passed, then the user is allowed to log in.
- **-L env_var** List of environment variables that need to be saved and passed along.
- **-M realm** Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the `krb5.conf(4)` file.
- **-s tos** Sets the IP TOS option.
- **-S keytab** Sets the KR85 keytab file to use. The `/etc/krb5/krb5.keytab` file is used by default.
Refuses connections that cannot be mapped to a name through the `getnameinfo(3SOCKET)` function.

**Usage**  
`rshd` and `in.rshd` are IPv6–enabled. See `ip6(7P)`. IPv6 is not currently supported with Kerberos V5 authentication.

The Kerberized `rshd` service runs on port 544 (kshell). The corresponding FMRI entry is:

```
svc:/network/shell:kshell (rshd with kerberos (ipv4 only))
```

**Security**  
`in.rshd` uses `pam(3PAM)` for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `in.rshd`. Here is a partial `pam.conf` file with entries for the `rsh` command using rhosts authentication, UNIX account management, and session management module.

```
rsh  auth required   pam_rhosts_auth.so.1

rsh  account required pam_unix_roles.so.1
rsh  session required pam_unix_projects.so.1
rsh  session required pam_unix_account.so.1

rsh  session required pam_unix_session.so.1
```

If there are no entries for the `rsh` service, then the entries for the “other” service are used. To maintain the authentication requirement for `in.rshd`, the rsh entry must always be configured with the `pam_rhosts_auth.so.1` module.

`in.rshd` can authenticate using Kerberos V5 authentication or `pam(3PAM)`. For Kerberized `rsh` service, the appropriate PAM service name is `krsh`.

**Files**  
`/etc/hosts.equiv`  
`$HOME/.k5login` File containing Kerberos principals that are allowed access.  
`/etc/krb5/krb5.conf` Kerberos configuration file.

**Attributes**

System Administration Guide: Security Services

Diagnostics  The following diagnostic messages are returned on the connection associated with stderr, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 in step 8 above (0 is returned above upon successful completion of all the steps prior to the command execution).

locuser too long  The name of the user on the client's machine is longer than 16 characters.
remuser too long  The name of the user on the remote machine is longer than 16 characters.
command too long  The command line passed exceeds the size of the argument list (as configured into the system).
Hostname for your address unknown.  No entry in the host name database existed for the client's machine.
Login incorrect.  No password file entry for the user name existed.
Permission denied.  The authentication procedure described above failed.
Can't make pipe.  The pipe needed for the stderr was not created.
Try again.  A fork by the server failed.

Notes  The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

The pam_unix(5) module is no longer supported. Similar functionality is provided by
pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5),
pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).

The in.rshd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/shell:default
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service’s status can be queried using the `svcs(1)` command.
**in.rwhod(1M)**

**Name**
in.rwhod, rwhod – system status server

**Synopsis**
/usr/sbin/in.rwhod [-m [ttl]]

**Description**
in.rwhod is the server which maintains the database used by the rwho(1) and runtime(1) programs. Its operation is predicated on the ability to broadcast or multicast messages on a network.

in.rwhod operates as both a producer and consumer of status information. As a producer of information it periodically queries the state of the system and constructs status messages which are broadcast or multicast on a network. As a consumer of information, it listens for other in.rwhod servers' status messages, validating them, then recording them in a collection of files located in the directory /var/spool/rwho.

The rwho server transmits and receives messages at the port indicated in the rwho service specification, see services(4). The messages sent and received are defined in /usr/include/protocols/rwhod.h and are of the form:

```c
struct outmp {
    char out_line[8];    /* tty name */
    char out_name[8];    /* user id */
    long out_time;       /* time on */
};
struct whod {
    char wd_vers;
    char wd_type;
    char wd_fill[2];
    int wd_sendtime;
    int wd_recvtime;
    char wd_hostname[32];
    int wd_loadav[3];
    int wd_boottime;
    struct whoent {
        struct outmp we_utmp;
        int we_idle;
    } wd_we[1024 / sizeof (struct whoent)];
};
```

All fields are converted to network byte order prior to transmission. The load averages are as calculated by the w(1) program, and represent load averages over the 1, 5, and 15 minute intervals prior to a server's transmission. The hostname included is that returned by the uname(2) system call. The array at the end of the message contains information about the users who are logged in to the sending machine. This information includes the contents of the utmpx(4) entry for each non-idle terminal line and a value indicating the time since a character was last received on the terminal line.
Messages received by the `rwho` server are discarded unless they originated at a `rwho` server’s port. In addition, if the host’s name, as specified in the message, contains any unprintable ASCII characters, the message is discarded. Valid messages received by `in.rwhod` are placed in files named `whod.hostname` in the directory `/var/spool/rwho`. These files contain only the most recent message, in the format described above.

Status messages are generated approximately once every 3 minutes.

**Options** The following options are supported:

- `-m [ ttl ]` Use the `rwho` IP multicast address (224.0.1.3) when transmitting. Receive announcements both on this multicast address and on the IP broadcast address. If `ttl` is not specified in `in.rwhod`, `multicasts` on all interfaces but with the IP TimeToLive set to 1 (that is, packets are not forwarded by multicast routers.) If `ttl` is specified in `in.rwhod`, only transmits packets on one interface and setting the IP TimeToLive to the specified `ttl`.

**Files** `/var/spool/rwho/*` information about other machines

**Attributes** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWrcmds</td>
</tr>
</tbody>
</table>

**See Also** `runtimel(1)` `rwho(1)` `w(1)` `uname(2)` `services(4)` `utmpx(4)` `attributes(5)`

**Warnings** This service can cause network performance problems when used by several hosts on the network. It is not run at most sites by default. If used, include the `-m` multicast option.

**Notes** This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

`in.rwhod` should relay status information between networks. People often interpret the server dying as a machine going down.
install(1M)

Name
install – install commands

Synopsis
/usr/sbin/install -c dira [-m mode] [-u user] [-g group]
   [-o] [-s] file
/usr/sbin/install -f dirb [-m mode] [-u user] [-g group]
   [-o] [-s] file
/usr/sbin/install -n dirc [-m mode] [-u user] [-g group]
   [-o] [-s] file
/usr/sbin/install -d | -i [-m mode] [-u user] [-g group]
   [-o] [-s] dirx...
/usr/sbin/install [-m mode] [-u user] [-g group] [-o] [-s] file
   [dirx]...

Description
install is most commonly used in “makefiles” (see make(1S)) to install a file in specific
locations, or to create directories within a file system. Each file is installed by copying it into
the appropriate directory.

install uses no special privileges to copy files from one place to another. The implications of
this are:

■ You must have permission to read the files to be installed.
■ You must have permission to copy into the destination directory.
■ You must have permission to change the modes on the final copy of the file if you want to
  use the -m option.
■ You must be super-user if you want to specify the ownership of the installed file with the -u
  or -g options. If you are not the super-user, the installed file is owned by you, regardless of
  who owns the original.

Note that if the ROOT environment variable is set, each of the default directory paths
are prefixed by its value (for example, $ROOT/bin and so on).

install prints messages telling the user exactly what files it is replacing or creating and where
they are going.

If no options or directories (dirx...) are given, install searches a set of default directories (/bin, /usr/bin, /etc, /lib, and /usr/lib, in that order) for a file with the same name as
file. When the first occurrence is found, install issues a message saying that it is
overwriting that file with file, and proceeds to do so. If the file is not found, the program
states this and exits.

If one or more directories (dirx...) are specified after file, those directories are searched
before the default directories.

This version of install (/usr/sbin/install) is not compatible with the install binaries in
many versions of Unix other than Solaris. For a higher degree of compatibility with other Unix
versions, use /usr/ucb/install, which is described in the install(1B) man page.
Options

The following options are supported:

\-c dira

Install file in the directory specified by dira, if file does not yet exist. If it is found, install issues a message saying that the file already exists, and exits without overwriting it.

\-f dirb

Force file to be installed in given directory, even if the file already exists. If the file being installed does not already exist, the mode and owner of the new file is set to 755 and bin, respectively. If the file already exists, the mode and owner is that of the already existing file.

\-n dirc

If file is not found in any of the searched directories, it is put in the directory specified in dirc. The mode and owner of the new file is set to 755 and bin, respectively.

\-d

Create a directory. Missing parent directories are created as required as in mkdir -p. If the directory already exists, the owner, group and mode is set to the values given on the command line.

\-i

Ignore default directory list, searching only through the given directories (dirx ...).

\-m mode

The mode of the new file is set to mode. Set to 0755 by default.

\-u user

The owner of the new file is set to user. Only available to the super-user. Set to bin by default.

\-g group

The group id of the new file is set to group. Only available to the super-user. Set to bin by default.

\-o

If file is found, save the “found” file by copying it to OLDfile in the directory in which it was found. This option is useful when installing a frequently used file such as /bin/sh or /lib/saf/ttymon, where the existing file cannot be removed.

\-s

Suppress printing of messages other than error messages.

Usage

See largefile(5) for the description of the behavior of install when encountering files greater than or equal to 2 Gbyte (2^31 bytes).

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>

installboot(1M)

Name  installboot – install bootblocks in a disk partition

Synopsis  installboot [-F zfs|ufs|hsfs] bootblk raw-disk-device

Description  The boot(1M) program, ufsboot, is loaded from disk by the bootblock program which resides in the boot area of a disk partition. This program is filesystem-specific, and must match the type of filesystem on the disk to be booted.

The boot objects are platform-dependent and reside in the 
/usr/platform/platform-name/lib/fs/file-system directory. The platform name can be found using the -i option of uname(1). The filesystem type can be found using:

% fstyp raw-disk-device

See fstyp(1M).

The installboot utility is a SPARC only program. It is not supported on the x86 architecture. x86 users should use installgrub(1M) instead.

Options  The following option is supported:

- F zfs|ufs|hsfs
  Specifies the file system type of the boot block to be installed. Required if you wish to specify zfs or hsfs. The default is ufs.

Operands  bootblk
  The name of the bootblock code.

  raw-disk-device
  The name of the disk device onto which the bootblock code is to be installed; it must be a character device which is readable and writable. Naming conventions for a SCSI or IPI drive are c?t?d?s? and c?d?s? for an IDE drive.

Examples  EXAMPLE 1  Installing UFS Boot Block

To install a ufs boot block on slice 0 of target 0 on controller 1 of the platform where the command is being run, use:

# installboot /usr/platform/`uname -i`/lib/fs/ufs/bootblk \
/dev/rdsk/c1t0d0s0

EXAMPLE 2  Installing ZFS Boot Block

To install a ZFS boot block on slice 0 of target 0 on controller 1 of the platform where the command is being run, use syntax such as the following:

# installboot -F zfs /usr/platform/`uname -i`/lib/fs/zfs/bootblk \
/dev/rdsk/c0t1d0s0
**Files**  
/usr/platform/platform-name/lib/fs/ Directory where boot objects reside.

**Attributes**  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**  od(1), uname(1), boot(1M), fstyp(1M), init(1M), kadb(1M), kernel(1M), monitor(1M), reboot(1M), rpc.bootparamd(1M), init.d(4), attributes(5)

*Oracle Solaris 10 08/11 Installation Guide: Basic Installations*

**Warnings**  The installboot utility fails if the bootblk or openfirmware files do not exist or if the raw disk device is not a character device.
### Name
installer – Solaris Web Start installer utility

### Synopsis
```
installer [-locales list] [-nodisplay] [-noconsole]
        [-debug]
```

### Description
The installer utility invokes a Web Start install wizard sequence which will lead the user through a sequence of installation panels. This installer utility is found on many CDs that are shipped with Solaris and it will be found among the top level files of these CDs.

When the installer is on a CD being accessed from a desktop file manager, the installer can be double clicked to start the installation sequence. If the user is not currently the system’s root user, the root user password will be requested.

The installer utility can also be run from other UNIX scripts. Usually, a script is used in conjunction with the utility’s `-nodisplay` option. Add the `-noconsole` option for non-interactive scripts.

### Options
The following options are supported:

- `-locales list` Selects product translations for install, corresponding to the specified list of locales if the specified locale translations are present on the installation media. Locales are supplied in a comma-separated list following the `-locales` option. An example `list` would appear as follows:

  ```
  installer -locales fr,de,it
  ```

  This would install products with translations for the French, German, and Italian locales.

- `-nodisplay` Runs the install without a graphical user interface. Use the default product install unless it was modified by the `-locales` options.

- `-noconsole` Run the install without any interactive text console device. Useful when paired with `-nodisplay` for non-interactive UNIX script use.

- `-debug` Outputs extra information about what the install is doing. Mainly for install diagnostic purposes.

### Files
/var/sadm/install/logs location of installation log files

### See Also
prodreg(1M)
installf(1M)

Name
installf – add a file to the software installation database

Synopsis
installf [-c class] [ [-M] -R root_path] [-V fs_file] pkginst pathname
    [ftype [major minor] [mode owner group]]
installf [-c class] [ [-M] -R root_path] [-V fs_file] pkginst –
installf -f [-c class] [ [-M] -R root_path] [-V fs_file] pkginst

Description
installf informs the system that a pathname not listed in the pkgmap(4) file is being created or modified. It should be invoked before any file modifications have occurred.

When the second synopsis is used, the pathname descriptions will be read from standard input. These descriptions are the same as would be given in the first synopsis but the information is given in the form of a list. The descriptions should be in the form:

pathname [ftype [ major minor ] [ mode owner group ] ]

After all files have been appropriately created and/or modified, installf should be invoked with the -f synopsis to indicate that installation is final. Links will be created at this time and, if attribute information for a pathname was not specified during the original invocation of installf, or was not already stored on the system, the current attribute values for the pathname will be stored. Otherwise, installf verifies that attribute values match those given on the command line, making corrections as necessary. In all cases, the current content information is calculated and stored appropriately.

Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgrms(1M) and other package commands can process a data stream of up to 4 GB.

Options
-c class
   Class to which installed objects should be associated. Default class is none.

-f
   Indicates that installation is complete. This option is used with the final invocation of installf (for all files of a given class).

-M
   Instruct installf not to use the $root_path/etc/vfstab file for determining the client’s mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-R root_path
   Define the full path name of a directory to use as the root_path. All files, including package system information files, are relocated to a directory tree starting in the specified root_path. The root_path can be specified when installing to a client from a server (for example, /export/root/client1).

   installf inherits the value of the PKG_INSTALL_ROOT environment variable. (See ENVIRONMENT VARIABLES, below.) If PKG_INSTALL_ROOT is set, such as when the -R option is used with pkgadd(1M) or pkgrm(1M)
Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-V fs_file

Specify an alternative fs_file to map the client's file systems. For example, used in situations where the $root_path/etc/vfstab file is non-existent or unreliable.

Operands

pkginst

Name of package instance with which the pathname should be associated.

pathname

Pathname that is being created or modified.

ftype

A one-character field that indicates the file type. Possible file types include:

- b
  block special device
- c
  character special device
- d
  directory
- e
  a file to be edited upon installation or removal
- f
  a standard executable or data file
- l
  linked file
- p
  named pipe
- s
  symbolic link
- v
  volatile file (one whose contents are expected to change)
- x
  an exclusive directory

major

The major device number. The field is only specified for block or character special devices.

minor

The minor device number. The field is only specified for block or character special devices.

mode

The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.

owner

The owner of the file (for example, bin or root). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files.

group

The group to which the file belongs (for example, bin or sys). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target machine.
This field is not used for linked or symbolically linked files.

**Examples**

**EXAMPLE 1** Basic Usage

The following example shows the use of `installf`, invoked from an optional pre-install or post-install script:

```bash
# create /dev/xt directory
# (needs to be done before drvinstall)
installf $PKGINST /dev/xt d 755 root sys ||
exit 2
majno=/usr/sbin/drvinstall -m /etc/master.d/xt
 -d $BASEDIR/data/xt.o -v1.0' ||
exit 2
i=0
while [ $i -lt $limit ]
do
    for j in 0 1 2 3 4 5 6 7
do
        echo /dev/xt$i$j c $majno 'expr $i ? 8 + $j'
        644 root sys |
        echo /dev/xt$i$j=/dev/xt/$i$j
    done
done | installf $PKGINST - || exit 2
# finalized installation, create links
installf -f $PKGININST || exit 2
```

**Environment Variables**

`installf` inherits the value of the following environment variable. This variable is set when `pkgadd(1M)` or `pkgrm(1M)` is invoked with the `-R` option.

- **PKG_INSTALL_ROOT** If present, defines the full path name of a directory to use as the system's `PKG_INSTALL_ROOT` path. All product and package information files are then looked for in the directory tree, starting with the specified `PKG_INSTALL_ROOT` path. If not present, the default system path of `/` is used.

**Exit Status**

- **0** Successful operation.
- **>0** An error occurred.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>
When *ftype* is specified, all applicable fields, as shown below, must be defined:

<table>
<thead>
<tr>
<th><em>ftype</em></th>
<th>Required Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>p, x, d, f, v, or e</td>
<td>mode owner group</td>
</tr>
<tr>
<td>c or b</td>
<td>major minor mode owner group</td>
</tr>
</tbody>
</table>

The `installf` command will create directories, named pipes and special devices on the original invocation. Links are created when `installf` is invoked with the `-f` option to indicate installation is complete.

Links should be specified as `path1=path2`. *path1* indicates the destination and *path2* indicates the source file.

Files installed with `installf` will be placed in the class `none`, unless a class is defined with the command. Subsequently, they will be removed when the associated package is deleted. If this file should not be deleted at the same time as the package, be certain to assign it to a class which is ignored at removal time. If special action is required for the file before removal, a class must be defined with the command and an appropriate class action script delivered with the package.

When classes are used, `installf` must be used in one of the following forms:

```
installf -c class1 . . .
installf -f -c class1 . . .
installf -c class2 . . .
installf -f -c class2 . . .
```
installgrub – install GRUB in a disk partition or a floppy

/sbin/installgrub [-f] stage1 stage2 raw-device

installgrub installs GRUB stage 1 and stage 2 files on the boot area of a disk partition. If you specify the -m option, installgrub installs the stage 1 file on the master boot sector of the disk.

installgrub command accepts the following options:

- **f**: Suppresses interaction when overwriting the master boot sector.
- **m**: Installs GRUB stage 1 on the master boot sector interactively.

installgrub command accepts the following operands:

- **stage1**: The name of the GRUB stage 1 file.
- **stage2**: The name of the GRUB stage 2 file.
- **raw-device**: The name of the device onto which GRUB code is to be installed. It must be a character device that is readable and writable. For disk devices, specify the slice where the GRUB menu file is located. (For Solaris it is the root slice.) For a floppy disk, it is /dev/rdiskette.

**Examples**

**EXAMPLE 1** Installing GRUB on a Hard Disk Slice

The following command installs GRUB on a system where the root slice is c0d0s0:

```
example# /sbin/installgrub /boot/grub/stage1 /boot/grub/stage2 /dev/rdsk/c0d0s0
```

**EXAMPLE 2** Installing GRUB on a Floppy

The following command installs GRUB on a formatted floppy:

```
example# mount -F pcfs /dev/diskette /mnt
# mkdir -p /mnt/boot/grub
# cp /boot/grub/* /mnt/boot/grub
# umount /mnt
# cd /boot/grub
# /sbin/installgrub stage1 stage2 /dev/rdiskette
```

**Files**

- /boot/grub Directory where GRUB files reside.

**Attributes**

See attributes(5) for descriptions of the following attributes:
installgrub(1M)

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also boot(1M), fdisk(1M), fmthard(1M), kernel(1M), attributes(5)

Warnings Installing GRUB on the master boot sector (-m option) overrides any boot manager currently installed on the machine. The system will always boot the GRUB in the Solaris partition regardless of which fdisk partition is active.
install_scripts(1M)

**Name**  
install_scripts, add_install_client, add_to_install_server, rm_install_client, setup_install_server, check – scripts used to install the Solaris software

media-mnt-pt/Solaris_XX/Tools/rm_install_client -f boot_file_name
media-mnt-pt/Solaris_XX/Tools/setup_install_server [-b]  
[-t install_boot_image_path] [-w wanboot_image_path] install_dir_path

**Description**  
These commands are located on slice 0 of the Solaris Software and Solaris Installer CDs or DVDs. (The terms “CD” and “DVD” are hereafter referred to as “installation media.”) If the Solaris installation media has been copied to a local disk, media_mnt_pt is the path to the copied Solaris installation media. They can be used for a variety of installation tasks.

The XX in Solaris_XX is the version number of the Solaris release being used.

There are three versions of the add_install_client command. See SYNOPSIS.
Use the following version of the `add_install_client` command to add clients for network installation (these commands update the `bootparams(4)` file). The `add_install_client` command must be run from the install server's Solaris installation image (a mounted Solaris installation media or a Solaris installation media copied to disk) or the boot server’s boot directory (if a boot server is required). The Solaris installation image or the boot directory must be the same Solaris release that you want installed on the client.

```
media-mnt-pt/Solaris_XX/Tools/add_install_client
   [ -i IP_address ]
   [ -e Ethernet_address ] [ -s server_name : path ]
   [ -c server_name : path ]
   [ -n [server] : name_service [( netmask )] ]
   [ -p server_name : path ]
   [ -t [server:]install_boot_image_path ]
   -t server:[install_boot_image_path ]
host_name platform_group
```

Use the following version of the `add_install_client` command to add support for instances of a platform within a platform group to the install server. This group is booted and configured using DHCP. The script performs the necessary configuration steps on the server, and prints the data that the user needs to add to the DHCP server for the group.

```
media-mnt-pt/Solaris_XX/Tools/add_install_client -d
   [ -s server:path ]
   [ -c server:path ] [ -p server:path ]
   [ -t [server:]install_boot_image_path ]
   -t server:[install_boot_image_path ]
   [-f boot_file_name ]
platform_name platform_group
```

Use the following version of the `add_install_client` command to add a single client to the install server. This client is booted and configured using DHCP. The script performs the necessary configuration steps on the server, and prints the data that the user needs to add to the DHCP server for the client. The `-f` flag used above needs to be added to the existing usage as well. `-f` allows the user to specify a boot file name to be used for a given client.

```
media-mnt-pt/Solaris_XX/Tools/add_install_client -d
   [ -s server_name:path ]
   [ -c server_name:path ] [ -p server_name:path ]
   [ -t [server:]install_boot_image_path ]
   -t server:[install_boot_image_path ]
   [-f boot_file_name ] -e Ethernet_address
   [-b property=value] platform_group
```

Always use the `-d` option when registering x86 Architecture Pre-boot eXecution Environment (PXE) clients. These clients use DHCP for their configuration.

Use `add_to_install_server` to merge other Solaris installation media with an existing image on a Net Install Server. Each installation media that can be merged (each OS CD or DVD, and
the Language CD or DVD) has its own add_to_install_server script. Do not use add_to_install_server scripts with installation media other than the ones with which they were delivered.

Use check to validate the rules in a rules file (this is only necessary if a custom JumpStart installation is being set up).

Use rm_install_client to remove clients for network installation (these commands update the bootparams(4) file).

Use setup_install_server to copy the Solaris installation media to a disk (to set up an install server), to build a WANboot miniroot image (to set up a WANboot install server), or to copy just the boot software of the Solaris installation media to a disk (to set up a boot server). An install server is required to install clients over the network. A boot server is also required for network installations if the install server and clients to be installed are on different subnets (the boot server must be located on the client's subnet).

**Options**

The add_install_client supports the following options:

- **-b** property=value
  
  Set a property value in the client-specific menu.lst file located on the boot server's TFTP directory, /tftpboot by default. Use this option to set boot properties that are specific to this client.

  Use this option only with an x86 client an only in conjunction with the -d and -e options.

- **-c** server_name:path
  
  This option is required only to specify a JumpStart directory for a custom JumpStart installation. server_name is the host name of the server with a JumpStart directory. path is the absolute path to the JumpStart directory.

- **-d**
  
  Specify as a DHCP client.

- **-e** Ethernet_address
  
  Specify the Ethernet address of the system to be installed.

- **-f**
  
  Specify the boot_file_name of the client to be installed.

- **-i** IP_address
  
  Specify the IP address of the client to be installed.

- **-n [server]: name_service[(netmask)]**
  
  This option specifies which name service should be used during system configuration. This sets the ns keyword in the bootparams(4) file.

    name_service

    Valid entries are nis, nisplus, and none.
**netmask**
A series of four numbers separated by periods, specifying which portion of an IP address is the network part, and which is the host part.

**server**
The name of the server or IP address of the specified name service. If the server specified is on a different subnet, then the netmask may be needed to enable the client to contact the server.

- **p server_name: path**
  This option is used to specify the NFS or ZFS shared directory that contains the user-defined sysidcfg file. When a client is booted, it attempts to read a file specifically named sysidcfg in this directory to obtain answers to the system and network identification questions. server_name is either a valid host name or IP address. path is the absolute pathname of the directory on the file server that contains the sysidcfg file.

- **s server_name: path**
  This option is required only when using add_install_client from a boot server. Specify the name of the server and the absolute path of the Solaris installation image that is used for this installation. path is either the path to a mounted Solaris installation media or a path to a directory with a copy of the Solaris installation media.

- **t [server:]path**
  path
  Allows you to specify an alternate miniroot.

  server
  The name or IP address of the boot server. This can be used on boot servers with multiple network interfaces to specify the particular IP address from which clients should be booted.

The add_to_install_server command supports the following options:

- **p**
  Specifies the location of the installation media (containing the supplemental products) to be copied.

- **s**
  Allows users to select from a list only the products needing installation.

The check command supports the following options:

- **p install_dir_path**
  Validates the rules file by using the check script from a specified Solaris installation image, instead of the check script from the system you are using. install_dir_path is the path to a Solaris installation image on a local disk or a mounted Solaris installation media.
Use this option to run the most recent version of check if your system is running a previous version of Solaris.

\textbf{-r rulesfile}

Specifies a rules file other than the one named \texttt{rules}. Using this option, the validity of a rule can be tested before integrating it into the rules file. check reports whether or not the rule is valid, but it does not create the \texttt{rules.ok} file necessary for a custom JumpStart installation.

The \texttt{rm\_install\_client} command supports the following options:

\textbf{-e Ethernet\_address}

Specify the Ethernet address of the system to be removed.

\textbf{-f}

Specify the \texttt{boot\_file\_name} of the client to be removed.

The \texttt{setup\_install\_server} command supports the following options:

\textbf{-b}

This option sets up the server only as a boot server.

\textbf{-t}

This option allows an alternate miniroot to be specified.

\textbf{-w}

This option builds a WANboot miniroot image.

**Operands** The \texttt{add\_install\_client} command supports the following operands:

\textbf{host\_name}

This is the name of the client to be installed.

\textbf{platform\_group}

Vendor-defined grouping of hardware platforms for the purpose of distributing specific software. Examples of valid platform groups are:

<table>
<thead>
<tr>
<th>System</th>
<th>Platform Group</th>
</tr>
</thead>
<tbody>
<tr>
<td>x86</td>
<td>i86pc</td>
</tr>
<tr>
<td>Sun Fire 4800</td>
<td>sun4u</td>
</tr>
</tbody>
</table>

Use the \texttt{uname(1)} command (with the \texttt{-m} option) to determine a system's platform group.

\textbf{platform\_name}

Use the \texttt{uname(1)} command (with the \texttt{-i} option) to determine a system's platform name.

The following example shows the use of the \texttt{uname} command to determine the system platform name for an Ultra 10:
uname -i
The system responds with:
SUNW,Ultra-5_10
Therefore, the system’s platform name is SUNW,Ultra-5_10.
The following command calls add_install_client for Ultra10s:
add_install_client -d SUNW,Ultra-5_10 sun4u
For IA32 platforms, the platform name is always SUNW.i86pc.
The following command calls add_install_client for IA32 platforms:
add_install_client -d SUNW.i86pc i86pc
install_boot_image_path
Pathname of alternate miniroot, specified with -t option.
The rm_install_client command supports the following operands:
host_name
Name of the client to be removed.
platform_name
The platform name of the client to be removed. See the description of this operand above.
Ethernet_address
Ethernet address of the client to be removed.
boot_file_name
Name of the boot file to be removed.
The setup_install_server command supports the following operands:
install_dir_path
The absolute path of the directory in which the Solaris software is to be copied. The
directory must be empty.
wanboot_image_path
The absolute path of the directory in which the file containing the WANboot miniroot
image is to be created.
install_boot_image_path
Pathname of alternate miniroot, specified with -t option.
Examples
EXAMPLE 1 Using add_install_client
The following add_install_client commands add clients for network installation from a
mounted Solaris installation media:
example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./add_install_client system_2/sun4u
EXAMPLE 2 Using add_install_client
The following add_install_client commands add clients for network installation from a mounted Solaris installation media on an install server. The -c option specifies a server and path to a JumpStart directory that has a rules file and a profile file for performing a custom JumpStart installation. Also, the Solaris installation media has been copied to the /export/install directory:

```
example# cd /export/install/Solaris_10/Tools
example# /add_install_client
   -c install_server:/jumpstart system_1 i86pc
example# ./add_install_client -c install_server:/jumpstart\n   system_2 i86pc
```

EXAMPLE 3 Using add_install_client
The following add_install_client command adds support for a specific sun4u platform machine (8:0:20:99:88:77) using the boot file: sun4u.solaris10.

```
example# add_install_client -d -f sun4u.solaris10\n   -e 8:0:20:99:88:77 sun4u
```

EXAMPLE 4 Using add_install_client
The following add_install_client command adds x86 clients that use the PXE standard for network booting:

```
example# add_install_client -d -s svrname:/mnt/export/root\n   SUNW.i86pc i86p
```

EXAMPLE 5 Using add_to_install_server
The following add_to_install_server command copies the packages in all the installation media's products directories to an existing install server:

```
example# cd /cdrom/cdrom0/s0
example# ./add_to_install_server /export/Solaris_10
```

EXAMPLE 6 Using check
The following check command validates the syntax of the rules file used for a custom JumpStart installation:

```
example# cd jumpstart_dir_path
example# ./check -p /cdrom/cdrom0/s0
```

EXAMPLE 7 Using rm_install_client
The following rm_install_client commands remove clients for network installation:

```
example# cd /export/install/Solaris_10/Tools
example# ./rm_install_client holmes
example# ./rm_install_client watson
```
install_scripts(1M)

EXAMPLE 8 Using setup_install_server
The following setup_install_server command copies the mounted Solaris installation media to a directory named /export/install on the local disk:

example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./setup_install_server /export/install

EXAMPLE 9 Using setup_install_server
The following setup_install_server command copies the boot software of a mounted Solaris installation media to a directory named /boot_dir on a system that is going to be a boot server for a subnet:

example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./setup_install_server -b /boot_dir

EXAMPLE 10 Using setup_install_server
By default, setup_install_server looks for an installation boot directory at the Solaris ..../Tools/Boot location of the mount Solaris distribution disc.

If an alternate boot directory is required, such as one saved on a network boot server by way of an earlier ./setup_install_server -b /boot_dir command, the -t option can be used.

example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./setup_install_server -t /boot_dir /export/install

EXAMPLE 11 Using setup_install_server with WANboot Option
The following setup_install_server command creates an image of the WANboot miniroot file systemd and stores it in the file /wanboot_dir/miniroot.

example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./setup_install_server -w /wanboot_dir /export/install

EXAMPLE 12 x86: Specifying a Serial Console to Use During a Network Installation (from Installation Media)
The following example illustrates how to add an x86 install client to an install server and specify a serial console to use during the installation. This example sets up the install client in the following manner:

- The -d option indicates that the client is set up to use DHCP to set installation parameters.
- The -e option indicates that this installation occurs only on the client with the ethernet address 00:07:e9:04:4a:bf.
- The first and second uses of the -b option instruct the installation program to use the serial port ttya as an input and an output device.

install server# cd /export/boot/Solaris_10/Tools
install server# ./add_install_client -d -e "00:07:e9:04:4a:bf" \
EXAMPLE 12  x86: Specifying a Serial Console to Use During a Network Installation (from Installation Media)  
(Continued)

    -b "input-device=ttya" -b "output-device=ttya" \ 
    i86pc

For a complete description of the boot property variables and values you can use with the -b option, see \eeeprom\(1M\).

EXAMPLE 13  Specifying a Boot Device to Use During a Network Installation (from Installation Media)

The following example illustrates how to add an x86 install client to an install server and specify a boot device to use during the installation. If you specify the boot device when you set up the install client, you are not prompted for this information by the Device Configuration Assistant during the installation.

This example sets up the install client in the following manner:

- The -d option indicates that the client is set up to use DHCP to set installation parameters.
- The -e option indicates that this installation occurs only on the client with the ethernet address 00:07:e9:04:4a:bf.
- The first and second uses of the -b option instruct the installation program to use the serial port ttya as an input and an output device.
- The third use of the -b option instructs the installation program to use a specific boot device during the installation.
- The value of the boot device path varies based on your hardware.
- The i86pc platform name indicates that the client is an x86-based system.

install server# cd /export/boot/Solaris_10/Tools
install server# ./add_install_client -d -e "00:07:e9:04:4a:bf" \    -b "input-device=ttya" -b "output-device=ttya" \    -b "bootpath=/pci@0,0/pci108e,16a8@8" i86pc

For a complete description of the boot property variables and values you can use with the -b option, see \eeeprom\(1M\).

Exit Status  The following exit values are returned:

0  Successful completion.

1  An error has occurred.

*Oracle Solaris 10 08/11 Installation Guide: Basic Installations*
install-solaris – install the Solaris operating system

install-solaris

install-solaris invokes the Solaris Install program. Depending on graphical capability and available memory at the time of invocation, install-solaris invokes either a text-based installer or a graphical installer.

For both SPARC and x86 machines, while you can install on a system with 512 KB of physical memory, 1 GB is the preferred minimum. Memory requirements vary depending on the applications being used, system configurations, and the number of clients or users you will be supporting.

In some cases, even if the minimum physical memory is present, available virtual memory after system startup can limit the number of features available.

install-solaris exists only on the Solaris installation media (CD or DVD) and should be invoked only from there. Refer to the for more details.

install-solaris allows installation of the operating system onto any stand-alone system. install-solaris loads the software available on the installation media. Refer to the Oracle Solaris 10 08/11 Installation Guide: Basic Installations for disk space requirements.

Usage Refer to the Oracle Solaris 10 08/11 Installation Guide: Basic Installations for more information on the various menus and selections.

Oracle Solaris 10 08/11 Installation Guide: Basic Installations

Notes It is advisable to exit install-solaris by means of the exit options in the install-solaris menus.
in.stdiscover – Service Tag Discovery Daemon

The in.stdiscover daemon allows a mechanism for discovering the location of the Service Tag Listener. By default, the in.stdiscover daemon listens for discovery probes (using a minimal built-in protocol) on UDP port 6481.

The daemon is under control of the service management facility, smf(5), under its inetd framework. It only runs upon demand and exits when no longer in use.

Notes

In open networks where the participants may not always be trusted, it is recommended that you deploy this daemon with the passphrase-encryption option. In smf(5) environments, the following command can be used to set the passphrase:

```
< prepare a text file "passfile" containing the passphrase >
# chown svctag:daemon passfile
# chmod 600 passfile
svccfg -s svc:/network/stlisten \
setprop servicetag/passphrase=passfile
```

where passfile is the path of a file containing the intended passphrase.

This passphrase can be subsequently cleared as follows:

```
svccfg -s svc:/network/stlisten \
setprop servicetag/passphrase=""
```
**Name**
in.talkd, talkd – server for talk program

**Synopsis**
in.talkd

**Description**
talkd is a server used by the talk(1) program. It listens at the UDP port indicated in the “talk” service description; see services(4). The actual conversation takes place on a TCP connection that is established by negotiation between the two machines involved.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>

<td>SUNWrcmds</td>
</tr>
</tbody>
</table>

**See Also**
svcs(1), talk(1), inetadm(1M), inetd(1M), svcadm(1M), services(4), attributes(5), smf(5)

**Notes**
The protocol is architecture dependent.

The in.talkd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/talk

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
in.telnetd(1M)

Name  in.telnetd, telnetd – DARPA TELNET protocol server

Synopsis  

```
/usr/sbin/in.telnetd [-a authmode] [-EXUh] [-s tos]
                 [-S keytab] [-N realm]
```

Description  in.telnetd is a server that supports the DARPA standard TELNET virtual terminal protocol. in.telnetd is normally invoked in the internet server (see inetd(1M)), for requests to connect to the TELNET port as indicated by the /etc/services file (see services(4)).

  in.telnetd operates by allocating a pseudo-terminal device for a client, then creating a login process which has the slave side of the pseudo-terminal as its standard input, output, and error. in.telnetd manipulates the master side of the pseudo-terminal, implementing the TELNET protocol and passing characters between the remote client and the login process.

  When a TELNET session starts up, in.telnetd sends TELNET options to the client side indicating a willingness to do remote echo of characters, and to suppress go ahead. The pseudo-terminal allocated to the client is configured to operate in “cooked” mode, and with XTABS, ICRNL and ONLCR enabled. See termio(7).

  in.telnetd is willing to do: echo, binary, suppress go ahead, and timing mark. in.telnetd is willing to have the remote client do: binary, terminal type, terminal size, logout option, and suppress go ahead.

  in.telnetd also allows environment variables to be passed, provided that the client negotiates this during the initial option negotiation. The DISPLAY environment variable may be sent this way, either by the TELNET general environment passing methods, or by means of the XDISPLOC TELNET option. DISPLAY can be passed in the environment option during the same negotiation where XDISPLOC is used. Note that if you use both methods, use the same value for both. Otherwise, the results may be unpredictable.

  These options are specified in Internet standards RFC 1096, RFC 1408, RFC 1510, RFC 1571, RFC 2941, RFC 2942, RFC 2946, and RFC 1572. The following Informational draft is also supported: RFC 2952.

  The banner printed by in.telnetd is configurable. The default is (more or less) equivalent to ‘uname -sr’ and will be used if no banner is set in /etc/default/telnetd. To set the banner, add a line of the form

```
BANNER="..."
```

to /etc/default/telnetd. Nonempty banner strings are fed to shells for evaluation. The default banner may be obtained by

```
BANNER="\r\n\n\n\r\n\n\n\r\n\n uname -sr'
```

and no banner will be printed if /etc/default/telnetd contains

```
BANNER=""
```
Options

The following options are supported:

- **a authmode**
  This option may be used for specifying what mode should be used for authentication. There are several valid values for `authmode`:

  **valid**
  Only allows connections when the remote user can provide valid authentication information to identify the remote user, and is allowed access to the specified account without providing a password.

  **user**
  Only allows connections when the remote user can provide valid authentication information to identify the remote user. The `login(1)` command will provide any additional user verification needed if the remote user is not allowed automatic access to the specified account.

  **none**
  This is the default state. Authentication information is not required. If no or insufficient authentication information is provided, then the `login(1)` program provides the necessary user verification.

  **off**
  This disables the authentication code. All user verification happens through the `login(1)` program.

- **E**
  Disables encryption support negotiation.

- **h**
  Disables displaying host specific information before login has been completed.

- **M realm**
  Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the `krb5.conf(4)` file.

- **s tos**
  Sets the IP TOS option.

- **S keytab**
  Sets the Kerberos keytab file to use. The `/etc/krb5/krb5.keytab` file is used by default.

- **U**
  Refuses connections that cannot be mapped to a name through the `getnameinfo(3SOCKET)` function.

- **X**
  Disables Kerberos V5 authentication support negotiation.

Usage

telnetd and `in.telnetd` are IPv6-enabled. See `ip6(7P)`.

Security

`in.telnetd` can authenticate using Kerberos V5 authentication, `pam(3PAM)`, or both. By default, the telnet server will accept valid Kerberos V5 authentication credentials from a telnet client that supports Kerberos. `in.telnetd` can also support an encrypted session from such a client if the client requests it.
The telnet protocol only uses single DES for session protection—clients request service tickets with single DES session keys. The KDC must know that host service principals that offer the telnet service support single DES, which, in practice, means that such principals must have single DES keys in the KDC database.

In order for Kerberos authentication to work, a host/<FQDN> Kerberos principal must exist for each Fully Qualified Domain Name associated with the telnetd server. Each of these host/<FQDN> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on the telnetd server. An example principal might be:

host/bigmachine.eng.example.com

See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a krb5.keytab file. See System Administration Guide: Security Services for a discussion of Kerberos authentication.

in.telnetd uses pam(3PAM) for authentication, account management, session management, and password management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.telnetd. Here is a partial pam.conf file with entries for the telnet command using the UNIX authentication, account management, session management, and password management modules.

telnet auth requisite pam_authtok_get.so.1
telnet auth required pam_dhkeys.so.1

telnet auth required pam_unix_auth.so.1

telnet account requisite pam_roles.so.1
telnet account required pam_projects.so.1

telnet account required pam_unix_account.so.1

telnet session required pam_unix_session.so.1

telnet password required pam_dhkeys.so.1

telnet password requisite pam_authtok_get.so.1

telnet password requisite pam_authtok_check.so.1

telnet password required pam_authtok_store.so.1

If there are no entries for the telnet service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

For a Kerberized telnet service, the correct PAM service name is ktelnet.

Files
/etc/default/telnetd

System Administration Guide: Security Services

Ts’o, T., Telnet Data Encryption Option, RFC 2946. September 2000.

Some TELNET commands are only partially implemented.

Binary mode has no common interpretation except between similar operating systems.

The terminal type name received from the remote client is converted to lower case.

The *packet* interface to the pseudo-terminal should be used for more intelligent flushing of input and output queues.

in.telnetd never sends TELNET *go ahead* commands.

The *pam_unix* module is no longer supported. Similar functionality is provided by *pam_authok_check, pam_authok_get, pam_authok_store, pam_dhkeys, pam_passwd_auth, pam_unix_account, pam_unix_auth*, and *pam_unix_session*.

