To add privileges to or modify privileges in a profile entry, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

Examples

EXAMPLE 1  Creating a new profile

The following creates a new User Manager profile on the local file system. The new profile description is Manage users and groups, and the authorizations assigned are solaris.admin.usermgr.write and solaris.admin.usermgr.read. The supplementary profile assigned is Operator. The help file name is RtUserMgmt.html.

```
./smprofile add -H myhost -p mypasswd -u root -- -n "User Manager" \
   -d "Manage users and groups" -a solaris.admin.usermgr.write \
   -a solaris.admin.usermgr.read -p Operator -m RtUserMgmt.html
```

EXAMPLE 2  Deleting a profile

The following deletes the User Manager profile from the local file system:

```
./smprofile delete -H myhost -p mypasswd -u root -- -n "User Manager"
```

EXAMPLE 3  Listing all profiles

The following lists all profiles and their associated profile descriptions on the local file system.

```
./smprofile list -H myhost -p mypasswd -u root --
```

EXAMPLE 4  Modifying a profile

The following modifies the User Manager profile on the local file system. The new profile description is Manage world, the new authorization assignment is solaris.admin.usermgr.* authorizations, and the new supplementary profile assignment is All. (The -a option argument must be enclosed in double quotes when the wildcard character (*) is used.)

```
./smprofile modify -H myhost -p mypasswd -u root -- -n "User Manager" \
   -d "Manage world" -a "solaris.admin.usermgr.*" -p All
```

Environment Variables

See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smprofile command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

Exit Status  The following exit values are returned:

0  Successful completion.
1  Invalid command syntax. A usage message displays.
An error occurred while executing the command. An error message displays.

**Files**
The following files are used by the `smprofile` command:

- `/etc/security/exec_attr`: Rights profiles database. See `exec_attr(4)`.  
- `/etc/security/prof_attr`: Profile description database. See `prof_attr(4)`.  
- `/etc/user_attr`: Extended user attribute database. See `user_attr(4)`.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

smreg(1M)

Name
smreg - register objects for the Sun Web Console

Synopsis
/usr/sbin/smreg [-h | --help] subcommand options

Description
The smreg utility is a Command Line Interface (CLI)-based registration mechanism to
manage the information in the console's registration databases. smreg adds management web
applications, libraries, and configuration information to registration databases. It also
validates an application’s deployment descriptor to make sure it has certain required tags that
enable the application to run in the console.

smreg has four subcommands: add, remove, check, and list.

Subcommands
The following subcommands are supported:

add
Registers objects of a specified type. If the object is already registered, any new registration
will replace the previous registration. The application registration descriptor app.xml is
verified to ensure that meets some initial requirements.

The format of the add subcommand is:

add -a [-x context] path
add -d path
add -l [-L] [-n lib_name] -s ALL | app_name path
add -m -b behavior [-s service] -o name=value ... module
add -p [-c | -e] name=value ...
add -h

remove
Unregisters named objects.

The format of the remove subcommand is:

remove -a app_name | context
remove -n app_name | -d path
remove -l -s ALL | app_name lib_name
remove -m [-s service] module
remove -p [-c | -e] name ...
remove -h

check
Check an application.
The check subcommand parses the application's web.xml file to make sure that it has the `filter` and `filter-mapping` tags. The console requires these tags to run an application.

The required tags are as follows:

```xml
<filter>
  <filter-name>SessionManagerFilter</filter-name>
  <filter-class>
    com.sun.management.services.session.AppSessionManagerFilter
  </filter-class>
  <init-param>
    <param-name>ignore-paths</param-name>
    <param-value>
      images/*
    </param-value>
  </init-param>
</filter>

<filter-mapping>
  <filter-name>SessionManagerFilter</filter-name>
  <url-pattern>/*</url-pattern>
</filter-mapping>
```

Elements in the web.xml file must appear in a fixed order. For example, the `filter` tag must appear in the web.xml file before the `filter-mapping` tag. For more information, see the Java Servlet Specifications 2.3.

The smreg check subcommand parses the application's web.xml file, checking for the existence of these tags and for the correct tag content. That is, the embedded `filter-name` tag content must be SessionManagerFilter, and the `filter-class` tag content must be:

```xml
com.sun.management.services.session.AppSessionManagerFilter
```

If the tag content is not correct, the application will not be registered.

If the tags are not included in the application's web.xml file, the script prints to standard output a corrected version the web.xml file, with the tags embedded in the correct location. Because multiple `filter` tags are allowed in a file, smreg also includes the new tags as the first in a series.

The format for the check subcommand is:

```
check [-d] path
check -h
```

The `-d` is used strictly to maintain interface compatibility with 1.0-based application packages, and is otherwise ignored.

```
list
Prints list of registered objects.
```

The format of the list subcommand is:
list [-a |-l | -m | -p]

If no options are specified, then all registered objects are listed.

Options

The following options are supported:

- **-a** | **--application**
  Object type is an application.

  See **app_name** under ARGUMENTS for more information on the name by which an application is registered.

- **-b** behavior | **--behavior** behavior
  A flag value that controls behavior as authentication proceeds down the login module stack. See behavior under ARGUMENTS for more information on values allowed.

- **-c** name=value ... | **--configuration** name=value ...
  When used with `-p`, this option specifies that the property arguments are server configuration properties. The name=value pairs are written to a datastore, to be read during the next server startup. Any property name can be created, but only those recognized by the server will have any effect.

- **-d** path | **--directory** path
  This option is deprecated and is preserved only for compatibility with existing 1.0-based applications. It will be removed in a future release.

  When used with the “add” subcommand, it has the same effect as “-a”.

  When used with the “remove” subcommand, path is the path to the original installation location of the application. This path will be mapped to the registered app_name so that the application can be unregistered using “smreg remove -a app_name”. When used with the “check” subcommand, -d is ignored. The -d option is preserved strictly to maintain 1.0 interface compatibility.

- **-e** name=value ... | **--environment** name=value ...
  When used with `-p`, this option specifies that the property arguments are server environment properties. The name=value pairs are placed into the server’s environment during the next server startup. Any environment name can be created, and is available for use by any application.

- **-h** | **-?** | **--help**
  Displays command and subcommand usage information.

- **-l** | **--library**
  Object type is a library JAR file.

  Library JAR files that are not installed in the same location as the application, or are not registered at the same time as the application (for example, localization JAR files), can be registered separately by using this option. See **lib_name** under ARGUMENTS for more information on the name by which a library is registered.
A library can be registered with global scope so that it can be used by all applications, by specifying the `-s ALL` option. A library can be registered so that it may only be used by a specific application, by specifying the `-s app_name` option. If a library must be shared by more than one application but not globally, then a separate registration is required for each instance in which the library is to be shared.

`-L` | `-link`
Specifies to register the library JAR as a symbolic link rather than as a file copy. This option is ignored on operating systems which do not support symbolic links.

`-m` | `-module`
Object type is a login module.

`-n` `[app_name | lib_name]` | `-name` `[app_name | lib_name]`
When used with the “add -l” subcommand, specifies the name by which an application or library is known to the registration service.

When used with the “remove” subcommand, specifies the name by which an application is known to the registry service. “remove -n” is deprecated and is preserved only for compatibility with existing 1.0-based applications. It will be removed in a future release.

See `app_name` under ARGUMENTS for more information on the name by which an application is registered.

See `lib_name` under ARGUMENTS for more information on the name by which a library is registered.

`-o name=value ...` | `-option name=value ...`
Options specific to the login module implementation. The options are specified as `name=value` pairs, each preceded by the `-o` option. Values containing more than one word must be enclosed in double quotes (").

`-p` | `-properties`
Object type is properties. This option is specified for use with either `-c` (for configuration properties) or `-e` (for environment properties). If neither `-c` nor `-e` are specified, then `-c` is assumed.

See the PROPERTIES section for information on specific configuration properties that are useful to a system administrator.

`-s` `[ALL | app_name]` | `-scope` `[ALL | app_name]`
When used with `-l`, specifies the sharing scope for the library being registered. A scope of `ALL` makes the library available to all applications. A scope of `app_name` makes the library available only to the application already registered as `app_name`. See `app_name` under ARGUMENTS for more information on the name by which an application is registered.

`-s service` | `-scope service`
When used with `-m`, specifies the login service scope for the module. If not specified, the default is `ConsoleLogin`, which is the web console’s browser login service.
-V|--version
Display console version information.

-x context|--context context
The deployment context path for an application. This option is to be used to register
applications built with the SDK version 2.1 or greater. If not provided and the application is
unpacked, the context is the parent directory of the application’s WEB-INF directory. This
option is ignored when registering applications built with an SDK version prior to 2.1.

Arguments
The subcommand arguments are:

app_name
The unique name of the registered application in the format of
pluginName_version, where pluginName and version are tags extracted
from the application’s registration descriptor, app.xml. All subsequent
references to the registered application must then be made by using this
registered name.

path
When used with the “add -a”, “add -d”, or “remove -d” subcommands,
the full directory path where the application has been installed.

When used with the check subcommand, if it is a directory then it is the
full directory path where the application has been installed. If it is a file,
then it is the path to a web.xml-compliant file.

When used with the “add -l” subcommand, the full path where the
library JAR file is installed.

behavior
Specifies the authentication behavior. The possible values are: required,
requisite, sufficient, or optional.

lib_name
The name by which a library JAR file is known to the registration service.
By default, libraries will be registered using the basename of the path to
the library. This default value can be overridden by using the -n lib_name
option to register the object by using a globally unique name.

module
The fully-qualified class name of the module. For example:
com.sun.management.services.authentication.MyLoginModule

Properties
While the list of configuration properties is unlimited, certain properties that may be useful
to a system administrator are mentioned here:

session.timeout.value
This is the time interval of no user activity after which the user will be prompted to log in
again to continue. The default session timeout is 15 minutes. Setting the value to -1 means
there is no timeout. To set the session timeout to 5 minutes, run the following command:

# smreg add -p -c session.timeout.value=5
debug.trace.path
This is the directory where log files are created. The default is /var/log/webconsole. To set the directory to /tmp/logs, run the following command:

# smreg add -p -c debug.trace.path=/tmp/logs

java.home
This is the path to the Java Development Kit (JDK) that will be used to run the web server. The default is /usr/j2se on Solaris and /usr/java/j2sdk1.4.2 on Linux. To set the path to /usr/jdk142, run the following command:

# smreg add -p -c java.home=/usr/jdk142

java.options
This contains the options for configuring the Java Virtual machine (JVM). The defaults are “-server -XX:+BackgroundCompilation”. To include setting the initial Java heap size to 64MB, run the following command:

# smreg add -p -c java.options="-Xms64 \ 
-server -XX:+BackgroundCompilation"

Examples

EXAMPLE 1 Registering an unpacked Application
The following command registers an application which has been installed unpacked in /opt/myCompany/myApp:

# smreg add -a /opt/myCompany/myApp

EXAMPLE 2 Unregistering an Application
The following command unregisters an application previous registered with an app_name of com.myCompany.myApp_1.2:

# smreg remove -a com.myCompany.myApp_1.2

EXAMPLE 3 Registering a Library JAR File with Global Scope
The following command registers myLibrary.jar, installed in /opt/myCompany/MyApp, as com_myCompany_myLibrary.jar for use by all applications:

# smreg add -l -n com_myCompany_myLibrary.jar \ 
-server -XX:+BackgroundCompilation

EXAMPLE 4 Registering a Library JAR file with a Specific Application Scope
The following command registers Utilities.jar, installed in /opt/SomeCompany/lib, with the application already registered as com.myCompany.myApp_1.2:

# smreg add -l -s com.myCompany.myApp_1.2 \ 
/opt/SomeCompany/lib/Utilities.jar
EXAMPLE 5  Unregister a Library JAR File from Global Scope
The following command unregisters com_myCompany_myLibrary.jar from global scope so that it is not available to applications:

# smreg remove -l -s ALL com_myCompany_myLibrary.jar

EXAMPLE 6  Unregister a Library JAR File from a Specific Application Scope
The following command unregisters Utilities.jar so that it is not available to the registered application com.myCompany.myApp_1.2:

# smreg remove -l -s com.myCompany.myApp_1.2 Utilities.jar

EXAMPLE 7  Checking that Application's Deployment Descriptor Meets Sun Web Console Guidelines
Either of the following commands to check to see if the deployment descriptor located at /opt/myCompany/myApp/WEB-INF/lib/web.xml meets the Sun Web Console guideline:

# smreg check /opt/myCompany/myApp
# smreg check /opt/myCompany/myApp/WEB-INF/lib/web.xml

EXAMPLE 8  Registering an Environment Property
The following command registers the environment property name GREETING with value "Hello World" and the name FOO with the value "bar" so that they appear in the server's environment and are available to any application:

# smreg add -p -e GREETING="Hello World" FOO=bar

EXAMPLE 9  Unregistering an Environment Property
The following command unregisters the environment property names GREETING and FOO so that they no longer appear in the server's environment and are not available to any application:

# smreg remove -p -e GREETING FOO

EXAMPLE 10  Registering a Login Module
The following command registers the module class com.sun.management.services.authentication.myLoginModule with "requisite" behavior and a commandPath argument:

# smreg add -m -b requisite \ 
  -o commandPath="/usr/lib/webconsole" \ 
  com.sun.management.services.authentication.myLoginModule

EXAMPLE 11  Unregistering a Login Module
The following command unregisters the module class com.sun.management.services.authentication.myLoginModule:

# smreg remove -m com.sun.management.services.authentication.myLoginModule
EXAMPLE 12  Print a List of All Registered Applications

`# smreg list -a`

Exit Status  The following exit values are returned:

0  Successful completion.
1  Usage error: missing or malformed arguments.
2  An error occurred that prevents registration - either a console configuration problem, or badly-formatted web.xml or app.xml.
3  Unable to determine OS for this machine.
4  Detected OS for this machine is not supported.

Attributes  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

smrole – manage roles and users in role accounts

**Synopsis**

```
/usr/sadm/bin/smrole subcommand [ auth_args ] - - [subcommand_args]
```

**Description**
The `smrole` command manages roles and adds or deletes users in role accounts.

**subcommands**

- **add**
  Adds a new role entry. To add an entry, the administrator must have the `solaris.role.write` authorization.

- **delete**
  Deletes one or more roles. To delete an entry, the administrator must have the `solaris.role.write` authorization.

- **list**
  Lists one or more roles. If you do not specify a role name, all roles are listed. To list an entry, the administrator must have the `solaris.admin.usermgr.read` authorization.

- **modify**
  Adds or deletes users from a role account. To modify an entry, the administrator must have the `solaris.role.write` authorization.

**Options**
The `smrole` authentication arguments, `auth_args`, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smrole` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, `subcommand_args`, must come after the `auth_args` and must be separated from them by the `- -` option.

**auth_args**
The `auth_args` are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u` are described below. They are all optional. These options are a subset of the full complement of supported options described in `smc(1M)`.

If no `auth_args` are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- -domain` with the `domain` argument.

```
-D | - -domain 13;domain
```

Specifies the default domain that you want to manage. The syntax of `domain` is `type/host_name/domin_name`, where `type` is `nis`, `nisplus`, `dns`, `ldap`, or `file`; `host_name` is the name of the machine that serves the domain; and `domain_name` is the name of the domain you want to manage. *(Note: Do not use nis+ for nisplus.)*
If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-H</code></td>
<td>Specifies the <code>host_name</code> and <code>port</code> to which you want to connect. If you do not specify a <code>port</code>, the system connects to the default port, 898. If you do not specify <code>host_name:port</code>, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <code>smc(1M)</code> -B option, or set your console preferences to load a “home toolbox” by default.</td>
</tr>
<tr>
<td><code>-l</code></td>
<td>Specifies the password for the <code>role_name</code>. If you specify a <code>role_name</code> but do not specify a <code>role_password</code>, the system prompts you to supply a <code>role_password</code>. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.</td>
</tr>
<tr>
<td><code>-p</code></td>
<td>Specifies the password for the <code>user_name</code>. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.</td>
</tr>
<tr>
<td><code>-r</code></td>
<td>Specifies a role name for authentication. If you do not specify this option, no role is assumed.</td>
</tr>
<tr>
<td><code>-u</code></td>
<td>Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.</td>
</tr>
</tbody>
</table>

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `-` option.

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.
To add or change privileges, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

For subcommand add:

- **-a adduser1 -a adduser2...** (Optional) Specifies the user name(s) to add to the new role. The administrator must have the solaris.role.assign authorization.

- **-c comment** (Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (:).

- **-d dir** (Optional) Specifies the home directory of the new role, limited to 1024 characters.

- **-F full_name** (Optional) Specifies the full, descriptive name of the role. The full_name must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the full_name in double quotes.

- **-G group1 -G group2...** (Optional) Specifies the new role's supplementary group membership in the system group database with the character string names of one or more existing groups. Note: You cannot assign a primary group to a role. A role's primary group is always sysadmin (group 14).

- **-h** (Optional) Displays the command's usage statement.

- **-n rolename** Specifies the name of the role you want to create.

- **-p addprof1 -p addprof2...** (Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the solaris.profmgr.assign or solaris.profmgr.delegate authorization.

- **-P password** (Optional) Specifies the role's password. The password can contain up to eight characters. If you do not specify a password, the system prompts you for one. To set the password, the administrator must have the solaris.admin.usermgr.pwd authorization. Note: When you specify a password using the -P option, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. However, if you do not specify a password (and the system prompts you for one), the echo is turned off when you type in the password.
-s shell  (Optional) Specifies the full pathname of the program used as the role’s shell on login. Valid entries are /bin/pfcsh (C shell), /bin/pngsh (Korn shell), and /bin/pfsh (Bourne shell), the default.

-u uid  (Optional) Specifies the ID of the role you want to add. If you do not specify this option, the system assigns the next available unique ID greater than 100.

-x autohome=Y|N  (Optional) Sets the role’s home directory. The home directory path in the password entry is set to /home/login name.

-x perm=home_perm  (Optional) Sets the permissions on the role’s home directory. perm is interpreted as an octal number, and the default is 0775.

-x serv=homedir_server  (Optional) If -D is nis, nisplus, or ldap, use this option to specify the name of the server where the user’s home directory resides. Users created in a local scope must have their home directory server created on their local machines.

-M limit_prives  Specifies the privilege name(s) to add to the new user_attr(4) entry. The default is all for limit privilege.

To add or change privileges, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

-D default_prives  Specifies the default privilege name(s) to add to the new user_attr(4) entry.

The options to the add subcommand listed below are available only if a system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.

-x clear=clearanceval  (Optional) Specifies the role’s clearance. clearanceval can be a string value or a hex value. If this option is not specified, the default, admin_high, is in effect. To set the clearance, the administrator must have the solaris.admin.usermgr.labels authorization.

-x label=labelval  (Optional) Specifies the role’s minimum label. labelval can be a string label or a
hex label. If this option is not specified, the default, admin_low, is in effect. To set the minimum label, the administrator must have the solaris.admin.usermgr.labels authorization.

-x labelview=HIDE|SHOW

(Optional) Specifies the second part of the labelview key-value pair. If SHOW is specified, labelview=*showsl will be recorded. If HIDE is specified, labelview=*hidesl will be recorded. The asterisk portion can be replaced by "internal," "external," or ""(null). If this option is not specified, the default, SHOW, is in effect.

-x view=INTERNAL|EXTERNAL|DEFAULT

(Optional) Specifies the label view type for the labelview in user_attr. If INTERNAL is specified, labelview=internal will be recorded; if EXTERNAL is specified, labelview=external will be recorded; if DEFAULT is specified, nothing will be recorded in user_attr. If this option is not specified, the default, INTERNAL, is in effect.

For subcommand delete:

-h

(Optional) Displays the command's usage statement.

-n rolename1 -n rolename2... Specifies the name of the role(s) you want to delete.

For subcommand list:

-h

(Optional) Displays the command's usage statement.

-l

(Optional) Displays the output for each user in a block of key:value pairs (for example, user name: root), followed by a blank line that delimits each user block. Each key:value pair is displayed on a separate line. The keys are: autohome setup, comment, home directory, login shell, primary group, secondary groups, server, user ID (UID), and user name.

-n role1 -n role2... (Optional) Specifies the role(s) that you want to list. If you do not specify a role name, all roles are listed.

For subcommand modify:
- `a adduser1 - a adduser2 ...` (Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization, or must have the `solaris.role.delegate` authorization and be a member of the role being modified.

- `c comment` (Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (`:`).

- `d dir` (Optional) Specifies the home directory of the new role, limited to 1024 characters.

- `F full_name` (Optional) Specifies the full, descriptive name of the role. The `full_name` must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the `full_name` in double quotes.

- `G group1 - G group2 ...` (Optional) Specifies the new role's secondary group membership in the system group database with the character string names of one or more existing groups. **Note:** You cannot assign a primary group to a role. A role's primary group is always `sysadmin` (group 14).

- `h` (Optional) Displays the command's usage statement.

- `n rolename` Specifies the name of the role you want to modify.

- `N new_rolename` (Optional) Specifies the new name of the role.

- `p addprof1 - p addprof2 ...` (Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.

- `P password` (Optional) Specifies the role's password. The `password` can contain up to eight characters. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. **Note:** When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.

- `q delprof1 - q delprof2 ...` (Optional) Specifies the profile(s) to delete from the role.

- `r deluser1 - r deluser2 ...` (Optional) Specifies the user name(s) to delete from the role.
-s shell  (Optional) Specifies the full pathname of the program used as the role’s shell on login. Valid entries are /bin/pfcsh (C shell), /bin/pfksh (Korn shell), and /bin/pfsh (Bourne shell), the default.

-x autohome=Y|N  (Optional) Sets the role’s home directory. The home directory path in the password entry is set to /home/login_name.

-x perm=home_perm  (Optional) Sets the permissions on the role’s home directory. perm is interpreted as an octal number, and the default is 0775.

-M limit_privs  Specifies the privilege name(s) to modify in a user_attr(4) entry.

To add or change privileges, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

-D default_prives  Specifies the default privilege name(s) to modify in a user_attr(4) entry.

The options to the modify subcommand listed below are available only if a system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.

-x clear=clearanceval  (Optional) Specifies the role’s clearance. clearanceval can be a string value or a hex value. If this option is not specified, the default, admin_high, is in effect. To set the clearance, the administrator must have the solaris.admin.usermgr.labels authorization.

-x label=labelval  (Optional) Specifies the role’s minimum label. labelval can be a string label or a hex label. If this option is not specified, the default, admin_low, is in effect. To set the minimum label, the administrator must have the solaris.admin.usermgr.labels authorization.

-x labelview=HIDE|SHOW  (Optional) Specifies the second part of the labelview key-value pair. If SHOW is
specified, labelview=*showsl will be recorded. If HIDE is specified, labelview=*hidesl will be recorded. The asterisk portion can be replaced by "internal,", "external," or ""(null). If this option is not specified, the default, SHOW, is in effect.

-x view=INTERNAL|EXTERNAL|DEFAULT
(Optional) Specifies the label view type for the labelview in user_attr. If INTERNAL is specified, labelview=internal will be recorded; if EXTERNAL is specified, labelview=external will be recorded; if DEFAULT is specified, nothing will be recorded in user_attr. If this option is not specified, the default, INTERNAL, is in effect.

To use an option that requires the Solaris Trusted Extensions feature, you must use the -B toolbox option to specify a toolbox that contains support for Trusted Extensions. For example:

```
# smrole add -H myhost -p mypasswd -u root -- -n role1 \
-F "Engineering Admin" -P abc123 -x clear=clearanceval \
-B http://<server>/toolboxes/tsol_files.tbx
```

In the command above, <server> is the name of the machine running the Solaris Management Console. See smc(1M) for a description of the -B option.

**Examples**

**EXAMPLE 1**  Creating a Role Account

The following creates the role1 account with a full name of Engineering Admin and a password of abc123 on the local file system, and assigns user1 and user2 to the role. This role has Name Service Security and Audit Review rights. The system assigns the next available unique UID greater than 100.

```
./smrole add -H myhost -p mypasswd -u root -- -n role1 \
  -F "Engineering Admin" -P abc123 -a user1 -a user2 \
   -p "Name Service Security" -p "Audit Review"
```

**EXAMPLE 2**  Deleting Role Accounts

The following deletes the role1 and role2 accounts from the local file system.

```
./smrole delete -H myhost -p mypasswd -u root -- -n role1 -n role2
```
EXAMPLE 3  Listing Role Accounts
The following lists all role accounts on the local file system in summary form.

  ./smrole list -H myhost -p mypasswd -u root --

EXAMPLE 4  Modifying a Role Account
The following modifies the role1 account so the role defaults to the Korn shell, includes the
user3 account, and does not include the user2 account.

  ./smrole modify -H myhost -p mypasswd -u root -- -n role1 
  -s /bin/pfksh -a user3 -r user2

Environment Variables
See environ(5) for a description of the JAVA_HOME environment variable, which affects the
execution of the smrole command. If this environment variable is not specified, the
/usr/java location is used. See smc(1M).

Exit Status  The following exit values are returned:

  0  Successful completion.

  1  Invalid command syntax. A usage message displays.

  2  An error occurred while executing the command. An error message displays.

Files
The following files are used by the smrole command:

  /etc/aliases    Mail aliases. See aliases(4).
  /etc/auto_home  Automatic mount points. See automount(1M).
  /etc/group      Group file. See group(4).
  /etc/passwd    Password file. See passwd(4).
  /etc/security/policy.conf Configuration file for security policy. See policy.conf(4).
  /etc/shadow    Shadow password file. See shadow(4).
  /etc/user_attr Extended user attribute database. See user_attr(4).

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>

**Name**  
smrsh – restricted shell for sendmail

**Synopsis**  
smrsh -c command

**Description**  
The smrsh program is intended as a replacement for the sh command in the prog mailer in sendmail(1M) configuration files. The smrsh program sharply limits commands that can be run using the |program syntax of sendmail. This improves overall system security. smrsh limits the set of programs that a programmer can execute, even if sendmail runs a program without going through an alias or forward file.

Briefly, smrsh limits programs to be in the directory /var/adm/sm.bin, allowing system administrators to choose the set of acceptable commands. It also rejects any commands with the characters: ,, ,>, |, ;, &, $, \r (RETURN), or \n (NEWLINE) on the command line to prevent end run attacks.

Initial pathnames on programs are stripped, so forwarding to /usr/ucb/vacation, /usr/bin/vacation, /home/server/mydir/bin/vacation, and vacation all actually forward to /var/adm/sm.bin/vacation.

System administrators should be conservative about populating /var/adm/sm.bin. Reasonable additions are utilities such as vacation(1) and procmail. Never include any shell or shell-like program (for example, perl) in the sm.bin directory. This does not restrict the use of shell or perl scripts in the sm.bin directory (using the #! syntax); it simply disallows the execution of arbitrary programs.

**Options**  
The following options are supported:
- -c command  
  Where command is a valid command, executes command.

**Files**  
/var/adm/sm.bin  
directory for restricted programs

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>

The `smserialport` command manages serial ports.

Sub-commands:

- **configure**: Configures a serial port's basic settings for a device such as a terminal, modem or no connection.
- **delete**: Deletes a given port. You can disable a port and prevent new services from being spawned for incoming connections, without interfering with existing services.
- **list**: Lists all serial ports.
- **modify**: Modifies a serial port's parameters.

Options:

There are two kinds of options: authentication arguments (`args`) and sub-command arguments (`subcommand_args`).

Authentication Arguments:

The `smserialport` authentication arguments, `args`, are derived from the `smc(1M)` argument set and are the same regardless of which sub-command you use.

Valid `args` are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no `args` are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes.

The single letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

The following authentication arguments (`args`) are supported:

- `-D` | `--domain domain` Specifies the default domain that you want to manage. `smserialport` accepts only the `file` value for this option. `file` is also the default value.

  The `file` default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the `domain` for all other tools.

- `-H` | `--hostname host_name:port` Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify
a host (host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc -B option, or set your console preferences to load a home toolbox by default.

- l | --rolepassword role_password
    Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

- p | --password password
    Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Because passwords specified on the command line can be seen by any user on the system, this option is considered insecure.

- r | --rolename role_name
    Specifies a role name for authentication. If you do not specify this option, no role is assumed.

- u | --username user_name
    Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

--
    This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

Sub-command Arguments
The sub-command specific options, subcommand_args, must come after the args and must be separated from them by the -- option. Enclose descriptions and arg options that contain white space in double quotes.

configure
    The configure sub-command requires the following sub-command argument:
    - n port_name
        Specifies the name of the serial port to reconfigure.

    The following sub-command arguments are optional for the configure sub-command:
    - b baudrate
        Specifies the port baud rate. The supported baud rate are 38400, 19200, 9600, 4800, 2400, 1200, 300 and auto. The default is 9600.
-c comment
  Specifies a short comment description of the service. The default is a description of the requested device type.

-h
  Displays the command's usage statement.

-l login_prompt
  Specifies the login prompt. The default is tty\'port_name\' login:.

-t terminal_type
  Specifies the terminal type. The default is tv i925.

-x device=device_name
  Specifies the device to be configured. Valid device_names are: terminal, modem dialin, modem dialout, modem dialinout or initializeonly for no connection. The default is terminal.

-x service=y | n
  Specifies the status of service, that is y for enabled or n for disabled. The default is y.

delete
  The delete sub-command requires the following sub-command arguments:

  -n port_name
    Specifies the name of the serial port to be disabled.

  The following sub-command arguments are optional for the delete sub-command:

  -h
    Displays the command's usage statement.

list
  The list sub-command does not require any sub-command arguments.

  The following sub-command arguments are optional for the list sub-command:

  -h
    Displays the command's usage statement.

  -v
    Displays the data in verbose format.

modify
  The modify sub-command requires the following sub-command arguments:

  -n port_name
    Specifies the name of the serial port to modify.

  The following sub-command arguments are optional for the modify sub-command:

  -b baudrate
    Specifies the port baud rate. The supported baud rate are 38400, 19200, 9600, 4800, 2400, 1200, 300 and auto.

  -c comment
    A short comment description of the service.

  -h
    Displays the command usage statement.
Specifiestheloginprompt.
- t terminal_type
  Specifiestheterminaltype.
- x bidirectional=y | n
  Specifiesthebi-directionalportflag,yforset

Examples

EXAMPLE 1  Listing Serial Ports

The following example lists the serial ports:

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Service</th>
<th>Baud-Rate</th>
<th>Terminal-Type</th>
<th>Prompt</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>enabled</td>
<td>9600</td>
<td>xterm</td>
<td>as</td>
<td>welcome</td>
</tr>
<tr>
<td>b</td>
<td>enabled</td>
<td>9600</td>
<td>tvi925</td>
<td>ttyb</td>
<td>login:</td>
</tr>
</tbody>
</table>

EXAMPLE 2  Modifying Serial Ports

The following example contains two commands. The first command modifies serial port b for
a baud rate of 4800, an xterm as terminal type, a b: for login prompt and a comment. The
second command lists the ports.

```
example% ./smserialport modify -H myhost -u root -p mypassword --
  -n b -b 4800 -t xterm -l b: -c "modified port b"
example% ./smserialport list -H myhost -u root -p mypassword --
```
EXAMPLE 2  Modifying Serial Ports  (Continued)
example% ./smserialport list -H myhost -u root -p mypassword --

<table>
<thead>
<tr>
<th>Port</th>
<th>Service</th>
<th>Baud-Rate</th>
<th>Terminal-Type</th>
<th>Prompt</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>enabled</td>
<td>9600</td>
<td>xterm</td>
<td>as</td>
<td>welcome</td>
</tr>
<tr>
<td>b</td>
<td>enabled</td>
<td>4800</td>
<td>xterm</td>
<td>b:</td>
<td>modified port b</td>
</tr>
</tbody>
</table>

EXAMPLE 3  Deleting a Serial Port
The following example contains two commands. The first command deletes serial port b. The second command lists the ports.
example% ./smserialport delete -H myhost -u root \
    -p mypassword -- -n b
example% ./smserialport list -H myhost -u root -p mypassword --

<table>
<thead>
<tr>
<th>Port</th>
<th>Service</th>
<th>Baud-Rate</th>
<th>Terminal-Type</th>
<th>Prompt</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>enabled</td>
<td>9600</td>
<td>xterm</td>
<td>as</td>
</tr>
<tr>
<td>b</td>
<td>disabled</td>
<td>9600</td>
<td>tvi925</td>
<td>ttyb</td>
</tr>
</tbody>
</table>

EXAMPLE 4  Configuring a Serial Port
The following example contains two commands. The first command configures serial port b for a bi-directional modem. The second command lists the ports.
example% ./smserialport configure -H myhost -u root \ 
    -p mypassword -- -n b -x device=modemdialinout
example% ./smserialport list -H myhost -u root -p mypassword --

<table>
<thead>
<tr>
<th>Port</th>
<th>Service</th>
<th>Baud-Rate</th>
<th>Terminal-Type</th>
<th>Prompt</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>enabled</td>
<td>9600</td>
<td>xterm</td>
<td>as welcome</td>
</tr>
<tr>
<td>b</td>
<td>enabled</td>
<td>9600</td>
<td>tvi925</td>
<td>ttyb login: Modem - Dial In and Out</td>
</tr>
</tbody>
</table>

Environment Variables
See environ(5) for descriptions of the following environment variables that affect the execution of smserialport: JAVA_HOME. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

Exit Status  The following exit values are returned:
0    Successful completion.
1    Invalid command syntax. A usage message displays.
2    An error occurred while executing the command. An error message displays.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
</tbody>
</table>

The `smtnrhdb` command adds, modifies, deletes, and lists entries in the `tnrhdb` database.

The `tnrhdb` database specifies which remote-host template to use for each host, including the local host, in the distributed system. If a host's IP address cannot be matched to some entry in the `tnrhdb` database, communication with the host is not permitted.

The `smtnrhdb` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first `smc` connection can time out, so you might need to retry the command.

Valid Host Addresses and Wildcards

The trusted network software uses a network "longest prefix of matching bits" mechanism when looking for a host. The software looks first for the IP address of the host. If the software does not find this address, then the software falls back to searching for an IP address with the longest prefix of a matching bit pattern, and so on.

**Note** – The actual numeric value of the subnet address or other subnetting information on the system (for example, from the `netmasks(4)` file) are not considered by this mechanism.

Using the "longest prefix of matching bits" mechanism, an IPv4 address of 0.0.0.0 is a wildcard address with a prefix length of 0 and hence matches any IPv4 address. For more information about prefix lengths in IPv4 and IPv6 addresses, see *System Administration Guide: IP Services*.

The `smtnrhdb` command accepts a hostname, IP address, and wildcard address with an optional prefix as valid addresses. See `subcommand_args`, below, for the format of valid addresses.

Sub-commands

The `smtnrhdb` subcommands are:

- **add**
  Adds a new entry to the `tnrhdb` database. To add an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

- **delete**
  Deletes an entry from the `tnrhdb` database. To delete an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

- **list**
  Lists all entries in the `tnrhdb` database. To list an entry, the administrator must have the `solaris.network.host.read` and `solaris.network.security.read` authorizations.

- **modify**
  Modifies an entry in the `tnrhdb` database. To modify an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.
Options

The smtnrhdb authentication arguments, auth_args, are derived from the smc arg set. These arguments are the same regardless of which subcommand you use.

The subcommand-specific options, subcommand_args, must be preceded by the - - option.

auth_args

The valid auth_args are -D, -H, -l, -p, -r, and -u; they are all optional. If no auth_args are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - - domain.

-D | - - domain domain

Specifies the default domain that you want to manage. The syntax of
domain=type:/host_name/domain_name, where type is dns, ldap, or file; host_name is
the name of the server; and domain_name is the name of the domain you want to manage.

If you do not specify this option, the Solaris Management Console assumes the file default
domain on whatever server you choose to manage, meaning that changes are local to the
server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies
the domain for all other tools.

-H | - - hostname host_name:port

Specifies the host_name and port to which you want to connect. If you do not specify a port,
the system connects to the default port, 898. If you do not specify host_name:port, the
Solaris Management Console connects to the local host on port 898.

-l | - - rolepassword role_password

Specifies the password for the role_name. If you specify a role_name but do not specify a
role_password, the system prompts you to supply a role_password. Passwords specified on
the command line can be seen by any user on the system, hence this option is considered
insecure.

-p | - - password password

Specifies the password for the user_name. If you do not specify a password, the system
prompts you for one. Passwords specified on the command line can be seen by any user on
the system, hence this option is considered insecure.

-r | - - rolename role_name

Specifies a role name for authentication. If you do not specify this option, no role is
assumed.

-u | - - username user_name

Specifies the user name for authentication. If you do not specify this option, the user
identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter
the preceding options, you must still enter the - - option.
**subcommand_args**  

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- `h`
  
  Displays the command's usage statement.

- `H hostname`
  
  Specifies the name of the host. For the list subcommand, the hostname argument is not specified. This is not required if the ipaddress subcommand argument is specified.

- `i ipaddress`
  
  Specifies the IP address of the host. This is not required if the hostname subcommand argument is specified. This option is not valid with the `-w` option.

- `n templatename`
  
  Specifies the name of an existing template.

- `p prefixlen`
  
  Specifies the prefix length (in bits) of a wildcard representation of the IP address. The prefix is the left-most portion of the IP address. This option is valid only with the `-w` option. For example, when the value of `-w ipaddress-wildcard` is 192.168.0.0, a prefixlen value of 24 indicates that the wildcard matches all addresses on the 192.168.0 network. With a prefixlen of 32, the wildcard 192.168.0.0 matches all addresses on the 192.168.0.0 network.

- `w ipaddress-wildcard`
  
  Specifies the IP address of the subnet using a wildcard.

- One of the following sets of arguments must be specified for subcommand `add`:

  - `H hostname -n templatename`
  
  - `i ipaddress -n templatename`
  
  - `w ipaddress-wildcard -n templatename [-p prefixlen]`
  
  - `h`

- One of the following sets of arguments must be specified for subcommand `modify`:

  - `H hostname -n templatename`
  
  - `i ipaddress -n templatename`
  
  - `w ipaddress-wildcard -n templatename [-p prefixlen]`
  
  - `h`

- One of the following sets of arguments must be specified for subcommand `delete`:

  - `H hostname`
  
  - `i ipaddress`
  
  - `w ipaddress-wildcard [-p prefixlen]`
  
  - `h`

- The subcommand `list` takes the following argument:

  - `h`
Examples

**EXAMPLE 1**  Specifying the Template Name for a Wildcard IP Address

The admin role specifies the template name, cipso_lan, for a series of hosts that use the IP address wildcard 192.168.113.0 on the local file system. Since no authorization arguments were specified, the administrator connects to port 898 of the local host on the local server with the file domain type, which are the defaults. The administrator is prompted for the admin password.

```bash
$ /usr/sadm/bin/smtnrhdb add -- -w 192.168.113.0 -n cipso_lan
```

**EXAMPLE 2**  Deleting an Entry in the tnrhdb Database

The admin role connects to port 898 (which happens to be the default) of the LDAP server and deletes a host entry from the database by specifying its IP address, 192.168.113.8. Since the domain was not specified, the file domain type and local server are used by default. The administrator is prompted for the admin password.

```bash
# /usr/sadm/bin/smtnrhdb delete \
-D ldap:/example.domain -i 192.168.113.8
```

**EXAMPLE 3**  Adding a Subnet to the tnrhdb Database

The following command adds all the addresses on the 192.168.55.0 subnet, from 192.168.55.1 to 192.168.55.255, to the tnrhdb database:

```bash
# /usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
-- -w 192.168.55.0 -n cipso
```

**EXAMPLE 4**  Adding Subnet 192.168.0 to the tnrhdb Database

The following command adds all the addresses on the 192.168.0 subnet, from 192.168.0.1 to 192.168.0.255 to the tnrhdb database. The prefix, 24, indicates that the first 24 bits (192.168.0) are fixed. Only the final zero is a wildcard.

```bash
# /usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
-- -w 192.168.0.0 -p 24 -n cipso
```

Login to machine1.ExampleCo.COM as user root was successful.
Download of com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli from machine1.ExampleCo.COM was successful.
Exit Status  The following exit values are returned:

0  
   Successful completion.

1  
   Invalid command syntax. A usage message displays.

2  
   An error occurred while executing the command. An error message displays.

Files  The following files are used by the smtnrhdb command:

/etc/security/tsol/tnrhdb  
   Trusted network remote-host database.

System Administration Guide: Security Services

Notes  The functionality described on this manual page is available only if the system is configured with Trusted Extensions.
smtnrhtp – manage entries in the trusted network template database

/usr/sadm/bin/smtnrhtpsubcommand [auth_args] -- [subcommand_args]

The smtnrhtp command adds, modifies, deletes, and lists entries in the tnrhtp database.

smtnrhtp subcommands are:

- **add** Adds a new entry to the tnrhtp database. To add an entry, the administrator must have the solaris.network.security.read and solaris.network.security.write authorizations.

- **modify** Modifies an entry in the tnrhtp database. To modify an entry, the administrator must have the solaris.network.security.read and solaris.network.security.write authorizations.

- **delete** Deletes an entry from tnrhtp database. To delete an entry, the administrator must have the solaris.network.security.read and solaris.network.security.write authorizations.

- **list** Lists entries in the tnrhtp database. To list an entry, the administrator must have the solaris.network.security.read authorizations.

Options

The smtnrhtp authentication arguments, *auth_args*, are derived from the smc argument set and are the same regardless of which subcommand you use. The smtnrhtp command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first smc connection can time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must be preceded by the **--** option.

- **auth_args** The valid *auth_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or --domain.

  - -D | --domain domain
    Specifies the default domain that you want to manage. The syntax of
    domain=type/host_name/domain_name, where type is dns, ldap, or file; host_name is
    the name of the server; and domain_name is the name of the domain you want to manage.

    If you do not specify this option, the Solaris Management Console assumes the file default
domain on whatever server you choose to manage, meaning that changes are local to the
server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the
domain for all other tools.
-H | --hostname host_name:port
Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898.

-l | --rolepassword role_password
Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | --password password
Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | --rolename role_name
Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | --username user_name
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

subcommand_args
Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

-h
Displays the command’s usage statement.

-n template_name
Specifies the name of the template.

-t hosttype
Specifies the host type of the new host. Valid values are unlabeled and cipso. The cipso host type is for hosts that use CIPSO (Common IP Security Options - Tag Type 1 only) to label packets.

-x doi=doi-value
Specifies the DOI value (the domain of interpretation). In the case of the unlabeled host type, this is the domain of interpretation for the def_label.

The domain of interpretation defines the set of rules for translating between the external or internal representation of the security attributes and their network representation. When systems that are configured with Trusted Extensions software have the same doi, they share that set of rules. In the case of the unlabeled host type, these systems also share the same
interpretation for the default attributes that are assigned to the unlabeled templates that have that same doi.

-\texttt{\textcolor{red}{-\textbf{x} \text{\color{red}max} = \textcolor{red}{\textit{maximum-label}}}} Specifies the maximum label. Together with \texttt{\textcolor{red}{-\textbf{x} \text{\color{red}min} = \textcolor{red}{\textit{minimum-label}}}} this value specifies the label accreditation range for the remote hosts that use this template. Values can be a hex value or string (such as admin\_high).

-\texttt{\textcolor{red}{-\textbf{x} \text{\color{red}min} = \textcolor{red}{\textit{minimum-label}}}} Specifies the minimum label. Together with \texttt{\textcolor{red}{-\textbf{x} \text{\color{red}max} = \textcolor{red}{\textit{maximum-label}}}} this value specifies the label accreditation range for the remote hosts that use this template. For gateway systems, \texttt{\textcolor{red}{min}} and \texttt{\textcolor{red}{max}} define the default range for forwarding labeled packets. The label range for routes is typically set by using a \texttt{\textcolor{red}{route(1M)}} subcommand with the \texttt{\textcolor{red}{-\textbf{secattr}}} option. When the label range for routes is not specified, the \texttt{\textcolor{red}{min}} to \texttt{\textcolor{red}{max}} range in the security template is used. Values can be a hex value or string (such as admin\_low).

-\texttt{\textcolor{red}{-\textbf{x} \text{\color{red}label} = \textcolor{red}{\textit{default-label}}}} Specifies the default label to be applied to incoming data from remote hosts that do not support these attributes. This option does not apply if \texttt{\textcolor{red}{hosttype}} is cipso. Values can be a hex value or string (such as admin\_low).