The in.telnetd service is managed by the service management facility, *smf*, under the service identifier:

```
svc:/network/telnet
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using *svcadm*. Responsibility for initiating and restarting this service is delegated to *inetd*. Use *inetadm* to make configuration changes and to view configuration information for this service. The service’s status can be queried using the *svcs* command.
in.tftpd(1M)

Name
in.tftpd, tftpd – Internet Trivial File Transfer Protocol server

Synopsis
in.tftpd [-d] [-T rexmtval] [-s] [homedir]

Description
tftpd is a server that supports the Internet Trivial File Transfer Protocol (TFTP).

Before responding to a request, the server attempts to change its current directory to homedir; the
default directory is /tftpboot.

The use of tftp does not require an account or password on the remote system. Due to the lack of
authentication information, in . tftpd will allow only publicly readable files to be accessed. Files may be written only if they already exist and are publicly writable. Note that this extends the concept of “public” to include all users on all hosts that can be reached through the network. This may not be appropriate on all systems, and its implications should be considered before enabling this service.

in. tftpd runs with the user ID and group ID set to [GU]ID_NOBODY under the assumption that no files exist with that owner or group. However, nothing checks this assumption or enforces this restriction.

Options
-d Debug. When specified it sets the SO_DEBUG socket option.
-s Secure. When specified, the directory change to homedir must succeed. The daemon also changes its root directory to homedir.
-T rexmtval Specifies the value of the retransmission timeout in seconds. This also affects the maximum session timeout in that the latter is set to five times the retransmission timeout value.

Usage
The in. tftpd server is IPv6–enabled. See ip6(7P).

in. tftpd supports transfers of greater than 32 MB, per RFC 2348.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>$UNWtftp</td>
</tr>
</tbody>
</table>

See Also
svcs(1), tftp(1), inetadm(1M), inetd(1M), svcadm(1M), netconfig(4), attributes(5), smf(5), ip6(7P)

Malkin, G. and Harkin, A. RFC 2349, TFTP Timeout Interval and Transfer Size Options. The Internet Society. May 1998
The tftpd server only acknowledges the transfer size option that is sent with a read request when the octet transfer mode is specified.

The in.tftpd.1m service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/tftp/udp6:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.

Unlike most smf(5) services, a manifest for the tftp service is not included in the system. To create one and enable this service, the administrator should:

1. Edit /etc/inet/inetd.conf and uncomment the tftp entry.
2. Run /usr/sbin/inetconv.

After you run inetconv, the svc:/network/tftp/udp6:default service is created and enabled.
in.timed – UDP or TCP time protocol service daemon

**Synopsis**

```
FMRI svc:/internet/time/default
```

**Description**

FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See `fmd(1M)` and `smf(5)`.

The `in.timed` service provides the server-side of the time protocol. The time server sends to requestors the time in seconds since midnight, January 1, 1900. The time protocol is available on both TCP and UDP transports through port 37.

The `in.timed` service is an `inetd(1M)` `smf(5)` delegated service. The `in.timed` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

**TCP-based service**

Once a connection is established, the `in.timed` sends the time as a 32-bit binary number and closes the connection. Any received data is ignored.

**UDP-based service**

The `in.timed` listens for UDP datagrams. When a datagram is received, the server generates a UDP datagram containing the time as a 32-bit binary number and sends it to the client. Any received data is ignored.

**Attributes**

RFC 868
in.tnamed(1M)

**Name**
in.tnamed, tnamed – DARPA trivial name server

**Synopsis**
/usr/sbin/in.tnamed [-v]

**Description**
in.tnamed is a server that supports the DARPA Name Server Protocol. The name server operates at the port indicated in the "name" service description (see `services(4)`), and is invoked by `inetd(1M)` when a request is made to the name server.

**Options**
- `-v`
  Invoke the daemon in verbose mode.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWtnamd</td>
</tr>
</tbody>
</table>

**See Also**
svcs(1), uucp(1C), inetadm(1M), inetd(1M), svcadm(1M), services(4), attributes(5), smf(5)

**Notes**
The protocol implemented by this program is obsolete. Its use should be phased out in favor of the Internet Domain Name Service (DNS) protocol.

The in.tnamed service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/tname

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetad(1M) to make configuration changes and to view configuration information for this service. The service’s status can be queried using the svcs(1) command.
intrstat – report interrupt statistics

/usr/sbin/intrstat [-c cpulist | -C processor_set_id]
               [interval [count]]

The intrstat utility gathers and displays run-time interrupt statistics. The output is a table of device names and CPU IDs, where each row of the table denotes a device, and each column of the table denotes a CPU. Each cell in the table contains both the raw number of interrupts for the given device on the given CPU, and the percentage of absolute time spent in that device’s interrupt handler on that CPU.

The device name is given in the form of \{name\}\#{instance}. The name is the normalized driver name, and typically corresponds to the name of the module implementing the driver. See ddi_driver_name(9F). Many Sun-delivered drivers have their own manual pages. See Intro(7).

If standard output is a terminal, the table contains as many columns of data as can fit within the terminal width. If standard output is not a terminal, the table contains at most four columns of data. By default, data is gathered and displayed for all CPUs. If the data cannot fit in a single table, it is printed across multiple tables. The set of CPUs for which data is displayed can be optionally specified with the -c or -C option.

By default, intrstat displays data once per second and runs indefinitely. Both of these behaviors can be optionally controlled with the interval and count parameters, respectively. See OPERANDS.

Because intrstat uses dynamic discovery, it reports only on devices that raise interrupts while the command is running. Any devices that are silent while intrstat is running are not displayed.

intrstat induces a small system-wide performance degradation. As a result, only the super-user can run intrstat by default. The Solaris Dynamic Tracing Guide explains how administrators can grant privileges to other users to permit them to run intrstat.

The following options are supported:

- **-c cpulist**
  Displays data for the CPUs specified by cpulist.

  cpulist can be a single processor ID (for example, 4), a range of processor IDs (for example, 4-6), or a comma separated list of processor IDs or processor ID ranges (for example, 4,5,6 or 4,6-8).

- **-C processor_set_id**
  Displays data for the CPUs in the processor set specified by processor_set_id.

intrstat modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, intrstat modifies its output to include the added CPU. If a CPU is removed from the set, intrstat modifies its output to exclude the removed CPU. At
most one processor set can be specified.

**Operands**  The following operands are supported:

- **count**
  Indicates the number of intervals to execute before exiting.

- **interval**
  Indicates the number of seconds to be executed before exiting.

**Examples**  **EXAMPLE 1  Using intrstat Without Options**

Without options, **intrstat** displays a table of trap types and CPUs. At most, four columns can fit in the default terminal width. If there are more than four CPUs, multiple tables are displayed.

The following example runs **intrstat** on a uniprocessor Intel IA/32-based laptop:

```
example# intrstat
-------------+---------------
device | cpu0 %tim
-------------+---------------
atad0 | 166 0.4
atat1 | 0 0.0
atad0 | 6 0.0
i8042d0 | 281 0.7
iprb0 | 6 0.0
uhci1 | 6 0.0
uhci2 | 6 0.0
-------------+---------------
```

```
device | cpu0 %tim
-------------+---------------
atad0 | 161 0.5
atat1 | 0 0.0
atad0 | 6 0.0
i8042d0 | 303 0.6
iprb0 | 6 0.0
uhci1 | 6 0.0
uhci2 | 6 0.0
...
```

**Attributes**  See **attributes(5)** for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWdtrc</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The command-line syntax is Evolving. The human-readable output is Unstable.

Solaris Dynamic Tracing Guide
in.uucpd(1M)

Name  in.uucpd, uucpd – UUCP server

Synopsis  /usr/sbin/in.uucpd [-n]

Description  in.uucpd is the server for supporting UUCP connections over networks.

in.uucpd is invoked by `inetd(1M)` when a UUCP connection is established, that is, a connection to the port indicated in the "uucp" service specification, and executes the following protocol. See `services(4):

1. The server prompts with `login:`. The `uucico(1M)` process at the other end must supply a username.

2. Unless the username refers to an account without a password, the server then prompts with `Password:`. The uucico process at the other end must supply the password for that account.

If the username is not valid, or is valid but refers to an account that does not have /usr/lib/uucp/uucico as its login shell, or if the password is not the correct password for that account, the connection is dropped. Otherwise, uucico is run, with the user ID, group ID, group set, and home directory for that account, with the environment variables USER and LOGNAME set to the specified username, and with a `-u` flag specifying the username. Unless the `-n` flag is specified, entries are made in /var/adm/utmpx, /var/adm/wtmpx, and /var/adm/lastlog for the username. in.uucpd must be invoked by a user with appropriate privilege (usually root) in order to be able to verify that the password is correct.

Security  in.uucpd uses `pam(3PAM)` for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for in.uucpd. Here is a partial `pam.conf` file with entries for uucp using the UNIX authentication, account management, and session management module.

```
   uucp auth requisite pam_aunhtok_get.so.1
   uucp auth required pam_dhkeys.so.1
   uucp auth required pam_unix_auth.so.1
   uucp account requisite pam_roles.so.1
   uucp account required pam_projects.so.1
   uucp account required pam_unix_account.so.1
   uucp session required pam_unix_session.so.1
```

If there are no entries for the uucp service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the peer may be prompted for multiple passwords.

Files  /var/adm/utmpx  accounting
       /var/adm/wtmpx  accounting
       /var/adm/lastlog  time of last login
Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWbnuu</td>
</tr>
</tbody>

Diagnostics

All diagnostic messages are returned on the connection, after which the connection is closed.

user read      An error occurred while reading the username.
passwd read    An error occurred while reading the password.
Login incorrect The username is invalid or refers to an account with a login shell other than /usr/lib/uucp/uucico, or the password is not the correct password for the account.

Notes

The in.uucpd service is managed by the service management facility, smf(5), under the service identifier:
	svc:/network/uucp

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svc(1) command.

The pam_unix(5) module is no longer supported. Similar functionality is provided by

pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5),

pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).
## Name
iostat – report I/O statistics

## Synopsis
```
/usr/bin/iostat [-cCdDeEiImMnpPrstxXYz] [-l n] [-t u | d]
[Disk][... [interval [count]]]
```

## Description
The `iostat` utility iteratively reports terminal, disk, and tape I/O activity, as well as CPU utilization. The first line of output is for all time since boot; each subsequent line is for the prior interval only.

To compute this information, the kernel maintains a number of counters. For each disk, the kernel counts reads, writes, bytes read, and bytes written. The kernel also takes hi-res time stamps at queue entry and exit points, which allows it to keep track of the residence time and cumulative residence-length product for each queue. Using these values, `iostat` produces highly accurate measures of throughput, utilization, queue lengths, transaction rates and service time. For terminals collectively, the kernel simply counts the number of input and output characters.

During execution of the kernel status command, the state of the system can change. If relevant, a state change message is included in the `iostat` output, in one of the following forms:

```
<<device added: sd0>>
<<device removed: sd0>>
<<partition added: sd0,a>>
<<partition removed: sd0,a>>
<<NFS mounted: nfs1>>
<<NFS unmounted: nfs1>>
<<multi-path added: ssd4>>
<<multi-path removed: ssd4>>
<<controller added: c1>>
<<controller removed: c1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

Note that the names printed in these state change messages are affected by the `-n` and `-m` options as appropriate.

For more general system statistics, use `sar(1), sar(1M),` or `vmstat(1M).

## Output
The output of the `iostat` utility includes the following information.

- **device** name of the disk
- **r/s** reads per second
- **w/s** writes per second
- **kr/s** kilobytes read per second
The average I/O size during the interval can be computed from \( kr/s \) divided by \( r/s \).

**kw/s** kilobytes written per second

The average I/O size during the interval can be computed from \( kw/s \) divided by \( w/s \).

**wait** average number of transactions waiting for service (queue length)

This is the number of I/O operations held in the device driver queue waiting for acceptance by the device.

**actv** average number of transactions actively being serviced (removed from the queue but not yet completed)

This is the number of I/O operations accepted, but not yet serviced, by the device.

**svc_t** average response time of transactions, in milliseconds

The \( svc_t \) output reports the overall response time, rather than the service time, of a device. The overall time includes the time that transactions are in queue and the time that transactions are being serviced. The time spent in queue is shown with the \(-x\) option in the \( wsvc_t \) output column. The time spent servicing transactions is the true service time. Service time is also shown with the \(-x\) option and appears in the \( asvc_t \) output column of the same report.

**%w** percent of time there are transactions waiting for service (queue non-empty)

**%b** percent of time the disk is busy (transactions in progress)

**wsvc_t** average service time in wait queue, in milliseconds

**asvc_t** average service time of active transactions, in milliseconds

**wt** the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero.

### Options

The following options are supported:

- **-c** Report the percentage of time the system has spent in user mode, in system mode, waiting for I/O, and idling. See the NOTES section for more information.

- **-C** When the \(-x\) option is also selected, report extended disk statistics aggregated by controller id.

- **-d** For each disk, report the number of kilobytes transferred per second, the number of transfers per second, and the average service time in milliseconds.

- **-D** For each disk, report the reads per second, writes per second, and percentage disk utilization.
-e Display device error summary statistics. The total errors, hard errors, soft errors, and transport errors are displayed.

-E Display all device error statistics.

-i In -E output, display the Device ID instead of the Serial No. The Device ID is a unique identifier registered by a driver through ddi_devid_register(9F).

-I Report the counts in each interval, rather than rates (where applicable).

-n Limit the number of disks included in the report to n; the disk limit defaults to 4 for -d and -D, and unlimited for -x. Note: disks explicitly requested (see disk below) are not subject to this disk limit.

-m Report file system mount points. This option is most useful if the -P or -p option is also specified or used in conjunction with -Xn or -en. The -m option is useful only if the mount point is actually listed in the output. This option can only be used in conjunction with the -n option.

-M Display data throughput in MB/sec instead of KB/sec.

-n Display names in descriptive format. For example, cXtYdZsN, server:/export/path.

By default, disks are identified by instance names such as ssd23 or md301. Combining the -n option with the -x option causes disk names to display in the cXtYdZsN format which is more easily associated with physical hardware characteristics. The cXtYdZsN format is particularly useful in FibreChannel (FC) environments where the FC World Wide Name appears in the t field.

-p For each disk, report per-partition statistics in addition to per-device statistics.

-P For each disk, report per-partition statistics only, no per-device statistics.

-r Display data in a comma-separated format.

-s Suppress messages related to state changes.

-t Report the number of characters read and written to terminals per second.

-T u | d Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See ctime(3C).

-x Report extended disk statistics. By default, disks are identified by instance names such as ssd23 or md301. Combining the x option with the -n option causes disk names to display in the cXtYdZsN format, more easily associated with physical hardware characteristics. Using the cXtYdZsN format is particularly helpful in the FibreChannel environments where the FC World Wide Name appears in the t field.
If no output display is requested (no -x, -e, -E), -x is implied.

- Y For disks under scsi_vhci(7D) control, in addition to disk lun statistics, also report statistics for lun.targetport and lun.targetport.controller.

In -n (descriptive) mode the targetport is shown using the target-port property of the path. Without -n the targetport is shown using the shorter port-id. All target ports with the same target-port property value share the same port-id. The target-port-to-port-id association does not persist across reboot.

If no output display is requested (no -x, -e, -E), -x is implied.

- z Do not print lines whose underlying data values are all zeros.

The option set -xcnCXTdz interval is particularly useful for determining whether disk I/O problems exist and for identifying problems.

Operands The following operands are supported:

count Display only count reports.
disk Explicitly specify the disks to be reported; in addition to any explicit disks, any active disks up to the disk limit (see -l above) will also be reported.

interval Report once each interval seconds.

Examples EXAMPLE 1 Using iostat to Generate User and System Operation Statistics

The following command displays two reports of extended device statistics, aggregated by controller id, for user (us) and system (sy) operations. Because the -n option is used with the -x option, devices are identified by controller names.

```bash
example% iostat -xcnCXTdz 5
```

```plaintext

**EXAMPLE 4**  Show Translation from Instance Name to Descriptive Name

The following example illustrates the use of `iostat` to translate a specific instance name to a descriptive name.

```bash
example% iostat -xn sd1
extended device statistics
r/s w/s kr/s kw/s wait actv wsvc_t asvc_t %w %b device  
0.0 0.0 0.0 0.0 0.0 0.0 0.0 0.0 0 0 c8t1d0
```

**EXAMPLE 5**  Show Target Port and Controller Activity for a Specific Disk

In the following example, there are four controllers, all connected to the same target port.

```bash
# iostat -Y ssd22
extended device statistics
device r/s w/s kr/s kw/s wait actv svc_t %w %b  
ssd22 0.2 0.0 1.5 0.0 0.0 0.0 0.7 0 0  
ssd22.t2 0.2 0.0 1.5 0.0 0.0 0.0 0.0 0 0  
ssd22.t2.fp0 0.0 0.0 0.4 0.0 0.0 0.0 0.0 0 0  
ssd22.t2.fp1 0.0 0.0 0.4 0.0 0.0 0.0 0.0 0 0  
ssd22.t2.fp2 0.0 0.0 0.4 0.0 0.0 0.0 0.0 0 0  
ssd22.t2.fp3 0.0 0.0 0.4 0.0 0.0 0.0 0.0 0 0  
```

Invocation is evolving. Human readable output is unstable.

**See Also**  `sar(1), sar(1M), mpstat(1M), vmstat(1M), time(2), ctime(3C), attributes(5), scsi_vhci(7D)`

**System Administration Guide: Basic Administration**

**Notes**  The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

The `svc_t` response time is not particularly significant when the I/O `(r/s+w/s)` rates are under 0.5 per second. Harmless spikes are fairly normal in such cases.

The `mpstat` utility reports the same `wt`, `usr`, and `sys` statistics. See `mpstat(1M)` for more information.

When executed in a zone and if the pools facility is active, `iostat(1M)` will only provide information for those processors in the processor set of the pool to which the zone is bound.
**Name**
ipaddrsel – configure IPv6 default address selection

**Synopsis**
/usr/sbin/ipaddrsel
/usr/sbin/ipaddrsel -f file
/usr/sbin/ipaddrsel -d

**Description**
Use the `ipaddrsel` utility to configure the IPv6 default address selection policy table. The policy table is a longest-matching-prefix lookup table that is used for IPv6 source address selection and for destination address ordering when resolving names to AF_INET6 addresses. For a description of how the policy table is used for source address selection, see `inet6(7P)`. For a description of how the policy table is used for destination address ordering, see `getaddrinfo(3SOCKET)`. The unmodified policy table is valid for all typical IPv6 deployments. Modify the table only if a circumstance exists for which the default behavior of the IPv6 source address selection or destination address ordering mechanism is unsatisfactory. See the `Examples` section for examples of such circumstances. You should carefully consider your addressing strategy before you change the table from the provided default.

When the `ipaddrsel` command is issued without any arguments, the address selection policy currently in use is printed. The format of the output is compatible with the format of the configuration file that the `-f` option accepts.

**Note** – If the `usesrc` subcommand to `ifconfig(1M)` is applied to a particular physical interface, the selection policy specified by `usesrc` overrides the source address selection policies specified by `ipaddrsel`. This is true for packets that are locally generated and for applications that do not choose a non-zero source address using `bind(3SOCKET)`.

**The Configuration File**
The configuration file that the `-f` option accepts can contain either comment lines or policy entries. Comment lines have a `#` character as the first non-blank character and they are ignored by the `ipaddrsel` utility. Policy entry lines have the following format:

```
prefix/prefix_length precedence label [# comment ]
```

The `prefix` must be an IPv6 prefix in a format consistent with `inet(3SOCKET)`. The `prefix_length` is an integer ranging from 0 to 128. The IPv6 source address selection and destination address ordering algorithms determine the precedence or label of an address by doing a longest-prefix-match lookup using the prefixes in this table, much like next-hop determination for a destination is done by doing a longest-prefix-match lookup using an IP routing table.

The precedence is a non-negative integer that represents how the destination address ordering mechanism will sort addresses returned from name lookups. In general, addresses with a higher precedence will be in front of addresses with a lower precedence. Other factors, such as destinations with undesirable source addresses can, however, override these precedence values.
The label is a string of at most fifteen characters, not including the NULL terminator. The label allows particular source address prefixes to be used with destination prefixes of the same label. Specifically, for a particular destination address, the IPv6 source address selection algorithm prefers source addresses whose label is equal that of the destination.

The label may be followed by an optional comment.

The file must contain a default policy entry, which is an entry with "::0/0" as its prefix and prefix_length. This is to ensure that all possible addresses match a policy.

Options

The ipaddrsel utility supports the following options:

- `-f file`
  Replace the address selection policy table with the policy specified in the file.

- `-d`
  Revert the kernel's address selection policy table back to the default table.

Invoking ipaddrsel in this way only changes the currently running kernel's policy table, and does not alter the configuration file /etc/inet/ipaddrsel.conf. To revert the configuration file back to its default settings, use ipaddrsel -d, then dump the contents of the table to the configuration file by redirecting the output of ipaddrsel to

```
example# ipaddrsel -d
example# ipaddrsel > /etc/inet/ipaddrsel.conf
```

Examples

**EXAMPLE 1** The Default Policy in /etc/inet/ipaddrsel.conf

The following example is the default policy that is located in /etc/inet/ipaddrsel.conf:

```
# Prefix Precedence Label
::1/128  50 Loopback
::/0    40 Default
2002::/16 30 6to4
::/96   20 IPv4_Compatible
::ffff:0.0.0.0/96 10 IPv4
```

**EXAMPLE 2** Assigning a Lower Precedence to Link-local and Site-local Addresses

By default, the destination address ordering rules sort addresses of smaller scope before those of larger scope. For example, if a name resolves to a global and a site-local address, the site local address would be ordered before the global address. An administrator can override this ordering rule by assigning a lower precedence to addresses of smaller scope, as the following table demonstrates.

```
# Prefix Precedence Label
::1/128  50 Loopback
::/0    40 Default
2002::/16 30 6to4
fec0::/10 27 Site-Local
```
EXAMPLE 2  Assigning a Lower Precedence to Link-local and Site-local Addresses  (Continued)

fe80::/10 23 Link-Local
::/96 20 IPv4 Compatible
::ffff:0.0.0.0/96 10 IPv4

EXAMPLE 3  Assigning Higher Precedence to IPv4 Destinations

By default, IPv6 addresses are ordered in front of IPv4 addresses in name lookups. ::ffff:0.0.0.0/96 has the lowest precedence in the default table. In the following example, IPv4 addresses are assigned higher precedence and are ordered in front of IPv6 destinations:

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Precedence</th>
<th>Label</th>
</tr>
</thead>
<tbody>
<tr>
<td>::1/128</td>
<td>50</td>
<td>Loopback</td>
</tr>
<tr>
<td>::/0</td>
<td>40</td>
<td>Default</td>
</tr>
<tr>
<td>2002::/16</td>
<td>30</td>
<td>6to4</td>
</tr>
<tr>
<td>::/96</td>
<td>20</td>
<td>IPv4 Compatible</td>
</tr>
<tr>
<td>::ffff:0.0.0.0/96</td>
<td>60</td>
<td>IPv4</td>
</tr>
</tbody>
</table>

EXAMPLE 4  Ensuring that a particular source address is only used when communicating with destinations in a particular network.

The following policy table assigns a label of 5 to a particular source address on the local system, 2001:1111:1111::1. The table assigns the same label to a network, 2001:2222:2222::/48. The result of this policy is that the 2001:1111:1111::1 source address will only be used when communicating with destinations contained in the 2001:2222:2222::/48 network. For this example, this network is the "ClientNet", which could represent a particular client's network.

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Precedence</th>
<th>Label</th>
</tr>
</thead>
<tbody>
<tr>
<td>::1/128</td>
<td>50</td>
<td>Loopback</td>
</tr>
<tr>
<td>2001:1111:1111::1/128</td>
<td>40</td>
<td>ClientNet</td>
</tr>
<tr>
<td>2001:2222:2222::/48</td>
<td>40</td>
<td>ClientNet</td>
</tr>
<tr>
<td>::/0</td>
<td>40</td>
<td>Default</td>
</tr>
<tr>
<td>2002::/16</td>
<td>30</td>
<td>6to4</td>
</tr>
<tr>
<td>::/96</td>
<td>20</td>
<td>IPv4 Compatible</td>
</tr>
<tr>
<td>::ffff:0.0.0.0/96</td>
<td>10</td>
<td>IPv4</td>
</tr>
</tbody>
</table>

This example assumes that the local system has one physical interface, and that all global prefixes are assigned to that physical interface.

Exit Status  ipaddrsel returns the following exit values:

0     ipaddrsel successfully completed.
>0    An error occurred. If a failure is encountered, the kernel's current policy table is unchanged.
The file that contains the IPv6 default address selection policy to be installed at boot time. This file is loaded before any Internet services are started.

</tr>
</tbody>
</table>

The ipnodes cache kept by nscl(1M) contains addresses that are ordered using the destination address ordering algorithm, which is one of the reasons why ipaddrsel is called before nscl in the boot sequence. If ipaddrsel is used to change the address selection policy after nscl has started, you should invalidate the nscl ipnodes cache invalidated by invoking the following command:

example# /usr/sbin/nscl -i ipnodes
### ipf(1M)

#### Name
ipf – alter packet filtering lists for IP packet input and output

#### Synopsis
```bash
ipf [-6AdDEInoPRrsVyzZ [-l block | pass | nomatch]
    [-T optionlist] [-F i | o | a | s | 5] [-f filename
    [-f filename...]
```

#### Description
The `ipf` utility is part of a suite of commands associated with the Solaris IP Filter feature. See `ipfilter(5)`.

The `ipf` utility opens the filenames listed (treating a hyphen (-) as stdin) and parses the file for a set of rules which are to be added or removed from the packet filter rule set.

If there are no parsing problems, each rule processed by `ipf` is added to the kernel's internal lists. Rules are added to the end of the internal lists, matching the order in which they appear when given to `ipf`.

`ipf`'s use is restricted through access to `/dev/ipauth`, `/dev/ipl`, and `/dev/ipstate`. The default permissions of these files require `ipf` to be run as root for all operations.

#### Enabling Solaris IP Filter Feature
Solaris IP Filter is installed with the Solaris operating system. However, packet filtering is not enabled by default. Use the following procedure to activate the Solaris IP Filter feature.

1. Assume a role that includes the IP Filter Management rights profile (see `rbac(5)`) or become superuser.
2. Create a packet filtering rule set. See `ipf(4)`.
3. (Optional) Create a network address translation (NAT) configuration file. See `ipnat.conf(4)`.
4. (Optional) Create an address pool configuration file. See `ippool(4)`.
   
   Create an `ippool.conf` file if you want to refer to a group of addresses as a single address pool. If you want the address pool configuration file to be loaded at boot time, create a file called `/etc/ipf/ippool.conf` in which to put the address pool. If you do not want the address pool configuration file to be loaded at boot time, put the `ippool.conf` file in a location other than `/etc/ipf` and manually activate the rules.
5. Enable Solaris IP Filter, as follows:
   ```bash
   # svcadm enable network/ipfilter
   ```

To re-enable packet filtering after it has been temporarily disabled either reboot the machine or perform the following series of commands:

1. Enable Solaris IP Filter:
   ```bash
   # ipf -E
   ```
2. Activate packet filtering:
   ```bash
   # ipf -f <ipf configuration file>
   ```
3. (Optional) Activate NAT:
ipnat -f <IPNAT configuration file>
See ipnat(1M).

Note – If you reboot your system, the packet filtering rules in the /etc/ipf/ipf.conf file and
the /etc/ipf/ipnat.conf file are activated.

Options The following options are supported:

-6
This option is required to parse IPv6 rules and to have them loaded. Loading of IPv6 rules
is subject to change in the future.

-A
Set the list to make changes to the active list (default).

-d
Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each
one.

-D
Disable the filter (if enabled). Not effective for loadable kernel versions.

-E
Enable the filter (if disabled). Not effective for loadable kernel versions.

-F i | o | a
Specifies which filter list to flush. The parameter should either be i (input), o (output) or a
(remove all filter rules). Either a single letter or an entire word starting with the appropriate
letter can be used. This option can be before or after any other, with the order on the
command line determining which used to execute options.

-F s | S
To flush entries from the state table, use the -F option in conjunction with either s (removes
state information about any non-fully established connections) or S (deletes the entire state
table). You can specify only one of these two options. A fully established connection will
show up in ipfstat -s output as 4/4, with deviations either way indicating the connection
is not fully established.

-f filename
Specifies which files ipf should use to get input from for modifying the packet filter rule
lists.

-I
Set the list to make changes to the inactive list.

-l pass | block | nomatch
Toggles default logging of packets. Valid arguments to this option are pass, block and
nomatch. When an option is set, any packet which exits filtering and matches the set
category is logged. This is most useful for causing all packets that do not match any of the
loaded rules to be logged.
-n
Prevents ipf from making any ioctl calls or doing anything which would alter the currently running kernel.

-o
Force rules by default to be added/deleted to/from the output list, rather than the (default) input list.

-P
Add rules as temporary entries in the authentication rule table.

-R
Disable both IP address-to-hostname resolution and port number-to-service name resolution.

-r
Remove matching filter rules rather than add them to the internal lists.

-s
Swap the currently active filter list to be an alternative list.

-T optionlist
Allows run-time changing of IPFilter kernel variables. To allow for changing, some variables require IPFilter to be in a disabled state (-D), others do not. The optionlist parameter is a comma-separated list of tuning commands. A tuning command is one of the following:

list
Retrieve a list of all variables in the kernel, their maximum, minimum, and current value.

single variable name
Retrieve its current value.

variable name with a following assignment
To set a new value.

Examples follow:

# Print out all IPFilter kernel tunable parameters
ipf -T list

# Display the current TCP idle timeout and then set it to 3600
ipf -D -T fr_tcpidletimeout,fr_tcpidletimeout=3600 -E

# Display current values for fr_pass and fr_chksrc, then set
# fr_chksrc to 1.
ipf -T fr_pass,fr_chksrc,fr_chksrc=1

-v
Turn verbose mode on. Displays information relating to rule processing.
Show version information. This will display the version information compiled into the ipf binary and retrieve it from the kernel code (if running or present). If it is present in the kernel, information about its current state will be displayed; for example, whether logging is active, default filtering, and so forth).

Manually resync the in-kernel interface list maintained by IP Filter with the current interface status list.

For each rule in the input file, reset the statistics for it to zero and display the statistics prior to them being zeroed.

Zero global statistics held in the kernel for filtering only. This does not affect fragment or state statistics.

Files
/dev/ipauth
/dev/ipf
/dev/ipstate
   Links to IP Filter pseudo devices.
/etc/ipf/ipf.conf
   Location of ipf startup configuration file. See ipf(4).
/usr/share/ipfilter/examples/
   Contains numerous IP Filter examples.

System Administration Guide: IP Services

Diagnostics
Needs to be run as root for the packet filtering lists to actually be affected inside the kernel.

Notes
To view license terms, attribution, and copyright for IP Filter, the default path is /usr/lib/ipf/IPFILTER.LICENCE. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.
**Name**  
`ipfs` saves and restores information for NAT and state tables

**Synopsis**  
`ipfs [-nv] [-l]

  `ipfs [-nv] [-u]

  `ipfs [-nv] [-d dirname] -R

  `ipfs [-nv] [-d dirname] -W

  `ipfs [-nNSv] [-f filename] -r

  `ipfs [-nNSv] [-f filename] -w

  `ipfs [-nNSv] -f filename -i <if1>,<if2>

**Description**  
The `ipfs` utility enables the saving of state information across reboots. Specifically, the utility allows state information created for NAT entries and rules using "keep state" to be locked (modification prevented) and then saved to disk. Then, after a reboot, that information is restored. The result of this state-saving is that connections are not interrupted.

**Options**  
The following options are supported:

- `-d`  
  Change the default directory used with `-R` and `-W` options for saving state information.

- `-n`  
  Do not take any action that would affect information stored in the kernel or on disk.

- `-v`  
  Provides a verbose description of `ipfs` activities.

- `-N`  
  Operate on NAT information.

- `-S`  
  Operate on filtering state information.

- `-u`  
  Unlock state tables in the kernel.

- `-l`  
  Lock state tables in the kernel.

- `-r`  
  Read information in from the specified file and load it into the kernel. This requires the state tables to have already been locked and does not change the lock once complete.

- `-w`  
  Write information out to the specified file and from the kernel. This requires the state tables to have already been locked and does not change the lock once complete.

- `-R`  
  Restores all saved state information, if any, from two files, `ipstate.ipf` and `ipnat.ipf`, stored in the `/var/db/ipf` directory. This directory can be changed with the `-d` option. The state tables are locked at the beginning of this operation and unlocked once complete.

- `-W`  
  Saves in-kernel state information, if any, out to two files, `ipstate.ipf` and `ipnat.ipf`, stored in the `/var/db/ipf` directory. This directory can be changed with the `-d` option. The state tables are locked at the beginning of this operation and unlocked once complete.
Files
- /var/db/ipf/ipstate.ipf
- /var/db/ipf/ipnat.ipf
- /dev/ipl
- /dev/ipstate
- /dev/ipnat

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWipfu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also
ipf(1M), ipmon(1M), ipnat(1M), attributes(5)

Notes
To view license terms, attribution, and copyright for IP Filter, the default path is
/usr/lib/ipf/IPFILTER.LICENCE. If the Solaris operating environment has been installed
anywhere other than the default, modify the given path to access the file at the installed
location.

Diagnostics
Arguably, the -W and -R operations should set the locking and, rather than undo it, restore it to
what it was previously.

Fragment table information is currently not saved.
ipfstat – reports on packet filter statistics and filter list

Synopsis ipfstat [-aACdfghILnoRstv]

             [-T refresh]time

Description The ipfstat command is part of a suite of commands associated with the Solaris IP Filter feature. See ipfilter(5).

The ipfstat command examines /dev/kmem using the symbols _fr_flags, _frstats, _filterin, and _filterout. To run and work, it needs to be able to read both /dev/kmem and the kernel itself.

The default behavior of ipfstat is to retrieve and display the statistics which have been accumulated over time as the kernel has put packets through the filter.

The role of ipfstat is to display current kernel statistics gathered as a result of applying the filters in place (if any) to packets going in and out of the kernel. This is the default operation when no command line parameters are present. When supplied with either -i or -o, ipfstat will retrieve and display the appropriate list of filter rules currently installed and in use by the kernel.

ipfstat uses kernel device files to obtain information. The default permissions of these files require ipfstat to be run as root for all operations.

The ipfstat command supports the kstat(3KSTAT) kernel facility. Because of this support, as an alternative to ipfstat, you can use kstat(1M). For example:

# kstat -m ipf

Using the ipfstat -t option causes ipfstat to enter the state top mode. In this mode the state table is displayed similarly to the way the Unix top utility displays the process table. The -C, -D, -P, -S and -T command line options can be used to restrict the state entries that will be shown and to specify the frequency of display updates.

In state top mode, use the following keys to influence the displayed information:

d   Select information to display.

\   Redraw the screen.

q   Quit the program.

s   Switch between different sorting criteria.

r   Reverse the sorting criteria.

States can be sorted by protocol number, by number of IP packets, by number of bytes, and by time-to-live of the state entry. The default is to sort by the number of bytes. States are sorted in descending order, but you can use the r key to sort them in ascending order.
It is not possible to interactively change the source, destination, and protocol filters or the refresh frequency. This must be done from the command line.

The screen must have at least 80 columns for correct display. However, `ipfstat` does not check the screen width.

Only the first $X$ entries that match the sort and filter criteria are displayed (where $X$ is the number of rows on the display). There is no way to see additional entries.

**Options**

The following options are supported:

- `-6` Display filter lists and states for IPv6, if available. This option might change in the future.
- `-a` Display the accounting filter list and show bytes counted against each rule.
- `-A` Display packet authentication statistics.
- `-C` Valid only in combination with `-t`. Display "closed" states as well in the top. Normally, a TCP connection is not displayed when it reaches the `CLOSE_WAIT` protocol state. With this option enabled, all state entries are displayed.
- `-d` Produce debugging output when displaying data.
- `-D addrport` Valid only in combination with `-t`. Limit the state top display to show only state entries whose destination IP address and port match the `addrport` argument. The `addrport` specification is of the form `ipaddress[,port]`. The `ipaddress` and `port` should be either numerical or the string `any` (specifying any IP address and any port, in that order). If the `-D` option is not specified, it defaults to `-D any,any`.
- `-f` Show fragment state information (statistics) and held state information (in the kernel) if any is present.
- `-g` Show groups currently configured (both active and inactive).
- `-h` Show per-rule the number of times each one scores a "hit". For use in combination with `-i`.
- `-i` Display the filter list used for the input side of the kernel IP processing.
- `-I` Swap between retrieving inactive/active filter list details. For use in combination with `-i`.
- `-l` When used with `-s`, show a list of active state entries (no statistics).
- `-n` Show the rule number for each rule as it is printed.
- `-o` Display the filter list used for the output side of the kernel IP processing.
-P protocol Valid only in combination with -t. Limit the state top display to show only state entries that match a specific protocol. The argument can be a protocol name (as defined in /etc/protocols) or a protocol number. If this option is not specified, state entries for any protocol are specified.

-R Disable both IP address-to-hostname resolution and port number-to-service name resolution.

-S addrport Valid only in combination with -t. Limit the state top display to show only state entries whose source IP address and port match the addrport argument. The addrport specification is of the form ipaddress[,port]. The ipaddress and port should be either numerical or the string any (specifying any IP address and any port, in that order). If the -S option is not specified, it defaults to -S any, any.

-s Show packet/flow state information (statistics only).

-T refresh time Valid only in combination with -t. Specifies how often the state top display should be updated. The refresh time is the number of seconds between an update. Any positive integer can be used. The default (and minimal update time) is 1.

-t Show the state table in a way similar to the way the Unix utility, top, shows the process table. States can be sorted in a number of different ways.

-v Turn verbose mode on. Displays additional debugging information.

ipmon(1M)

Name ipmon – monitors /dev/ipl for logged packets

Synopsis

ipmon [-abDFhnpstvxX] [-N device] [ [o] [NSI]] [-O [NSI]]
[-P pidfile] [-S device] [-f device] [filename]

Description

The ipmon command is part of a suite of commands associated with the Solaris IP Filter feature. See ipfilter(5).

The ipmon command opens /dev/ipl for reading and awaits data to be saved from the packet filter. The binary data read from the device is reprinted in human readable form. However, IP addresses are not mapped back to hostnames, nor are ports mapped back to service names.

The output goes to standard output, by default, or a filename, if specified on the command line. Should the -s option be used, output is sent instead to syslogd(1M). Messages sent by means of syslog have the day, month, and year removed from the message, but the time (including microseconds), as recorded in the log, is still included.

Messages generated by ipmon consist of whitespace-separated fields. Fields common to all messages are:

- The date of packet receipt. This is suppressed when the message is sent to syslog.
- The time of packet receipt. This is in the form HH:MM:SS.F, for hours, minutes, seconds, and fractions of a second (which can be several digits long).
- The name of the interface on which the packet was processed, for example, ib1.
- The group and rule number of the rule, for example, @0:17. These can be viewed with ipfstat -in for input rules or ipfstat -in for output rules. See ipfstat(1M).
- The action: p for passed, b for blocked, s for a short packet, n did not match any rules, or L for a log rule.
- The addresses. This is actually three fields: the source address and port (separated by a comma), the symbol →, and the destination address and port. For example:
  209.53.17.22,80 → 198.73.220.17,1722.
- PR followed by the protocol name or number, for example, PR tcp.
- len followed by the header length and total length of the packet, for example, len 20 40.

If the packet is a TCP packet, there will be an additional field starting with a hyphen followed by letters corresponding to any flags that were set. See ipf.conf(4) for a list of letters and their flags.

If the packet is an ICMP packet, there will be two fields at the end, the first always being icmp, the next being the ICMP message and submessage type, separated by a slash. For example, icmp 3/3 for a port unreachable message.

Options

The following options are supported:

- a
  Open all of the device logfiles for reading log entries. All entries are displayed to the same output device (stderr or syslog).
-b
For rules which log the body of a packet, generate hex output representing the packet contents after the headers.

-D
Cause ipmon to turn itself into a daemon. Using subshells or backgrounding of ipmon is not required to turn it into an orphan so it can run indefinitely.

- f device
Specify an alternative device/file from which to read the log information for normal IP Filter log records.

-F
Flush the current packet log buffer. The number of bytes flushed is displayed, even if the result is zero.

-h
Displays usage information.

-n
IP addresses and port numbers will be mapped, where possible, back into hostnames and service names.

-N device
Set the logfile to be opened for reading NAT log records from or to device.

-o letter
Specify which log files from which to actually read data. N, NAT logfile; S, state logfile; I, normal IP Filter logfile. The -a option is equivalent to using - o NSI.

-O letter
Specify which log files you do not wish to read from. This is most commonly used in conjunction with the - a. Letters available as parameters are the same as for - o.

-p
Cause the port number in log messages always to be printed as a number and never attempt to look it up.

-P pidfile
Write the PD of the ipmon process to a file. By default this is /var/run/ipmon.pid.

-s
Packet information read in will be sent through syslogd rather than saved to a file. The default facility when compiled and installed is local10. The following levels are used:

LOG_INFO
Packets logged using the log keyword as the action rather than pass or block.

LOG_NOTICE
Packets logged that are also passed.
LOG_WARNING
Packets logged that are also blocked.

LOG_ERR
Packets that have been logged and that can be considered “short”.

-5 device
Set the logfile to be opened for reading state log records from or to device.

-t
Read the input file/device in the way performed by tail(1).

-v
Show TCP window, ack, and sequence fields

-x
Show the packet data in hex.

-X
Show the log header record data in hex.

System Administration Guide: IP Services

Diagnostics
ipmon expects data that it reads to be consistent with how it should be saved and aborts if it fails an assertion which detects an anomaly in the recorded data.

Notes
To view license terms, attribution, and copyright for IP Filter, the default path is /usr/lib/ipf/IPFILTER.LICENCE. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.
ipnat(1M)

Name
ipnat – user interface to the NAT subsystem

Synopsis
ipnat [-CdFhnRrsFv] -f filename

Description
The ipnat utility opens a specified file (treating - as stdin) and parses it for a set of rules that are to be added or removed from the IP NAT.

If there are no parsing problems, each rule processed by ipnat is added to the kernel’s internal lists. Rules are appended to the internal lists, matching the order in which they appear when given to ipnat.

ipnat’s use is restricted through access to /dev/ipauth, /dev/ipl, and /dev/ipstate. The default permissions of these files require ipnat to be run as root for all operations.

ipnat’s use is restricted through access to /dev/ipnat. The default permissions of /dev/ipnat require ipnat to be run as root for all operations.

Options
The following options are supported:
- C Delete all entries in the current NAT rule listing (NAT rules).
- d Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each one.
- F Delete all active entries in the current NAT translation table (currently active NAT mappings).
- f filename Parse specified file for rules to be added or removed from the IP NAT. filename can be stdin.
- h Print number of hits for each MAP/Redirect filter.
- l Show the list of current NAT table entry mappings.
- n Prevents ipf from doing anything, such as making ioctl calls, which might alter the currently running kernel.
- R Disable both IP address-to-hostname resolution and port number-to-service name resolution.
- r Remove matching NAT rules rather than add them to the internal lists.
- s Retrieve and display NAT statistics.
- v Turn verbose mode on. Displays information relating to rule processing and active rules/table entries.

Files
/dev/ipnat Link to IP Filter pseudo device.
/dev/kmem Special file that provides access to virtual address space.
/etc/ipf/ipnat.conf Location of ipnat startup configuration file.
Contains numerous IP Filter examples.

### Name
ippool – user interface to the IP Filter pools

### Synopsis
ippool -a [-dnv] [-m num] [-o role] -i ipaddr [/netmask]
ippool -A [-dnv] [-m num] [-o role] [-S seed] [-t type]
ippool -f [-dnv] [-m num] [-o role] [-t type]
ippool -F [-dvv] [-m num] [-o role] [-S seed] [-t type]
ippool -l [-dnv] [-m num] [-o role] [-t type]
ippool -r [-dnv] [-m num] [-o role] -i ipaddr [/netmask]
ippool -R [-dnv] [-m num] [-o role] [-t type]
ippool -s [-dtv] [-M core] [-N namelist]

### Description
The ippool utility is used to manage information stored in the IP pools subsystem of IP Filter software. Configuration file information can be parsed and loaded into the kernel and currently configured pools can be removed, changed, or inspected.

ippool’s use is restricted through access to /dev/ippool. The default permissions of /dev/ippool require ippool to be run as root for all operations.

The command line options used are divided into two sections: the global options and the instance-specific options.

ippool’s use is restricted through access to /dev/ipauth, /dev/ipl, and /dev/ipstate. The default permissions of these files require ippool to be run as root for all operations.

### Options
ippool supports the option categories described below.

#### Global Options
The following global options are supported:

- **-d**
  
  Toggle debugging of processing the configuration file.

- **-n**
  
  Prevents ippool from doing anything, such as making ioctl calls, that would alter the currently running kernel.

- **-v**
  
  Turn verbose mode on.

#### Instance-Specific Options
The following instance-specific options are supported:

- **-a**
  
  Add a new data node to an existing pool in the kernel.

- **-A**
  
  Add a new (empty) pool to the kernel.

- **-f file**
  
  Read in IP pool configuration information from file and load it into the kernel.
Flush loaded pools from the kernel.

Display a list of pools currently loaded into the kernel.

Remove an existing data node from a pool in the kernel.

Remove an existing pool from within the kernel.

Display IP pool statistical information.

The following, additional options are supported:

- Set the IP address for the operation being undertaken with an all-one’s mask or, optionally, a specific netmask, given in either dotted-quad notation or as a single integer.

- Set the pool name for the current operation.

- Specify an alternative path to /dev/kmem from which to retrieve statistical information.

- Specify an alternative path to lookup symbol name information when retrieving statistical information.

- Sets the role with which this pool is to be used. Currently only ipf, auth, and count are accepted as arguments to this option.

- Sets the hashing seed to the number specified. For use with hash-type pools only.

- Sets the type of pool being defined. Must be one of pool, hash, or group-map.

- When parsing a configuration file, rather than load new pool data into the kernel, unload it.

Files
/dev/ippool
   Link to IP Filter pseudo device.

/dev/kmem
   Special file that provides access to virtual address space.

/etc/ipf/ippool.conf
   Location of ippool startup configuration file.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWipfu</td>

See Also  ipf(1M), ipfstat(1M), ippool(4), attributes(5)

Notes  To view license terms, attribution, and copyright for IP Filter, the default path is /usr/lib/ipf/IPFILTER_LICENSE. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.
ipqosconf(1M)

Name  ipqosconf – configure the IPQoS facility

Synopsis  /usr/sbin/ipqosconf

/usr/sbin/ipqosconf -a conf_file [-vs]
/usr/sbin/ipqosconf -c
/usr/sbin/ipqosconf -f
/usr/sbin/ipqosconf -l
/usr/sbin/ipqosconf -L

Description  The ipqosconf utility configures the Quality of Service facility of the Internet Protocol (IP). Only superusers can use this command.

Without arguments, ipqosconf displays the actual IPQoS configuration.

Configuration is not preserved across reboot. You must apply the configuration every time that the machine reboots. To apply the configuration early in the boot phase, you can populate the /etc/inet/ipqosinit.conf file, which is then read from the svc:/network/initial:default service.

Options  The following options are supported:

- a conf_file     Apply the configuration in conf_file. If the conf_file is –, ipqosconf reads from standard input.
- c              Populate the boot file with the current configuration.
- f              Flush the configuration.
- l              List the current applied configuration.
- L              List the current configuration in verbose mode.

In addition to the information that the - l option provides, the - L option provides filters and classes configured through other means than the ipqosconf command. This option also provides the full set of filters that were created by ipqosconf by representing a multi-homed host in a configuration file

- s              Log messages to syslog during an - a operation.
- v              Toggle verbose mode during an - a operation.

The - v option causes all messages to go to the console in addition to their normal destination. Messages intended to go to syslog, because the - s flag is set or because it is a log message, still go to syslog as well as the console.
The configuration file is composed of a format version and a succession of configuration (action) blocks. There are different configuration blocks for each type of action that is being configured.

**Format Version**
The first line of the configuration file specifies the format version contained in the configuration file.

The following entry specifies the format version:
```
fmt_version x.x
```

where `x.x` is the format version. `1.0` is the only supported version.

**Configuration Blocks**
Following the format version, are a succession of configuration (action) blocks that are different for each type of action being configured. A configuration block always has the following structure:

```
action {
    name action_name
    module module_name
    params_clause | ""
    cf_clauses
}
```

- `action_name` ::=` string`
- `module_name` ::= `ipqos | dcosmk | dscpmk | flowacct | tswtclmt | tokenmt`
- `params_clause` ::= `params {
    parameters
    params_stats | ""
}
```
- `parameters` ::= `prm_name_value parameters | ""
```
- `prm_name_value` ::= `param_name param_value`

**Modules**
The `param_name` and the types of `param_value` are specific to a given module.