-\texttt{\textcolor{red}{-\textbf{x} \text{\color{red}slset} = \textcolor{red}{l1,l2,l3,l4}}}} Specifies a set of sensitivity labels. For gateway systems, the labels in \texttt{\textcolor{red}{slset}} are used for forwarding labeled packets. \texttt{\textcolor{red}{slset}} is optional. You can specify up to four label values, separated by commas. Values can be a hex value or string (such as admin\_low).
If the host type is changed, all options for the new host type must be specified.

- One of the following sets of arguments must be specified for subcommand delete:
  
  ```plaintext
  -n template | 
  -h 
  ```

- The following argument can be specified for subcommand list:

  ```plaintext
  -n template | 
  -h 
  ```

### Examples

**EXAMPLE 1  Adding a New Entry to the Network Template Database**

The admin role connects to port 898 of the LDAP server and creates the `unlabeled_ntk` entry in the tnrhttp database. The new template is assigned a host type of `unlabeled`, a domain of interpretation of 1, minimum label of `public`, maximum label of `restricted`, and a default label of `need to know`. The administrator is prompted for the admin password.

```bash
$ /usr/sadm/bin/smtnrhtp add -D ldap:directoryname -H servername:898 -- 
-n unlabeled_ntk -t unlabeled -x DOI=1 
-x min=public -x max=restricted -x label="need to know"
```

### Exit Status

The following exit values are returned:

- **0** Successful completion.
- **1** Invalid command syntax. A usage message displays.
- **2** An error occurred while executing the command. An error message displays.

### Files

The following files are used by the `smtnrhtp` command:

```plaintext
/etc/security/tsol/tnrhttp    Trusted network remote-host templates.
```

### Notes

The functionality described on this manual page is available only if the system is configured with Trusted Extensions.
Changing a template while the network is up can change the security view of an undetermined number of hosts.

Allowing unlabeled hosts onto a Solaris Trusted Extensions network is a security risk. To avoid compromising the rest of your network, such hosts must be trusted in the sense that the administrator is certain that these unlabeled hosts will not be used to compromise the distributed system. These hosts should also be physically protected to restrict access to authorized individuals. If you cannot guarantee that an unlabeled host is physically secure from tampering, it and similar hosts should be isolated on a separate branch of the network.

If the security template is modified while the network is up, the changes do not take effect immediately unless tntcctl(1M) is used to update the template entries. Otherwise, the changes take effect when next polled by the trusted network daemon, tnd(1M). Administrators are allowed to add new templates and modify attributes of existing templates while the network is up.

**Warnings**

Changing a template while the network is up can change the security view of an undetermined number of hosts.
smtnzonecfg – manage entries in the zone configuration database for Trusted Extensions networking

/usr/sadm/bin/smtnzonecfg subcommand [auth_args] -- {subcommand_args}

The smtnzonecfg command adds, modifies, deletes, and lists entries in the tnzonecfg database.

smtnzonecfg subcommands are:

add       Adds a new entry to the tnzonecfg database. To add an entry, the administrator must have the solaris.network.host.write and solaris.network.security.write authorizations.

modify    Modifies an entry in the tnzonecfg database. To modify an entry, the administrator must have the solaris.network.host.write and solaris.network.security.write authorizations.

delete    Deletes an entry from the tnzonecfg database. To delete an entry, the administrator must have the solaris.network.host.write and solaris.network.security.write authorizations.

list      Lists entries in the tnzonecfg database. To list an entry, the administrator must have the solaris.network.host.read and solaris.network.security.read authorizations.

Options The smtnzonecfg authentication arguments, auth_args, are derived from the smc argument set and are the same regardless of which subcommand you use. The smtnzonecfg command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first smc connection can time out, so you might need to retry the command.

The subcommand-specific options, subcommand_args, must be preceded by the -- option.

auth_args The valid auth_args are -D, -H, -l, -p, -r, and -u; they are all optional. If no auth_args are specified, certain defaults will be assumed and the user can be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or --domain.

-D | --domain domain

Specifies the default domain that you want to manage. The syntax of 
domain=type://host_name/domain_name, where type is dns, ldap, or file; host_name is the name of the server; and domain_name is the name of the domain you want to manage.

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis. This option specifies the domain for all other tools.
-H | -h --hostname host_name:port
Specifies the host_name and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify host_name:port, the Solaris Management Console connects to the local host on port 898.

-l | -l --rolepassword role_password
Specifies the password for the role_name. If you specify a role_name but do not specify a role_password, the system prompts you to supply a role_password. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | -p --password password
Specifies the password for the user_name. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | -r --rolename role_name
Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | -u --username user_name
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

---
This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

**subcommand_args**

Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

-h
Displays the command’s usage statement.

-n zonename
Specifies the zone name for the entry. This name is used when the zone is configured. See zonecfg(1M), under the -z zonename option, for the constraints on zone names. The specified zone name must be one of the configured zones on the system. The following command returns a list of configured zones:

/usr/sbin/zoneadm list -c

-l label
Specifies the label for the zone. This field is used to label the zone when the zone is booted. Each zone must have a unique label.

-x policymatch=0|1
Specifies the policy match level for non-transport traffic. Only values of 0 (match the label) or 1 (be within the label range of the zone) are accepted.
ICMP packets that are received on the global zone IP address are accepted based on the label range of the global zone’s security template if the global zone’s policymatch field is set to 1. When this field is set to 0 for a zone, the zone will not respond to an ICMP echo request from a host with a different label.

This subcommand argument is optional. If not specified, it will have a default value of 0.

-x mlpzone=""|port/protocol
Specifies the multilevel port configuration entry for zone-specific IP addresses. Multiple port/protocol combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP zone values. This subcommand argument is optional.

An MLP is used to provide multilevel service in the global zone as well as in non-global zones. As an example of how a non-global zone can use an MLP, consider setting up two labeled zones, internal and public. The internal zone can access company networks; the public zone can access public internet but not the company’s internal networks. For safe browsing, when a user in the internal zone wants to browse the internet, the internal zone browser forwards the URL to the public zone, and the web content is then displayed in a public zone web browser. That way, if the download in public zone compromises the web browser, it cannot affect the company’s internal network. To set this up, TCP port 8080 in the public zone is an MLP (8080/tcp), and the security template for the public zone has a label range from PUBLIC to INTERNAL.

-x mlpshared=""|port/protocol
Specifies the multilevel port configuration entry for shared IP addresses. Multiple port/protocol combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP shared values. This subcommand argument is optional.

A shared IP address can reduce the total number of IP addresses that are needed on the system, especially when configuring a large number of zones. Unlike the case of the zone-specific IP address, when MLPs are declared on shared IP addresses, only the global zone can receive the incoming network traffic that is destined for the MLP.

- One of the following sets of arguments must be specified for subcommand add:

  -n zonename -l label [-x policymatch=policy-match-level \n  -x mlpzone=port/protocol;.... | \n  -x mlpshared=port/protocol;.... ] \n  -h

- One of the following sets of arguments must be specified for subcommand modify:

  -n zonename [-l label] [-x policymatch=policy-match-level \n  -x mlpzone=port/protocol;.... | \n  -x mlpshared=port/protocol;.... ] \n  -h

- One of the following arguments must be specified for subcommand delete:
The following argument can be specified for subcommand list:

- n zonename
- h

Examples

EXAMPLE 1 Adding a New Entry to the Zone Configuration Database

The admin role creates a new zone entry, public, with a label of public, a policy match level of 1, and a shared MLP port and protocol of 666 and TCP. The administrator is prompted for the admin password.

$ /usr/sadm/bin/smtzonecfg add -- -n public -l public
   -x policymatch=1 -x mlpshared=666/tcp

EXAMPLE 2 Modifying an Entry in the Zone Configuration Database

The admin role changes the public entry in the tnzonecfg database to needtoknow. The administrator is prompted for the admin password.

$ /usr/sadm/bin/smtzonecfg modify -- -n public -l needtoknow

EXAMPLE 3 Listing the Zone Configuration Database

The admin role lists the entries in the tnzonecfg database. The administrator is prompted for the admin password.

$ /usr/sadm/bin/smtzonecfg list --

Exit Status

The following exit values are returned:

0 Successfull completion.
1 Invalid command syntax. A usage message displays.
2 An error occurred while executing the command. An error message displays.

Files

The following files are used by the smtnzonecfg command:

/etc/security/tsol/tnzonecfg Trusted zone configuration database.

See Also  smc(1M), attributes(5)

Notes  The functionality described on this manual page is available only if the system is configured with Trusted Extensions.
**Name**  
`smuser` – manage user entries

**Synopsis**  
`/usr/sadm/bin/smuser subcommand [ auth_args] - - [subcommand_args]`

**Description**  
The `smuser` command manages one or more user entries in the local `/etc` filesystem or a NIS or NIS+ target name service.

**subcommands**  
`smuser` subcommands are:

- **add**  
  Adds a new user entry to the appropriate files. You can use a template and input file instead of supplying the additional command line options. If you use a template and command line options, the command line options take precedence and override any conflicting template values. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

- **delete**  
  Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. Note: You cannot delete the system accounts with IDs less than 100, or 60001, 60002, or 65534.

- **list**  
  Lists one more user entries from the appropriate files. To list entries, the administrator must have the `solaris.admin.usermgr.read` authorization.

- **modify**  
  Modifies a user entry in the appropriate files. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

**Options**  
The `smuser` authentication arguments, `auth_args`, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smuser` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, `subcommand_args`, must come after the `auth_args` and must be separated from them by the `- -` option.

**auth_args**  
The valid `auth_args` are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u` are described below. They are all optional. These options are a subset of the full complement of supported options described in `smc(1M)`.

If no `auth_args` are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `-domain` with the `domain` argument.

- `-D` or `--domain 13:domain`  
  Specifies the default domain that you want to manage. The syntax of `domain` is `type/host_name/domain_name`, where `type` is `nis`, `nisplus`, `dns`, `ldap`, or `file`; `host_name` is...
the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note: Do not use nis+ for nisplus.*)

If you do not specify this option, the Solaris Management Console assumes the *file* default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

- **H** | -host name 13;host_name:port

  Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the **smc(1M)** -B option, or set your console preferences to load a "home toolbox" by default.

- **-l** | -role password 13;role_password

  Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

- **-p** | -password 13;password

  Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

- **-r** | -rolename 13;role_name

  Specifies a role name for authentication. If you do not specify this option, no role is assumed.

- **-u** | -username 13;user_name

  Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- **-**

  This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - **-**
options.

**subcommand_args**

Notes: Descriptions and other arg options that contain whitespace must be enclosed in double quotes.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- For subcommand `add`:
  - `-c comment` (Optional) Includes a short description of the login, which is typically the user's name. Consists of a string of up to 256 printable characters, excluding the colon (:).
  - `-d dir` (Optional) Specifies the home directory of the new user, limited to 1024 characters.
  - `-e ddmmyyyy` (Optional) Specifies the expiration date for a login. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (""") to indicate that the login is always valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
  - `-f inactive` (Optional) Specifies the maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. Enter zero to indicate that the login account is always active.
  - `-F full_name` (Optional) Specifies the full, descriptive name of the user. The `full_name` must be unique within a domain and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the `full_name` in double quotes.
  - `-g group` (Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.
  - `-G group1 -G group2 ...` (Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the `-g` and `-G` options are ignored.
  - `-h` (Optional) Displays the command's usage statement.
  - `-n login` Specifies the new user's login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.
-P password  (Optional) Specifies up to an eight-character password assigned to the user account. Note: When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. To set the password, the administrator must have the solaris.admin.usermgr.pswd authorization.

-s shell  (Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, /bin/csh (C shell), /bin/ksh (Korn shell), and the default, /bin/sh (Bourne shell).

-t template  (Optional) Specifies a template, created using the User Manager tool, that contains a set of pre-defined user attributes. You may have entered a name service server in the template. However, when a user is actually added with this template, if a name service is unavailable, the user's local server will be used for both the Home Directory Server and Mail Server.

-u uid  (Optional) Specifies the user ID of the user you want to add. If you do not specify this option, the system assigns the next available unique user ID greater than 100.

-x autohome=Y|N  (Optional) Sets the home directory to automount if set to Y. The user's home directory path in the password entry is set to /home/login name.

-x mail=mail_server  (Optional) Specifies the host name of the user's mail server, and creates a mail file on the server. Users created in a local scope must have a mail server created on their local machines.

-x perm=home_perm  (Optional) Sets the permissions on the user's home directory. perm is interpreted as an octal number, and the default is 0775.

-x pwmax=days  (Optional) Specifies the maximum number of days that the user's password is valid. The administrator must have the solaris.admin.usermgr.pswd authorization.

-x pwmin=days  (Optional) Specifies the minimum number of days between user password changes. The administrator must have the solaris.admin.usermgr.pswd authorization.

-x pwwarn=days  (Optional) Specifies the number of days relative to pwmax that the user is warned about password expiration prior to the password expiring. The administrator must have the solaris.admin.usermgr.pswd authorization.
-x serv=homedir_server  (Optional) Specifies the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.

-M limit_privs  Specifies the privilege name(s) to add to the new user_attr entry. The default is all for limit privilege.

To add or change privileges, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

-D default_privs  Specifies the default privilege name(s) to add to the new user_attr entry.

The following options to the add subcommand are available only if a system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.

- x clear=clearanceval  (Optional) Specifies the role's clearance. clearanceval can be a string value or a hex value. If this option is not specified, the default is the user's system default clearance. To set the clearance, the administrator must have the solaris.admin.usermgr.labels authorization.

- x idlecmd=LOGOUT|LOCK  Specifies the command to execute if the system has been idled. If LOGOUT is specified, idlecmd=logout will be recorded in user_attr. If LOCK is specified, idlecmd=lock will be recorded in user_attr. If this option is not specified, the default is the IDLECMD in the /etc/security/policy.conf file.

- x idletime=minutes  (Optional) Specifies the number of minutes before the specified idle command gets executed. Any integer value in the range from 1 to 120 is valid. This value is recorded in user_attr as idletime=val. If this option is not specified, the default is the IDLETIME in the /etc/security/policy.conf file.
-x label=labelval  
(Optional) Specifies the user's minimum label. labelval can be a string label or a hex label. If this option is not specified, the default is the user's system default minimum label. To set the minimum label, the administrator must have the solaris.admin.usermgr.labels authorization.

- x labelview=HIDE|SHOW  
(Optional) Specifies the second part of the labelview key-value pair. If SHOW is specified, labelview=*showsl will be recorded. If HIDE is specified, labelview=*hidesl will be recorded. The asterisk portion can be replaced by "internal," "external," or ""(null). If this option is not specified, the default is the LABELVIEW in the /etc/security/policy.conf file.

- x lock=Y|N  
(Optional) Specifies if an account is locked after a specified number of failed logins. This value is recorded in user_attr as lock_after_retries. If this option is not specified, the default is the LOCK_AFTER_RETRIES in the /etc/security/policy.conf file.

- x view=INTERNAL|EXTERNAL|DEFAULT  
(Optional) Specifies the label view type for the labelview in user_attr. If INTERNAL is specified, labelview=internal will be recorded; if EXTERNAL is specified, labelview=external will be recorded; if DEFAULT is specified, nothing will be recorded in user_attr. If this option is not specified, the default action, that nothing gets recorded in user_attr, is in effect.

For subcommand delete:

- h  
(Optional) Displays the command's usage statement.

- n login1  
Specifies the login name of the user you want to delete.
For subcommand `list`:

- `-h` (Optional) Displays the command's usage statement.
- `-l` Displays the output for each user in a block of `key:value` pairs (for example, `user name : root`) followed by a blank line to delimit each user block. Each `key:value` pair is displayed on a separate line. The keys are: autohome setup, comment, days to warn, full name, home directory, home directory permissions, login shell, mail server, max days change, max days inactive, min days change, password expires, password type, primary group, rights, roles, secondary groups, server, user ID (UID), and user name.

- `-n login1` Specifies the login name of the user you want to list.
- `-n login2...` (Optional) Specifies the additional login name(s) of the user(s) you want to list.

For subcommand `modify`:

- `-a addrole1 -a addrole2...` (Optional) Specifies the role(s) to add to the user account. To assign a role to a user, the administrator must have the `solaris.role.assign` authorization or must have the `solaris.role.delegate` authorization and be a member of each of the roles specified.
- `-c comment` (Optional) Describes the changes you made to the user account. Consists of a string of up to 256 printable characters, excluding the colon (:).
- `-d description` (Optional) Specifies the user's home directory, limited to 1024 characters.
- `-e ddimmyyyy` (Optional) Specifies the expiration date for a login in a format appropriate to the locale. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (""”) to indicate that the login is always valid.
- `-f inactive` (Optional) Specifies the maximum number of days allowed between uses of a login ID before the ID is declared invalid. Normal values are positive integers. Specify zero to indicate that the login account is always active.
- `-F full_name` (Optional) Specifies the full, descriptive name of the user. The `full_name` must be unique within a domain and can
contain alphanumeric characters and spaces. If you use spaces, you must enclose the full_name in double quotes.

- `g group` (Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.

- `G group1 - G group2 . . .` (Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the -g and -G options are ignored.

- `-h` (Optional) Displays the command's usage statement.

- `-n name` Specifies the user's current login name.

- `-N new_name` (Optional) Specifies the user's new login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

- `-p addprof1 - p addprof2 . . .` (Optional) Specifies the profile(s) to add to the user account. To assign a profile to a user, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.

- `-P password` (Optional) Specifies up to an eight-character password assigned to the user account.

When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.

- `-q delprof1 - q delprof2 . . .` (Optional) Specifies the profile(s) to delete from the user account.

- `-r delrole1 - r delrole2 . . .` (Optional) Specifies the role(s) to delete from the user account.

- `-s shell` (Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `/bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).

- `-x autohome=Y|N` (Optional) Sets up the home directory to automount if set to Y. The user's home directory path in the password entry is set to `/home/login name`. 
-x `pymax=days` *(Optional) Specifies the maximum number of days that the user's password is valid.*

- x `pmin=days` *(Optional) Specifies the minimum number of days between password changes.*

- x `pwarn=days` *(Optional) Specifies the number of days relative to `pymax` that the user is warned about password expiration before the password expires.*

- M `limit_prives` Specifies the privilege name(s) to modify in the `user_attr(4)` entry. The default is `all` for limit privilege.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- D `default_prives` Specifies the default privilege name(s) to modify in the `user_attr(4)` entry.

The following options to the `modify` subcommand are available only if a system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

- x `clear=clearanceval` *(Optional) Specifies the role's clearance. `clearanceval` can be a string value or a hex value. If this option is not specified, the default is the user's system default clearance. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.

- X `idlecmd=LOGOUT|LOCK` Specifies the command to execute if the system has been idled. If `LOGOUT` is specified, `idlecmd=logout` will be recorded in `user_attr`. If `LOCK` is specified, `idlecmd=lock` will be recorded in `user_attr`. If this option is not specified, the default is the `IDLECMD` in the `/etc/security/policy.conf` file.

- x `idletime=minutes` *(Optional) Specifies the number of minutes before the specified idle command gets executed. Any integer value in the range from 1 to 120 is valid.*
This value is recorded in user_attr as idletime=val. If this option is not specified, the default is the IDLETIME in the /etc/security/policy.conf file.

-x label=labelval

(Optional) Specifies the user's minimum label. labelval can be a string label or a hex label. If this option is not specified, the default is the user's system default minimum label. To set the minimum label, the administrator must have the solaris.admin.usermgr.labels authorization.

-x labelview=HIDE|SHOW

(Optional) Specifies the second part of the labelview key-value pair. If SHOW is specified, labelview=*showsl will be recorded. If HIDE is specified, labelview=*hidesl will be recorded. The asterisk portion can be replaced by "internal," "external," or "" (null).
If this option is not specified, the default is the LABELVIEW in the /etc/security/policy.conf file.

-x lock=Y|N

(Optional) Specifies if an account is locked after a specified number of failed logins. This value is recorded in user_attr as lock_after_retries. If this option is not specified, the default is the LOCK_AFTER_RETRIES in the /etc/security/policy.conf file.

-x view=INTERNAL|EXTERNAL|DEFAULT

(Optional) Specifies the label view type for the labelview in user_attr. If INTERNAL is specified, labelview=internal will be recorded; if EXTERNAL is specified, labelview=external will be recorded; if DEFAULT is specified, nothing will be recorded in user_attr. If this option is not specified, the default action, that nothing gets recorded in user_attr, is in effect.
Using Options that Require Solaris Trusted Extensions

To use an option that requires the Solaris Trusted Extensions feature, you must use the -B toolbox option to specify a toolbox that contains support for Trusted Extensions. For example:

```
# smuser add -H myhost -p mypasswd -x idlecmd=LOGOUT \
  -B http://<server>/toolboxes/tsol_files.tbx
```

In the command above, `<server>` is the name of the machine running the Solaris Management Console. See `smc(1M)` for a description of the -B option.

**Examples**

**EXAMPLE 1**  Creating a New User Account

The following creates a new user account on the local file system. The account name is `user1`, and the full name is Joe Smith. The comment field verifies that the account is for Joe Smith. The system will assign the next available user ID greater than 100 to this account. There is no password set for this account, so when Joe Smith logs in for the first time, he will be prompted to enter a password.

```
./smuser add -H myhost -p mypasswd -u root -- -F "Joe Smith" \ 
  -n user1 -c "Joe's account"
```

**EXAMPLE 2**  Deleting a User Account

The following deletes the `user1` account from the local file system:

```
./smuser delete -H myhost -p mypasswd -u root -- -n user1
```

**EXAMPLE 3**  Listing All User Accounts

The following lists all user accounts on the local file system in summary form:

```
./smuser list -H myhost -p mypasswd -u root --
```

**EXAMPLE 4**  Modifying a User Account

The following modifies the `user1` account to default to a Korn shell, and assigns the account to the qa_group secondary group.

```
./smuser modify -H myhost -p mypasswd -u root -- -n user1 \ 
  -s /bin/ksh -G qa_group
```

**Environment Variables**

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smuser` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

**Exit Status**

The following exit values are returned:

- 0  Successful completion.
- 1  Invalid command syntax. A usage message displays.
- 2  An error occurred while executing the command. An error message displays.
The following files are used by the `smuser` command:

- `/etc/aliases`: Mail aliases. See `aliases(4)`.  
- `/etc/auto_home`: Automatic mount points. See `automount(1M)`.  
- `/etc/group`: Group file. See `group(4)`.  
- `/etc/passwd`: Password file. See `passwd(4)`.  
- `/etc/security/policy.conf`: Configuration file for security policy. See `policy.conf(4)`.  
- `/etc/shadow`: Shadow password file. See `shadow(4)`.  
- `/etc/user_attr`: Extended user attribute database. See `user_attr(4)`.  

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWmga</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also `automount(1M), smc(1M), aliases(4), group(4), passwd(4), policy.conf(4), shadow(4), user_attr(4), attributes(5), environ(5)`
The `snmpbulkget` utility is an SNMP application that uses the SNMP GETBULK operation to send information to a network manager. You can specify one or more object identifiers (OIDs) on the command line. Each variable name must be entered in the format specified in `snmp_variables(4)`.

If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

Options

The following options are supported:

- `-Cnnum` Set the `non-repeaters` field in the GETBULK PDU. This specifies the number of supplied variables that should not be iterated over. The default is 0.

- `-Crnum` Set the `max-repetitions` field in the GETBULK PDU. This specifies the maximum number of iterations over the repeating variables. The default is 10.

In addition to this option, `snmpbulkget` takes the common options described in the `snmpcmd(1M)` manual page.

Examples

**EXAMPLE 1** Retrieving Multiple Objects

The following `snmpbulkget` command retrieves the variable `system.sysDescr.0` (which is the lexicographically next object to `system`) and the first five objects in the `ifTable`:

```sh
# snmpbulkget -v2c -Cn1 -Cr5 -Os -c public zeus system ifTable
```

This command produces output such as the following:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
ifIndex.1 = INTEGER: 1
ifIndex.2 = INTEGER: 2
ifDescr.1 = STRING: "lo0"
[...]
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsmcmd</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>External</td>
</tr>
</tbody>
</table>

Exit Status

0  Successful completion.

1  A usage syntax error. A usage message is displayed. Also used for timeout errors.
An error occurred while executing the command. An error message is displayed.

RFC 1905

**Notes**  
As the name implies, `snmpbulkget` uses the SNMP GETBULK message, which is not available in SNMPv1.
Name snmpbulkwalk – communicate with a network entity using SNMP BULK requests

Synopsis /usr/sfw/bin/snmpbulkwalk [application_options]
[common_options] [oid]

Description The snmpbulkwalk utility is an SNMP application that uses SNMP GETBULK requests to query a network entity efficiently for a tree of information.

You can specify an object identifier (OID) on the command line. This OID identifies the portion of the object identifier space that will be searched using GETBULK requests. All variables in the subtree below the given OID are queried and their values returned. Each variable name is given in the format specified in snmp_variables(4). If no OID argument is present, snmpbulkwalk searches MIB-2.

If a network entity has an error processing the request packet, an error packet is returned and a message is displayed. The message helps to pinpoint the way in which the request was malformed.

If the tree search causes attempts to search beyond the end of the MIB, the message "End of MIB" is displayed.

Options The following options are supported:

- Cc  Do not check whether the returned OIDs are increasing. Some agents (agents for Laser-Jet printers are an example) return OIDs out of order, but can complete the walk anyway. Other agents return OIDs that are out of order and can cause snmpbulkwalk to loop indefinitely. By default, snmpbulkwalk tries to detect this behavior and warns you when it hits an agent acting illegally. Use -Cc to turn off this behavior.

- Ci  Include the given OID in the search range. Normally, snmpbulkwalk uses GETBULK requests starting with the OID you specify and returns all results in the MIB tree beyond that OID. Use this option to include the OID specified on the command line in the printed results if it is a valid OID in the tree itself.

- Cn
num  Set the non-repeaters field in the GETBULK PDUs. This specifies the number of supplied variables that should not be iterated over. The default is 0.

- Cp  Upon completion of the walk, display the number of variables found.

- Cn
num  Set the max-repetitions field in the GETBULK PDUs. This specifies the maximum number of iterations over the repeating variables. The default is 10.

In addition to these options, snmpbulkwalk takes the common options described in the snmpcmd(1M) manual page.
The following command retrieves all of the variables under system:

```bash
# snmpbulkwalk -v2c -0s -c public zeus system
```

The return from `snmpbulkwalk` is as follows:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3 U1 1 sun4m"
sysObjectID.0 = OID: enterprises.hp.nm.hpsystem.10.1.1
sysUpTime.0 = Timeticks: (155274552) 17 days, 23:19:05
sysContact.0 = STRING: ""
sysName.0 = STRING: "zeus.net.cmu.edu"
sysLocation.0 = STRING: ""
sysServices.0 = INTEGER: 72
```

In contrast to `snmpwalk(1M)`, this information will be gathered in a single transaction with the agent, rather than one transaction per variable found. `snmpbulkwalk` is thus more efficient in terms of network utilization, which might be especially important when retrieving large tables.

**Exit Status**

- **0** Successful completion.
- **1** A usage syntax error. A usage message displays. Also used for timeout errors.
- **2** An error occurred while executing the command. An error message displays.

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>

**Notes**

As the name implies, `snmpbulkwalk` uses the SNMP GETBULK message, which is not available in SNMP v1.
Name  snmpcmd – commands to communicate with a network entity using SNMP requests

Synopsis  snmpcmd [options] agent [parameters]

Description  This manual page describes the common options for the following SNMP commands:
  ■ snmpbulkget(1M)
  ■ snmpbulkwalk(1M)
  ■ snmpdf(1M)
  ■ snmpget(1M)
  ■ snmpgetnext(1M)
  ■ snmpnetstat(1M)
  ■ snmpset(1M)
  ■ snmptrap(1M)
  ■ snmpusm(1M)
  ■ snmpvacm(1M)
  ■ snmpwalk(1M)

The command line applications use the SNMP protocol to communicate with an
SNMP-capable network entity, an agent. Individual applications usually (but not invariably)
take additional parameters that are given after the agent specification. These parameters are
documented in the manual pages for each application.

Options  The following options are supported:

-a authProtocol  Set the authentication protocol (MD5|SHA) used for authenticated
SNMPv3 messages. Overrides the defAuthType token in the
snmp.conf file.

A authPassword  Set the authentication pass phrase used for authenticated
SNMPv3 messages. Overrides the defAuthPassphrase token in the
snmp.conf file. Insecure to specify pass word phrases on the
command line, see snmp.conf(4).

-c community  Set the community string for SNMPv1/v2c transactions.
Oversrides the defcommunity token in the snmp.conf file.

-d  Dump (in hexadecimal) the sent and received SNMP packets.

-D token[,...]  Turn on debugging output for the given token(s). Try ALL for
extremely verbose output.

-e engineID  Set the authoritative (security) engineID used for SNMPv3
REQUEST messages. This is the engineID of the agent or proxy
(for example, 800000020109840301). This value will be
discovered if not supplied.
-E engineID  Set the context engineID used for SNMPv3 REQUEST messages scopedPdu. This is the engineID of the agent (for example, 800000020109840301). This will be the authoritative engineID if not specified.

-h, --help    Display a brief usage message and then exit.

-H           Display a list of configuration file directives understood by the command and then exit.

-I brRhu     Specifies input parsing options. See INPUT OPTIONS below.

-\ secLevel  Set the securityLevel used for SNMPv3 messages (noAuthNoPriv|authNoPriv|authPriv). Appropriate pass phrase(s) must be provided when using any level higher than noAuthNoPriv. Overrides the defSecurityLevel token in the snmp.conf file.

-m miblist   Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable MIBS.

The special keyword ALL is used to specify all modules in all directories when searching for MIB files. Every file whose name does not begin with a period (.) will be parsed as if it were a MIB file.

If the miblist has a leading plus sign (+), then the listed MIB modules are loaded in addition to MIB modules specified in the environment variable MIBS.

If a mibfile token is specified in the snmp.conf file, the -m MIB option overrides the mibfile token.

-M dirlist    Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable MIBDIRS.

If dirlist has a leading plus sign (+), then the given directories are added to the list of MIB directories. Without the leading +, the given directory list overrides the list specified with the environment variable MIBDIRS. Note that the directories listed at the end of the list have precedence over directories at the beginning of the list.

If no value is specified for the environment variable MIBDIRS, then the command will still search a default mib directory, after it searches the MIB directories specified on the -M option. The default directory is /etc/sma/snmp/mibs. To avoid having a default mib directory searched, set the MIBDIRS environment
variable to the empty string ("""). Even if the default MIB directory is searched, the directories specified in the -M option have precedence in the search order over the default directory.

If the -M option is specified and either a mibfile or mibdirs token is also specified in the snmp.conf file, the directories in the -M option have precedence in the MIB search order, over the directories set with either the mibdirs token and the mibfile token.

- n contextName
  Set the destination contextName used for SNMPv3 messages. The default contextName is the empty string ("""). Overrides the defContext token in the snmp.conf file.

- O anEebqQfsvXTuxUt
  Specifies output printing options. See OUTPUT OPTIONS below.

- P cdeRuwW
  Specifies MIB parsing options. See MIB PARSING OPTIONS below.

- r retries
  Specifies the number of retries to be used in the requests. The default is 5.

- t timeout
  Specifies the timeout in seconds between retries. The default is 1.

- u secName
  Set the securityName used for authenticated SNMPv3 messages. Overrides the defSecurityName token in the snmp.conf file.

- v 1 | 2c | 3
  Specifies the protocol version to use: 1 (RFCs 1155-1157), 2c (RFCs 1901-1908), or 3 (RFCs 2571-2574). The default is version 1. This option overrides the defVersion token in the snmp.conf file.

- V, --version
  Display version information for the application and then exit.

- x privProtocol
  Set the privacy protocol (DES) used for encrypted SNMPv3 messages.

- X privPassword
  Set the privacy pass phrase used for encrypted SNMPv3 messages. Overrides the defPrivPassphrase token in the snmp.conf file. Note that it is insecure to specify password phrases on the command line. See snmp.conf(4).

- Z boots,time
  Set the engineBoots and engineTime used for authenticated SNMPv3 messages. This will initialize the local notion of the agents boots/time with an authenticated value stored in the LCD. This value will be discovered if not supplied.
The string *agent* specifies the remote SNMP entity with which to communicate. The format of this parameter is defined in the AGENT SPECIFICATION section below.

**Agent Specification**

The *agent* specification (see SYNOPSIS) takes the form:

```
[transport-specifier:]transport-address
```

At its simplest, the *agent* specification consists of a hostname or an IPv4 address in the standard, "dotted quad" notation. In this case, communication will be attempted using UDP/IPv4 to port 161 of the given host. Otherwise, the *transport-address* part of the specification is parsed according to the following table:

```
<transport-specifier> <transport-address> format
udp            hostname[::port]
```

Note that *transport-specifier* strings are case-insensitive so that, for example, "tcp" and "TCP" are equivalent. Here are some examples, along with interpretations:

```
myhost:161
```

Perform query using UDP/IPv4 datagrams sent to *myhost* on port 161. The :161 is redundant here because that is the default SNMP port.

```
udp:myhost
```

Identical to the previous specification. The *udp:* is redundant here because UDP/IPv4 is the default transport.

**MIB Parsing Options**

The Net-SNMP MIB parser mostly adheres to the Structure of Management Information (SMI). As that specification has changed through time, and in recognition of the diversity in compliance expressed in MIB files, additional options provide more flexibility in reading MIB files.

- **-Pw** Show some warning messages in resolving the MIB files. Can be also set with the configuration token *mibWarningLevel*.

- **-PW** Show additional warning messages. Can be also set with the configuration token *mibWarningLevel*.

- **-Pe** Show MIB errors. Can be also set with the configuration token *showMibErrors*. An example of an error that would be shown is if an imported module is not found during MIB parsing.

- **-Pc** Allow ASN.1 comment to extend to the end of the MIB source line (that is, disallow the use of two dashes (--) to terminate comments). This overcomes some problems with manually maintained MIB files. Can be also set with the configuration token *strictCommentTerm*.
-Pd  Toggles the default of whether or not to save the DESCRIPTIONs of the MIB objects when parsing. Since the default is to save the DESCRIPTIONs, specifying -Pd causes the DESCRIPTIONs not to be saved during MIB parsing. For example:

```bash
snmptranslate -Td -OS -IR system.sysDescr.0
```
will show a description, while:

```bash
snmptranslate -Td -OS -IR -Pd system.sysDescr.0
```
will not show a description. Collecting the DESCRIPTION information into the parsed hierarchy increases the memory used by the size of each DESCRIPTION clause.

-Pu  Allow underline characters in symbols. Can be also set with the configuration token mibAllowUnderline.

-PR  Replace MIB objects using the last read MIB file. The parser replaces MIB objects in its hierarchy whenever it sees a subidentifier and name match.

**Caution** – Setting this option might result in an incorrect hierarchy. Can be also set with the configuration token mibReplaceWithLatest.

**Output Options**  Output display can be controlled by passing various parameters to the -O flag. The following examples demonstrate this feature.

The default output displays as follows:

```bash
snmpget -c public -v 1 localhost system.sysUpTime.0
SNMPv2-MIB::sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

- Oq  Removes the equal sign and type information:

```bash
system.sysUpTime.0 1:15:09:27.63
```

- OQ  Removes the type information:

```bash
system.sysUpTime.0 = 1:15:09:27.63
```

- Of  Gives you the complete OID:

```bash
.iso.org.dod.internet.mgmt.mib-2.system.sysUpTime.0 = \
  Timeticks: (14096763) 1 day, 15:09:27.63
```

- Os  Deletes all but the last symbolic part of the OID:

```bash
sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

- OS  A variation on -Os that adds the name of the MIB that defined the object:

```bash
SNMPv2-MIB::sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```
Starting with release 5.0, this is the default output format.

- Ou  Displays the OID in the UCD-style (inherited from the original CMU code). That means removing a series of "standard" prefixes, if relevant, and breaking down the
OID into the displayable pieces. For example, the OID vacmSecurityModel.0.3.119.101.115 is broken down by default and the string hidden in the OID is shown. The result would be: vacmSecurityModel.0."test". The -Ob option disables this feature.

system.sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63

-On Displays the OID numerically:

.1.3.6.1.2.1.1.3.0 = Timeticks: (14096763) 1 day, 15:09:27.63

-Oe Removes the symbolic labels from enumerations:

snmpget -c public -v 1 localhost ip.ipForwarding.0
ip.ipForwarding.0 = INTEGER: forwarding(1)

snmpget -c public -v 1 -Oe localhost ip.ipForwarding.0
ip.ipForwarding.0 = INTEGER: 1

-Ob When OIDs contain a index to a table, they are broken into the displayable pieces and shown to you. For example, the OID vacmSecurityModel.0.3.119.101.115 is nicely broken down by default and the string hidden in the OID is shown to you as vacmSecurityModel.0."test". The -Ob option disables this feature and displays it as vacmSecurityModel.0.3.119.101.115 once again.

-OE Modifies the index strings to include a backslash (\) to escape the quotes, to allow them to be reused in shell commands, such as vacmSecurityModel.0."test"

-OX Modifies the output of index OIDs to look more "program-like". Square brackets are placed around each index and the DISPLAY-HINT information and string conversions are used to format each index. If you take an entry from the IPV6-MIB::ipv6RouteTable, it is indexed with an IPv6 address and two integers, and if you are used to IPv6 addresses you know that decimal OIDs are not the preferred notation. Compare:

snmpgetnext -OS host IPV6-MIB::ipv6RouteTable
IPV6-MIB::ipv6RouteIfIndex.63.254.1.0.255.0.0.0.0.0.0.0.0.0.0.0.0.0.0.64.1 = INTEGER: 2

snmpgetnext -OSX host IPV6-MIB::ipv6RouteTable
IPV6-MIB::ipv6RouteIfIndex[3ffe:100:0:0:0:0:0:0][64][1] = INTEGER: 2

-Oa If a string-valued object definition does not include a display hint, then the library attempts to determine whether it is an ASCII or binary string, and displays the value accordingly. This flag bypasses this check, and displays all strings as ASCII. Note that this does not affect objects that do have a display hint.

-Ox This works similarly to -Oa, but displays strings as hexadecimal values.

-OT If hexadecimal code is displayed, this will also display any printable characters after the hexadecimal codes.
Input Options

The -I flag specifies various options that control how your input to the program is parsed. By default, unless one of the following flags is specified, all input parsing methods are used: First the OID is parsed in the normal way, then -IR is used, then -Ib is used. The use of one of the following flags forces a command to use only one method.

-IR Specifies random access lookup, so that if the entire OID path is not specified, it will search for a node in the MIB tree with the given name. Normally, you’d have to specify the \vacmSecurityModel\ OID above as:

```
.iso.org.dod.internet.snmpV2.snmpModules.snmpMIB.vacmMIBObjects.\ vacmSecurityToGroupTable.vacmSecurityToGroupEntry.vacmSecurityModel.0.\ "wes"
```

But the use of the -IR flag allows you to shorten that to \vacmSecurityModel.0."wes". This OID needs to be quoted to prevent the shell from swallowing the double quotes: But the use of the -IR flag allows you to shorten that to just \vacmSecurityModel.0."wes". This OID must be quoted to prevent the shell from swallowing the double quotes: 'vacmSecurityModel.0."wes"'.

For more information, see the RANDOM ACCESS MIBS section, below.

-Ib Indicates that the expression you gave the command is a regular expression that should be used to search for the best match possible in the MIB tree. This would allow you to specify the \vacmSecurityModel\ MIB node as something as generic as \vacmSecurityModel\ (since case-insensitive searches are done) or \vacm.(**model. Note that multiple matches are obviously possible (.\(\** matches everything). The best result is calculated as the one that matches the closest to the beginning of the node name and the highest in the tree. A side effect of this option is that you cannot specify indexes or multiple nodes, because the period (.) is treated as part of the regular expression.

-Iu Use the traditional UCD-style input approach of assuming that OIDs are rooted at the mib-2 point in the tree (unless they start with an explicit period (.)). If random access lookup is in effect (which is the default for most commands), then this will affect only
OIDs specified with a leading numeric subidentifier (and no initial period). Thus an input of `snmpcmd ... 1` would refer to `iso` (from v5.0 onwards) while `snmpcmd -Iu ... 1` would refer to `system`.

- **Ir**
  By default, indices into tables and values to be assigned to objects are checked against the range and type specified in the MIB. The `-Ir` flag disables this check. This flag is mostly useful when you are testing an agent. For normal operation, it is useful to get your requests checked before they are sent to the remote agent. The diagnostic that the library can provide is also much more precise.

- **Ih**
  By default, the library will use `DISPLAY-HINT` information when assigning values. This flag disables this behavior. The result is that, instead of:

  ```
  snmpset localhost HOST-RESOURCES-MIB::hrSystemDate.0 = "2002-12-10,2:4:6:8"
  ```

  you will have to write:

  ```
  snmpset localhost HOST-RESOURCES-MIB::hrSystemData.0 x "07 D2 0C 0A 02 04 06 08"
  ```

**Random Access MIBs**

In previous releases of the UCD-SNMP package (and if using the `-Iu` option), an object identifier such as `system.sysDescr.0` is looked up in a single "well known" place, built into the SNMP library (or specified by the `@PREFIX` environment variable). The standard place is `.iso.org.dod.internet.mgmt.mib-2`. The identifier can alternatively be a complete object identifier. This is designated by a leading "dot" if using UCD-input style, and is the first thing tried otherwise. To simplify the specification of object identifiers the library supports random access to the identifiers in the MIBs. This is requested by the `-IR` option to the SNMP applications. Additionally, `-Os` prints OIDs in this manner. Using this, `system.sysDescr.0` can also be entered as `sysDescr.0`.

To search only a single MIB for the identifier (if it appears in more than one), specify it as `SNMPv2-MIB::sysDescr.0`. Use `-Os` to print output OIDs in this manner; this is the default since v5.0. This notation also ensures that the specified MIB is loaded, that is, it need not be mentioned in the `-m` option (or MIBS environment variable).

**Environment Variables**

- **MIBS** The list of MIBs to load. Defaults to:

  ```
  ```

  Overridden by the `-m` option.

- **MIBDIRS** The list of directories to search for MIBs. Defaults to `/etc/sma/snmp/mibs`. Overridden by the `-m` option.
### Files

- `/etc/sma/snmp/snmpd.conf`: Agent configuration file. See `snmpd.conf(4)`.
- `~/.snmp/snmp.conf`: Application configuration files. See `snmp.conf(4)`.

snmpconf(1M)

**Name**  
`snmpconf` – creates and modifies SNMP configuration files

**Synopsis**  
```bash
snmpconf
snmpconf -g basic_setup
snmpconf [options] [file_to_create]
```

**Description**  
The `snmpconf` utility is a simple script that walks you through setting up a configuration file, step-by-step. It works by asking you a series of questions. It creates the configuration file based on your responses.

In its default mode of operation, `snmpconf` prompts you with menus showing sections of the various configuration files it knows about. When you select a section, a submenu is shown listing the descriptions of the tokens that can be created in that section. When a description is selected, you are prompted with questions that determine the specification of the selected token.

When you quit `snmpconf`, any configuration files that have been edited are saved to the local directory. `snmpconf` supplies comments in the configuration files for each change.

A particularly useful option is the `-g` switch, which walks you through a specific set of configuration questions. For an example, invoke:

```
# snmpconf -g basic_setup
```

This command walks you through an initial setup of the `snmpd` daemon.

**Options**  
The following options are supported:

- `-f`  
  Force overwriting existing files in the current directory without prompting the user.

- `-i`  
  When finished, install the files in the location where the global system commands expect to find them.

- `-p`  
  When finished, install the files into the user’s home directory’s `.snmp` subdirectory. Applications will search for configuration files in this location.

- `-I directory`  
  When finished, install the files into the directory `directory`.

- `-a`  
  Do not issue queries. Read in the various known configuration files and write them back out again. This has the effect of "auto-commenting" the configuration files for you.

- `-r all | none`  
  Read in either all or none of the found configuration files. Normally, `snmpconf` prompts you for which files you wish to read in.

- `-R file,...`  
  Read in a specific list of configuration files.

- `-g groupname`  
  Groups of configuration entries can be created that can be used to walk a user through a series of questions to create an initial configuration file. There are no menus to navigate, just a list of questions. The command:
# snmpconf -g basic_setup
provides a good example.

- G List all the known groups.
- c configdir snmpconf uses a directory of configuration information to learn about the files and questions that it should be asking. This option tells the utility to use a different location for configuring itself.
- q Run slightly more quietly than the default. Because this is an interactive program, this option is not recommended. It removes information from the output that might be helpful to you.
- d Turn on copious debugging output.
- D Add more (beyond -d) debugging output in the form of Perl variable dumps.

**Examples**

**EXAMPLE 1** Adding Comments to snmpd.conf

The following command reads in an `snmpd.conf` file and adds comments describing what each token does.

```
# snmpconf -R /etc/sma/snmp/snmpd.conf -a -f snmpd.conf
```

**Exit Status**

0 Successful completion.
1 A usage syntax error. A usage message displays.

<table>
<thead>
<tr>
<th>Name</th>
<th>snmpd – daemon to respond to SNMP request packets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synopsis</td>
<td>/usr/sfw/sbin/snmpd [options] [listening addresses]</td>
</tr>
<tr>
<td>Description</td>
<td>The snmpd daemon is an SNMP agent that binds to a port and awaits requests from SNMP management software. Upon receiving a request, it processes the request(s), collects the requested information, performs any requested operation(s), and, finally, returns information to the requester.</td>
</tr>
<tr>
<td>Options</td>
<td>The following options are supported:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-a Log the source addresses of incoming requests.</td>
</tr>
<tr>
<td></td>
<td>-A Append to the log file rather than truncating it.</td>
</tr>
<tr>
<td></td>
<td>-c file Read file as a configuration file.</td>
</tr>
<tr>
<td></td>
<td>-C Do not read any configuration files except the one optionally specified by the -c option.</td>
</tr>
<tr>
<td></td>
<td>Note that this behavior also covers the persistent configuration files. This can result in dynamically-assigned values being reset following an agent restart, unless the relevant persistent configuration files are explicitly loaded using the -c option.</td>
</tr>
<tr>
<td></td>
<td>-d Dump (in hexadecimal) the sent and received SNMP packets.</td>
</tr>
<tr>
<td></td>
<td>-D[token[,...]] Turn on debugging output for the given token(s). Without any tokens specified, this option defaults to printing all of the tokens (which is equivalent to the keyword ALL). Use ALL for extremely verbose output. Note that you must not put a space between the -D flag and the listed tokens.</td>
</tr>
<tr>
<td></td>
<td>-f Do not fork() from the calling shell.</td>
</tr>
<tr>
<td></td>
<td>-g GID Change to the numerical group ID GID after opening listening sockets.</td>
</tr>
<tr>
<td></td>
<td>-h, --help Display a brief usage message and then exit.</td>
</tr>
<tr>
<td></td>
<td>-H Display a list of configuration file directives understood by the agent and then exit.</td>
</tr>
<tr>
<td></td>
<td>-I -initlist This option specifies which modules you do (or do not) want to be initialized when the agent starts up. If the comma-separated initlist is preceded with an hyphen (-), it is the list of modules that you do not want to be started. Otherwise, initlist is the list of modules to be started.</td>
</tr>
<tr>
<td></td>
<td>To obtain a list of compiled modules, run the agent with the arguments -Dmib init -H This command assumes you have debugging support compiled in.</td>
</tr>
</tbody>
</table>
Log all output from the agent (including stdout and stderr) to file. If no filename is given, log to a default file set at compile time, normally /var/log/snmpd.log.

Do not open a log file. Send all messages to stderr instead.

Save the process ID of the daemon in file.

Print simpler output for easier automated parsing.

Do not require root access to run the daemon. Specifically, do not exit if files accessible only to root (such as /dev/kmem) cannot be opened.

Use syslog for logging. See syslogd(1M)

Specifies the syslog facility to use when logging to syslog. d means LOG_DAEMON and the integers 0 through 7 refer to LOG_LOCAL0 through LOG_LOCAL7. LOG_DAEMON is the default.

Change to the user ID UID (which can be given in numerical or text form) after opening listening sockets.

Display version information for the agent and then exit.

Symbolically dump SNMP transactions.

Listens for AgentX connections on address rather than on the default /var/agentx/master. The address can either be a Unix domain socket path or the address of a network interface. The format is the same as the format of listening addresses described below. Note that it is a possible security risk to expose the master agent listening address through TCP/UDP. See section 9 of RFC 2741 for more details.

Run as an AgentX subagent rather than as an SNMP master agent.

By default, snmpd listens for incoming SNMP requests only on UDP port 161. However, it is possible to modify this behavior by specifying one or more listening addresses as arguments to the daemon. A listening address takes the form:

[<transport-specifier>]:<transport-address>

At its simplest, a listening address can consist of only a port number, in which case snmpd listens on that UDP port on all IPv4 interfaces. Otherwise, the <transport-address> part of the specification is parsed according to the following table:

<table>
<thead>
<tr>
<th>&lt;transport-specifier&gt;</th>
<th>&lt;transport-address&gt; format</th>
</tr>
</thead>
<tbody>
<tr>
<td>udp</td>
<td>hostname[:port] or IPv4-address[:port]</td>
</tr>
<tr>
<td>tcp</td>
<td>hostname[:port] or IPv4-address[:port]</td>
</tr>
</tbody>
</table>
Currently transports TCP/UDP over IPv4/IPv6 and unix domain sockets. Note that `<transport-specifier>` strings are case-insensitive so that, for example, tcp and TCP are equivalent. Below are some examples, with accompanying explanations.

### Examples

- **127.0.0.1:161**
  - Listen on UDP port 161, but only on the loopback interface.
  - This prevents `snmpd` from being queried remotely. The :161 is redundant because that is the default SNMP port.

- **TCP:1161**
  - Listen on TCP port 1161 on all IPv4 interfaces.

- **unix:/tmp/local-agent**
  - Listen on the Unix domain socket /tmp/local-agent.
  - Identical to the previous specification, because the Unix domain is the default transport if and only if the first character of `<transport-address>` is a slash (/).

- **udp6:10161**
  - Listen on port 10161 on all IPv6 interfaces.

Note that not all the transport domains listed above will always be available. For example, hosts with no IPv6 support will not be able to use udp6 transport addresses, and attempts to do so will result in the error “Error opening specified endpoint”.

### Files

`snmpd` checks for the existence of and parses the following files:

- **snmp.conf**
  - Common configuration for the agent and applications. See `snmp.conf(4)` for details.

- **snmpd.local.conf**
  - Agent-specific configuration. See `snmp.conf(4)` for details. These files are optional and can be used to configure access control, trap generation, subagent protocols, and other features.

  In addition to these two configuration files, the agent will read any files with the names `snmpd.conf` and `snmpd.local.conf` in a colon-separated path specified in the `SNMPCONFPATH` environment variable, the default location upon agent startup are `/etc/sma/snmp and /usr/local/share/snmp`.

- **/etc/sma/snmp/mibs**
  - The agent loads all files in this directory as MIBs. It does not, however, load any file that begins with a dot (.) or descend into subdirectories.

### Exit Status

- **0**  
  - Successful completion.

- **1**  
  - A usage syntax error. A usage message is displayed. Also used for timeout errors.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsmagt</td>
</tr>
<tr>

<td>Stable</td>
</tr>
</tbody>
</table>

See Also  svcadm(1M), svcfg(1M), snmp.conf(4), attributes(5), smf(5)

Notes  In addition to basic privileges, to run successfully, the agent requires PRIV_NET_PRIVADDR. See privileges(5).

The snmpd service is managed by the service management facility, smf(5), under the service identifiers:

svc:/application/management/sma
svc:/application/management/seaport

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The service uses the solaris.smf.manage.sma privilege. If /etc/sma/snmp/snmpd.conf contains DISABLE=YES, then the service does not start and displays the message:

snmpd disabled by config file /etc/sma/snmp/snmpd.conf
### NAME
snmpdelta – monitor deltas of integer valued SNMP variables

### Synopsis
```
/usr/sfw/bin/snmpdelta [common options] [-Cf] [-Ct] [-Cs]
[-CS] [-Cm] [-CF configfile] [-Cl] [-Cp period]
[-CP peaks] [-Ck] [-CT] [-Cv vars/pkt] agent OID
[OID]...
```

### Description
The `snmpdelta` command monitors the specified integer-valued OIDs and reports changes over time.

The operand `agent` identifies a target SNMP agent, which is instrumented to monitor a given set of objects. At its simplest, the `agent` specification will consist of a hostname or an IPv4 address. With such an operand, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the given target host. See `snmpcmd(1M)` for a full list of the possible formats for `agent`.

The operand `OID` is an object identifier that uniquely identifies the object type within a MIB. Multiple OIDs can be specified in a single `snmpdelta` command.

### Options
See `snmpcmd(1M)` for a list of `common options`. In addition to the `common options`, `snmpdelta` supports the options described below.

- `-Cf` Do not fix errors and then retry the request. Without this option, if multiple OIDs have been specified for a single request and if the request for one or more of the OIDs fails, `snmpdelta` will retry the request so that data for OIDs apart from the ones that failed will still be returned. Specifying `-Cf` tells `snmpdelta` not to retry a request, even if there are multiple OIDs specified.

- `-Ct` Determines time interval from the monitored entity.

- `-Cs` Displays a timestamp.

- `-CS` Generates a "sum count" in addition to the individual instance counts. The "sum count" is the total of all the individual deltas for each time period.

- `-Cm` Displays the maximum value ever attained.

- `-CF configfile` Tells `snmpdelta` to read its configuration from the specified file. This option allows the input to be set up in advance rather than having to be specified on the command line.

- `-Cl` Tells `snmpdelta` to write its configuration to files whose names correspond to the MIB instances monitored. For example:

  ```
  % snmpdelta -c public -v 1 -Cl localhost ifInOctets.1
  ...
  ```
  ```
  will create a file localhost-ifInOctets.1.
  ```

- `-Cp` Specifies the number of seconds between polling periods. Polling involves sending a request to the agent. The default polling period is one second.
- CP peaks  Specifies the reporting period in number of polling periods. If this option is specified, snmpdelta polls the agent peaks number of times before reporting the results. The result reported includes the average value over the reporting period. In addition, the highest polled value within the reporting period is shown.

- Ck  When the polling period (- Cp) is an increment of 60 seconds and the timestamp is displayed in the output (- Cs), then the default display shows the timestamp in the format hh:mm mm/dd. This option causes the timestamp format to be hh:mm:ss mm/dd (adding seconds).

- CT  Display output in tabular form.

- Cv vars/pkt  Specifies the maximum number of OIDs allowed to be packaged in a single PDU. Multiple PDUs can be created in a single request. The default value of variables per packet is 60. This option is useful if a request response results in an error because the request packet is too big.

**Examples**

**EXAMPLE 1** Obtaining Timestamped Output

The following command uses the -Cs option to timestamp output. This example assumes that there are at least three entries in your ifTable.

```bash
% snmpdelta -c public -v 1 -Cs localhost \
IF-MIB::ifInUcastPkts.3 IF-MIB::ifOutUcastPkts.3
```

```
[20:15:43 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:44 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:46 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:47 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:49 6/14] ifInUcastPkts.3 /1 sec: 158
^C
```

**EXAMPLE 2** Displaying Output in Tabular Form

The following command uses the -CT option to format output as a table. This example assumes that there are at least three entries in your ifTable.

```bash
% snmpdelta -c public -v 1 -Cs -CT localhost \
IF-MIB::ifInUcastPkts.3 IF-MIB::ifOutUcastPkts.3
```

```
[20:15:43 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:44 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:46 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:47 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:49 6/14] ifInUcastPkts.3 /1 sec: 158
```
EXAMPLE 2  Displaying Output in Tabular Form  (Continued)

localhost ifInUcastPkts.3 ifOutUcastPkts.3

<table>
<thead>
<tr>
<th>Time</th>
<th>In Ucast Pkt</th>
<th>Out Ucast Pkt</th>
</tr>
</thead>
<tbody>
<tr>
<td>20:15:59 6/14</td>
<td>184.00</td>
<td>184.00</td>
</tr>
<tr>
<td>20:16:00 6/14</td>
<td>158.00</td>
<td>158.00</td>
</tr>
<tr>
<td>20:16:01 6/14</td>
<td>184.00</td>
<td>184.00</td>
</tr>
<tr>
<td>20:16:02 6/14</td>
<td>184.00</td>
<td>184.00</td>

</tr>
<tr>
<td>20:16:06 6/14</td>
<td>158.00</td>
<td>158.00</td>
</tr>
</tbody>
</table>

EXAMPLE 3  Sending Output to a File

The following example uses a number of options. This example assumes that there are at least four entries in your ifTable. Because the -Cl option is specified, the output is sent to a file and not to the screen.

% snmpdelta -c public -v 1 -Ct -Cs -Cm -Cl -Cp 60 -CP 60 \
interlink.sw.net.cmu.edu .1.3.6.1.2.1.2.2.1.16.3 \
.1.3.6.1.2.1.2.2.1.16.4

Exit Status  0  Successful completion.

1  A usage syntax error. A usage message is displayed. Also used for timeout errors and for cases where an SNMP client session could not be opened.

snmpdf – get a listing of disk space usage on a remote machine by means of SNMP

Synopsis
/usr/sfw/bin/snmpdf [common options] [-Cu] agent

Description
The snmpdf command is a networked version of the df(1M) command. It checks the disk space on the remote machine by examining the HOST-RESOURCES-MIB's hrStorageTable or the UCD-SNMP-MIB's dskTable. By default, the hrStorageTable is preferred, as it typically contains more information than the dskTable. However, the -Cu argument can be passed to snmpdf to force the usage of dskTable.

The agent operand identifies a target SNMP agent, which is instrumented to monitor specified objects. At its simplest, the agent specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent using UDP/IPv4 to port 161 of the target host.

See the snmpcmd(1M) manual page for a full list of the possible formats for agent.

See the snmpd.conf(4) manual page for guidance on setting up dskTable using the disk directive in the snmpd.conf file.

Options
The following options are supported:

common options
See snmpcmd(1M) for a list of possible values for common options, as well as their descriptions.

-Cu
Forces the command to use dskTable in UCD-SNMP-MIB instead of the default to determine the storage information. Generally, the default use of hrStorageTable in HOST-RESOURCES-MIB is preferred because it usually contains more information than dskTable.

Examples
EXAMPLE 1 Obtaining Disk Usage of a Remote System

The following command returns a display of the disk usage of a remote system.

**Name**

snmpdx – Sun Solstice Enterprise Master Agent

**Synopsis**

```
/usr/lib/snmp/snmpdx [-hy] [-a filename] [-c config-dir]
[-d debug-level] [-i filename] [-m GROUP -m SPLIT]
[-o filename] [-p port] [-r filename]
```

**Description**

The Master Agent, `snmpdx`, is the main component of Solstice Enterprise Agent (SEA) technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file.

Upon invocation, `snmpdx` reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents.

The Master Agent is invoked by the service management facility `smf(5)` at boot time if `svc:/application/management/snmpdx` is enabled (see NOTES) and contents of the resource configuration file `/etc/snmp/conf/snmpdx.rsrc` are non-trivial.

**Note** – The SMA (Systems Management Agent) is the default SNMP agent in the Solaris operating system. See `netsnmp(5)`. `snmpdx` is Obsolete and may not be supported in a future release of Solaris.

**Options**

The following options are supported:

- `-a filename`
  Specify the full path of the access control file used by the Master Agent. The default access control file is `/etc/snmp/conf/snmpdx.acl`.

- `-c config-dir`
  Specify the full path of the directory containing the Master Agent configuration files. The default directory is `/etc/snmp/conf`.

- `-d debug-level`
  Debug Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.

- `-h`
  Help. Print the command line usage.

- `-i filename`
  Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is `/var/snmp/snmpdx.st`.

- `-m GROUP | -m SPLIT`
  Specify the mode to use for forwarding of SNMP requests.
Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at most, one send-request per agent.

Each variable in the incoming request results in one send-request to each subagent.

The default is GROUP.

-Ofilename Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is /etc/snmp/conf/enterprises.oid.

-Pport Specify the port number. The default port number is 161.

-Rfilename Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is /etc/snmp/conf/snmpdx.rsrc.

-Y Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.

Files
/etc/snmp/conf/enterprises.oid Enterprise-name OID map

### Notes
The `snmpdx` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/application/management/snmpdx
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.
snmpget – communicate with a network entity using SNMP GET requests

Synopsis
/usr/sfw/bin/snmpget [common options] [-Cf] oid [oid]...

Description
The snmpget utility is an SNMP application that uses the SNMP GET request to query for information on a network entity. You can specify one or more object identifiers (OIDs) as arguments on the command line. Each variable name must be specified in the format specified in snmp_variables(4).

For example, the command:

```
# snmpget -c public zeus system.sysDescr.0
```

retrieves the variable system.sysDescr.0:

```
system.sysDescr.0 = "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed. The message indicates the way in which the request was malformed. If there were other variables in the request that were correctly formed, the request will be resent without the bad variable.

Options
The following option is supported:

- **-Cf**

  If -Cf is not specified, some applications (including snmpgetnext(1M) and snmpget) attempt to fix errors returned by the agent that you were talking to and resend the request. The -Cf option suppresses this fix-and-resend feature.

  Fix-and-resend is useful if you specified a nonexistent OID in your request and you are using SNMPv1, which requires "all or nothing" types of requests. In the following example note that system.sysUpTime is an incomplete OID, because it requires the .0 index appended to it:

  ```
  # snmpget -v1 -Cf -c public localhost system.sysUpTime \
  system.sysContact.0
  Error in packet
  Reason: (noSuchName) There is no such variable name in this MIB.
  This name doesn't exist: system.sysUpTime
  # snmpget -v1 -c public localhost system.sysUpTime system.sysContact.0
  Error in packet
  Reason: (noSuchName) There is no such variable name in this MIB.
  This name doesn't exist: system.sysUpTime
  system.sysContact.0 = STRING: root@localhost
  ```

  In addition to this option, snmpwalk takes the common options described in the snmpcmd(1M) manual page.
Exit Status  0  Successful completion.
  1  A usage syntax error. A usage message is displayed. Also used for timeout errors.
  2  An error occurred while executing the command. An error message is displayed.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsmcmd</td>
</tr>
<tr>

<td>External</td>
</tr>
</tbody>
</table>

See Also  snmpcmd(1M), snmp_variables(4), attributes(5)
snmpgetnext(1M)

**Name**
snmpgetnext – communicate with a network entity using SNMP GETNEXT requests

**Synopsis**
```
snmpgetnext [-Cf] [common options] oid [oid]...
```

**Description**
The `snmpgetnext` utility is an SNMP application that uses the SNMP GETNEXT request to query for information on a network entity. You can specify one or more object identifiers (OIDs) as arguments on the command line. Each variable name must be specified in the format specified in `snmp_variables(4)`. For each variable, the one that is lexicographically “next” in the remote entity's MIB is returned.

For example, the command:
```
# snmpgetnext -c public zeus interfaces.ifTable.ifEntry.ifType.1
```
retrieves the variable `interfaces.ifTable.ifEntry.ifType.2`:
```
interfaces.ifTable.ifEntry.ifType.2 = softwareLoopback(24)
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed. The message indicates the way in which the request was malformed.

**Options**
The following options are supported:

- `-Cf`  
  If `-Cf` is not specified, some applications (including `snmpget(1M)` and `snmpgetnext`) attempt to fix errors returned by the agent that you were talking to and resend the request. The `-Cf` option suppresses this fix-and-resend feature.

  Fix-and-resend is useful if you specified a nonexistent OID in your request and you are using SNMPv1, which requires “all or nothing” types of requests.

In addition to this option, `snmpgetnext` takes the common options described in the `snmpcmd(1M)` manual page.

**Attributes**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsmcmd</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>External</td>
</tr>
</tbody>
</table>

**Exit Status**

0  Successful completion.
1  A usage syntax error. A usage message is displayed. Also used for timeout errors.
2  An error occurred while executing the command. An error message is displayed.

snmpnetstat – show network status using SNMP

Synopsis
/usr/sbin/bin/snmpnetstat [common options] [-a] [-n] agent
/usr/sbin/sma_snmp/bin/snmpnetstat [common options] [-iorns] agent
/usr/sbin/sma_snmp/bin/snmpnetstat [common options] [-in]
    [-I interface] agent [interval]
/usr/sbin/sma_snmp/bin/snmpnetstat [common options] [-an]
    [-s] [-P protocol] agent

Description
The snmpnetstat command symbolically displays the values of various network-related information retrieved from a remote system using the SNMP protocol. There are a number of output formats, depending on the options for the information presented. Referring to the SYNOPSIS, above:

- The first form of the command displays a list of active sockets.
- The second form presents the values of other network-related information according to the option selected.
- The third form, with an interval specified, continuously displays the information regarding packet traffic on the configured network interfaces.
- The fourth form displays statistics about the named protocol.

The operand agent identifies a target SNMP agent that is instrumented to monitor the given objects. At its simplest, the agent specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent using UDP/IPv4 to port 161 of the target host. See snmpcmd(1M) for a full list of the possible formats for agent.

The version 1 and version 2c community specifies the community name for the transaction with the remote system.

Options
The following options are supported:

common options
See snmpcmd(1M) for a list of possible values for common options, as well as their descriptions.

- a
  With the default display, show the state of all sockets. Normally, sockets used by server processes are not shown.

- i
  Show the state of all of the network interfaces. The interface display provides a table of cumulative statistics regarding packets transferred, errors, and collisions. The network addresses of the interface and the maximum transmission unit (MTU) are also displayed.

- o
  Show an abbreviated interface status, giving octets in place of packets. This is useful when observing virtual interfaces (such as Frame Relay circuits) on a router.
-I interface  Show information only about this interface; used with an interval as
described below.

-n  Show network addresses as numbers. (Normally, `snmpnetstat` interprets
addresses and attempts to display them symbolically). This option can be
used with any of the display formats.

-P protocol  Show statistics about `protocol`, which is either a well-known name for a
protocol or an alias for it. Some protocol names and aliases are listed in
the file `/etc/protocols` or in a naming service. A null response typically
means that there are no interesting numbers to report. The program will
complain if `protocol` is unknown or if there is no statistics routine for it.

-s  Show per-protocol statistics. When used with the -r option, show
routing statistics instead.

-r  Show the routing tables. When -s is also present, show per-protocol
routing statistics instead of the routing tables.

interval  When `snmpnetstat` is invoked with an interval argument, it displays a
running count of statistics related to network interfaces. `interval` is the
number of seconds between reporting of statistics.

`smpnetstat` supports the following types of display:

active sockets display (default)  The default display, for active sockets, shows
the local and remote addresses, protocol, and
the internal state of the protocol. Address
formats are of the form `host:port` or
`network:port` if a socket’s address specifies a
network but no specific host address. When
known, the host and network addresses are
displayed symbolically according to
`/etc/hosts` and `/etc/networks`, respectively.
If a symbolic name for an address is unknown,
or if the -n option is specified, the address is
printed numerically, according to the address
family. For more information regarding the
Internet “dot format,” refer to
`inet(3SOCKET)`. Unspecified, or wildcard,
addresses and ports appear as `(*)`.

interface display  The interface display provides a table of
cumulative statistics regarding packets
transferred, errors, and collisions. The network
addresses of the interface and the maximum
transmission unit (MTU) are also displayed.
The routing table display indicates the available routes and their status. Each route consists of a destination host or network and a gateway to use in forwarding packets. The flags field shows the state of the route (U if the route is up), whether the route is to a gateway (G), whether the route was created dynamically by a redirect (D), and whether the route has been modified by a redirect (M). Direct routes are created for each interface attached to the local host. The gateway field for such entries shows the address of the outgoing interface. The interface entry indicates the network interface used for the route.

When snmpnetstat is invoked with an interval argument, it displays a running count of statistics related to network interfaces. This display consists of a column for the primary interface and a column summarizing information for all interfaces. The primary interface can be replaced with another interface with the -I option. The first line of each screen of information contains a summary since the system was last rebooted. Subsequent lines of output show values accumulated over the preceding interval.

When a protocol is specified with the -P option, the information displayed is similar to that in the default display for active sockets, except the display is limited to the given protocol.

Note that figures snmpnetstat reports in the Ipkts column (part of the interface display) might differ from figures in the Ipkts column in netstat(1M). snmpnetstat displays a total of unicast, multicast, and broadcast packets. netstat omits broadcast packets from its total.

**Examples**

**EXAMPLE 1** Displaying Active Sockets

The following is an example of snmpnetstat’s default display, which is to display active sockets.

```
% snmpnetstat -v 2c -c public -a testhost
```

*Active Internet (tcp) Connections (including servers)*

Proto Local Address Foreign Address (state)
EXAMPLE 1  Displaying Active Sockets  (Continued)

tcp *.echo *.* LISTEN
tcp *.discard *.* LISTEN
tcp *.daytime *.* LISTEN
tcp *.chargen *.* LISTEN
tcp *.ftp *.* LISTEN
tcp *.telnet *.* LISTEN
tcp *.smtp *.* LISTEN

Active Internet (udp) Connections
Proto Local Address
udp *.echo
udp *.discard
udp *.daytime
udp *.chargen
udp *.time

% snmpnetstat -v 2c -c public -i testhost

Name Mtu Network Address Ipkts Ierrs Opkts Oerrs Queue
eri0 1500 10.6.9/24 testhost 170548881 245601 687976 0 0
lo0 8232 127 localhost 7530982 0 7530982 0 0

EXAMPLE 2  Displaying Statistics for a Specific Protocol

The following example shows how snmpnetstat displays statistics for a specific protocol.

% snmpnetstat -v 2c -c public -P tcp testhost

Active Internet (tcp) Connections
Proto Local Address Foreign Address (state)
tcp *.echo *.* LISTEN
tcp *.discard *.* LISTEN
tcp *.daytime *.* LISTEN
tcp *.chargen *.* LISTEN
tcp *.ftp *.* LISTEN
tcp *.telnet *.* LISTEN
tcp *.smtp *.* LISTEN

Exit Status  0  Successful completion.
1  A usage syntax error. A usage message is displayed.

**Name**  
`snmpset` – communicate with a network entity using SNMP SET requests

**Synopsis**  
`snmpset [common options] oid type value [oid type value]...`

**Description**  
The `snmpset` utility is an SNMP application that uses the SNMP SET request to set information on a network entity. A type and a value must accompany each object identifier. Each variable name must be entered in the format specified in `snmp_variables(4)`.

The type is a single character, one of:

- `i` INTEGER
- `u` UNSIGNED
- `c` COUNTER32
- `s` STRING
- `x` HEX STRING
- `d` DECIMAL STRING
- `n` NULLOBJ
- `o` OBJID
- `t` TIMETICKS
- `a` IPADDRESS
- `b` BITS

If you have the proper MIB file loaded, you can, in most cases, replace the type with an equal sign (`=`). For an object of type OCTET STRING this assumes a string such as the "s"-type notation. For other types, `snmpset` interprets the data in the way you would expect.

For example, the command:

```
snmpset -c private -v 1 test-hub system.sysContact.0 s dpz@noc.rutgers.edu
ip.ipForwarding.0 = 2
```

sets the variables `sysContact.0` and `ipForwarding.0`, as follows:

```
system.sysContact.0 = STRING: "dpz@noc.rutgers.edu"
ip.ipForwarding.0 = INTEGER: not-forwarding(2)
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

**Options**  
`snmpset` takes the common options described in the `snmpcmd(1M)` manual page.

**Attributes**  
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsmcmd</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>External</td>
</tr>
</tbody>
</table>
Exit Status  
0  Successful completion.
1  A usage syntax error. A usage message is displayed. Also used for timeout errors.
2  An error occurred while executing the command. An error message is displayed.

See Also  snmpcmd(1M), snmp_variables(4), attributes(5)
The `snmptable` command is an SNMP application that repeatedly uses the SNMP GETNEXT or GETBULK requests to query for information on a network entity. The operand `table-oid` must specify an SNMP table. Both numeric and symbolic (string) OIDs are supported.

The operand `agent` identifies a target SNMP agent that is instrumented to monitor manageable objects. At its simplest, the `agent` specification consists of a hostname or an IPv4 address. With such an address, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the given target host. See `snmpcmd(1M)` for a full list of the possible formats for `agent`.

### Options

See `snmpcmd(1M)` for a list of common options. In addition to the common options, `snmptable` supports the options described below.

- **-Cb**
  Display only a brief heading. Any common prefix of the table field names is not displayed.

- **-CB**
  Use only GETNEXT, not GETBULK, requests to retrieve data.

- **-Cf string**
  The string `string` is used to separate table columns. With this option, each table entry is printed in compact form, using only the specified string to separate the columns. This option can be useful if you intend to import the table into a database. Without this option, the table is displayed in vertically aligned columns.

- **-Ch**
  Display only the column headings.

- **-CH**
  Do not display the column headings or the table name. Only raw data is displayed.

- **-Ci**
  Prepends the index of the entry to all printed lines.

- **-Cw width**
  Specifies the width of the lines when the table is printed. If a line is longer than `width`, lines are truncated to fit within `width`.

### Examples

**EXAMPLE 1** Retrieving an SNMP Table

The following commands retrieve two-column SNMP tables.

```
% snmptable -v 2c -c public localhost at.atTable

SNMP table: at.atTable RFC1213-MIB::atTable
  atIfIndex atPhysAddress atNetAddress
1 8:0:20:20:0:ab 130.225.243.33
```
EXAMPLE 1  Retrieving an SNMP Table  (Continued)

% snmpTable -v 2c -c public + localhost at.atTable

SNMP table: at.atTable
atIfIndex+atPhysAddress+atNetAddress
   1+8:0:20:20:0:ab+130.225.243.33

Exit Status  0  Successful completion.
1  A usage syntax error. A usage message is displayed. Also used for timeout errors.
2  An error occurred while executing the command. An error message is displayed.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsmcmd</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>External</td>
</tr>
</tbody>
</table>

See Also  snmpcmd(1M), snmp_variables(4), attributes(5)

Bugs  The test for table-oid actually specifying a table is not perfect. Note also that the test requires the defining MIB file to be loaded.
snmptest is a flexible SNMP application that can monitor and manage information on a network entity.

Invoking `snmptest` invokes a command line interpreter that accepts commands. This interpreter enables you to send different types of SNMP requests to target agents.

The operand `agent` identifies a target SNMP agent that is instrumented to monitor manageable objects. At its simplest, the `agent` specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the target host. See `snmpcmd(1M)` for a full list of the possible formats for `agent`.

After you invoke `snmptest`, the command line interepretor prompts with:

```
Variable:
```

At this point you can enter one or more variable names, one per line. A blank line ends the parameter input and sends the request (variables entered) in a single packet to the remote entity. Each variable name is given in the format specified in `snmp_variables(4)`. For example, the command:

```
snmptest -c public -v 1 zeus
```

```
Variable: system.sysDescr.0
Variable:
```

...returns information about the request and reply packets, as well as the data:

```
requestid 0x5992478A  errstat 0x0  errindex 0x0
system.sysDescr.0 = STRING: "Unix 4.3BSD"
```

The `errstatus` value shows the error status code for the call. The possible values for `errstat` are in the header file `/usr/sfw/include/net-snmp/library/snmp.h`. The `errindex` value identifies the variable that has an error. Index values are assigned to all the variables entered at the `Variable:` prompt. The first value is assigned an index of 1.

Upon startup, the program defaults to sending a GET request packet. The type of request can be changed by typing one of the following commands at the `Variable:` prompt:

- `$G$` Send a GET request.
- `$N$` Send a GETNEXT request.
- `$S$` Send a SET request.
- `$B$` Send a GETBULK request. Note that GETBULK is not available in SNMPv1.
- `$I$` Send an inform request.
$T  Send an SNMPv2 trap request.

Other values that can be entered at the Variable: prompt are:

$D  Toggle the dumping of each sent and received packet.

$QP  Toggle a quicker, less verbose output form.

$Q  Quit the program.

The following are valid request types:

**GET request**
When in "GET request" mode ($G or default), you can enter an OID at the Variable: prompt. You can enter multiple OIDs, one per prompt. Enter a blank line to send the GET request.

**GETNEXT request**
The "GETNEXT request" mode ($N) is similar to the "GET request" mode, described above.

**SET request**
When in the "SET request" mode ($S), more information is requested by the prompt for each variable. The prompt:

```
Type \{i|s|x|d|n|o|t|a\}:
```

...requests the type of the variable be entered. Depending on the type of value you want to set, type one of the following:

- `i` integer
- `u` unsigned integer
- `s` octet string in ASCII
- `x` octet string in hex bytes, separated by whitespace
- `d` octet string as decimal bytes, separated by whitespace
- `a` IP address in dotted IP notation
- `o` object identifier
- `n` null
- `t` timeticks

At this point a value will be prompted for. To enter an integer value, just type the integer (in decimal). If it is a decimal string, type in whitespace-separated decimal numbers, one per byte of the string. Again, enter a blank line at the prompt for the variable name to send the packet.

**GETBULK request**
The "GETBULK request" mode ($B) is similar to the "SET request" mode. Note, however, that GETBULK is not available in SNMPv1.
Inform request

The "Inform request" mode ($I) is similar to the "SET request" mode. However, this type of request is not available in SNMPv1. Also, the agent specified in the snmptest command should correspond to the target snmptrap agent.

SNMPv2 trap request

The "SNMPv2 trap request" mode ($T) is similar to the "SET request" mode. However, this type of request is not available in SNMPv1. Also, the agent specified in the snmptest command should correspond to the target snmptrap agent.

Options

snmptest takes the common options described in the snmpcmd(1M).

Examples

EXAMPLE 1  Sending a GET Request for Two OIDs

The following is an example of sending a GET request for two OIDs:

```bash
% snmptest -v 2c -c public testhost:161
```

Variable: system.sysDescr.0
Variable: system.sysContact.0
Variable:
Received Get Response from 128.2.56.220
requestid 0x7D9FCD63 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysDescr.0 = STRING: SunOS testhost 5.9 Generic_112233-02 sun4u
SNMPv2-MIB::sysContact.0 = STRING: x1111

EXAMPLE 2  Sending a GETNEXT Request

The following is an example of sending a GETNEXT request:

Variable: $N
Request type is Getnext Request
Variable: SNMPv2-MIB::sysORUpTime.1
Variable:
Received Get Response from 128.2.56.220
requestid 0x7D9FCD64 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysORUpTime.2 = Timeticks: (6) 0:00:00.06
Variable:

EXAMPLE 3  Sending a SET Request

The following is an example of sending a SET request:

Variable: $S
Request type is Set Request
Variable: system.sysLocation.0
Type [i|u|x|d|n|o|t|a]: s
Value: building 17
Variable:
Received Get Response from 128.2.56.220
EXAMPLE 3  Sending a SET Request  (Continued)

requestid 0x7D9FCD65 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysLocation.0 = STRING: building A

EXAMPLE 4  Sending a GETBULK Request

The following is an example of sending a GETBULK request:

Variable: $B
Request type is Bulk Request
Enter a blank line to terminate the list of non-repeaters
and to begin the repeating variables
Variable:
Now input the repeating variables
Variable: system.sysContact.0
Variable: system.sysLocation.0
Variable:
What repeat count? 2
Received Get Response from 128.2.56.220
requestid 0x2EA7942A errstat 0x0 errindex 0x0
SNMPv2-MIB::sysName.0 = STRING: testhost
SNMPv2-MIB::sysORLastChange.0 = Timeticks: (58) 0:00:00.58
SNMPv2-MIB::sysLocation.0 = STRING: bldg A
SNMPv2-MIB::sysORID.1 = OID: IF-MIB::ifMIB

EXAMPLE 5  Sending an Inform Request

The following is an example of sending an Inform request:

snmptest -v 2c -c public snmptrapd_host:162
Variable: $I
Request type is Inform Request
(Are you sending to the right port?)
Variable: system.sysContact.0
Type [i|u|sIx|d|n|o|t|a]: s
Value: x12345
Variable:
Inform Acknowledged
Variable:

The snmptrapd_host will show:

snmptrapd_host [<ip address>]: Trap SNMPv2-MIB::sysContact.0 = STRING: x12345

EXAMPLE 6  Sending an SNMPv2 Trap Request

The following is an example of sending an SNMPv2 Trap request:
EXAMPLE 6  Sending an SNMPv2 Trap Request  (Continued)

snmptest -v 2c -c public snmptrapd_host:162
Variable: $T
Request type is SNMPv2 Trap Request
(Are you sending to the right port?)
Variable: system.sysLocation.0
Type [i|u|s|x|d|n|o|t|a]: s
Value: building a
Variable:

The snmptrapd_host will show:

snmptrapd_host [<ip address>]: Trap SNMPv2-MIB::sys.0 = STRING:
building A

Exit Status  0  Successful completion.

1  A usage syntax error. A usage message is displayed. Also used for timeout errors.

Name  snmptranslate – translate SNMP OID values into a more useful form

Synopsis  /usr/sfw/bin/snmptranslate [ -D token...] [ -h] [ -m miblist]
           [ -M dirlist] [ -T transopts] [common options] OID
           [OID]...

Description  snmptranslate is an application that translates one or more SNMP object identifier values from their symbolic (text) forms into their numerical forms or vice-versa.

OID is either a numeric or text object identifier.

Options  The following options are supported:

- D token[...]
         Turn on debugging output for the specified token(s). Use ALL for extremely verbose output.

- h
         Display a brief usage message and then exit.

- m miblist
         Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable MIBS.

         The special keyword ALL is used to specify all modules in all directories when searching for MIB files. Every file whose name does not begin with "." is parsed as if it were a MIB file.

- M dirlist
         Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable MIBDIRS.

- T transopts
         Provides control over the translation of the OID values. The following transopts are available:

- Td
         Display full details of the specified OID.

- Tp
         Display a graphical tree, rooted at the specified OID.

- Ta
         Dump the loaded MIB in a trivial form.

- Tl
         Dump a labeled form of all objects.

- To
         Dump a numeric form of all objects.

- Ts
         Dump a symbolic form of all objects.

- Tt
         Dump a tree form of the loaded MIBs (most useful for debugging).

- V
         Display version information for the application and then exit.

- w width
         Specifies the width of -Tp and -Td output. The default is very large.
In addition to the preceding options, `snmptranslate` takes the OID input (-I), MIB parsing (-M) and OID output (-O) options described in the INPUT OPTIONS, MIB PARSING OPTIONS and OUTPUT OPTIONS sections of `snmpcmd(1M)`.

**Examples**

**EXAMPLE 1  Expanding sysDescr**

The following command translates `sysDescr` to a more qualified form:

```
% snmptranslate -On -IR sysDescr
.1.3.6.1.2.1.1.1
```

The following command does further translation of `sysDescr`:

```
% snmptranslate -Onf -IR sysDescr
.iso.org.dod.internet.mgmt.mib-2.system.sysDescr
```

Again, the following command does further translates `sysDescr`:

```
% snmptranslate -Td -IR -OS system.sysDescr
```

**EXAMPLE 2  Displaying a Tree**

The following command displays the tree shown below:

```
% snmptranslate -Tp -IR -OS system

+-system(1)
  | +--system(1)
  |     +-- String sysDescr(1)
  |     | Textual Convention: DisplayString
  |     | Size: 0..255
  |     +-- ObjID sysObjectID(2)
  |     +-- TimeTicks sysUpTime(3)
```

SNMPv2-MIB::sysDescr

`sysDescr` OBJECT-TYPE

```-- FROM SNMPv2-MIB
-- TEXTUAL CONVENTION DisplayString
SYNTAX OCTET STRING (0..255)
DISPLAY-HINT "255a"
MAX-ACCESS read-only
STATUS current
DESCRIPTION "A textual description of the entity. This
value should include the full name and
version identification of the system's
hardware type, software operating-system,
and networking software."
::= { iso(1) org(3) dod(6) internet(1) mgmt(2) mib-2(1) system(1) 1 }
```
EXAMPLE 2  Displaying a Tree  (Continued)

| +-- sysUpTimeInstance(0) |
| +-- -RW- String sysContact(4) |
|   Textual Convention: DisplayString |
|   Size: 0..255 |
| +-- -RW- String sysName(5) |
|   Textual Convention: DisplayString |
|   Size: 0..255 |
| +-- -RW- String sysLocation(6) |
|   Textual Convention: DisplayString |
|   Size: 0..255 |
| +-- -R-- INTEGER sysServices(7) |
|   Range: 0..127 |
| +-- -R-- TimeTicks sysORLastChange(8) |
|   Textual Convention: TimeStamp |
| +-- sysORTable(9) |

| +-- -R-- String sysORDescr(3) |
|   Textual Convention: DisplayString |
|   Size: 0..255 |
| +-- -R-- TimeTicks sysORUpTime(4) |
|   Textual Convention: TimeStamp |

EXAMPLE 3  Dumping MIB Contents

The commands shown below produce the dumps that follow.

% snmptranslate -Ta | head

dump DEFINITIONS ::= BEGIN
org ::= { iso 3 }
dod ::= { org 6 }
internet ::= { dod 1 }
directory ::= { internet 1 }
mgmt ::= { internet 2 }
experimental ::= { internet 3 }
private ::= { internet 4 }
EXAMPLE 3  Dumping MIB Contents  (Continued)

security ::= { internet 5 }
snmpV2 ::= { internet 6 }

Here is use of the -Tl option:

% snmptranslate -Tl | head

.iso(1).org(3)
.iso(1).org(3).dod(6)
.iso(1).org(3).dod(6).internet(1)
.iso(1).org(3).dod(6).internet(1).directory(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1).sysObjectID(2)

Here is the use of the -To option:

% snmptranslate -To | head

.1.3
.1.3.6
.1.3.6.1
.1.3.6.1.1
.1.3.6.1.2
.1.3.6.1.2.1
.1.3.6.1.2.1.1
.1.3.6.1.2.1.1.1
.1.3.6.1.2.1.1.2
.1.3.6.1.2.1.1.3

Here is the use of the -Ts option:

% snmptranslate -Ts | head

.iso.org
.iso.org.dod
.iso.org.dod.internet
.iso.org.dod.internet.directory
.iso.org.dod.internet.mgmt
.iso.org.dod.internet.mgmt.mib-2
.iso.org.dod.internet.mgmt.mib-2.system
.iso.org.dod.internet.mgmt.mib-2.system.sysDescr
.iso.org.dod.internet.mgmt.mib-2.system.sysObjectID
.iso.org.dod.internet.mgmt.mib-2.system.sysUpTime
EXAMPLE 3  Dumping MIB Contents  (Continued)

Here is the use of the -Tt option:

% snmptranslate -Tt | head

org(3) type=0
dod(6) type=0
  internet(1) type=0
directory(1) type=0
mgmt(2) type=0
  mib-2(1) type=0
  system(1) type=0
    sysDescr(1) type=2 tc=4 hint=255a
    sysObjectID(2) type=1
    sysUpTime(3) type=8

Exit Status  0  Successful completion.

1  A usage syntax error. A usage message is displayed. Also used for matching object
errors, after which an error message is displayed.

2  An error occurred while executing the command. An error message is displayed.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsmcmd</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>External</td>
</tr>
</tbody>
</table>

See Also  snmpcmd(1M), snmp_variables(4), attributes(5)
The snmptrap utility is an SNMP application that uses the SNMP TRAP operation to send information to a network manager. You can specify one or more object identifiers (OIDs) on the command line. A type and a value must accompany each object identifier. Each variable name must be entered in the format specified in `snmp_variables(4)`.

When invoked as `snmpinform`, or when you specify the `-Ci` option to `snmptrap`, it sends an INFORM-PDU, expecting a response from the trap receiver, and retransmitting if required. Otherwise, it sends a TRAP-PDU or TRAP2-PDU.

If any of the required version 1 parameters—`enterprise-oid`, `agent`, and `uptime`—are specified as empty, they default to `1.3.6.1.4.1.3.1.1 (enterprises.cmu.1.1)`, hostname, and `host-uptime` respectively.

The `type` is a single character, one of:

- `i` INTEGER
- `u` UNSIGNED
- `c` COUNTER32
- `s` STRING
- `x` HEX STRING
- `d` DECIMAL STRING
- `n` NULLOBJ
- `o` OBJID
- `t` TIMETICKS
- `a` IPADDRESS
- `b` BITS

For example, the following command sends a generic linkUp trap to manager, for interface 1:
```
# snmptrap -v 1 -c public manager enterprises.spider test-hub 3 0 ' interfaces.iftable.ifentry.ifindex.1 i 1
```

Options

- `-Ci` Sends an INFORM-PDU, as described above. Applies only to `snmptrap`. This option provides the equivalent function of `snmpinform`.

In addition to this option, `snmptrap` takes the common options described in the `snmpcmd(1M)` manual page.

Exit Status

- `0` Successful completion.
A usage syntax error. A usage message is displayed.

Name

snmptrapd – receive and log SNMP trap messages

Synopsis

/usr/sfw/sbin/snmptrapd [options] [listening addresses]

Description

The snmptrapd utility is an SNMP application that receives and logs SNMP TRAP and INFORM messages.

The default is to listen on UDP port 162 on all IPv4 interfaces. Because 162 is a privileged port, snmptrapd must be run as root.

Options

This command supports the following options:

-a Ignore authentication failure traps.

-c file Read file as a configuration file.

-C Do not read any configuration files except the one optionally specified by the -c option.

-d Dump (in hexadecimal) the sent and received SNMP packets.

-D token[,...] Turn on debugging output for the specified token(s). Use ALL for extremely verbose output.

-e Print event numbers (rising/falling alarm, and so forth).

-f Do not call fork() from the calling shell.

-F format When logging to standard output, use the format in the string format. See Format Specifications below for more details.

-h, --help Display a brief usage message and then exit.

-H Display a list of configuration file directives understood by the trap daemon and then exit.

-l d | 0–7 Specifies the syslog(3C) facility to use when logging to syslog. d means LOG_DAEMON; 0 through 7 means LOG_LOCAL0 through LOG_LOCAL7. LOG_LOCAL0 is the default.

-m miblist Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable MIBS.

-M dirlist Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable MIBDIRS.

-n Do not attempt to translate source addresses of incoming packets into host names.

-o file Log formatted incoming traps to file. Upon receipt of a SIGHUP, the daemon will close and reopen the log file. This feature is useful when rotating the log file with other utilities such as logrotate.
-P  Print formatted incoming traps to stderr.
-s  Log formatted incoming traps to syslog(3C). These syslog messages are
sent with a level of LOG_WARNING and facility as determined by the -l flag
(LOG_LOCAL0 by default). This is the default unless you use the -o or -P flag.
-u file  Save the process ID of the trap daemon in file.
-v, --version  Print version information for the trap daemon and then exit.

In addition to the preceding options, snmptrapd takes the same output formatting options as
the other Net-SNMP commands. See the section OUTPUT OPTIONS in snmpcmd(1M).

For extensibility and configuration information, see snmptrapd.conf(4).

Format Specifications
snmptrapd interprets format strings similarly to printf(3C). It interprets the following
formatting sequences:
  %         A literal percent sign(\%).
  %t        Decimal number of seconds since the operating system's epoch, as returned by time(2).
  %y        Current year on the local system.
  %m        Current (numeric) month on the local system.
  %l        Current day of month on the local system.
  %h        Current hour on the local system.
  %j        Current minute on the local system.
  %k        Current second on the local system.
  %T        The value of the sysUpTime.0 varbind in seconds.
  %Y        The year field from the sysUpTime.0 varbind.
  %M        The numeric month field from the sysUpTime.0 varbind.
  %L        The day of month field from the sysUpTime.0 varbind.
  %H        The hour field from the sysUpTime.0 varbind.
  %J        The minute field from the sysUpTime.0 varbind.
  %K        The seconds field from the sysUpTime.0 varbind.
  %a        The contents of the agent-addr field of the PDU (v1 TRAPs only).
  %A        The hostname corresponding to the contents of the agent-addr field of the PDU, if
available. Otherwise the contents of the agent-addr field of the PDU (v1 TRAPs only).
  %b        PDU source address (note that this is not necessarily an IPv4 address).
%B  PDU source hostname if available, otherwise PDU source address (which is not necessarily an IPv4 address).

%N  Enterprise string.

%w  Trap type (numeric, in decimal).

%W  Trap description.

%q  Trap sub-type (numeric, in decimal).

%P  Security information from the PDU (community name for v1/v2c, user and context for v3).

%V  List of trap's variable-bindings.

In addition to these values, you can also specify an optional field width and precision, just as in printf(3C), and a flag value. The following flags are valid:

-  left justify
0  use leading zeros
#  use alternate form

The "use alternate form" flag changes the behavior of some format flags. Normally, the fields that display time information base it on the local timezone, but this flag tells them to use GMT instead. Also, the variable-binding list is normally a tab-separated list, but this flag changes it to a comma-separated one. The alternate form for the uptime is similar to "3 days, 0:14:34.65".

Listening Addresses

By default, snmptrapd listens for incoming SNMP TRAP and INFORM packets on UDP port 162 on all IPv4 interfaces. However, it is possible to modify this behavior by specifying one or more listening addresses as arguments to snmptrapd. See snmpd(1M) for more information about the format of listening addresses.

NOTIFICATION-LOG-MIB Support

As of Net-SNMP 5.0, the snmptrapd application supports the NOTIFICATION-LOG-MIB. It does this by opening an AgentX subagent connection to the master snmpd agent and registering the notification log tables. As long as the snmpd application is started first, it will attach itself to it. Thus you should be able to view the last recorded notifications by means of the nlmLogTable and nlmLogVariableTable. See snmptrapd.conf(4) and the dontRetainLogs token for turning off this support. See the NOTIFICATION-LOG-MIB for more details about the MIB itself.

Examples

**EXAMPLE 1  Using snmptrapd**

To get a message such as 14:03 TRAP3.1 from humpty.example.edu you can use a command similar to:

```
# snmptrapd -P -F "%02.2h:%02.2j TRAP%w.%q from %A\n"
```
EXAMPLE 1 Using snmptrapd (Continued)

If you want the same effect, but in GMT rather than local time, use:

```
# snmptrapd -P -F "%#02.2h:%#02.2j TRAP%w.%q from %A\n"
```

EXAMPLE 2 Viewing Traps on the Host on Which You Invoke snmptrapd

To view traps on the host from which you invoke snmptrapd, enter:

```
# snmptrapd -P
```

The preceding command sends output to stdout rather than to a log file.

**Exit Status**

0   Successful completion.
1   A usage syntax error. A usage message is displayed. Also used for timeout errors.

**Attributes**

See attributes(5) for descriptions of the following attributes:

snmpusm(1M)

**Name**
snmpusm – create and maintain SNMPv3 users on a remote entity

**Synopsis**
```
snmpusm [common options] AGENT create user [clonefrom-user]
snmpusm [common options] AGENT delete user
snmpusm [common options] AGENT cloneFrom user clonefrom-user
```

**Description**
The snmpusm utility is an SNMP application that can be used to do simple maintenance on an SNMP agent’s User-based Security Module (USM) table. The user needs write access to the usmUserTable MIB table. You can create, delete, clone, and change the passphrase of users configured on a running SNMP agent.

The SNMPv3 USM specifications (see RFC 3414) dictate that users are created and maintained by adding and modifying rows to the usmUserTable MIB table. To create a new user you simply create the row using `snmpset(1M)`. User’s profiles contain private keys that are never transmitted over the wire in clear text, regardless of whether the administration requests are encrypted.

The secret key for a user is initially set by cloning another user in the table, so that a new user inherits the cloned user’s secret key. A user can be cloned only once, however, after which they must be deleted and re-created to be re-cloned. The authentication and privacy security types are also inherited during this cloning (for example, MD5 vs. SHA1). To change the secret key for a user, you must know the user’s old passphrase as well as the new one. The `passwd` subcommand of the `snmpusm` command requires both the new and the old passphrases be supplied. After cloning from the appropriate template, you should immediately change the new user’s passphrase.

The Net-SNMP agent must first be initialized so that at least one user is setup in it before you can use this command to clone new ones. See the `snmpd.conf(4)` manual page for a description of the `createUser` configuration parameter.

Passphrases must be a minimum of eight characters in length.

**Options**
See `snmpcmd(1M)` for a description of `common options`.

**Examples**
Assume for our examples that the following VACM and USM configurations lines are in the `snmpd.conf` file for a Net-SNMP agent. These lines set up a default user named `initial` with the authentication passphrase `setup_passphrase`. Establishing these parameters enables the initial setup of an agent.

```
# VACM configuration entries
rwuser initial
# The name of the new user that is going to be created
rwuser wes
# USM configuration entries
createUser initial MD5 setup_passphrase DES
```
Note that the initial user's setup should be removed after creating a real user to whom you grant administrative privileges. The real user is wes in this example.

**EXAMPLE 1**  Creating a New User

The following command creates a new user, wes, which is cloned from initial. wes inherits that user's passphrase, setup_passphrase.

```
# snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
   localhost create wes initial
```

**EXAMPLE 2**  Changing the User's Passphrase

After creating the user wes with the same passphrase as the user initial, we need to change his passphrase for wes. The following command changes it from setup_passphrase, which was inherited from initial, to new_passphrase.

```
# snmpusm -v3 -u wes -n "" -l authNoPriv -a MD5 -A setup_passphrase \
   localhost passwd setup_passphrase new_passphrase
```

**EXAMPLE 3**  Testing the New User

If the preceding commands were successful, the following command should perform an authenticated SNMPv3 GET request to the agent.

```
# snmpget -v3 -u wes -n "" -l authNoPriv -a MD5 -A new_passphrase \
   localhost sysUpTime.0
```

Following a successful test, remove the VACM group snmpd.conf entry for the user initial. At this point, you have a valid user wes that you can use for future transactions.

**Exit Status**  
0  Successful completion.  
1  A usage syntax error. A usage message is displayed. Also used for timeout errors.  
2  An error occurred while executing the command. An error message is displayed.

RFC 3414
Name  snmpvacm – perform maintenance on an SNMP agent’s View-based Access Control Module (VACM) table

Synopsis  /usr/sfw/bin/snmpvacm [common options] [subcommand options] AGENT subcommand subcommand-args

Description  snmpvacm is a SNMP application that can be used to do maintenance on an SNMP agent’s View-based Access Control Module (VACM) table. The VACM table defines a set of services that can be used for checking access rights, that is, checking whether a specific type of access to a specific managed object is allowed. snmpvacm supports three types of entries: group, view, and access. The agent maintains these entries in memory and stores VACM groups, views, and access entries in the persistent configuration file upon agent shutdown.

Subcommands  This section describes the snmpvacm subcommands.

createSec2Group  Creates SNMPv3 security to group name entries. A group name is used to define an access control policy for a group of principals.

Creates SNMPv3 security to group name entries. A group name is used to define an access control policy for a group of principals.

snmpvacm [common options] createSec2Group MODEL SECURITYNAME GROUPNAME

MODEL  An integer greater than zero representing a SNMPv3 security model, such as USM. The reserved values are as follows:

1  reserved for SNMPv1
2  reserved for SNMPv2c
3  User-Based Security Model (USM)

SECURITYNAME  A string representing a security name for the principal, represented in a security-model-independent format, which is mapped from this entry to a GROUPNAME.

GROUPNAME  A string that identifies the group to which this table entry (the combination of securityModel and securityName) belongs.

deleteSec2Group  Deletes SNMPv3 security to group name entries. The group entry to be deleted is indexed by the specified MODEL and SECURITYNAME.

snmpvacm [common options] deleteSec2Group MODEL SECURITYNAME

MODEL  An integer greater than zero representing a SNMPv3 security model, such as USM. The reserved values are as follows:

1  reserved for SNMPv1
reserved for SNMPv2c

User-Based Security Model (USM)

SECURITYNAME  A string representing a security name for the principal, represented in a security-model-independent format, which is mapped from this entry to a GROUPNAME.

createView  Creates a MIB view. A MIB view is a family of view subtrees, which are pairings of OID subtree values with bit string mask values.

Each MIB view is defined by two sets of view subtrees, included in or excluded from the MIB view.

`snmpvacm [common options] [-Ce] createView NAME SUBTREE MASK`

- Ce  An optional flag used when the MIB view type needs to be "excluded" from the MIB view. If not used, the type is defaulted to "included".

NAME  The OID subtree which when combined with the corresponding instance of MASK defines a family of view subtrees.

SUBTREE  The OID subtree which when combined with the corresponding instance of MASK defines a family of view subtrees.

MASK  The bit mask, a hex string, which, in combination with the corresponding instance SUBTREE, defines a family of view subtrees.

The mask indicates which sub-identifiers of the associated subtree OID are significant to a particular MIB view instance.

deleteView  Deletes a MIB view. A MIB view is a family of view subtrees. A view subtree is a pairing of an OID subtree value with a bit string mask value.

`snmpvacm [common options] deleteView NAME SUBTREE`

NAME  A string representing a MIB view name that is associated to a subtree/mask pairing.

SUBTREE  The OID subtree which, when combined with the corresponding instance of MASK, defines a family of view subtrees.

createAccess  Creates SNMPv3 access configuration entries. These entries are used to store the access rights defined for the groups. Each entry is indexed by a
group name, a context prefix, a security model, and a security level. A group and view need to be defined in order to make use of the access check.

```bash
snmpvacm [common options] createAccess GROUPNAME

[CONTEXTPREFIX] SECURITYMODEL SECURITYLEVEL
CONTEXTMATCH READVIEWNAME WRITEVIEWNAME NOTIFYVIEWNAME

GROUPNAME The name of the group to which this access right applies.

CONTEXTPREFIX A string representing a contextName must match the value of the instance of this object exactly when CONTEXTMATCH is set to "exact" or partially when CONTEXTMATCH is set to "prefix".

If not specified, the value reverts to the default, an empty string, "".

SECURITYMODEL An integer representing the securityModel that must be used in order to gain access to this access right.

SECURITYLEVEL An integer representing the minimum security level that must be used to gain access to this access right. A security level of noAuthNoPriv is less than authNoPriv and authNoPriv is less than authPriv.

Integer values supported:

1 noAuthNoPriv
2 authNoPriv
3 authPriv

CONTEXTMATCH An integer whose value determines the type of match required. When set to "exact", the context name must exactly match the value in CONTEXTPREFIX. If set to "prefix", the context name must match the first few starting characters of the value in CONTEXTPREFIX.

Integer values supported:

1 exact
2 prefix
**READVIEWNAME**  The authorized MIB view name used for read access. If the value is an empty string, then there is no active view configured for read access.

**WRITEVIEWNAME**  The authorized MIB view name used for write access. If the value is an empty string, then there is no active view configured for write access.

**NOTIFYVIEWNAME**  The authorized MIB view name used for notify access. If the value is an empty string, then there is no active view configured for notify access.

deleteAccess  Deletes SNMPv3 access configuration entries, given a group name, context prefix, security model, and security level.

```
snmpvacm [common options] deleteAccess GROUPNAME
           [CONTEXTPREFIX] SECURITYMODEL SECURITYLEVEL
```

**GROUPNAME**  The name of the group to which this access right applies.

**CONTEXTPREFIX**  A string representing a contextName must match the value of the instance of this object exactly when CONTEXTMATCH is set to "exact" or partially when CONTEXTMATCH is set to "prefix".

**SECURITYMODEL**  An integer representing the securityModel that must be used to gain access to this access right.

**SECURITYLEVEL**  An integer representing the minimum security level that must be used to gain access to this access right. A security level of noAuthNoPriv is less than authNoPriv and authNoPriv is less than authPriv.

The following integer values are supported:

1  noAuthNoPriv
2  authNoPriv
3  authPriv

**Examples**  For the following examples, the user is my_user and the password is my_password. Use net-snmp-config to create the first user (my_user). Then clone my_user to configure another SNMPv3 user, my_user_2. See snmpusm(1M).

**EXAMPLE 1**  Creating a VACM Group Entry

Create a VACM group entry, as follows:
Creating a VACM Group Entry

(Continued)

```bash
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
my_password -x DES -X my_password localhost createSec2Group
3 my_user_2 my_group
```

Run `snmpwalk(1M)` to verify the group name was created:

```bash
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
my_password -x DES -X my_password localhost
SNMP-VIEW-BASED-ACM-MIB::vacmGroupName
```

In addition to other configured VACM group entries, you will note an entry such as the following:

```bash
SNMP-VIEW-BASED-ACM-MIB::vacmGroupName.3."my_user_2" = STRING: my_group
```

Creating a MIB View Entry

The command below creates a MIB view entry applicable only to the system group MIB.

```bash
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
my_password -x DES -X my_password localhost createView
my_view .1.3.6.1.2.1.1 FF
```

Run `snmpwalk(1M)` to verify the `my_view` MIB view was created:

```bash
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
my_password -x DES -X my_password localhost
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyTable
```

In `snmpwalk` output, observe the lines, such as those below, related to the `my_view` MIB view.

```bash
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyMask."my_view".2.1.3.6.1.2.1.1 = Hex-STRING: FF
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyType."my_view".2.1.3.6.1.2.1.1 = INTEGER: included(1)
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyStorageType."my_view".2.1.3.6.1.2.1.1 = INTEGER: nonVolatile(3)
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyStatus."my_view".2.1.3.6.1.2.1.1 = INTEGER: active(1)
```

Creating an Access Entry

The command below creates an access entry using the following components:

- the "my_group" entry created above
- an empty prefix string ("")
- the USM security model (3)
- the security level (3)
EXAMPLE 3  Creating an Access Entry  (Continued)

- the context match (1)
- the read view name ("my_view")
- the write view name ("")
- the notify view name ("")

```
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A my_password -x DES -X my_password localhost createAccess
    my_group ** 3 3 1 my_view ** **
```

Run `snmpwalk(1M)` to verify the access entry was created:

```
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A my_password -x DES -X my_password localhost
SNMP-VIEW-BASED-ACM-MIB::vacmAccessTable
  SNMP-VIEW-BASED-ACM-MIB::vacmAccessContextMatch."my_group"."3.authPriv" = INTEGER: exact(1)
  SNMP-VIEW-BASED-ACM-MIB::vacmAccessReadViewName."my_group"."3.authPriv" = STRING: my_view
  SNMP-VIEW-BASED-ACM-MIB::vacmAccessWriteViewName."my_group"."3.authPriv" = STRING:
  SNMP-VIEW-BASED-ACM-MIB::vacmAccessNotifyViewName."my_group"."3.authPriv" = STRING:
  SNMP-VIEW-BASED-ACM-MIB::vacmAccessStorageType."my_group"."3.authPriv" = INTEGER: nonVolatile(3)
  SNMP-VIEW-BASED-ACM-MIB::vacmAccessStatus."my_group"."3.authPriv" = INTEGER: active(1)
```

EXAMPLE 4  Testing the Configuration

Test the preceding setup by verifying the access setup. You do this by accessing an object in the system group and another object outside this range. Note the use of the username `my_user_2`.

```
snmpget -mALL -v 3 -u my_user_2 -l authPriv -a MD5
    -A my_password -x DES -X my_password localhost sysObjectID.0
```

At this point, when you access an object outside the access range, the attempt fails with an appropriate error:

```
snmpgetnext -mALL -v 3 -u my_user_2 -l authPriv -a MD5
    -A my_password -x DES -X my_password localhost ifTable

RFC1213-MIB::ifTable = No more variables left in this MIB View (It is past the end of the MIB tree)
```
Exit Status
0   Successful completion.
1   A usage syntax error. A usage message displays. Also used for time out errors.
2   An error occurred while executing the command. An error message displays.

RFC 3415
Name  

snmpwalk – communicate with a network entity using SNMP GETNEXT requests

Synopsis  

snmpwalk [application options] [common options] [oid]

Description  

The snmpwalk utility is an SNMP application that uses SNMP GETNEXT requests to query a network entity for a tree of information.

You can specify an object identifier (OID) on the command line. This OID specifies which portion of the object identifier space will be searched using GETNEXT requests. All variables in the subtree below the specified OID are queried and their values returned. Each variable name must be entered in the format specified in snmp_variables(4).

If no OID argument is present, snmpwalk searches MIB-2. If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

If the tree search causes attempts to search beyond the end of the MIB, the message "End of MIB" is displayed.

Options  

The following options are supported:

- -Cc  

Do not check whether the returned OIDs are increasing. Some agents (for example, agents for Laser-Jet printers) return OIDs out of order, but can complete the walk anyway. Other agents return OIDs that are out of order and can cause snmpwalk to loop indefinitely. By default, snmpwalk tries to detect this behavior and warns you when it encounters an agent acting illegally. Use -Cc to turn off this feature.

- -Ci  

Include the given OID in the search range. Normally, snmpwalk uses GETNEXT requests starting with the OID you specify and returns all results in the MIB tree beyond that OID. This option allows you to include the OID specified on the command line in the displayed results (assuming the OID is a valid OID in the tree).

- -Cp  

Upon completion of the walk, display the number of variables found.

In addition to these options, snmpwalk takes the common options described in the snmpcmd(1M) manual page.

Examples  

EXAMPLE 1  

Retrieving All of the Variables Under system

The following command retrieves all of the variables under system:

# snmpwalk -Os -c public -v 1 zeus system

Output from this command will be similar to:

sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
sysObjectID.0 = OID: enterprises.hp.nm.hpsystem.10.1.1
sysUpTime.0 = Timeticks: (155274552) 17 days, 23:19:05
sysContact.0 = STRING: ""
sysName.0 = STRING: "zeus.net.cmu.edu"
EXAMPLE 1  Retrieving All of the Variables Under system  

(Continued)

sysLocation.0 = STRING: ""
sysServices.0 = INTEGER: 72

**Name**  
`snmpXdmid` – Sun Solstice Enterprise SNMP-DMI mapper subagent

**Synopsis**  
`/usr/lib/dmi/snmpXdmid -s hostname [-h] [-c config-dir]`  
`[-d debug-level]`

**Description**  
The `snmpXdmid` utility is a subagent in the Solstice Enterprise Agent Desktop Management Interface package. It maps the SNMP requests forwarded by the Master Agent (`snmpdx(1M)`) into one or more equivalent DMI requests. Further, it remaps the DMI response into SNMP response back to `snmpdx`. By default, `snmpXdmid` also forwards the DMI indications as SNMP traps to `snmpdx`. The feature is configurable and can be disabled by setting `TRAP_FORWARD_TO_MAGENT=0` in the `snmpXdmid.conf` configuration file.

This subagent runs as a daemon in the system. The subagent uses a set of .MAP files located in `/var/dmi/map` to map the SNMP Object Identifier (OID) into a corresponding DMI component. The map files are generated using the MIF-to-MIB utility, `miftomib`. They are read by `snmpXdmid` when a corresponding MIF file gets registered with the DMI Service Provider (`dmispd(1M)`).

**Note** – The SMA (Systems Management Agent) is the default SNMP agent in Solaris. See `sma_snmp(5)`. `snmpdx` is Obsolete and may not be supported in a future release of Solaris.

The `snmpXdmid.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by an equal sign (=), followed by a parameter string. The keyword must begin in the first position. A line beginning with a pound sign (#) is treated as a comment and the subsequent characters on that line are ignored. The keywords currently supported are:

- `WARNING_TIMESTAMP`  
  Indication subscription expiration, warning time.

- `EXPIRATION_TIMESTAMP`  
  Indication subscription expiration timestamp.

- `FAILURE_THRESHOLD`  
  DMI SP retries before dropping indication due to comm errors.

- `TRAP_FORWARD_TO_MAGENT`  
  Drop indication at the subagent level.

    - `0`  
      Drop indication at the subagent level.

    - `non-zero`  
      Forward indications as SNMP traps to `snmpdx`.

By default, the configuration file `snmpXdmid.conf` is located in the `/etc/dmi/conf` directory. You can specify an alternative directory with the `-c` option.

**Options**  
The following options are supported:

- `-c config-dir`  
  Specify the directory where `snmpXdmid.conf` file is located.

- `-d debug-level`  
  Debug. Levels from 1 to 5 are supported, giving various levels of debug information.
-h Help. Print the command line usage.
-s hostname Specify the host on which dmi-sp is running.

Files /etc/dmi/conf/snmpXdmid.conf DMI mapper configuration file

snmpXwbemd – SNMP Adapter Subagent for WBEM

### Synopsis

```
/usr/sadm/lib/wbem/snmpXwbemd [-d] [-h] [-p port]
```

### Description

The `snmpXwbemd` daemon is a subagent in the Web-Based Enterprise Management (WBEM) services package.

This daemon maps the Simple Network Management Protocol (SNMP) requests forwarded by the Solstice Enterprise Agents (SEA) Master Agent `snmpdx(1M)` into one or more equivalent WBEM Common Information Model (CIM) properties and instances. Further, it remaps the response from the CIM Object Manager into an SNMP response, which it passes back to `snmpdx(1M)`.

A mapping file contains the corresponding Object Identifier (OID), class name, property name, and Abstract Syntax Notation 1 (ASN.1) type for each object. You can also create your own mapping file.

### Options

The following options are supported:

- `-d` Displays all debug information.
- `-h` Displays help by printing the correct command line usage.
- `-p` Specifies the port number to use.

### Operands

The following operand is supported:

- `port` Specifies the port number you want to use.

### Examples

**EXAMPLE 1** An Example of a `050SUNWwbcou.map` File

This mapping file that Sun Microsystems provides contains definitions of objects, in this format:

```
#       #pragma ident "@(#)050SUNWwbcou.map  1.0  01/04/03 SMI"
#
# Copyright (c) 2001 by Sun Microsystems, Inc.
# All rights reserved.
#
# *** Description of contents ***
#
# First non-commented non-blank line contains required Version label.
# Remaining non-commented non-blank lines are considered map entries
# used as described below:
#
# Column 1 - SNMP OID - Uniquely describes an SNMP variable
# Column 2 - CIM Class Name - CIM class associated with this variable
# Column 3 - CIM Property Name - CIM property that maps to SNMP OID variable
# Column 4 - ASN.1 type - SNMP datatype that dictates how data is mapped
# to/from SNMP requests. Supported types are: SnmpString, SnmpOid,
```
An Example of a `050SUNWwbcou.map` File (Continued)

```
# SnmpTimeticks, SnmpCounter, SnmpInt, SnmpGauge, SnmpIpAddress,
# SnmpOpaque)
# Column 5 and greater are ignored
#
Version 1.0

1.3.6.1.2.1.1.1.0 Solaris_ComputerSystem Description SnmpString
1.3.6.1.2.1.1.3.0 Solaris_OperatingSystem LastBootUpTime SnmpTimeticks

1.3.6.1.2.1.5.0 Solaris_ComputerSystem Name SnmpString

1.3.6.1.2.1.25.1.5.0 Solaris_OperatingSystem NumberOfUsers SnmpGauge
1.3.6.1.2.1.25.1.6.0 Solaris_OperatingSystem NumberOfProcesses SnmpGauge
1.3.6.1.2.1.25.1.7.0 Solaris_OperatingSystem MaxNumberOfProcesses SnmpGauge
1.3.6.1.2.1.25.1.2.0 Solaris_OperatingSystem LocalDateTime SnmpString

Each definition of an object in this file contains an OID, its corresponding CIM class name, its
 corresponding CIM property name, and its corresponding ASN.1 type. Each of these elements
 is separated by a space character.

Files  /var/sadm/wbem/snmp/map/050SUNWwbcou.map

The SNMP Adapter Subagent for
WBEM MIB-2 mapping file that Sun Microsystems provides contains SNMP
Management Information Base (MIB) definitions for the CIM instrumentation
that SNMP manages.

Exit Status  The following exit values are returned:

  0  Successful completion.
  1  An error occurred.

**Synopsis**

`snoop [-aqrCDNPSvV] [-t [r | a | d]] [-c maxcount]
[-d device] [-i filename] [-n filename] [-o filename]
[-p first [, last]] [-s snaplen] [-x offset [, length]]
[expression]

**Description**

`snoop` captures packets from the network and displays their contents. `snoop` uses both the network packet filter and streams buffer modules to provide efficient capture of packets from the network. Captured packets can be displayed as they are received, or saved to a file (which is RFC 1761–compliant) for later inspection.

`snoop` can display packets in a single-line summary form or in verbose multi-line forms. In summary form, with the exception of certain VLAN packets, only the data pertaining to the highest level protocol is displayed. If a packet has a VLAN header and its VLAN ID is non-zero, then `snoop` will show that the packet is VLAN tagged. For example, an NFS packet will have only NFS information displayed. Except for VLAN information under the condition just described, the underlying RPC, UDP, IP, and Ethernet frame information is suppressed, but can be displayed if either of the verbose options are chosen.

In the absence of a name service, such as LDAP or NIS, `snoop` displays host names as numeric IP addresses.

`snoop` requires an interactive interface.

**Options**

**-C**
List the code generated from the filter expression for either the kernel packet filter, or `snoop`'s own filter.

**-D**
Display number of packets dropped during capture on the summary line.

**-N**
Create an IP address-to-name file from a capture file. This must be set together with the `-i` option that names a capture file. The address-to-name file has the same name as the capture file with `.names` appended. This file records the IP address to hostname mapping at the capture site and increases the portability of the capture file. Generate a `.names` file if the capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used.

**-P**
Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets addressed to the host machine will be seen.

**-S**
Display size of the entire link layer frame in bytes on the summary line.

**-V**
Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For
instance, for an NFS packet it will display a line each for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through grep to extract packets of interest. For example, to view only RPC summary lines, enter the following: example:

```
snoop -i rpc.cap -V | grep RPC
```

-a
Listen to packets on /dev/audio (warning: can be noisy).

-c maxcount
Quit after capturing maxcount packets. Otherwise keep capturing until there is no disk space left or until interrupted with Control-C.

-d device
Receive packets from the network using the interface specified by device, for example, eri0 or hme0. The program netstat(1M), when invoked with the -i flag, lists all the interfaces that a machine has. Normally, snoop will automatically choose the first non-loopback interface it finds.

-i filename
Display packets previously captured in filename. Without this option, snoop reads packets from the network interface. If a filename.names file is present, it is automatically loaded into the snoop IP address-to-name mapping table (See -N flag).

-n filename
Use filename as an IP address-to-name mapping table. This file must have the same format as the /etc/hosts file (IP address followed by the hostname).

-o filename
Save captured packets in filename as they are captured. (This filename is referred to as the “capture file”.) The format of the capture file is RFC 1761–compliant. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file /dev/null.

-p first [ , last ]
Select one or more packets to be displayed from a capture file. The first packet in the file is packet number 1.

-q
When capturing network packets into a file, do not display the packet count. This can improve packet capturing performance.

-r
Do not resolve the IP address to the symbolic name. This prevents snoop from generating network traffic while capturing and displaying packets. However, if the -n option is used, and an address is found in the mapping file, its corresponding name will be used.

-s snaplen
Truncate each packet after snaplen bytes. Usually the whole packet is captured. This option is useful if only certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means
less chance of dropped packets due to buffer overflow during periods of high traffic. It also
saves disk space when capturing large traces to a capture file. To capture only IP headers
(no options) use a snaplen of 34. For UDP use 42, and for TCP use 54. You can capture RPC
headers with a snaplen of 80 bytes. NFS headers can be captured in 120 bytes.

-t [ r | a | d ]
Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default
is for times to be presented in d (delta) format (the time since receiving the previous
packet). Option a (absolute) gives wall-clock time. Option r (relative) gives time relative to
the first packet displayed. This can be used with the -p option to display time relative to any
selected packet.

-v
Verbose mode. Print packet headers in lots of detail. This display consumes many lines per
packet and should be used only on selected packets.

-x offset [, length]
Display packet data in hexadecimal and ASCII format. The offset and length values select a
portion of the packet to be displayed. To display the whole packet, use an offset of 0. If a
length value is not provided, the rest of the packet is displayed.

Operands

Select packets either from the network or from a capture file. Only packets for which the
expression is true will be selected. If no expression is provided it is assumed to be true.

Given a filter expression, snoop generates code for either the kernel packet filter or for its
own internal filter. If capturing packets with the network interface, code for the kernel
packet filter is generated. This filter is implemented as a streams module, upstream of the
buffer module. The buffer module accumulates packets until it becomes full and passes the
packets on to snoop. The kernel packet filter is very efficient, since it rejects unwanted
packets in the kernel before they reach the packet buffer or snoop. The kernel packet filter
has some limitations in its implementation; it is possible to construct filter expressions that
it cannot handle. In this event, snoop tries to split the filter and do as much filtering in the
kernel as possible. The remaining filtering is done by the packet filter for snoop. The -C flag
can be used to view generated code for either the packet filter for the kernel or the packet
filter for snoop. If packets are read from a capture file using the -i option, only the packet
filter for snoop is used.

A filter expression consists of a series of one or more boolean primitives that may be
combined with boolean operators (AND, OR, and NOT). Normal precedence rules for boolean
operators apply. Order of evaluation of these operators may be controlled with
parentheses. Since parentheses and other filter expression characters are known to the
shell, it is often necessary to enclose the filter expression in quotes. Refer to Example 2 for
information about setting up more efficient filters.

The primitives are:
**host hostname**

True if the source or destination address is that of hostname. The `hostname` argument may be a literal address. The keyword `host` may be omitted if the name does not conflict with the name of another expression primitive. For example, `pinky` selects packets transmitted to or received from the host `pinky`, whereas `pinky` and `dinky` selects packets exchanged between hosts `pinky` AND `dinky`.

The type of address used depends on the primitive which precedes the `host` primitive. The possible qualifiers are `inet`, `inet6`, `ether`, or `none`. These three primitives are discussed below. Having none of the primitives present is equivalent to “inet host hostname or inet6 host hostname”. In other words, `snoop` tries to filter on all IP addresses associated with hostname.

**inet or inet6**

A qualifier that modifies the `host` primitive that follows. If it is `inet`, then `snoop` tries to filter on all IPv4 addresses returned from a name lookup. If it is `inet6`, `snoop` tries to filter on all IPv6 addresses returned from a name lookup.

**ipaddr, atalkaddr, or etheraddr**

Literal addresses, IP dotted, AppleTalk dotted, and Ethernet colon are recognized. For example,

- “172.16.40.13” matches all packets with that IP
- “2::9255:a00:20ff:fe73:6e35” matches all packets with that IPv6 address as source or destination;
- “65281.13” matches all packets with that AppleTalk address;
- “8:0:20::b1:51” matches all packets with the Ethernet address as source or destination.

An Ethernet address beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the Ethernet address is `aa:0:45:23:52:44`, then specify it by add a leading zero to make it `0aa:0:45:23:52:44`.

**from or src**

A qualifier that modifies the following `host`, `net`, `ipaddr`, `atalkaddr`, `etheraddr`, `port` or `rpc` primitive to match just the source address, port, or RPC reply.

**to or dst**

A qualifier that modifies the following `host`, `net`, `ipaddr`, `atalkaddr`, `etheraddr`, `port` or `rpc` primitive to match just the destination address, port, or RPC call.

**ether**

A qualifier that modifies the following `host` primitive to resolve a name to an Ethernet address. Normally, IP address matching is performed. This option is not supported on media such as IPoIB (IP over InfiniBand).
ethertype \textit{number}

True if the Ethernet type field has value \textit{number}. If \textit{number} is not 0x8100 (VLAN) and the packet is VLAN tagged, then the expression will match the encapsulated Ethernet type.

\texttt{ip}, \texttt{ip6}, \texttt{arp}, \texttt{rarp}, \texttt{pppoed}, \texttt{pppoes}

True if the packet is of the appropriate ethertype.

\texttt{vlan}

True if the packet has ethertype VLAN and the VLAN ID is not zero.

\texttt{vlan-id \textit{id}}

True for packets of ethertype VLAN with the id \textit{id}.

\texttt{pppoed}

True if the ethertype of the packet is either \texttt{pppoed} or \texttt{pppoes}.

\texttt{broadcast}

True if the packet is a broadcast packet. Equivalent to \texttt{ether[2:4] = 0xffffffff} for Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

\texttt{multicast}

True if the packet is a multicast packet. Equivalent to "\texttt{ether[0] & 1 = 1}" on Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

\texttt{bootp, dhcp}

True if the packet is an unfragmented IPv4 UDP packet with either a source port of \texttt{BOOTPS} (67) and a destination port of \texttt{BOOTPC} (68), or a source port of \texttt{BOOTPC} (68) and a destination of \texttt{BOOTPS} (67).

\texttt{dhcp6}

True if the packet is an unfragmented IPv6 UDP packet with either a source port of \texttt{DHCPV6-SERVER} (547) and a destination port of \texttt{DHCPV6-CLIENT} (546), or a source port of \texttt{DHCPV6-CLIENT} (546) and a destination of \texttt{DHCPV6-SERVER} (547).

\texttt{apple}

True if the packet is an Apple Ethertalk packet. Equivalent to "ethertype 0x809b or ethertype 0x80f3".

\texttt{decnet}

True if the packet is a DECNET packet.

\texttt{greater length}

True if the packet is longer than \texttt{length}.

\texttt{less length}

True if the packet is shorter than \texttt{length}.

\texttt{udp, tcp, icmp, icmp6, ah, esp}

True if the IP or IPv6 protocol is of the appropriate type.
net net
  True if either the IP source or destination address has a network number of net. The from or to qualifier may be used to select packets for which the network number occurs only in the source or destination address.

port port
  True if either the source or destination port is port. The port may be either a port number or name from /etc/services. The tcp or udp primitives may be used to select TCP or UDP ports only. The from or to qualifier may be used to select packets for which the port occurs only as the source or destination.

rpc prog [, vers [, proc ]]
  True if the packet is an RPC call or reply packet for the protocol identified by prog. The prog may be either the name of an RPC protocol from /etc/rpc or a program number. The vers and proc may be used to further qualify the program version and procedure number, for example, rpc nfs,2,0 selects all calls and replies for the NFS null procedure. The to or from qualifier may be used to select either call or reply packets only.

ldap
  True if the packet is an LDAP packet on port 389.

gateway host
  True if the packet used host as a gateway, that is, the Ethernet source or destination address was for host but not the IP address. Equivalent to “ether host host and not host host”.

nofrag
  True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to ip[6:2] & 0xfff = 0.

expr relop expr
  True if the relation holds, where relop is one of >, <, >=, <=, =, !=, and expr is an arithmetic expression composed of numbers, packet field selectors, the length primitive, and arithmetic operators +, -, *, |, & , ^, and %. The arithmetic operators within expr are evaluated before the relational operator and normal precedence rules apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:

  base[expr [: size ] ]

  where expr evaluates the value of an offset into the packet from a base offset which may be ether, ip, ip6, udp, tcp, or icmp. The size value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4. For example,

  ether[0] & 1 = 1

  is equivalent to multicast
ether[2:4] = 0xffffffff

is equivalent to broadcast.

ip[ip[0] & 0xf * 4 : 2] = 2049

is equivalent to udp[0:2] = 2049

ip[0] & 0xf > 5

selects IP packets with options.

ip[6:2] & 0x1fff = 0

eliminates IP fragments.

udp and ip[6:2]&0x1fff = 0 and udp[6:2] != 0

finds all packets with UDP checksums.

The length primitive may be used to obtain the length of the packet. For instance "length > 60" is equivalent to "greater 60", and "ether[length - 1]" obtains the value of the last byte in a packet.

Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example "dinky pinky" is the same as "dinky AND pinky".

or or,

Perform a logical OR operation between two boolean values. A comma may be used instead, for example, "dinky,pinky" is the same as "dinky OR pinky".

not or!

Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

slp

True if the packet is an SLP packet.

sctp

True if the packet is an SCTP packet.

ospf

True if the packet is an OSPF packet.

Examples

**EXAMPLE 1**  Using the snoop Command

Capture all packets and display them as they are received:

eexample# snoop

Capture packets with host funky as either the source or destination and display them as they are received:

eexample# snoop funky
EXAMPLE 1 Using the snoop Command  (Continued)

example# snoop funky

Capture packets between funky and pinky and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

example# snoop -o cap funky pinky
example# snoop -i cap -t r | more

To look at selected packets in another capture file:

example# snoop -i pkts -p 99,108

To look at packet 101 in more detail:

example# snoop -i pkts -v -p101

ETHER: ----- Ether Header -----  
ETHER: Packet 101 arrived at 16:09:53.59
ETHER: Packet size = 210 bytes
ETHER: Destination = 8:0:20:1:3d:94, Sun
ETHER: Source = 8:0:69:1:5f:e, Silicon Graphics
ETHER: Ethertype = 0800 (IP)
ETHER: 
IP: ----- IP Header -----  
IP: Version = 4, header length = 20 bytes

RPC:  Type = 0 (Call)
RPC:  RPC version = 2
RPC:  Program = 100003 (NFS), version = 2, procedure = 1
RPC:  Credentials: Flavor = 1 (Unix), len = 32 bytes
RPC:  Time = 06-Mar-90 07:26:58
RPC:  Hostname = boutique
RPC:  Uid = 0, Gid = 1
RPC:  Groups = 1
RPC:  Verifier : Flavor = 0 (None), len = 0 bytes
RPC:
NFS:  ----- SUN NFS -----  
NFS:
NFS:  Proc = 11 (Rename)
NFS:  File handle = 0000164300000000100000000305A1C47
NFS:  597A00000000002046314AFC450000
NFS:  File name = MTra00192
NFS:  File handle = 0000164300000000100000000305A1C47
NFS:  597A00000000002046314AFC450000
NFS:  File name = .nfs08
NFS:

To view just the NFS packets between sunroof and boutique:

example# snoop -i pkts rpc nfs and sunroof and boutique
1  0.0000  boutique -> sunroof  NFS C GETATTR FH=8E6C
2  0.0046  sunroof -> boutique  NFS R GETATTR OK
3  0.0080  boutique -> sunroof  NFS C RENAME FH=8E6C MTra00192 to .nfs08

To save these packets to a new capture file:

example# snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique

To view encapsulated packets, there will be an indicator of encapsulation:
EXAMPLE 1  Using the snoop Command  (Continued)

example# snoop ip-in-ip
sunroof -> boutique ICMP Echo request  (1 encap)

If -V is used on an encapsulated packet:

example# snoop -V ip-in-ip
sunroof -> boutique ETHER Type=0800 (IP), size = 118 bytes
sunroof -> boutique IP D=172.16.40.222 S=172.16.40.200 LEN=104, ID=27497
sunroof -> boutique IP D=10.1.1.2 S=10.1.1.1 LEN=84, ID=27497
sunroof -> boutique ICMP Echo request

EXAMPLE 2  Setting Up A More Efficient Filter

To set up a more efficient filter, the following filters should be used toward the end of the expression, so that the first part of the expression can be set up in the kernel: greater, less, port, rpc, nofrag, and relop. The presence of OR makes it difficult to split the filtering when using these primitives that cannot be set in the kernel. Instead, use parentheses to enforce the primitives that should be OR'd.

To capture packets between funky and pinky of type tcp or udp on port 80:

example# snoop funky and pinky and port 80 and tcp or udp

Since the primitive port cannot be handled by the kernel filter, and there is also an OR in the expression, a more efficient way to filter is to move the OR to the end of the expression and to use parentheses to enforce the OR between tcp and udp:

example# snoop funky and pinky and (tcp or udp) and port 80

Exit Status  0  Successful completion.
1  An error occurred.

Files  
/dev/audio  Symbolic link to the system’s primary audio device.
/dev/null  The null file.
/etc/hosts  Host name database.
/etc/rpc  RPC program number data base.
/etc/services  Internet services and aliases.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>

snoop(1M)

See Also  netstat(1M), hosts(4), rpc(4), services(4), attributes(5), audio(7I), bufmod(7M),
dlpi(7P), pfmod(7M), tun(7M)

Warnings  The processing overhead is much higher for realtime packet interpretation. Consequently, the
packet drop count may be higher. For more reliable capture, output raw packets to a file using
the -o option and analyze the packets off-line.

Unfiltered packet capture imposes a heavy processing load on the host computer, particularly
if the captured packets are interpreted realtime. This processing load further increases if
verbose options are used. Since heavy use of snoop may deny computing resources to other
processes, it should not be used on production servers. Heavy use of snoop should be
restricted to a dedicated computer.

snoop does not reassemble IP fragments. Interpretation of higher level protocol halts at the
end of the first IP fragment.

snoop may generate extra packets as a side-effect of its use. For example it may use a network
name service (NIS or NIS+) to convert IP addresses to host names for display. Capturing into
a file for later display can be used to postpone the address-to-name mapping until after the
capture session is complete. Capturing into an NFS-mounted file may also generate extra
packets.

Setting the snaplen (-s option) to small values may remove header information that is needed
to interpret higher level protocols. The exact cutoff value depends on the network and
protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s Ethernet, do not set
snaplen less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s Ethernet,
snaplen should be 250 bytes or more.

snoop requires information from an RPC request to fully interpret an RPC reply. If an RPC
reply in a capture file or packet range does not have a request preceding it, then only the RPC
reply header will be displayed.
soconfig – configure transport providers for use by sockets

/sbin/soconfig -f
/sbin/soconfig family type protocol [path]

Description
The soconfig utility configures the transport provider driver for use with sockets. It specifies how the family, type, and protocol parameters in the socket(3SOCKET) call are mapped to the name of a transport provider such as /dev/tcp. This utility can be used to add an additional mapping or remove a previous mapping.

The init(1M) utility uses soconfig with the sock2path(4) file during the booting sequence.

Options
The following options are supported:
- -f file Set up the soconfig configuration for each driver according to the information stored in file. A soconfig file consists of lines of at least the first three fields listed below, separated by spaces:

family type protocol path

These fields are described in the OPERANDS section below.

An example of file can be found in the EXAMPLES section below.

Operands
The following operands are supported:

- family The protocol family as listed in the /usr/include/sys/socket.h file, expressed as an integer.
- type The socket type as listed in the /usr/include/sys/socket.h file, expressed as an integer.
- protocol The protocol number as specified in the family-specific include file, expressed as an integer. For example, for AF_INET this number is specified in /usr/include/netinet/in.h. An unspecified protocol number is denoted with the value zero.
- path The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.

Examples

EXAMPLE 1 Using soconfig
The following example sets up /dev/tcp for family AF_INET and type SOCK_STREAM:

example# soconfig 2 2 0 /dev/tcp

The following is a sample file used with the -f option. Comment lines begin with a number sign (#):

Network Interface Guide
**soladdapp(1M)**

**Name**
soladdapp – add an application to the Solstice application registry

**Synopsis**
/usr/snadm/bin/soladdapp [-r registry] -n name -i icon -e executable
[ARGS]

**Description**
soladdapp adds an application to the Solstice application registry. After it is added, the application is displayed in the Solstice Launcher main window (see solstice(1M)).

**Options**
- `-r registry` Define the full path name of the Solstice registry file.
- `-n name` Define the name of the tool to be registered.
- `-i icon` Define the full path name of the tool icon.
- `-e executable` Define the full path name of the tool.
- `ARGS` Specify any arguments to use with the tool.

When executed without options, soladdapp uses /opt/SUNWadm/etc/.solstice_registry (the default registry path).

**Return Values**
0 on success
1 on failure
2 if the registry is locked
3 if the entry is a duplicate.

**Examples**

**EXAMPLE 1** A sample display of the soladdapp command.
The following adds an application called Disk Manager to the Solstice application registry for display in the Solstice Launcher main window.
```
# soladdapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
   -i /opt/SUNWdsk/etc/diskmgr.xpm -e /opt/SUNWdsk/bin/diskmgr
```

**Files**
/opt/SUNWadm/etc/.solstice_registry The default registry path.

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsadml</td>
</tr>
</tbody>
</table>

**See Also**
soldelapp(1M), solstice(1M), attributes(5)

**Notes**
Globally registered applications are used by local and remote users sharing the software in a particular /opt directory. They can be added only using soladdapp.
soldelapp removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see solstice(1M)).

Options
- `-r registry` Define the full path name of the Solstice registry file.
- `-n name` Define the name of the tool to be removed.

When executed without options, soldelapp uses /opt/SUNWadm/etc/.solstice_registry (the default registry path).

Return Values
0 on success
1 on failure
2 if the registry is locked
3 if `name` is not found in the registry
4 if the named registry or default registry is not found

Examples
EXAMPLE 1 A sample display of the soldelapp command.
The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window.