```
params_stats ::= `global_stats boolean`
```

```
 cf_clauses ::= `class_clause cf_clauses | ""
```

```
class_clause ::= `class {
    name class_name
    next_action next_action_name
    class_stats | ""
}
```

```
There must be exactly one configuration block belonging to module ipqpc. The action must be named ipqpc.classify. All other actions should be reachable from ipqpc by way of parameters of type action or the next_action of a class.

The set of types that are used for parameters of the different modules are:

- **action** := string
- **protocol** := 1..255
- **port** := 1..65535
- **uint8** := 0..255
- **uint32** := 0..4294967296
- **int32** := -2147483648..2147483648
- **address** := <see the description section>
- **ifname** := <interface name recognized by SIOGLIFINDEX ioctl>
- **enum** := string | { string_list }
- **boolean** := TRUE | FALSE
- **integer_array** := { range_value_list }
- **map_index** := uint32
- **address** := ip_address | ip_node_name
- **user** := uid | username
- **uid** := 0..65535
- **username** := string
- **string_list** := string sl_entries
- **sl_entries** := ',' string sl_entries | ""
- **range_value_list** := range_value_entry range_value_entrys
- **range_value_entry** := range ':' integer_array_value
- **range** := uint32 '-' uint32
- **integer_array_value** := string | integer_array_number
- **integer_array_number** := uint8 | uint32
- **range_value_entrys** := ';' range_value_entry range_value_entrys | ""
- **ip_node_name** := string
- **ip_address** := v4 address | v6_address
- **v4_address** := v4_ip_address / v4_cidr_mask | v4_ip_address
v4_cidr_mask ::= 1-32
v6_address ::= v6_ip_address / v6_cidr_mask |
v6_ip_address
v6_cidr_mask ::= 1-128

METER module tokenmt configuration syntax:
red_action_name      action
yellow_action_name   action
green_action_name    action
committed_rate       uint32
committed_burst      uint32
peak_rate            uint32
<if present this signifies that this will be a two rate meter, not
a single rate meter>
peak_burst           uint32
<this is the 'peak' burst size for a two rate meter, but
the 'excess' burst size for a single rate meter>
color_aware          boolean
color_map            integer_array
global_stats         boolean

METER module tswtclmt configuration syntax:
red_action_name      action
yellow_action_name   action
green_action_name    action
committed_rate       uint32
peak_rate            uint32
window               uint32
global_stats         boolean

MARKER module dscpmk configuration syntax:
next_action          action
dscp_map             int_array
dscp_detailed_stats  boolean
global_stats         boolean

MARKER module dlcosmk configuration syntax:
next_action          action
cos                  map_index
global_stats         boolean

CLASSIFIER module ipgpwc configuration syntax:
if_grpname           string
user                 user
projid               int32
if_name ifname
direction enum {
    LOCAL_IN,
    LOCAL_OUT,
    FWD_IN,
    FWD_OUT}
protocol protocol
dsfield uint8
dsfield_mask uint8
saddr address
daddr address
sport port
dport port
priority uint32
precedence uint32
ip_version enum {
    V4,
    V6 }
global_stats boolean

ACCOUNTING module flowacct configuration syntax
next_action action
timer uint32
timeout uint32
max_limit uint32

Types  

action  A string of characters with a matching action definition. The character string can be up to twenty three characters in length. To allow for spaces the string needs to be enclosed in quotes and cannot span lines. Two special actions are pre-defined and can not have an explicit action definition. The two pre-defined actions are continue and drop. continue causes the packet that is passed to it to continue normal processing. drop causes the packet that is passed to it to be dropped.

address  A machine name or address recognized by getipnodebyname(3SOCKET). If a machine name is specified, and ip_version has been defined, the query is done using that address family. If a machine name is not specified and ip_version has not been defined, the query is done using the AI_DEFAULT flag to getipnodebyname() (..AF_INET6..). CIDR address masks following an IP address are allowed. Specify the CIDR address masks as 1-32 (for v4) or 1-128 (for v6). CIDR addresses are disallowed for node names.

enum  Either one of the supported values or comma delimited list of support values, enclosed in curly braces.

ifname  A non-NULL, existing interface name recognized by the SIOGLIFINDEX socket ioctl.

ipqoscon(1M)
**integer_array**
A comma delimited set of range/value pairs, enclosed in curly braces.

Specify range in the format x-y, where x and y are integers that denote the range of array indexes to which the value applies. The minimum value for both x and y is 0. The maximum value for x is particular to the parameter. Any array indexes not referred to in the set of ranges are left at their previous value.

**map_index**
A non-negative integer used as an index into any maps associated with a parameter of this type.

The maximum value of this type is dictated by the number of entries in the associated maps. The index starts at 0.

**port**
Either a service name recognized by getservbyname(3SOCKET) or an integer 1-65535.

**protocol**
Either a protocol name recognized by getprotobyname(3SOCKET) or an integer 1-255.

**string**
A character string. Enclose string in quotes. string cannot span multiple lines.

**user**
Either a valid user ID or username for the system that is being configured.

**Parameters**
The configuration file can contain the following parameters

- **color_aware**
  A value of TRUE or FALSE, indicating whether or not the configured action takes account of the previous packet coloring when classifying.

- **color_map**
  An integer array that defines which values of the dscp field correspond with which colors for when the color_aware parameter is set to TRUE.

- **committed_burst**
  The committed burst size in bits.

- **committed_rate**
  The committed rate in bits per second.

- **cos**
  The value used to determine the underlying driver level priority applied to the packet which is defined in 802.1D.

- **daddr**
  The destination address of the datagram.

- **direction**
  The value used to build a filter matching only part of the traffic.

  This parameter is of type enum with valid values of LOCAL_IN (local bound traffic), LOCAL_OUT (local sourced traffic), FWD_IN (forwarded traffic entering the system), and FWD_OUT (forwarded traffic exiting the system).

- **dport**
  The destination port of the datagram.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dscp_detailed_stats</td>
<td>A value of TRUE or FALSE that determines whether detailed statistics are switched on for this dscp action. Specify TRUE to switch on or FALSE to switch off.</td>
</tr>
<tr>
<td>dscp_map</td>
<td>The integer_array that supplies the values that IP packets with a given dscp value have their dscp re-marked with. The existing value is used to index into the array where the new value is taken from. The array is of size 64, meaning valid indexes are 0-63 and valid values are also 0-63.</td>
</tr>
<tr>
<td>dsfield</td>
<td>The DS field of the IP datagram header. This is an 8-bit value, with each bit position corresponding with the same one in the header; this enables matches to be done on the CU bits. If you specify this parameter, you must also specify the dsfield_mask parameter.</td>
</tr>
<tr>
<td>dsfield_mask</td>
<td>The mask applied to the dsfield parameter to determine the bits against which to match. This is an 8-bit value, with each bit position corresponding with the same one in the dsfield parameter.</td>
</tr>
<tr>
<td>global_stats</td>
<td>A value of TRUE or FALSE to enable or disable the statistic collection for this action.</td>
</tr>
<tr>
<td>green_action_name</td>
<td>The action to be executed for packets that are deemed to be green.</td>
</tr>
<tr>
<td>if_grpname</td>
<td>The interface group name.</td>
</tr>
<tr>
<td>if_name</td>
<td>The name of an interface recognized by the SIOGLIFINDEX ioctl. This parameter is of type ifname.</td>
</tr>
<tr>
<td>ip_version</td>
<td>This parameter is of type enum and has valid values of V4 and V6. If it is set to V4 only then only ipv4addresses are requested for a specified hostname. If it is set to V6, only ipv6 addresses are returned if there are any, otherwise v4 mapped v6 addresses are returned. If both V4 and V6 are specified, or if ip_version is not specified, then both ipv4 and ipv6 addresses are requested for a specified hostname.</td>
</tr>
<tr>
<td>max_limit</td>
<td>The maximum number of flow entries present at one time in the flowacct actions in the memory resident table.</td>
</tr>
<tr>
<td>next_action</td>
<td>The action to be executed when the current action is complete. This value can be either the name of an action defined in the configuration file, or one of the two special action types: drop and continue. See Types for additional information on special action types.</td>
</tr>
</tbody>
</table>
peak_burst: The peak burst size, for a two rate meter, or excess burst size, for a single rate meter, in bits.

peak_rate: The peak rate in bits per second.

precedence: An integer that is used to order filters. If there are two matching filters that have the same priority value, the one with the lower precedence value is the one matched. This parameter should be used because the order of the filters in a configuration file has no influence on their relative precedence.

priority: An integer that represents the relative priority of a filter. If there are two matching filters, the one with the higher priority value is the one matched. Multiple filters can have the same priority.

projid: The project ID of the process sending the data. This value is always -1 for received traffic.

protocol: The Upper Layer Protocol against which this entry is matched.

red_action_name: The action to be executed for packets that are determined to be red.

saddr: The source address of the datagram.

sport: The source port of the datagram.

timeout: The timeout in milliseconds after which flows are written to the accounting file.

timer: The period in milliseconds at which timed-out flows are checked for.

user: The user ID or username of the process sending the data. This value is always -1 for received traffic.

window: The window size in ms.

yellow_action_name: The action to be executed for packets that are determined to be yellow.

**Security**

None.

**Examples**

**EXAMPLE 1** Sending All Traffic From eng to the AF 1 Class of Service

This example sends all traffic from eng to the AF 1 class of service. It is documented in four separate steps:

The following step creates a tokenmt action with three outcomes:

```
#meter for class 1.
action {
    name AF_CL1
    module tokenmt
```
EXAMPLE 1  Sending All Traffic From eng to the AF 1 Class of Service  

(Continued)

params{
    committed_rate 64
    committed_burst 75
    peak_burst 150
    global_stats TRUE
    red_action_name drop
    yellow_action_name markAF12
    green_action_name markAF11
}

The following step creates two dscpmk actions:

#class 1, low drop precedence.
action {
    name markAF11
    module dscpmk
    params{
        dscp_map {0-63:28}
        dscp_detailed_stats TRUE
        global_stats TRUE
        next_action acct1
    }
}

#class 1, medium drop precedence.
action {
    name markAF12
    module dscpmk
    params {
        dscp_map {0-63:30}
        dscp_detailed_stats TRUE
        global_stats TRUE
        next_action acct1
    }
}

The following step creates an accounting action:

#billing for transmitted class 1 traffic.
action {
    name acct1
    module flowacct
    params {
        timer 10
        timeout 30
        global_stats TRUE
    }
}
EXAMPLE 1 Sending All Traffic From eng to the AF 1 Class of Service (Continued)

max_limit 1024
next_action continue
}
}
The following step creates an ipgpc action:

#traffic from eng sent, traffic from ebay dropped.
action {
    name ipgpc.classify
    module ipgpc
    class {
        name from_eng
        enable_stats TRUE
        next_action AF_CL1
    }
    class {
        name from_ebay
        enable_stats TRUE
        next_action drop
    }
    filter {
        name from_eng
        saddr eng-subnet
        class from_eng
    }
    filter {
        name from_ebay
        saddr ebay-subnet
        class from_ebay
    }
}

Files /etc/inet/ipqosinit.conf Contains the IPQoS configuration loaded at boot time. If this file exists, it is read from the network/initial:default service.

/etc/inet/ipqosconf.1.sample Sample configuration file for an application server

/etc/inet/ipqosconf.2.sample Sample configuration file that meters the traffic for a specified application

/etc/inet/ipqosconf.3.sample Sample configuration file that marks the ethernet headers of web traffic with a given user priority

Diagnostics

ipqosconf sends messages to syslog of facility user, severity notice when any changes are made to the IPQoS configuration.

Errors that occur during an ipqosconf operation send an error message to the console by default. For the application of a new configuration if the -s option is set then these messages are sent to syslog as facility user, severity error instead. If the -v option is present during an application then all error and change notification messages are sent to the console as well as their default destination.
The `ipsecalgs` command is used to configure the IPsec protocols and algorithms table. It can be used to:

- List the currently defined IPsec protocols and algorithms
- Modify IPsec protocols definitions
- Modify IPsec algorithms definitions

Never edit the `/etc/inet/ipsecalgs` file manually. The valid IPsec protocols and algorithms are described by the ISAKMP DOI. See RFC 2407. In the general sense, a Domain of Interpretation (DOI) defines data formats, network traffic exchange types, and conventions for naming security-relevant information such as security policies or cryptographic algorithms and modes. For `ipsecalgs`, the DOI defines naming and numbering conventions for algorithms and the protocols they belong to. These numbers are defined by the Internet Assigned Numbers Authority (IANA). Each algorithm belongs to a protocol. Algorithm information includes supported key lengths, block or MAC length, and the name of the cryptographic mechanism corresponding to that algorithm. This information is used by the IPsec modules, `ipsecesp(7P)` and `ipsecah(7P)`, to determine the authentication and encryption algorithms that can be applied to IPsec traffic.

The following protocols are predefined:

- **IPSEC_PROTO_ESP**: Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality.
- **IPSEC_PROTO_AH**: Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication.
The mechanism name specified by an algorithm entry must correspond to a valid Solaris Cryptographic Framework mechanism. You can obtain the list of available mechanisms by using the `cryptoadm(1M)` command.

Applications can retrieve the supported algorithms and their associated protocols by using the functions `getipsecalgbyname(3NSL), getipsecalgbynum(3NSL), getipsecprotobyname(3NSL) and getipsecprotobynum(3NSL)`.

Modifications to the protocols and algorithm by default update only the contents of the `/etc/inet/ipsecalgs` configuration file. In order for the new definitions to be used for IPsec processing, the changes must be communicated to the kernel using the `-s` option. See NOTES for a description of how the `ipsecalgs` configuration is synchronized with the kernel at system restart.

When invoked without arguments, `ipsecalgs` displays the list of mappings that are currently defined in `/etc/inet/ipsecalgs`. You can obtain the corresponding kernel table of protocols and algorithms by using the `-1` option.

**Options** `ipsecalgs` supports the following options:

- `-a` Adds an algorithm of the protocol specified by the `-P` option. The algorithm name(s) are specified with the `-n` option. The supported key lengths and block sizes are specified with the `-k`, `-i`, and `-b` options.

- `-b` Specifies the block or MAC lengths of an algorithm, in bytes. Set more than one block length by separating the values with commas.

- `-e` Designates the execution mode of cryptographic requests for the specified protocol in the absence of cryptographic hardware provider. See `cryptoadm(1M)`.

  - `exec-mode` can be one of the following values:

    - `sync` Cryptographic requests are processed synchronously in the absence of a cryptographic hardware provider. This execution mode leads to better latency when no cryptographic hardware providers are available.

    - `async` Cryptographic requests are always processed asynchronously in the absence of cryptographic hardware provider. This execution can improve the resource utilization on a multi-CPU system, but can lead to higher latency when no cryptographic hardware providers are available.

  This option can be specified when defining a new protocol or to modify the execution mode of an existing protocol. By default, the `sync` execution mode is used in the absence of a cryptographic hardware provider.

- `-f` Used with the `-a` option to force the addition of an algorithm or protocol if an entry with the same name or number already exists.
-i Specifies the valid key length increments in bits. This option must be used when the valid key lengths for an algorithm are specified by a range with the -k option.

-K Specifies the default key lengths for an algorithm, in bits. If the -K option is not specified, the minimum key length will be determined as follows:

- If the supported key lengths are specified by range, the default key length will be the minimum key length.
- If the supported key lengths are specified by enumeration, the default key length will be the first listed key length.

-k Specifies the supported key lengths for an algorithm, in bits. You can designate the supported key lengths by enumeration or by range.

Without the -i option, -k specifies the supported key lengths by enumeration. In this case, keylen-list consists of a list of one or more key lengths separated by commas, for example:

```
128,192,256
```

The listed key lengths need not be increasing, and the first listed key length will be used as the default key length for that algorithm unless the -K option is used.

With the -i option, -k specifies the range of supported key lengths for the algorithm. The minimum and maximum key lengths must be separated by a dash (`-`) character, for example:

```
32-448
```

-1 Displays the kernel algorithm tables.

-m Specifies the name of the cryptographic framework mechanism name corresponding to the algorithm. Cryptographic framework mechanisms are described in the cryptoadm(1M) man page.

-N Specifies an algorithm number. The algorithm number for a protocol must be unique. IANA manages the algorithm numbers. See RFC 2407.

-n Specifies one or more names for an algorithm. When adding an algorithm with the -a option, alg-names contains a string or a comma-separated list of strings, for example:

```
des-cbs,des
```

When used with the -r option to remove an algorithm, alg-names contains one of the valid algorithm names.

-P Adds a protocol of the number specified by protocol-number with the name specified by the -p option. This option is also used to specify an IPsec protocol when used with the -a and the -R options. Protocol numbers are managed by the IANA. See RFC 2407.

-p Specifies the name of the IPsec protocol.
-R Removes and IPsec protocol from the algorithm table. The protocol can be specified by number by using the -P option or by name by using the -p option. The algorithms associated with the protocol are removed as well.

-r Removes the mapping for an algorithm. The algorithm can be specified by algorithm number using the -N option or by algorithm name using the -A option.

-s Synchronizes the kernel with the contents of /etc/inet/ipsecalgs. The contents of /etc/inet/ipsecalgs are always updated, but new information is not passed on to the kernel unless the -s is used. See NOTES for a description of how the ipsecalgs configuration is synchronized with the kernel at system restart.

Examples

EXAMPLE 1 Adding a Protocol for IPsec Encryption

The following example shows how to add a protocol for IPsec encryption:

example# ipsecalgs -P 3 -p "IPSEC_PROTO_ESP"

EXAMPLE 2 Adding the Blowfish Algorithm

The following example shows how to add the Blowfish algorithm:

example# ipsecalgs -a -P 3 -k 32-488 -K 128 -i 8 -n "blowfish" \ 
     -b 8 -N 7 -m CKM_BF_CBC

EXAMPLE 3 Updating the Kernel Algorithm Table

The following example updates the kernel algorithm table with the currently defined protocol and algorithm definitions:

example# svcadm refresh ipsecalgs

Files /etc/inet/ipsecalgs

File that contains the configured IPsec protocols and algorithm definitions. Never edit this file manually.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>

See Also
cryptoadm(1M), ipseccnf(1M), ipseckey(1M), svcadm(1M), getipsecalgbyname(3NSL), getipsecprotobynome(3NSL), ike.config(4), attributes(5), smf(5), ipsecah(7P), ipsecesp(7P)

When protocols or algorithm definitions that are removed or altered, services that rely upon these definitions can become unavailable. For example, if the IPSEC_PROTO_ESP protocol is removed, then IPsec cannot encrypt and decrypt packets.

Synchronization of the ipsecalgs configuration with the kernel at system startup is provided by the following smf(5) service:

```
svc:/network/ipsec/ipsecalgs:default
```

The IPsec services are delivered as follows:

```
svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)
```

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See ipsec(1M) and ike.config(4). The default policy for the policy service is to allow all traffic to pass without IPsec protection. See ipsecconf(1M).

The correct administrative procedure is to create the configuration file for each service, then enable each service using svcadm(1M), as shown in the following example:

```
example# svcadm enable ipsecalgs
```

The service's status can be queried using the svcs(1) command.

If the ipsecalgs configuration is modified, the new configuration should be resynchronized as follows:

```
example# svcadm refresh ipsecalgs
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

See auths(1), user_attr(4), rbac(5).

The ipsecalgs smf(5) service does not have any user-configurable properties.

The smf(5) framework records any errors in the service-specific log file. Use any of the following commands to examine the logfile property:

```
example# svcs -l ipsecalgs
example# svcprop ipsecalgs
example# svccfg -s ipsecalgs listprop
```
This command requires `sys_ip_config` privilege to operate and thus can run in the global zone and in exclusive-IP zones. All shared-IP zones share the same available set of algorithms; however, you can use `ipsecconf(1M)` to set up system policy that uses differing algorithms for various shared-IP zones. All exclusive-IP zones have their own set of algorithms.
Name  ipsecconf – configure system-wide IPsec policy

Synopsis  
/usr/sbin/ipsecconf
/usr/sbin/ipsecconf -a file [-q]
/usr/sbin/ipsecconf -c file
/usr/sbin/ipsecconf -d [-i tunnel-name] {index, tunnel-name, index}
/usr/sbin/ipsecconf -f [-i tunnel-name]
/usr/sbin/ipsecconf -F
/usr/sbin/ipsecconf -l [-i tunnel-name] [-n]
/usr/sbin/ipsecconf -L [-n]

Description  The ipsecconf utility configures the IPsec policy for a host or for one of its tunnels. Once the policy is configured, all outbound and inbound datagrams are subject to policy checks as they exit and enter the host or tunnel. For the host policy, if no entry is found, no policy checks will be completed, and all the traffic will pass through. For a tunnel, if no entry is found and there is at least one entry for the tunnel, the traffic will automatically drop. The difference in behavior is because of the assumptions about IPsec tunnels made in many implementations. Datagrams that are being forwarded will not be subjected to policy checks that are added using this command. See ifconfig(1M) and tun(7M) for information on how to protect forwarded packets. Depending upon the match of the policy entry, a specific action will be taken.

This command can be run only by superuser.

Each entry can protect traffic in either one direction (requiring a pair of entries) or by a single policy entry which installs the needed symmetric sadb rules.

When the command is issued without any arguments, the list of file policy entries loaded are shown. To display the (spd p. e. s) use the -l option. Both will display the index number for the entry. To specify a single tunnel’s SPD, use the -i option in combination with -l. To specify all SPDs, both host and for all tunnels, use -L.

Note, since one file policy entry (FPE) can generate multiple SPD pol entries (SPEs), the list of FPEs may not show all the actual entries. However, it is still useful in determining what what rules have been added to get the spd into its current state.

You can use the -d option with the index to delete a given policy in the system. If the -d option removes an FPE entry that produces multiple SPEs, only then SPD with the same policy index as the FPE will be removed. This can produce a situation where there may be SPEs when there are no FPEs.

As with -l, -d can use the -i flag to indicate a tunnel. An alternate syntax is to specify a tunnel name, followed by a comma (,), followed by an index. For example, ip.tun0,1.

With no options, the entries are displayed in the order that they were added, which is not necessarily the order in which the traffic match takes place.
To view the order in which the traffic match will take place, use the `-l` option. The rules are ordered such that all bypass rules are checked first, then ESP rules, then AH rules. After that, they are checked in the order entered.

Policy entries are not preserved across system restarts. Permanent policy entries should be added to `/etc/inet/ipsecinit.conf`. This file is read by the following `smf(5)` service:

```
svc:/network/ipsec/policy
```

See `NOTES` for more information on managing IPsec security policy and `SECURITY` for issues in securing `/etc/inet/ipsecinit.conf`.

### Options

`ipseccconf` supports the following options:

- `-a file`
  
  Add the IPsec policy to the system as specified by each entry in the file. An IPsec configuration file contains one or more entries that specify the configuration. Once the policy is added, all outbound and inbound datagrams are subject to policy checks.

  Entries in the files are described in the `Operands` section below. Examples can be found in the `Examples` section below.

  Policy is latched for TCP/UDP sockets on which a `connect(3SOCKET)` or `accept(3SOCKET)` is issued. So, the addition of new policy entries may not affect such endpoints or sockets. However, the policy will be latched for a socket with an existing non-null policy. Thus, make sure that there are no preexisting connections that will be subject to checks by the new policy entries.

  The feature of policy latching explained above may change in the future. It is not advisable to depend upon this feature.

- `-c file`
  
  Check the syntax of the configuration file and report any errors without making any changes to the policy. This option is useful when debugging configurations and when `smf(5)` reports a configuration error. See `SECURITY`.

- `-d index`
  
  Delete the host policy denoted by the index. The index is obtained by invoking `ipseccconf` without any arguments, or with the `-l` option. See `DESCRIPTION` for more information. Once the entry is deleted, all outbound and inbound datagrams affected by this policy entry will not be subjected to policy checks. Be advised that with connections for which the policy has been latched, packets will continue to go out with the same policy, even if it has been deleted. It is advisable to use the `-l` option to find the correct policy index.

- `-d name,index`
  
  Delete the policy entry denoted by `index` on a tunnel denoted by `name`. Since tunnels affect traffic that might originate off-node, latching does not apply as it does in the host policy case. Equivalent to: `-d index -i name`.
-\( f \)
Flush all the policies in the system. Constraints are similar to the \(-d\) option with respect to latching and host versus per-tunnel behavior.

-\( F \)
Flush all policies on all tunnels and also flush all host policies.

-\( i \ \text{name} \)
Specify a tunnel interface name for use with the \(-d\), \(-f\), or \(-l\) flags.

-\( \ell \)
Listing of a single policy table, defaulting to the host policy. When `ipsecconf` is invoked without any arguments, a complete list of policy entries with indexes added by the user since boot is displayed. The current table can differ from the previous one if, for example, a multi-homed entry was added or policy reordering occurred, or if a single rule entry generates two spd rules. In the case of a multi-homed entry, all the addresses are listed explicitly. If a mask was not specified earlier but was instead inferred from the address, it will be explicitly listed here. This option is used to view policy entries in the correct order. The outbound and inbound policy entries are listed separately.

-\( L \)
Lists all policy tables, including host policy and all tunnel instances (including configured but unplumbed).

If \(-i\) is specified, \(-L\) lists the policy table for a specific tunnel interface.

-\( n \)
Show network addresses, ports, protocols in numbers. The \(-n\) option may only be used with the \(-\ell\) option.

-\( q \)
Quiet mode. Suppresses the warning message generated when adding policies.

**Operands**

Each policy entry contains three parts specified as follows:

\[
\{\text{pattern}\} \text{ action } \{\text{properties}\}
\]

or

\[
\{\text{pattern}\} \text{ action } \{\text{properties}\} \ ["or" \text{ action } \{\text{properties}\}]^*\]

Every policy entry begins on a new line and can span multiple lines. If an entry exceeds the length of a line, you should split it only within a “braced” section or immediately before the first (left-hand) brace of a braced section. Avoid using the backslash character (\). See EXAMPLES.

The \textit{pattern} section, as shown in the syntax above, specifies the traffic pattern that should be matched against the outbound and inbound datagrams. If there is a match, a specific \textit{action} determined by the second argument will be taken, depending upon the \textit{properties} of the policy entry.
If there is an or in the rule (multiple action-properties for a given pattern), a transmitter will use the first action-property pair that works, while a receiver will use any that are acceptable.

*pattern* and *properties* are name-value pairs where name and value are separated by a `<space>`, `<tab>` or `<newline>`. Multiple name-value pairs should be separated by `<space>`, `<tab>` or `<newline>`. The beginning and end of the pattern and properties are marked by `{` and `}` respectively.

Files can contain multiple policy entries. An unspecified name-value pair in the *pattern* will be considered as a wildcard. Wildcard entries match any corresponding entry in the datagram.

One thing to remember is that UDP port 500 is always bypassed regardless of any policy entries. This is a requirement for *in.iked(1M)* to work.

File can be commented by using a `#` as the first character. Comments may be inserted either at the beginning or the end of a line.

The complete syntax of a policy entry is:

```
policy ::= { <pattern1> } <action1> { <properties1> } |
         { <pattern2> } <action2> { <properties2> } |
         ['or' <action2> { <properties2> }] *

pattern1 ::= <pattern_name_value_pair1>**

pattern2 ::= <pattern_name_value_pair2>**

action1 ::= apply | permit | bypass | pass
action2 ::= bypass | pass | drop | ipsec

properties1 ::= {<prop_name_value_pair1>}
properties2 ::= {<prop_name_value_pair2>}

  encr_algs <encr_alg> |
  encr_auth_algs <auth_alg> |
  sa <sa_val>
auth_alg ::= <auth_algname> ['(' <keylen> ')']
auth_algname ::= any | md5 | hmac-md5 | sha | sha1 | hmac-sha |
               hmac-shaal | hmac-sha256 | hmac-sha384 |
               hmac-sha512 |<number>

encr_alg ::= <encr_algname> ['(' <keylen> ')']
encr_algname ::= any | aes | aes-cbc | des | des-cbc | 3des |
               3des-cbc | blowfish | blowfish-cbc | <number>

keylen ::= <number> | <number>','..' | '..'<number> | <number>','..' \ 
          <number>

sa_val ::= shared | unique

dir_val1 ::= out | in

dir_val2 ::= out | in | both

number ::= <0 | 1 | 2 ... 9> <number>

icmp-type ::= <number> | unreach | echo | echorep | squench |
             redir | timex | paramprob | timest | timestrep |
             inforeq | inforep | maskreq | maskrep | unreach6 |
             pkttooobig6 | timex6 | paramprob6 | echo6 | echorep6 |
             router-sol6 | router-ad6 | neigh-sol6 | neigh-ad6 | redir6

icmp-code ::= <number> | net-unr | host-unr | proto-unr | port-unr |
             needfrag | srcfail | net-unk | host-unk | isolate |
             net-prohib | host-prohib | net-tos | host-tos |
             filter-prohib | host-preced | cutoff-preced |
             no-route6 | adm-prohib6 | addr-unr6 | port-unr6 |
             hop-limex6 | frag-re-timex6 | err-head6 | unrec-head6 | unreq-opt6

Policy entries may contain the following (name value) pairs in the pattern field. Each (name value) pair may appear only once in given policy entry.

laddr/plen
local/plen
The value that follows is the local address of the datagram with the prefix length. Only plen leading bits of the source address of the packet will be matched. plen is optional. Local means destination on incoming and source on outgoing packets. The source address value can be a hostname as described in getaddrinfo(3SOCKET) or a network name as described in getnetbyname(3XNET) or a host address or network address in the Internet standard dot notation. See inet_addr(3XNET). If a hostname is given and getaddrinfo(3SOCKET) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

raddr/plen
remote/plen
The value that follows is the remote address of the datagram with the prefix length. Only plen leading bits of the remote address of the packet will be matched. plen is optional. Remote means source on incoming packets and destination on outgoing packets. The remote address value can be a hostname as described in `getaddrinfo(3SOCKET)` or a network name as described in `getnetbyname(3XNET)` or a host address or network address in the Internet standard dot notation. See `inet_addr(3XNET)`. If a hostname is given and `getaddrinfo(3SOCKET)` returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

**src/plen**
**srcaddr/plen**
**saddr/plen**

The value that follows is the source address of the datagram with the prefix length. Only plen leading bits of the source address of the packet will be matched. plen is optional.

The source address value can be a hostname as described in `getaddrinfo(3SOCKET)` or a network name as described in `getnetbyname(3XNET)` or a host address or network address in the Internet standard dot notation. See `inet_addr(3XNET)`.

If a hostname is given and `getaddrinfo(3SOCKET)` returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

**daddr/plen**
**dest/plen**
**dstaddr/plen**

The value that follows is the destination address of the datagram with the prefix length. Only plen leading bits of the destination address of the packet will be matched. plen is optional.

See `saddr` for valid values that can be given. If multiple source and destination addresses are found, then a policy entry that covers each source address-destination address pair will be added to the system.

**smask**

For IPv4 only. The value that follows is the source mask. If prefix length is given with `saddr`, this should not be given. This can be represented either in hexadecimal number with a leading 0x or 0X, for example, 0xffff0000, 0xffff0000 or in the Internet decimal dot notation, for example, 255.255.0.0 and 255.255.255.0. The mask should be contiguous and the behavior is not defined for non-contiguous masks.

`smask` is considered only when `saddr` is given.

For both IPv4 and IPv6 addresses, the same information can be specified as a `slen` value attached to the `saddr` parameter.

**dmask**

Analogous to `smask`. 
**lport**
The value that follows is the local port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in `getservbyname(3XNET)`.

**rport**
The value that follows is the remote port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in `getservbyname(3XNET)`.

**sport**
The value that follows is the source port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in `getservbyname(3XNET)`.

**dport**
The value that follows is the destination port of the datagram. This can be either a port number or a string as described in `getservbyname(3XNET)` searched with NULL proto argument.

**proto ulp**
The value that follows is the Upper Layer Protocol that this entry should be matched against. It could be a number or a string as described in `getprotobyname(3XNET)`. If no smask or plen is specified, a plen of 32 for IPv4 or 128 for IPv6 will be used, meaning a host. If the `ulp` is `icmp` or `ipv6-icmp`, any action applying IPsec must be the same for all `icmp` rules.

**type num or num-num**
The value that follows is the ICMP type that this entry should be matched against. The type must be a number from 0 to 255, or one of the appropriate `icmp-type` keywords. Also, `ulp` must be present and must specify either `icmp` or `ipv6-icmp`. A range of types can be specified with a hyphen separating numbers.

**code num or num-num**
The value that follows is the ICMP code that this entry should be matched against. The value following the keyword code must be a number from 0 to 254 or one of the appropriate `icmp-code` keywords. Also, `type` must be present. A range of codes can be specified with a hyphen separating numbers.

**tunnel name**
Specifies a tunnel network interface, as configured with `ifconfig(1M)`. If a tunnel of `name` does not yet exist, the policy entries are added anyway, and joined with the tunnel state when it is created. If a tunnel is unplumbed, its policy entries disappear.

**negotiate tunnel**
**negotiate transport**
For per-tunnel security, specify whether the IPsec SAs protecting the traffic should be tunnel-mode SAs or transport-mode SAs. If transport-mode SAs are specified, no addresses can appear in the policy entry. Transport-mode is backward compatible with Solaris 9, and tunnel IPsec policies configured with `ifconfig(1M)` will show up as transport mode entries here.
Policy entries may contain the following (name-value) pairs in the properties field. Each (name-value) pair may appear only once in a given policy entry.

**auth-algs**

An acceptable value following this implies that IPsec AH header will be present in the outbound datagram. Values following this describe the authentication algorithms that will be used while applying the IPsec AH on outbound datagrams and verified to be present on inbound datagrams. See **RFC 2402**.

This entry can contain either a string or a decimal number.

**string**

This should be either MD5 or HMAC-MD5 denoting the HMAC-MD5 algorithm as described in **RFC 2403** and SHA1, or HMAC-SHA1 or SHA or HMAC-SHA denoting the HMAC-SHA algorithm described in **RFC 2404**. You can use the `ipsecalgs(1M)` command to obtain the complete list of authentication algorithms.

The string can also be **ANY**, which denotes no-preference for the algorithm. Default algorithms will be chosen based upon the SAs available at this time for manual SAs and the key negotiating daemon for automatic SAs. Strings are not case-sensitive.

**number**

A number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If `auth-algs` is not present, the AH header will not be present in the outbound datagram, and the same will be verified for the inbound datagram.

**encr-algs**

An acceptable value following this implies that IPsec ESP header will be present in the outbound datagram. The value following this describes the encryption algorithms that will be used to apply the IPsec ESP protocol to outbound datagrams and verify it to be present on inbound datagrams. See **RFC 2406**.

This entry can contain either a string or a decimal number. Strings are not case-sensitive.

**string**

Can be one of the following:

<table>
<thead>
<tr>
<th>string value:</th>
<th>Algorithm Used:</th>
<th>See RFC:</th>
</tr>
</thead>
<tbody>
<tr>
<td>DES or DES-CBC</td>
<td>DES-CBC</td>
<td>2405</td>
</tr>
<tr>
<td>3DES or 3DES-CBC</td>
<td>3DES-CBC</td>
<td>2451</td>
</tr>
<tr>
<td>BLOWFISH or BLOWFISH-CBC</td>
<td>BLOWFISH-CBC</td>
<td>2451</td>
</tr>
<tr>
<td>AES or AES-CBC</td>
<td>AES-CBC</td>
<td>2451</td>
</tr>
</tbody>
</table>
You can use the `ipsecalgs(1M)` command to obtain the complete list of authentication algorithms.

The value can be `NULL`, which implies a NULL encryption, pursuant to RFC 2410. This means that the payload will not be encrypted. The string can also be `ANY`, which indicates no-preference for the algorithm. Default algorithms will be chosen depending upon the SAs available at the time for manual SAs and upon the key negotiating daemon for automatic SAs. Strings are not case-sensitive.

`number`

A decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

`encr_auth_algs`

An acceptable value following `encr_auth_algs` implies that the IPsec ESP header will be present in the outbound datagram. The values following `encr_auth_algs` describe the authentication algorithms that will be used while applying the IPsec ESP protocol on outbound datagrams and verified to be present on inbound datagrams. See RFC 2406. This entry can contain either a string or a number. Strings are case-insensitive.

`string`

Valid values are the same as the ones described for `auth_algs` above.

`number`

This should be a decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If `encr_algs` is present and `encr_auth_algs` is not present in a policy entry, the system will use an ESP SA regardless of whether the SA has an authentication algorithm or not.

If `encr_algs` is not present and `encr_auth_algs` is present in a policy entry, null encryption will be provided, which is equivalent to `encr_algs` with `NULL`, for outbound and inbound datagrams.

If both `encr_algs` and `encr_auth_algs` are not present in a policy entry, ESP header will not be present for outbound datagrams and the same will be verified for inbound datagrams.

If both `encr_algs` and `encr_auth_algs` are present in a policy entry, ESP header with integrity checksum will be present on outbound datagrams and the same will be verified for inbound datagrams.