```
# soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
```

Files
/opt/SUNWadm/etc/.solstice_registry The default registry file.

Attributes
See attributes(5) for descriptions of the following attributes:

Notes
Globally registered applications are used by local and remote users sharing the software in a particular /opt directory. They can be removed only using soldelapp.
Name: solstice – access system administration tools with a graphical user interface

Synopsis: /bin/solstice

Description: solstice used on a system presents the Solstice Launcher, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system.

Help is available by using the Help button.

Usage: The Solstice Launcher allows you to do the following tasks:

- **Launch applications**: Use the Solstice Launcher to launch system administration tools.
- **Register applications**: Use the Solstice Launcher to add and register applications locally with the launcher.
- **Remove applications**: Use the Solstice Launcher to remove locally registered applications.
- **Customize application properties**: Use the Solstice Launcher to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.

Files: $HOME/.solstice_registry

Local registry information.

Attributes: See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWsadml</td>
</tr>
</tbody>
</table>

See Also: soladdapp(1M), soldelapp(1M), attributes(5)

Notes: The Solstice Launcher adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular /opt directory cannot be modified from the Solstice Launcher. To register global applications for use by local and remote users, use the soladdapp(1M) command. To remove globally registered applications, use the soldelapp(1M) command.
The `sppptun` utility is used to configure and query the Solaris PPP tunneling device driver, `/dev/sppptun`. Currently, only PPP over Ethernet (PPPoE) is supported, so the `plumb` and `unplumb` arguments are used to specify Ethernet interfaces that are to be used for PPPoE, and the `query` option lists the plumbed interfaces.

The use of `sppptun` to add interfaces is similar to the use of `ifconfig(1M)` to add interfaces to IP. The plumbing is done once for each interface, preferably at system start-up time, and is not normally manipulated on a running system. If multiple instances of PPP are run over a single interface, they share the plumbing to that interface. Plumbing for each session is not required (and not possible for PPPoE).

The proper way to plum interfaces for PPPoE is to list the interfaces, one per line, in the `/etc/ppp/pppoe.if` file.

**Usage**

- `sppptun plumb` When specified with no additional arguments, the plumb argument lists the protocols that are supported by the utility. These are the strings that are used as the `protocol` argument below.

- `sppptun plumb protocol device` This plumbs a new interface into the driver. The `protocol` parameter is `pppoe` for the PPP-carrying "Session Stage" connection or `pppoed` for the PPPoE "Discovery Stage" connection. Both connections must be present for each Ethernet interface that is to be used for PPPoE. The `device` parameter is the path name of the Ethernet interface to use (use `ifconfig(1M)` to list available devices). If the path begins with `/dev/`, then this portion may be omitted.

- `sppptun unplumb interface` This removes an existing interface from the driver and terminates any PPP sessions that were using the interface. The `interface` parameter is the name of the interface as reported when the interface was plumbed.

- `sppptun query` Displays the canonical names of all interfaces plumbed into the `/dev/sppptun` device driver.

**Examples**

**Example 1** Setting up to Use PPPoE on `hme0`

Plumb the `hme0` interface.

```bash
sppptun plumb
sppptun plumb pppoe hme0
```
EXAMPLE 1 Setting up to Use PPPoE on hme0 (Continued)

```
# sppptun plumb pppoed hme0
hme0:pppoed
# sppptun plumb pppoe hme0
hme0:pppoe
```

Remove the hme0 interface.

```
# sppptun unplumb hme0:pppoed
# sppptun unplumb hme0:pppoe
```

EXAMPLE 2 Script to Remove All Plumbed Interfaces

```
#!/bin/sh
for intf in 'sppptun query'
do
    sppptun unplumb $intf
done
```

The following exit values are returned:

<table>
<thead>
<tr>
<th>Exit Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion.</td>
</tr>
<tr>
<td>1</td>
<td>One or more errors occurred.</td>
</tr>
</tbody>
</table>

**Files**

- `/etc/ppp/pppoed.if` list of Ethernet interfaces to be plumbed at boot time
- `/usr/sbin/sppptun` executable command
- `/dev/sppptun` Solaris PPP tunneling device driver

**Attributes**

`RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999`
**Spray** sends a one-way stream of packets to **host** using RPC, and reports how many were received, as well as the transfer rate. The **host** argument can be either a name or an Internet address.

**Spray** is not useful as a networking benchmark, as it uses unreliable connectionless transports, UDP for example. **Spray** can report a large number of packets dropped when the drops were caused by **spray** sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.

**Options**

- **-c count** Specify how many packets to send. The default value of **count** is the number of packets required to make the total stream size 100000 bytes.
- **-d delay** Specify how many microseconds to pause between sending each packet. The default is 0.
- **-l length** The **length** parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of **length** are possible, and **spray** rounds up to the nearest possible value. When **length** is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the **length** field no longer has a simple correspondence to Ethernet packet size. The default value of **length** is 86 bytes, the size of the RPC and UDP headers.
- **-t nettype** Specify class of transports. Defaults to **netpath**. See **rpc(3NSL)** for a description of supported classes.

**Attributes**

See **attributes(5)** for descriptions of the following attributes:

<table>
<thead>
<tr>

The `sshd` (Secure Shell daemon) is the daemon program for `ssh(1)`. Together these programs replace `rlogin` and `rsh`, and provide secure encrypted communications between two untrusted hosts over an insecure network. The programs are intended to be as easy to install and use as possible.

`sshd` is the daemon that listens for connections from clients. It forks a new daemon for each incoming connection. The forked daemons handle key exchange, encryption, authentication, command execution, and data exchange.

This implementation of `sshd` supports both SSH protocol versions 1 and 2 simultaneously. Because of security weaknesses in the v1 protocol, sites should run only v2, if possible. In the default configuration, only protocol v2 is enabled for the server. To enable v1 and v2 simultaneously, see the instructions in `sshd_config(4)`.

Support for v1 is provided to help sites with existing `ssh v1` clients and servers to transition to v2. v1 might not be supported in a future release.

**SSH Protocol Version 1**

Each host has a host-specific RSA key (normally 1024 bits) used to identify the host. Additionally, when the daemon starts, it generates a server RSA key (normally 768 bits). This key is normally regenerated every hour if it has been used, and is never stored on disk.

Whenever a client connects the daemon responds with its public host and server keys. The client compares the RSA host key against its own database to verify that it has not changed. The client then generates a 256–bit random number. It encrypts this random number using both the host key and the server key, and sends the encrypted number to the server. Both sides then use this random number as a session key which is used to encrypt all further communications in the session. The rest of the session is encrypted using a conventional cipher, currently Blowfish or 3DES, with 3DES being used by default. The client selects the encryption algorithm to use from those offered by the server.

Next, the server and the client enter an authentication dialog. The client tries to authenticate itself using `.rhosts` authentication, `.rhosts` authentication combined with RSA host authentication, RSA challenge-response authentication, or password-based authentication.

`.rhosts` authentication is normally disabled because it is fundamentally insecure, but can be enabled in the server configuration file if desired. System security is not improved unless `rshd(1M), rlogind(1M), rexecd(1M), and rexd(1M)` are disabled (thus completely disabling `rlogin(1)` and `rsh(1)` into the machine).
SSH Protocol Version 2  Version 2 works similarly to version 1: Each host has a host-specific DSA/RSA key. However, when the daemon starts, it does not generate a server key. Forward security is provided through a Diffie-Hellman key agreement. This key agreement results in a shared session key. The rest of the session is encrypted using a symmetric cipher, currently 128-bit AES, Blowfish, 3DES, or AES. The client selects the encryption algorithm to use from those offered by the server. Additionally, session integrity is provided through a cryptographic message authentication code (hmac-sha1 or hmac-md5).

Protocol version 2 provides a public key based user authentication method (PubKeyAuthentication) GSS–API based user authentication, conventional password authentication, and a generic prompt/reply protocol for password-based authentication.

Command Execution and Data Forwarding  If the client successfully authenticates itself, a dialog for preparing the session is entered. At this time the client can request things like allocating a pseudo-tty, forwarding X11 connections, forwarding TCP/IP connections, or forwarding the authentication agent connection over the secure channel.

Finally, the client either requests a shell or execution of a command. The sides then enter session mode. In this mode, either side may send data at any time, and such data is forwarded to/from the shell or command on the server side, and the user terminal on the client side.

When the user program terminates and all forwarded X11 and other connections have been closed, the server sends command exit status to the client, and both sides exit.

sshd can be configured using command-line options or the configuration file /etc/ssh/ssh_config, described in ssh_config(4). Command-line options override values specified in the configuration file.

sshd rereads its configuration file when it receives a hangup signal, SIGHUP, by executing itself with the name it was started as, that is, /usr/lib/ssh/sshd.

Host Access Control  The sshd daemon uses TCP Wrappers to restrict access to hosts. It uses the service name of sshd for hosts_access(). For more information on TCP Wrappers see tcpd(1M) and hosts_access(3) man pages, which are part of the SUNWsfsman package (they are not SunOS man pages). TCP wrappers binaries, including libwrap, are in SUNWtcpd, a required package for SUNWsshd, the package containing sshd.

Options  The options for sshd are as follows:

-b bits
   Specifies the number of bits in the server key (the default is 768).
-d
   Debug mode. The server sends verbose debug output to the system log, and does not put itself in the background. The server also will not fork and will only process one connection. This option is only intended for debugging for the server. Multiple -d options increase the debugging level. Maximum is 3.
When this option is specified, `sshd` will send the output to standard error instead of to the system log.

- `configuration_file`
  Specifies the name of the configuration file. The default is `/etc/ssh/sshd_config`. `sshd` refuses to start if there is no configuration file.

- `login_grace_time`
  Gives the grace time for clients to authenticate themselves (the default is 300 seconds). If the client fails to authenticate the user within this number of seconds, the server disconnects and exits. A value of zero indicates no limit.

- `host_key_file`
  Specifies a file from which a host key is read. This option must be given if `sshd` is not run as root (as the normal host key files are normally not readable by anyone but root). The default is `/etc/ssh/ssh_host_key` for protocol version 1, and `/etc/ssh/ssh_host_rsa_key` and `/etc/ssh/ssh_host_dsa_key` for protocol version 2. It is possible to have multiple host key files for the different protocol versions and host key algorithms.

- `i`
  Specifies that `sshd` is being run from `inetd`. `sshd` is normally not run from `inetd` because it needs to generate the server key before it can respond to the client, and this may take tens of seconds. Clients would have to wait too long if the key was regenerated every time. However, with small key sizes (for example, 512) using `sshd` from `inetd` may be reasonable.

- `key_gen_time`  
  (SSHv1-specific) Specifies how often the server key is regenerated (the default is 3600 seconds, or one hour). The motivation for regenerating the key fairly often is that the key is not stored anywhere, and after about an hour, it becomes impossible to recover the key for decrypting intercepted communications even if the machine is cracked into or physically seized. A value of zero indicates that the key will never be regenerated.

- `o option`
  Can be used to specify options in the format used in the configuration file. This is useful for specifying options for which there are no separate command-line flags.

- `p port`
  Specifies the port on which the server listens for connections (the default is 22).

- `q`
  Quiet mode. Nothing is sent to the system log. Normally the beginning, authentication, and termination of each connection is logged.

- `t`
  Test mode. Check only the validity of the configuration file and the sanity of the keys. This is useful for updating `sshd` reliably as configuration options might change.
-D
When this option is specified sshd does not detach and does not become a daemon. This allows easy monitoring of sshd.

-4
Forces sshd to use IPv4 addresses only.

-6
Forces sshd to use IPv6 addresses only.

Extended Description

The $HOME/.ssh/authorized_keys file lists the public keys that are permitted for RSA authentication in protocol version 1 and for public key authentication (PubkeyAuthentication) in protocol version 2. The AuthorizedKeysFile configuration option can be used to specify an alternative file.

Each line of the file contains one key (empty lines and lines starting with a hash mark [#] are ignored as comments).

For each RSA key for protocol version 1, the file consists of the following space-separated fields:

options bits exponent modulus comment

For the public key for protocol version 2, the file consists of the following space-separated fields:

options key-type base64-encoding-key comment

For protocol version 2, key-type is one of ssh-rsa or ssh-dsa.

The options field is optional; its presence is determined by whether the line starts with a number. (The option field never starts with a number.) The bits, exponent, and modulus fields give the RSA key; the comment field is a convenient place for you to identify the key.

Lines in this file are usually several hundred bytes long (because of the size of the key modulus). You will find it very inconvenient to type them in; instead, copy the public key file and edit it.

Permissions of this file must be set so that it is not world or group writable. See the StrictModes option of sshd_config(4).

The options (if present) consist of comma-separated option specifications. No spaces are permitted, except within double quotes. The following option specifications are supported:

from="pattern-list"
Specifies that, in addition to public key authentication, the canonical name of the remote host must be present in the comma-separated list of patterns (‘*’ and ‘?’ serve as wildcards). The list can also contain negated patterns by prefixing the patterns with ‘!’ If the canonical host name matches a negated pattern, the key is not accepted.
The purpose of this option is to give you the option of increasing security: public key authentication by itself does not trust the network or name servers or anything but the key. However, if someone manages to steal the key, possession of the key would permit the intruder to log in from anywhere in the world. This option makes using a stolen key more difficult, because name servers and routers would have to be compromised, in addition to just the key.

command="command"
Specifies that the command is executed whenever this key is used for authentication. The command supplied by the user (if any) is ignored. The command is run on a pty if the client requests a pty; otherwise it is run without a tty. If an 8-bit clean channel is required, one must not request a pty or should specify no-pty. You can include a quote in the command by escaping it with a backslash. This option might be useful to restrict certain public keys from performing a specific operation. An example is a key that permits remote backups but nothing else. Note that the client can specify TCP/IP and/or X11 forwarding unless they are explicitly prohibited from doing so. Also note that this option applies to shell, command, or subsystem execution.

environment="NAME=value"
Specifies that the string NAME=value is to be added to the environment when logging in using this key. Environment variables set this way override other default environment values. Multiple options of this type are permitted. Environment processing is disabled by default and is controlled via the PermitUserEnvironment option.

no-port-forwarding
Forbids TCP/IP forwarding when this key is used for authentication. Any port forward requests by the client will return an error. This might be used, for example, in connection with the command option.

no-X11-forwarding
Forbids X11 forwarding when this key is used for authentication. Any X11 forward requests by the client will return an error.

no-agent-forwarding
Forbids authentication agent forwarding when this key is used for authentication.

no-pty
Prevents tty allocation (a request to allocate a pty will fail).

permitopen="host:port"
Limit local ssh -L port forwarding such that it can connect only to the specified host and port. IPv6 addresses can be specified with an alternative syntax: host/port. You can invoke multiple permitopen options, with each instance separated by a comma. No pattern matching is performed on the specified hostnames. They must be literal domains or addresses.
The `/etc/ssh/ssh_known_hosts` and `$HOME/.ssh/known_hosts` files contain host public keys for all known hosts. The global file should be prepared by the administrator (optional), and the per-user file is maintained automatically: whenever the user connects from an unknown host its key is added to the per-user file.

For the RSA key for protocol version 1, these files consist of the following space-separated fields:

```
hostnames bits exponent modulus comment
```

For the public key for protocol version 2, these files consist of the following space-separated fields:

```
hostnames key-type base64-encoding-key comment
```

For protocol version 2, `key-type` is one of `ssh-rsa` or `ssh-dsa`.

Hostnames is a comma-separated list of patterns (* and ? act as wildcards); each pattern in turn is matched against the canonical host name (when authenticating a client) or against the user-supplied name (when authenticating a server). A pattern can also be preceded by ! to indicate negation: if the host name matches a negated pattern, it is not accepted (by that line) even if it matched another pattern on the line.

Alternately, hostnames can be stored in a hashed form, which hides host names and addresses should the file's contents be disclosed. Hashed hostnames start with a vertical bar (`|`) character. Only one hashed hostname can appear on a single line and none of the above negation or wildcard operators may be applied.

Bits, exponent, and modulus are taken directly from the RSA host key; they can be obtained, for example, from `/etc/ssh/ssh_host_rsa_key.pub`. The optional comment field continues to the end of the line, and is not used.

Lines starting with a hash mark (`#`) and empty lines are ignored as comments.

When performing host authentication, authentication is accepted if any matching line has the proper key. It is thus permissible (but not recommended) to have several lines or different host keys for the same names. This will inevitably happen when short forms of host names from different domains are put in the file. It is possible that the files contain conflicting information; authentication is accepted if valid information can be found from either file.

The lines in these files are typically hundreds of characters long. You should definitely not type in the host keys by hand. Rather, generate them by a script or by taking `/etc/ssh/ssh_host_rsa_key.pub` and adding the host names at the front.

### Environment Variables

`sshd` sets the following environment variables for commands executed by `ssh` users:

**DISPLAY**

Indicates the location of the X11 server. It is automatically set by `sshd` to point to a value of the form `hostname:n`, where `hostname` indicates the host where the shell runs, and `n` is an integer greater than or equal to 1. `ssh` uses this special value to forward X11 connections.
over the secure channel. Unless you have important reasons to do otherwise, you should not set DISPLAY explicitly, as that will render the X11 connection insecure and will require you to manually copy any required authorization cookies.

**HOME**
Set to the path of the user's home directory.

**LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, LC_TIME**
A locale setting. The locale defaults to that of sshd (usually the system-wide default locale), or is negotiated between the client and server during initial key exchange (as per RFC 4253).

Following initial key exchange, each of the variables can be overridden in the following sequence:

1. If a locale setting is set in a client's environment and that client supports "Environment Variable Passing" (see RFC 4254), then the setting will be passed over to the server side.
2. If the public key authentication method was used to authenticate the server and the PermitUserEnvironment variable in `sshd_config(4)` is set to yes on the server side, then the setting can be changed through the use of the environment option in the client's AuthorizedKeysFile file.
3. The setting can be change in the client's ~/.ssh/environment file on the server.

See PermitUserEnvironment in `sshd_config(4)` as to when the AuthorizedKeysFile and ~/.ssh/environment files are processed and used for setting the user environment.

**LOGNAME**
Synonym for USER. Set for compatibility with systems that use this variable.

**MAIL**
Set to point to the user's mailbox.

**SSH_AUTH_SOCK**
Indicates the path of a unix-domain socket used to communicate with the agent.

**SSH_CONNECTION**
Identifies the client and server ends of the connection. The variable contains four space-separated values: client IP address, client port number, server IP address and server port number.

**SSH_CLIENT**
Identifies the client end of the connection. The variable contains three space-separated values: client IP address, client port number, and server port number.

**SSH_TTY**
Set to the name of the tty (path to the device) associated with the current shell or command. If the current session has no tty, this variable is not set.
TZ
Indicates the present timezone, if TIMEZONE is set in /etc/default/login or if TZ was set when the daemon was started.

HZ
If set in /etc/default/login, the daemon sets it to the same value.

SHELL
The user's shell, if ALTSHHELL=YES in /etc/default/login.

PATH
Set to the value of PATH or SUPATH (see login(1)) in /etc/default/login, or, if not set, to /usr/bin:/bin.

USER
Set to the name of the user logging in.

Additionally, ssdh reads $HOME/.ssh/environment and adds lines of the format VARNAME=value to the environment.

Examples
In the following examples, certain lines might wrap due to line length limits in your display. You should nevertheless consider the wrapped line as a single line.

EXAMPLE 1  authorized_key File Entries
The following are examples of authorized_key file entries for protocol 1:

1024 33 12121...312314325 ylo@foo.bar
from="*.niksula.hut.fi,!pc.niksula.hut.fi" 1024 35 23...2334 ylo@niksula
command="dump /home",no-pty,no-port-forwarding 1024 33 23...2323 backup.hut.fi

EXAMPLE 2  authorized_key File Entries for Protocol 2
The following are examples of authorized_key file entries for protocol 2:

ssh-rsa AAAAB3NzaC1y.....EU88ovYKg4GfcLWGCFTUuw8= ylo@foo.bar
from="*.niksula.hut.fi" ssh-rsa AAAAB3NzaC....uw8= ylo@niksula
command="dump /home",no-pty,no-port-forwarding ssh-rsa AA...8= backup.hut.fi

EXAMPLE 3  ssh_known_hosts File Entries for Protocol 1
The following are examples of ssh_known_hosts file entries for protocol 1:

closenet,closenet.hut.fi,...,130.233.208.41 1024 37 159...93 closenet.hut.fi

EXAMPLE 4  ssh_known_hosts File Entries for Protocol 2
The following are examples of ssh_known_hosts file entries for protocol 2:

closenet,closenet.hut.fi,...,130.233.208.41 ssh-rsa AA...8= closenet.hut.fi

2364  man pages section 1M: System Administration Commands  •  Last Revised 17 Mar 2009
Exit Status  The following exit values are returned:

0    Successful completion.

>0   An error occurred.

Files  /etc/default/login

Contains defaults for several sshd_config parameters, environment variables, and other environmental factors.

The following parameters affect environment variables (see login(1) and descriptions of these variables, above):

- TIMEZONE
- HZ
- ALTSHELL
- PATH
- SUPATH

The following /etc/default/login parameters supply default values for corresponding sshd_config(4) parameters:

- CONSOLE (see PermitRootLogin in sshd_config(4))
- PASSREQ (see PermitEmptyPasswords in sshd_config(4))
- TIMEOUT (see LoginGraceTime in sshd_config(4))

The following /etc/default/login parameters:

- UMASK
- ULIMIT

...set the umask(2) and file size limit of, respectively, the shells and commands spawned by sshd.

Finally, two /etc/default/login parameters affect the maximum allowed login attempts per-connection using interactive user authentication methods (for example, keyboard-interactive but not publickey), as per login(1):

- RETRIES
- SYSLOG_FAILED_LOGINS

/etc/ssh/sshd_config

Contains configuration data for sshd. This file should be writable by root only, but it is recommended (though not necessary) that it be world-readable.

/etc/ssh/ssh_host_key
/etc/ssh/ssh_host_dsa_key
/etc/ssh/ssh_host_rsa_key

Contains the private part of the host key. This file should only be owned by root, readable only by root, and not accessible to others. sshd does not start if this file is group/world-accessible.
Contains the public part of the host key. This file should be world-readable but writable only by root. Its contents should match the private part. This file is not used for encryption; it is provided only for the convenience of the user so its contents can be copied to known hosts files. These two files are created using `ssh-keygen(1)`.

Contains the process ID of the sshd listening for connections. If there are several daemons running concurrently for different ports, this contains the pid of the one started last. The content of this file is not sensitive; it can be world-readable. You can use the PidFile keyword in `sshd_config` to specify a file other than `/var/run/sshd.pid`. See `sshd_config(4)`.

These files are consulted when using `rhosts` with public key host authentication to check the public key of the host. The key must be listed in one of these files to be accepted. The client uses the same files to verify that the remote host is the one it intended to connect. These files should be writable only by root or the owner. `/etc/ssh/ssh_known_hosts` should be world-readable, and `$HOME/.ssh/known_hosts` can but need not be world-readable.

If this file exists, sshd refuses to let anyone except root log in. The contents of the file are displayed to anyone trying to log in, and non-root connections are refused. The file should be world-readable.

Lists the public keys (RSA or DSA) that can be used to log into the user’s account. This file must be readable by root. This might, on some machines, imply that it is world-readable if the user’s home directory resides on an NFS volume. It is recommended that it not be accessible by others. The format of this file is described above. Users will place the contents of their `identity.pub`, `id_dsa.pub` and/or `id_rsa.pub` files into this file, as described in `ssh-keygen(1)`.

This file contains host-username pairs, separated by a space, one per line. The given user on the corresponding host is permitted to log in without password. The same file is used by `rlogind` and `rshd`. The file must be writable only by the user; it is recommended that it not be accessible by others. It is also possible to use netgroups in the file. Either host or user name may be of the form `+@groupname` to specify all hosts or all users in the group.

For ssh, this file is exactly the same as for `rhosts`. However, this file is not used by `rlogin` and `rshd`, so using this permits access using SSH only.
/etc/hosts.equiv
This file is used during .rhosts authentication. In its simplest form, this file contains host names, one per line. Users on these hosts are permitted to log in without a password, provided they have the same user name on both machines. The host name can also be followed by a user name; such users are permitted to log in as any user on this machine (except root). Additionally, the syntax +@group can be used to specify netgroups. Negated entries start with a hyphen (-).

If the client host/user is successfully matched in this file, login is automatically permitted, provided the client and server user names are the same. Additionally, successful RSA host authentication is normally required. This file must be writable only by root; it is recommended that it be world-readable.

Warning: It is almost never a good idea to use user names in hosts.equiv. Beware that it really means that the named user(s) can log in as anybody, which includes bin, daemon, adm, and other accounts that own critical binaries and directories. For practical purposes, using a user name grants the user root access. Probably the only valid use for user names is in negative entries. This warning also applies to rsh/rlogin.

/etc/ssh/moduli
A private file.

/etc/ssh/hosts.equiv
This file is processed exactly as /etc/hosts.equiv. However, this file might be useful in environments that want to run both rsh/rlogin and ssh.

$HOME/.ssh/environment
This file is read into the environment at login (if it exists). It can contain only empty lines, comment lines (that start with #), and assignment lines of the form name=value. The file should be writable only by the user; it need not be readable by anyone else. Environment processing is disabled by default and is controlled by means of the PermitUserEnvironment option.

$HOME/.ssh/rc
If this file exists, it is run with /bin/sh after reading the environment files but before starting the user’s shell or command. If X11 spoofing is in use, this will receive the proto cookie pair in standard input (and DISPLAY in environment). This must call xauth in that case.

The primary purpose of $HOME/.ssh/rc is to run any initialization routines that might be needed before the user’s home directory becomes accessible; AFS is a particular example of such an environment. If this file exists, it is run with /bin/sh after reading the environment files, but before starting the user’s shell or command. It must not produce any output on stdout; stderr must be used instead. If X11 forwarding is in use, it will receive the proto cookie pair in its standard input and DISPLAY in its environment. The script must call xauth because sshd will not run xauth automatically to add X11 cookies.

This file will probably contain some initialization code followed by something similar to:
If this file does not exist, /etc/ssh/sshrc is run, and if that does not exist, xauth is used to store the cookie. $HOME/.ssh/rc should be writable only by the user, and need not be readable by anyone else.

/etc/ssh/sshrc
Similar to $HOME/.ssh/rc. This can be used to specify machine-specific login-time initializations globally. This file should be writable only by root, and should be world-readable.

Security
sshd supports the use of several user authentication mechanisms: a public key system where keys are associated with users (through users’ authorized_keys files), a public key system where keys are associated with hosts (see the HostbasedAuthentication configuration parameter), a GSS-API based method (see the GssAuthentication and GssKeyEx configuration parameters) and three initial authentication methods: none, password, and a generic prompt/reply protocol, keyboard-interactive.

sshd negotiates the use of the GSS-API with clients only if it has a GSS-API acceptor credential for the "host" service. This means that, for GSS-API based authentication, the server must have a Kerberos V keytab entry (see below) or the equivalent for any other GSS-API mechanism that might be installed.

In order for Kerberos authentication to work, a host/<FQDN> Kerberos principal must exist for each Fully Qualified Domain Name associated with the in.sshd server. Each of these host/<FQDN> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on the in.sshd server. An example principal might be:

host/bigmachine.eng.example.com

See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a krb5.keytab file. See System Administration Guide: Security Services for a discussion of Kerberos authentication.

GSS-API authorization is covered in gss_auth_rules(5).
sshd uses `pam(3PAM)` for the three initial authentication methods as well as for account management, session management, and password management for all authentication methods.

Specifically, `sshd` calls `pam_authenticate()` for the "none," "password" and "keyboard-interactive" SSHv2 userauth types, as well as for the null and password authentication methods for SSHv1. Other SSHv2 authentication methods do not call `pam_authenticate()`. `pam_acct_mgmt()` is called for each authentication method that succeeds.

`pam_setcred()` and `pam_open_session()` are called when authentication succeeds and `pam_close_session()` is called when connections are closed.

`pam_open_session()` and `pam_close_session()` are also called when SSHv2 channels with ptys are opened and closed.

Each SSHv2 userauth type has its own PAM service name:

<table>
<thead>
<tr>
<th>SSHv2 Userauth</th>
<th>PAM Service Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>sshd-none</td>
</tr>
<tr>
<td>password</td>
<td>sshd-password</td>
</tr>
<tr>
<td>keyboard-interactive</td>
<td>sshd-kbdint</td>
</tr>
<tr>
<td>pubkey</td>
<td>sshd-pubkey</td>
</tr>
<tr>
<td>hostbased</td>
<td>sshd-hostbased</td>
</tr>
<tr>
<td>gssapi-with-mic</td>
<td>sshd-gssapi</td>
</tr>
<tr>
<td>gssapi-keyex</td>
<td>sshd-gssapi</td>
</tr>
</tbody>
</table>

For SSHv1, `sshd-v1` is always used.

If `pam_acct_mgmt()` returns `PAM_NEW_AUTHTOK_REQD` (indicating that the user's authentication tokens have expired), then `sshd` forces the use of "keyboard-interactive" userauth, if version 2 of the protocol is in use. The "keyboard-interactive" userauth will call `pam_chauthtok()` if `pam_acct_mgmt()` once again returns `PAM_NEW_AUTHTOK_REQD`. By this means, administrators are able to control what authentication methods are allowed for SSHv2 on a per-user basis.

To establish host-based authentication, you must perform the following steps:

- Configure the client.
- Configure the server.
- Publish known hosts.
- Make appropriate entries in `/etc/ssh/hosts.equiv` and `~/.ssh/hosts`.

These steps are expanded in the following paragraphs.
On a client machine, in the system-wide client configuration file, /etc/ssh/ssh_config, you must have the entry:

```
HostbasedAuthentication yes
```

See `ssh_config(4)` and `ssh-keysign(1M)`.

On the server, in the system-wide server configuration file, /etc/ssh/sshd_config, you must have the entry:

```
HostbasedAuthentication yes
```

If per-user .shost files are to be allowed (see last step), in the same file, you must have:

```
IgnoreRhosts no
```

See `sshd_config(4)` for a description of these keywords.

To publish known hosts, you must have entries for the clients from which users will be allowed host-based authentication. Make these entries in either or both of the system-wide file (/etc/ssh/ssh_known_hosts) or the per-user file (~/.ssh/known_hosts).

Note that sshd uses .shosts, not .rhosts. If you want the functionality provided by .rhosts, but do not want to use rlogin or rsh because of their security shortcomings, you can use .shosts in conjunction with sshd. To use this feature, make appropriate entries in /etc/ssh/shosts.equiv and ~/.shosts, in the format specified in `rhosts(4)`.

For the vast majority of network environments, .shosts is preferred over .rhosts.

**Attributes**

**System Administration Guide: Security Services**

**Notes**

The sshd service is managed by the service management facility, `smf(5)`, under the service identifier:

`svc:/network/ssh:default`
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

`sshd` always sets `PAM_RHOST` and sets `PAM_AUSER` in the case of host-based user auth. This behavior allows for remote logins to roles using host-based authentication. See `pam_roles(5)`. 
**Name**  ssh-keysign – ssh helper program for host-based authentication

**Synopsis**  ssh-keysign

**Description**  ssh-keysign is used by ssh(1) to access the local host keys and generate the digital signature required during host-based authentication with SSH protocol version 2. This signature is of data that includes, among other items, the name of the client host and the name of the client user.

ssh-keysign is disabled by default and can be enabled only in the global client configuration file /etc/ssh/ssh_config by setting HostbasedAuthentication to yes.

ssh-keysign is not intended to be invoked by the user, but from ssh. See ssh(1) and ssdh(1M) for more information about host-based authentication.

**Files**  
/etc/ssh/ssh_config Controls whether ssh-keysign is enabled.

/etc/ssh/ssh_host_dsa_key /etc/ssh/ssh_host_rsa_key These files contain the private parts of the host keys used to generate the digital signature. They should be owned by root, readable only by root, and not accessible to others. Because they are readable only by root, ssh-keysign must be set-uid root if host-based authentication is used.

**Security**  ssh-keysign will not sign host-based authentication data under the following conditions:

- If the HostbasedAuthentication client configuration parameter is not set to yes in /etc/ssh/ssh_config. This setting cannot be overridden in users’ ~/.ssh/ssh_config files.
- If the client hostname and username in /etc/ssh/ssh_config do not match the canonical hostname of the client where ssh-keysign is invoked and the name of the user invoking ssh-keysign.

In spite of ssh-keysign’s restrictions on the contents of the host-based authentication data, there remains the ability of users to use it as an avenue for obtaining the client’s private host keys. For this reason host-based authentication is turned off by default.

History  ssh-keysign first appeared in OpenBSD 3.2.
statd(1M)

**Name**
statd – network status monitor

**Synopsis**
/usr/lib/nfs/statd

**Description**
statd is an intermediate version of the status monitor. It interacts with lockd(1M) to provide the crash and recovery functions for the locking services on NFS. statd keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, statd sends a message to the statd on each client indicating that the server has rebooted. The client statd processes then inform the lockd on the client that the server has rebooted. The client lockd then attempts to reclaim the lock(s) from the server.

statd on the client host also informs the statd on the server(s) holding locks for the client when the client has rebooted. In this case, the statd on the server informs its lockd that all locks held by the rebooting client should be released, allowing other processes to lock those files.

lockd is started by automountd(1M), mount_nfs(1M), and share(1M) if NFS automounts are needed.

**Files**
/var/statmon/sm lists hosts and network addresses to be contacted after a reboot
/var/statmon/sm.bak lists hosts and network addresses that could not be contacted after last reboot
/var/statmon/state includes a number which changes during a reboot
/usr/include/rpcssvc/sm_inter.x contains the rpcgen source code for the interface services provided by the statd daemon.

*System Administration Guide: IP Services*

**Notes**
The crash of a server is only detected upon its recovery.

The statd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nfs/status
Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M), share_nfs(1M), and automountd(1M)` unless its application/auto_enable property is set to false.
The `stclient` command displays, finds, adds, updates and deletes records in the Service Tag registry. The registry is in the XML file `/var/sadm/servicetag/registry/servicetag.xml`, and contains the inventory of the product instances installed in the machine. Each record has a unique product instance identifier which is generated when the service tag is added in the registry. This product instance identifier is used as a key when finding, updating or deleting the service tag records. The extract option prints out the registry contents in XML format in stdout.

The `stclient` command also runs in interactive mode. This mode is invoked by running `stclient` without any parameters. A menu of all the available options are displayed, and the user is prompted to enter different parameters depending on the option chosen.

Any user can extract or get the contents of the registry, but only users with the appropriate privileges, the “svctag” user, or the creator of the service tag is authorized to update or delete a service tag record.

The following options are supported:

- `-p product_name`  Sets the product name of the service tag to be added. For example, `“stclient -p “Solaris 10 Operating System””` sets the product name to the “Solaris 10 Operating System”.

- `-e product_version`  Sets the product version of the service tag to be added. For example, `“stclient -e 5.10”` sets the product version to “5.10”.

- `-t product_URN`  Sets the Sun product unique identifier of the service tag to be added. For example, `“stclient -t urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113”` sets
the Sun product unique identifier to “urn:uuid:5005588c-36f3-11d6-9cee-fc96f718e113”.

-\textit{\texttt{\textbf{-i} instance\textunderscore URN}}\hspace{1em}
\textit{Sets the product instance unique identifier of the service tag. For example, “\texttt{stclient -i 3a44ab2-1dd2-11b2-a69d-830020782a6b}” sets the product instance unique identifier to “3a44ab2-1dd2-11b2-a69d-830020782a6b” This field may also be set when the service tag is added but is not typically used. The generation of the instance ID is normally left to the \texttt{stclient}.

-\textit{\texttt{\textbf{-F} product\textunderscore parent\_URN}}\hspace{1em}
\textit{Sets the Sun product unique identifier of parent product. For example, “\texttt{stclient -F urn:uuid:5005588c-36f3-11d6-9cee-fc96f718e113}” sets the Sun product unique identifier of parent product to “urn:uuid:5005588c-36f3-11d6-9cee-fc96f718e113”.

-\textit{\texttt{\textbf{-P} product\_parent}}\hspace{1em}
\textit{Sets the parent product of the service tag. For example, “\texttt{stclient -P JES}” sets the product parent to “JES”.

-\textit{\texttt{\textbf{-I} product\_defined\_instance\_id}}\hspace{1em}
\textit{Sets the product defined instance identifier. For example, “\texttt{stclient -I ser:abc-klm-000-7190}” sets the product defined instance identifier to “ser:abc-klm-000-7190”.

-\textit{\texttt{\textbf{-m} product\_vendor}}\hspace{1em}
\textit{Sets the vendor of the product. For example, “\texttt{stclient -m Sun}” sets the product vendor to “Sun”.

-\textit{\texttt{\textbf{-A} platform\_arch}}\hspace{1em}
\textit{Sets the platform architecture that the product is running on. For example, “\texttt{stclient -A sparc}” sets the platform architecture to “sparc”

-\textit{\texttt{\textbf{-z} container}}\hspace{1em}
\textit{Sets the container that the product is running on. For example, “\texttt{stclient -z "global zone"}” sets the container to “global zone”.

-\textit{\texttt{\textbf{-S} source}}\hspace{1em}
\textit{Sets the source of this service tag, naming the entity that created it.

-\textit{\texttt{\textbf{-r} root\_dir}}\hspace{1em}
\textit{Sets the root directory where the command searches for the registry. The command searches /var/sadm/servicetag/registry by default. When this option is used, the command looks for the Registry in the specified root directory, (for example, “\texttt{-r /home/user1}” searches /home/user1/var/sadm/servicetag). This is typically used for testing.

\texttt{stclient(1M)}
### Operands

<table>
<thead>
<tr>
<th>Function Letters</th>
<th>The function portion of the key is specified by one of the following letters:</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Extract. Extracts and prints the contents of the Service Tag registry in XML format. An alternate root directory may be specified for testing purposes.</td>
</tr>
<tr>
<td>a</td>
<td>Add. Adds a service tag in the registry. A unique product instance identifier may be supplied and is automatically generated if not provided. This field is returned by the command. The required fields for add are product name, product version, product URN, product parent, vendor, platform architecture, container and source.</td>
</tr>
<tr>
<td>u</td>
<td>Update. Updates a service tag in the registry using the product instance URN as the key. The parent URN and product defined instance id fields can be updated.</td>
</tr>
<tr>
<td>d</td>
<td>Delete. Deletes a service tag in the registry using the product instance URN as the key.</td>
</tr>

<tr>
<td>v</td>
<td>Version. Displays the version number of the command.</td>
</tr>
</tbody>
</table>

### Exit Status

The following exit values are returned:

- 0  Successful completion.
- > 0  An error occurred.

### Examples

**EXAMPLE 1  Adding a Service Tag in the Registry**

To add a service tag, enter the following:

```
# stclient -a -p "Java Enterprise Web Server 6.0" -e 6.0 \ 
   -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \ 
   -P Java Enterprise Server -m Sun -A sparc -z global -s patch
```

The screen displays the following:

```
Java Enterprise Web Server 6.0 6.0 added
Product instance URN=urn:st:7fc61914-1dd2-11b2-b992-830020782a6b
```

**EXAMPLE 2  Updating a Service Tag in the Registry**

To update a service tag, enter the following:
EXAMPLE 2  Updating a Service Tag in the Registry  (Continued)

```
# stclient -u -i 7fc61914-1dd2-11b2-b992-830020782a6b \
   -I urn:st:product.defined.id
```

The screen displays the following:

Service tag updated

EXAMPLE 3  Extracting a Service Tag Registry

To extract a service tag, enter the following:

```
# stclient -x
```

The screen displays output similar to the following:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<registry urn="urn:uuid:1234ab-00e1-11b3-98737646873" version="1.0">
   <service_tag>
      .
      .
      .
   </service_tag>
</registry>
```

EXAMPLE 4  Finding all product instances

To find all product instances, enter the following:

```
# stclient -f -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \
   fc61914-1dd2-11b2-b992-830020782a6b
```

EXAMPLE 5  Listing the Environmental Information

To list the environmental information associated with the registered Service Tags on this system, enter the following:

```
# stclient -E
```

The screen displays output similar to the following:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<agent>
   <agent_urn>urn:st:af15ee62-0bb3-ef2d-fa96-85a11996cc71</agent_urn>
   .
   .
   .
</system_info>
</agent>
```
Environment Variables
See environ(5) for descriptions of the following environment variables that affect the execution of stclient: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Name  stmsboot – administration program for the Solaris I/O multipathing feature

Synopsis  /usr/sbin/stmsboot [[-D (fp | mpt | mpt_sas | iscsi)] -d | -e | -u] 

| -L | -l controller_number

Description  The Solaris I/O multipathing feature is a multipathing solution for storage devices that is part of the Solaris operating environment. This feature was formerly known as Sun StorEdge Traffic Manager (STMS) or MPxIO.

The stmsboot program is an administrative command to manage enumeration of multipath–capable devices with Solaris I/O multipathing. Solaris I/O multipathing-enabled devices are enumerated under scsi_vhci(7D), providing multipathing capabilities. Solaris I/O multipathing-disabled devices are enumerated under the physical controller.

In the /dev and /devices trees, Solaris I/O multipathing-enabled devices receive new names that indicate that they are under Solaris I/O multipathing control. This means a device will have a different name from its original name (after enabling) when it is under Solaris I/O multipathing control. The stmsboot command automatically updates /etc/vfstab and dump configuration to reflect the device names changes when enabling or disabling Solaris I/O multipathing. One reboot is required for changes to take effect.

Options  The following options are supported:

- e  [-E fp | mpt | mpt_sas | iscsi]  
Enables Solaris I/O multipathing on all supported multipath–capable controller ports, including fp(7d), mpt(7D), mpt_sas(7D), and iscsi(7D) port drivers. Multipath–capable ports include fibre channel (fp(7d)) controller ports and SAS (mpt(7D) or mpt_sas(7D)) controller ports. Following this enabling, you are prompted to reboot. During the reboot, vfstab and the dump configuration will be updated to reflect the device name changes. Specifying -D mpt, -D mpt_sas, or -D fp limits the enabling operation to ports attached using the specified driver.

- d  [-D fp | mpt | mpt_sas | iscsi]  
Disables Solaris I/O multipathing on all supported multipath–capable controller ports, including fp(7d), mpt(7D), mpt_sas(7D), and iscsi(7D) port drivers. Multipath–capable ports include fibre channel (fp(7d)) controller ports and SAS (mpt(7D) or mpt_sas(7D)) controller ports. Following this disabling, you are prompted to reboot. During the reboot, vfstab and the dump configuration will be updated to reflect the device name changes. Specifying -D mpt, -D mpt_sas, or -D fp limits the disabling operation to ports attached using the specified driver.

- u  [-U fp | mpt | mpt_sas | iscsi]  
Updates vfstab and the dump configuration after you have manually modified the configuration to have Solaris I/O multipathing enabled or disabled on specific fp(7d), mpt(7D), mpt_sas(7D), and iscsi(7D) controller ports. This option prompts you to reboot. During the reboot, vfstab and the dump configuration will be updated to reflect the device name changes.
Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for multipath-enabled controller ports. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for the specified controller. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

Note that `mpt_sas(7D)` has MPxIO turned on by default. This means that when using the `-L` or `-l` option with `-D mpt_sas`, `stmsboot` does not display any non-multipathed and multipathed device names.

The primary function of `stmsboot` is to control the enabling and disabling of Solaris I/O multipathing on the host. The utility automatically updates `vfstab(4)` and `dumpadm(1M)` configuration to reflect device name changes. The system administrator is responsible for modifying application configuration (for example, backup software, DBMS, and so forth) to reflect updated device names.

The `-L` and `-l` options display the mapping between multipathed and non-multipathed device names. These options function only after changes to the Solaris I/O multipathing configuration have taken effect, that is, following the reboot after invoking `stmsboot -e`.

ZFS datasets, including ZFS root datasets, are correctly handled by `stmsboot`.

### Examples

**EXAMPLE 1** Enabling Solaris I/O Multipathing

To enable Solaris I/O multipathing for all multipath-capable controllers, run:

```
# stmsboot -e
```

To enable Solaris I/O multipathing on multipath-capable `mpt(7D)` controller ports, enter:

```
# stmsboot -D mpt -e
```

To enable Solaris I/O multipathing on multipath-capable `mpt_sas(7D)` controller ports, enter:

```
# stmsboot -D mpt_sas -e
```

To enable Solaris I/O Multipathing on multipath-capable fibre channel controller ports, enter:

```
# stmsboot -D fp -e
```

To enable Solaris I/O Multipathing on multipath-capable iSCSI controller ports, enter:

```
# stmsboot -D iscsi -e
```
EXAMPLE 2  Disabling Solaris I/O Multipathing
To disable Solaris I/O multipathing on all multipath-capable controllers, enter:

# stmsboot -d

To disable Solaris I/O multipathing on multipath-capable mpt(7D) controller ports, enter:

# stmsboot -D mpt -d

To disable Solaris I/O multipathing on multipath-capable mpt_sas(7D) controller ports, enter:

# stmsboot -D mpt_sas -d

To disable Solaris I/O multipathing on multipath-capable iSCSI controller ports, enter:

# stmsboot -D iscsi -d

To disable Solaris I/O multipathing on multipath-capable fibre channel controller ports, enter:

# stmsboot -D fp -d

EXAMPLE 3  Enabling Solaris I/O Multipathing on Selected Ports
To enable Solaris I/O multipathing on specific fibre channel controller ports and disable the feature on others, manually edit the /kernel/drv/fp.conf file. (See fp(7d).) The following command will update vfstab(4) and dumpadm(1M) configurations to reflect the changed device names:

# stmsboot -u

A similar procedure involving the /kernel/drv/mpt.conf file should be followed for devices attached by means of the mpt(7D) driver. For devices attached by means of the iscsi(7D) driver, follow a similar procedure that uses the /kernel/drv/iscsi.conf file.

Solaris SAN Configuration and Multipathing Guide (see http://docs.sun.com)

Consult a particular storage product’s system administrator’s guide and release notes for further information specific to that product.
Solaris I/O multipathing is not supported on all devices. After enabling Solaris I/O multipathing, only supported devices are placed under Solaris I/O multipathing control. Non-supported devices remain unchanged.

For Solaris releases prior to the current release, the -e and -d options replace `mpxio-disable` property entries with a global `mpxio-disable` entry in `fp.conf`.

The following applies to Sun StoreEdge T3, 3910, 3960, 6120, and 6320 storage subsystems.

To place your Sun StoreEdge disk subsystem under Solaris I/O multipathing control, in addition to enabling Solaris I/O multipathing, the `mp_support` of the subsystem must be set to `mpxio` mode. The preferred sequence is to change the subsystem's `mp_support` to `mpxio` mode, then run `stmsboot -e`. If Solaris I/O multipathing is already enabled but the subsystem's `mp_support` is not in `mpxio` mode, then change the `mp_support` to `mpxio` mode and run `stmsboot -u`.

Refer to the *Sun StorEdge Administrator's Guide* for your subsystem for more details.

The `ufsdump(1M)` command records details of filesystem dumps in `/etc/dumpdates` (see `ufsdump(4)`). Among other items, the entries contain device names. An effect of the "active" `stmsboot` options (-e, -d, and -u) is to change the device name of a storage device.

Because `stmsboot` does not modify `dumpdates`, entries will refer to obsolete device names, that is, device names that were in effect before Solaris I/O multipathing configuration changes were performed. In this situation `ufsdump` will behave as if no previous dump of the filesystem had been performed. A level 0 dump will be performed.

If possible, invoke `stmsboot -e` before installing Sun Cluster software. After executing `stmsboot`, install Sun Cluster software normally.

If Sun Cluster software is installed before executing `stmsboot`, follow this procedure:

On each machine in the cluster where Solaris I/O multipathing is required, execute:

```bash
# stmsboot -e
```

...and allow the system to reboot.

When the system comes up, enter the following two commands:

1. `#/usr/cluster/bin/scdidadm -C`
2. `#/usr/cluster/bin/scdidadm -r`

   The preceding commands update `did` mappings with new device names while preserving `did` instance numbers for disks that are connected to multiple cluster nodes. `did` instance numbers of the local disks might not be preserved. For this reason, the `did` disk names for local disks might change.

3. Update `/etc/vfstab` to reflect any new `did` disk names for your local disks.
4. Reboot the system.

To disable the Solaris multipathing feature, use `stmsboot -d` (instead of `stmsboot -e`), then follow the procedure above.

To view mappings between the old and new device names, run `stmsboot -L`. To view did device name mappings, run `/usr/cluster/bin/scdidadm -L`.

With active-passive storage arrays, it is possible that while your host is rebooting the array controller could failover the path that a particular target is using. In this scenario, `fsck(1M)` will fail to open the physical path listed in `/etc/vfstab`. The `svc:/system/filesystem/local`; default SMF service will transition to a maintenance state as a result. To rectify this, consult the documentation for your storage array to failback the path. The `mpathadm(1M)` can assist with determining the active and passive path(s).

**Limitations** On x86 platforms, the current Solaris release does not support disabling Solaris I/O multipathing of boot devices attached by means of fibre channel. Solaris I/O multipathing is always enabled for supported fibre channel-attached boot devices. Disabling Solaris I/O multipathing in this situation must be performed on a per-port basis. See `fp(7d)`.

Executing `devfsadm -C` removes obsolete device entries that `stmsboot` relies on. This will prevent correct operation of the `-d` option for boot devices (regardless of platform type) and the `-L` option.
strace(1M)

**Name**
strace – print STREAMS trace messages

**Synopsis**
strace [mid sid level]...

**Description**
strace without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see log(7D)). If arguments are provided, they must be in triplets of the form mid, sid, level, where mid is a STREAMS module ID number, sid is a sub-ID number, and level is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token all may be used for any member to indicate no restriction for that attribute.

The format of each trace message output is:

<seq> <time> <ticks> <level> <flags> <mid> <sid> <text>

<seq> trace sequence number
<time> time of message in hh:mm:ss
<ticks> time of message in machine ticks since boot
<level> tracing priority level
<flags> E: message is also in the error log F: indicates a fatal error N: mail was sent to the system administrator (hardcoded as root)
<mid> module ID number of source
<sid> sub-ID number of source
<text> formatted text of the trace message

Once initiated, strace will continue to execute until terminated by the user.

**Examples**

**EXAMPLE 1** A sample output of the strace command:

The following example outputs all trace messages from the module or driver whose module ID is 41:

strace 41 all all

The following example outputs those trace messages from driver or module ID 41 with sub-IDs 0, 1, or 2:

strace 41 0 1 41 1 1 41 2 0

Messages from sub-IDs 0 and 1 must have a tracing level less than or equal to 1. Those from sub-ID 2 must have a tracing level of 0.

STREAMS Programming Guide

Notes  ■ There is no restriction to the number of strace processes opening the STREAMS log driver at a time.

■ The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the strace process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running strace will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the strace process. If trace messages are generated faster than the strace process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.
strclean(1M)

Name  strclean – STREAMS error logger cleanup program

Synopsis  strclean [-a age] [-d logdir]

Description  strclean is used to clean up the STREAMS error logger directory on a regular basis (for example, by using cron. By default, all files with names matching error. * in /var/adm/streams that have not been modified in the last three days are removed.

Options  The following options are supported:

-  a  age  The maximum age in days for a log file can be changed using the -a option.
-  d  logdir  A directory other than /var/adm/streams can be specified using the -d option.

Examples  EXAMPLE 1  A sample of using the strclean command.

This example has the same result as running strclean with no arguments:

example% strclean -d /var/adm/streams -a 3

Files  /var/adm/streams/error. *

Attributes  See attributes(5) for descriptions of the following attributes:

</tr>
</tbody>
</table>

See Also  cron(1M), strerr(1M), attributes(5)

STREAMS Programming Guide

Notes  strclean is typically run from cron on a daily or weekly basis.
**Name**  
strerr – STREAMS error logger daemon

**Synopsis**  
strerr

**Description**  
strerr receives error log messages from the STREAMS-based log driver (see log(7D)) and appends them to a log file. The resultant error log files reside in the directory /var/adm/streams, and are named error.mm-dd, where mm is the month and dd is the day of the messages contained in each log file.

The format of an error log message is:

\[<seq> <time> <ticks> <flags> <mid> <sid> <text>\]

- `<seq>` error sequence number
- `<time>` time of message in hh:mm:ss
- `<ticks>` time of message in machine ticks since boot priority level
- `<flags>` T: the message was also sent to a tracing process F: indicates a fatal error N: send mail to the system administrator (hardcoded as root)
- `<mid>` module ID number of source
- `<sid>` sub-ID number of source
- `<text>` formatted text of the error message

Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS-based driver or module should have the F flag set. Those messages requiring the immediate attention of the administrator will have the N flag set, which causes the error logger to send the message to the system administrator using mail. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process.

Once initiated, strerr continues to execute until terminated by the user. It is commonly executed asynchronously.

**Files**  
/var/adm/streams/error.mm-dd error log file.

attributes(5), log(7D)

*STREAMS Programming Guide*
Notes  There is no restriction to the number of `strerr` processes opening the STREAMS–based log driver at a time.

If a module or driver is generating a large number of error messages, running the error logger will cause a degradation in STREAMS performance. If a large burst of messages are generated in a short time, the log driver may not be able to deliver some of the messages. This situation is indicated by gaps in the sequence numbering of the messages in the log files.
**Name**
sttydefs – maintain line settings and hunt sequences for TTY ports

**Synopsis**
/usr/sbin/sttydefs [-attylabel [-b] [-f final-flags]
                      [-i initial-flags] [-n nextlabel]

/usr/sbin/sttydefs -l [ttylabel]
/usr/sbin/sttydefs -r ttylabel

**Description**
sttydefs is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the /etc/ttydefs file.

sttydefs with a -a or -r option may be invoked only by the super-user. sttydefs with -l may be invoked by any user on the system.

**Options**
The following options are supported:

- **-a ttylabel** Add a record to the ttydefs file, using ttylabel as its label. The following describes the effect of the -b, -n, -i, or -f options when used in conjunction with the -a option:

- **-b** Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention.

- **-f final-flags** Specify the value to be used in the final-flags field in /etc/ttydefs. final-flags must be in a format recognized by the stty command. final-flags are the termio(7I) settings used by ttymon after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, sttydefs will set final-flags equal to the termio(7I) flags 9600 and sane.

- **-i initial-flags** Specify the value to be used in the initial-flags field in /etc/ttydefs. initial-flags must be in a format recognized by the stty command. These flags are used by ttymon when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, sttydefs will set initial-flags equal to the termio(7I) flag 9600.

- **-n nextlabel** Specify the value to be used in the nextlabel field in /etc/ttydefs. If this option is not specified, sttydefs will set nextlabel equal to ttylabel.

- **-l ttylabel** If a ttylabel is specified, sttydefs displays the record from /etc/ttydefs whose TTY label matches the specified ttylabel. If no ttylabel is specified, sttydefs displays the entire contents of /etc/ttydefs. sttydefs verifies that each entry it displays is correct and that the entry's nextlabel field references an existing

- **-r ttylabel** Remove any record in the ttydefs file that has ttylabel as its label.
If successful, `sttydefs` will exit with a status of 0. `sttydefs -l` will generate the requested information and send it to standard output.

**Examples**

**EXAMPLE 1** A sample of `sttydefs` command.

The following command lists all the entries in the `ttydefs` file and prints an error message for each invalid entry that is detected.

```bash
example# sttydefs -l
```

The following shows a command that requests information for a single label and its output:

```bash
example# sttydefs -l 9600
```

```
------------------------------------------------------------------
9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800
------------------------------------------------------------------
```

TTYLABEL: 9600
INITIAL FLAGS: 9600 hupcl erase ^h
FINAL FLAGS: 9600 sane ixany tab3 hupcl erase ^h
AUTOBAUD: no
NEXTLABEL: 4800

The following sequence of commands will add the labels 1200, 2400, 4800, and 9600 and put them in a circular list:

```bash
sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane"
sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane"
sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane"
sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"
```

**Files** `/etc/ttydefs`

su(1M)

Name su – become superuser or another user

Synopsis su [-] [username [arg...]]

Description The su command allows one to become another user without logging off or to assume a role. The default user name is root (superuser).

To use su, the appropriate password must be supplied (unless the invoker is already root). If the password is correct, su creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified username. Additionally, the new shell’s project ID is set to the default project ID of the specified user. See getprojent(3PROJECT), setproject(3PROJECT). The new shell will be the shell specified in the shell field of username’s password file entry (see passwd(4)). If no shell is specified, /usr/bin/sh is used (see sh(1)). If superuser privilege is requested and the shell for the superuser cannot be invoked using exec(2), /sbin/sh is used as a fallback. To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell.

Any additional arguments given on the command line are passed to the new shell. When using programs such as sh, an arg of the form -c string executes string using the shell and an arg of -r gives the user a restricted shell.

To create a login environment, the command “su –” does the following:

- In addition to what is already propagated, the LC* and LANG environment variables from the specified user’s environment are also propagated.
- Propagate TZ from the user’s environment. If TZ is not found in the user’s environment, su uses the TZ value from the TIMEZONE parameter found in /etc/default/login.
- Set MAIL to /var/mail/new_user.

If the first argument to su is a dash (-), the environment will be changed to what would be expected if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of $PATH, which is controlled by PATH and SUPATH in /etc/default/su.

All attempts to become another user using su are logged in the log file /var/adm/sulog (see sulog(4)).

Security su uses pam(3PAM) with the service name su for authentication, account management, and credential establishment.

Examples EXAMPLE 1 Becoming User bin While Retaining Your Previously Exported Environment

To become user bin while retaining your previously exported environment, execute:

eexample% su bin
### Example 2: Becoming User `bin` and Changing to `bin`'s Login Environment

To become user `bin` but change the environment to what would be expected if `bin` had originally logged in, execute:

```
example% su - bin
```

### Example 3: Executing command with user `bin`'s Environment and Permissions

To execute command with the temporary environment and permissions of user `bin`, type:

```
example% su - bin -c "command args"
```

### Environment Variables

Variables with `LD_` prefix are removed for security reasons. Thus, `su bin` will not retain previously exported variables with `LD_` prefix while becoming user `bin`.

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `su` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `su` behaves.

- **LC_CTYPE**: Determines how `su` handles characters. When `LC_CTYPE` is set to a valid value, `su` can display and handle text and filenames containing valid characters for that locale. `su` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `su` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

- **LC_MESSAGES**: Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

### Files

- `/etc/passwd`: System's password file
- `/etc/profile`: System-wide `sh` and `ksh` login commands
- `/var/adm/sulog`: Log file
- `/etc/default/su`: The default parameters in this file are:
  - **SULOG**: If defined, all attempts to `su` to another user are logged in the indicated file.
  - **CONSOLE**: If defined, all attempts to `su` to `root` are logged on the console.
PATH  Default path. (/usr/bin:)
SUPATH Default path for a user invoking su to root. (/usr/sbin:/usr/bin)
SYSLOG Determines whether the syslog(3C) LOG_AUTH facility should be used to log all su attempts. LOG_NOTICE messages are generated for su's to root, LOG_INFO messages are generated for su's to other users, and LOG_CRIT messages are generated for failed su attempts.

/etc/default/login   the default parameters in this file are:

TIMEZONE   Sets the TZ environment variable of the shell.

Attributes   See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also   csh(1), env(1), ksh(1), login(1), roles(1), sh(1), syslogd(1M), exec(2), getprojent(3PROJECT), setproject(3PROJECT), pam(3PAM), pam_authenticate(3PAM), pam_acct_mgmt(3PAM), pam_setcred(3PAM), pam.conf(4), passwd(4), profile(4), sulog(4), syslogd(3C), attributes(5), environ(5)
The `sulogin` utility is automatically invoked by `init` when the system is first started. It prompts the user to type the root password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). The user should never directly invoke `sulogin`.

The `sulogin` utility can prompt the user to enter the root password on a variable number of serial console devices, in addition to the traditional console device. See `consadm(1m)` and `msglog(7D)` for a description of how to configure a serial device to display the single-user login prompt.

Files
- `/etc/default/sulogin`
  Default value can be set for the following flag:
  - `PASSREQ` Determines if login requires a password. Default is `PASSREQ=YES`.
- `/etc/default/login`
  Default value can be set for the following flag:
  - `SLEEPTIME` If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

**suninstall(1M)**

**Name** suninstall – install the Solaris operating system

**Synopsis** suninstall

**Description** `install-solaris(1M)` is now the preferred command for starting and restarting the Solaris Installation program. It should be used instead of `suninstall`. `suninstall` is symbolically linked to `install-solaris`.

`suninstall` is a forms-based and graphical subsystem for installing the operating system.

`suninstall` exists only on the Solaris installation media (CD or DVD) and should only be invoked from there. Refer to the *Oracle Solaris 10 08/11 Installation Guide: Basic Installations* for more details.

`suninstall` allows installation of the operating system onto any standalone system. `suninstall` loads the software available on the installation media. Refer to the *Oracle Solaris 10 08/11 Installation Guide: Basic Installations* for disk space requirements.

**Usage** Refer to the *Oracle Solaris 10 08/11 Installation Guide: Basic Installations* for more information on the various menus and selections.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

```

```
fbconfig [-help | -list]
```

Description

SUNWgfb_config is the Sun XVR-1000 Graphics Accelerator device dependent layer for fbconfig(1M). It configures the Sun XVR-1000 Graphics Accelerator and some of the X11 window system defaults. The device can drive two monitors, each with a unique video stream (called stream a and stream b).

The first form of SUNWgfb_config shown in the synopsis above sets card options, which are options common to both stream a and stream b, and apply to the entire card.

The second form is used to set stream options, which are options specific to either stream a or stream b. The second form usage requires the -stream option to define which stream is affected.

Both the first form and the second form store the specified options in the OWconfig file. These options will be used to initialize the device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. For -res with now or try, -slave, -master, -port, and -g, the device will be immediately programmed.

The third form, which invokes the -defaults option, sets all card options and all stream options to their default values and saves these defaults in the OWconfig file.

The fourth form, which invokes the -propt, -prconf, and -res \? options, queries the device for status that is card-specific.
The fifth form, which invokes the -help, and -list options, provides instruction on using SUNWgfb_config and a list of available devices. Additionally for the fifth form, all other options are ignored.

You can specify options for only one device at a time. Specifying options for multiple devices requires multiple invocations of SUNWgfb_config.

Only Sun XVR-1000 Graphics Accelerator-specific options can be specified through SUNWgfb_config. The normal window system options for specifying default depth, default visual class, and so forth are still specified as device modifiers on the command line when the X server is started.

You can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. You can use the -file option to specify an alternate file. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

**General Options**

- **-dev device-filename**
  Specifies the device’s special file. The default is /dev/fb.

- **-file machine|system**
  Specifies which OWconfig file to update. If machine is specified, the machine-specific OWconfig file in the /etc/openwin directory tree is updated. If system is specified, the global OWconfig file in the /usr/openwin directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is machine.

- **-res video-mode[now | try] [noconfirm]**
  Specifies the video mode used to drive the monitor connected to the specified device. If -res is invoked with now or try, you must specify a -stream option or a device, such as /dev/fbs/gfb0a. If -active is set to both or auto, then both stream video-mode values will be modified.

The video-mode argument specifies resolution and timing information for the display (for example, SUNW_STD_1280x1024x76). The naming convention for the video-mode specifier is:

```
origin_type_widthxheightxrate
```

The elements of the specifier are described as follows:
origin This can be one of:
- SUNW, Sun derived resolution
- VESA, Video Electronics Standards Association-derived resolution
- other, other source

type This can be one of:
- STD, normal resolution, usable by most display devices
- DIG, resolution tuned only for LCD flat panels
- INT, interlaced
- STEREO, stereo

width screen width in pixels
height screen height in pixels
rate vertical frequency of the screen refresh

Note that some video-modes supported by the device, might not be supported by the monitor. The list of video-modes supported by the device and the monitor can be obtained by running SUNWgfb_config with the -res \? option (the fourth form shown in the command synopsis above).

The -res option also accepts additional, optional arguments, listed below, immediately following the video mode specification. Either now or try (try subsumes now) and noconfirm can be present.

now If present, not only is the video mode updated in the 0Wconfig file, but the device is immediately programmed to display this video mode. This is useful for changing the video mode before starting the window system.
Note – It is recommended that you not use this suboption with SUNWgfb_config while the configured device is being used (for example, while running the window system). Unpredictable results can occur. To run SUNWgfb_config with the now suboption, first bring the window system down. If the now suboption is used within a window system session, the video mode is changed immediately, but the width and height of the affected screen do not change until the window system is exited and reentered. In addition, the system might not recognize changes in stereo mode.

noconfirm  Using the -res option, the user can put the system into an unusable state, with no video output. To reduce the chance of this, the default behavior of SUNWgfb_config is to display a warning message and to ask the user whether to continue. The noconfirm bypasses this confirmation. This option is useful when SUNWgfb_config is being run from a shell script.

try  If present, the specified video mode will be programmed on a trial basis. The user is asked to confirm the video mode by typing y within 10 seconds. Alternatively, the user can
terminate the trial before 10 seconds elapse by typing any character other than y or carriage return. Such input is considered a no and the previous video mode is restored. With a negative response, SUNWgfb_config does not change the video mode in the OWconfig file; other options specified still take effect. If a carriage return is typed, the user is asked (y or n) whether to keep the new video mode.

This sub-option should not be used with SUNWgfb_config while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run SUNWgfb_config with the try sub-option, the window system should be brought down first.

-defaults

Resets all option values to their default values. Writes these values to the OWconfig file.

-propt

Displays the current values of all options in the OWconfig file specified by the -file option for the device specified by the -dev option. Displays the values of options as they will be in the OWconfig file after the call to SUNWgfb_config completes. The following is an example display:

--- OpenWindows Configuration for /dev/fbs/gfb0 ---
OWconfig: machine
Active Streams: both
Samples Per Pixel: 2
Multisample Allocation Model: static
Multisample Mode: auto
Doublewide: disable
Gamma Correction Value: 2.22

--- OpenWindows Configuration for Stream a ---
Video Mode: SUNW_STD_1280x1024x76

--- OpenWindows Configuration for Stream b ---
Video Mode: VESA_STD_640x480x60

-prconf Displays the XVR-1000 hardware configuration. The following is an example display:

--- Hardware Configuration for /dev/fb (SUNWgfb0) ---
Type: Sun Graphics Accelerator
Part: 501-5865
Memory:

MAJC: 32MB
Texture: 256MB total
3DRAM64: 5.0M pixels

Versions: FCode 1.14 MCode 0.19 MAJC 2.1 FBC3 3.0 XChip 2.0

Video Streams:
Stream a
Current resolution Setting: SUNW_STD_1280x1024x76
Monitor/EDID data (13W3)
Monitor Manufacturer: SUN
Monitor Name: GDM-5410
EDID: Version 1, Revision 2

Stream b
Current resolution Setting: VESA_STD_640x480x60
Port: svideo

-help Displays a list of the SUNWgfb_config command line options, along with a brief explanation of each.

-res \? Displays list of defined video-mode names.

Card Options -active a | b | both | auto
Specifies which streams are enabled. both select both streams. The default is auto, which means whichever stream is chosen by the console.

-multisample enable|disable|auto[ static|dynamic]
The suboptions for -multisample are described as follows:
disable No multisample is possible.
Multisample is possible but is selected on a per-application basis.

All Sun OpenGL applications are rendered using multisampling.

Multisample allocation occurs at X startup/config load time. The config
samples-per-pixel or max parameter specifies the depth that is pre-allocated.

OpenGL tasks allocate buffers themselves.

Specifies the number of samples/pixel to pre-allocate in static mode. Provides a hint to
OpenGL in dynamic mode. The allowable choices for samples-per-pixel are 2, 3, 4, 5, 6, 8,
10, 16, and max. The default is max, which means to use the maximum number of samples
that can be supported with the amount of memory available.

This option makes it easy for you to combine both streams into one side-by-side virtual
display. If you specify enable, stream a is to the left of stream b. If reverse is specified,
stream b is to the left of stream b. Both will be the same resolution defined with the -res
option. If you specify disable, only one stream will be enabled. -doublewide precludes
-doulehigh.

This option makes it easy for you to combine both streams into one virtual display, with
one monitor on a shelf above the other. If you specify enable, stream a is above stream b. If
reverse is specified, stream b is above stream a. Both will be the same resolution defined
with the -res option. If you specify disable, only one stream will be enabled. -doublehigh
precludes -doublewide.

This option changes the gamma correction value. By default the gamma correction value is
2.22. Any value less than zero is illegal. This option can be used while the window system is
running. Changing the gamma correction value will affect all the windows being displayed
using gamma-corrected visuals. The gamma correction value is also saved in the OWconfig
file for the next time the window system starts.

This option controls the setting frame pins on the stereo/sync connector on the device. It
also controls which stream drives stereo glasses, which attach to the same connector.

If a (the default) or b is selected, the card is setup to be a sync master, and the frame sync
signal from the corresponding stream will be sent out this connector.

If you select input, the card is setup to take its frame sync from another card through this
connector. This sync can then be used to sync either or both streams by setting the
stream-specific -slave option(s) to external.

If stereo glasses are used, the a or b options select which stream is used for the sync signal to
the glasses.
Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is 255 (all bits 1), but some applications require 0. All other color indices display a colormap color.

Stream Options

Specifies for which stream options will be set. It is a required option for each of the other options in this section. It is optional for -res. Only one -stream option can be specified.

Directs stream b to the appropriate output connector: hd -15, dvid, or svideo. If auto, then the output connector for stream b is selected by the console. Stream a is always output through the 13W3 connector.

Offsets the display of the stream (specified by -stream) relative to the adjoining edge of the other stream when doublewide or doublehigh is enabled. This can be used to cause an overlap.

Number of pixels offset in horizontal direction for the right-hand stream when doublewide is enabled. Positive direction is to the right (create a gap); negative is to the left (overlap the streams). Default is 0, which means the two edges touch.

Number of pixels offset in vertical direction for the bottom stream when doublehigh is enabled. Positive direction is down (create a gap); negative is up (overlap the streams). Default is 0, which means the two edges touch.

This option allows you to specify the sync source for the specified stream. internal indicates that the sync source is the other stream of this device. external indicates the sync is taken from a source outside the device. If you use external, you also need to use the card option -master input.

For a given invocation of SUNWgfb_config, if an option does not appear on the command line, the corresponding 0Wconfig option is not updated. It retains its previous value.

When the window system is run, if an option has never been specified through SUNWgfb_config, a default value is used. The option defaults are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dev</td>
<td>/dev/fb</td>
</tr>
<tr>
<td>-file</td>
<td>machine</td>
</tr>
<tr>
<td>-res</td>
<td>none</td>
</tr>
</tbody>
</table>
-samples max
-multisample enable/dynamic
-clearpixel 255
-master a
-slave disable/external
-doublewide not set
-g 2.22
-active auto
-port auto
-offset 0/0

The default for the -res option of none means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This provides compatibility for users who are used to specifying the device resolution through the PROM.

**Examples**

**EXAMPLE 1** Switching Resolution of a Monitor

The following example switches to the resolution of 1280 by 1024 at 76 Hz:

```
example% fbconfig -stream a -res -SUNW_STD_1280x1024x76
```

**Files**

```
/usr/lib/fbconfig/SUNWgfb_config

Name
SUNWifb_config – configure the Sun Expert3D Graphics Accelerator

Synopsis
/usr/lib/fbconfig/SUNWifb_config [-dev device-filename]
   [-res video-mode [now | try] [noconfirm | nocheck]]
   [-file machine | system] [-deflinear true | false]
   [-defoverlay true | false]
   [-linearorder first | last]
   [-overlayorder first | last]
   [-expvis enable | disable] [-slave enable | disable]
   [-accum enable | disable] [-g gamma-correction-value]
   [-gfile gamma-correction-file] [-propt] [-prconf]
   [-defaults] [-slave] [-samples 1 | 2 | 4 | 8 | 16]
   [-multisample enable | disable | auto]
   /usr/lib/fbconfig/SUNWifb_config [-propt] [prconf]
   /usr/lib/fbconfig/SUNWifb_config [-help] [-res \?]

Description
SUNWifb_config configures the Sun Expert3D Graphics Accelerator, Sun Expert3D-Lite, and Sun XVR-500 Graphics Accelerators, and some of the X11 window system defaults for the graphics accelerator.

The first form of SUNWifb_config shown in the synopsis above stores the specified options in the OWconfig file. These options will be used to initialize the Sun Expert3D device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms of SUNWifb_config, which invoke only the -prconf, -propt, -help, and -res \? options, do not update the OWconfig file. Additionally, for the third form of the command, all other options are ignored.

Options may be specified for only one Sun Expert3D device at a time. Specifying options for multiple Sun Expert3D devices requires multiple invocations of SUNWifb_config.

Only options specific to the Sun Expert3D device can be specified through SUNWifb_config. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line (see the Xsun(1) manual page in the OpenWindows Desktop Reference Manual).

Options
The following options are supported:

- **-dev device-filename**
  Specifies the Sun Expert3D special file. The default is /dev/fbs/ifb0.

- **-filemachine| system**
  Specifies which OWconfig file to update. If machine is specified, the machine-specific OWconfig file in the /etc/openwin directory tree is updated. If system is specified, the global OWconfig file in the /usr/openwin directory tree is updated. If the
specified file does not exist, it is created. This option has no effect unless other options are specified. The default is `machine`.

**-res video-mode**

Specifies the video mode used to drive the monitor connected to the specified Sun Expert3D device.

The format of these built-in video modes is:

`widthxheightxrate`

where `width` is the screen width in pixels, `height` is the screen height in pixels, and `rate` is the vertical frequency of the screen refresh. The `s` suffix of `960x680x112s` and `960x680x108s` means that these are stereo video modes. The `i` suffix of `640x480x60i` and `768x575x50i` designates interlaced video timing. If absent, non-interlaced timing will be used. As a convenience, `-res` also accepts formats with `@` (at sign) in front of the refresh rate instead of `x`. For example: `1280x1024@76`.

Note that some video-modes supported by the Sun Expert3D device might not be supported by the monitor. The list of video-modes supported by the Sun Expert3D device and the monitor can be obtained by running `SUNWifb_config` with the `-res` `?` option (shown in the command synopsis above). The following is a list of all possible video-modes supported on the Sun Expert3D device:
Symbolic names

For convenience, some of the above video modes have symbolic names defined for them. Instead of the form width x height x rate, one of these names may be supplied as the argument to -res. The meaning of the symbolic name none is that when the window system is run the screen resolution will be the

1920x1080x72
1920x1200x70
1920x1200x75
The res option also accepts additional, optional arguments immediately following the video mode specification. Any or all of the following might be present.

If present, not only will the video mode be updated in the OWconfig file, but the Sun Expert3D device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

Note that it is inadvisable to use this suboption with SUNWifb_config while the configured device is being used (for example, while running the window system); unpredictable results might occur. To run SUNWifb_config with the now suboption, first bring the window system down. If the now suboption is used within a window system.
session, the video mode will be changed immediately, but the width and height of the affected screen will not change until the window system is exited and reentered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

**noconfirm**

Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of SUNWifb_config is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The noconfirm option instructs SUNWifb_config to bypass this confirmation and to program the requested video mode anyway. This option is useful when SUNWifb_config is being run from a shell script.

**nocheck**

If present, the normal error checking based on the monitor sense code (described above) will be suspended. The video mode specified by the user
will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the Sun Expert3D device). Use of this option implies noconfirm as well.

try

If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing y within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than y or carriage return is considered a no and the previous video mode will be restored and SUNWifb_config will not change the video mode in the OWconfig file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with SUNWifb_config while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run SUNWifb_config with the
try sub-option, the window system should be brought down first.

-deflinear true | false

The Sun Expert3D device possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray. If true, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the Xsun(1) -defdepth and -defclass options described in the OpenWindows Desktop Reference Manual). If false, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options will be chosen to be the default. This option cannot be used when the -defoverlay option is present, because the Sun Expert3D does not possess a linear overlay visual.

-defoverlay true | false

The Sun Expert3D device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the Sun Expert3D visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. If the value of this option is true, the overlay visual will be made the default visual. If false, the nonoverlay visual that satisfies the other default visual selection options, such as -defdepth and -defclass, will be chosen as the default visual. See the Xsun(1) manual page in the OpenWindows Desktop Reference Manual. Whenever -defoverlay true is used, the default depth and class chosen on the openwin command line must be 8-bit PseudoColor. If not, a warning message will be printed and the -defoverlay option will be treated as false. This option cannot be used when the -deflinear option is present, because the Sun Expert3D device does not possess a linear overlay visual.
-linearorder first | last

If first, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the Sun Expert3D screen. If last, the nonlinear visuals will come before the linear ones.

-overlayorder first | last

If first, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the Sun Expert3D screen. If last, the non-overlay visual will come before the overlay one.

-expvis enable | disable

If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor, and so forth) can be found in the screen visual list.

-slave enable | disable

If enabled, the video for this frame buffer will be synced with the video of the display which is connected to it. For applications which support it buffers will also be swapped synchronously.

-accum enable | disable

If enabled, frame buffer memory is allocated for accelerated accumulation buffer for windows. If disabled, software accumulation buffering will be done for windows. Accelerated accumulation buffers for pBuffers are always available as memory allows.

-g gamma-correction_value

This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by XSolarisGetVisualGamma(). See XSolarisGetVisualGamma(3) for a description of that function. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

-gfile gamma-correction_file

This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. Each of these values
should be in hexadecimal format and separated from each other by at least one space. Also, this file should provide 1024 such triplets. An example of this file is as follows.

```
0x00 0x00 0x000
0x01 0x01 0x001
0x02 0x02 0x002
...
...
0x3ff 0x3ff 0x3ff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note that, when gamma correction is being done using a user-specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

- defaults

Resets all option values to their default values.

- propt

Prints the current values of all Sun Expert3D options in the OWconfig file specified by the - file option for the device specified by the - dev option. Prints the values of options as they will be in the OWconfig file after the call to SUNWifb_config completes. This is a typical display:

--- OpenWindows Configuration for /dev/fbs/ifb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Accum: Disabled (do not allocate an accumulation buffer)
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
Overlay Visuals are last
OpenGL Visual Expansion: enabled
Gamma Correction Value: 2.22
Gamma Correction Table: Available

--- Hardware Configuration for /dev/fbs/ifb0 ---
PROM Information: @(#)ifb.fth 1.25 99/10/12 SMI
EDID Data: Available - EDID version 1 revision 1
Monitor possible resolutions: 1024x768x60, 1024x768x70, 1024x768x75,
1152x900x66, 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680x112s,
640x480x60
Current resolution setting: 1280x1024x76

-help
Prints a list of the SUNWfb_config command-line options, along with a brief explanation of each.

-samples 1|2|4|8|16
Requested number of samples to compute per display pixel. The requested number of samples per pixel will be used if -multisample is not disabled and resources exist for the request.

Query the number of samples used with -propt (see above) or the xglinfo utility. The xglinfo utility can return the number of multisamples after you specify the option -multisample enable.
The default is 16.

-multisample enable|disable|auto
If set to disable, no multisample is possible. If set to enable, multisample is possible but is selected on a per-window basis using a library interface. If set to auto, all Sun OpenGL windows are rendered using multisampling.

Query the number of samples used with -propt (see above) or the xglinfo utility. The xglinfo utility can return the number of multisamples if -multisample is set to enable.
The default is disable.

The xglinfo utility is shipped with the Sun OpenGL package, SUNWglrt. The man page for xglinfo is part of another Sun OpenGL package, SUNWgldoc.

Defaults For a given invocation of SUNWfb_config command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value. When the window system is run, if an Sun Expert3D option has never been specified via SUNWfb_config, a default value is used. The option defaults are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dev</td>
<td>/dev/fbs/ifb0</td>
</tr>
<tr>
<td>-file</td>
<td>machine</td>
</tr>
<tr>
<td>-res</td>
<td>none</td>
</tr>
<tr>
<td>-deflinear</td>
<td>false</td>
</tr>
</tbody>
</table>
The default for the -res option of none means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This design choice provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX), this is the only way of specifying the video mode. This means that the PROM ultimately determines the default Sun Expert3D video mode.