For `encr_algs`, `encr_auth_algs`, and `auth_algs` a key length specification may be present. This is either a single value specifying the only valid key length for the algorithm or a range specifying the valid minimum and/or maximum key lengths. Minimum or maximum lengths may be omitted.
dir
Values following this decides whether this entry is for outbound or inbound datagram.
Valid values are strings that should be one of the following:

out
This means that this policy entry should be considered only for outbound datagrams.
in
This means that this policy entry should be considered only for inbound datagrams.
both
This means that this policy entry should be considered for both inbound and outbound datagrams.

This entry is not needed when the action is “apply”, “permit” or “ipsec”. But if it is given while the action is “apply” or “permit”, it should be “out” or “in” respectively. This is mandatory when the action is “bypass”.

sa
Values following this decide the attribute of the security association. Value indicates whether a unique security association should be used or any existing SA can be used. If there is a policy requirement, SAs are created dynamically on the first outbound datagram using the key management daemon. Static SAs can be created using ipseckey(1M). The values used here determine whether a new SA will be used/obtained. Valid values are strings that could be one of the following:

unique
Unique Association. A new/unused association will be obtained/used for packets matching this policy entry. If an SA that was previously used by the same 5 tuples, that is, {Source address, Destination address, Source port, Destination Port, Protocol (for example, TCP/UDP)} exists, it will be reused. Thus uniqueness is expressed by the 5 tuples given above. The security association used by the above 5 tuples will not be used by any other socket. For inbound datagrams, uniqueness will not be verified.

For tunnel-mode tunnels, unique is ignored. SAs are assigned per-rule in tunnel-mode tunnels. For transport-mode tunnels, unique is implicit, because the enforcement happens only on the outer-packet addresses and protocol value of either IPv4-in-IP or IPv6-in-IP.

shared
Shared association. If an SA exists already for this source-destination pair, it will be used. Otherwise a new SA will be obtained. This is the default.

This is mandatory only for outbound policy entries and should not be given for entries whose action is “bypass”. If this entry is not given for inbound entries, for example, when “dir” is in or “action” is permit, it will be assumed to be shared.

Action follows the pattern and should be given before properties. It should be one of the following and this field is mandatory.
ipsec
Use IPsec for the datagram as described by the properties, if the pattern matches the datagram. If ipsec is given without a dir spec, the pattern is matched to incoming and outgoing datagrams.

apply
Apply IPsec to the datagram as described by the properties, if the pattern matches the datagram. If apply is given, the pattern is matched only on the outbound datagram.

permit
Permit the datagram if the pattern matches the incoming datagram and satisfies the constraints described by the properties. If it does not satisfy the properties, discard the datagram. If permit is given, the pattern is matched only for inbound datagrams.

bypass
Bypass any policy checks if the pattern matches the datagram. dir in the properties decides whether the check is done on outbound or inbound datagrams. All the bypass entries are checked before checking with any other policy entry in the system. This has the highest precedence over any other entries. dir is the only field that should be present when action is bypass.

drop
Drop any packets that match the pattern.

If the file contains multiple policy entries, for example, they are assumed to be listed in the order in which they are to be applied. In cases of multiple entries matching the outbound and inbound datagram, the first match will be taken. The system will reorder the policy entry, that is, add the new entry before the old entry, only when:

The level of protection is "stronger" than the old level of protection.

Currently, strength is defined as:

AH and ESP > ESP > AH

The standard uses of AH and ESP were what drove this ranking of "stronger". There are flaws with this. ESP can be used either without authentication, which will allow cut-and-paste or replay attacks, or without encryption, which makes it equivalent or slightly weaker than AH. An administrator should take care to use ESP properly. See ipsecesp(7P) for more details.

If the new entry has bypass as action, bypass has the highest precedence. It can be added in any order, and the system will still match all the bypass entries before matching any other entries. This is useful for key management daemons which can use this feature to bypass IPsec as it protects its own traffic.

Entries with both AH (auth_algs present in the policy entry) and ESP (encr_auth_algs or encr_auth_a1gs present in the policy entry) protection are ordered after all the entries with
AH and ESP and before any AH–only and ESP–only entries. In all other cases the order specified by the user is not modified, that is, newer entries are added at the end of all the old entries. See Examples.

A new entry is considered duplicate of the old entry if an old entry matches the same traffic pattern as the new entry. See Examples for information on duplicates.

**Security** If, for example, the policy file comes over the wire from an NFS mounted file system, an adversary can modify the data contained in the file, thus changing the policy configured on the machine to suit his needs. Administrators should be cautious about transmitting a copy of the policy file over a network.

To prevent non-privileged users from modifying the security policy, ensure that the configuration file is writable only by trusted users.

The configuration file is defined by a property of the policy smf(5) service. The default configuration file, is /etc/inet/ipsecinit.conf. This can be changed using the svcprop(1) command. See NOTES for more details.

The policy description language supports the use of tokens that can be resolved by means of a name service, using functions such as gethostbyname(3NSL). While convenient, these functions are only secure as the name service the system is configured to use. Great care should be taken to secure the name service if it is used to resolve elements of the security policy.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will no longer be trustworthy.

If the name switch is configured to use a name service that is not local to the system, bypass policy entries might be required to prevent the policy from preventing communication to the name service. See nsswitch.conf(4).

Policy is latched for TCP/UDP sockets on which a connect(3SOCKET) or accept(3SOCKET) has been issued. Adding new policy entries will not have any effect on them. This feature of latching may change in the future. It is not advisable to depend upon this feature.

The ipseconff command can only be run by a user who has sufficient privilege to open the pf_key(7P) socket. The appropriate privilege can be assigned to a user with the Network IPsec Management profile. See profiles(1), rbac(5), prof_attr(4).

Make sure to set up the policies before starting any communications, as existing connections may be affected by the addition of new policy entries. Similarly, do not change policies in the middle of a communication.

Note that certain ndd tunables affect how policies configured with this tool are enforced; see ipsecesp(7P) for more details.
Examples

**EXAMPLE 1**  Protecting Outbound TCP Traffic With ESP and the AES Algorithm

The following example specified that any TCP packet from spiderweb to arachnid should be encrypted with AES, and the SA could be a shared one. It does not verify whether or not the inbound traffic is encrypted.

```
# # Protect the outbound TCP traffic between hosts spiderweb
# and arachnid with ESP and use AES algorithm.
#
{   laddr spiderweb
    raddr arachnid
    ulp tcp
    dir out
} ipsec {
    encr_algs AES
}
```

**EXAMPLE 2**  Verifying Whether or Not Inbound Traffic is Encrypted

Example 1 does not verify whether or not the inbound traffic is encrypted. The entry in this example protects inbound traffic:

```
# # Protect the TCP traffic on inbound with ESP/DES from arachnid
# to spiderweb
#
{   laddr spiderweb
    raddr arachnid
    ulp tcp
    dir in
} ipsec {
    encr_algs AES
}
```

`sas` can be absent for inbound policy entries as it implies that it can be a shared one. Uniqueness is not verified on inbound. Note that in both the above entries, authentication was never specified. This can lead to cut and paste attacks. As mentioned previously, though the authentication is not specified, the system will still use an ESP SA with `encr_auth_alg` specified, if it was found in the SA tables.

**EXAMPLE 3**  Protecting All Traffic Between Two Hosts

The following example protects both directions at once:

```
EXAMPLE 3  Protecting All Traffic Between Two Hosts  

```plaintext
ulp tcp

{ ipsec {
    encr_algs AES

} }
```

EXAMPLE 4  Authenticating All Inbound Traffic to the Telnet Port

This entry specifies that any inbound datagram to telnet port should come in authenticated with the SHA1 algorithm. Otherwise the datagram should not be permitted. Without this entry, traffic destined to port number 23 can come in clear. sa is not specified, which implies that it is shared. This can be done only for inbound entries. You need to have an equivalent entry to protect outbound traffic so that the outbound traffic is authenticated as well, remove the dir.

```plaintext
#
# All the inbound traffic to the telnet port should be
# authenticated.
#
{ lport telnet
dir in
} ipsec {
    auth_algs sha1
}
```

EXAMPLE 5  Verifying Inbound Traffic is Null-Encrypted

The first entry specifies that any packet with address host-B should not be checked against any policies. The second entry specifies that all inbound traffic from network-B should be encrypted with a NULL encryption algorithm and the MD5 authentication algorithm. NULL encryption implies that ESP header will be used without encrypting the datagram. As the first entry is bypass it need not be given first in order, as bypass entries have the highest precedence. Thus any inbound traffic will be matched against all bypass entries before any other policy entries.

```plaintext
#
# Make sure that all inbound traffic from network-B is NULL
# encrypted, but bypass for host-B alone from that network.
# Add the bypass first.
{
    raddr host-B
dir in
} bypass {}
```

```plaintext
#
# Now add for network-B.
{
    raddr network-B/16
```
EXAMPLE 5  Verifying Inbound Traffic is Null-Encrypted  (Continued)

    dir in
} ipsec {
  encr_algs NULL
  encr_auth_algs md5
}

EXAMPLE 6  Entries to Bypass Traffic from IPsec

The first two entries provide that any datagram leaving the machine with source port 53 or
coming into port number 53 should not be subjected to IPsec policy checks, irrespective of any
other policy entry in the system. Thus the latter two entries will be considered only for ports
other than port number 53.

# # Bypass traffic for port no 53
#
{ lport 53} bypass {}
{ rport 53} bypass {}
{ raddr spiderweb } ipsec { encr_algs any sa unique}

EXAMPLE 7  Protecting Outbound Traffic

# # Protect the outbound traffic from all interfaces.
#
{ raddr spiderweb dir out} ipsec { auth_algs any sa unique}

If the gethostbyname(3XNET) call for spiderweb yields multiple addresses, multiple policy
entries will be added for all the source address with the same properties.

{  laddr arachnid
   raddr spiderweb
   dir in
} ipsec { auth_algs any sa unique}

If the gethostbyname(3XNET) call for spiderweb and the gethostbyname(3XNET) call for
arachnid yield multiple addresses, multiple policy entries will be added for each (saddr daddr)
pair with the same properties. Use ipsecconf -l to view all the policy entries added.

EXAMPLE 8  Bypassing Unauthenticated Traffic

# # Protect all the outbound traffic with ESP except any traffic
# to network-b which should be authenticated and bypass anything
# to network-c
#
{ raddr network-b/16 dir out} ipsec { auth_algs any}
EXAMPLE 8  Bypassing Unauthenticated Traffic  

(dir out) ipsec {encr_algs any}
{raddr network-c/16 dir out} bypass {} # NULL properties

Note that bypass can be given anywhere and it will take precedence over all other entries. NULL pattern matches all the traffic.

EXAMPLE 9  Encrypting IPv6 Traffic with 3DES and MD5

The following entry on the host with the link local address fe80::a00:20ff:fe21:4483 specifies that any outbound traffic between the hosts with IPv6 link-local addresses fe80::a00:20ff:fe21:4483 and fe80::a00:20ff:fe21:4483 must be encrypted with 3DES and MD5.

{  
  laddr fe80::a00:20ff:fe21:4483  
  raddr fe80::a00:20ff:fe21:4483  
  dir out
} ipsec {  
  encr_algs 3DES  
  encr_auth_algs MD5
}

EXAMPLE 10  Verifying IPv6 Traffic is Authenticated with SHA1

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network fec0:abcd::0/32 be authenticated with SHA1.

{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }

EXAMPLE 11  Key Lengths

# use aes at any key length  
{raddr spiderweb} ipsec {encr_algs aes}

# use aes with a 192 bit key  
{raddr spiderweb} ipsec {encr_algs aes(192)}

# use aes with any key length up to 192 bits  
# i.e. 192 bits or less  
{raddr spiderweb} ipsec {encr_algs aes(..192)}

# use aes with any key length of 192 or more  
# i.e. 192 bits or more  
{raddr spiderweb} ipsec {encr_algs aes(192..)}

# use aes with any key from 192 to 256 bits  
{raddr spiderweb} ipsec {encr_algs aes(192..256)}
EXAMPLE 11  Key Lengths  

(use any algorithm with a key of 192 bits or longer
{raddr spiderweb} ipsec {encr_algs any(192..)})

EXAMPLE 12  Correct and Incorrect Policy Entries

The following are examples of correctly formed policy entries:

{ raddr that_system rport telnet } ipsec { encr_algs 3des encr_auth_algs
shal sa shared}

{ raddr that_system
   rport telnet
} ipsec {
   encr_algs 3des
   encr_auth_algs sham
   sa shared
}

{ raddr that_system rport telnet } ipsec
{ encr_algs 3des encr_auth_algs sham sa shared}

{ raddr that_system rport telnet } ipsec
{ encr_algs 3des encr_auth_algs sham sa shared} or ipsec
{ encr_algs aes encr_auth_algs sham sa shared}

...and the following is an incorrectly formed entry:

{ raddr that_system rport telnet } ipsec
{ encr_algs 3des encr_auth_algs sham sa shared} or ipsec { encr_algs aes encr_auth_algs sham sa shared}

In the preceding, incorrect entry, note that the third line begins with "or ipsec". Such an entry causes ipseconf to return an error.

EXAMPLE 13  Allowing Neighbor Discovery to Occur in the Clear

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network fec0:abcd::/32 be authenticated with SHA1. The second entry allows neighbor discovery to operate correctly.

{raddr fec0:abcd::/32} ipsec { auth_algs SHA1 }
{raddr fec0:abcd::/32 ulp ipv6-icmp type 133-137 dir both }
   pass { }

EXAMPLE 14  Using "or"

The following entry allows traffic using the AES or Blowfish algorithms from the remote machine spiderweb:
EXAMPLE 14 Using "or"  (Continued)

{raddr spiderweb} ipsec {encr_algs aes} or ipsec {encr_algs blowfish}

EXAMPLE 15 Configuring a Tunnel to be Backward-Compatible with Solaris 9

The following example is equivalent to "encr_algs aes encr_auth_algs md5" in ifconfig(1M):

{tunnel ip.tun0 negotiate transport} ipsec {encr_algs aes
encr_auth_algs md5}

EXAMPLE 16 Configuring a Tunnel to a VPN client with an Assigned Address

The following example assumes a distinct "inside" network with its own topology, such that a client's default route goes "inside".

# Unlike route(1m), the default route has to be spelled-out.
{tunnel ip.tun0 negotiate tunnel raddr client-inside/32
laddr 0.0.0.0/0} ipsec {encr_algs aes encr_auth_algs sha1}

EXAMPLE 17 Transit VPN router between Two Tunnelled Subnets and a Third

The following example specifies a configuration for a VPN router that routes between two tunnelled subnets and a third subnet that is on-link. Consider remote-site A, remote-site B, and local site C, each with a /24 address allocation.

# ip.tun0 between me (C) and remote-site A.
# Cover remote-site A to remote-site B.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr B-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# Cover remote-site A traffic to my subnet.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr C-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# ip.tun1 between me (C) and remote-site B.
# Cover remote-site B to remote-site A.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr A-prefix/24} ipsec {encr_algs aes encr_auth_algs md5}

# Cover remote-site B traffic to my subnet.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr C-prefix/24} ipsec {encr_algs aes encr_auth_algs md5}

Files
/var/run/ipsecpolicy.conf
Cache of IPsec policies currently configured for the system, maintained by ipseccnf command. Do not edit this file.
File containing IPsec policies to be installed at system restart by the policy smf(5) service. See NOTES for more information.

Sample input file for ipseconf.

See attributes(5) for descriptions of the following attributes:

Diagnostics Bad "string" on line N.
Duplicate "string" on line N.

"string" refers to one of the names in pattern or properties. A Bad string indicates that an argument is malformed; a Duplicate string indicates that there are multiple arguments of a similar type, for example, multiple Source Address arguments.
Interface name already selected
   Dual use of -i name and name,index for an index.

Error before or at line N.
   Indicates parsing error before or at line N.

Non-existent index
   Reported when the index for delete is not a valid one.

spd_msg return: File exists
   Reported when there is already a policy entry that matches the traffic of this new entry.

Notes
IPsec manual keys are managed by the service management facility, smf(5). The services listed below manage the components of IPsec. These services are delivered as follows:

svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)

The manual-key service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in ipseckey(1M), before enabling that service.

The policy service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file /etc/inet/ipsecinit.conf, as described in this man page, and refresh the service (svcadm refresh, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode.

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See ike.config(4) for the ike service.

See ipsecalgs(1M) for the ipsecalgs service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using svcadm(1M).

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

example# svcadm refresh policy

The smf(5) framework will record any errors in the service-specific log file. Use any of the following commands to examine the logfile property:

example# svc -l policy
example# svcprop policy
example# svccfg -s policy listprop

The following property is defined for the policy service:
This property can be modified using `svccfg(1M)` by users who have been assigned the following authorization:

```
solaris.smf.value.ipsec
```

See `auths(1), user_attr(4), rbac(5)`.

The service needs to be refreshed using `svcadm(1M)` before the new property is effective. General non-modifiable properties can be viewed with the `svcprop(1)` command.

```
# svccfg -s ipsec/policy setprop config/config_file = /new/config_file
# svcadm refresh policy
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using `svcadm(1M)`. A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

The service's status can be queried using the `svcs(1)` command.

The `ipsecconf` command is designed to be managed by the `policy smf(5)` service. While the `ipsecconf` command can be run from the command line, this is discouraged. If the `ipsecconf` command is to be run from the command line, the `policy smf(5)` service should be disabled first. See `svcadm(1M)`.
The `ipseckey` command is used to manually manipulate the security association databases of the network security services, `ipsecah(7P)` and `ipsecesp(7P)`. You can use the `ipseckey` command to set up security associations between communicating parties when automated key management is not available.

While the `ipseckey` utility has only a limited number of general options, it supports a rich command language. The user may specify requests to be delivered by means of a programmatic interface specific for manual keying. See `pf_key(7P)`. When `ipseckey` is invoked with no arguments, it will enter an interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached. Some commands require an explicit security association ("SA") type, while others permit the SA type to be unspecified and act on all SA types.

`ipseckey` uses a PF_KEY socket and the message types SADB_ADD, SADB_DELETE, SADB_GET, SADB_UPDATE, SADB_FLUSH, and SADB_X_PROMISC. Thus, you must be a superuser to use this command.

`ipseckey` handles sensitive cryptographic keying information. Please read the Security section for details on how to use this command securely.

**Options**

- **-c** `[filename]`
  Analogous to the `-f` option (see following), except that the input is not executed but only checked for syntactical correctness. Errors are reported to stderr. This option is provided to debug configurations without making changes. See SECURITY and "Service Management Facility" for more information.

- **-f** `[filename]`
  Read commands from an input file, `filename`. The lines of the input file are identical to the command line language. The `load` command provides similar functionality. The `-s` option or the `save` command can generate files readable by the `-f` argument.
-n
Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.

-p
Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.

-s [filename]
The opposite of the -f option. If '-f' is given for a filename, then the output goes to the standard output. A snapshot of all current SA tables will be output in a form readable by the -f option. The output will be a series of add commands, but with some names not used. This occurs because a single name may often indicate multiple addresses.

-v
Verbose. Print the messages being sent into the PF_KEY socket, and print raw seconds values for lifetimes.

Commands

add
Add an SA. Because it involves the transfer of keying material, it cannot be invoked from the shell, lest the keys be visible in ps(1) output. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The add command accepts all extension-value pairs described below.

update
Update SA lifetime, and in the cases of larval SAs (leftover from aborted automated key management), keying material and other extensions. Like add, this command cannot be invoked from the shell because keying material would be seen by the ps(1) command. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The update command accepts all extension-value pairs, but normally is only used for SA lifetime updates.

update-pair
As update, but apply the update to the SA and its paired SA, if there is one.

delete
Delete a specific SA from a specific SADB. This command requires the spi extension, and the dest extension for IPsec SAs. Other extension-value pairs are superfluous for a delete message. If the SA to be deleted is paired with another SA, the SA is deleted and the paired SA is updated to indicate that it is now unpaired.

delete-pair
Delete a specific SA from a specific SADB. If the SA is paired with another SA, delete that SA too. This command requires the spi extension and the dest extension for the IPsec SA, or its pair.

get
Lookup and display a security association from a specific SADB. Like delete, this command only requires spi and dest for IPsec.
flush
   Remove all SA for a given SA_TYPE, or all SA for all types.

monitor
   Continuously report on any PF_KEY messages. This uses the SADB_X_PROMISC message to enable messages that a normal PF_KEY socket would not receive to be received. See pf_key(7P).

passive_monitor
   Like monitor, except that it does not use the SADB_X_PROMISC message.

pmonitor
   Synonym for passive_monitor.

dump
   Will display all SAs for a given SA type, or will display all SAs. Because of the large amount of data generated by this command, there is no guarantee that all SA information will be successfully delivered, or that this command will even complete.

save
   Is the command analog of the -s option. It is included as a command to provide a way to snapshot a particular SA type, for example, esp or ah.

help
   Prints a brief summary of commands.

 SA_TYPE
   all
      Specifies all known SA types. This type is only used for the flush and dump commands. This is equivalent to having no SA type for these commands.

   ah
      Specifies the IPsec Authentication Header ("AH") SA.

   esp
      Specifies the IPsec Encapsulating Security Payload ("ESP") SA.

Extension Value Types
Commands like add, delete, get, and update require that certain extensions and associated values be specified. The extensions will be listed here, followed by the commands that use them, and the commands that require them. Requirements are currently documented based upon the IPsec definitions of an SA. Required extensions may change in the future. <number> can be in either hex (0xnnn), decimal (nnn) or octal (0nnn).<string> is a text string. <hexstr> is a long hexadecimal number with a bit-length. Extensions are usually paired with values; however, some extensions require two values after them.

spi <number>
   Specifies the security parameters index of the SA. This extension is required for the add, delete, get and update commands.
pair-spi <number>
When pair-spi is used with the add or update commands, the SA being added or updated will be paired with the SA defined by pair-spi. A pair of SAs can be updated or deleted with a single command.

The two SAs that make up the pair need to be in opposite directions from the same pair of IP addresses. The command will fail if either of the SAs specified are already paired with another SA.

If the pair-spi token is used in a command and the SA defined by pair-spi does not exist, the command will fail. If the command was add and the pairing failed, the SA to be added will instead be removed.

inbound | outbound
These optional flags specify the direction of the SA. When the inbound or outbound flag is specified with the add command, the kernel will insert the new SA into the specified hash table for faster lookups. If the flag is omitted, the kernel will decide into which hash table to insert the new SA based on its knowledge the IP addresses specified with the src and dst extensions.

When these flags are used with the update, delete, update-pair or get commands, the flags provide a hint as to the hash table in which the kernel should find the SA.

replay <number>
Specifies the replay window size. If not specified, the replay window size is assumed to be zero. It is not recommended that manually added SAs have a replay window. This extension is used by the add and update commands.

replay_value <number>
Specifies the replay value of the SA. This extension is used by the add and update commands.

state <string>|<number>
Specifies the SA state, either by numeric value or by the strings “larval”, “mature”, “dying” or “dead”. If not specified, the value defaults to mature. This extension is used by the add and update commands.

auth_alg <string>|<number>
authalg <string>|<number>
Specifies the authentication algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current authentication algorithms include:

- HMAC-MD5
  md5, hmac-md5
- HMAC-SH-1
  sha, sha-1, hmac-sha1, hmac-sha
HMAC-SHA-256
   sha256, sha-256, hmac-sha256, hmac-sha-256

HMAC-SHA-384
   sha384, sha-384, hmac-sha384, hmac-sha-384

HMAC-SHA-512
   sha512, sha-512, hmac-sha512, hmac-sha-512

Often, algorithm names will have several synonyms. This extension is required by the add command for certain SA types. It is also used by the update command.

Use the ipsecalgs(1M) command to obtain the complete list of authentication algorithms.

encr_alg <string>|<number>
encrAlg <string>|<number>
   Specifies the encryption algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current encryption algorithms include DES (“des”), Triple-DES (“3des”), Blowfish (“blowfish”), and AES (“aes”). This extension is required by the add command for certain SA types. It is also used by the update command.

Use the ipsecalgs(1M) command to obtain the complete list of encryption algorithms.

The next six extensions are lifetime extensions. There are two varieties, “hard” and “soft”. If a hard lifetime expires, the SA will be deleted automatically by the system. If a soft lifetime expires, an SADB_EXPIRE message will be transmitted by the system, and its state will be downgraded to dying from mature. See pf_key(7P). The monitor command to key allows you to view SADB_EXPIRE messages.

idle_addtime <number>
idle_usetime <number>
   Specifies the number of seconds that this SA can exist if the SA is not used before the SA is revalidated. If this extension is not present, the default value is half of the hard_addtime (see below). This extension is used by the add and update commands.

soft_bytes <number>
hard_bytes <number>
   Specifies the number of bytes that this SA can protect. If this extension is not present, the default value is zero, which means that the SA will not expire based on the number of bytes protected. This extension is used by the add and update commands.

soft_addtime <number>
hard_addtime <number>
   Specifies the number of seconds that this SA can exist after being added or updated from a larval SA. An update of a mature SA does not reset the initial time that it was added. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the add and update commands.
soft usetime <number>

hard usetime <number>

Specifies the number of seconds this SA can exist after first being used. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the `add` and `update` commands.

saddr address | name
srcaddr address | name
saddr6 IPv6 address
srcaddr6 IPv6 address
src address | name
src6 IPv6 address

`saddr address` and `src address` are synonyms that indicate the source address of the SA. If unspecified, the source address will either remain unset, or it will be set to a wildcard address if a destination address was supplied. To not specify the source address is valid for IPsec SAs. Future SA types may alter this assumption. This extension is used by the `add`, `update`, `get`, and `delete` commands.

daddr <address> | <name>
dstaddr <address> | <name>
daddr6 <IPv6 address> | <name>
dstaddr6 <IPv6 address> | <name>
dst <addr> | <name>
dst6 <IPv6 address> | <name>

dstaddr <addr> and `dst <addr>` are synonyms that indicate the destination address of the SA. If unspecified, the destination address will remain unset. Because IPsec SAs require a specified destination address and `spi` for identification, this extension, with a specific value, is required for the `add`, `update`, `get` and `delete` commands.

If a name is given, `ipseckey` will attempt to invoke the command on multiple SAs with all of the destination addresses that the name can identify. This is similar to how `ipsecconf` handles addresses.

If `dst6` or `dstaddr6` is specified, only the IPv6 addresses identified by a name are used.

sport <portnum>

eSport specifies the source port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

dport <portnum>

edPort specifies the destination port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

encap <protocol>

edIdentifies the protocol used to encapsulate NAT-traversal IPsec packets. Other NAT-traversal parameters (nat_*) are below. The only acceptable value for `<protocol>` currently is `udp`.

ipseckey(1M)
proto <protocol number>
ulp <protocol number>
    proto, and its synonym ulp, specify the IP protocol number of the SA.

nat_loc <address>|<name>
    If the local address in the SA (source or destination) is behind a NAT, this extension
    indicates the NAT node's globally-routable address. This address can match the SA's local
    address if there is a nat_lport (see below) specified.

nat_rem <address>|<name>
    If the remote address in the SA (source or destination) is behind a NAT, this extension
    indicates that node's internal (that is, behind-the-NAT) address. This address can match
    the SA's local address if there is a nat_rport (see below) specified.

nat_lport <portnum>
    Identifies the local UDP port on which encapsulation of ESP occurs.

nat_rport <portnum>
    Identifies the remote UDP port on which encapsulation of ESP occurs.

isrc <address> | <name>[/<prefix>]
innersrc <address> | <name>[/<prefix>]
isrc6 <address> | <name>[/<prefix>]
innersrc6 <address> | <name>[/<prefix>]
proxyaddr <address> | <name>[/<prefix>]
proxynode <address> | <name>[/<prefix>]
    isrc <address>[/<prefix>] and innersrc <address>[/<prefix>] are synonyms. They
    indicate the inner source address for a tunnel-mode SA.

    An inner-source can be a prefix instead of an address. As with other address extensions,
    there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or prefixes.

    Previous versions referred to this value as the proxy address. The usage, while deprecated,
    remains.

idst <address> | <name>[/<prefix>]
innerdst <address> | <name>[/<prefix>]
idst6 <address> | <name>[/<prefix>]
innersdst6 <address> | <name>[/<prefix>]
    idst <address>[/<prefix>] and innerdst <address>[/<prefix>] are synonyms. They
    indicate the inner destination address for a tunnel-mode SA.

    An inner-destination can be a prefix instead of an address. As with other address
    extensions, there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or
    prefixes.

innersport <portnum>
isport <portnum>
innersport specifies the source port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

innerdport <portnum>
idport <portnum>

innerdport specifies the destination port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

iproto <protocol number>iulp <protocol number>
iproto, and its synonym iulp, specify the IP protocol number of the inner header of a tunnel-mode SA.

authkey <hexstring>
Specifies the authentication key for this SA. The key is expressed as a string of hexadecimal digits, with an optional / at the end, for example, 123/12. Bits are counted from the most-significant bits down. For example, to express three ‘1’ bits, the proper syntax is the string “e/3”. For multi-key algorithms, the string is the concatenation of the multiple keys. This extension is used by the add and update commands.

encrkey <hexstring>
Specifies the encryption key for this SA. The syntax of the key is the same as authkey. A concrete example of a multi-key encryption algorithm is 3des, which would express itself as a 192-bit key, which is three 64-bit parity-included DES keys. This extension is used by the add and update commands.

Certificate identities are very useful in the context of automated key management, as they tie the SA to the public key certificates used in most automated key management protocols. They are less useful for manually added SAs. Unlike other extensions, srcidtype takes two values, a type, and an actual value. The type can be one of the following:

prefix
An address prefix.

fqdn
A fully-qualified domain name.

domain
Domain name, synonym for fqdn.

user_fqdn
User identity of the form user@fqdn.

mailbox
Synonym for user_fqdn.

The value is an arbitrary text string that should identify the certificate.
srcidtype <type, value>
Specifies a source certificate identity for this SA. This extension is used by the add and update commands.

dstidtype <type, value>
Specifies a destination certificate identity for this SA. This extension is used by the add and update commands.

An IPsec SA is a Tunnel Mode SA if the "proto" value is either 4 (IPv4) or 41 (IPv6) and there is an inner-address or inner-port value specified. Otherwise, the SA is a Transport Mode SA.

Security
Keying material is very sensitive and should be generated as randomly as possible. Some algorithms have known weak keys. IPsec algorithms have built-in weak key checks, so that if a weak key is in a newly added SA, the add command will fail with an invalid value.

The ipseckey command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the ipseckey command.

1. Is the TTY going over a network (interactive mode)?
   - If it is, then the security of the keying material is the security of the network path for this TTY’s traffic. Using ipseckey over a clear-text telnet or rlogin session is risky.
   - Even local windows might be vulnerable to attacks where a concealed program that reads window events is present.

2. Is the file accessed over the network or readable to the world (-f option)?
   - A network-mounted file can be sniffed by an adversary as it is being read.
   - A world-readable file with keying material in it is also risky.

3. The ipseckey command is designed to be managed by the manual-key smf(5) service. Because the smf(5) log files are world-readable, the ipseckey does not record any syntax errors in the log files, as these errors might include secret information.
   - If a syntax error is found when the manual-key smf(5) service is enabled, the service enters maintenance mode. The log file will indicate that there was a syntax error, but will not specify what the error was.
   - The administrator should use ipseckey -c filename from the command line to discover the cause of the errors. See OPTIONS.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will not be trustworthy.

Security weaknesses often lie in misapplication of tools, not in the tools themselves. Administrators are urged to be cautious when using ipseckey. The safest mode of operation is probably on a console or other hard-connected TTY.

For further thoughts on this subject, see the afterward by Matt Blaze in Bruce Schneier’s Applied Cryptography: Protocols, Algorithms, and Source Code in C.
IPsec manual keys are managed by the service management facility, **smf(5)**. The services listed below manage the components of IPsec. These services are delivered as follows:

- `svc:/network/ipsec/policy:default` (enabled)
- `svc:/network/ipsec/ipsecalgs:default` (enabled)
- `svc:/network/ipsec/manual-key:default` (disabled)
- `svc:/network/ipsec/ike:default` (disabled)

The manual-key service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in this man page, before enabling that service.

The policy service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file `/etc/inet/ipsecinit.conf` and refresh the service (`svcadm refresh`, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode. See **ipseconff(1M)**.

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See **ike.conf(4)** for the ike service.

See **ipsecalgs(1M)** for the ipsecalgs service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using **svcadm(1M)**.

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

```
example# svcadm refresh manual-key
```

*Warning:* To prevent ipseckey complaining about duplicate Associations, the ipseckey command flushes the Security Association Data Base (SADB) when the ipseckey command is run from **smf(5)**, before adding any new Security Associations defined in the configuration file. This differs from the command line behavior where the SADB is not flushed before adding new Security Associations.

The **smf(5)** framework will record any errors in the service-specific log file. Use any of the following commands to examine the `logfile` property:

```
example# svcs -l manual-key
example# svcprop manual-key
example# svccfg -s manual-key listprop
```

The following property is defined for the `manual-key` service:

```
config/config_file
```

This property can be modified using **svccfg(1M)** by users who have been assigned the following authorization:
solaris.smf.value.ipsec

See auths(1), user_attr(4), rbac(5).

The service needs to be refreshed using svcadm(1M) before the new property is effective. General non-modifiable properties can be viewed with the svcprop(1) command.

```
# svccfg -s ipsec/manual-key setprop config/config_file = \
/new/config_file
# svcadm refresh manual-key
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using svcadm(1M). A user who has been assigned the authorization shown below can perform these actions:

solaris.smf.manage.ipsec

The service's status can be queried using the svcs(1) command.

The ipseckey command is designed to be run under smf(5) management. While the ipsecconf command can be run from the command line, this is discouraged. If the ipseckey command is to be run from the command line, the manual-key smf(5) service should be disabled first. See svcadm(1M).

**Examples**

**EXAMPLE 1**  Emptying Out All SAs  
To empty out all SA:

example# ipseckey flush

**EXAMPLE 2**  Flushing Out IPsec AH SAs Only  
To flush out only IPsec AH SAs:

example# ipseckey flush ah

**EXAMPLE 3**  Saving All SAs To Standard Output  
To save all SAs to the standard output:

example# ipseckey save all

**EXAMPLE 4**  Saving ESP SAs To The File /tmp/snapshot  
To save ESP SAs to the file /tmp/snapshot:

example# ipseckey save esp /tmp/snapshot

**EXAMPLE 5**  Deleting an IPsec SA  
To delete an IPsec SA, only the SPI and the destination address are needed:

example# ipseckey delete esp spi 0x2112 dst 224.0.0.1

An alternative would be to delete the SA and the SAs pair if it has one:
EXAMPLE 5  Deleting an IPsec SA  (Continued)

example# ipseckey delete-pair esp spi 0x2112 dst 224.0.0.1

EXAMPLE 6  Getting Information on an IPsec SA
Likewise, getting information on a SA only requires the destination address and SPI:

example# ipseckey get ah spi 0x5150 dst mypeer

EXAMPLE 7  Adding or Updating IPsec SAs
Adding or updating SAs requires entering interactive mode:

example# ipseckey
ipseckey> add ah spi 0x90125 src me.domain.com dst you.domain.com \
  authalg md5 authkey 1234567890abcdef1234567890abcdef
ipseckey> update ah spi 0x90125 dst you.domain.com hard_bytes \ 
  1000000
ipseckey> exit

Adding two SAs that are linked together as a pair:

example# ipseckey
ipseckey> add esp spi 0x2345 src me.domain.com dst you.domain.com \ 
  authalg md5 authkey bde359723576fdea08e56cbe876e24ad \ 
  encralg des encrkey be02938e7def2839
ipseckey> add esp spi 0x5432 src me.domain.com dst you.domain.com \ 
  authalg md5 authkey bde359723576fdea08e56cbe876e24ad \ 
  encralg des encrkey be02938e7def2839 pair-spi 0x2345
ipseckey> exit

EXAMPLE 8  Adding an SA in the Opposite Direction
In the case of IPsec, SAs are unidirectional. To communicate securely, a second SA needs to be added in the opposite direction. The peer machine also needs to add both SAs.

example# ipseckey
ipseckey> add ah spi 0x2112 src you.domain.com dst me.domain.com \ 
  authalg md5 authkey bde359723576fdea08e56cbe876e24ad \ 
  hard_bytes 16000000
ipseckey> exit

EXAMPLE 9  Monitoring PF_KEY Messages
Monitoring for PF_KEY messages is straightforward:

example# ipseckey monitor

EXAMPLE 10  Using Commands in a File
Commands can be placed in a file that can be parsed with the -f option. This file may contain comment lines that begin with the “#” symbol. For example:
EXAMPLE 10   Using Commands in a File  (Continued)

# This is a sample file for flushing out the ESP table and
# adding a pair of SAs.

flush esp

### Watch out! I have keying material in this file. See the
### SECURITY section in this manual page for why this can be
### dangerous .

add esp spi 0x2112 src me.domain.com dst you.domain.com \
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
    encralg des encrkey be02938e7def2839 hard usetime 28800
add esp spi 0x5150 src you.domain.com dst me.domain.com \
    authalg md5 authkey 930987dbe09743ade09d92b4097d9e93 \
    encralg des encrkey 8bd4a52e10127deb hard usetime 28800

## End of file - This is a gratuitous comment

EXAMPLE 11   Adding SAs for IPv6 Addresses

The following commands from the interactive-mode create an SA to protect IPv6 traffic
between the site-local addresses

eexample # ipseckey
ipseckey> add esp spi 0x6789 src6 fec0:bbbb::4483 dst6 fec0:bbbb::7843\n    authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
    encralg des encrkey be02938e7def2839 hard usetime 28800
ipseckey>exit

EXAMPLE 12   Linking Two SAs as a Pair

The following command links two SAs together, as a pair:

eexample# ipseckey update esp spi 0x123456 dst 192.168.99.2 \ 
    pair-spi 0x654321

Files  /etc/inet/secret/ipseckeys
      Default configuration file used at boot time. See “Service Management Facility” and
      SECURITY for more information.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>
The *ipseckey* command parses the configuration file and reports any errors. In the case of multiple errors, *ipseckey* reports as many of these as possible.

The *ipseckey* command does not attempt to use a COMMAND that has a syntax error. A COMMAND might be syntactically correct but can nevertheless generate an error because the kernel rejected the request made to *pf_key(7P)*. This might occur because a key had an invalid length or because an unsupported algorithm was specified.

If there are any errors in the configuration file, *ipseckey* reports the number of valid COMMANDS and the total number of COMMANDS parsed.

**Parse error on line N.**
If an interactive use of *ipseckey* would print usage information, this would print instead. Usually proceeded by another diagnostic. Because COMMANDS can cover more than a single line in the configuration file by using the backslash character to delimit lines, its not always possible to pinpoint in the configuration file the exact line that caused the error.

**Unexpected end of command line.**
An additional argument was expected on the command line.

**Unknown**
A value for a specific extension was unknown.

**Address type N not supported.**
A name-to-address lookup returned an unsupported address family.

**N is not a bit specifier**
**bit length N is too big for**
**string is not a hex string**
Keying material was not entered appropriately.

**Can only specify single**
A duplicate extension was entered.

**Don't use extension for <string> for <command>.**
An extension not used by a command was used.

**One of the entered values is incorrect: Diagnostic code NN: <msg>**
This is a general invalid parameter error. The diagnostic code and message provides more detail about what precise value was incorrect and why.
In spite of its IPsec-specific name, **ipseckey** is analogous to **route(1M)**, in that it is a command-line interface to a socket-based administration engine, in this case, **PF_KEY**. **PF_KEY** was originally developed at the United States Naval Research Laboratory.

To have machines communicate securely with manual keying, SAs need to be added by all communicating parties. If two nodes wish to communicate securely, both nodes need the appropriate SAs added.

In the future **ipseckey** may be invoked under additional names as other security protocols become available to **PF_KEY**.

This command requires **sys_ip_config** privilege to operate and thus can run in the global zone and in exclusive-IP zones. The global zone can set up security associations with **ipseckey** to protect traffic for shared-IP zones on the system.
Name  iscsiadm – enable management of iSCSI initiators

Synopsis  iscsiadm subcommand direct-object [options] [operand]

Description  The iscsiadm command enables management of the iSCSI (Internet SCSI) initiator on a host. iscsiadm is implemented as a set of subcommands, many with their own options, which are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS.

iscsiadm works only when the following service is online:

svc:/network/iscsi/initiator:default

The iscsiadm command supports the following subcommands, which are described in detail in subsections that follow:

add    Adds element(s) to an object.
list   Lists element(s) of an object.
modify  Modifies attributes of an object.
remove Removes an element from an object.

The iscsiadm subcommands operate on a direct-object. These are described in the section for each subcommand.

The iscsiadm command supports the Internet Storage Name Service (iSNS) for the discovery of iSCSI targets. The command supports the Challenge Handshake Authentication Protocol (CHAP) for authentication.

add Subcommand  The syntax for the add subcommand is:

# iscsiadm add direct_object [operands...]

The add subcommand adds the following direct_objects:

discovery-address discovery-address [...]  Adds a target to a list of discovery addresses. A discovery address (as in the syntax shown below) is an IP address:port combination used in a SendTargets discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. Connection to a target is not attempted unless the SendTargets method of discovery has been enabled on the host. You enable this method with the modify subcommand.

The discovery-address parameter is formatted as:

<IP address>[:port]

If port is not specified, the default of 3260 will be used.
isns-server isns-server [...]
Add an iSNS server to the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. Connection to the iSNS server is not attempted unless the iSNS method of discovery has been enabled on the host. You enable this method with the modify subcommand, described below.

The isns-server parameter is formatted as:

`IP_address[:port]`

If a port is not specified, the default of 3205 is used.

static-config static_target [...]
Adds a target to the list of statically configured targets. A connection to the target will not be attempted unless the static configuration method of discovery has been enabled.

The static_target parameter is formatted as:

`<target-name>,<target-address>[:port-number],tpgt`

`<target-name>` can be up to 223 characters.

list Subcommand
The syntax for the list subcommand is:

```
# iscsiadm list direct-object [options]
```

The list subcommand displays data for the following `direct-objects`:

discovery
Lists the discovery methods and their current activation state, enabled or disabled.
Discovery methods are:
- iSNS (Internet Storage Name Service)
- Static
- SendTargets

initiator-node
Lists information for the initiator node on the host. The iSCSI initiator node represents a logical HBA and is a logical host connection point for iSCSI targets. The parameter values listed in the response are default parameter settings for the initiator. Each connected target for an initiator can have parameter values that differ from the parameter values on the initiator node.

static-config [static_target,...]
Lists the target name and address for specified targets or, if no static targets are specified, all statically discovered targets.
target [-S] [-v] [target[...]]
Lists a target's current parameters, connection state, and which method was used for the target's discovery. Reports information for specified targets or, if no targets are specified, all targets that have been discovered or have had parameters modified by the modify target subcommand.

When used with the -S option for a specified target, this subcommand returns:
- target name
- logical unit number
- vendor ID
- product ID
- OS device name (for example, /dev/rdsk/c0t2d0s0)

The -v option gives more details, such as the current login parameters, the detailed connection information, and the discovery method used to discover the target.

A return of NA as the discovery method parameter indicates that the target was created with a iscsiadm modify target-param command and does not exist as a discovered object. To remove such targets, use iscsiadm remove target-param.

target-param [-v] target[...]
Lists a target's default and user-defined parameters.

discovery-address [-v] [discovery-address[...]]
Lists the discovery-address objects that have been added using the iscsiadm add discovery-address subcommand.

When used with the -v option, lists all known targets at a specified discovery-address. The -v option returns one or more target names along with zero or more target addresses and associated target portal group tags (TPGT), if applicable.

isns-server [-v] [isns-server[...]]
Lists the isns-server objects that have been added using the iscsiadm add isns-server subcommand.

When used with the -v option, this subcommand lists all known targets at a specified isns-server address. The -v option returns one of more target names along with zero or more target addresses and associated target portal group tags, if applicable.

modify Subcommand
The syntax for the modify subcommand is:

# iscsiadm modify direct_object [options]

The modify subcommand supports the following direct_objects:

discovery [options]
Enabling a discovery method initiates a discovery using that method. Disabling a discovery method that is currently enabled does not affect connections to any targets that have already been discovered by that method.
Options for `modify discovery` are as follows:

- `-i`, `--iSNS enable` | `disable`
  Enable or disable iSNS discovery.
- `-s`, `--static enable` | `disable`
  Enable or disable static discovery.
- `-t`, `--sendtargets enable` | `disable`
  Enable or disable SendTargets discovery.

`initiator-node [options]`
Modifies an initiator's properties. If a target is currently connected, this operation can succeed. However, the modified set of parameters will not be in effect for that target until an existing connection session no longer exists and a new connection has been established. The options `-C` and `--CHAP-secret` require a CHAP secret entry in response to a prompt.

Options for `modify initiator-node` are as follows:

- `-A`, `--node-alias <initiator node alias>`
  Modifies the initiator node alias. Maximum length of 223 characters.
- `-a`, `--authentication chap | none`
  Sets the authentication mode.
- `-C`, `--CHAP-secret`
  Sets the CHAP secret value. There is no default value. Maximum length is 16 characters.
- `-c`, `--configured-sessions <num_sessions> | <IP address>,<IP address>...`
  Sets the number of configured iSCSI sessions that will be created for each iSCSI target. The feature should be used in combination with the Solaris I/O multipathing feature described in `scsi_vhci(7D)`.
- `-d`, `--datadigest none | CRC32`
  Sets whether CRC32 is enabled to check SCSI data transfers.
- `-H`, `--CHAP-name CHAP name`
  Specifies a CHAP username. If you do not use this option, upon initialization, the CHAP name is set to the initiator node name. When the authentication method is set to CHAP (see `-a` | `--authentication` option, above), the CHAP username is displayed with the command `iscsiadm list initiator-node`.
- `-h`, `--headerdigest none | CRC32`
  Sets whether CRC32 is enabled to check SCSI packet headers.
- `-N`, `--node-name <initiator node name>`
  Modifies the initiator node name. Maximum of 223 characters.

**Note** – During Solaris installation, the initiator node name is set to a globally unique value. Changing this value can adversely affect operation within the iSCSI network.
-P, --radius-shared-secret (exclusive)
Sets the RADIUS shared secret.

-R, --radius-access enable | disable
Sets whether a RADIUS server will be used.

-r, --radius-server <IP address>[:<port>]
Sets the IP address and port of the radius server to be used.

-T, --tunable-param <<tunable-prop>=<value>, ...>
Specify one or more tunable parameters for all targets that initiator node connected.

**Note** – These values should only be modified by an administrator with a good working knowledge of the parameter’s impact within the iSCSI network.

Supported tunable-prop options are:

recv-login-rsp-timeout
Session Login Response Time

The `recv-login-rsp-timeout` option specifies how long iSCSI initiator will wait for the response of iSCSI session login request from the iSCSI target. Valid value is from 0 to 60*60, default to 60 seconds.

conn-login-max
Maximized Connection Retry Time

The `conn-login-max` option lets the iSCSI initiator reestablish the connection to the target in case of IO timeout or connection failure during the given time window. Valid value is from 0 to 60*60, default to 180 seconds.

polling-login-delay
Login Retry Time Interval

The `polling-login-delay` option specifies the time interval between each login retry when iSCSI initiator to target IO timeout or connection failure. Valid value is from 0 to 60*60, default to 60 seconds.

**target-param [options] target**
Modifies a target’s parameters. If a target is currently connected, the modify operation will succeed, although the modified settings might not take effect for a few seconds. To confirm that these settings are active, use `iscsiadm list target -v`. If a specified target is not associated with any discovery method, a target object is created with the specified parameters. After using this command to modify a target’s parameters, the new parameters will persist until they are modified or removed with a `iscsiadm remove target-param` command on that target. The options `-C` and `-CHAP-secret` require a CHAP secret entry in response to a prompt.

Options for modify target-param are as follows:
-B, --bidirectional-authentication enable | disable
   Sets the bidirectional option. If set to enable, the initiator performs bidirectional
   authentication for the specified target.

-C, --CHAP-secret
   Sets the target's CHAP secret value. There is no default value. Maximum acceptable
   length is 16 characters.

-c, --configured-sessions <num_sessions> | <IP address>[,<IP address>...]
   Sets the number of configured iSCSI sessions that will be created for each iSCSI target.
   The feature should be used in combination with the Solaris I/O multipathing feature
   described in scsi_vhci(7D).

-d, --datadigest none | CRC32
   Sets whether CRC32 is enabled or disabled for the data.

-H, --CHAP-name CHAP name
   Sets a CHAP username. If you do not use this option, upon initialization, the CHAP
   name is set to the target name. When the authentication method is set to CHAP (see
   -a/--authentication option, under the initiator-node direct object, above), the
   CHAP username is displayed with the command iscsiadm list initiator-node.

-h, --headerdigest none | CRC32
   Sets whether CRC32 is enabled or disabled for the header.

-p, --login-param
   Specify one or more login parameter settings.

   Note – These values should only be modified by an administrator with a good working
   knowledge of the parameter’s impact within the iSCSI network.

   The login parameters are derived from iSCSI proposed standard RFC 3720. Valid values
   are:

   dataseqinorder yes or no
   defaulttime2retain 0–3600
   defaulttime2wait 0–3600
   firstburstlength 512 to $2^{24}$–1
   immediatedata yes or no
   initialr2t yes or no
   maxburstlength 512 to $2^{24}$–1
   datapduinorder yes or no
   maxoutstandingr2t 1 to 65535
   maxrecvdataseglen 512 to $2^{24}$–1
Specify one or more tunable parameters for all targets that initiator node connected.

**Note** – Tunable values should only be modified by an administrator with a good working knowledge of the parameter’s impact within the iSCSI network.

Supported tunable-prop options are:

**recv-login-rsp-timeout**
Session Login Response Time

The `recv-login-rsp-timeout` option specifies how long iSCSI initiator will wait for the response of iSCSI session login request from the iSCSI target. Valid value is from 0 to 60*60, default to 60 seconds.

**conn-login-max**
Maximized Connection Retry Time

The `conn-login-max` option lets the iSCSI initiator reestablish the connection to the target in case of IO timeout or connection failure during the given time window. Valid value is from 0 to 60*60, default to 180 seconds.

**polling-login-delay**
Login Retry Time Interval

The `polling-login-delay` option specifies the time interval between each login retry when iSCSI initiator to target IO timeout or connection failure. Valid value is from 0 to 60*60, default to 60 seconds.

**remove Subcommand**

The syntax for the `remove` subcommand is:

```
# iscsiadm remove direct_object
```

The `remove` subcommand supports the following `direct_objects`:

**discovery-address**

Removes a target device from the list of discovery addresses. A discovery address (as in the syntax shown below) is an IP address-port combination used in a SendTargets discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. If any target exposed by the discovery address is currently mounted or there is active I/O on the device, an error of “logical unit in use” is returned and the operation fails. If the associated devices are not in use, they are removed.

`discovery-address` must be formatted as:

```
<IP address>[:<port>]
```

There are no options associated with this direct object.
isns-server

Removes an iSNS server from the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. If any target discovered by means of iSNS is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If the associated devices are not in use, they are removed.

isns-server must be formatted as:

IP_address[:port]

There are no options associated with this direct object.

static-config

Removes a target from the list of statically discovered targets. If the target being removed is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If a device is not in use, it will be removed.

static_target must be formatted as:

<target-name>, <target-address>[:port-number] [tpgt]

There are no options associated with this direct object.

target-param

Removes target specified by target-name. The target name is formatted as:

<target-name>

There are no options associated with this direct object.

Proper Use of Discovery Methods

Do not configure a target to be discovered by both static and dynamic discovery methods. The consequence of using redundant discovery methods might be slow performance when communicating with the iSCSI target device.

Options

The following generic options are supported:

- V, --version Displays version information. Stops interpretation of subsequent arguments.

- ?, --help Displays help information. Can be used following an iscsiadm command with no arguments, following a subcommand, or following a subcommand-direct object combination. Responds with help information appropriate for your entry. For example, if you enter:

# iscsiadm modify initiator-node --help

...iscsiadm responds with a display of the options available for that combination of subcommand and direct object.
**Examples**

**EXAMPLE 1** Adding a Discovery Address

The following command uses the `add` subcommand to add a discovery address.

```
# iscsiadm add discovery-address 10.0.0.1:3260 10.0.0.2:3260
```

**EXAMPLE 2** Adding a Static Target

The following command uses the `add` subcommand to add a static target.

```
# iscsiadm add static-config \ 
  iqn.1999-08.com.array:sn.01234567,10.0.0.1:3260
```

**EXAMPLE 3** Listing Current Discovery Settings

The following command uses the `list` subcommand to list current discovery settings.

```
# iscsiadm list discovery
Discovery:
  Static: enabled
  Send Targets: disabled
  iSNS: enabled
```

**EXAMPLE 4** Obtaining Verbose Discovery Output

The following commands use the `-v` option (one with, one without) with the `list` subcommand to obtain verbose output.

```
# iscsiadm list discovery-address
  Discovery Address: 10.0.0.1:3260
  Discovery Address: 10.0.0.2:3260

# iscsiadm list discovery-address -v 10.0.0.1:3260
  Discovery Address: 10.0.0.1:3260
    Target name: eui.210000203787d1f7
    Target address: 10.0.0.1:3260
    Target name: eui.210000203787a693
    Target address: 10.0.0.1:3260
```

**EXAMPLE 5** Displaying Information on the Initiator

The following command uses the `list` subcommand to display information on the initiator.

```
# iscsiadm list initiator-node
Initiator node name: iqn.1986-03.com.company.central.interopv20-1
Initiator node alias: interopv20-1
  Login Parameters (Default/Configured):
    Header Digest: NONE/NONE
    Data Digest: NONE/NONE
  Authentication Type: CHAP
    CHAP Name: iqn.1986-03.com.company.central.interopv20-1
    RADIUS Server: NONE
EXAMPLE 5  Displaying Information on the Initiator  (Continued)

RADIUS access: disabled
Tunable Parameters (Default/Configured):
  Session Login Response Time: 60/-
  Maximum Connection Retry Time: 180/-
  Login Retry Time Interval: 60/-
Configured Sessions: 1

EXAMPLE 6  Displaying Static Configuration Information

The following command uses the list subcommand to display information about static configurations.

# iscsiadm list static-config
  Static target: eui.210000203787a693,10.0.0.1:3260

EXAMPLE 7  Displaying Target Information

The following commands show the use of the list subcommand with various options to display information about targets.

# iscsiadm list target
    Alias: -
    TPGT: 12288
    ISID: 4000002a0000
    Connections: 1
# iscsiadm list target -v iqn.2004-05.com.abcStorage:Tgt-1
    Alias: -
    TPGT: 12288
    ISID: 4000002a0000
    Connections: 1
    CID: 0
      IP address (Local): 10.4.52.158:32803
      IP address (Peer): 10.4.49.70:3260
      Discovery Method: SendTargets
      Login Parameters (Negotiated):  
        Data Sequence In Order: yes
        Data PDU In Order: yes
        Default Time To Retain: 20
        Default Time To Wait: 2
        Error Recovery Level: 0
        First Burst Length: 65536
        Immediate Data: yes
        Initial Ready To Transfer (R2T): yes
        Max Burst Length: 262144
        Max Outstanding R2T: 1
        Max Receive Data Segment Length: 65536
EXAMPLE 7 Displaying Target Information (Continued)

Max Connections: 1
Header Digest: NONE
Data Digest: NONE

# iscsiadm list target -S iqn.2004-05.com.abcStorage:Tgt-1
Alias: -
TPGT: 12288
ISID: 4000002a0000
Connections: 1
LUN: 6
   Vendor: ABCStorage
   Product: iSCSI Target
   OS Device Name: /dev/rdsk/c3t1d0s2
LUN: 5
   Vendor: ABCStorage
   Product: iSCSI Target
   OS Device Name: /dev/rdsk/c3t0d0s2

EXAMPLE 8 Displaying Target Parameter Information

The following command uses the list subcommand to display target information for a specific target.

# iscsiadm list target-param -v iqn.2004-05.com.abcStorage:Tgt-1
Alias: -
   Bi-directional Authentication: disabled
   Authentication Type: NONE
Login Parameters (Default/Configured):
   Data Sequence In Order: yes/-
   Data PDU In Order: yes/-
   Default Time To Retain: 20/-
   Default Time To Wait: 2/-
   Error Recovery Level: 0/-
   First Burst Length: 65536/-
   Immediate Data: yes/-
   Initial Ready To Transfer (R2T): yes/-
   Max Burst Length: 262144/-
   Max Outstanding R2T: 1/-
   Max Receive Data Segment Length: 65536/-
   Max Connections: 1/-
   Header Digest: NONE/-
   Data Digest: NONE/-
Tunable Parameters (Default/Configured):
   Session Login Response Time: 60/-
   Maximum Connection Retry Time: 180/-
EXAMPLE 8  Displaying Target Parameter Information  
(Continued)
   Login Retry Time Interval: 60/-
   Configured Sessions: 1

EXAMPLE 9  Enabling Static Discovery Method
The following command uses the modify subcommand to enable the static discovery method.
   # iscsiadm modify discovery --static enable

EXAMPLE 10  Setting the IP Address for the Radius Server
The following command uses the modify subcommand to set the IP address for the radius server, which will be used for CHAP authentication.
   # iscsiadm modify initiator --radius-server 10.0.0.1

EXAMPLE 11  Setting the Node Name for Initiator
The following command uses the modify subcommand to set the node name for the initiator node.
   # iscsiadm modify initiator-node -N iqn.2004-10.com.SUN.host-1

EXAMPLE 12  Changing Target Parameters
The following command uses the modify subcommand to change the target parameters for a specified target.
   # iscsiadm modify target-param -d none -h none eui.210000203787a693

EXAMPLE 13  Removing a Discovery Address
The following command uses the remove subcommand to remove a discovery address.
   # iscsiadm remove discovery-address 10.0.0.1:3260

EXAMPLE 14  Removing Target Parameters
The following command uses the remove subcommand to remove a set of target parameters.
   # iscsiadm remove target-param eui.210000203787a693

*System Administration Guide: Devices and File Systems*
The `iscsitadm` command enables you to manage Internet SCSI (iSCSI) target nodes. It is a companion to `iscsiadm(1M)`, which enables you to manage iSCSI initiator nodes.

The `iscsitadm` command has the following subcommands:

- **create**: Creates a target using a local target as a reference.
- **modify**: Modifies a target or a list of targets.
- **delete**: Deletes a target or a list of targets.
- **list**: Lists names and information about targets.
- **show**: Displays target-related statistics.

The preceding subcommands work on the following objects:

- **target**: An iSCSI target node, or list of target nodes.
- **initiator**: An iSCSI initiator node, or list of initiator nodes.
- **admin**: Stores administrative information, such as server locations and passwords.
- **tpgt**: Stands for TargetPortGroupTag. A number that represents a list of connections that an initiator can use for a given target.
- **stats**: Displays statistics; can accept interval and count values. Used only with the `show` subcommand.

These objects are discussed in greater detail under the options descriptions for each subcommand.
As indicated in the SYNONYM, `iscsitadm` has two levels of help. If you invoke `-?` or `--help` following a subcommand, the command displays available operands, options, and objects. If you invoke an help option following an object, `iscsitadm` displays options and operands.

**Options**
The `iscsitadm` options and objects are discussed below in the context of each subcommand. Note that the help options (-? or `--help`) are invoked as shown in the SYNONYM. See EXAMPLES.

**create Options**
The following are the options and objects for the create subcommand:

```bash
target -z lun_size [-l lun number]
    [--type disk|tape|raw] [-b pathname] local_name
```
Create a target using `local_name` as a reference. `local_name` is only used within the context of `iscsitgtd`. `--size` is a multiplier and is specified as a number followed by a single letter. The letter is one of:

- k kilobyte
- m megabyte
- g gigabyte
- t terabyte

`-l` specifies the logical unit number. `--type` specifies which type of emulation will occur for the LUN. `disk` and `tape` are the familiar devices. `raw` indicates that the emulator will use the uSCSI interface and pass the command blocks directly to and from the device. The use of `raw` also implies the option `-b` will be entered. The argument to this option is the full pathname to the device node normally found in `/dev`. If you use `-b`, the size of the store is determined by a SCSI `READ_CAPACITY` command or, if the backing store is a regular file, by `stat(2)`.

If `local_name` already exists, a new target name is not generated for this LUN. The LUN is created within the `local_name` storage hierarchy. You can use the `-b` option to specify a different location for the data. If you use `-b`, it is up to you to allocate actual storage instead of having the target create the data file.

```bash
initiator -i iqn -n iSCSI_node_name local_initiator
```
To use access control lists you must know the name of the initiator. Since the iSCSI initiator name can be quite long (223 bytes) and made up of a long list of numbers, it is best to enter this information once and then refer to the initiator using a simplified name of `local_initiator`.

```bash
tpgt tpgt_number
```
If a host has multiple NICs, you might want to limit the number of connections that an initiator can use for a given target. To establish this limit, you must first create a TargetPortGroupTag (TPGT), which can be any number from 1 to 65535. Once this tag is created, the IP addresses of the NICs can be added to the TPGT, using the `modify`
subcommand. Then, the TPGT can itself be added to the target.

modify Options

The following are the options and objects for the modify subcommand:

- **target --tpgt|p local_tpgt local_target**
  Specifies one or more target portal groups to use when initiators reference local_target during discovery.

- **target --acl|-l local_initiator local_target**
  Adds to the list a local initiator that can access local_target. By adding an initiator to a target all initiators from that point on must be in the ACL.

- **target --alias|-a TargetAlias local_target**
  Sets the alias if it was not done during the creation of the target or change an existing target’s alias.

- **target --maxrecv|-m value local_target**
  Sets the MaxRecvDataSegmentLength, which can be any value between 512 to \((2^{24} - 1)\). You can use this option to limit the amount of memory used by the target.

- **initiator --chap-secret|-C local_initiator**
  Prompts the user to enter the value, using `getpassphrase(3C)`. Associates the secret used for CHAP authentication during login with local_initiator.

- **initiator --chap-name|-H value local_initiator**
  Specifies the CHAP username used during authentication.

- **tpgt --ip-address|-i address tpgt_number**
  Adds the NIC’s address to tpgt_number.

- **admin --base-directory|-d directory**
  Sets the location of where to store the data files that represent the individual LUNs. This should be done before any other function is performed. Otherwise, an error will be generated when attempting to set a persistent value.

- **admin --chap-secret|-C**
  Upon entering this option, you will be prompted to enter the value using `getpassphrase(3C)`. For bidirectional authentication, this is the value used to generate a response to the initiator’s challenge.

- **admin --chap-name|-H value**
  Specifies the user name portion of the CHAP protocol.
admin --radius-access|-R enable|disable

Enables or disables the use of the RADIUS server. Even with a RADIUS server address defined, the use of that server must be enabled. If the server becomes inaccessible and you need to fall back on configuration file access, you can use this option to disable the server.

admin --radius-server|-r hostname:port

Location of RADIUS server. hostname can be either a resolvable name or an IP address.

admin --radius-secret|-P

Used to initiate contact with the RADIUS server. Interaction with server uses getpassphrase(3C).

admin --isns-access|-S enable|disable

Enables or disables access to an iSNS server. iSNS servers broadcast their locations.

admin --isns-server|-s hostname

Location of the iSNS server. "hostname" can be either a resolvable host name or an IP address.

admin --fast-write-ack|-f enable|disable

Enables or disables fast-write acknowledgment. You should enable this option only if a system is connected to the power grid through a UPS. Otherwise, data corruption could occur if power is lost and some writes that were acknowledged have not been completely flushed to the backing store.

delete Options

The following are the options and objects for the delete subcommand:

target --lun|-u lun_number local_target

Removes information about the LUN identified by lun_number. This includes the data that is stored in the LUNs.

target --acl|-l local_initiator local_target

Remove access to local_target by local_initiator. If the initiator is currently logged into the target, this option sends an asynchronous event message to the initiator.

target --tpgt|-p local_tpgt local_target

Removes the local_tpgt from local_target. Does not affect existing connections.
initiator --all|-A local_initiator

Removes information about local_initiator. Does not affect current connections. This option search all targets, seeking those that reference local_initiator. On these, it performs the action defined by the command:

```
# iscsitadm delete target --acl local_initiator target
```

tpgt --all|-A tpgt_number

Removes from the system all knowledge of the target portal group identified by tpgt_number. This includes removal of the references by targets to this group.

tpg --ip-address|-i address tpgt_number

Removes a NIC’s address from the target portal group identified by tpgt_number. Does not affect current connections.

The following are the options and objects for the list subcommand:

target [--verbose] [local_target]
target [-v|-s num] [local_target]

By default, displays a list of target local names followed by the iSCSI TargetName, as it was created. By specifying local_target, the same information is displayed for that target and can be used to validate the name of local_target. With the --verbose option, information about the target’s LUNs and current connections is displayed.

You can use the iostat(1M) command to obtain information on the number of SCSI commands issued and sectors read and written.

initiator [--verbose|-v] local_initiator

Displays detailed information about local_initiator. Among this data is CHAP information, what target portal groups this initiator belongs to, and any available connections.

tpgt [--verbose|-v] tpgt_number

Displays detailed information about target group identified by tpgt_number. Among this data is the list of NICs that are a part of this target group.

The following are the options and objects for the show subcommand:
admin
Displays a list of administrative information, including the base directory used by the
target, CHAP, RADIUS, iSNS, and if fast writes are enabled.

stats [ - - interval | - I seconds | - - count | - N value ] [ local_target ]
Displays statistics for all available targets, unless you specify local_target, in which case,
displays statistics only for local_target. If you use - - interval, displays statistics for an
interval specified by seconds. If you do not specify - - count, the display continues until you
enter a Control-C.

Examples

EXAMPLE 1  Invoking Help
All of the commands shown below are valid ways of invoking help.

# iscsitadm -?
# iscsitadm modify -?
# iscsitadm modify target -?
# iscsitadm --help
# iscsitadm create --help
# iscsitadm create tpgt --help

EXAMPLE 2  Establishing Backing Store
The following command establishes the default location for the backing store. In addition to
the backing store, certain configuration files will be stored in the same location.

# iscsitadm modify admin --base-directory /zfs/data/targets

The short form of the - - base-directory option is - d.

EXAMPLE 3  Simplest-Case Target Creation
The following command creates a target that will emulate an LBA device that has 10 GB of
storage available. With the base directory set up and as well as a single target, it is possible to
use the system as an iSCSI target. Note that because the LUN is not specified on the command
line, it reverts to the default, 0.

# iscsitadm create target --size 10g play_area

The short form of the - - size option is - z.

EXAMPLE 4 Creating with Both Size and Backing Store
The following iscsitadm create command specifies LUN size and a backing store location.
The result of this command is that the daemon will create a LUN file at the named location, of
the specified size (20 GB).

# iscsitadm create target -z 20g -b /zfs/mirror/data/payroll payroll

A target such as the one created by the preceding command might be useful, for example,
when most of the LUN can be created in a default area, using whatever redundancy is
EXAMPLE 4  Creating with Both Size and Backing Store  (Continued)

provided by the underlying file system. Alternatively, you might want to create a special LUN
on a higher speed storage medium or one with better failover characteristics.

The long form of the -z option is --size. The long form of the -b option is --backing-store

EXAMPLE 5  Specifying a Local Name for a SCSI Initiator

Consider that you want to restrict access to the payroll target, created in the previous
example, to a limited set of initiators. Because the initiator names can be quite long (and
therefore prone to be entered incorrectly), you create a local name for each initiator, as in the
command below.

# iscsitadm create initiator --iqn \
iqn.1986-03.com.example [node name continues...] multistrada

The short form of the --iqn option is -q.

EXAMPLE 6  Granting an Initiator Access to a Target

Upon completion of the command below, only the initiator multistrada is allowed to log
into the daemon and access the payroll target. This presents a potential gap in security,
which is addressed in the following example.

# iscsitadm modify target --acl multistrada payroll

The short form of the --acl option is -l.

EXAMPLE 7  Adding CHAP Secret and Name for an Initiator

The initiator is allowed to identify itself. Because of this, it is prudent to add a CHAP secret an
name for an initiator. This is accomplished with the following command.

# iscsitadm modify initiator -C multistrada

The preceding command prompts you for a secret to use. This must be the same secret that
was setup on the initiator with the local name of multistrada. If it is not, the target daemon
will issue a challenge to multistrada when it attempts to login. A non-matching response will
cause the target to drop the connection. If you have many targets that require authentication,
it is probably best to setup a RADIUS server to administer the secrets.

The long form of the -C option is --chap-secret.

EXAMPLE 8  Displaying Target Information

The following commands displays information about iSCSI targets.

# iscsitadm list target
Target: vol0
   iSCSI Name: iqn.1986-03.com.sun:01:00093d12170c.434c5250.vol0
EXAMPLE 8  Displaying Target Information (Continued)

Target: disk0
    iSCSI Name: iqn.1986-03.com.sun:01:00093d12170c.434c6f05.disk0

The following command differs from the preceding in that it uses the verbose (-v) option and it specifies a single target.

# iscsitadm list target -v vol0
Target: vol0
    iSCSI Name: iqn.1986-03.com.sun:01:00093d12170c.434c5250.vol0
    ACL list:
    TPGT list:
    LUN information:
        LUN: 0
            GUID: 010000093d12170c00002a00434c5251
            VID: SUN
            PID: SOLARIS
            Type: raw
            Size: 0x1400000 blocks

EXAMPLE 9  Displaying Administrative Information

The following command uses the show subcommand to display administrative information.

# iscsitadm show admin
iscsitadm:
        Base Directory: /zfs/stress/play/targets
        CHAP Name: Not set
        RADIUS Access: Not set
        RADIUS Server: Not set
        iSNS Access: Not set
        Fast Write ACK: Not set

EXAMPLE 10  Displaying Statistics

The following command uses the show subcommand to display statistics.

# iscsitadm show stats
device      operations      bandwidth
            read  write  read  write
----------------------  ------  ------  ------  ------
  vol0             0    0     0K    0K
  disk0            0    0     0K    0K

Exit Status  0    Command successful.
>0    An error occurred.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>

<td>Volatile</td>
</tr>
</tbody>
</table>

See Also  iostat(1M), iscsadm(1M), getpassphrase(3C), attributes(5), rbac(5), smf(5)

Notes  This command set is considered to be experimental. Future releases, both minor and micro, might introduce incompatible changes to the command set. A future release will stabilize the command set. Any future changes in stability level will be reflected in the ATTRIBUTES section of this man page.

The iSCSI Target daemon, iscsitgt, is managed by the service management facility (smf(5)), under the fault management resource identifier (FMRI):

tvc/system/iscsitgt:default

Use iscsitadm to perform administrative actions, such as are performed by the create, modify, and delete subcommands, on iSCSI Target properties. Such actions require that you become superuser or assume the Primary Administrator role. See rbac(5).
The `iscsitgtd` daemon process implements the iSCSI configuration, control, and data paths, providing iSCSI Target Mode support in the Solaris operating system.

The configuration and control path is by means of the Solaris Doors subsystem (see `door_create(3DOOR)`), and provides the interface between the iSCSI Target administration utility, `iscsitadm(1M)`, persistence configuration data stored in `/etc/iscsi/target_config.xml` and the operational state of the daemon process itself.

The data path, managed by the daemon, exists between TPC/IP port 3260, and the files, block devices, or raw SCSI devices configured as iSCSI target LUNs.

### Options

The following options are supported:

- `-c config_file`
  Override the location of the persistence configuration data from `/etc/iscsi/target_config.xml` to a file location of one's choosing.

- `-d door_file`
  Override the location of the Solaris Door used for configuration from `/var/run/iscsi_tgt_door` to a door of one's choosing.

### Files

- `/etc/iscsi/target_config.xml`
  Persistent configuration data.

### Notes

The iSCSI Target daemon, `iscsitgtd`, is managed by the service management facility, `smf(5)`, under the fault management resource identifier:

`svc:/system/iscsitgt:default`
The `itu` utility converts driver packages to Driver Update (DU) format and patches a Solaris install media with driver packages and patches for Install Time Update (ITU). `itu` has three subcommands: `makedu`, `updatemedia` and `makeiso`.

### Description
The `itu` utility converts driver packages to Driver Update (DU) format and patches a Solaris install media with driver packages and patches for Install Time Update (ITU). `itu` has three subcommands: `makedu`, `updatemedia` and `makeiso`.

### Options
The following options are supported:

- `-d output_dir`
  Directory where the Driver Update directory is to be created.

- `-f`
  If `output_dir/DU` or `iso_file` already exists, remove it without asking first.

- `-l iso_label`
  Label/volume name of the ISO image (if `-o` option is specified).

- `-o iso_file`
  Path of the ISO image file to be created. For subcommands `updatemedia` and `makeiso`, it will be a bootable ISO image. This option must be specified for subcommand `makeiso`.

- `-R media_root`
  Top-level directory of on-disk image of Solaris installation media. This option must be specified for subcommand `updatemedia`.

- `-r solaris_release`
  Solaris release number for which the Driver Update is intended. It takes the form of the output of `uname -r`, for example, `5.10`. This option must be specified for subcommand `makedu`.

- `-v`
  Verbose. Multiple `-v` options increase verbosity.

### Sub-commands
The `itu` subcommands are described as follows.

- `makedu`
  The `makedu` subcommand takes one or more driver packages as input and converts them to DU format. At the beginning of an interactive Solaris installation session, these driver updates can be applied to the running kernel, which will then also automatically apply them to the newly installed Solaris at the end of the installation process.

  The `-r` option is required to specify the Solaris release number for which the driver updates apply. The `solaris_release` option argument takes the form `uname - r output`, for example, `5.10` or `5.11`. 
If the -d option is specified, the resulting DU directory tree is placed in the directory `output_dir`.

If the -o option is specified, a (non-bootable) ISO image of the DU directory tree is written in the file `iso_file`. This ISO image can be burned onto a CD/DVD using `cdrw(1)` or `cdrecord(1)` (not a SunOS man page). See the “Examples” section below for an example of creating a DU on a floppy.

At least one of -d and -o option must be specified. If both are specified, then both an ISO image and a directory tree are generated.

The `updatemedia` subcommand takes a list of driver packages and patches as input and applies them to the miniroot of a Solaris install media. It also places them in a subdirectory called ITUs under the Solaris install media's top-level directory:

```
media_root/ITUs
```

When booting a system from the updated media, the patches and packages will be part of the booted Solaris image. They will also be applied to the target system being installed at the end of the installation process.

The -R option must be entered on the command line to specify the Solaris install media. Note that the install media must be on a location that is writable by `itu`.

If the -o option is specified, a bootable ISO image of the patched install media is also created in the file `iso_file`. The ISO image can then be burned onto a CD or DVD.

The `makeiso` subcommand runs `mkisofs(8)` to create a bootable Solaris ISO image of the Solaris install media `media_root` and writes it to the file `iso_file`. The ISO image file can then be burned onto a CD or DVD with utilities such as `cdrw(1)` or `cdrecord(1)`. (Note that `mkisofs(8)` and `cdrecord(1)` are not SunOS man pages.)

**Caution** – The Solaris install media `media-root` must contain the file `boot/grub/stage2_eltorito`, which will be written to the media boot sectors. This file will be modified with some boot information, thus it has to be writable. If necessary, first save a copy, prior to running this subcommand.

**Operands**

The following operands are supported:

- `package [package...]`
  One or more driver packages.

- `pkg_or_patch [pkg_or_patch...]`
  One or more patches or packages.

- `media_root`
  The top-level directory of a Solaris install media.
Examples

EXAMPLE 1  Creating a DU CD/DVD

The following commands create a Driver Update CD/DVD containing the packages `SAMPLEpkg1` and `SAMPLEpkg2`.

```
# itu makedu -r 5.10 -o my.iso SAMPLEpkg1 SAMPLEpkg2
# cdrw -i my.iso
```

EXAMPLE 2  Creating a DU Floppy

The following commands create a Driver Update floppy containing the driver package `MYdriver`.

```
# rmformat -F quick /dev/rdiskette
# mkfs -F pcfs /dev/rdiskette
# mount -F pcfs /dev/rdiskette /mnt
# /usr/bin/itu makedu -r 5.10 -d /mnt /export/MYdriver
# umount /mnt
# dd if=/dev/rdiskette of=floppy.dd
```

The `itu` command above creates the DU directly onto the floppy mounted on `/mnt`. The `dd` invocation stores an image of the floppy in the file `floppy.dd`. This is useful for distributing a DU floppy in file form. From the file, the floppy can then be recreated as follows:

```
# dd if=floppy.dd of=/dev/rdiskette
```

EXAMPLE 3  Patching the Solaris Install Media

The following command patches the Solaris install media in `/export/s10u1` with patch `/opt/patches/123456-07` and driver package `/opt/pkgs/MYdriver`. The command also creates a bootable ISO image with ISO label "MyS10U1" in the file `/tmp/dvd.iso`.

```
# /usr/bin/itu updatemedia -R /export/s10u1 -o /tmp/dvd.iso -l MyS10U1 /opt/patches/123456-07 /opt/pkgs/MYdriver
```

EXAMPLE 4  Creating a Bootable ISO Image

The following commands create the bootable ISO image `mydvd.iso` of the Solaris install image `/export/solaris-10u1` with ISO label "Special-S10".

```
# /usr/bin/itu makeiso -o mydvd.iso -l "Special-S10" /export/solaris-10u1
# cdrw -i mydvd.iso
```

mkisofs(8), (/usr/share/man/man8/mkisofs.8), in the SUNWfsman package (not a SunOS
man page)
**Name**
k5srvutil – host key table (keytab) manipulation utility

**Synopsis**

```
/usr/sbin/k5srvutil operation [-ik] [-f filename]
```

**Description**
The k5srvutil command allows a system manager to list or change keys currently in his keytab or to add new keys to the keytab.

The operand *operation* must be one of the following:

- **list**
  - Lists the keys in a keytab, showing version number and principal name.

- **change**
  - Changes all the keys in the keytab to new randomly-generated keys, updating the keys in the Kerberos server's database to match those by using the *kadmin* protocol. If a key's version number does not match the version number stored in the Kerberos server's database, the operation fails. The old keys are retained so that existing tickets continue to work. If the `-i` flag is specified, `k5srvutil` prompts for *yes* or *no* before changing each key. If the `-k` option is used, the old and new keys are displayed.

- **delold**
  - Deletes keys that are not the most recent version from the keytab. This operation should be used at some point after a change operation to remove old keys. If the `-i` flag is specified, `k5srvutil` asks the user whether the old keys associated with each principal should be removed.

- **delete**
  - Deletes particular keys in the keytab, interactively prompting for each key.

In all cases, the default keytab file is `/etc/krb5.keytab` file unless this is overridden by the `-f` option.

k5srvutil uses the *kadmin(1M)* program to edit the keytab in place. However, old keys are retained, so they are available in case of failure.

**Options**
The following options are supported:

- `-f filename`
  - Specify a keytab file other than the default file, `/etc/krb5.keytab`.

- `-i`
  - Prompts user before changing keys when using the *change* or *delold* operands.

- `-k`
  - Displays old and new keys when using the *change* operand.

Name  kadb – a kernel debugger

Synopsis

SPARC  ok boot device_specifier kadb [-d] [boot-flags]

x86  select (b)oot or (i)nterpreter: b kadb [-d] [boot-flags]

Description  kadb, an interactive kernel debugger, has been replaced by kmdb(1). For backwards compatibility, the methods used to load kadb will be interpreted as requests to load kmdb(1). Unlike with the compatibility link from adb(1) to mdb(1), kmdb(1) will always load in its native user interface mode, regardless of the name used to load it.

kmdb(1) is based on mdb(1), and thus shares mdb's user interface style and feature set. The mdb(1) man page describes the features and operation of mdb. The kmdb(1) man page describes the differences between mdb and kmdb. This man page describes the major changes and incompatibilities between kadb and kmdb.

Consult the Solaris Modular Debugger Guide for a detailed description of both mdb and kmdb.

Major changes  This section briefly lists the major differences between kadb and kmdb. It is not intended to be exhaustive.

Debugger Loading and Unloading  kmdb(1) may be loaded at boot, as with kadb. It may also be loaded after boot, thus allowing for kernel debugging and execution control without requiring a system reboot. If kmdb(1) is loaded after boot, it may be unloaded.

mdb Feature Set  The features introduced by mdb(1), including access to kernel type data, debugger commands (dcmds), debugger modules (dmods), and enhanced execution control facilities, are available under kmdb(1). Support for changing the representative CPU (:x) is available for both SPARC and x86. Furthermore, full execution-control facilities are available after the representative CPU has been changed.

Significant Incompatibilities  This section lists the significant features that have changed incompatibly between kadb and kmdb(1). It is not intended to be exhaustive. All kmdb(1) commands referenced here are fully described in the kmdb(1) man page. A description as well as examples can be found in the Solaris Modular Debugger Guide.

Deferred Breakpoints  The kadb-style “module#symbol::b” syntax is not supported under kmdb(1). Instead, use “::bp module::symbol”.

Watchpoints  The ::wp dcmd is the preferred way to set watchpoint with kmdb. Various options are available to control the type of watchpoint set, including -p for physical watchpoints.
(SPARC only), and -i for I/O port watchpoints (x86 only). Sl is not supported, therefore, the watchpoint size must be specified for each watchpoint created.

Access to I/O Ports (x86 only) The commands used to access I/O ports under kadb have been replaced with the ::in and ::out dcmds. These two dcmds allow both read and write of all I/O port sizes supported by kadb.

Solaris Modular Debugger Guide
Name  
kadmin, kadmin.local – Kerberos database administration program

Synopsis  
/usr/sbin/kadmin [-r realm] [-p principal] [-q query]
[-s admin_server [:port]] [ -c credential_cache]
[ -k [-t keytab]] | [-w password]] [-x db_args]...
/usr/sbin/kadmin.local [-r realm] [-p principal]
[-q query] [-d dbname] [-e "enc: salt..."] [-m] [-D]

Description  
kadmin and kadmin.local are interactive command-line interfaces to the Kerberos V5 administration system. They provide for the maintenance of Kerberos principals, policies, and service key tables (keytabs). kadmin and kadmin.local provide identical functionality; the difference is that kadmin.local can run only on the master KDC and does not use Kerberos authentication.

Except as explicitly noted otherwise, this man page uses kadmin to refer to both versions.

By default, both versions of kadmin attempt to determine your user name and perform operations on behalf of your “username/admin” instance. Operations performed are subject to privileges granted or denied to this user instance by the Kerberos ACL file (see kadm5.acl(4)). You may perform administration as another user instance by using the -p option.

The remote version, kadmin, uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network. It normally prompts for a password and authenticates the user to the Kerberos administration server, kadmind, whose service principal is kadmin/fqdn. Some options specific to the remote version permit the password prompt to be bypassed. The -c option searches the named credentials cache for a valid ticket for the kadmin/fqdn service and uses it to authenticate the user to the Kerberos admin server without a password. The -k option searches a keytab for a credential to authenticate to the kadmin/fqdn service, and again no password is collected. If kadmin has collected a password, it requests a kadmin/fqdn Kerberos service ticket from the KDC, and uses that service ticket to interact with kadmind.

The local version, kadmin.local, must be run with an effective UID of root, and normally uses a key from the /var/krb5/.k5.realm stash file (see kdb5_util(1M)) to decrypt information from the database rather than prompting for a password. The -m option will bypass the .k5.realm stash file and prompt for the master password.

Options  
The following options are supported:

-c credentials_cache
Search credentials_cache for a service ticket for the kadmin/fqdn service; it can be acquired with the kinit(1) program. If this option is not specified, kadmin requests a new service ticket from the KDC, and stores it in its own temporary credentials cache.

-d dbname
Specify a non-standard database name. [Local only]

-D
Turn on debug mode. [Local only]
-e "enc:salt ...
Specify a different encryption type and/or key salt. [Local only]

-k [-t keytab]
Use the default keytab (-k) or a specific keytab (-t keytab) to decrypt the KDC response instead of prompting for a password. In this case, the default principal will be host/hostname. This is primarily used for keytab maintenance.

-m
Accept the database master password from the keyboard rather than using the /var/krb5/.k5.realm stash file. [Local only]

-p principal
Authenticate principal to the kadmin/fqdn service. Otherwise, kadmin will append /admin to the primary principal name of the default credentials cache, the value of the USER environment variable, or the username as obtained with getpwuid, in that order of preference.

-q query
Pass query directly to kadmin, which will perform query and then exit. This can be useful for writing scripts.

-r realm
Use realm as the default database realm.

-s admin_server[:port]
Administer the specified admin server at the specified port number (port). This can be useful in administering a realm not known to your client.

-w password
Use password instead of prompting for one. Note that placing the password for a Kerberos principal with administration access into a shell script can be dangerous if unauthorized users gain read access to the script or can read arguments of this command through ps(1).

-x db_args
Pass database-specific arguments to kadmin. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:

binddn=binddn
LDAP simple bind DN for authorization on the directory server. Overrides the ldap_kadmind_dn parameter setting in krb5.conf(4).

bindpwd=bindpwd
Bind password.

dbname=name
For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

nconns=num
Maximum number of server connections.
port=num
Directory server connection port.