**Examples**

**EXAMPLE 1**  Changing Monitor Resolution

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```bash
example% /usr/lib/fbconfig/SUNWifb_config -res 1280x1024x76
```

[-prconf] [-defaults]

fbconfig [-propt] [-prconf]

fbconfig [-help] [-res ?]

**Description**
SUNWjfb_config configures the Sun XVR-600 and XVR-1200 Graphics Accelerator and some of the X11 window system defaults for the Sun XVR-600 and XVR-1200.

You can specify options for only one device at a time. If you want to specify options for multiple devices, you must invoke the SUNWjfb_config utility multiple times.

You can use the SUNWjfb_config utility to specify Sun XVR-600 or XVR-1200 specific options. Use the normal window system options to specify default depth, default visual class and so forth. Specify these as device modifiers on the command line. See Xsun(1)

You can also specify which OWconfig file to update. By default, SUNWjfb_config updates the machine-specific file in the /etc/openwin. You can specify an alternate file by using the -file option. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the SUNWjfb_config program, which is owned by the root user, always runs with setuid root permission.

The first form of SUNWjfb_config shown in the SYNOPSIS section stores the specified options in the OWconfig file. These options initialize the Sun XVR-600 and XVR-1200 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.
The second and third forms which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options, do not update the OWConfig file. Additionally, for the third form all other options are ignored.

**Options**

The following options are supported:

- **-accum enable | disable**
  Enable or disable frame buffer memory. If enabled, frame buffer memory is allocated for the accelerated accumulation buffer for windows. If disabled, software accumulation buffering for windows is used. Accelerated accumulation buffers for pBuffers are always available as memory allows.

- **-dev device-filename**
  Specify the SunSun XVR-600 or XVR-1200 special file. The default is `/dev/fbs/jfb0`.

- **-defaults**
  Reset all option values except `-dev` to their default values.

  This option sets the resolution override to none which implies the last video mode setting is preserved. If no monitor is attached, the video mode is set to 1152x900x66.

- **-deflinear true | false**
  Both the Sun XVR-600 and XVR-1200 possess two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray. If the value of this option is `true`, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the Xsun `defdepth` and `defclass` options; see `Xsun(1)`). If `false`, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options is chosen as the default visual. This option cannot be used when the `-defoverlay` option is present, because the Sun XVR-600 and XVR-1200 do not possess a linear overlay visual.

- **-defoverlay true | false**
  Both the Sun XVR-600 and XVR-1200 provide an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows.

  If the value of this option is `true`, the overlay visual is the default visual. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `defdepth` and `defclass`, is chosen as the default visual. See `Xsun(1)`. Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message is printed and the `-defoverlay` option is treated as `false`. This option cannot be used when the `-deflinear` option is present, because the Sun XVR-600 and XVR-1200 do not possess a linear overlay visual.
-defdepth 8 | 24
Set the depth (bits per pixel) on the device. Possible values for the -defdepth option are 8 or 24. You must log out of the current window system session and log back in again for the change to take effect. Any depth setting in the Xserver command line takes precedence over what is set using fbconfig. The default is determined by the X Server smf(5) default depth property. You can query this property with the following command:

% /usr/sbin/svccfg -s svc:/application/x11/x11-server listprop \"options/default_depth\"

-doublehigh enable | disable
Configure the two outputs of the Sun XVR-1200 into one vertical virtual display. The default is disable.

This option is not applicable to the Sun XVR-600 device.

-doublewide enable | disable
Configure the two outputs of the Sun XVR-1200 into one horizontal virtual display. The default is disable.

This option is not applicable to the Sun XVR-600 device.

-fake8 enable | disable
Enable or disable simple 8 bit X windows to be rendered without a hardware colormap to reduce colormap flashing. You might notice performance reductions. The default is disable.

-file machine|system
Specifies which OWconfig file to update. If machine is specified, the machine-specific OWconfig file in the /etc/openwin directory tree is updated. If system is specified, the global OWconfig file in the /usr/openwin directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is machine.

-g gamma-correction value
Change the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.

-gfile gamma-correction file
Load the gamma correction table from the file specified by gamma-correction file. You should format this file to provide the gamma correction values for R, G, and B channels on each line. Specify each value in hexadecimal format and separate it from another value by at least 1 space. The gamma-correction file file should provide 1024 such triplets.

You can load the gamma correction table with this option can while the window system is running. The new gamma correction affects all the window being displayed using the linear visuals. When gamma correction is done using a user specified table, the gamma correction
value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

The following is an example of a gamma-correction file:

```
0x000 0x000 0x000
0x001 0x001 0x001
0x002 0x002 0x002
...  
...  
0x3ff 0x3ff 0x3ff
```

**-help**
Print a list of the SUNWjfb_config command line options, along with a brief explanation of each.

**-multisample available | disable | forceon**
If set to disable, no multisample is possible. If set to available, multisample is possible but is selected on a per-window basis using a library interface. If set to forceon, all Sun OpenGL windows are rendered using multisampling. Query the number of samples used with -propt or the xglinfo(1) utility. The xglinfo utility can return the number of multisamples if -multisample is set to enable. The default is disable.

**-offset xval yval**
Adjust the position of the specified stream by the value specified. This option is only implemented in -doublewide and -doublehigh modes. For -doublewide, use the xval to position the rightmost stream. Negative is left (overlaps with the left stream). For -doublehigh, use the yval to position the bottom stream. Negative is up (overlaps with top stream). The default is \([0, 0]\).

**-outputs swapped | direct**
If either -doublewide or -doublehigh are enabled, reverse the position of the two outputs relative to each other. The default is direct.

**-propt**
Print the current values of all Sun XVR-600 and XVR-1200 options in the OWconfig file specified by the -file option for the device specified by the -dev option. Print the values of options as they will be in the OWconfig file after the call to SUNWjfb_config completes.

This is a typical display:

```
# fbconfig -dev jfb2 -propt

--- OpenWindows Configuration for /dev/fbs/jfb2 ---

OWconfig: machine
Video Mode: 1280x1024x60
Accum: Enabled (allocate an accumulation buffer if possible)

Multisample Information:
```
Multisample Mode: Disabled (multisample visuals will not be available)
Samples Per Pixel: N/A (multisampling disabled)

Screen Information:
DoubleWide: Disabled
DoubleHigh: Disabled
Output Configuration: Direct
Offset/Overlap: [0, 0]

Visual Information:
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
Gamma Correction Value: 2.22
Gamma Correction Table: Available
Fake8 rendering: disabled
Default Visual Depth (defdepth): 8

-prconf
Print the Sun XVR-1200 hardware configuration. This is a typical display:

# fbconfig -dev jfb2 -prconf

--- Hardware Configuration for /dev/fbs/jfb2 ---

Type: XVR-1200
Sun Serial Number: 3753101000022
Hardware Revision: -01 rev01

Total Display List Memory: 33554432
-res video-mode [ now | try [ noconfirm | nocheck ]]

Specify the video mode of the monitor connected to the specified Sun XVR-600 or XVR-1200 device.

The -res option requires you to specify the video-mode. You can specify video-mode in the format of \textit{width}x\textit{height}x\textit{rate} or as a symbolic name.

\textit{width}x\textit{height}x\textit{rate}

Specify video-mode in the format of \textit{width}x\textit{height}x\textit{rate}, where \textit{width} is the screen width in pixels, \textit{height} is the screen height in pixels, and \textit{rate} is the vertical frequency of the screen refresh.

You can use the \texttt{s} suffix to specify stereo video modes. The \texttt{s} suffix of \texttt{960x680x112s} and \texttt{960x680x108s} means that these are stereo video modes.

The -res option also accepts formats with @ (at sign) in front of the refresh rate instead of \texttt{x}, (\texttt{280x1024@76}). Some video-modes, supported by Sun XVR-600 and XVR-1200, might not be supported by the monitor.

The list of video-modes supported by the Sun XVR-600 and XVR-1200 device and the monitor can be obtained by running \texttt{SUNWjfb_config} with the \texttt{-res ?} option. See \texttt{SYNOPSIS}.

Symbolic Names

Some video modes have symbolic names defined for them. Instead of using the \textit{width}x\textit{height}x\textit{rate} format, you can specify one of the symbolic names as the argument to the -res option. The meaning of the symbolic name none is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

\begin{verbatim}
svga 1024x768x60
1152 1152x900x76
1280 1280x1024x76
stereo 960x680x112s
ntsc 640x480x60i
pal 768x575x50i
none Programmed video mode
\end{verbatim}

The -res option accepts additional, optional arguments immediately following the video mode specification. The following additional, optional arguments are supported:

\texttt{now}

If present, updates the video mode be updated in the \texttt{OWconfig} file. Programs the Sun XVR-600 or XVR-1200 device to display the video mode. This is useful for changing the video mode before starting the window system.

Do not use this suboption with \texttt{SUNWjfb_config} while the configured device is being used, for example, while running the window system. Unpredictable results can occur.
If you want to run `SUNWjfb_config` with the `now` suboption, first bring the window system down. If you use the `now` suboption within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is discouraged.

`noconfirm`

Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `SUNWjfb_config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `-noconfirm` option instructs `SUNWjfb_config` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `SUNWjfb_config` is run from a shell script.

`nocheck`

If present, the normal error checking based on the monitor sense code is suspended. The video mode specified is accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the Sun XVR-600 or XVR-1200 device. Use of this option implies `noconfirm`.

`try`

If present, programs the specified video mode on a trial basis. You are asked to confirm the video mode by entering a `y` within 10 seconds. You can terminate the trial before 10 seconds by entering any character but `y` or RETURN.

Terminating the trial by entering a character other than `y` or RETURN restores the previous video mode. `SUNWjfb_config` does not change the video mode in the OWconfig file. Other specified options still take effect. If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` suboption.

If you want to run `SUNWjfb_config` with the `now` suboption, first bring the window system down. If you use the `now` suboption within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is strongly discouraged.

`-samples 1 | 4 | 8 | 16 | adaptive`

Request the number of samples to compute per display pixel. The requested number of samples per pixel will be used if `-multisample` is not disabled and resources exist for the request. If set to `adaptive`, variable multisampling is possible, with the minimum samples per pixel set to 2. Query the number of samples used with `-propt` or the `xglinfo(1)` utility. The `xglinfo` utility can return the number of multisamples after you specify the option `-multisample enable`. The default is 16.
-slave disable | multiview | stereo | bnc
Enable or disable a specific port. Specify multiview for the DB9 connector, stereo for the mini-DIN connector, or bnc for the bnc connector. Specify disable to disable a specific port. If set, the option is an exclusive slave instance in the Framelock Configuration Setup. The default is disable.

multiview and bnc are only applicable to the Sun XVR-1200 device.

**Defaults**

For a given invocation of SUNWjfb_config command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if an option has never been specified by way of SUNWjfb_config, a default value is used. The options and their corresponding defaults are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dev</td>
<td>/dev/fbs/jfb0</td>
</tr>
<tr>
<td>-file</td>
<td>machine</td>
</tr>
<tr>
<td>-res</td>
<td>none</td>
</tr>
<tr>
<td>-deflinear</td>
<td>false</td>
</tr>
<tr>
<td>-defoverlay</td>
<td>false</td>
</tr>
<tr>
<td>-linearorder</td>
<td>last</td>
</tr>
<tr>
<td>-slave</td>
<td>disable</td>
</tr>
<tr>
<td>-accum</td>
<td>enable</td>
</tr>
<tr>
<td>-g</td>
<td>2.22</td>
</tr>
<tr>
<td>-samples</td>
<td>16</td>
</tr>
<tr>
<td>-multisample</td>
<td>disable</td>
</tr>
<tr>
<td>-doublewide</td>
<td>disable</td>
</tr>
<tr>
<td>-doublehigh</td>
<td>disable</td>
</tr>
<tr>
<td>-outputs</td>
<td>direct</td>
</tr>
<tr>
<td>-offset</td>
<td>[0,0]</td>
</tr>
</tbody>
</table>

The default for the -res option of none means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.
This provides compatibility for users who are used to specifying the device resolution through the PROM. This means that the PROM ultimately determines the default video mode.

**Examples**

**EXAMPLE 1**  Switching the Resolution of the Monitor Type

The following example switches the monitor type to 1280 × 1024 at 76 Hz resolution:

```
example% fbconfig –dev jfb0 –res 1280x1024x76
```

**Files**

- /dev/fbs/jfb
  - Device special file for the XVR-600 or XVR-1200 high performance single screen
- /dev/fbs/jfbna
  - Device special file for the XVR-1200 first video out
- /dev/fbs/jfbnb
  - Device special file for the XVR-1200 second video out
- /usr/lib/jfb.ucode
  - jfb microcode file
- /usr/sbin/jfbdaemon
  - jfb microcode loader file

SUNWkfb_config – fbconfig module for configuring the Sun XVR-2500 Graphics Device

/sunw/lib/fbconfig/SUNWkfb_config [-dev device-filename]
        [-res video-mode] [-file machine | system]
        [-deflinear true | false] [-defoverlay true | false]
        [-deftransparent true | false]
        [-slave disable | multiview]
        [-g gamma-correction-value]
        [-gfile gamma-correction-file]
        [-doublewide enable | disable]
        [-doublehigh enable | disable]
        [-multisample available | disable | forceon]
        [-samples 1 | 2 | 4 | 8 | 16 ] [-offset xval yval]
        [-propt] [-prconf] [-defaults]

/usr/lib/fbconfig/SUNWkfb_config [-propt] [-prconf]
/usr/lib/fbconfig/SUNWkfb_config [-help] [-res ?]

SUNWkfb_config configures the Sun XVR-2500 Graphics Accelerator and some of the X11 window system defaults for the Sun XVR-2500. The first form of SUNWkfb_config shown in the SYNOPSIS section stores the specified options in the OWconfig file. These options initialize the Sun XVR-2500 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. The second and third forms which invoke only the -prconf, -propt, -help, and -res ? options, do not update the OWconfig file. For the third form, all other options are ignored. You can specify options for only one device at a time. If you want to specify options for multiple devices, invoke the SUNWkfb_config utility multiple times.

Only the Sun XVR-2500 options can be specified through the SUNWkfb_config utility. Use the normal window system options to specify default depth (see svccfg(1M)), default visual class and so forth. Specify these as device modifiers on the command line. See Xsun(1).

You can also specify which OWconfig file to update. By default, SUNWkfb_config updates the machine-specific file in the /etc/openwin directory tree. Use the -file option to specify an alternate file. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the SUNWkfb_config program, which is owned by the root user, always runs with setuid root permission.
The following options are supported:

- **defaults**
  - Resets all option values except -dev to their default values. This option sets the resolution override to none which implies that the last video mode setting is preserved. If no monitor is attached, the video mode is set to 1152x900x66.

- **deflinear true|false**
  - This option selects the default X visual. The Sun XVR-2500 device supports two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not.

  If the value of this option is true, the default visual is set to default depth 24 and the default class is TrueColor with gamma correction enabled. If false, a non-linear visual that satisfies the other default visual selection options, such as the default depth and default class, is chosen as the default visual. See Xsun(1).

  The -deflinear, -defoverlay, and -deftransparent options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

- **defoverlay true|false**
  - This option selects the default X visual. The Sun XVR-2500 device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows.

  If the value of this option is true, the overlay visual is the default visual. The default depth is 8 bit and the default class is PseudoColor. If false, the nonoverlay...
The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

This option selects the default X visual. The Sun XVR-2500 device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals.

If the value of this option is `true`, the overlay visual used as the default is a transparent overlay visual. A visual with transparency supports a colormap with 255 colors and one transparent pixel. The default depth is 8 bit and the default class is PseudoColor. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual. See `Xsun(1)`.

The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

The SunXVR-2500 special file. The default is `/dev/fbs/kfb0`.

```
-dev device-filename
```

Specifies the SunXVR-2500 special file. The default is `/dev/fbs/kfb0`.  

visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual. See `Xsun(1)`.
-doublehigh enable | disable
Configures the two outputs of the Sun XVR-2500 device into one vertical virtual display. The default is disable.

-doublewide enable | disable
Configures the two outputs of the Sun XVR-2500 device into one horizontal virtual display. The default is disable.

-file machine | system
Specifies which OWconfig file to update. If machine is specified, the machine-specific OWconfig file in the /etc/openwin directory tree is updated. If system is specified, the global OWconfig file in the /usr/openwin directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is machine.

-g gamma-correction value
Changes the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.

-gfile gamma-correction file
Loads the gamma correction table from the file specified by gamma-correction file. Format this file to provide the gamma correction values for R, G, and B channels on each line. Specify each value in hexadecimal format, separated from another value by at least one space. The gamma-correction file file should provide 1024 such triplets.

You can load the gamma correction table with this option while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is done using a user specified table, the gamma correction value is undefined. By default, the window system
assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

The following is an example of a gamma-correction file:

```
0x000 0x000 0x000
0x001 0x001 0x001
0x002 0x002 0x002
...
...
0x3ff 0x3ff 0x3ff
```

- **-help**
  Prints a list of the SUNWkfb_config command line options, along with a brief explanation of each.

- **-multisample available|disable|forceon**
  If set to **disable**, no multisample is possible. If set to **available**, multisample is possible but is selected on a per-window basis using a library interface. If set to **forceon**, all Sun OpenGL windows are rendered using multisampling. Query the number of samples used with **-propt** or the **xglinfo(1)** utility. The **xglinfo** utility can return the number of multisamples if **-multisample** is set to **available**. The default is **disable**.

- **-offset xval yval**
  Adjusts the position of the specified stream by the value specified. This option is only implemented in **-doublewide** and **-doublehigh** modes. For **-doublewide**, use the **xval** to position the rightmost stream. Negative is left (overlaps with the left stream). For **-doublehigh**, use the **yval** to position the bottom stream. Negative is up (overlaps with top stream). The default is **[0, 0]**.

- **-prconf**
  Prints the Sun XVR-2500 hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/kfb2 ---

Type: XVR-2500
PROM Information: @(#) xvr2500.fth 14.106 05/08/15 SMI
```
Monitor/Resolution Information:
Monitor Manufacturer: SUN
Product code: 1352
Serial #: 7225675
Manufacture date: 1997, week 51
Monitor dimensions: 48x31 cm
Monitor preferred resolution: 1920x1200x70
Separate sync supported: yes
Composite sync supported: yes
EDID: Version 1, Revision 1
Supported resolutions: 1920x1200x70, SUNW_STD_1600x1000x76,
SUNW_STD_1600x1000x66, SUNW_STD_1440x900x76, 1920x1080x70,
1600x1000x76, 1600x900x66, 1440x810x76, 1280x720x76,
1920x1080x72, VESA_STD_720x400x70, VESA_STD_720x400x88,
VESA_STD_640x480x60, VESA_STD_640x480x67,
VESA_STD_800x600x56, VESA_STD_800x600x60,
VESA_STD_800x600x72, VESA_STD_800x600x75,
VESA_STD_1024x768x70, VESA_STD_1280x1024x75,
Current resolution setting: SUNW_STD_1280x1024x76

Framelock Configuration:
Slave Mode: Disabled

-propt
Prints the current values of all Sun XVR-2500 options in the OWconfig file
specified by the -file option for the device
specified by the -dev option. Prints the
values of options as they will be in the
OWconfig file after the call to
SUNWkfb_config completes.

This is a typical display:

--- OpenWindows Configuration for /dev/fbs/kfb2 ---

OWconfig: machine
Video Mode: SUNW_STD_1280x1024x76

Multisample Information:
Multisample Mode: Disabled (multisample visuals
will not be available)
Samples Per Pixel: N/A (multisampling disabled)

Screen Information:
DoubleWide: Disabled
DoubleHigh: Disabled
Offset/Overlap: [0, 0]
-res video-mode

Specifies the video mode of the monitor connected to the specified Sun XVR-2500 device.

You must specify the video mode with the -res option. You can specify video-mode in the format of widthxheightxrate or as a symbolic name. The format of these built-in video modes is:

\[ \text{width} x \text{height} x \text{rate} \]

width is the screen width in pixels, height is the screen height in pixels, and rate is the vertical frequency of the screen refresh.

You can use the s suffix to specify stereo video modes. The s suffix of 960x680x112s and 960x680x108s means that these are stereo video modes.

As a convenience, the -res option also accepts formats with @ (at sign) in front of the refresh rate instead of x, as for example, 1280x1024@76.

Some video-modes supported by the Sun XVR-2500 device may not be supported by the monitor.
You can obtain the list of video-modes supported by the Sun XVR-2500 device and the monitor by running `SUNWkfb_config` with the `-res ?` option. See SYNOPSIS.

**Symbolic Names**

Some video modes have symbolic names defined for them. Instead of using the `widthxheightxrate` format, you can specify one of the symbolic names as the argument to the `-res` option. The meaning of the symbolic name `none` is that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

<table>
<thead>
<tr>
<th>Name</th>
<th>Corresponding Video Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>svga</td>
<td>1024x768x60</td>
</tr>
<tr>
<td>1152</td>
<td>1152x900x76</td>
</tr>
<tr>
<td>1280</td>
<td>1280x1024x76</td>
</tr>
<tr>
<td>stereo</td>
<td>960x680x112s</td>
</tr>
<tr>
<td>none</td>
<td>(see text above)</td>
</tr>
</tbody>
</table>
-samples 1 | 2 | 4 | 8 | 16  Requests the number of samples to compute per display pixel. The requested number of samples per pixel is used if -multisample is not disabled and resources exist for the request. Query the number of samples used with -prop or the xglinfo(1) utility. The xglinfo utility can return the number of multisamples after you specify the option -multisample available. The default is 4.

-slave disable | multiview  If you set the multiview argument for the -slave option, the device synchronizes video with a master through the multiview ribbon cable. Both devices should be running the same resolution and the option should be issued when the window system is running. The default is disable.

**Defaults**  For a given invocation of the SUNWkfb_config command line, if an option does not appear on the command line, the corresponding OWconfig option is not updated and retains its previous value.

When the window system is run, if a Sun XVR-2500 option has never been specified by way of SUNWkfb_config, a default value is used. The options and their corresponding defaults are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dev</td>
<td>/dev/fbs/kfb0</td>
</tr>
<tr>
<td>-file</td>
<td>machine</td>
</tr>
<tr>
<td>-res</td>
<td>none</td>
</tr>
<tr>
<td>-deflinear</td>
<td>false</td>
</tr>
<tr>
<td>-defoverlay</td>
<td>false</td>
</tr>
<tr>
<td>-deftransparent</td>
<td>false</td>
</tr>
<tr>
<td>-slave</td>
<td>disable</td>
</tr>
<tr>
<td>-g</td>
<td>2.22</td>
</tr>
<tr>
<td>-samples</td>
<td>4</td>
</tr>
<tr>
<td>-multisample</td>
<td>disable</td>
</tr>
</tbody>
</table>
The default for the -res option of none means that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

**Examples**

**EXAMPLE 1** Switching the Resolution of the Monitor Type

The following example switches the monitor type to 1280 × 1024 at 76 Hz resolution:

```
example% fbconfig -dev kfb0 -res 1280x1024x76
```

**Files**

/dev/fbs/kfbh Device special file for the XVR-2500 high performance single screen

/usr/sbin/kfbdaemon The kfb memory manager

SUNWnfb_config – fbconfig module for configuring XVR-300 Graphics Accelerator

SUNWnfb_config is the XVR-300 device dependent layer for fbconfig. It configures the XVR-300 Graphics Accelerator and some of the X11 window system defaults for XVR-300. The XVR-300 provides the capability to drive two monitors, each with a unique video stream (Stream #1 and Stream #2).

The first form of SUNWnfb_config shown in the SYNOPSIS section sets options for the XVR-300. This form stores the specified options in the OWconfig file. These options will be used to initialize the XVR-300 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. For -res now, the XVR-300 device will be immediately programmed.

The second form, which invokes the -prconf and -propt options, queries the XVR-300 for status.

The third form, which invokes the -help and -res ? options, provides instruction on using SUNWnfb_config. Additionally, for the third form all other options are ignored.

Options may be specified for only one XVR-300 device at a time. Specifying options for multiple XVR-300 devices requires multiple invocations of SUNWnfb_config.

Only XVR-300-specific options can be specified through SUNWnfb_config. The normal window system options for specifying default depth, default visual class and so forth can still be specified as device modifiers on the command line when the X Server is started. See the dtlogin(1) reference to Xservers File.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

**Options**

- **-dev device-filename**
  Specifies the XVR-300 special file. The default is /dev/fb.
-file machine | system
   Specifies which OWconfig file to update. If machine, the machine-specific OWconfig file in
   the /etc/openwin directory tree is used. If system, the global OWconfig file in the
   /usr/openwin directory tree is used. If the file does not exist, it is created.

-res video-mode [now | try] [noconfirm | nocheck]
   Specifies the video mode used to drive the monitor connected to the specified XVR-300
   device. Video modes are built-in.

video-mode
   Specifies resolution and timing information for the display (for example,
   1280x1024x76). The format of the video-mode specifier is:
   widthxheightxrate. width is the screen width in pixels, height is the screen
   height in pixels, and rate is the vertical frequency of the screen refresh. As a
   convenience, -res also accepts formats with @ preceding the refresh rate
   instead of x. For example, 1280x1024@76.

Symbolic names. For convenience, some video modes have symbolic
names defined for them. Instead of the form widthxheightxrate, one of
these names may be supplied as the argument to -res. The meaning of the
symbolic name none is that when the window system is run, the screen
resolution will be the video mode that is currently programmed in the
device.

Some video-modes supported by XVR-300 may not be supported by the
monitor. The list of video-modes supported by the XVR-300 device and
the monitor can be obtained by running SUNWnfb_config with the -res ?
option (the third form shown in the command SYNOPSIS section).

-res option arguments. The -res option also accepts additional, optional
arguments immediately following the video mode specification. Any or all
of these may be present.

now
   If present, not only will the video mode be updated in the
   OWconfig file, but the XVR-300 device will be immediately
   programmed to display this video mode. (This is useful for
   changing the video mode before starting the window
   system).

   It is inadvisable to use this suboption with SUNWnfb_config
   while the configured device is being used (for example,
   while running the window system) because unpredictable
   results may occur. To run SUNWnfb_config with the now
   suboption, first bring the window system down. If the now
   suboption is used within a window system session, the
   video mode will be changed immediately, but the width
   and height of the affected screen won't change until the
window system is exited and reentered again. Consequently, this usage is discouraged.

`noconfirm` Using the `-res` option, the user could put the system into an unusable state, which has no video output. To reduce the chance of this, the default behavior of `SUNWnfb_config` is to print a warning message and to ask the user whether to continue. The `noconfirm` suboption bypasses this confirmation. This suboption is useful when `SUNWnfb_config` is being run from a shell script.

`nocheck` If present, the normal error checking based on the monitor sense code will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This suboption is useful if a different monitor is to be connected to the XVR-300 device. Use of this suboption implies `noconfirm` as well.

`try` If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing 'y' within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than 'y' or carriage return is considered a no and the previous video mode will be restored and `SUNWnfb_config` will not change the video mode in the `OWconfig` file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` suboption (see the warning note on the `now` suboption).

- `doublewide enable | disable` This option allows you to configure the two outputs of the Sun XVR-300 into one horizontal virtual display. Both video outputs will be set to the same resolution. Default is `disable`.

- `doublehigh enable | disable` This option allows you to configure the two outputs of the Sun XVR-300 into one vertical virtual display. Both video outputs will be set to the same resolution. Default is `disable`.

- `clone enable | disable` If this option is set to enable, the two outputs will display identically. Default is `disable`.

- `outputs swapped | direct` If either `doublewide` or `doublehigh` is enabled, this option allows you to reverse the positions of the two outputs relative to each other. Default is `direct`.
-fake8 enable | disable
  If enabled, simple 8 bit X windows will be rendered without a hardware colormap to reduce colormap flashing. Some performance reductions may be observed. Default is disable.

-depth 8 | 24
  Sets the default depth for the window system to start with. Possible values are 8 or 24. Log out of the current window system session and log back in for the change to take effect. Any defdepth setting in the Xserver command line takes precedence over what is set using fbconfig. Default is 24. This option is only supported on Solaris 9. For Solaris 10 and above, use /usr/sbin/svccfg to configure depth.

-offset xval yval
  Adjusts the position of the specified stream by the value specified. Currently only implemented in -doublewide and -doublehigh modes. For -doublewide, the xval is used to position the rightmost stream. Negative is left (overlaps with the left stream). For -doublehigh, the yval is used to position the bottom stream. Negative is up (overlaps with top stream). Positive values are treated as 0. Default is [0, 0]

-defaults
  Resets all option values to their default values.

-prop
  Prints the current values of all XVR-300 options in the OWconfig file specified by the -file option for the device specified by the -dev option. Prints the values of options as they will be in the OWconfig file after the call to SUNWnfb_config completes. This is a typical display:

  --- Graphics Configuration for /dev/fbs/nfb0 ---
  OWconfig: machine
  Video Mode: NONE
  Screen Information:
    Doublewide: Disable
    Doublehigh: Disable
    Clone: Disable
    Offset/Overlap: [0, 0]
    Output Configuration: Direct
    Fake8 Rendering: Disable

-prconf
  Prints the XVR-300 hardware configuration. This is a typical display:

  --- Hardware Configuration for /dev/fbs/nfb0 ---

  Current resolution setting: 1152x900x66

help
  Prints a list of the SUNWnfbs_config command line options, along with a brief explanation of each.
- res?
   Prints list of defined video-mode names.

 Defaults
 For a given invocation of a SUNWnfb_config command line if an option does not appear on the
 command line, the corresponding OWconfig option is not updated and retains its previous
 value.

 When the window system is run, if an XVR-300 option has never been specified via
 SUNWnfb_config, a default value is used. The option defaults are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dev</td>
<td>/dev/fb</td>
</tr>
<tr>
<td>-file</td>
<td>machine</td>
</tr>
<tr>
<td>-res</td>
<td>none</td>
</tr>
<tr>
<td>-fake8</td>
<td>disable</td>
</tr>
<tr>
<td>-doublewide</td>
<td>disable</td>
</tr>
<tr>
<td>-doublehigh</td>
<td>disable</td>
</tr>
<tr>
<td>-clone</td>
<td>disable</td>
</tr>
<tr>
<td>-outputs</td>
<td>direct</td>
</tr>
<tr>
<td>-offset</td>
<td>[0,0]</td>
</tr>
</tbody>
</table>

The default for the - res option of none means that when the window system is run, the screen
resolution will be the video mode that is currently programmed in the XVR-300 PROM.

This provides compatibility for users who are used to specifying the device resolution through
the XVR-300 PROM. On some devices (for example, GX) this is the only way of specifying the
video mode. This means that the PROM ultimately determines the default XVR-300 video
mode.

 Examples

 Examples
 Switching the monitor type

 The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

 example% fbconfig -res 1280x1024x76

SUNWpfb_config – fbconfig module for configuring the XVR-50 and the Sun XVR-100 Graphics Accelerator

**Synopsis**

For XVR-50:

```
/usr/lib/fbconfig/SUNWpfb_config [-dev device-filename]
    [-res video-mode [now | try] [noconfirm | nocheck]]
    [-file machine | system]
    [-fake8 enable | disable]
    [-g enable | disable | gamma-value]
    [-defaults]
```

For Sun XVR-100:

```
/usr/lib/fbconfig/SUNWpfb_config [-dev device-filename]
    [-res video-mode [now | try] [noconfirm | nocheck]]
    [-file machine | system]
    [-fake8 enable | disable]
    [-g enable | disable | gamma-value]
    [-doublewide enable | disable]
    [-doublehigh enable | disable]
    [-outputs swapped | direct]
    [-depth 8 | 24]
    [-offset xval yval]
    [-defaults]
```

For Sun XVR-100 and XVR-50:

```
/usr/lib/fbconfig/SUNWpfb_config [-pt] [-prconf]
/usr/lib/fbconfig/SUNWpfb_config [-help] [-res \?]
```

**Description**

SUNWpfb_config is the XVR-50 and the Sun XVR-100 device dependent layer for fbconfig(1M). It configures the XVR-50 and the Sun XVR-100 Graphics Accelerator and some of the X11 window system defaults for the XVR-50 and Sun XVR-100. The Sun XVR-100 provides the capability to drive two monitors, each with a unique video stream (Stream #1 and Stream #2). The XVR-50 drives one video stream.

The first two forms of SUNWpfb_config shown in the SYNOPSIS section sets options for the XVR-50 and the Sun XVR-100 devices. It stores the specified options in the OWconfig file. These options initialize the XVR-50 and the Sun XVR-100 devices the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. The XVR-50 and the Sun XVR-100 devices are immediately programmed if you specify the -res now.

The third form, which invokes the -prconf and -propt options, queries the XVR-50 and the Sun XVR-100 device for status.

The fourth form, which invokes the -help, and -res \? options, provides instruction on using SUNWpfb_config. Additionally, for the fourth form all other options are ignored.
You can only specify options for only one XVR-50 or Sun XVR-100 device at a time. If you want to specify options for multiple XVR-50 or Sun XVR-100 devices, you must use multiple invocations of the SUNWpfb_config command.

You can only use SUNWpfb_config to specify XVR-50 or Sun XVR-100 specific options. You can use the normal window system options to specify the default depth, default visual class and so forth as device modifiers on the command line when the X Server is started. See dtlogin(1) for information regarding the Xservers File.

You can also specify the OWconfig file to update. The machine-specific file in the /etc/openwin directory tree is updated by default. You can used the -file option to specify an alternate file. For example, you can update the system-global OWconfig file in the /usr/openwin directory tree instead.

Options

The following options are supported:

- **defaults**
  Reset all option values to their default values.

- **depth 8 | 24**
  Set the depth (bits per pixel) for the window system. Possible values for the -depth option are 8 or 24. You must log out of the current window system session and log back in again for the change to take effect. Any depth setting in the Xserver command line takes precedence over what is set using fbconfig. The default is 8. This option is only available with Solaris 8 or Solaris 9.

- **dev device-filename**
  Specify the XVR-50 or the Sun XVR-100 special file. The default is /dev/fb.

- **doublehigh enable | disable**
  Configure the two outputs of the Sun XVR-100 into one vertical virtual display. You must log out of the current window system session and log back in again for the change to take effect. The default is disable.

- **doublewide enable | disable**
  Configure the two outputs of the Sun XVR-100 into one horizontal virtual display. You must log out of the current window system session and log back in again for the change to take effect. The default is disable.

- **fake8 enable | disable**
  Enable or disable simple 8 bit X windows to be rendered without a hardware colormap to reduce colormap flashing. You might notice performance reductions. You must log out of the current window system session and log back in again for the change to take effect. The default is disable.

- **file machine|system**
  Specifies which OWconfig file to update. If machine is specified, the machine-specific OWconfig file in the /etc/openwin directory tree is updated. If system is specified, the
global OWconfig file in the /usr/openwin directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is machine.

- g enable | disable | gamma-value
This option allows you to change the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is 2.22. Any value less than zero is illegal.

This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals. You must log out of the current window system session and log back in again for the change to take effect. The default is disable.

-help
Print a list of the SUNWpfb_config command line options, along with a brief explanation of each option.

-offset xval yval
Adjust the position of the secondary stream on the Sun XVR-100. This option is currently implemented only for the -doublewide and -doublehigh modes. For -doublewide, use the xval to position the DVI stream, if -outputs are direct (VGA stream if -outputs are swapped). A negative value specifies the overlapped region with the primary stream. This is similar for -doublehigh, except the yval is used. Positive values are treated as 0. You must log out of the current window system session and log back in again for the change to take effect. The default is [0, 0].

-outputs swapped | direct
Reverse the positions of the -doublewide or -doublehigh outputs relative to each other on the Sun XVR-100. You must log out of the current window system session and log back in again for the change to take effect. The default is direct.

-propt
Print the current values of all XVR-50 and Sun XVR-100 options in the OWconfig file specified by the -file option for the device specified by the -dev option. Print the values of options as they will be in the OWconfig file after the call to SUNWpfb_config completes.

This is a typical display for the Sun XVR-100:

--- Graphics Configuration for /dev/fbs/pfb0 ---

OWconfig: machine
Video Mode: not set
Depth: not set

Screen Information:
    Doublewide: Disable
    Doublehigh: Disable
    Offset/Overlap: [0.0]
-prconf
Print the XVR-50 and Sun XVR-100 hardware configuration.

This is a typical display:

--- Hardware Configuration for /dev/fbs/pfb0 ---

Type: XVR-100
ASIC: version 0x5159 REV : version 0x3000000
PROM: version 4.2

Monitor/Resolution Information:
EDID Data: Not Available
Current resolution setting: 1152x900x66

Depth Information:
Possible depths: 8, 24
Current depth: 8

-res video-mode [ now | try [ noconfirm | nocheck ]]
Specify the video mode that drives the monitor connected to the specified XVR-50 or Sun XVR-100 device.

Video modes are built-in. The -res option requires you to specify the video-mode. You can specify video-mode in the format of widthxheightxrate or as a symbolic name.

video-mode Specify video-mode in the format of widthxheightxrate, where width is the screen width in pixels, height is the screen height in pixels, and rate is the vertical frequency of the screen refresh. An example video mode specified in this format is 1280x1024x60.

The -res option also accepts formats with @ preceding the refresh rate instead of x (1280x1024@60).

Symbolic Names Some video modes have symbolic names defined for them. Instead of the form widthxheightxrate format, you can specify one of the symbolic names as the argument to the -res option. The meaning of the symbolic name “none” is that when the window system is run the screen resolution is the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

<table>
<thead>
<tr>
<th>Name</th>
<th>Corresponding Video Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>svga</td>
<td>1024x768x60</td>
</tr>
</tbody>
</table>
Some video-modes, supported by XVR-50 and Sun XVR-100, might not be supported by the monitor. Use the -res \? option to obtain the list of video-modes supported by the XVR-50 and Sun XVR-100 device and the monitor.

The -res option also accepts additional, optional arguments immediately following the video mode specification. The following additional, optional arguments are supported:

- **nocheck**
  If present, the normal error checking based on the monitor sense code is suspended. The video mode specified by the user is accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the XVR-50 or the Sun XVR-100 device. Use of this option implies noconfirm as well.

- **noconfirm**
  You could put the system into an unusable state using the -res option, which has no video output. To reduce the chance of this, the default behavior of SUNWpfb_config is to print a warning message and to ask the user whether to continue. The noconfirm option bypasses this confirmation. This option is useful when you are running SUNWpfb_config from a shell script.

- **now**
  If present, updates the video mode in the OWconfig file and immediately programs the XVR-50 or Sun XVR-100 device to display this video mode. This is useful for changing the video mode before starting the window system.

  Do not use this suboption with SUNWpfb_config while the configured device is being used (for example, while running the window system) as unpredictable results can occur.

  If you want to run SUNWpfb_config with the now suboption, first bring the window system down, and executed from the console command line. If you use the now option within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is discouraged.

- **try**
  If present, programs the specified video mode on a trial basis. You are asked to confirm the video mode by entering a y within 10 seconds. You can terminate the trial before 10 seconds by entering any character but y or <RETURN>.
This sub-option should not be used with SUNwpfbconfig while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run SUNwpfbconfig with the try sub-option, the window system should be brought down first, and executed from the console command line.

-res 
- Print a list of defined video-mode names.

**Defaults**

For a given invocation of SUNwpfb_config command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the windows system is run, if a XVR-50 or Sun XVR-100 option has never been specified by SUNwpfb_config, a default value is used. The options and their corresponding defaults for a XVR-50 are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dev</td>
<td>/dev/fb</td>
</tr>
<tr>
<td>-file</td>
<td>machine</td>
</tr>
<tr>
<td>-res</td>
<td>none</td>
</tr>
<tr>
<td>-fake8</td>
<td>disable</td>
</tr>
<tr>
<td>-g</td>
<td>disable</td>
</tr>
</tbody>
</table>

The options and their corresponding defaults for a Sun XVR-100 are as follows:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>-dev</td>
<td>/dev/fb</td>
</tr>
<tr>
<td>-file</td>
<td>machine</td>
</tr>
<tr>
<td>-res</td>
<td>none</td>
</tr>
<tr>
<td>-fake8</td>
<td>disable</td>
</tr>
<tr>
<td>-g</td>
<td>disable</td>
</tr>
<tr>
<td>-depth</td>
<td>8 (Solaris 8 and Solaris 9)</td>
</tr>
<tr>
<td>-doublewide</td>
<td>disable</td>
</tr>
<tr>
<td>-doublehigh</td>
<td>disable</td>
</tr>
<tr>
<td>-outputs</td>
<td>direct</td>
</tr>
<tr>
<td>-offset</td>
<td>[0,0]</td>
</tr>
</tbody>
</table>

The default for the -res option none means that when the window system is run, the screen resolution will be the video mode that is currently programmed in the XVR-50 or Sun XVR-100 PROM.

This provides compatibility for users who are used to specifying the device resolution through the XVR-50 or the Sun XVR-100 PROM. On some devices (e.g. GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default XVR-50 or Sun XVR-100 video mode.
Examples

EXAMPLE 1  Switching the Monitor Type

The following example switches the monitor type to the resolution of 1280 × 1024 at 60 Hz:

eample% fbconfig --res 1280x1024x60

Files

/dev/fbs/pfb
Device special file for XVR-50 or Sun XVR-100 single screen

/dev/fbs/pfbna
Device special file for the Sun XVR-100 first video out

/dev/fbs/pfbnb
Device special file for the Sun XVR-100 second video out

/usr/lib/fbconfig/SUNWpfb_config
Device special file

```

**Description**

SUNWzulu_config is the Sun XVR-4000 Graphics Accelerator device-dependent layer for fbconfig(1M). It configures the Sun XVR-4000 Graphics Accelerator and some of the X11 window system defaults and some interactions with 3D-accelerated graphics (through OpenGL).

The first through third synopses, above, show the general form of a SUNWzulu_config command. The fourth synopsis (with -res as the first option) shows card options. The fifth synopsis is for managed-area options. The sixth and last synopsis shows stream options. These option categories—card, managed-area, and streams—are used mainly to explain the SUNWzulu_config functions. Where appropriate, you can use options of different types on the same command line.

The Sun XVR-4000 device can support one or two unique video streams (called stream a and stream b), each of which can drive a display device.

**Option Classes**

The many options that fbconfig can select on the Sun XVR-4000 Graphics Accelerator are divided into the following categories:

- **general options**
  Shared among different invocation forms or used for query without selecting device settings.
card options          Of the entire XVR-4000 Graphics Accelerator, shared between up
to two video streams.

managed area options  Pertain to an area of the frame buffer managed by X and possibly
shared between two video streams.

stream options        Specific to a video stream.

To use the device to provide a single X managed area with one video stream, use a
stream-independent device argument (for example, -dev zulu0) without a trailing a or b. The
device name (for example, /dev/fb or /dev/fbs/zulu0), without any trailing stream
indicator should appear on the Xsun command line. Stream options will control stream a (the
only stream used).

To enable two streams from a single X managed area (without needing X’s +xinerama option),
use the device name (for example, -dev zulu0) without any trailing a or b. Enable card option
.doublewide or .doublehigh. Without using the .stream option, any stream options you
specify are applied to both streams. Stream options can differ between the video streams if
fbconfig is be run separately for each stream, using the .stream a | b option, as shown in
EXAMPLES (second example), below.

To use the device’s two streams as independent X screens, run fbconfig separately for each
stream ( -dev zulu0a and -dev zulu0b), as shown in EXAMPLES (third example). Card
options .doublehigh and .doublewide are not available. The device names with trailing
stream indicators (for example, /dev/fbs/zulu0a and /dev/fbs/zulu0b) must be added to
the Xsun command line to use these independent X screens. The .stream option is not
needed; the stream is implied by the stream-specific device name.

The fbconfig utility checks settings for the two stream devices to assure X can use them
simultaneously. Therefore, you might need to use fbconfig to reduce resource consumption
(for example, .samples) used by one stream’s device (for example, zulu0a) before you can use
fbconfig to increase consumption by the other stream’s device (for example, zulu0b).

The first form of SUNWzulu_config shown in SYNOPSIS, above, stores the specified options in
the OWconfig file associated with the device and (for stream options) the stream. These
options are used to initialize the device the next time the window system is started on that
device-filename. Updating options in the OWconfig file provides persistence of these options
across window system sessions and system reboots. You can select the OWconfig file that is to
be updated using the .file option. For .jitter and all stream options, the device will also be
immediately programmed.

The second form, which invokes any of the .prconf and .propt options, queries the device
for status that is card-specific.
The third form, which invokes the `-help`, `-list`, or `-res` options, provides instruction on using SUNWzulu_config, a list of available devices, or a list of available resolutions. When using this form, all other options are ignored.

You can specify options for only one device at a time. Specifying options for multiple devices (or multiple independent X managed areas or streams) requires multiple invocations of `fbconfig`.

Only Sun XVR-4000 Graphics Accelerator-specific options can be specified through SUNWzulu_config. Window system options for specifying default depth, default visual class, `-nobanner`, and so forth are still specified as device modifiers on the Xsun command line when the X server is started, probably in CDE’s `xservers` file. See the `Xsun(1)` man page in the OpenWindows man page collection and `/usr/dt/config/Xservers`.

This section is subdivided into general, card, managed area, and stream options.

**Options**

### General Options

- `-dev device-filename` Specifies the device’s special file, such as `/dev/fbs/zulu0` or the basename such as `zulu0` as a shorthand. The default is `/dev/fb`. See “Device Usage and Invocation Forms,” above.

- `-file machine|system` Specifies which OWconfig file to update. If `machine` is specified, the machine-specific OWconfig file in the `/etc/openwin` directory tree is updated. If `system` is specified, the global OWconfig file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is `machine`.

- `-defaults` Resets all option values to their default values, listed in the DEFAULTS section, below. For example, invoking `-defaults` on `zulu0`, `zulu0a`, or `zulu0b` will reset all card, managed area, and stream options for all these `zulu0` subdevices.

- `-propt` Displays the current values of all options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Displays the values of options as they will be in the OWconfig file after the call to SUNWzulu_config completes. The following is an example display:

```
--- OpenWindows Configuration for /dev/fbs/zulu0 ---

OWconfig File: machine

Card:

    Double(wide/high): disable
    Stream to Port Mapping: direct (Stream A to Port A; B to B)
    Clearpixel Value: 255

Managed Area:
```

---
Resolution: SUNW_STD_1280x1024x76
Samples Per Pixel: max
Multisample Mode: forceon
Jitter Table: auto

Video Streams:
Stream A:
  Offset (x,y): (0, 0)
  Gamma Correction Value: 2.22
  Filter Type: mitchell

Stream B:
  Offset (x,y): (0, 0)
  Gamma Correction Value: 2.22
  Filter Type: mitchell

Framelock:
  Framelock/Stereo Port: Output from Stream A
  Stream A Sync: Free Run (no frame sync)
  Stream B Sync: Free Run (no frame sync)

-prconf
Displays the current XVR-4000 hardware configuration, including version numbers of each class of chip. The following is an example display:

--- Hardware Configuration for /dev/fbs/zulu0 ---
Type: XVR-4000 Graphics Accelerator
Part: 501-5588

Memory:
  MAJC: 128MB
  Texture: 1GB total
  3DRAM64: 10.0M samples

Versions:
  Fcode 1.19  MCode 1.4  MAJC 2.1
  FBC3 3.0  Master 1.0  Convolve 0.0
  Sched 1.0  I/O 1.0  FPGA 0.0

Power Level:
  Monitor Power: On
  Board Power: On

Video Streams:
Stream A:
  Current resolution setting: SUNW_STD_1280x1024x76
  Flags: Allocated Default Primary
  Samples per pixel: 6
Stream B:
Current resolution setting: SUN_W_STD_1280x1024x76
Flags: Allocated
Samples per pixel: 2
Port: 13W3b
Monitor/EDID data (13W3)
Monitor Manufacturer: SUN
EDID: Version 1, Revision 3

-hel[p  Displays a list of the SUNWzulu_config command line options, along with a brief explanation of each.

-res\? Displays list of defined video mode names supported by the XVR-4000 Graphics Accelerator and the display device.

Card Options  -doublewide enable|disable This option makes it easy for you to combine both streams into one side-by-side virtual display. When enabled with -outputs direct, stream a is to the left of stream b. Both streams will use the same video mode defined with the -res option. If you specify disable, only stream a will be enabled. Enabling -doublewide disables -doublehigh.

-doublehigh enable|disable This option makes it easy for you to combine both streams into one virtual display with one display device above the other. When enabled with -outputs direct, stream a is above stream b. Both streams will use the same video mode defined with the -res option. If you specify disable, only stream a will be enabled. Enabling -doublehigh disables -doublewide.

-outputs direct|swapped|streamA|streamB Controls the internal routing of video streams to output ports (that is, backplane 13W3 connectors). The choices are:
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>direct</code></td>
<td>Stream a to output port a, stream b to output port b</td>
</tr>
<tr>
<td><code>swapped</code></td>
<td>Stream a to output port b, stream b to output port a</td>
</tr>
<tr>
<td><code>streamA</code></td>
<td>Stream a to both output ports</td>
</tr>
<tr>
<td><code>streamB</code></td>
<td>Stream b to both output ports</td>
</tr>
</tbody>
</table>

The default is `direct`. `swapped` can be used to reverse the connectors when `-doublewide` or `-doublehigh` is enabled. The `streamA` and `streamB` arguments are incompatible with stream-specific device names (for example, `zulu0a` or `zulu0b`). When the `-res` option selects an S-video (NTSC or PAL composite) video mode, the svideo output port is automatically selected, sometimes overriding `-outputs` selection.

- `-master a | b`  
  This option controls which stream drives the FIELD and FRAME_OUT pins on the device's stereo/sync connector. This pin can drive stereo shutter glasses, and allow another device to framlock to this device's output. The default is a.

Independent of this option, the `-slave` external option allows a stream to sync to another card by means of this connector's FIELD_IN pin.

- `-clearpixel 0 | 255`  
  Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is 255 (all bits 1), but some applications require 0. All other color indices display a colormap color.

**Managed Area Options**  

- `-res video_mode`  
  The `video_mode` argument specifies resolution and timing information for the display (for example,
The naming convention for the video mode specifier is:

*origin_type_widthxheightxrate*

The elements of the specifier are described as follows:

**origin**  
This can be one of:

- **SUNW**  Sun-derived resolution
- **VES**  Video Electronics Standards Association-derived resolution
- **other**  other source

**type**  
This can be one or more of:

- **STD**  normal resolution, usable by most display devices
- **DIG**  resolution tuned only for LCD flat panels
- **INT**  interlaced
- **STEREO**  stereo

**width**  
screen width in pixels

**height**  
screen height in pixels

**rate**  
vertical frequency of the screen refresh (in hertz, that is, video frames per second)

Note that some video modes supported by the XVR-4000 might not be supported by the display device. The list of video modes supported by the device and the display device can be obtained by running `SUNWzulu_config` with the `-res \?` option.

**-multisample available|disable|forceon**  
The `-multisample` option controls whether a multisample buffer is allocated.
by the window system and used by OpenGL applications. The suboptions are:

- `disable` No multisample rendering is possible. Only one sample per pixel is allocated, despite the `-samples` option value. Furthermore, display filtering is disabled.

- `available` Multisample is possible but is selected on a per-application basis. (Each process may choose whether to multisample at the density allocated when the window system started, or not to multisample at all. Intermediate densities are not possible.)

- `forceon` Sun OpenGL will use multisample rendering for all applications. There may be a minor performance penalty for rendering at higher sample densities.

Multisample allocation occurs when the window system starts up. This is the only allocation mode supported on the Sun XVR-4000 Graphics Accelerator.

- `-samples samples-per-pixel` Specifies the number of samples per pixel to allocate when multisample is not `disable`. Allowable choices are 1 to 16 or `max`, but a very high sample density can be allocated only at low resolution. Setting sample density to 1 is not equivalent to disabling multisampling; samples will still be subject to filtering and jitter. Sample resolutions (without frame rates) and their maximum sample densities follow.
The default is `max`, which means to use the maximum number of samples that can be supported with the amount of memory available, possibly dependent on the video timing (horizontal frequency).

For dual independent streams, if the first stream used by the window system (typically, the first in the `Xservers` file) chooses `max`, it takes most of the memory and video resources. The second stream can then use only a low sample density. If it also chooses `max`, X automatically finds the highest sample density remaining, such as 1 or 2 samples per pixel. To assign sample density more evenly, set each stream’s density explicitly. `SUNWzulu_config` allows a combination of resolutions and sample densities only if they will coexist successfully. You might have to reduce one stream’s sample density (or choose `max`) before you can increase the other stream’s.