Commands
list_requests
Lists all the commands available for kadmin. Aliased by lr and ?.

get_prives
Lists the current Kerberos administration privileges (ACLs) for the principal that is
currently running kadmin. The privileges are based on the /etc/krb5/kadm5.acl file on
the master KDC. Aliased by getprives.

add_principal [options] newprinc
Creates a new principal, newprinc, prompting twice for a password. If the -policy option is
not specified and a policy named default exists, then the default policy is assigned to the
principal; note that the assignment of the default policy occurs automatically only when a
principal is first created, so the default policy must already exist for the assignment to
occur. The automatic assignment of the default policy can be suppressed with the
-clearpolicy option. This command requires the add privilege. Aliased by addprinc and
ank. The options are:

-expires expdate
Expiration date of the principal. See the Time Formats section for the valid absolute time
formats that you can specify for expdate.

-pwexpire pwexpdate
Password expiration date. See the Time Formats section for the valid absolute time
formats that you can specify for pwexpdate.

-maxlife maxlife
Maximum ticket life for the principal. See the Time Formats section for the valid time
duration formats that you can specify for maxlife.

-maxrenewlife maxrenewlife
Maximum renewable life of tickets for the principal. See the Time Formats section for
the valid time duration formats that you can specify for maxrenewlife.

-ktvno kvno
Explicitly set the key version number.

-policy policy
Policy used by the principal. If both the -policy and -clearpolicy options are not
specified, the default policy is used if it exists; otherwise, the principal will have no
policy. Also note that the password and principal name must be different when you add
a new principal with a specific policy or the default policy.

-clearpolicy
-clearpolicy prevents the default policy from being assigned when -policy is not
specified. This option has no effect if the default policy does not exist.
[-+]allow_postdated
   -allow_postdated prohibits the principal from obtaining postdated tickets. (Sets the
     KRB5_KDB_DISALLOW_POSTDATED flag.) +allow_postdated clears this flag.

[-+]allow_forwardable
   -allow_forwardable prohibits the principal from obtaining forwardable tickets. (Sets
     the KRB5_KDB_DISALLOW_FORWARDABLE flag.) +allow_forwardable clears this flag.

[-+]allow_renewable
   -allow_renewable prohibits the principal from obtaining renewable tickets. (Sets the
     KRB5_KDB_DISALLOW_RENEWABLE flag.) +allow_renewable clears this flag.

[-+]allow_proxiable
   -allow_proxiable prohibits the principal from obtaining proxiable tickets. (Sets the
     KRB5_KDB_DISALLOW_PROXIABLE flag.) +allow_proxiable clears this flag.

[-+]allow_dup_skey
   -allow_dup_skey disables user-to-user authentication for the principal by prohibiting
   this principal from obtaining a session key for another user. (Sets the
     KRB5_KDB_DISALLOW_DUP_SKEY flag.) +allow_dup_skey clears this flag.

[-+]requires_preauth
   +requires_preauth requires the principal to preauthenticate before being allowed to
   kinit. (Sets the KRB5_KDB_REQUIRES_PRE_AUTH flag.) -requires_preauth clears this
   flag.

[-+]requires_hwaouth
   +requires_hwaouth requires the principal to preauthenticate using a hardware device
   before being allowed to kinit. (Sets the KRB5_KDB_REQUIRES_HW_AUTH flag.)
   -requires_hwaouth clears this flag.

[-+]allow_svr
   -allow_svr prohibits the issuance of service tickets for the principal. (Sets the
     KRB5_KDB_DISALLOW_SVR flag.) +allow_svr clears this flag.

[-+]allow_tgs_req
   +allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service
   ticket for the principal is not permitted. This option is useless for most things.
   The default is +allow_tgs_req. In effect, +allow_tgs_req sets the KRB5_KDB_DISALLOW_TGT_BASED
   flag on the principal in the database.

[-+]allow_tix
   +allow_tix forbids the issuance of any tickets for the principal. +allow_tix clears this
   flag. The default is +allow_tix. In effect, -allow_tix sets the
   KRB5_KDB_DISALLOW_ALL_TIX flag on the principal in the database.
needchange
+needchange sets a flag in attributes field to force a password change; --needchange clears it. The default is --needchange. In effect, +needchange sets the KRB5_KDB_REQUIRES_PWCHANGE flag on the principal in the database.

password_changing_service
+password_changing_service sets a flag in the attributes field marking this as a password change service principal (useless for most things).
--password_changing_service clears the flag. This flag intentionally has a long name. The default is --password_changing_service. In effect, +password_changing_service sets the KRB5_KDB_PWCHANGE_SERVICE flag on the principal in the database.

randkey
Sets the key of the principal to a random value.

pw password
Sets the key of the principal to the specified string and does not prompt for a password. Note that using this option in a shell script can be dangerous if unauthorized users gain read access to the script.

e "enc:salt ..."
Override the list of enc:type:salttype pairs given in kdc.conf(4) for setting the key of the principal. The quotes are necessary if there are multiple enc:type:salttype pairs. One key for each similar encType and same saltType will be created and the first one listed will be used. For example, in a list of two similar encTypes with the same salt, “des-cbc-crc:normal des-cbc-md5:normal”, one key will be created and it will be of type des-cbc-crc:normal.

Example:

```
kadmin: addprinc tlyu/admin
WARNING: no policy specified for "tlyu/admin@ACME.COM";
defaulting to no policy.
Enter password for principal tlyu/admin@ACME.COM:
Re-enter password for principal tlyu/admin@ACME.COM:
Principal "tlyu/admin@ACME.COM" created.
kadmin:
```

Errors:

KADM5_AUTH_ADD (requires add privilege)

KADM5_BAD_MASK (should not happen)

KADM5_DUP (principal exists already)

KADM5_UNK_POLICY (policy does not exist)

KADM5_PASS_Q_ (password quality violations)
delete_principal [-force] principal
Deletesthespecifiedprincipalfromthedatabase.Thisscommandpromptsfordeletion,
unlessthe -forceoptionisgiven.Thiscmandorequsthesemotionalell. Aliasedby
delprinc.

Example:

kadmin: delprinc mwm_user
Are you sure you want to delete the principal
"mwm_user@ACME.COM"? (yes/no): yes
Principal "mwm_user@ACME.COM" deleted.
Make sure that you have removed this principal from
all kadmind ACLs before reusing.
kadmin:

Errors:
KADM5_AUTH_DELETE (requires delete privilege)
KADM5_UNK_PRINC (principal does not exist)

modify_principal [options] principal
Modifiesthespecifiedprincipal,changingthefieldsasspecified.Theoptionsareshownabove
for add_principal, except that password changing is forbidden by this command. In
addition, the option -clearpolicy will clear the current policy of a principal. Thiss
cmandorequsthesemotionalell. Aliasedby modprinc.

Errors:
KADM5_AUTH_MODIFY (requires modify privilege)
KADM5_UNK_PRINC (principal does not exist)
KADM5_UNK_POLICY (policy does not exist)
KADM5_BAD_MASK (should not happen)

change_password [options] principal
Changes the password of principal. Prompts for a new password if neither -randkey or -pw
is specified. Requires the changepw privilege, or that the principal that is running the
program to be the same as the one changed. Aliased by cpw. The following options are
available:

- randkey
Sets the key of the principal to a random value.

- pw password
Sets the password to the specified string. Not recommended.
-e "enc:salt..."
   Override the list of enctype:salttype pairs given in kdc.conf(4) for setting the key of the principal. The quotes are necessary if there are multiple enctype:salttype pairs. For each key, the first matching similar enctype and same salttype in the list will be used to set the new key(s).

-keepold
   Keeps the previous kvno's keys around. There is no easy way to delete the old keys, and this flag is usually not necessary except perhaps for TGS keys as it will allow existing valid TGTs to continue to work.

Example:

kadmin: cpw systest
Enter password for principal systest@ACME.COM:
Re-enter password for principal systest@ACME.COM:
Password for systest@ACME.COM changed.

Errors:
   KADM5_AUTH_MODIFY (requires the modify privilege)
   KADM5_UNK_PRINC (principal does not exist)
   KADM5_PASS_Q_* (password policy violation errors)
   KADM5_PASS_REUSE (password is in principal's password history)
   KADM5_PASS_TOOSOON (current password minimum life not expired)

get_principal [-terse] principal
   Gets the attributes of principal. Requires the inquire privilege, or that the principal that is running the program to be the same as the one being listed. With the -terse option, outputs fields as quoted tab-separated strings. Aliased by getprinc.

Examples:

kadmin: getprinc tlyu/admin
Principal: tlyu/admin@ACME.COM
Expiration date: [never]
Last password change: Mon Aug 12 14:16:47 EDT 1996
Password expiration date: [none]
Maximum ticket life: 0 days 10:00:00
Maximum renewable life: 7 days 00:00:00
Last modified: Mon Aug 12 14:16:47 EDT 1996
(example_user/admin@ACME.COM)
Last successful authentication: [never]
Last failed authentication: [never]
Failed password attempts: 0
Number of keys: 2 Key: vno 1, DES cbc mode with CRC-32,
no salt Key: vno 1, DES cbc mode with CRC-32,
Version 4 Attributes:
Policy: [none]

kadmin: **getprinc -terse systest**
systest@ACME.COM 3 86400 604800 1 785926535 753241234
785900000

tlyu/admin@ACME.COM 786100034 0 0
ekadmin:

Errors:
  KADM5_AUTH_GET (requires the get [inquire] privilege)
  KADM5_UNK_PRINC (principal does not exist)

**list_principals [expression]**
Retrieves all or some principal names. *expression* is a shell-style glob expression that can contain the wild-card characters ?, *, and [ ]'s. All principal names matching the expression are printed. If no expression is provided, all principal names are printed. If the expression does not contain an “@” character, an “@” character followed by the local realm is appended to the expression. Requires the list privilege. Aliased by listprincs, get_principals, and getprincs.

Examples:
  kadmin: **listprincs test**
test3@ACME.COM
test2@ACME.COM
test1@ACME.COM
testuser@ACME.COM
ekadmin:

**add_policy [options] policy**
Adds the named policy to the policy database. Requires the add privilege. Aliased by addpol. The following options are available:

- **-maxlife maxlife**
  sets the maximum lifetime of a password. See the Time Formats section for the valid time duration formats that you can specify for maxlife.

- **-minlife minlife**
  sets the minimum lifetime of a password. See the Time Formats section for the valid time duration formats that you can specify for minlife.

- **-minlength length**
  sets the minimum length of a password.

- **-minclasses number**
  sets the minimum number of character classes allowed in a password. The valid values are:
1 only letters (himom)
2 both letters and numbers (hi2mom)
3 letters, numbers, and punctuation (hi2mom!)

-history number
sets the number of past keys kept for a principal.

Errors:
KADM5_AUTH_ADD (requires the add privilege)
KADM5_DUP (policy already exists)

delete_policy [-force] policy
Deletes the named policy. Unless the -force option is specified, prompts for confirmation before deletion. The command will fail if the policy is in use by any principals. Requires the delete privilege. Aliased by delpol.

Example:

    kadmin: del_policy guests
    Are you sure you want to delete the policy "guests"? (yes/no): yes
    Policy "guests" deleted.
    kadmin:

Errors:
KADM5_AUTH_DELETE (requires the delete privilege)
KADM5_UNK_POLICY (policy does not exist)
KADM5_POLICY_REF (reference count on policy is not zero)

modify_policy [options] policy
Modifies the named policy. Options are as above for add_policy. Requires the modify privilege. Aliased by modpol.

Errors:
KADM5_AUTH_MODIFY (requires the modify privilege)
KADM5_UNK_POLICY (policy does not exist)

get_policy [-terse] policy
Displays the values of the named policy. Requires the inquire privilege. With the -terse flag, outputs the fields as quoted strings separated by tabs. Aliased by getpol.
Examples:

```bash
kadmin: get_policy admin
Policy: admin
Maximum password life: 180 days 00:00:00
Minimum password life: 00:00:00
Minimum password length: 6
Minimum number of password character classes: 2
Number of old keys kept: 5
Reference count: 17
kadmin: get_policy -terse
admin admin 15552000 0 6 2 5 17
```

Errors:

- KADM5_AUTH_GET (requires the get privilege)
- KADM5_UNK_POLICY (policy does not exist)

`list_policies [expression]`

Retrieves all or some policy names. `expression` is a shell-style glob expression that can contain the wild-card characters `?`, `*`, and `[ ]`’s. All policy names matching the expression are printed. If no expression is provided, all existing policy names are printed. Requires the `list` privilege. Aliased by `listpols`, `get_policies`, and `getpols`.

Examples:

```bash
kadmin: listpols
  test-pol dict-only once-a-min test-pol-nopw
kadmin: listpols t*
  test-pol test-pol-nopw kadmin:
```

`ktadd [-k keytab] [-q] [-e enctype:salt]`

Adds a principal or all principals matching `princ-exp` to a keytab, randomizing each principal’s key in the process.

`ktadd` requires the `inquire` and `changepw` privileges. An entry for each of the principal’s unique encryption types is added, ignoring multiple keys with the same encryption type but different salt types. If the `-k` argument is not specified, the default keytab file, `/etc/krb5/krb5.keytab`, is used.

The `".-e enctype:salt"` option overrides the list of `enctype` given in `krb5.conf(4)`, in the `permitted_enctypes` parameter. If `".-e enctype:salt"` is not used and `permitted_enctypes` is not defined in `krb5.conf(4)`, a key for each `enctype` supported by the system on which `kadmin` is run will be created and added to the keytab. Restricting the `enctype` of keys in the keytab is useful when the system for which keys are being created does not support the same set of `enctype` as the KDC. Note that `ktadd` modifies the `enctype` of the keys in the principal database as well.
If the `-q` option is specified, less status information is displayed. Aliased by `xst`. The `-glob` option requires the `list privile ge`. Also, note that if you use `-glob` to create a keytab, you need to remove `/etc/krb5/kadm5.keytab` and create it again if you want to use `-p` */admin with `kadmin`.

`princ-exp`

`princ-exp` follows the same rules described for the `list_principals` command.

Example:

```
kadmin: ktadd -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2, encryption type DES-CBC-CRC added to keytab
WRFILE:/tmp/new-keytab.
kadmin:
```

```
kadmin: ktremove [-k keytab] [-q] principal [kvno | all | old]
```

Removes entries for the specified principal from a keytab. Requires no privileges, since this does not require database access. If `all` is specified, all entries for that principal are removed; if `old` is specified, all entries for that principal except those with the highest `kvno` are removed. Otherwise, the value specified is parsed as an integer, and all entries whose `kvno` match that integer are removed. If the `-k` argument is not specified, the default keytab file, `/etc/krb5/krb5.keytab`, is used. If the `-q` option is specified, less status information is displayed. Aliased by `ktrem`.

Example:

```
kadmin: ktremove -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2 removed from keytab
WRFILE:/tmp/new-keytab.
kadmin:
```

```
quit
```

Quits `kadmin`. Aliased by `exit` and `q`.

### Time Formats

Various commands in `kadmin` can take a variety of time formats, specifying time durations or absolute times. The `kadmin` option variables `maxrenewlife`, `maxlife`, and `minlife` are time durations, whereas `expdate` and `pwexpdate` are absolute times.

Examples:

```
kadmin: modprinc -expire "12/31 7pm" jdb
kadmin: modprinc -maxrenewlife "2 fortnight" jdb
kadmin: modprinc -pwexpire "this sunday" jdb
kadmin: modprinc -expire never jdb
kadmin: modprinc -maxlife "7:00:00pm tomorrow" jdb
```

Note that times which do not have the “ago” specifier default to being absolute times, unless they appear in a field where a duration is expected. In that case, the time specifier will be interpreted as relative. Specifying “ago” in a duration can result in unexpected behavior.
The following time formats and units can be combined to specify a time. The time and date format examples are based on the date and time of July 2, 1999, 1:35:30 p.m.

<table>
<thead>
<tr>
<th>Time Format</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>hh:mm:ss[am/pm/a.m./p.m.]</td>
<td>1p.m., 1:35, 1:35:30pm</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variable Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hh</td>
</tr>
<tr>
<td>mm</td>
</tr>
<tr>
<td>ss</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Date Format</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>mm/dd[yy]</td>
<td>07/02, 07/02/99</td>
</tr>
<tr>
<td>yyyy-mm-dd</td>
<td>1999-07-02</td>
</tr>
<tr>
<td>dd-month-yyyy</td>
<td>02-July-1999</td>
</tr>
<tr>
<td>month [yyyy]</td>
<td>Jul 02, July 02,1999</td>
</tr>
<tr>
<td>dd month[yyyy]</td>
<td>02 JULY, 02 july 1999</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variable Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd</td>
</tr>
<tr>
<td>mm</td>
</tr>
<tr>
<td>yy</td>
</tr>
<tr>
<td>yyyy</td>
</tr>
<tr>
<td>month</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Time Units</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>[+</td>
<td>-] # year</td>
</tr>
<tr>
<td>[+</td>
<td>-] # month</td>
</tr>
<tr>
<td>[+</td>
<td>-] # fortnight</td>
</tr>
</tbody>
</table>
You can also use the following time modifiers: first, second, third, fourth, fifth, sixth, seventh, eighth, ninth, tenth, eleventh, twelfth, and ago.

### Environment Variables

See `environ(5)` for descriptions of the following environment variables that affect the execution of `kadmin`:

**PAGER**

The command to use as a filter for paging output. This can also be used to specify options. The default is `more(1)`. 

<table>
<thead>
<tr>
<th>Time Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>week</td>
<td>today</td>
</tr>
<tr>
<td>day</td>
<td>tomorrow</td>
</tr>
<tr>

<tr>
<td>min</td>
<td>“next month”</td>
</tr>
</tbody>
</table>
Files
/var/krb5/principal
   Kerberos principal database.
/var/krb5/principal.ult
   The update log file for incremental propagation.
/var/krb5/principal.kadm5
   Kerberos administrative database. Contains policy information.
/var/krb5/principal.kadm5.lock
   Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, kadmin will exit with an error if this file does not exist).
/var/krb5/kadm5.dict
   Dictionary of strings explicitly disallowed as passwords.
/etc/krb5/kadm5.acl
   List of principals and their kadmin administrative privileges.
/etc/krb5/kadm5.keytab
   Keytab for kadmin principals: kadmin/fqdn, changew/pw/fqdn, and kadmin/changepw.

History
The kadmin program was originally written by Tom Yu at MIT, as an interface to the OpenVision Kerberos administration program.

Diagnostics
The kadmin command is currently incompatible with the MIT kadmin daemon interface, so you cannot use this command to administer an MIT-based Kerberos database. However, clients running the Solaris implementation of Kerberos can still use an MIT-based KDC.
kadmind - Kerberos administration daemon

## Synopsis

```
/usr/lib/krb5/kadmind [-d] [-m] [-p port-number] [-r realm]
                 -x db_args]...
```

## Description

 kadmind runs on the master key distribution center (KDC), which stores the principal and
 policy databases.  kadmind accepts remote requests to administer the information in these
 databases.  Remote requests are sent, for example, by `kpasswd(1)`, `gkadmin(1M)`, and
 `kadmin(1M)` commands, all of which are clients of kadmind. When you install a KDC, kadmind
 is set up in the init scripts to start automatically when the KDC is rebooted.

 kadmind requires a number of configuration files to be set up for it to work:

### /etc/krb5/kdc.conf

The KDC configuration file contains configuration information for the KDC and the
Kerberos administration system. kadmind understands a number of configuration variables
(called relations) in this file, some of which are mandatory and some of which are optional.
In particular, kadmind uses the acl_file, dict_file, admin_keytab, and kadmind_port
relations in the [realms] section. Refer to the `kdc.conf(4)` man page for information
regarding the format of the KDC configuration file.

### /etc/krb5/kadm5.keytab

kadmind requires a keytab (key table) containing correct entries for the `kadmin/fqdn`,
`kadmin/changepw` and `kadmin/changepw` principals for every realm that kadmind answers
requests. The keytab can be created with the `kadmin(1M)` or `kdb5_util(1M)` command.
The location of the keytab is determined by the admin_keytab relation in the `kdc.conf(4)`
file.

### /etc/krb5/kadm5.acl

kadmind uses an ACL (access control list) to determine which principals are allowed to
perform Kerberos administration actions. The path of the ACL file is determined by the
acl_file relation in the `kdc.conf(4)` file. See `kdc.conf(4)`. For information regarding the
format of the ACL file, refer to `kadm5.acl(4)`.

The kadmind daemon will need to be restarted to reread the `kadm5.acl` file after it has been
modified. You can do this, as root, with the following command:

```
# svcadm restart svc:/network/security/kadmin:default
```

After kadmind begins running, it puts itself in the background and disassociates itself from its
controlling terminal.

kadmind can be configured for incremental database propagation. Incremental propagation
allows slave KDC servers to receive principal and policy updates incrementally instead of
receiving full dumps of the database. These settings can be changed in the `kdc.conf(4)` file:

```
suw_dbprop_enable = [true | false]
```

Enable or disable incremental database propagation. Default is false.
sunw_dbprop_master_uologsize = N
    Specifies the maximum amount of log entries available for incremental propagation to the
    slave KDC servers. The maximum value that this can be is 2500 entries. Default value is
    1000 entries.

The kprop/<hostname>@<REALM> principal must exist in the master's kadm5.keytab file
    to enable the slave to authenticate incremental propagation from the master. In the principal
    syntax above, <hostname> is the master KDC's host name and <REALM> is the realm in
    which the master KDC resides.

Kerberos client machines can automatically migrate Unix users to the default Kerberos realm
    specified in the local krb5.conf(4), if the user does not have a valid kerberos account already.
    You achieve this by using the pam_krb5_migrate(5) service module for the service in
    question. The Kerberos service principal used by the client machine attempting the migration
    needs to be validated using the u privilege in kadm5.acl(4). When using the u privilege,
    kadm5 validates user passwords using PAM, specifically using a PAM_SERVICE name of
    k5migrate by calling pam_authenticate(PAM) and pam_acct_mgmt(PAM).

A suitable PAM stack configuration example for k5migrate would look like:

    k5migrate auth required pam_unix_auth.so.1
    k5migrate account required pam_unix_account.so.1

Options
    The following options are supported:

    -d
        Specifies that kadmin does not put itself in the background and does not disassociate itself
        from the terminal. In normal operation, you should use the default behavior, which is to
        allow the daemon to put itself in the background.

    -m
        Specifies that the master database password should be retrieved from the keyboard rather
        than from the stash file. When using -m, the kadmin daemon receives the password prior
        to putting itself in the background. If used in combination with the -d option, you must
        explicitly place the daemon in the background.

    -p port-number
        Specifies the port on which the kadmin daemon listens for connections. The default is
        controlled by the kadmin_port relation in the kdc.conf(4) file.

    -r realm
        Specifies the default realm that kadmin serves. If realm is not specified, the default realm
        of the host is used. kadmin answers requests for any realm that exists in the local KDC
        database and for which the appropriate principals are in its keytab.

    -x db_args
        Pass database-specific arguments to kadmin. Supported arguments are for LDAP and the
        Berkeley-db2 plug-in. These arguments are:
binddn=binddn
   LDAP simple bind DN for authorization on the directory server. Overrides the
   ldap_kadmind_dn parameter setting in krb5.conf(4).

bindpwd=bindpwd
   Bind password.

dbname=name
   For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

nconns=num
   Maximum number of server connections.

port=num
   Directory server connection port.

Files
/var/krb5/principal
   Kerberos principal database.

/var/krb5/principal.ulong
   The update log file for incremental propagation.

/var/krb5/principal.kadm5
   Kerberos administrative database containing policy information.

/var/krb5/principal.kadm5.lock
   Kerberos administrative database lock file. This file works backwards from most other lock
   files (that is, kadmin exits with an error if this file does not exist).

/var/krb5/kadm5.dict
   Dictionary of strings explicitly disallowed as passwords.

/etc/krb5/kadm5.acl
   List of principals and their kadmin administrative privileges.

/etc/krb5/kadm5.keytab
   Keytab for kadmin principals: kadmin/fqdn, changepw/fqdn, and kadmin/changepw.

/etc/krb5/kdc.conf
   KDC configuration information.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWkdcu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>
The Kerberos administration daemon (kadmind) is now compliant with the change-password standard mentioned in RFC 3244, which means it can now handle change-password requests from non-Solaris Kerberos clients.

The kadmind service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/security/kadmin

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
The kcfd daemon helps in managing CPU usage by cryptographic operations performed in software by kernel threads. The system utilization associated with these threads is charged to the kcfd process. It also does module verification for kernel cryptographic modules.

Only a privileged user can run this daemon.

The kcfd daemon is automatically invoked in run level 1, after /usr is mounted. A previously invoked kcfd daemon that is still running must be stopped before invoking another kcfd command.

Manually starting and restarting kcfd is not recommended. If it is necessary to do so, use the cryptoadm(1M) start and stop subcommands.

The following exit values are returned:

- 0 Daemon started successfully.
- > 1 Daemon failed to start.

See attributes(5) for descriptions of the following attributes:

<td>Evolving</td>
</tr>
</tbody>
</table>

See Also cryptoadm(1M), attributes(5)
You can use the `kclient` utility to:

- Configure a machine as a Kerberos client for a specified realm and for KDC by setting up `krb5.conf(4)`.
- Add the Kerberos host principal to the local host’s `keytab` file (`/etc/krb5/krb5.keytab`).
- Optionally set up the machine to do kerberized NFS.
- Optionally bring over a master `krb5.conf` copy from a specified pathname.
- Optionally setup a machine to do server and/or host/domain name-to-realm mapping lookups by means of DNS.

The `kclient` utility needs to be run on the client machine with root permission and can be run either interactively or non-interactively. In the non-interactive mode, the user feeds in the required inputs by means of a profile, command-line options, or a combination of profile and command-line options. The user is prompted for “required” parameter values (`realm`, `kdc`, and `adminuser`), if found missing in the non-interactive run. The interactive mode is invoked when the utility is run without any command-line arguments.

Both the interactive and non-interactive forms of `kclient` always add the `host/fqdn` entry to the local host’s `keytab` file. They also require the user to enter the password for the administrative user requested, to obtain the Kerberos Ticket Granting Ticket (TGT) for `adminuser`. The `host/fqdn`, `nfs/fqdn`, and `root/fqdn` principals are added to the KDC database (if not already present) before their addition to the local host’s `keytab`.

The `kclient` utility assumes that the local host has been setup for DNS and requires the presence of a valid `resolv.conf(4)`. Also, `kclient` can fail if the localhost time is not synchronized with that of the KDC. For Kerberos to function the localhost time must be within five minutes of that of the KDC. It is advised that both systems run some form of time synchronization protocol, such as the Network Time Protocol (NTP). See `xntpd(1M)`.

**Options**

The non-interactive mode supports the following options:

- `-n` Set up the machine for kerberized NFS. This involves making changes to `nfssec.conf(4)` and addition of the `nfs/fqdn` and `root/fqdn` entries to the local host's `keytab` file.
- `-R [ realm ]` Specifies the Kerberos realm.
- `-k [ kdc ]` Specifies the machine to be used as the Kerberos Key Distribution Center (KDC).
- `-a [ adminuser ]` Specifies the Kerberos administrative user.
-c [filepath] Specifies the pathname to the krb5.conf(4) master file, to be copied over to the local host. The path specified normally points to a master copy on a remote host and brought over to the local host by means of NFS.

-\(d\) [dnsarg] Specifies the DNS lookup option to be used and specified in the krb5.conf(4) file. Valid dnsarg entries are: none, dns_lookup_kdc, dns_lookup_realm and dns_fallback. Any other entry is considered invalid. The latter three dnsarg values assume the same meaning as those described in krb5.conf. dns_lookup_kdc implies DNS lookups for the KDC and the other servers. dns_lookup_realm is for host/domain name-to-realm mapping by means of DNS. dns_fallback is a superset and does DNS lookups for both the servers and the host/domain name-to-realm mapping. A lookup option of none specifies that DNS is not be used for any kind of mapping lookup.

-\(f\) [fqdn_list] This option creates a service principal entry (host/nfs/root) associated with each of the listed fqdn's, if required, and subsequently adds the entries to the local host’s keytab.

fqdn_list is a comma-separated list of one or more fully qualified DNS domain names.

This option is especially useful in Kerberos realms having systems offering kerberized services, but situated in multiple different DNS domains.

-\(p\) [profile] Specifies the profile to be used to enable the reading in of the values of all the parameters required for setup of the machine as a Kerberos client.

The profile should have entries in the format:

PARAM <value>

Valid PARAM entries are: REALM, KDC, ADMIN, FILEPATH, NFS, DNSLOOKUP, and FQDN. These profile entries correspond to the -R [realm], -k [kdc], -a [adminuser], -c [filepath], -n, -d [dnsarg], and -\(f\) [fqdn_list] command-line options, respectively. Any other PARAM entry is considered invalid and is ignored.

The NFS profile entry can have a value of 0 (do nothing) or 1 (operation is requested). Any other value is considered invalid and is ignored.

Keep in mind that the command line options override the PARAM values listed in the profile.
Examples

EXAMPLE 1  Setting Up a Kerberos Client Using Command-Line Options

To setup a Kerberos client using the clntconfig/admin administrative principal for realm 'ABC.COM', kdc 'example1.com' and that also does kerberized NFS, enter:

# /usr/sbin/kclient -n -R ABC.COM -k example1.com -a clntconfig

Alternatively, to set up a Kerberos client using the clntconfig/admin administrative principal for the realm 'EAST.ABC.COM', kdc 'example2.east.abc.com' and that also needs service principal(s) created and/or added to the local keytab for multiple DNS domains, enter:

# /usr/sbin/kclient -n -R EAST.ABC.COM -k example2.east.abc.com \ 
  -f west.abc.com,central.abc.com -a clntconfig

Note that the krb5 administrative principal used by the administrator needs to have only add, inquire, change-pwd and modify privileges (for the principals in the KDC database) in order for the kclient utility to run. A sample kadm5.acl(4) entry is:

clntconfig/admin@ABC.COM acmi

EXAMPLE 2  Setting Up a Kerberos Client Using the Profile Option

To setup a Kerberos client using the clntconfig/admin administrative principal for realm 'ABC.COM', kdc 'example1.com' and that also copies over the master krb5.conf from a specified location, enter:

# /usr/sbin/kclient -p /net/example1.com/export/profile.krb5

The contents of profile.krb5:

REALM ABC.COM
KDC example1
ADMIN clntconfig
FILEPATH /net/example1.com/export/krb5.conf
NFS 0
DNSLOOKUP none

Files

/etc/krb5/kadm5.acl  Kerberos access control list (ACL) file.
/etc/krb5/krb5.conf  Default location for the local host's configuration file.
/etc/krb5/krb5.keytab Default location for the local host's keytab file.
/etc/nfssec.conf  File listing NFS security modes.
/etc/resolv.conf  DNS resolver configuration file.

Attributes  See attributes(5) for descriptions of the following attributes:
### ATTRIBUTES

<table>

### See Also

`xntpd(1M), kadm5. acl(4), krb5.conf(4), nfssec.conf(4), resolv.conf(4), attributes(5)`

### Notes

`fqdn` stands for the Fully Qualified Domain Name of the local host. The `kclient` utility saves copies of both the `krb5.conf(4)` and `nfssec.conf(4)` files to files with corresponding names and `.sav` extensions. The optional copy of the `krb5.conf(4)` master file is neither encrypted nor integrity-protected and it takes place over regular NFS.
kdb5_ldap_util - Kerberos configuration utility

Name  kdb5_ldap_util – Kerberos configuration utility

Synopsis  kdb5_ldap_util [-D user_dn [-w passwd]] [-H ldap_uri] command
[command_options]

Description  The kdb5_ldap_util utility allows an administrator to manage realms, Kerberos services, and ticket policies. The utility offers a set of general options, described under OPTIONS, and a set of commands, which, in turn, have their own options. Commands and their options are described in their own subsections, below.

Options  kdb5_ldap_util has a small set of general options that apply to the kdb5_ldap_util utility itself and a larger number of options that apply to specific commands. A number of these command-specific options apply to multiple commands and are described in their own section, below.

General Options  The following general options are supported:

-D user_dn
  Specifies the distinguished name (DN) of a user who has sufficient rights to perform the operation on the LDAP server.

-H ldap_uri
  Specifies the URI of the LDAP server.

-w passwd
  Specifies the password of user_dn. This option is not recommended.

The following options apply to a number of kdb5_ldap_util commands.

-subtrees subtree_dn_list
  Specifies the list of subtrees containing the principals of a realm. The list contains the DNs of the subtree objects separated by a colon.

-sscope search_scope
  Specifies the scope for searching the principals under a subtree. The possible values are 1 or one (one level), 2 or sub (subtrees).

-containerref container_reference_dn
  Specifies the DN of the container object in which the principals of a realm will be created. If the container reference is not configured for a realm, the principals will be created in the realm container.

-maxktlife max_ticket_life
  Specifies maximum ticket life for principals in this realm.

-maxrenewlife max_renewable_ticket_life
  Specifies maximum renewable life of tickets for principals in this realm.

-r realm
  Specifies the Kerberos realm of the database; by default the realm returned by krb5_default_local_realm(3) is used.
The kdb5_ldap_util utility comprises a set of commands, each with its own set of options. These commands are described in the following subsections.

The create Command

The create command creates a realm in a directory. The command has the following syntax:

```bash
create
[-subtree subtree_dn_list]
[-scope search_scope]
[-containerref container_reference_dn]
[-k mkeytype]
[-m | -P password] [-sf stashfilename]
[-s]
[-r realm]
[-maxtktlife max_ticket_life]
[-kcdn kdc_service_list]
[-addncn admin_service_list]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
```

The create command has the following options:

- **-subtree subtree_dn_list**
  See "Common Command-specific Options," above.

- **-scope search_scope**
  See "Common Command-specific Options," above.

- **-containerref container_reference_dn**
  See "Common Command-specific Options," above.

- **-k mkeytype**
  Specifies the key type of the master key in the database; the default is that given in `kdc.conf(4)`.

- **-m**
  Specifies that the master database password should be read from the TTY rather than fetched from a file on the disk.

- **-P password**
  Specifies the master database password. This option is not recommended.

- **-sf stashfilename**
  Specifies the stash file of the master database password.

- **-s**
  Specifies that the stash file is to be created.

- **-maxtktlife max_ticket_life**
  See "Common Command-specific Options," above.

- **-maxrenewlife max_renewable_ticket_life**
  See "Common Command-specific Options," above.
The modify command modifies the attributes of a realm. The command has the following syntax:

```
modify \n[-subtrees subtree_dn_list] 
[-scope search_scope] 
[-containerref container_reference_dn] 
[-r realm] 
[-maxtktlife max_ticket_life] 
[-maxrenewlife max_renewable_ticket_life] 
[ticket_flags]
```

The modify command has the following options:

- **-subtree subtree_dn_list**
  See “Common Command-specific Options,” above.

- **-scope search_scope**
  See “Common Command-specific Options,” above.

- **-containerref container_reference_dn**
  See “Common Command-specific Options,” above.

- **-maxtktlife max_ticket_life**
  See “Common Command-specific Options,” above.

- **-maxrenewlife max_renewable_ticket_life**
  See “Common Command-specific Options,” above.

- **-r realm**
  See “Common Command-specific Options,” above.

- **ticket_flags**
  Specifies the ticket flags. If this option is not specified, by default, none of the flags are set. This means all the ticket options will be allowed and no restriction will be set. See “Ticket Flags” for a list and descriptions of these flags.

The view command displays the attributes of a realm. The command has the following syntax:

```
view [-r realm]
```

The view command has the following option:
The `destroy` command destroys a realm, including the master key stash file. The command has the following syntax:

```plaintext
destroy [-f] [-r realm]
```

The `destroy` command has the following options:

- `-f`
  - If specified, `destroy` does not prompt you for confirmation.
- `-r realm`
  - See “Common Command-specific Options,” above.

The `list` command displays the names of realms. The command has the following syntax:

```plaintext
list
```

The `list` command has no options.

The `stashsrvpw` command enables you to store the password for service object in a file so that a KDC and Administration server can use it to authenticate to the LDAP server. The command has the following syntax:

```plaintext
stashsrvpw [-f filename] servicedn
```

The `stashsrvpw` command has the following option and argument:

- `-f filename`
  - Specifies the complete path of the service password file. The default is:
    ```plaintext
    /var/krb5/service_passwd
    ```
  - `servicedn`
    - Specifies the distinguished name (DN) of the service object whose password is to be stored in file.

The `create_policy` command creates a ticket policy in a directory. The command has the following syntax:

```plaintext
create_policy \ [-r realm] [-maxtktlife max_ticket_life] [-maxrenewlife max_renewable_ticket_life] [ticket_flags] policy_name
```

The `create_policy` command has the following options:

- `-r realm`
  - See “Common Command-specific Options,” above.
The **modify_policy** command modifies the attributes of a ticket policy. The command has the following syntax:

```bash
modify_policy \n[-r realm] \n[-maxtktlife max_ticket_life] \n[-maxrenewlife max_renewable_ticket_life] \n[ticket_flags] \npolicy_name
```

The `modify_policy` command has the same options and argument as those for the `create_policy` command.

The **view_policy** command displays the attributes of a ticket policy. The command has the following syntax:

```bash
view_policy [-r realm] policy_name
```

The `view_policy` command has the following options:

- `-r realm`
  
  See “Common Command-specific Options,” above.

- `policy_name`
  
  Specifies the name of the ticket policy.

The **destroy_policy** command destroys an existing ticket policy. The command has the following syntax:

```bash
destroy_policy [-r realm] [-force] policy_name
```

The `destroy_policy` command has the following options:

- `-r realm`
  
  See “Common Command-specific Options,” above.
-force
   Forces the deletion of the policy object. If not specified, you will be prompted for
   confirmation before the policy is deleted. Enter yes to confirm the deletion.

policy_name
   Specifies the name of the ticket policy.

The list_policy Command
   The list_policy command lists the ticket policies in the default or a specified realm. The
   command has the following syntax:
   
   list_policy [-r realm]
   
   The list_policy command has the following option:
   
   -r realm
      See "Common Command-specific Options," above.

Ticket Flags
   A number of kdb5_ldap_util commands have ticket_flag options. These flags are
   described as follows:

   {+-}allow_dup_skey
      -allow_dup_skey disables user-to-user authentication for principals by prohibiting
      principals from obtaining a session key for another user. This setting sets the
      KRB5_KDB_DISALLOW_DUP_SKEY flag. +allow_dup_skey clears this flag.

   {+-}allow_forwardable
      -allow_forwardable prohibits principals from obtaining forwardable tickets. This setting
      sets the KRB5_KDB_DISALLOW_FORWARDABLE flag. +allow_forwardable clears this flag.

   {+-}allow_postdated
      -allow_postdated prohibits principals from obtaining postdated tickets. This setting sets
      the KRB5_KDB_DISALLOW_POSTDATED flag. +allow_postdated clears this flag.

   {+-}allow_proxiable
      -allow_proxiable prohibits principals from obtaining proxiable tickets. This setting sets
      the KRB5_KDB_DISALLOW_PROXIAble flag. +allow_proxiable clears this flag.

   {+-}allow_renewable
      -allow_renewable prohibits principals from obtaining renewable tickets. This setting sets
      the KRB5_KDB_DISALLOW_RENEWABLE flag. +allow_renewable clears this flag.

   {+-}allow_svr
      -allow_svr prohibits the issuance of service tickets for principals. This setting sets the
      KRB5_KDB_DISALLOW_SRV flag. +allow_svr clears this flag.

   {+-}allow_tgs_req
      -allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service ticket
      for principals is not permitted. This option is useless for most purposes. +allow_tgs_req
      clears this flag. The default is +allow_tgs_req. In effect, -allow_tgs_req sets the
      KRB5_KDB_DISALLOW_TGT_BASED flag on principals in the database.
{-|+}allow_tix

-allow_tix forbids the issuance of any tickets for principals. +allow_tix clears this flag. The default is +allow_tix. In effect, -allow_tix sets the KRB5_KDB_DISALLOW_ALL_TIX flag on principals in the database.

{-|+}needchange

+needchange sets a flag in the attributes field to force a password change; -needchange clears that flag. The default is -needchange. In effect, +needchange sets the KRB5_KDB_REQUIRES_PWCHANGE flag on principals in the database.

{-|+}password_changing_service

+password_changing_service sets a flag in the attributes field marking a principal as a password-change-service principal (a designation that is most often not useful). -password_changing_service clears the flag. That this flag has a long name is intentional. The default is -password_changing_service. In effect, +password_changing_service sets the KRB5_KDB_PWCHANGE_SERVICE flag on principals in the database.

{-|+}requires_hwauth

+requires_hwauth requires principals to preauthenticate using a hardware device before being allowed to kinit(1). This setting sets the KRB5_KDB_REQUIRES_HW_AUTH flag. -requires_hwauth clears this flag.

{-|+}requires_preauth

+requires_preauth requires principals to preauthenticate before being allowed to kinit(1). This setting sets the KRB5_KDB_REQUIRES_PRE_AUTH flag. -requires_preauth clears this flag.

Examples

**EXAMPLE 1** Using create

The following is an example of the use of the create command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
create -subtrees o=org -sscope SUB -r ATHENA.MIT.EDU
```

Password for "cn=admin,o=org": password entered

Initializing database for realm ‘ATHENA.MIT.EDU’

You will be prompted for the database Master Password. It is important that you NOT FORGET this password.

Enter KDC database master key: master key entered

Re-enter KDC database master key to verify: master key re-entered jjjjjjjj

**EXAMPLE 2** Using modify

The following is an example of the use of the modify command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
modify +requires_preauth -r ATHENA.MIT.EDU
```

Password for "cn=admin,o=org": password entered

Password for "cn=admin,o=org": password entered
EXAMPLE3  Using view

The following is an example of the use of the view command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  view -r ATHENA.MIT.EDU
```

Password for "cn=admin,o=org":

<table>
<thead>
<tr>
<th>Realm Name:</th>
<th>ATHENA.MIT.EDU</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subtree:</td>
<td>ou=users,o=org</td>
</tr>
<tr>
<td>Subtree:</td>
<td>ou=servers,o=org</td>
</tr>
<tr>
<td>SearchScope:</td>
<td>ONE</td>
</tr>
<tr>
<td>Maximum ticket life:</td>
<td>0 days 01:00:00</td>
</tr>
<tr>
<td>Maximum renewable life:</td>
<td>0 days 10:00:00</td>
</tr>
<tr>
<td>Ticket flags:</td>
<td>DISALLOW_FORWARDABLE REQUIRES_PWCHANGE</td>
</tr>
</tbody>
</table>

EXAMPLE4  Using destroy

The following is an example of the use of the destroy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  destroy -r ATHENA.MIT.EDU
```

Password for "cn=admin,o=org": password entered

Deleting KDC database of 'ATHENA.MIT.EDU', are you sure?
(type 'yes' to confirm)? yes

OK, deleting database of 'ATHENA.MIT.EDU'...

EXAMPLE5  Using list

The following is an example of the use of the list command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu list
```

Password for "cn=admin,o=org": password entered

Re-enter Password for "cn=admin,o=org": password re-entered

ATHENA.MIT.EDU
OPENLDAP.MIT.EDU
MEDIA-LAB.MIT.EDU

EXAMPLE6  Using stashsrvpw

The following is an example of the use of the stashsrvpw command.

```
# kdb5_ldap_util stashsrvpw -f \ 
  /home/andrew/conf_keyfile cn=service-kdc,o=org
```

Password for "cn=service-kdc,o=org": password entered

Re-enter password for "cn=service-kdc,o=org": password re-entered

EXAMPLE7  Using create_policy

The following is an example of the use of the create_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  create_policy -r ATHENA.MIT.EDU \
  -maxtktlife "1 day" -maxrenewlife "1 week" \
```

System Administration Commands - Part 1
EXAMPLE7 Using create_policy (Continued)

-allow_postdated +needchange -allow_forwardable tktpolicy
Password for "cn=admin,o=org": password entered

EXAMPLE8 Using modify_policy
The following is an example of the use of the modify_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  modify_policy -r ATHENA.MIT.EDU \
  -maxtktlife "60 minutes" -maxrenewlife "10 hours" \
  +allow_postdated -requires_preauth tktpolicy
Password for "cn=admin,o=org": password entered
```

EXAMPLE9 Using view_policy
The following is an example of the use of the view_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  view_policy -r ATHENA.MIT.EDU tktpolicy
Password for "cn=admin,o=org": password entered
  Ticket policy: tktpolicy
    Maximum ticket life: 0 days 01:00:00
    Maximum renewable life: 0 days 10:00:00
    Ticket flags: DISALLOW_FORWARDABLE REQUIRES_PWCHANGE
```

EXAMPLE10 Using destroy_policy
The following is an example of the use of the destroy_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  destroy_policy -r ATHENA.MIT.EDU tktpolicy
Password for "cn=admin,o=org": password entered
This will delete the policy object 'tktpolicy', are you sure?
(type 'yes' to confirm)? yes
** policy object 'tktpolicy' deleted.
```

EXAMPLE11 Using list_policy
The following is an example of the use of the list_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
  list_policy -r ATHENA.MIT.EDU
Password for "cn=admin,o=org": password entered
tktpolicy
tmppolicy
userpolicy
```

EXAMPLE12 Using setsrvpw
The following is an example of the use of the setsrvpw command.
EXAMPLE 12 Using setsrvpw (Continued)

```bash
# kdb5_ldap_util setsrvpw -D cn=admin,o=org setsrvpw \
-fileonly -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Password for "cn=service-kdc,o=org": password entered
Re-enter password for "cn=service-kdc,o=org": password re-entered
```

EXAMPLE 13 Using create_service

The following is an example of the use of the create_service command.

```bash
# kdb5_ldap_util -D cn=admin,o=org create_service \
-kdc -randpw -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
File does not exist. Creating the file /home/andrew/conf_keyfile...
```

EXAMPLE 14 Using modify_service

The following is an example of the use of the modify_service command.

```bash
# kdb5_ldap_util -D cn=admin,o=org modify_service \
-realm ATHENA.MIT.EDU cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Changing rights for the service object. Please wait ... done
```

EXAMPLE 15 Using view_service

The following is an example of the use of the view_service command.

```bash
# kdb5_ldap_util -D cn=admin,o=org view_service \
 cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Service dn: cn=service-kdc,o=org
Service type: kdc
Service host list:
Realm DN list: cn=ATHENA.MIT.EDU, cn=Kerberos, cn=Security
```

EXAMPLE 16 Using destroy_service

The following is an example of the use of the destroy_service command.

```bash
# kdb5_ldap_util -D cn=admin,o=org destroy_service \
 cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
This will delete the service object 'cn=service-kdc,o=org', are you sure?
(type 'yes' to confirm)? yes
** service object 'cn=service-kdc,o=org' deleted.
```

EXAMPLE 17 Using list_service

The following is an example of the use of the list_service command.
EXAMPLE 17 Using list_service (Continued)

# kdb5_ldap_util -D cn=admin,o=org list_service
Password for "cn=admin,o=org": password entered
  cn=service-kdc,o=org
  cn=service-adm,o=org
  cn=service-pwd,o=org

**Name**  kdb5_util – Kerberos Database maintenance utility

**Synopsis**  
```
/usr/sbin/kdb5_util [-d dbname] [-f stashfile_name] 
[-k mkeytype] [-m] [-M mkeyname] [-P password] [-r realm] 
[-x db_args]... cmd
```

**Description**  The kdb5_util utility enables you to create, dump, load, and destroy the Kerberos V5 database. You can also use kdb5_util to create a stash file containing the Kerberos database master key.

**Options**  The following options are supported:

- `-d dbname`
  Specify the database name. `.db` is appended to whatever name is specified. You can specify an absolute path. If you do not specify the `-d` option, the default database name is `/var/krb5/principal`.

- `-f stashfile_name`
  Specify the stash file name. You can specify an absolute path.

- `-k mkeytype`

- `-m`
  Enter the master key manually.

- `-M mkeyname`
  Specify the master key name.

- `-P password`
  Use the specified `password` instead of the stash file.

- `-r realm`
  Use `realm` as the default database realm.

- `-x db_args`
  Pass database-specific arguments to `kadmin`. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:

  `binddn=binddn`
  LDAP simple bind DN for authorization on the directory server. Overrides the `ldap_kadmind_dn` parameter setting in `krb5.conf(4)`.

  `bindpwd=bindpwd`
  Bind password.

  `dbname=name`
  For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.
\texttt{nconns=num}

Maximum number of server connections.

\texttt{port=num}

Directory server connection port.

**Operands**
The following operands are supported:

\textit{cmd}

Specifies whether to create, destroy, dump, or load the database, or to create a stash file.

You can specify the following commands:

\texttt{create -s}

Creates the database specified by the \texttt{-d} option. You will be prompted for the database master password. If you specify \texttt{-s}, a stash file is created as specified by the \texttt{-f} option. If you did not specify \texttt{-f}, the default stash file name is \texttt{/var/krb5/.k5.realm}. If you use the \texttt{-f}, \texttt{-k}, or \texttt{-M} options when you create a database, then you must use the same options when modifying or destroying the database.

\texttt{destroy}

Destroys the database specified by the \texttt{-d} option.

\texttt{stash}

Creates a stash file. If \texttt{-f} was not specified, the default stash file name is \texttt{/var/krb5/.k5.realm}. You will be prompted for the master database password. This command is useful when you want to generate the stash file from the password.

Dumps the current Kerberos and KADM5 database into an ASCII file. By default, the database is dumped in current format, \texttt{"kdb5\_util\ load\_dump\ version\ 5"}. If \texttt{filename} is not specified or is the string \texttt{"-"}, the dump is sent to standard output. Options are as follows:

\texttt{-old}

Causes the dump to be in the Kerberos 5 Beta 5 and earlier dump format (\texttt{"kdb5\_edit\ load\_dump\ version\ 2.0"}).

\texttt{-b6}

Causes the dump to be in the Kerberos 5 Beta 6 format (\texttt{"kdb5\_edit\ load\_dump\ version\ 3.0"}).

\texttt{-b7}

Causes the dump to be in the Kerberos 5 Beta 7 format (\texttt{"kdb5\_util\ load\_dump\ version\ 4"}). This was the dump format produced on releases prior to 1.2.2.

\texttt{-ov}

Causes the dump to be in \texttt{ovsec\_adm\_export} format.
-verbose
Causes the name of each principal and policy to be displayed as it is dumped.

-mkey_convert
Prompts for a new master key. This new master key will be used to re-encrypt the key
data in the dump file. The key data in the database will not be changed.

-new_mkey_file mkey_file
The filename of a stash file. The master key in this stash file will be used to re-encrypt
the key data in the dump file. The key data in the database will not be changed.

-rev
Dumps in reverse order. This might recover principals that do not dump normally,
in cases where database corruption has occurred.

-recurse
Causes the dump to walk the database recursively (btree only). This might recover
principals that do not dump normally, in cases where database corruption has
occurred. In cases of such corruption, this option will probably retrieve more
principals than will the -rev option.

[admin dbname]
Loads a database dump from filename into dbname. Unless the -old or -b6 option is
specified, the format of the dump file is detected automatically and handled
appropriately. Unless the -update option is specified, load creates a new database
containing only the principals in the dump file, overwriting the contents of any existing
database. The -old option requires the database to be in the Kerberos 5 Beta 5 or earlier
format ("kdb5_edit load_dump version 2.0").

-b6
Requires the database to be in the Kerberos 5 Beta 6 format ("kdb5_edit load_dump
version 3.0").

-b7
Requires the database to be in the Kerberos 5 Beta 7 format ("kdb5_util load_dump
version 4").

-ov
Requires the database to be in ovsec_adm_import format. Must be used with the
-update option.

-hash
Requires the database to be stored as a hash. If this option is not specified, the
database will be stored as a btree. This option is not recommended, as databases
stored in hash format are known to corrupt data and lose principals.

-verbose
Causes the name of each principal and policy to be displayed as it is dumped.
-update
Records from the dump file are added to or updated in the existing database.
Otherwise, a new database is created containing only what is in the dump file and the
old one is destroyed upon successful completion.

filename
Required argument that specifies a path to a file containing database dump.

dbname
Required argument that overrides the value specified on the command line or
overrides the default.

admin_dbname
Optional argument that is derived from dbname if not specified.

Examples

EXAMPLE 1 Creating File that Contains Information about Two Principals

The following example creates a file named slavedata that contains the information about
two principals, jdb@ACME.COM and pak@ACME.COM.

# /usr/krb5/bin/kdb5_util dump -verbose slavedata
jdb@ACME.COM pak@ACME.COM

Files
/var/krb5/principal
Kerberos principal database.

/var/krb5/principal.kadm5
Kerberos administrative database. Contains policy information.

/var/krb5/principal.kadm5.lock
Lock file for the Kerberos administrative database. This file works backwards from most
other lock files (that is, kadmin exits with an error if this file does not exist).

/var/krb5/principal. ulog
The update log file for incremental propagation.

Name

kdmconfig – configure or unconfigure keyboard, display, and mouse options for OpenWindows and internationalization

Synopsis

kdmconfig

kdmconfig [-fv] [-s hostname] -c | -t | -u | -d filename

Description

The kdmconfig program applies only to the Xsun window system environment, which is no longer the default in Solaris x86. If you want to use Xsun, you must run kdmconfig from the command line, select Xsun, and perform the remaining configuration steps.

The kdmconfig program configures or unconfigures the /etc/openwin/server/etc/OWconfig file with the keyboard, display, and mouse information relevant to a client's machine on x86 based systems for Solaris software. kdmconfig can also be used to set up the display, pointer, and keyboard entries in the bootparams(4) database on a server machine or the monitor, keyboard, display, and pointer keywords in a sysidcfg(4) file. kdmconfig can only be run as root or with privileges comparable to root. Upon completion of device selection, kdmconfig prompts the user to test the configuration, which is done by running the window system.

Options

The valid options are:

-c
Run the program in the configuration mode. This mode is used to create or update the OWconfig file. When invoked in this way, kdmconfig first looks for the relevant configuration information in the bootparams(4) databases. It also takes into account the information returned from device probes, unless the -s option is also used. The bootparams(4) databases available to the client are all of the /etc/bootparams files on servers on the same subnet as the client, provided the server machine is running the bootparam(1M) daemon. kdmconfig is invoked with the -c option when called by sysidconfig(1M)

-d filename
Set up a sysidcfg(4) file. This option displays the same screens as the -c option, but the information you specify is saved as sysidcfg(4) keywords (monitor, keyboard, display, and pointer). This enables you to use a sysidcfg(4) file to preconfigure a system's device information and bypass kdmconfig during an installation.

filename is the sysidcfg(4) file that is created, and it is created in the directory where kdmconfig is being run unless a path is specified. If filename already exists in the specified directory, the keywords are appended to the existing file.

-f
Force screens mode. When this option is invoked, no network probing will be performed. This is helpful when debugging the client's configuration environment. Note that the -s option implies the use of -f, bypassing network probing when setting up a server.
Setup the bootparams(4) database on this machine for the specified client. This option presents the same screens as it does when run on a client, but instead writes the resulting information to the /etc/bootparams file. Also, -s implies the use of the -f option. That is, the program will always present the screens to the user when invoked this way. This option will reconfigure the nsswitch.conf(4) file to look for a bootparams(4) database on a local server. This option is only available to the super-user.

-t
Run the program in test mode. In this mode, kdmconfig will use device probe information to determine whether the OWconfig file contains complete and up-to-date information about the keyboard, display, and mouse. If the information is accurate, kdmconfig will exit silently. Otherwise, kdmconfig will prompt for the super-user password and proceed to a normal editing session (as though it had been run without options).

-u
Unconfigure the system, returning it to an "out-of-the-box" state. In this state, the factory default keyboard, mouse, and display are selected as a result of removing the device configuration entries from the /etc/openwin/server/etc/OWconfig file. This may result in an unusable configuration for the display server.

-v
Enable verbose mode. Normally, kdmconfig will not produce any output. This option is helpful for debugging, as it records the different actions taken by kdmconfig on stderr.

No Options
Run without options, kdmconfig is used to edit the current configuration. kdmconfig uses the information from the OWconfig file in addition to information obtained from the bootparams(4) file and from device probes. In other respects, it is similar to using the -c option of kdmconfig.

Files
/etc/openwin/server/etc/OWconfig OpenWindows configuration file
/etc/bootparams contains list of clients that diskless clients use for booting
/etc/nsswitch.conf name service configuration file
x86 Only /dev/openprom installed devices and properties

Name  
kernel – UNIX system executable file containing basic operating system services

Synopsis  
kernel-name [-asrvx] [-m smf_options] [-i altinit]

Description  
The operating system image, or kernel, is the collection of software comprising the image files (unix and genunix) and the modules loaded at any instant in time. The system will not function without a kernel to control it.

The kernel is loaded by the boot(1M) command in a machine-specific way. The kernel may be loaded from disk, CD-ROM, or DVD (diskfull boot) or over the network (diskless boot). In either case, the directories under /platform and /kernel must be readable and must contain executable code which is able to perform the required kernel service. If the -a flag is given, the user is able to supply different pathnames for the default locations of the kernel and modules. See boot(1M) for more information on loading a specific kernel.

The moddir variable contains a list of module directories separated by whitespace. moddir can be set in the /etc/system file. The minimal default is:

/platform/platform-name/kernel /kernel /usr/kernel

This default can be supplemented by a specific platform. It is common for many SPARC systems to override the default path with:

/platform/platform-name/kernel:/platform/hardware-class-name:/kernel:/kernel:/usr/kernel

where platform-name can be found using the -i option of uname(1), and hardware-class-name can be found using the -m option of uname(1).

The kernel configuration can be controlled using the /etc/system file (see system(4)).

genunix is the platform-independent component of the base kernel.

Options  
The following options are supported:

- a  
Asks the user for configuration information, such as where to find the system file, where to mount root, and even override the name of the kernel itself. Default responses will be contained in square brackets ([]), and the user may simply enter RETURN to use the default response (note that RETURN is labeled ENTER on some keyboards). To help repair a damaged /etc/system file, enter /dev/null at the prompt that asks for the pathname of the system configuration file. See system(4).

- i altinit  
Select an alternative executable to be the primordial process. altinit must be a valid path to an executable. The default primordial process is init(1M).

- m smf_options  
The smf_options include two categories of options to control booting behavior of the service management facility: recovery options and messages options.
Message options determine the type and amount of messages that `smf(5)` displays during boot. Service options determine the services which are used to boot the system.

Recovery options

`debug`
Prints standard per-service output and all `svc.startd` messages to log.

`milestone=[milestone]`
Boot with some SMF services temporarily disabled, as indicated by `milestone`. `milestone` can be “none”, “single-user”, “multi-user”, “multi-user-server”, or “all”. See the `milestone` subcommand of `svcadm(1M)`.

Messages options

`quiet`
Prints standard per-service output and error messages requiring administrative intervention.

`verbose`
Prints standard per-service output with more informational messages.

`-r`
Reconfiguration boot. The system will probe all attached hardware devices and configure the logical namespace in `/dev`. See `add_drv(1M)` and `rem_drv(1M)` for additional information about maintaining device drivers.

`-s`
Boots only to init level 's'. See `init(1M)`.

`-v`
Boots with verbose messages enabled. If this flag is not given, the messages are still printed, but the output is directed to the system log file. See `syslogd(1M)`.

`-x`
Does not boot in clustered mode. This option only has an effect when a version of Sun Cluster software that supports this option has been installed.

**Examples**

See `boot(1M)` for examples and instructions on how to boot.

**Files**
`/kernel`
Contains kernel components common to all platforms within a particular instruction set that are needed for booting the system. of the core image file.

`/platform/platform-name/kernel`
The platform-specific kernel components.

`/platform/hardware-class-name/kernel`
The kernel components specific to this hardware class.
/usr/kernel
   Contains kernel components common to all platforms within a particular instruction set.

   The directories in this section can potentially contain the following subdirectories:

   drv
   Loadable device drivers

   exec
   The modules that execute programs stored in various file formats.

   fs
   File system modules

   misc
   Miscellaneous system-related modules

   sched
   Operating system schedulers

   strmod
   System V STREAMS loadable modules

   sys
   Loadable system calls

   SPARC
   cpu
   Processor specific modules

   tod
   Time-Of-Day hardware interface modules

   As only 64-bit SPARC platforms are supported, all SPARC executable modules are contained
   within sparcv9 directories in the directories listed above.

   x86
   mach
   x86 hardware support

   Modules comprising the 32-bit x86 kernel are contained in the above directories, with the
   64-bit x86 kernel components contained within amd64 subdirectories.

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcar, SUNWcarx</td>
</tr>
</tbody>
</table>

See Also  uname(1), isainfo(1), add_drv(1M), boot(1M), init(1M), kadb(1M), rem_drv(1M),
         savecore(1M), svc.startd(1M), svcadm(1M), syslogd(1M), system(4), attributes(5),
         smf(5), devfs(7FS)
The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

Reconfiguration boot will, by design, not remove /dev entries for some classes of devices that have been physically removed from the system.
keyserv(1M)

Name  keyserv – server for storing private encryption keys

Description  keyserv is a daemon that is used for storing the private encryption keys of each user logged into the system. These encryption keys are used for accessing secure network services such as secure NFS and NIS+.

Normally, root's key is read from the file /etc/.rootkey when the daemon is started. This is useful during power-fail reboots when no one is around to type a password.

keyserv does not start up if the system does not have a secure rpc domain configured. Set up the domain name by using the /usr/bin/domainname command. Usually the svc:/system/identity:domain service reads the domain from /etc/defaultdomain. Invoking the domainname command without arguments tells you if you have a domain set up.

The /etc/default/keyserv file contains the following default parameter settings. See Files.

ENABLE_NOBODY_KEYS   Specifies whether default keys for nobody are used.
ENABLE_NOBODY_KEYS=NO is equivalent to the -d command-line option. The default value for ENABLE_NOBODY_KEYS is YES.

Options  The following options are supported:

- c   Do not use disk caches. This option overrides any -s option.
- D   Run in debugging mode and log all requests to keyserv.
- d   Disable the use of default keys for nobody. See Files.
- e   Enable the use of default keys for nobody. This is the default behavior. See Files.
- n   Root's secret key is not read from /etc/.rootkey. Instead, keyserv prompts the user for the password to decrypt root's key stored in the publickey database and then stores the decrypted key in /etc/.rootkey for future use. This option is useful if the /etc/.rootkey file ever gets out of date or corrupted.
- s sizespec   Specify the size of the extended Diffie-Hellman common key disk caches. The sizespec can be one of the following forms:

    mechtype=size   size is an integer specifying the maximum number of entries in the cache, or an integer immediately followed by the letter M, denoting the maximum size in MB.

    size   This form of sizespec applies to all caches.

See nisauthconf(1M) for mechanism types. Note that the des mechanism, AUTH_DES, does not use a disk cache.
Files
/etc/.rootkey
/etc/default/keyserv Contains default settings. You can use command-line options to override these settings.

Attributes
See attributes(5) for descriptions of the following attributes:

http://www.sun.com/directory/nisplus/transition.html

Notes
NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The keyserv service is managed by the service management facility, smf(5), under the service identifier:
svc:/network/rpc/keyserv:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svc(1) command.
killall(1M)

**Name**
killall – kill all active processes

**Synopsis**
/usr/sbin/killall [signal]

**Description**
killall is used by shutdown(1M) to kill all active processes not directly related to the shutdown procedure.

killall terminates all processes with open files so that the mounted file systems will be unbusied and can be unmounted.

killall sends signal (see kill(1)) to the active processes. If no signal is specified, a default of 15 is used.

The killall command can be run only by the super-user.

The `kmscfg` command is used to initialize the PKCS#11 KMS provider (pkcs11_kms) for use with the Solaris Cryptographic Framework. In order for the KMS provider to communicate with the Oracle Key Manager (OKM), it must have some configuration information available. This configuration data contains information such as the name of the profile to be used, the name of the OKM Agent, the IP address of an OKM appliance (KMA) and some other parameters (see **SYNOPSIS**).

By default, `kmscfg` stores the configuration information in `/var/kms/$USERNAME/`. This directory will be created if it is not already present. If the configuration is already detected, the user will be given the option to override the existing data. The default location can be overridden by using the `KMSTOKEN_DIR` environment variable, which must be set prior to invoking `kmscfg`.

Prior to running `kmscfg`, the OKM administrator must have performed the required initialization and configuration steps on the appliance itself to setup the individual Profiles and Agents that PKCS11 KMS consumers will use. The instructions for configuring these profiles are available in the Oracle Key Manager Administration Guide on the Oracle website (http://docs.oracle.com).

Once the administrator has configured the KMA, the necessary identification information (profile name, agent ID, IP address) must be provided to be able to run `kmscfg` and initialize the provider on the Oracle Solaris client.

The options listed below are supported. Note that, if the profile, agent id, or KMA address are not specified on the command line, `kmscfg` prompts you to provide these items.

- **-a Agent_ID**
  The user agent ID as configured on the OKM to be used for the KMS token being configured. It is not unusual for the Profile and Agent ID to be the same, for example, `MyAgent`.

- **-d Discovery_Freq**
  Frequency in seconds with which the client will try to discover the availability of other KMAs in an OKM cluster. If not specified, `Discovery_Freq` defaults to 10.
-f Failover_Limit
   The number of times communications to the KMA can fail before the client gives up. If not
   specified, Failover_Limit defaults to 3.

-1 Agent_Addr
   Address of the KMA. This can be an IPv4 address (xxx.xxx.xxx.xxx) or an IPv6 address. A
   fully qualified host name can also be used, as long as that name can be resolved by the name
   service configured on the client. If an OKM cluster is being used, the address of any
   member of the cluster can be specified.

-p Profile_Name
   A name for the profile to be used for the KMS token being configured. The profile name
   and the Agent ID must be the same.

-t Transaction_Timeout
   Timeout period for individual KMS commands, in seconds. If not specified, this value
   defaults to 10.

Exit Status
   After completing the requested operation, kmscfg exits with one of the following status values.
   
0
   Successful termination.

1
   Failure. The requested operation could not be completed.

Files
   /var/kms/$USERNAME
   Default KMS token configuration directory.

$({KMSTOKEN_DIR})
   Alternate KMS token configuration directory.

Oracle Key Manager Administration Guide (http://docs.oracle.com)

Notes
   PKCS#11 clients require Oracle Key Manager Software Version 2.4 be installed on the OKM.

   If PKCS#11 clients will use the same Agent ID from multiple systems, that agent should be
   created without the "One Time Passphrase" flag set. This option will not be available in OKM
   clusters with some members running versions of the OKM software prior to 2.4. Please refer
   to the OKM Administration Guide for assistance in creating Agents.
OKM Agents must have a Default Key Group assigned prior to being used to create keys with a PKCS#11 client. If a Default Key Group is not assigned to the Agent, operations will fail with a CKR_PIN_INCORRECT error. Please refer to the OKM Administration Guide for assistance in assigning key groups to agents.
kprop is a command-line utility used for propagating a Kerberos database from a master KDC to a slave KDC. This command must be run on the master KDC. See the Solaris System Administration Guide, Vol. 6 on how to set up periodic propagation between the master KDC and slave KDCs.

To propagate a Kerberos database, the following conditions must be met:

- The slave KDCs must have an /etc/krb5/kpropd.acl file that contains the principals for the master KDC and all the slave KDCs.
- A keytab containing a host principal entry must exist on each slave KDC.
- The database to be propagated must be dumped to a file using kdb5_util(1M).

The following options are supported:

- `-d`  
  Enable debug mode. Default is debug mode disabled.

- `-f file`  
  File to be sent to the slave KDC. Default is the /var/krb5/slave_data file.

- `-p port-number`  
  Propagate port-number. Default is port 754.

- `-r realm`  
  Realm where propagation will occur. Default realm is the local realm.

- `-s keytab`  
  Location of the keytab. Default location is /etc/krb5/krb5.keytab.

The following operands are supported:

- `host`  
  Name of the slave KDC.

EXAMPLE 1  
Propagating the Kerberos Database

The following example propagates the Kerberos database from the /tmp/slave_data file to the slave KDC london. The machine london must have a host principal keytab entry and the kpropd.acl file must contain an entry for all the KDCs.

```bash
# kprop -f /tmp/slave_data london
```

Files  
- `/etc/krb5/kpropd.acl`  
  List of principals of all the KDCs; resides on each slave KDC.

- `/etc/krb5/krb5.keytab`  
  Keytab for Kerberos clients.
Kerberos database propagated to the KDC slaves.

System Administration Guide: Security Services
**Name**

kpropd – Kerberos propagation daemon for slave KDCs

**Synopsis**

```
/usr/lib/krb5/kpropd [-d] [-f temp_dbfile] [-F dbfile]
[-p kdb_util] [-P port_number] [-r realm]
[-s srv_tabfile] [-S] [-a acl_file]
```

**Description**

The `kpropd` command runs on the slave KDC server. It listens for update requests made by `kprop(1M)` from the master KDC and periodically requests incremental updates from the master KDC.

When the slave receives a kprop request from the master, `kpropd` copies principal data to a temporary text file. Next, `kpropd` invokes `kdb5_util(1M)` (unless a different database utility is selected) to load the text file in database format.

When the slave periodically requests incremental updates, `kpropd` update its `principal.ulog` file with any updates from the master. `kproplog(1M)` can be used to view a summary of the update entry log on the slave KDC.

`kpropd` is not configured for incremental database propagation by default. These settings can be changed in the `kdc.conf(4)` file:

```
sunw_dbprop_enable = [true | false]
```

- Enables or disables incremental database propagation. Default is false.

```
sunw_dbprop_slave_poll = N[s, m, h]
```

- Specifies how often the slave KDC polls for any updates that the master might have. Default is 2m (two minutes).

The `kprop/<hostname>@<REALM>` principal must exist in the slave's `keytab` file to enable the master to authenticate incremental propagation requests from the slave. In this syntax, `<hostname>` is the slave KDC's host name and `<REALM>` is the realm in which the slave KDC resides.

**Options**

The following options are supported:

```
-d
```

- Enable debug mode. Default is debug mode disabled.

```
-f temp_dbfile
```

- The location of the slave's temporary principal database file. Default is `/var/krb5/from_master`.

```
-F dbfile
```

- The location of the slave's principal database file. Default is `/var/krb5/principal`.

```
-p kdb_util
```

- The location of the Kerberos database utility used for loading principal databases. Default is `/usr/sbin/kdb5_util`.

<table>
<thead>
<tr>
<th>Name</th>
<th>Synopsis</th>
<th>Description</th>
<th>Options</th>
</tr>
</thead>
</table>
-P port_number
   Specifies the port number on which kpropd will listen. Default is 754 (service name: krb5_prop).

-r realm
   Specifies from which Kerberos realm kpropd will receive information. Default is specified in /etc/krb5/krb5.conf.

-s srv_tabfile
   The location of the service table file used to authenticate the kpropd daemon.

-S
   Run the daemon in standalone mode, instead of having inetd listen for requests. Default is non-standalone mode.

-a acl_file
   The location of the kpropd's access control list to verify if this server can run the kpropd daemon. The file contains a list of principal name(s) that will be receiving updates. Default is /etc/krb5/kpropd.acl.

 Files
 /var/krb5/principal
   Kerberos principal database.
 /var/krb5/principal.ulog
   The update log file.
 /etc/krb5/kdc.conf
   KDC configuration information.
 /etc/krb5/kpropd.acl
   List of principals of all the KDCs; resides on each slave KDC.
 /var/krb5/from_master
   Temporary file used by kpropd before loading this to the principal database.

**Name**
kproplcg – display the contents of the Kerberos principal update log

**Synopsis**
/usr/sbin/kproplcg [-h | -e num]

**Description**
The kproplcg displays the contents of the Kerberos principal update log to standard output. This command can be used to keep track of the incremental updates to the principal database, which is enabled by default. The /var/krb5/principal. ulog file contains the update log maintained by the kadmind(1M) process on the master KDC server and the kpropd(1M) process on the slave KDC servers. When updates occur, they are logged to this file. Subsequently any KDC slave configured for incremental updates will request the current data from the master KDC and update their principal. ulog file with any updates returned.

The kproplcg command can only be run on a KDC server by someone with privileges comparable to the superuser. It will display update entries for that server only.

If no options are specified, the summary of the update log is displayed. If invoked on the master, all of the update entries are also displayed. When invoked on a slave KDC server, only a summary of the updates are displayed, which includes the serial number of the last update received and the associated time stamp of the last update.

**Options**
The following options are supported:

- **-h**
  Display a summary of the update log. This information includes the database version number, state of the database, the number of updates in the log, the time stamp of the first and last update, and the version number of the first and last update entry.

- **-e num**
  Display the last num update entries in the log. This is useful when debugging synchronization between KDC servers.

- **-v**
  Display individual attributes per update. An example of the output generated for one entry:

```
Update Entry
  Update serial #: 4
  Update operation: Add
  Update principal: test@EXAMPLE.COM
  Update size: 424
  Update committed: True
  Update time stamp: Fri Feb 20 23:37:42 2004
  Attributes changed: 6
    Principal
    Key data
    Password last changed
    Modifying principal
    Modification time
    TL data
```
Files /var/krb5/principal.elog The update log file for incremental propagation.

Name  krb5kdc – KDC daemon

Synopsis  

```bash
/usr/lib/krb5/krb5kdc [-d dbpath] [-r realm] [-m]
 [-k masterenctype] [-M masterkeyname]
 [-p port] [-n] [-x db_args]...
```

Description  krb5kdc is the daemon that runs on the master and slave KDCs to process the Kerberos tickets. For Kerberos to function properly, krb5kdc must be running on at least one KDC that the Kerberos clients can access. Prior to running krb5kdc, you must initialize the Kerberos database using `kdb5_util(1M)`. See the `System Administration Guide: Security Services` for information regarding how to set up KDCs and initialize the Kerberos database.

Options  The following options are supported:

- `-d dbpath`
  Specify the path to the database; default value is `/var/krb5`.

- `-k masterenctype`
  Specify the encryption type for encrypting the database. The default value is `des-cbc-crc`, `des3-cbc-sha1`, `arcfour-hmac-md5`, `arcfour-hmac-md5-exp`, `aes128-cts-hmac-sha1-96`, and `aes256-cts-hmac-sha1-96` are also valid.

- `-m`
  Specify that the master key for the database is to be entered manually.

- `-M masterkeyname`
  Specify the principal to retrieve the master Key for the database.

- `-n`
  Specify that krb5kdc should not detach from the terminal.

- `-p port`
  Specify the port that will be used by the KDC to listen for incoming requests.

- `-r realm`
  Specify the realm name; default is the local realm name.

- `-x db_args`
  Pass database-specific arguments to `kadmin`. Supported arguments are for the LDAP plug-in. These arguments are:

    `binddn=binddn`
    Specifies the DN of the object used by the KDC server to bind to the LDAP server. This object should have the rights to read the realm container, principal container and the subtree that is referenced by the realm. Overrides the `ldap_kdc_dn` parameter setting in `krb5.conf(4)`.

    `bindpwd=bindpwd`
    Specifies the password for the above-mentioned `binddn`. It is recommended not to use this option. Instead, the password can be stashed using the `stashsrvpw` command of `kdb5_ldap_util(1M)`.
nconns=num
   Specifies the number of connections to be maintained per LDAP server.

host=ldapuri
   Specifies, by an LDAP URI, the LDAP server to which to connect.

Files
/var/krb5/principal.db
   Kerberos principal database.
/var/krb5/principal.kadm5
   Kerberos administrative database. This file contains policy information.
/var/krb5/principal.kadm5.lock
   Kerberos administrative database lock file. This file works backwards from most other lock files (that is, kadmin will exit with an error if this file does not exist).
/etc/krb5/kdc.conf
   KDC configuration file. This file is read at startup.
/etc/krb5/kpropd.acl
   File that defines the access control list for propagating the Kerberos database using kprop.

System Administration Guide: Security Services

Notes
   The following signal has the specified effect when sent to the server process using the
   kill(1) command:

   SIGHUP
      krb5kdc closes and re-opens log files that it directly opens. This can be useful for external
      log-rotation utilities such as logadm(1M). If this method is used for log file rotation, set the
      krb5.conf(4) kdc_rotate period relation to never.
ksslcfg(1M)

Name
ksslcfg – enable and configure SMF instance of Kernel SSL

Synopsis
ksslcfg create -f pkcs11 -T token_label -c certificate_label
[-d softtoken_directory]
[-p password_file [-u username]]
[-h ca_certchain_file] [-c ciphersuites]
[-t ssl_session_cache_timeout]
[-z ssl_session_cache_size] [-v] -x proxy_port [host] ssl_port

ksslcfg create -f pkcs12 -i cert_and_keyPk12file
[-p password_file [-u username]]
[-c ciphersuites] [-t ssl_session_cache_timeout]
[-z ssl_session_cache_size] [-v] -x proxy_port [host] ssl_port

ksslcfg create -f pem -i cert_and_key_pemfile
[-p password_file [-u username]]
[-c ciphersuites] [-t ssl_session_cache_timeout]
[-z ssl_session_cache_size] [-v] -x proxy_port [host] ssl_port

ksslcfg delete [-v] [host] ssl_port

ksslcfg -V
ksslcfg -?

Description
ksslcfg manages smf(5) instances for the Kernel SSL proxy module. An SSL-enabled web
server can use the services of its Kernel SSL proxy to improve the performance of the HTTPS
packets processing. It does so by creating an instance of the Kernel SSL service, specifying the
SSL proxy port and parameters, and by listening on the proxy port.

The create subcommand creates an instance and enables the service for the given address and
SSL port.

The delete subcommand disables the service for the given address and port, if it is enabled,
and deletes the instance from the SMF repository.

ksslcfg can be run as root or by other users assigned to the Network Security profile. See
rbac(5) and user_attr(4). You must run ksslcfg to configure your Kernel SSL proxy before
you start your application.

ksslcfg allows you to specify an ssl_port operand, described under OPERANDS, and, with
the -x option, a proxy_port value. When specified for use with the Kernel SSL proxy, these
values cannot also be configured for the Solaris Network Cache and Acceleration (NCA)
feature. See nca(1) for a description of the NCA feature.

The Fault Managed Resource Identifier (FMRI) for the kernel SSL proxy instances is
svc://network/ssl/proxy. ksslcfg creates an instance of that service unique to the
combination of host and SSL port. Instance FMRI for particular proxy entries can be found
with svcs(1) and used for dependencies of other services.
Options

The following options are supported:

- `-c ciphersuites`
  Set of ciphers a client is allowed to negotiate in a sorted order. The supported SSL version3 and TLS ciphers are listed below. Note that the names are case-insensitive.
  
  - rsa_rc4_128_sha
  - rsa_rc4_128_md5
  - rsa_aes_256_cbc_sha
  - rsa_aes_128_cbc_sha
  - rsa_3des_ede_cbc_sha
  - rsa_des_cbc_sha

- `-f key_format`
  Uses the certificate/key format specified in `key_format`. The supported options are pkcs11, pkcs12, and pem.

- `-i key_and_certificate_file`
  When pkcs12 or pem is specified with the `-f` option, reads a key and a certificate of the web server from `key_and_certificate_file`. This file can also contain any intermediate CA certificates that form the certificate chain to the root CA for the server certificate. These certificates must follow the server certificate in the file and the order must be bottom up: lowest level CA certificate followed by the next higher level CA certificate, and so on.

- `-C certificate_label`
  PKCS#11 can store multiple certificates in single token. This option enables you to specify a single certificate, identified by `certificate_label`. This label must match the `CKA_LABEL` on the certificate object in the token specified by `-T`. This option is to be used only with `-f pkcs11`.

- `-d softtoken_directory`
  This option is applicable only with the pkcs11 key format, when the token label is the Sun Software PKCS#11 softtoken. Use this option to override the default location of the PKCS#11 softtoken directory (`$HOME/.sunw`). See `pkcs11_softtoken(5)`.

- `-h ca_certchain_file`
  When pkcs11 is specified with the `-f` option, reads a set of intermediate CA certificates that form the certificate chain to the root CA for the server certificate (specified with the `-C` option), from `ca_certchain_file`. The file must be in PEM format.

- `-p password_file`
  Obtains the password used to encrypt the private key from `password_file`. When using the pkcs11 option (see `-f`, above), the password is used to authenticate the user to the PKCS#11 token.
### ksslcfg(1M)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-t ssl_session_cache_timeout</code></td>
<td>The timeout value, in seconds, for an SSL session. It corresponds to SSL3SessionTimeout of the Sun ONE web server configuration or SSLSessionCacheTimeout of mod_ssl.</td>
</tr>
<tr>
<td><code>-T token_label</code></td>
<td>When pkcs11 is specified with <code>-f</code>, uses the PKCS#11 token specified in <code>token_label</code>. Use cryptoadm list -v to display all PKCS#11 tokens available.</td>
</tr>
<tr>
<td><code>-u username</code></td>
<td>The username of the user who owns the password file. If omitted, the system will try to read the password file as root.</td>
</tr>
<tr>
<td><code>-v</code></td>
<td>Verbose mode.</td>
</tr>
<tr>
<td><code>-V</code></td>

</tr>
<tr>
<td><code>-x proxy_port</code></td>
<td>The SSL proxy port. The port number is designated exclusively for clear-text HTTP communication between the web server and the kernel SSL proxy module. No external HTTP packets are delivered to this port.</td>
</tr>
<tr>
<td><code>-z ssl_session_cache_size</code></td>
<td>The maximum number of SSL sessions that can be cached. It corresponds to SSLCacheEntries of the Sun ONE web server configuration. When this option is not specified, the default is 5000 entries.</td>
</tr>
<tr>
<td><code>-?</code></td>
<td>Displays the usage of the command.</td>
</tr>
</tbody>
</table>

### Operands

- `[host]` [ssl_port]  
The address and the port of the web server for which the kernel SSL entry is created. If `host` is omitted, the entry will be used for all requests that arrived at the `ssl_port`, regardless of the destination address. Both a host name and an IP address are acceptable forms for `host`. `ssl_port` is required. Typically, this has a value of 443.

### Examples

#### EXAMPLE 1  Create and Enable a Kernel SSL Instance

The following command creates and enables a Kernel SSL instance using a certificate and a key in PKCS#11 format.

```bash
# ksslcfg create -f pkcs11 -T "Sun Software PKCS#11 softtoken" -C "Server-Cert" -p /some/directory/password -u webservd -x 8080 www.mysite.com 443
```

```bash
% svc svcs svc:/network/ssl/proxy
STATE STIME FMRI
online Sep_27 svc:/network/ssl/proxy:kssl-www-mysite-com-443
```
EXAMPLE 2  Create and Enable a Default Instance for All Addresses

The following command creates and enables a default instance for all addresses from a certificate and key in a pkcs#12 file.

```
# ksslcfg create -x 8888 -f pkcs12 -i /some/directory/keypair.p12 \
   -p /some/directory/password -u webservd 443
```

EXAMPLE 3  Create and Enable an Instance with Specific Cipher Suites

The following command creates and enables an instance with specific cipher suites.

```
# ksslcfg create -x 8080 -f pem \
   -i /some/directory/keypair.pem -p /some/directory/password \
   -c "rsa_rc4_128_md5,rsa_rc4_128_sha" \
   209.249.116.195 443
```

EXAMPLE 4  Disable and Delete an Instance

The following command disables and deletes an instance.

```
# ksslcfg delete www.mysite.com 443
```

Exit Status  

- 0  Successful completion.
- >0  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWkssl</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

Command line options are Evolving; command output is Unstable. The FMRI service name (svc://network/ssl/proxy) is Unstable, as is the FMRI instance's name format. The utility name is Stable.

See Also  nca(1), svcprop(1), svcs(1), cryptoadm(1M), svcadm(1M), svccfg(1M), user_attr(4), attributes(5), kssl(5), pkcs11_softtoken(5), rbac(5), smf(5)

Notes  ksslcfg create without an host argument creates an INADDR_ANY smf instance. ksslcfg delete without an host argument deletes only the INADDR_ANY instance. ksslcfg delete needs a host argument to delete any non-INADDR_ANY instance.

On a system with zones(5) installed, the ksslcfg command can be used only in the global zone at this time.
The `kstat` utility examines the available kernel statistics, or kstats, on the system and reports those statistics which match the criteria specified on the command line. Each matching statistic is printed with its module, instance, and name fields, as well as its actual value.

Kernel statistics may be published by various kernel subsystems, such as drivers or loadable modules; each kstat has a module field that denotes its publisher. Since each module might have countable entities (such as multiple disks associated with the `sd(7D)` driver) for which it wishes to report statistics, the kstat also has an instance field to index the statistics for each entity; kstat instances are numbered starting from zero. Finally, the kstat is given a name unique within its module.

Each kstat may be a special kstat type, an array of name-value pairs, or raw data. In the name-value case, each reported value is given a label, which we refer to as the statistic. Known raw and special kstats are given statistic labels for each of their values by `kstat`; thus, all published values can be referenced as `module:instance:name:statistic`.

When invoked without any module operands or options, kstat will match all defined statistics on the system. Example invocations are provided below. All times are displayed as fractional seconds since system boot.

**Options**

The tests specified by the following options are logically ANDed, and all matching kstats will be selected. A regular expression containing shell metacharacters must be protected from the shell by enclosing it with the appropriate quotes.

The argument for the `-c`, `-i`, `-m`, `-n`, and `-s` options may be specified as a shell glob pattern, or a Perl regular expression enclosed in `'` characters.

- `-c class` Displays only kstats that match the specified class. `class` is a kernel-defined string which classifies the “type” of the kstat.
- `-i instance` Displays only kstats that match the specified instance.
- `-l` Lists matching kstat names without displaying values.
- `-m module` Displays only kstats that match the specified module.
- `-n name` Displays only kstats that match the specified name.
- `-p` Displays output in parseable format. All example output in this document is given in this format. If this option is not specified, `kstat` produces output in a human-readable, table format.
-q Displays no output, but return appropriate exit status for matches against given criteria.
-s statistic Displays only kstats that match the specified statistic.
-T d | u Displays a time stamp before each statistics block, either in ctime(3C) format ('d') or as an alphanumeric representation of the value returned by time(2) ('u').

Operands

The following operands are supported:

module:instance:name:statistic Alternate method of specifying module, instance, name, and statistic as described above. Each of the module, instance, name, or statistic specifiers may be a shell glob pattern or a Perl regular expression enclosed by '/' characters. It is possible to use both specifier types within a single operand. Leaving a specifier empty is equivalent to using the "*" glob pattern for that specifier.

interval The number of seconds between reports.

count The number of reports to be printed.

Examples

In the following examples, all the command lines in a block produce the same output, as shown immediately below. The exact statistics and values will of course vary from machine to machine.

EXAMPLE 1 Using the kstat Command
exmple$ kstat -p -m unix -i 0 -n system_misc -s 'avenrun*'
exmple$ kstat -p -s 'avenrun*'
exmple$ kstat -p 'unix:0:system_misc:avenrun*'
exmple$ kstat -p '::*:avenrun*'
exmple$ kstat -p '::*:/avenrun_\d+min$/'

unix:0:system_misc:avenrun 15min 3
unix:0:system_misc:avenrun 1min 4
unix:0:system_misc:avenrun 5min 2

EXAMPLE 2 Using the kstat Command
exmple$ kstat -p -m cpu_stat -s 'intr*'
exmple$ kstat -p cpu_stat::,/intr/

cpu stat:0:cpu stat0:intr 29682330
cpu stat:0:cpu stat0:intrblk 87
cpu stat:0:cpu stat0:intrthread 15054222
cpu stat:1:cpu stat1:intr 426073
cpu stat:1:cpu stat1:intrblk 51
EXAMPLE 2 Using the kstat Command (Continued)

```
cpu_stat:1:cpu_stat1:intrthread 289668
cpu_stat:2:cpu_stat2:intr 134160
cpu_stat:2:cpu_stat2:intrblk 0
cpu_stat:2:cpu_stat2:intrthread 131
cpu_stat:3:cpu_stat3:intr 196566
cpu_stat:3:cpu_stat3:intrblk 30
cpu_stat:3:cpu_stat3:intrthread 59626
```

EXAMPLE 3 Using the kstat Command

```
example$ kstat -p :::state ':::avenrun*'  
exampless kstat -p :::state :::/^avenrun/
```

```
cpu_info:0:cpu_info0:state on-line
cpu_info:1:cpu_info1:state on-line
cpu_info:2:cpu_info2:state on-line
cpu_info:3:cpu_info3:state on-line
unix:0:system_misc:avenrun_15min 4
unix:0:system_misc:avenrun_1min 10
unix:0:system_misc:avenrun_5min 3
```

EXAMPLE 4 Using the kstat Command

```
exampless kstat -p 'unix:0:system_misc:avenrun*' 1 3
unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
unix:0:system_misc:avenrun_15min 15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
```

EXAMPLE 5 Using the kstat Command

```
exampless kstat -p -T d 'unix:0:system_misc:avenrun*' 5 2
Thu Jul 22 19:39:50 1999
unix:0:system_misc:avenrun_15min 12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11
Thu Jul 22 19:39:55 1999
unix:0:system_misc:avenrun_15min 12
unix:0:system_misc:avenrun_1min 0
```
EXAMPLE 5 Using the kstat Command

unix:0:system_misc:avenrun_5min 11

EXAMPLE 6 Using the kstat Command

example$ kstat -p -T u 'unix:0:system_misc:avenrun*'  
93268656  
unix:0:system_misc:avenrun_15min 14  
unix:0:system_misc:avenrun_1min 5  
unix:0:system_misc:avenrun_5min 18

Exit Status  The following exit values are returned:

0  One or more statistics were matched.
1  No statistics were matched.
2  Invalid command line options were specified.
3  A fatal error occurred.

Files  /dev/kstat    kernel statistics driver

Notes  If the pattern argument contains glob or Perl RE metacharacters which are also shell metacharacters, it will be necessary to enclose the pattern with appropriate shell quotes.
**Name**  
ktkt_warnd – Kerberos warning daemon

**Synopsis**  
/usr/lib/krb5/ktkt_warnd

**Description**  
ktkt_warnd is a daemon on Kerberos clients that can warn users when their Kerberos tickets are about to expire or renew the tickets before they expire. It is invoked by inetd when a ticket-granting ticket (TGT) is obtained for the first time, such as after using the kinit command. kktkt_warnd can be configured through the /etc/krb5/warn.conf file on the client. In warn.conf, you can specify that you be supplied notice, through syslog or terminal or mail, of ticket expiration or to renew the TGT.

**Files**  
/etc/krb5/warn.conf  
Kerberos warning configuration file

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

**See Also**  
svcs(1), inetadm(1M), inetd(1M), svcadm(1M), warn.conf(4), attributes(5), kerberos(5), smf(5)

**Notes**  
The kktkt_warnd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/security/ktkt_warn:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.
The label daemon is a system daemon which is started at boot time when Trusted Extensions is enabled. This daemon is started automatically and should not be invoked directly. It does not constitute a programming interface.

To enable Trusted Extensions, enter the following at the command line:

```bash
% svcadm enable svc:/system/labeld
```

Because Trusted Extensions affects the initialization and operation of zones, all zones must be removed before enabling Trusted Extensions. After enabling, the system should be rebooted to allow Trusted Extensions to come up properly initialized.

Enabling or disabling Trusted Extensions can only be done by a user or role with the `solaris.smf.manage.labels` authorization. (For example, a user or role that has either the Information Security or Object Label Management Rights Profile, or superuser.)

Other configuration steps are needed before using Trusted Extensions functionality. For more information, see the `Solaris Trusted Extensions Installation and Configuration Guide`.

## Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWtsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Uncommitted</td>
</tr>
</tbody>
</table>

## See Also

`svis(1), svcadm(1M), syslogd(1M), attributes(5), smf(5)`

## Notes

The `labels(5)` service is managed by the service management facility, `smf(5)`, under the service identifier:

`svc:/system/labeld:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
The `labelit` utility is used to write or display labels on unmounted disk file systems.

### Options

The following options are supported:

- `-F FSType`
  - Specify the FSType on which to operate. The FSType should either be specified here or be determinable from `/etc/vfstab` by matching the `special` with an entry in the table. If no matching entry is found, the default file system type specified in `/etc/default/fs` will be used.

- `-V`
  - Echo complete command line. This option may be used to verify and validate the command line. Additional information obtained using a `/etc/vfstab` lookup is included in the output. The command is not executed.

- `-o FSType-specific-options`
  - Specify FSType-specific options. See the manual page for the `labelit` module specific to the file system type.

### Operands

The following operands are supported. If no operands are specified, `labelit` will display the value of the labels.

- `special` The disk partition (for example, `/dev/rdsk/c0t3d0s6`). The device may not be on a remote machine.

- `operands` FSType-specific operands. Consult the manual page of the FSType-specific `labelit` command for detailed descriptions.

### Usage

See `largefile(5)` for the description of the behavior of `labelit` when encountering files greater than or equal to 2 Gbyte ($2^{31}$ bytes).

### Exit Status

The following exit values are returned:

- `0`
  - Write or display of labels was successful.

- non-zero
  - An error occurred.

### Files

- `/etc/vfstab`
  - List of default parameters for each file system.

- `/etc/default/fs`
  - Default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example:

```
LOCAL=ufs
LOCAL
```

  - The default partition for a command if no FSType is specified.

### Attributes

See `attributes(5)` for descriptions of the following attributes:
<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>

</tbody>
</table>

**See Also**  
labelit_hfs(1M), labelit_udfs(1M), labelit_ufs(1M), volcopy(1M), vfstab(4), attributes(5), largefile(5)

**Notes**  
This utility may not be supported for all FSTypes.
Name  labelit_hsfs – provide and print labels for hsfs file systems

Synopsis  
/usr/sbin/labelit -F hsfs [generic_options]
    [-o specific_options] special

Description  labelit can be used to provide labels for unmounted CD-ROM images (CD-ROMs may not be labeled, as they are read-only media).

generic_options are options supported by the generic labelit command.

If no specific_options are specified, labelit prints the current value of all label fields.

The special name should be the physical disk section (for example, /dev/dsk/c0d0s6).

Options  -o  Use one or more of the following name=value pairs separated by commas (with no intervening spaces) to specify values for specific label fields. According to the ISO 9660 specification, only certain sets of characters may be used to fill in these labels. Thus, "d-characters" below refers to the characters 'A' through 'Z', the digits '0' through '9', and the '_' (underscore) character. "a-characters" below refers to 'A' through 'Z', '0' through '9', space, and the following characters: '!%&()*+,-./:;<=>?_.

    absfile= Abstract file identifier, d-characters, 37 characters maximum.
    applid= Application identifier, d-characters, 128 characters maximum.
    bibfile= Bibliographic file identifier, d-characters, 37 characters maximum.
    copyfile= Copyright file identifier, d-characters, 128 maximum.
    prepid= Data preparer identifier, d-characters, 128 maximum.
    pubid= Publisher identifier, d-characters, 128 maximum.
    sysid= System identifier, a-characters, 32 maximum.
    volid= Volume identifier, d-characters, 32 maximum.
    volsetid= Volume set identifier, d-characters, 128 maximum.

labelit_udfs – provide and print labels for udfs file systems

**Labelit** -F udfs [generic_options] [-o specific_options] special [fsname volume]

**Description** The **labelit** command writes labels on an unmounted disk that contains a universal disk file (udf) system. These labels can be used to identify volumes.

**Options** The following options are supported:

- **generic_options** Specify generic_options supported by the generic labelit command. See **labelit**(1M) for descriptions of supported options.

- **-o specific_options** Specify udfs-file-system-specific options in a comma-separated list with no intervening spaces. The following specific_options are available:

  - **lvinfo1=string** Specify information to be inserted into the LVInfo1 field of the Implementation Use Volume Descriptor. Information in LVInfo1 is generally used to identify the person creating the file system. The maximum length of the string specified is 35 bytes.

  - **lvinfo2=string** Specify information to be inserted into the LVInfo2 field of the Implementation Use Volume Descriptor. Information in LVInfo2 is generally used to identify the organization responsible for creating the file system. The maximum length of the string specified is 35 bytes.

  - **lvinfo3=string** Specify information to be inserted into the LVInfo3 field of the Implementation Use Volume Descriptor. Information in LVInfo3 is generally used to identify the contact information for the medium. The maximum length of the string specified is 35 bytes.

**Operands** The following operands are supported:

- **special** Specify special as the physical disk slice, for example, /dev/rdsk/c0t0d0s6. The device cannot be on a remote machine.

- **fsname** Specify fsname as the mount point, (for example, root, u1, and so forth), of the file system.

- **volume** Specify volume as the physical volume name.

If none of the options (fsname, volume, specific_options) is specified, labelit prints the current values of fsname, volume, LVInfo1, LVInfo2 and LVInfo3.
Exit Status  The following exit values are returned:

0   Successful completion.
non-zero   An error occurred.

labelit_ufs – provide and print labels for ufs file systems

Synopsis

labelit -F ufs [generic_options] special [fsname volume]

Description

labelit is used to write labels on unmounted disk file systems. Such labels may be used to uniquely identify volumes and are used by volume-oriented programs such as volcopy(1M).

Options

The following option is supported:

  generic_options options supported by the generic labelit command. See labelit(1M).

Operands

The following operands are supported:

  special name should be the physical disk section (for example, /dev/dsk/c0d0s6). The device may not be on a remote machine.

  fsname represents the mount point (for example, root, u1, and so on) of the file system.

  volume may be used to represent the physical volume name.

If fsname and volume are not specified, labelit prints the current values of these labels. Both fsname and volume are limited to six or fewer characters.

Exit Status

The following exit values are returned:

  0 Write or display of labels was successful.
  non-zero An error occurred.

ldapaddent -d [-v] [-a authenticationMethod] [-D bindDN]
 -w bind_password] [-j passwdFile] database

ldapaddent [-cpv] -h LDAP_server[:serverPort] [-M domainName]
 [-N profileName] [-P certifPath] [-a authenticationMethod]
 [-b baseDN] -D bindDN [-w bind_password] [-f filename]
 [-j passwdFile] database

ldapaddent [-cpv] -h LDAP_server[:serverPort] [-M domainName]
 [-N profileName] [-P certifPath] [-a authenticationMethod]
 [-b baseDN] [-f filename] database

ldapaddent -d [-v] -h LDAP_server[:serverPort] [-M domainName]
 [-N profileName] [-P certifPath] [-a authenticationMethod]
 [-b baseDN] -D bindDN [-w bind_password] [-j passwdFile]
database
```

Description

`ldapaddent` creates entries in LDAP containers from their corresponding /etc files. This operation is customized for each of the standard containers that are used in the administration of Solaris systems. The `database` argument specifies the type of the data being processed. Legal values for this type are one of `aliases`, `auto_*`, `bootparams`, `ethers`, `group`, `hosts` (including both IPv4 and IPv6 addresses), `ipnodes` (alias for `hosts`), `netgroup`, `netmasks`, `networks`, `passwd`, `shadow`, `protocols`, `publickey`, `rpc`, and `services`. In addition to the preceding, the `database` argument can be one of the RBAC-related files (see `rbac(5)`):

- `/etc/user_attr`
- `/etc/security/auth_attr`
- `/etc/security/prof_attr`
- `/etc/security/exec_attr`

By default, `ldapaddent` reads from the standard input and adds this data to the LDAP container associated with the database specified on the command line. An input file from which data can be read is specified using the `-f` option.

If you specify the `-h` option, `ldapaddent` establishes a connection to the server indicated by the option in order to obtain a DUAProfile specified by the `-N` option. The entries will be stored in the directory described by the configuration obtained.

By default (if the `-h` option is not specified), entries will be stored in the directory based on the client's configuration. To use the utility in the default mode, the Solaris LDAP client must be set up in advance.
The location where entries are to be written can be overridden by using the `-b` option.

If the entry to be added exists in the directory, the command displays an error and exits, unless the `-c` option is used.

Although, there is a shadow database type, there is no corresponding shadow container. Both the shadow and the passwd data is stored in the people container itself. Similarly, data from networks and netmasks databases are stored in the networks container.

The `user_attr` and `audit_user` data is stored by default in the people container. The `prof_attr` and `exec_attr` data is stored by default in the SolarisProfAttr container.

You must add entries from the passwd database before you attempt to add entries from the shadow database. The addition of a shadow entry that does not have a corresponding passwd entry will fail.

The passwd database must precede both the `user_attr` and `audit_user` databases.

For better performance, the recommended order in which the databases should be loaded is as follows:

- passwd database followed by shadow database
- networks database followed by netmasks database
- bootparams database followed by ethers database

Only the first entry of a given type that is encountered will be added to the LDAP server. The ldapaddent command skips any duplicate entries.

**Options**

The `ldapaddent` command supports the following options:

- `-a` authenticationMethod
  Specify authentication method. The default value is what has been configured in the profile.
  The supported authentication methods are:

  simple
  sasl/CRAM-MD5
  sasl/DIGEST-MD5
  sasl/GSSAPI
  tls:simple
  tls:sasl/CRAM-MD5
  tls:sasl/DIGEST-MD5

  Selecting `simple` causes passwords to be sent over the network in clear text. Its use is strongly discouraged. Additionally, if the client is configured with a profile which uses no authentication, that is, either the `credentialLevel` attribute is set to `anonymous` or `authenticationMethod` is set to `none`, the user must use this option to provide an authentication method. If the authentication method is `sasl/GSSAPI`, `bindDN` and `bindPassword` is not required and the `hosts` and `ipnodes` fields of `/etc/nsswitch.conf` must be configured as:
hosts: dns files
ipnodes: dns files

See nsswitch.conf(4).

-b baseDN
Create entries in the baseDN directory. baseDN is not relative to the client's default search base, but rather, it is the actual location where the entries will be created. If this parameter is not specified, the first search descriptor defined for the service or the default container will be used.

-c
Continue adding entries to the directory even after an error. Entries will not be added if the directory server is not responding or if there is an authentication problem.

-D bindDN
Create an entry which has write permission to the baseDN. When used with -d option, this entry only needs read permission.

-d
Dump the LDAP container to the standard output in the appropriate format for the given database.

-f filename
Indicates input file to read in an /etc/ file format.

-h LDAP_server[:serverPort]
Specify an address (or a name) and an optional port of the LDAP server in which the entries will be stored. The current naming service specified in the nsswitch.conf file is used. The default value for the port is 389, except when TLS is specified as the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the address and port number for an IPv6 address is:

[ipv6_addr]:port
To specify the address and port number for an IPv4 address, use the following format:

ipv4_addr:port
If the host name is specified, use the format:

host_name:port

-j passwdFile
Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w option.

-M domainName
The name of a domain served by the specified server. If not specified, the default domain name will be used.
-N profileName
Specify the DUAProfile name. A profile with such a name is supposed to exist on the server specified by -h option. Otherwise, a default DUAProfile will be used. The default value is default.

-P certifPath
The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the authenticationMethod and serviceAuthenticationMethod attributes. The default is /var/ldap.

-p
Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid, as the actual password appears in a shadow file.

-w bindPassword
Password to be used for authenticating the bindDN. If this parameter is missing, the command will prompt for a password. NULL passwords are not supported in LDAP.

EXAMPLE1
Adding Password Entries to the Directory Server
The following example shows how to add password entries to the directory server:

delete the following exampleshowshowtoaddpasswordentries
tothe directory server:

```
example# ldapaddent -D "cn=directory manager" -w secret \ 
-f /etc/passwd passwd
```

EXAMPLE 2
Adding Group Entries
The following example shows how to add group entries to the directory server using sasl/CRAM-MD5 as the authentication method:

```
example# ldapaddent -D "cn=directory manager" -w secret \ 
-a "sasl/CRAM-MD5" -f /etc/group group
```
EXAMPLE 3  Adding auto_master Entries

The following example shows how to add auto_master entries to the directory server:

```bash
example# ldapaddent -D "cn=directory manager" -w secret \
    -f /etc/auto_master auto_master
```

EXAMPLE 4  Dumping passwd Entries from the Directory to File

The following example shows how to dump password entries from the directory to a file foo:

```bash
example# ldapaddent -d passwd > foo
```

EXAMPLE 5  Adding Password Entries to a Specific Directory Server

The following example shows how to add password entries to a directory server that you specify:

```bash
example# ldapaddent -h 10.10.10.10:3890 \
    -M another.domain.name -N special_duaprofile \
    -D "cn=directory manager" -w secret \
    -f /etc/passwd passwd
```

Exit Status  The following exit values are returned:

- 0  Successful completion.
- >0  An error occurred.

Files  /var/ldap/ldap_client_file
/var/ldap/ldap_client_cred

Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use `ldapclient(1M)` to update these files.

Attributes  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

</table>

See Also  `ldap(1), ldaplist(1), ldapmodify(1), ldapmodrdn(1), ldapsearch(1), idsconfig(1M),
ldapclient(1M), suninstall(1M), nsswitch.conf(4), attributes(5)`

`System Administration Guide: Security Services`
Currently StartTLS is not supported by libldap.so.5, therefore the port number provided refers to the port used during a TLS open, rather than the port used as part of a StartTLS sequence. For example:

```
-h foo:1000 -a tls:simple
```

The preceding refers to a raw TLS open on host foo port 1000, not an open, StartTLS sequence on an unsecured port 1000. If port 1000 is unsecured the connection will not be made.
**ldap_cachemgr**

**Name**
ldap_cachemgr – LDAP daemon to manage client configuration for LDAP based Network Information Service lookups

**Synopsis**
/usr/lib/ldap/ldap_cachemgr [-l log-file] [-g]

**Description**
The ldap_cachemgr daemon is a process that provides an up-to-date configuration cache for LDAP naming services. It is started during multi-user boot.

The ldap_cachemgr utility provides caching for all parameters as specified and used by the LDAP naming service clients. The ldap_cachemgr utility uses the cache files which are originally created by executing the ldapclient(1M) utility, as cold start files. Updates to the cache files take place dynamically if profiles are used to configure the client. See the init option to ldapclient(1M).

The ldap_cachemgr utility helps improve the performance of the clients that are using LDAP as the Naming service repository. In order for the LDAP naming services to function properly, the ldap_cachemgr daemon must be running. ldap_cachemgr also improves system security by making the configuration files readable by superuser only.

The cache maintained by this daemon is shared by all the processes that access LDAP Naming information. All processes access this cache through a door call. On startup, ldap_cachemgr initializes the cache from the cache files. See ldapclient(1M). Thus, the cache survives machine reboots.

The ldap_cachemgr daemon also acts as its own administration tool. If an instance of ldap_cachemgr is already running, commands are passed transparently to the running version.

**Options**
The following options are supported:

- `-g`
  Print current configuration and statistics to standard output. This is the only option executable without superuser privileges.

- `-l log-file`
  Cause ldap_cachemgr to use a log file other than the default /var/ldap/cachemgr.log.

**Examples**

**EXAMPLE 1** Stopping and Restarting the ldap_cachemgr Daemon

The following example shows how to stop and to restart the ldap_cachemgr daemon.

```
example# svcadm disable network/ldap/client
example# svcadm enable network/ldap/client
```

**EXAMPLE 2** Forcing ldap_cachemgr to Reread Configuration Files

The following example shows how to force ldap_cachemgr to reread the /var/ldap/ldap_client_file and /var/ldap/ldap_client_cred files.

```
example# pkill -HUP ldap_cachemgr
```
Files

/var/ldap/cachemgr.log
Default log file.

/var/ldap/ldap_client_file
/var/ldap/ldap_client_cred
Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use `ldapclient(1M)` to update these files.

Warnings
The `ldap_cachemgr` utility is included in the current Solaris release on an uncommitted basis only. It is subject to change or removal in a future minor release.

Attributes
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

See Also
`ldap(1), ldapadd(1), ldapdelete(1), ldaplist(1), ldapmodify(1), ldapmodrdn(1), ldapsearch(1), pkill(1), svcs(1), idsconfig(1M), ldapaddent(1M), suninstall(1M), svcadm(1M), signal.h(3HEAD), resolv.conf(4), attributes(5), smf(5)`

Notes
The `ldap_cachemgr` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/ldap/client
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
Name
ldapclient – initialize LDAP client machine or output an LDAP client profile in LDIF format

Synopsis
/usr/sbin/ldapclient [-v | -q] init [-a profileName=profileName]
[-a domainName=domain] [-a proxyDN=proxyDN]
[-a proxyPassword=password]
[-a authenticationMethod=authenticationMethod]
[-a certificatePath=path] [-d bindDN] [-w bindPassword]
[-j passwdFile] [-y passwdFile] LDAP_server[:port_number]

/usr/sbin/ldapclient [-v | -q] manual [-a attrName=attrVal]

/usr/sbin/ldapclient [-v | -q] mod [-a attrName=attrVal]

/usr/sbin/ldapclient [-v | -q] list

/usr/sbin/ldapclient [-v | -q] uninit

/usr/sbin/ldapclient [-v | -q] genprofile [-a profileName=profileName]
[-a attrName=attrVal]

Description
The ldapclient utility can be used to:

- initialize LDAP client machines
- restore the network service environment on LDAP clients
- list the contents of the LDAP client cache in human readable format.

The init form of the ldapclient utility is used to initialize an LDAP client machine, using a profile stored on an LDAP server specified by LDAP_server. The LDAP client will use the attributes in the specified profile to determine the configuration of the LDAP client. Using a configuration profile allows for easy installation of LDAP client and propagation of configuration changes to LDAP clients. The ldap_cachemgr(1M) utility will update the LDAP client configuration when its cache expires by reading the profile. For more information on the configuration profile refer to IETF document A Configuration Schema for LDAP Based Directory User Agents.

The manual form of the ldapclient utility is used to initialize an LDAP client machine manually. The LDAP client will use the attributes specified on the command line. Any unspecified attributes will be assigned their default values. At least one server must be specified in the defaultServerList or the preferredServerList attributes. The domainName attribute must be specified if the client's domainName is not set.

The mod form of the ldapclient utility is used to modify the configuration of an LDAP client machine that was setup manually. This option modifies only those LDAP client configuration attributes specified on the command line. The mod option should only be used on LDAP clients that were initialized using the manual option.

Regardless of which method is used for initialization, if a client is to be configured to use a proxy credentialLevel, proxy credentials must be provided using -a proxyDN=proxyDN and -a proxyPassword=proxyPassword options. However, if -a proxyPassword=proxyPassword is
not specified, \ldapclient will prompt for it. Note that NULL passwords are not allowed in LDAP. If a self credential level is configured, authentication method must be sasl/GSSAPI.

If any file is modified during installation, it will be backed up to /var/ldap/restore. The files that are typically modified during initialization are:

- /etc/nsswitch.conf
- /etc/defaultdomain (if it exists)
- /var/yp/binding/'domainname' (for a NIS(YP) client)
- /var/nis/NIS_COLD_START (for a NIS+ client)
- /var/ldap/ldap_client_file (for an existing LDAP client)
- /var/ldap/ldap_client_cred (for an existing LDAP client)

\ldapclient does not set up a client to resolve hostnames using DNS. It simply copies /etc/nsswitch.ldap to /etc/nsswitch.conf. If you prefer to use DNS for host resolution, please refer to the DNS documentation for information on setting up DNS. See resolv.conf(4). If you want to use sasl/GSSAPI as the authentication method, you have to use DNS for hosts and ipnodes resolution.

The list form of the \ldapclient utility is used to list the LDAP client configuration. The output will be human readable. LDAP configuration files are not guaranteed to be human readable.

The uninit form of the \ldapclient utility is used to uninitialize the network service environment, restoring it to the state it was in prior to the last execution of \ldapclient using init or manual. The restoration will succeed only if the machine was initialized with the init or manual form of \ldapclient, as it uses the backup files created by these options.

The genprofile option is used to write an LDIF formatted configuration profile based on the attributes specified on the command line to standard output. This profile can then be loaded into an LDAP server to be used as the client profile, which can be downloaded by means of the \ldapclient init command. Loading the LDIF formatted profile to the directory server can be done through ldapadd(1), or through any server specific import tool. Note that the attributes proxyDN, proxyPassword, certificatePath, and domainName are not part of the configuration profile and thus are not permitted.

You must have superuser privileges to run the \ldapclient command, except with the genprofile option.

To access the information stored in the directory, clients can either authenticate to the directory, or use an unauthenticated connection. The LDAP client is configured to have a credential level of either anonymous or proxy. In the first case, the client does not authenticate to the directory. In the second case, client authenticates to the directory using a proxy identity. In the third case, client authenticates to the directory using a Kerberos principal that is mapped to an LDAP identity by the LDAP server. Refer to the chapter on implementing security in the Sun ONE Directory Server Administration Guide or your appropriate directory server documentation for identity mapping details.
If a client is configured to use an identity, you can configure which authentication method the client will use. The LDAP client supports the following authentication methods:

- none
- simple
- sasl/CRAM-MD5
- sasl/DIGEST-MD5
- sasl/GSSAPI
- tls:simple
- tls:sasl/CRAM-MD5
- tls:sasl/DIGEST-MD5

Note that some directory servers may not support all of these authentication methods. For simple, be aware that the bind password will be sent in the clear to the LDAP server. For those authentication methods using TLS (transport layer security), the entire session is encrypted. You will need to install the appropriate certificate databases to use TLS.

**Commands**

The following commands are supported:

- **init**
  Initialize client from a profile on a server.

- **manual**
  Manually initialize client with the specified attribute values.

- **mod**
  Modify attribute values in the configuration file after a manual initialization of the client.

- **list**
  Write the contents of the LDAP client cache to standard output in human readable form.

- **uninit**
  Uninitialize an LDAP client, assuming that `ldapclient` was used to initialize the client.

- **genprofile**
  Generate a configuration profile in LDIF format that can then be stored in the directory for clients to use, with the `init` form of this command.

**Attributes**

The following attributes are supported:

- **attributeMap**
  Specify a mapping from an attribute defined by a service to an attribute in an alternative schema. This can be used to change the default schema used for a given service. The syntax of `attributeMap` is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is NULL. In the example,

  `attributeMap: passwd:uid=employeeNumber`
the LDAP client would use the LDAP attribute employeeNumber rather than uid for the passwd service. This is a multivalued attribute.

authenticationMethod
Specify the default authentication method used by all services unless overridden by the serviceAuthenticationMethod attribute. Multiple values can be specified by using a semicolon-separated list. The default value is none. For those services that use credentialLevel and credentialLevel is anonymous, this attribute is ignored. Services such as pam_ldap will use this attribute, even if credentialLevel is anonymous. The supported authentication methods are described above. If the authenticationMethod is sasl/GSSAPI, the hosts and ipnodes of /etc/nsswitch.conf must be configured with DNS support, for example:

hosts: dns files
ipnodes: dns files

bindTimeLimit
The maximum time in seconds that a client should spend performing a bind operation. Set this to a positive integer. The default value is 30.

certificatePath
The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the authenticationMethod and serviceAuthenticationMethod attributes. The default is /var/ldap.

credentialLevel
Specify the credential level the client should use to contact the directory. The credential levels supported are either anonymous or proxy. If a proxy credential level is specified, then the authenticationMethod attribute must be specified to determine the authentication mechanism. Further, if the credential level is proxy and at least one of the authentication methods require a bind DN, the proxyDN and proxyPassword attribute values must be set. If a self credential level is specified, the authenticationMethod must be sasl/GSSAPI.

defaultSearchBase
Specify the default search base DN. There is no default. The serviceSearchDescriptor attribute can be used to override the defaultSearchBase for given services.

defaultSearchScope=one | sub
Specify the default search scope for the client's search operations. This default can be overridden for a given service by specifying a serviceSearchDescriptor. The default is one level search.

defaultServerList
A space separated list of server names or server addresses, either IPv4 or IPv6. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers' names by using either files or dns. If the LDAP server name cannot be resolved, your naming service will fail.
The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:

[ipv6_addr]:port

To specify the port number for an IPv4 address, use the following format:

ipv4_addr:port

If the host name is specified, use the format:

host_name:port

If you use TLS, the LDAP server's hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use files or dns to resolve the host address.

domainName

Specify the DNS domain name. This becomes the default domain for the machine. The default is the current domain name. This attribute is only used in client initialization.

followReferrals=true | false

Specify the referral setting. A setting of true implies that referrals will be automatically followed and false would result in referrals not being followed. The default is true.

objectclassMap

Specify a mapping from an objectclass defined by a service to an objectclass in an alternative schema. This can be used to change the default schema used for a given service. The syntax of objectclassMap is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is NULL. In the example,

objectclassMap=passwd:posixAccount=unixAccount

the LDAP client would use the LDAP objectclass of unixAccount rather than the posixAccount for the passwd service. This is a multivalued attribute.

preferredServerList

Specify the space separated list of server names or server addresses, either IPv4 or IPv6, to be contacted before servers specified by the defaultServerList attribute. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers' names by using either files or dns. If the LDAP server name cannot be resolved, your naming service will fail.

The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:
To specify the port number for an IPv4 address, use the following format:

```
ipv4_addr:port
```

If the host name is specified, use the format:

```
host_name:port
```

If you use TLS, the LDAP server's hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use files or dns to resolve the host address.

**profileName**
Specify the profile name. For `ldapclient init`, this attribute is the name of an existing profile which may be downloaded periodically depending on the value of the `profileTTL` attribute. For `ldapclient genprofile`, this is the name of the profile to be generated. The default value is `default`.

**profileTTL**
Specify the TTL value in seconds for the client information. This is only relevant if the machine was initialized with a client profile. If you do not want `ldap_cachemgr(1M)` to attempt to refresh the LDAP client configuration from the LDAP server, set `profileTTL` to 0 (zero). Valid values are either zero 0 (for no expiration) or a positive integer in seconds. The default value is 12 hours.

**proxyDN**
Specify the Bind Distinguished Name for the proxy identity. This option is required if the credential level is `proxy`, and at least one of the authentication methods requires a bind DN. There is no default value.

**proxyPassword**
Specify client proxy password. This option is required if the credential level is `proxy`, and at least one of the authentication methods requires a bind DN. There is no default.

**searchTimeLimit**
Specify maximum number of seconds allowed for an LDAP search operation. The default is 30 seconds. The server may have its own search time limit.

**serviceAuthenticationMethod**
Specify authentication methods to be used by a service in the form `servicename:authenticationmethod`, for example:

```
pam_ldap:tls:simple
```

For multiple authentication methods, use a semicolon-separated list. The default value is no service authentication methods, in which case, each service would default to the `authenticationMethod` value. The supported authentications are described above.
Three services support this feature: passwd-cmd, keyserv, and pam_ldap. The passwd-cmd service is used to define the authentication method to be used by passwd(1) to change the user's password and other attributes. The keyserv service is used to identify the authentication method to be used by the chkey(1) and newkey(1M) utilities. The pam_ldap service defines the authentication method to be used for authenticating users when pam_ldap(5) is configured. If this attribute is not set for any of these services, the authenticationMethod attribute is used to define the authentication method. This is a multivalued attribute.

**serviceCredentialLevel**
Specify credential level to be used by a service. Multiple values can be specified in a space-separated list. The default value for all services is NULL. The supported credential levels are: anonymous or proxy. At present, no service uses this attribute. This is a multivalued attribute.

**serviceSearchDescriptor**
Override the default base DN for LDAP searches for a given service. The format of the descriptors also allow overriding the default search scope and search filter for each service. The syntax of serviceSearchDescriptor is defined in the profile IETF draft. The default value for all services is NULL. This is a multivalued attribute. In the example,

```
  serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one
```

the LDAP client would do a one level search in ou=people,dc=a1,dc=acme,dc=com rather than ou=people, defaultSearchBase for the passwd service.

**Options**
The following options are supported:

- **-a attrName=attrValue**
  Specify attrName and its value. See SYNOPSIS for a complete list of possible attribute names and values.

- **-D bindDN**
  Specifies an entry that has read permission for the requested database.

- **-j passwdFile**
  Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w option.

- **-q**
  Quiet mode. No output is generated.

- **-v**
 Verbose output.

- **-w bindPassword**
  Password to be used for authenticating the bind DN. If this parameter is missing, the command will prompt for a password. NULL passwords are not supported in LDAP.
When you use `-w bindPassword` to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files, or in shell history.

If you supply “-” (hyphen) as a password, the command will prompt for a password.

-y passwdFile
Specify a file containing the password for the proxy DN. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the `-a proxyPassword` option.

Operands The following operand is supported:

LDAP_server
An address or a name for the LDAP server from which the profile will be loaded. The current naming service specified in the `nsswitch.conf` file is used. Once the profile is loaded, the `preferredServerList` and `defaultServerList` specified in the profile are used.

Examples

Example 1 Setting Up a Client By Using the Default Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the default profile stored on the specified LDAP server. This command will only be successful if either the credential level in the profile is set to anonymous or the authentication method is set to none.

example# ldapclient init 172.16.100.1

Example 2 Setting Up a Client By Using the simple Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the simple profile stored on the specified LDAP server. The domainname is set to `xyz.mycompany.com` and the proxyPassword is secret.

example# ldapclient init -a profileName=simple \
-a domainName=xyz.mycompany.com \
-a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \
-a proxyPassword=secret '[:fe80::a00:20ff:fea3:388:]':386

Example 3 Setting Up a Client Using Only One Server

The following example shows how to set up a client using only one server. The authentication method is set to none, and the search base is `dc=mycompany,dc=com`.

example# ldapclient manual -a authenticationMethod=none \
-a defaultSearchBase=dc=mycompany,dc=com \
-a defaultServerList=172.16.100.1
EXAMPLE 4  Setting Up a Client Using Only One Server That Does Not Follow Referrals

The following example shows how to set up a client using only one server. The credential level is set to proxy. The authentication method is sasl/CRAM-MD5, with the option not to follow referrals. The domain name is xyz.mycompany.com, and the LDAP server is running on port number 386 at IP address 172.16.100.1.

example# ldapclient manual
  -a credentialLevel=proxy
  -a authenticationMethod=sasl/CRAM-MD5
  -a proxyPassword=secret
  -a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com
  -a defaultSearchBase=dc=xyz,dc=mycompany,dc=com
  -a domainName=xyz.mycompany.com
  -a followReferrals=false
  -a defaultServerList=172.16.100.1:386

EXAMPLE 5  Using genprofile to Set Only the defaultSearchBase and the Server Addresses

The following example shows how to use the genprofile command to set the defaultSearchBase and the server addresses.

example# ldapclient genprofile -a profileName=myprofile
  -a defaultSearchBase=dc=eng,dc=sun,dc=com
  -a "defaultServerList=172.16.100.1 172.16.234.15:386"
> myprofile.ldif

EXAMPLE 6  Creating a Profile on IPv6 servers

The following example creates a profile on IPv6 servers.

example# ldapclient genprofile -a profileName=eng
  -a credentialLevel=proxy
  -a authenticationMethod=sasl/DIGEST-MD5
  -a defaultSearchBase=dc=eng,dc=acme,dc=com
  -a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one"
  -a preferenceserverList='[fe80::a00:20ff:fea3:388]'
  -a defaultServerList='[fe80::a00:20ff:fea3:edf]'
  '-[fe80::a00:20ff:feb5:e41]' > eng.ldif

EXAMPLE 7  Creating a Profile That Overrides Every Default Value

The following example shows a profile that overrides every default value.

example# ldapclient genprofile -a profileName=eng
  -a credentialLevel=proxy -a authenticationMethod=sasl/DIGEST-MD5
  -a bindTimeLimit=20
  -a defaultSearchBase=dc=eng,dc=acme,dc=com
  -a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one"
  -a serviceAuthenticationMethod=pam_ldap:tls:simple
  -a defaultSearchScope=sub
EXAMPLE 7 Creating a Profile That Overrides Every Default Value (Continued)

-a attributeMap=passwd:uid=employeeNumber  \n-a objectClassMap=passwd:posixAccount=unixAccount  \n-a followReferrals=false -a profileTTL=6000  \n-a preferredServerList=172.16.100.30 -a searchTimeLimit=30  \n-a "defaultServerList=172.16.200.1 172.16.100.1 192.168.5.6" > eng.ldif

Exit Status The following exit values are returned:

0 The command successfully executed.
1 An error occurred. An error message is output.
2 proxyDN and proxyPassword attributes are required, but they are not provided.

Files
/var/ldap/ldap_client_cred
/var/ldap/ldap_client_file
  Contain the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use ldapclient to update them.

/etc/defaultdomain
  System default domain name, matching the domain name of the data in the LDAP servers. See defaultdomain(4).

/etc/nsswitch.conf
  Configuration file for the name-service switch. See nsswitch.conf(4).

/etc/nsswitch.ldap
  Sample configuration file for the name-service switch configured with LDAP and files.

Caution Currently StartTLS is not supported by libldap.so.5, therefore the port number provided refers to the port used during a TLS open, rather than the port used as part of a StartTLS sequence. To avoid timeout delays, mixed use of TLS and non-TLS authentication mechanisms is not recommended.

For example:

- h foo:1000 -a authenticationMethod=tls:simple
...or:

defaultServerList= foo:1000
authenticationMethod= tls:simple

The preceding refers to a raw TLS open on host foo port 1000, not an open, StartTLS sequence on an unsecured port 1000. If port 1000 is unsecured the connection will not be made.

As a second example, the following will incur a significant timeout delay while attempting the connection to foo:636 with an unsecured bind.

defaultServerList= foo:636 foo:389
authenticationMethod= simple
ldmad – Logical Domains Agents daemon

ldmad (1M)

Synopsis
/usr/lib/ldoms/ldmad

Description
The ldmad daemon is part of the framework that enables Logical Domain agents to run on a Logical Domain. A Logical Domain agent is a component that interacts with the control domain to provide features or information.

ldmad is responsible for running agents on a Logical Domain. ldmad must be enabled to ensure the proper functionality of all features provided by the domain manager on the control domain. The daemon is started at boot time and has no configuration options.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWldomu</td>
</tr>
<tr>

<td>Unstable</td>
</tr>
</tbody>
</table>

See Also
svcs(1), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Logical Domains 1.2 Administration Guide

Errors
ldmad uses syslog(3C) to report status and error messages. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities. Informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file specify that all ldmad error messages are written to the /var/adm/messages log.

Notes
The ldmad service is managed by the service management facility, smf(5), under the service identifier:

tsvc:/ldoms/agents:default

Administrative actions on this service, such as enabling, disabling, or requesting restart can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
The `link` and `unlink` commands link and unlink files and directories. Only super-users can use these commands on directories.

Use `link` to create a new file that points to an existing file. The `existing-file` and `new-file` operands specify the existing file and newly-created files. See OPERANDS.

`link` and `unlink` directly invoke the `link(2)` and `unlink(2)` system calls, performing exactly what they are told to do and abandoning all error checking. This differs from the `ln(1)` command. See `ln(1)`.

While linked files and directories can be removed using `unlink`, it is safer to use `rm(1)` and `rmdir(1)` instead. See `rm(1)` and `rmdir(1)`.

If the existing file being hard linked is itself a symbolic link, then the newly created file (`new-file`) will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (`existing-file`).

The following operands are supported:

- `existing-file` specifies the name of the existing file to be linked.
- `file` specifies the name of the file to be unlinked.
- `new-file` specifies the name of newly created (linked) file.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `link`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

listdgrp(1M)

Name  listdgrp – lists members of a device group

Synopsis  /usr/bin/listdgrp dgroup...

Description  listdgrp displays the members of the device groups specified by the dgroup list.

Examples  EXAMPLE 1  An example of listdgrp.

The following example lists the devices that belong to group partitions:

```
example% listdgrp partitions
  root
  swap
  usr
```

Exit Status  The following exit values are returned:

- 0  Successful completion.
- 1  Command was syntax incorrect, an invalid option used, or an internal error occurred.
- 2  A device group table could not be opened for reading.
- 3  A device group dgroup could not be found in the device group table.

Files  /etc/dgroup.tab

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