```
-jitter regular|random|permutated|auto
```

Indirectly determines the subpixel (X,Y) locations of the samples stored in the...
sample buffer. (The sample density also affects the sample locations.) Choices are:

- **regular**: Samples are regularly-spaced both vertically and horizontally. The sample locations repeat every pixel or two in X and Y.

- **random**: Samples are pseudo-randomly (irregularly) spaced within the pixel. The sample locations repeat every 2 pixels in X and Y.

- **permuted**: Samples are pseudo-randomly spaced within the pixel, and also permuted (stirred) in hardware so that the sample locations repeat every 128 pixels in X and Y. At moderate to high sample density, this choice can improve visual quality. At low sample density, straight lines or edges can appear jagged.

- **auto**: Automatically selects the best jitter option for the current sample density. This is the default.

The same jitter selection must be used by OpenGL when rendering and by the display subsystem when refreshing the display from the sample buffer. The jitter value is changed immediately in hardware, but any multisamples already in the sample buffer were rendered using the prior jitter selection; that will look incorrect (for example, unstraight lines or edges) if the jitter selection is changed.
When a new OpenGL application starts up, it will render using the new jitter selection. (The window system need not be restarted.) The jitter value is also saved in the OWconfig file for the next time the window system starts.

Stream Options -stream a|b
Determine whether stream options will be set for stream a or stream b. The "Device Usage and Invocation Forms" section, above, describes the usage and the default. The -stream option is required only to set different stream options for the two video streams enabled using card option -doublewide or -doublehigh.

-filter cylinder|gaussian|mitchell|catmull
-filter_file filter_filename
There are two ways to configure filtering. The -filter option is the simpler. It selects from these predefined filters:

cylinder Poorest visual quality, most like a box filter.

 gaussian Blurriest; suitable for users who want to forgo detail to avoid all visible sampling artifacts.

 mitchell The best photo-realistic compromise between sharp detail and noticeable blurriness. This filter is the default.

catmull The Catmull-Rom filter produces images a little sharper than Mitchell, but are more likely to have visible sampling artifacts, widely known as "jaggies".

The -filter_file option allows a user to provide his own filter by producing a filter file and copying or linking it into the directory /etc/openwin/server/etc/filters or /usr/openwin/server/etc/filters. (Both directories are writable by super-user by default.) The filter_filename must not start with / or ../ nor contain the substring /../, but can contain subdirectory components.

fbconfig and X search the directories above in the order listed. If the filter_filename is present and valid, the file takes precedence over a predefined filter.

The format of the file is a sequence of floating-point radius and weight values, each value separated by whitespace. Radius values must be monotonically increasing from 0. Weight values must be between -1.0 and +1.0, inclusive. Though more values can be present in the file, only values through radius 2.0 are used. Whitespace and comment lines prefixed with a hash mark (#) are ignored.

Example files contain the (irregular) radius values for which the device uses weight values. The file reader interpolates between existing values if the required radius is not present.
A valid filter option is changed immediately in hardware and saved in the OWconfig file for the next time the window system starts. However, when multisample is disabled, no filtering occurs.

-offset xoff-value yoff-value
Offsets the display of the stream (specified by -stream) relative to the adjoining edge of the other stream when doublewide or doublehigh is enabled. This can be used to cause an overlap.

xoff-value Number of pixels offset in horizontal direction for the righthand stream when doublewide is enabled. Positive direction is to the right (create a gap); negative is to the left (overlap the streams). Default is 0, which means the two edges abut.

yoff-value Number of pixels offset in vertical direction for the bottom stream when doublehigh is enabled. Positive direction is down (create a gap); negative is up (overlap the streams). Default is 0, which means the two edges touch.

-g gamma-correction-value
This option changes the gamma correction value. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using gamma-corrected visuals. The gamma correction value is also saved in the OWconfig file for the next time the window system starts.

-slave [enable | disable]
[framelock [internal | external] | genlock | bothlock]
This option allows you to enable a synchronization technique for the specified stream. Available techniques:

framemlock [internal | external] This provides "asynchronous frame reset": multiple streams all start a frame at roughly the same time. This allows stereo shutters to view the same eye's image from all the synchronized display devices. Using framemlock requires the incoming synchronization signal have the same frame rate as the stream's video format.

When using framemlock (or bothlock), you can also specify the synchronization source:

internal Indicates that the sync source is the other stream of this device.

external Indicates the sync is taken from a source outside the device. Using external requires a Frame Lock Cable (part number 530-2754) to be
connected. If -slave enable is used without specifying a technique, framelock external is used.

genlock
This provides pixel-accurate horizontal synchronization, which is important in some video mixing situations. Use of genlock requires a genlock cable. Use of both lock is recommended, when possible. Certain video formats are incompatible with genlock.

both lock
This enables both framelock and genlock techniques, and requires both framelock (if external) and genlock cables.

-genlock [defaults] [hphase ±hphs][vphase ±vphs]
[sync [auto][tip][tri][slice]][ pol [ auto][pos][neg ]]
When -slave is enabled and the genlock technique is selected, the selections chosen with the -genlock option determine genlock details. These details are used immediately by the hardware, and saved in the OWconfig file for future use. Note that they may no longer be desired after changing to a different video format.

defaults
Reset all genlock details to their defaults.

hphase ±hphs
The horizontal phase allows a pixel offset between the external video format and the stream's output. It may be specified as an absolute integer ranging from 0 to the total number of pixel clocks in a horizontal period (active video plus blanked pixels). Or, if the hphs starts with a + or -, the value will be added to the current horizontal phase and and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

vphase ±vphs
The vertical phase allows a scanline offset between the external video format and the stream's output. It can be specified as an absolute integer ranging from 0 to the total number of scanlines in a frame (active video plus blanked scanlines). Or, if the vphs starts with a + or -, the value will be added to the current vertical phase and and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

sync [auto][tip][slice][tri]
This option controls the details of input sync signal sampling, if necessary:

auto Sample the genlock input pulses as most appropriate for the (Sun) video format. This is
the default, and should be used whenever the sync master is also a Sun video format.

tip Consider the sync to have occurred at the minimum signal value. This can be used with RS-170 (NTSC or PAL) or with TTL signals.

slice Consider the frame sync to have occurred halfway between the minimum and maximum value (sync tip and back porch "blank" levels). This can be used with RS-170 (NTSC or PAL) or with TTL signals.

tri Synchronize to a tri-level signal, used by HDTV analog formats.

pol [auto|pos|neg] When the sync master is not a Sun video format, it might be necessary to choose which edge of the genlock input sync pulse should be used for genlock.

auto Choose rising or falling edge for sync pulse, whichever is most appropriate for the video format. This is the default, and should be used whenever the sync master is also a Sun video format.

pos Synchronize with a rising edge of a sync pulse.

neg Synchronize with a falling edge of a sync pulse.

Defaults For a given invocation of SUNWzulu_config, if an option does not appear on the command line, the corresponding OWconfig option is not updated. It retains its previous value.

When the window system starts, if an option has never been specified through SUNWzulu_config, a default value is used. The option defaults are as follows:

<table>
<thead>
<tr>
<th>Option Class</th>
<th>Option</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>General</td>
<td>-dev</td>
<td>/dev/fb</td>
</tr>
<tr>
<td>General</td>
<td>-file</td>
<td>machine (/etc/openwin/server/etc/OWconfig)</td>
</tr>
<tr>
<td>Card</td>
<td>-doublewide</td>
<td>disable</td>
</tr>
<tr>
<td>Card</td>
<td>-doublehigh</td>
<td>disable</td>
</tr>
<tr>
<td>Card</td>
<td>-master</td>
<td>a</td>
</tr>
<tr>
<td>Card</td>
<td>-outputs</td>
<td>direct</td>
</tr>
<tr>
<td>Card</td>
<td>-clearpixel</td>
<td>255</td>
</tr>
<tr>
<td>Managed Area</td>
<td>-res</td>
<td>SUNW_STD_1280x1024x76</td>
</tr>
</tbody>
</table>
Examples

**EXAMPLE 1  Switching Resolution of a Monitor**
The following example switches to the resolution of 1280 by 1024 at 76 hertz:

```
% fbconfig -dev zulu0 -res SUNW_STD_1280x1024x76
```

**EXAMPLE 2  Using Two Side-by-side Monitors with One Large X Screen**
The following example enables use of two side-by-side monitors to display together a single
large shared X window system "screen" (frame buffer managed area):

```
% fbconfig -dev zulu0 -doublewide enable
```

If the wrong monitor is on the left, they can be swapped in software:

```
% fbconfig -dev zulu0 -outputs swapped
```

A stream option selects a Gaussian (blurry) filter for video stream b:

```
% fbconfig -dev zulu0 -stream b -filter gaussian
```

For the two examples above, the factory-installed /usr/dt/config/Xservers file is sufficient
(if /dev/fb is a link to the Sun XVR-4000 Graphics Accelerator device). If an
/etc/dt/config/Xservers file exists, for Example 1 or 2, the file would refer to device zulu0
(not zulu0a or zulu0b):

```
:0 Local local_uid@console root /usr/openwin/bin/Xsun -dev /dev/fbs/zulu0
```

**EXAMPLE 3  Using Two Displays as Independent X Screens**
The following example enables use of two displays, each with their own X window system
managed frame buffer area and resolution. The larger resolution is not multisampled or
filtered, so the smaller resolution will have more samples available to it.

```
% fbconfig -dev zulu0a -res SUNW_STD_1920x1200x75 -multisample disable
% fbconfig -dev zulu0b -res SUNW_STD_1280x1024x76 -samples max
```

In this example, and assuming the display device for stream b is to the right of that for stream
a, the /etc/dt/config/Xservers file might contain (as one long line):

```
EXAMPLE 3  Using Two Displays as Independent X Screens  (Continued)

:: Local local_uid@console root /usr/openwin/bin/Xsun -nobanner
   -dev /dev/fbs/zulu0a -dev /dev/fbs/zulu0b right

Files  /dev/fb                     default device file
       /usr/lib/fbconfig/SUNWzulu_config  device configuration program
       /etc/openwin/server/etc/filters/   root file system directory for filter files
       /usr/openwin/server/etc/filters/  /usr file system directory for filter files

An administrator might also have to edit /etc/dt/config/Xservers.

**Name**  
svcadm – manipulate service instances

**Synopsis**  
```
/usr/sbin/svcadm [-v] enable [-rst] {FMRI | pattern}...
/usr/sbin/svcadm [-v] disable [-st] {FMRI | pattern}...
/usr/sbin/svcadm [-v] restart {FMRI | pattern}...
/usr/sbin/svcadm [-v] refresh {FMRI | pattern}...
/usr/sbin/svcadm [-v] clear {FMRI | pattern}...
/usr/sbin/svcadm [-v] mark [-It] instance_state
   {FMRI | pattern}...
/usr/sbin/svcadm [-v] milestone [-d] milestone_FMRI
```

**Description**  
svcadm issues requests for actions on services executing within the service management facility (see `smf(5)`). Actions for a service are carried out by its assigned service restarter agent. The default service restarter is `svc.startd` (see `svc.startd(1M)`).

**Options**  
The following options are supported:

- `-v`  
Print actions verbosely to standard output.

**Subcommands**

**Common Operations**  
The subcommands listed below are used during the typical administration of a service instance.

For subcommands taking one or more operands, if the operand specifies a service (instead of a service instance), and that service has only a single instance, `svcadm` operates on that instance. If an abbreviated FMRI (a fault management resource identifier) or pattern matches more than one service, a warning message is displayed and that operand is ignored. See `smf(5)`.

In the case that the service has more than one instance, `svcadm` return a non-zero exit status.

- `enable [-rst] [FMRI | pattern]...`  
Enables the service instances specified by the operands. For each service instance, the assigned restarter will try to bring it to the online state. This action requires permission to modify the "general" property group of the service instance (see `smf_security(5)`).

  If the `-r` option is specified, `svcadm` enables each service instance and recursively enables its dependencies.

  If the `-s` option is specified, `svcadm` enables each service instance and then waits for each service instance to enter the online or degraded state. `svcadm`
will return early if it determines that the service cannot reach these states without administrator intervention.

If the -t option is specified, svcadm temporarily enables each service instance. Temporary enable only lasts until reboot. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)). By default, enable is persistent across reboot.

disable [-st] [FMRI|pattern]...

Disables the service instance specified by the operands. For each service instance, the assigned restarter will try to bring it to the disabled state. This action requires permission to modify the "general" property group of the service instance (see smf_security(5)).

If the -s option is specified, svcadm disables each service instance and then waits for each service instance to enter the disabled state. svcadm will return early if it determines that the service cannot reach this state without administrator intervention.

restart [FMRI|pattern]...

Requests that the service instances specified by the operands be restarted. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)).

This subcommand can restart only those services that are in the online or degraded states, as those states are defined in smf(5).

refresh [FMRI|pattern]...

For each service instance specified by the operands, requests that the assigned restarter update the service's running configuration snapshot with the values from the current configuration. Some of these values take effect immediately (for example, dependency changes). Other values do not take effect until the next service restart. See the restarter and service documentation for more information.
If the service is managed by `svc.startd(1M)`, the refresh method will be invoked if it exists to request the service reread its own configuration. For other restarters, see the recharger documentation.

This action requires permission to modify the "recharger_actions" property group of the service instance (see `smf_security(5)`).

`clear [FMRI | pattern]...` For each service instance specified by the operands, if the instance is in the maintenance state, signal to the assigned recharger that the service has been repaired. If the instance is in the degraded state, request that the assigned recharger take the service to the online state. This action requires permission to modify the "recharger_actions" property group of the service instance (see `smf_security(5)`).

Exceptional Operations

The following subcommands are used for service development and temporary administrative manipulation.

`mark [-It] instance_state [FMRI | pattern]...` If `instance_state` is "maintenance", then for each service specified by the operands, `svcadm` requests that the assigned recharger place the service in the maintenance state. See `svc.startd(1M)` and `inetd(1M)` for a detailed description of the actions taken for each recharger.

If `instance_state` is "degraded", then for services specified by the operands in the online state, `svcadm` requests that the restarters assigned to the services move them into the degraded state.

If the `-I` option is specified, the request is flagged as immediate.

The `-t` option is only valid for maintenance requests. When this option is specified, the request is flagged as temporary, and its effect will only last until the next reboot.

`milestone [-d] milestone_FMRI` If `milestone_FMRI` is the keyword "none", all services other than the master recharger,
If `milestone_FMRI` is the keyword "all", temporary enable and disable requests for all services will be nullified.

If `milestone_FMRI` is one of the following:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

then temporary enable and disable requests for the indicated service and all services it depends on (directly or indirectly) will be nullified. All other services will be temporarily disabled.

Changing the system's current milestone with the "milestone" subcommand will not change the current run level of the system. To change the system's run level, invoke `/sbin/init` directly.

This action requires permission to modify the "options_ovr" property group of the svc:/system/svc/restarter:default service instance (see `smf_security(5)`).

The -d option immediately changes the milestone to the requested milestone, as above. Additionally, it makes the specified milestone the default boot milestone, which persists across reboot. The default milestone is defined by the options/milestone property on the master restarter, svc:/system/svc/restarter:default. If this property is absent, "all" is the default. This action requires permission to modify the "options" property group of the svc:/system/svc/restarter:default service instance (see `smf_security(5)`).
The following operands are supported:

**FMRI**  
An FMRI that specifies one or more instances. FMRIs can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the FMRI:

```
svc:/network/smtp:sendmail
```

All the following are valid abbreviations:

```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```

While the following are invalid:

```
mail
network
network/smt
```

If the FMRI specifies a service, then the command applies to all instances of that service. Abbreviated forms of FMRIs are unstable, and should not be used in scripts or other permanent tools.

**pattern**  
A pattern that is matched against the FMRIs of service instances according to the “globbing” rules described by `fnmatch(5)`. If the pattern does not begin with “svc:”, then “svc:/” is prepended.

If an abbreviated FMRI or pattern matches more than one service, a warning message is displayed and that operand is ignored.

**Examples**

**EXAMPLE 1**  
Restarting a Service Instance

The following command restarts the NFS server. The full FMRI for the default service instance is: `svc:/network/nfs/server:default`

However, you can abbreviate the full FMRI as follows:

```
# svcadm restart nfs/server
```

**EXAMPLE 2**  
Disabling the Standard HTTP Server

The following command disables the standard HTTP server, using an abbreviated FMRI:

```
$ svcadm disable http
```
Enabling an Instance and Its Dependent Instances

The following command enables the foo:bar instance, and all instances on which it depends:

```
$ svcadm enable -r foo:bar
```

Synchronously enabling an instance

The following command enables the foo:bar instance. The command will not return until the instance comes online or `svcadm` determines it is not possible for the service to come online.

```
$ svcadm enable -s foo:bar
```

Restricting and Restoring the Running Services

The following command restricts the running services to single user mode:

```
# svcadm milestone milestone/single-user
```

The following command restores the running services:

```
# svcadm milestone all
```

**Exit Status**

The following exit values are returned:

- **0**  
  Successful completion.

- **1**  
  A fatal error occurred. One or more error messages are displayed on standard error.

- **2**  
  Invalid command line options were specified.

- **3**  
  `svcadm` determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service instance itself.

- **4**  
  `svcadm` determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service’s dependencies.

**Attributes**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.
The amount of time `svcadm` will spend waiting for services and their dependencies to change state is implicitly limited by their method timeouts. For example, a service using the default restarter whose start method hangs will be transitioned to the maintenance state when its timeout expires. `svcadm` will then consider it impossible for this service to come online without administrator intervention.

Attempts to synchronously enable a service which depends (directly or indirectly) on a file may fail with an exit status indicating that dependencies are unsatisfied if the caller does not have the privileges necessary to search the directory containing the file. This limitation may be removed in a future Solaris release.
svccfg(1M)

Name
svccfg – import, export, and modify service configurations

Synopsis
/usr/sbin/svccfg [-v] [-s FMRI]

/usr/sbin/svccfg [-v] [-s FMRI] subcommand [args]...

/usr/sbin/svccfg [-v] [-s FMRI] -f command-file

Description
The svccfg command manipulates data in the service configuration repository. svccfg can be
invoked interactively, with an individual subcommand, or by specifying a command file that
contains a series of subcommands.

Changes made to an existing service in the repository typically do not take effect for that
service until the next time the service instance is refreshed. See the refresh subcommand on
the svcadm(1M) man page for more details.

Options
The following options are supported:

- f command-file
  Reads and executes svccfg subcommands from command-file.

- s FMRI
  Selects the entity indicated by FMRI (a fault management resource identifier) before
executing any subcommands. See smf(5).

- v
  Verbose.

Subcommands
Subcommands are divided into the categories specified in the subsections that follow.

All subcommands that accept FMRIs also accept abbreviated or globed patterns. Instances
and services can be abbreviated by specifying the instance name, or the trailing portion of the
service name. For example, given the FMRI:

svc:/network/smtp:sendmail

All the following are valid abbreviations:

sendmail
:sendmail
smtp
smtp:sendmail
network/smtp

While the following are invalid:

mail
network
network/smt

Abbreviated forms of FMRIs are unstable, and should not be used in scripts or other
permanent tools. If a pattern matches more than one instance or service, an error message is
printed and no action is taken.
General Subcommands

- `end`
- `exit`
- `quit`
  Exits immediately.

Repository `repfile`

- Uses `repfile` as a repository. By default, `svccfg` uses the system repository.

  Use repository only with files from the identical version of Solaris, including patches, that you are currently running. Do not use this subcommand with the system repository, `/etc/svc/repository.db`.

Set `[-v] [-V]`

- Sets optional behavior. If no options are specified, set displays the options currently in effect.
  - `-v`
    - Turns on verbose mode.
  - `-V`
    - Turns off verbose mode.

Service Profile Subcommands

Apply `file`

If file is a service profile, then service instances specified within the file are enabled or disabled according to it. See `smf(5)` for a description of service profiles. This command requires privileges to modify the “general/enabled” property of the service instances. See `smf_security(5)` for the privileges required to modify properties. If file is not a service profile, the subcommand fails.

Extract `[-f] file`

Prints a service profile which represents the enabled status of the service instances in the repository to standard output. The output may be redirected to a file.

Service Manifest Subcommands

Archive

Dumps a full XML service description for all services, instances, and their persistent properties in the repository. This does not include transient properties such as service state, and is suitable for a relocatable repository backup.

Export `service_FMRI [-f] file`

The service description for the specified service and its instances is written to standard output or redirected to the given file. Dependencies with a boolean “external” property set to true are omitted in the belief that they were created on behalf of another service.

Without the `-a` option, property groups containing protected information (identified by the presence of the read_authorization property—see `smf_security(5)`) will be exported without their property values. When the `-a` option is specified, all values will be archived. An error results if there are insufficient privileges to read these values.
Note that `export` requires a service FMRI. If you specify an instance (including an abbreviation, such as `apache2` or `sendmail`, that specifies an instance), the command fails.

**import file**

If `file` is a service manifest, then the services and instances it specifies are imported into the repository. According to the file, dependencies may be created in other services. See `smf(5)` for a description of service manifests. See `smf_security(5)` for the privileges required to create and modify service configurations.

For existing services and instances, properties which have not changed since the last `import` snapshot were taken are upgraded to those specified by the manifest. Conflicts (properties which have been changed both in the repository and the manifest) are reported on the standard error stream. `svccfg` will never upgrade the “general/enabled” and “general/restarter” properties, since they represent administrator preference.

**inventory file**

If `file` is determined to be a service manifest, then the FMRIs of the services and instances the `file` describes are printed. For each service, the FMRIs of its instances are displayed before the FMRI of the service.

**validate file**

`file` is processed similarly to `import`, but no changes are made to the repository. If any errors are detected, `svccfg(1M)` exits with a nonzero exit status.

An “entity” refers to a scope, service, or service instance.

**add name**

A new entity with the given name is created as a child of the current selection. See `smf_security(5)` for the privileges required to create entities.

**delete [-f] {name | fmri}**

The named child of the current selection or the entity specified by `fmri` is deleted. Attempts to delete service instances in the “online” or “degraded” state will fail unless the `-f` flag is specified. If a service or service instance has a “dependents” property group of type “framework”, then for each of its properties with type “astring” or “fmri”, if the property has a single value which names a service or service instance then the dependency property group in the indicated service or service instance with the same name as the property will be deleted. See `smf_security(5)` for the privileges required to delete service configurations.

**list [pattern]**

The child entities of the current selection whose names match the glob pattern `pattern` are displayed (see `fnmatch(5)`). `properties` is also listed for property-bearing entities, namely services and service instances.

**select {name | fmri}**

If the argument names a child of the current selection, it becomes the current selection. Otherwise, the argument is interpreted as an FMRI and the entity that the argument specifies becomes the current selection.
unselect
    The parent of the current selection becomes the current selection.

adpg name type [flags]
    Adds a property group with the given name and type to the current selection. flags is a
    string of characters which designates the flags with which to create the property group. 'P'
    represents SCF_PG_FLAG_NONPERSISTENT (see scf_service_add_pg(3SCF)). See
    smf_security(5) for the privileges required to create property groups.

addpropvalue pg/name [type:] value
    Adds the given value to a property. If type is given and the property exists, then if type does
    not agree with the property's type, the subcommand fails. The values may be enclosed in
    double-quotes. String values containing double-quotes or backslashes must be enclosed by
    double-quotes and the contained double-quotes and backslashes must be quoted by
    backslashes. Nonexistent properties are created, in which case the type specifier must be
    present. See scf_value_create(3SCF) for a list of available property types. See
    smf_security(5) for the privileges required to modify properties.

de10g name
    Deletes the property group name of the current selection. See smf_security(5) for the
    privileges required to delete property groups.

delprop pg[/name]
    Deletes the named property group or property of the current selection. See
    smf_security(5) for the privileges required to delete properties.

delpropvalue pg/name globpattern
    Deletes all values matching the given glob pattern in the named property. Succeeds even if
    no values match. See smf_security(5) for the privileges required to modify properties.

editprop
    Comments of commands to reproduce the property groups and properties of the current
    selection are placed in a temporary file and the program named by the EDITOR
    environment variable is invoked to edit it. Upon completion, the commands in the
    temporary file are executed. The default editor is vi(1). See smf_security(5) for the
    privileges required to create, modify, or delete properties.

listpg [pattern]
    Displays the names, types, and flags of property groups of the current selection. If an
    argument is given, it is taken as a glob pattern and only property groups with names which
    match the argument are listed.

listprop [pattern]
    Lists property groups and properties of the current selection. For property groups, names,
    types, and flags are listed. For properties, names (prepended by the property group name
    and a slash (/)), types, and values are listed. See scf_value_create(3SCF) for a list of
    available property types. If an argument is supplied it is taken as a glob pattern and only
    property groups and properties with names which match the argument are listed.
setenv [-i | -s] [-m method_name] envvar value
Sets a method environment variable for a service or instance by changing the
"environment" property in the method_name property group, if that property group has
type "method". If method_name is not specified and the -i option is used, the
"method_context" property group is used, if an instance is currently selected. If the -s
option is used and a service is currently selected, its "method_context" property group is
used. If the -s option is used and an instance is currently selected, the "method_context"
property group of its parent is used. If neither the -i option nor the -s option is used, the
"start" property group is searched for in the currently selected entity and, if an instance is
currently selected, its parent is also searched. If the "inetd_start" property group is not
located, it is searched for in a similar manner.

Once the property is located, all values which begin with envvar followed by a "=" are
removed, and the value "envvar=value" is added. See smf_security(5) for the privileges
required to modify properties.

setprop pg/name = [type:] value
setprop pg/name = [type:] ([values ...])
Sets the name property of the pg property group of the current selection to the given values
of type type. See scf_value_create(3SCF) for a list of available property types. If the
property already exists and the type disagrees with the existing type on the property, the
subcommand fails. Values may be enclosed in double-quotes. String values which contain
double-quotes or backslashes must be enclosed by double-quotes and the contained
double-quotes and backslashes must be quoted by backslashes. If the named property does
not exist, it is created, as long as the type is specified. See smf_security(5) for the privileges
required to create or modify properties.

unsetenv [-i | -s] [-m method_name] envvar value
Removes a method environment variable for a service or instance by changing the
"environment" property in the method_name property group, if that property group has
type "method". If method_name is not specified and the -i option is used, the
"method_context" property group is used, if an instance is currently selected. If the -s
option is used and a service is currently selected, its "method_context" property group is
used. If the -s option is used and an instance is currently selected, the "method_context"
property group of its parent is used. If neither the -i option nor the -s option is used, the
"start" property group is searched for in the currently selected entity and, if an instance is
currently selected, its parent is also searched. If the "inetd_start" property group is not
located, it is searched for in a similar manner.

Once the property is located, all values which begin with envvar followed by "=" are
removed. See smf_security(5) for the privileges required to modify properties.

listsnap
Displays snapshots available for the currently selected instance.
revert [snapshot]
Reverts the properties of the currently selected instance and its service to those recorded in
the named snapshot. If no argument is given, use the currently selected snapshot and
deselect it on success. The changed property values can be made active via the refresh
subcommand of svcadm(1M). See smf_security(5) for the privileges required to change
properties.

selectsnap [name]
Changes the current snapshot to the one named by name. If no name is specified, deselect
the currently selected snapshot. Snapshots are read-only.

Examples
EXAMPLE 1 Importing a Service Description
The following example imports a service description for the seismic service in the XML
manifest specified on the command line.
# svccfg import /var/svc/manifest/site/seismic.xml

Note that the manifest must follow the format specified in service_bundle(4).

EXAMPLE 2 Exporting a Service Description
To export a service description on the local system:
$ svccfg export dumpadm >/tmp/dump.xml

EXAMPLE 3 Deleting a Service Instance
To delete a service instance:
$ svccfg delete network/inetd-upgrade:default

EXAMPLE 4 Checking Properties in an Alternate Repository
To examine the state of a service’s properties after loading an alternate repository, use the
sequence of commands shown below. One might use such commands, for example, to
determine whether a service was enabled in a particular repository backup.

# svccfg
svc:> repository /etc/svc/repository-boot
svc:> select telnet:default
svc:/network/telnet:default> listprop general/enabled
general/enabled boolean false
svc:/network/telnet:default> exit

EXAMPLE 5 Enabling Debugging
To modify LD_PRELOAD for a start method and enable the use of libumem(3LIB) with
debugging features active:
$ svccfg -s system/service setenv LD_PRELOAD libumem.so
$ svccfg -s system/service setenv UMEM_DEBUG default
EDITOR

The command to run when the editprop subcommand is used. The default editor is vi(1).

Exit Status

The following exit values are returned:

0
    Successful execution.

1
    One or more subcommands resulted in failure. Error messages are written to the standard error stream.

2
    Invalid command line options were specified.

Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>See below.</td>
</tr>
</tbody>
</table>

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.

svc.configd – Service Management Facility repository daemon

**Synopsis**  
/lib/svc/bin/svc.configd

**Description**  
svc.configd is the repository daemon for the Service Management Facility. svc.configd is invoked automatically during system startup, and restarted if any failures occur. svc.configd should never be invoked directly.

Interaction with svc.configd is by way of libscf(3LIB) and the command line tools: svcs(1), svcprop(1), svcadm(1M), and svccfg(1M).

**Attributes**  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>

svcs(1), svcprop(1), svcadm(1M), svccfg(1M), libscf(3LIB), attributes(5)
svc.startd(1M)

Name  svc.startd – Service Management Facility master rearter

Synopsis  /lib/svc/bin/svc.startd
           svc:/system/svc/restarter:default

Description  svc.startd is the master rearter daemon for Service Management Facility (SMF) and the
default rearter for all services. svc.startd starts, stops, and restarts services based on
administrative requests, system failures, or application failures.

svc.startd maintains service state, as well as being responsible for managing faults in
accordance with the dependencies of each service.

svc.startd is invoked automatically during system startup. It is restarted if any failures
occur. svc.startd should never be invoked directly.

See smf_restarter(5) for information on configuration and behavior common to all
restarters.

svcs(1) reports status for all services managed by the Service Configuration Facility.
svcadm(1M) allows manipulation of service instances with respect to the service’s rearter.

Environment Variables

Environment variables with the “SMF_” prefix are reserved and may be overwritten.

svc.startd supplies the “SMF_” environment variables specified in smf_method(5) to
the method. PATH is set to “/usr/sbin:/usr/bin” by default. By default, all other environment
variables supplied to svc.startd are those inherited from init(1M).

Duplicate entries are reduced to a single entry. The value used is undefined. Environment
entries that are not prefixed with “<name>=” are ignored.

Restarter Options  svc.startd is not configured by command line options. Instead, configuration is read from
the service configuration repository. You can use svccfg(1M) to set all options and
properties.

The following configuration variables in the options property group are available to
developers and administrators:

boot_messages
   An astring (as defined in scf_value_is_type; see scf_value_create(3SCF)) that
describes the default level of messages to print to the console during boot. The supported
message options include quiet and verbose. The quiet option prints minimal messages to
console during boot. The verbose option prints a single message per service started to
indicate success or failure. You can use the boot -m option to override the boot_messages
setting at boot time. See kernel(1M).

logging
   Control the level of global service logging for svc.startd. An astring (as defined in
scf_value_is_type; see scf_value_create(3SCF)) that describes the default level of
messages to log to syslog (see syslog(3C) and svc.startd’s global logfile,
The supported message options include quiet, verbose, and debug. The quiet option sends error messages requiring administrative intervention to the console, syslog and svc.startd's global log file. The verbose option sends error messages requiring administrative intervention to the console, syslog and svc.startd's global log file, and information about errors which do not require administrative intervention to svc.startd's global log file. A single message per service started is also sent to the console. The debug option sends svc.startd debug messages to svc.startd's global log file, error messages requiring administrative intervention to the console, syslog and svc.startd's global log file, and a single message per service started to the console.

**milestone**

An FMRI which determines the milestone used as the default boot level. Acceptable options include only the major milestones:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

or the special values all or none. all represents an idealized milestone that depends on every service. none is a special milestone where no services are running apart from the master svc:/system/svc/restarter:default. By default, svc.startd uses all, a synthetic milestone that depends on every service. If this property is specified, it overrides any initdefault setting in init(4).

**system/reconfigure**

Indicates that a reconfiguration reboot has been requested. Services with actions that must key off of a reconfiguration reboot may check that this property exists and is set to 1 to confirm a reconfiguration boot has been requested.

This property is managed by svc.startd and should not be modified by the administrator.

Configuration errors, such as disabling svc.startd are logged by syslog, but ignored.

**SERVICE STATES**

Services managed by svc.startd can appear in any of the states described in smf(5). The state definitions are unmodified by this restarter.

**SERVICE REPORTING**

In addition to any logging done by the managed service, svc.startd provides a common set of service reporting and logging mechanisms.

Reporting properties svc.startd updates a common set of properties on all services it manages. These properties are a common interface that can be used to take action based on service instance health. The svc(1) command can be used to easily display these properties.

```
restarter/state
restarter/next_state
```

The current and next (if currently in transition) state for an instance.
restarter/auxiliary_state
A caption detailing additional information about the current instance state. The auxiliary
state available for services managed by `svc.startd` is:

- maintenance
- fault_threshold_reached
- stop_method_failed
- administrative_request

restarter/state_timestamp
The time when the current state was reached.

restarter/contract
The primary process contract ID, if any, that under which the service instance is executing.

Logs
By default, `svc.startd` provides logging of significant restarter actions for the service as well
as method standard output and standard error file descriptors to
`/var/svc/log/service:instance.log`. The level of logging to system global locations like
`/var/svc/log/svc.startd.log` and `syslog` is controlled by the `options/logging` property.

SERVICE DEFINITION
When developing or configuring a service managed by `svc.startd`, a common set of
properties are used to affect the interaction between the service instance and the restarter.

Methods
The general form of methods for the fork/exec model provided by `svc.startd` are presented
in `smf_method(5)`. The following methods are supported as required or optional by services
managed by `svc.startd`.

refresh
Reload any appropriate configuration parameters from the repository or `config` file, without interrupting service. This is often implemented using `SIGHUP` for system daemons. If the service is unable to recognize configuration changes without a restart, no refresh method is provided.

This method is optional.

start
Start the service. Return success only after the application is available to consumers. Fail if a conflicting instance is already running, or if the service is unable to start.

This method is required.

stop
Stop the service. In some cases, the stop method can be invoked when some or all of the service has already been stopped. Only return an error if the service is not entirely stopped on method return.

This method is required.
If the service does not need to take any action in a required method, it must specify the :true

token for that method.

svc.startd honors any method context specified for the service or any specific method. The
method expansion tokens described in smf_method(5) are available for use in all methods
invoked by svc.startd.

Properties

An overview of the general properties is available in smf(5). The specific way in which these
general properties interacts with svc.startd follows:

general/enabled
   If enabled is set to true, the restarter attempts to start the service once all its dependencies
   are satisfied. If set to false, the service remains in the disabled state, not running.

general/restarter
   If this FMRI property is empty or set to svc:/system/svc/restarter:default, the
   service is managed by svc.startd. Otherwise, the retester specified is responsible (once it
   is available) for managing the service.

general/single_instance
   If single_instance is set to true, svc.startd only allows one instance of this service to
   transition to online or degraded at any time.

Additionally, svc.startd managed services can define the optional properties listed below in
the startd property group.

startd/duration
   The duration property defines the service’s model. It can be set to transient, child also
   known as “wait” model services, or contract (the default).

startd/ignore_error
   The ignore_error property, if set, specifies a comma-separated list of ignored events.
   Legitimate string values in that list are core and signal. The default is to restart on all
   errors.

startd/need_session
   The need_session property, if set to true, indicates that the instance should be launched in
   its own session. The default is not to do so.

startd/utmpx_prefix
   The utmpx_prefix string property defines that the instance requires a valid utmpx entry
   prior to start method execution. The default is not to create a utmpx entry.

SERVICE FAILURE svc.startd assumes that a method has failed if it returns a non-zero exit code or if fails to
complete before the timeout specified expires. If $SMF_EXIT_ERR_CONFIG or
$SMF_EXIT_ERR_FATAL is returned, svc.startd immediately places the service in the
maintenance state. For all other failures, svc. startd places the service in the offline state. If a service is offline and its dependencies are satisfied, svc. startd tries again to start the service (see smf(5)).

If a contract or transient service does not return from its start method before its defined timeout elapses, svc. startd sends a SIGKILL to the method, and returns the service to the offline state.

If five failures happen in a row, or if the service is restarting due to an error more than once every ten minutes, svc. startd places the service in the maintenance state.

The conditions of service failure are defined by a combination of the service model (defined by the startd/duration property) and the value of the startd/ignore_error property.

A contract model service fails if any of the following conditions occur:
- all processes in the service exit
- any processes in the service produce a core dump
- a process outside the service sends a service process a fatal signal (for example, an administrator terminates a service process with the pkill command)

The last two conditions may be ignored by the service by specifying core and/or signal in startd/ignore_error.

Defining a service as transient means that svc. startd does not track processes for that service. Thus, the potential faults described for contract model services are not considered failures for transient services. A transient service only enters the maintenance state if one of the method failure conditions occurs.

"Wait" model services are restarted whenever the child process associated with the service exits. A child process that exits is not considered an error for "wait" model services, and repeated failures do not lead to a transition to maintenance state.

LEGACY SERVICES svc. startd continues to provide support for services invoked during the startup run level transitions. Each /etc/rc?.d directory is processed after all managed services which constitute the equivalent run level milestone have transitioned to the online state. Standard init scripts placed in the /etc/rc?.d directories are run in the order of their sequence numbers.

The milestone to run-level mapping is:
- milestone/single-user Single-user (S)
- milestone/multi-user Multi-user (2)
- milestone/multi-user-server Multi-user with network services (3)
Additionally, svc.startd gives these legacy services visibility in SMF by inserting an instance per script into the repository. These legacy instances are visible using standard SMF interfaces such as svcs(1), always appear in the LEGACY-RUN state, cannot be modified, and can not be specified as dependencies of other services. The initial start time of the legacy service is captured as a convenience for the administrator.

**Files**

/var/svc/log Directory where svc.startd stores log files.
/etc/svc/volatile Directory where svc.startd stores log files in early stages of boot, before /var is mounted read-write.

**Example**

**EXAMPLE 1** Turning on Verbose Logging

To turn on verbose logging, type the following:

```
# /usr/sbin/svccfg -s system/svc/restarter:default
svc:/system/svc/restarter:default> addpg options application
svc:/system/svc/restarter:default> setprop options/logging = \astring: verbose
svc:/system/svc/restarter:default> exit
```

This request will take effect on the next restart of svc.startd.

swap(1M)

Name  swap – swap administrative interface

Synopsis  
/usr/sbin/swap -a  swapname [swaplow] [swaplen]
/usr/sbin/swap -d  swapname [swaplow]
/usr/sbin/swap -l
/usr/sbin/swap -s

Description  The swap utility provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.

Options  The following options are supported:

-a  swapname [swaplow] [swaplen]  
Add the specified swap area. This option can only be used by the superuser or by one who has assumed the Primary Administrator role. swapname is the name of the swap area or regular file. For example, on system running a UFS root file system, specify a slice, such as /dev/dsk/c0t0d0s1, or a regular file for a swap area. On a system running a ZFS file system, specify a ZFS volume, such as /dev/zvol/dsk/rpool/swap, for a swap area. Using a regular file for swap is not supported on a ZFS file system. In addition, you cannot use the same ZFS volume for both the swap area and a dump device when the system is running a ZFS root file system.

swaplow is the offset in 512-byte blocks into the file where the swap area should begin. swaplen is the desired length of the swap area in 512-byte blocks. The value of swaplen can not be less than 16. For example, if \( n \) blocks are specified, then \((n - 1)\) blocks would be the actual swap length. swaplen must be at least one page in length. The size of a page of memory can be determined by using the pagesize command. See pagesize(1). Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a multiple of 2 pagesize bytes. The size of a page of memory is machine-dependent.

swaplow + swaplen must be less than or equal to the size of the swap file. If swaplen is not specified, an area will be added starting at swaplow and extending to the end of the designated file. If neither swaplow nor swaplen are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the /sbin/swapadd script. This script adds all swap areas which have been specified in the /etc/vfstab file; for the syntax of these specifications, see vfstab(4).

To use an NFS or local file system swapname, you should first create a file using mkfile(1M). A local file system swap file can now be added to the running system by just running the swap -a command. For NFS mounted swap files, the server needs to export the file. Do this by performing the following steps:

1. Add the following line to /etc/dfs/dfstab:

   share -F nfs -o \\
   rw=clientname, root=clientname path-to-swap-file
2. Run `shareall(1M)`.

3. Have the client add the following line to `/etc/vfstab`:

```bash
server: path-to-swap-file - local-path-to-swap-file nfs \
    - - - local-path-to-swap-file - - swap - -
```

4. Have the client run `mount`:

```bash
# mount local-path-to-swap-file
```

5. The client can then run `swap -a` to add the swap space:

```bash
# swap -a local-path-to-swap-file
```

- `d swapname`
  Delete the specified swap area. This option can only be used by the super-user. `swapname` is the name of the swap file: for example, `/dev/dsk/c0t0d0s1` or a regular file. `swaplow` is the offset in 512-byte blocks into the swap area to be deleted. If `swaplow` is not specified, the area will be deleted starting at the second page. When the command completes, swap blocks can no longer be allocated from this area and all swap blocks previously in use in this swap area have been moved to other swap areas.

- `l`
  List the status of all the swap areas. The output has five columns:

  ```bash
  path
  The path name for the swap area.
  
  dev
  The major/minor device number in decimal if it is a block special device; zeroes otherwise.
  
  swaplo
  The `swaplow` value for the area in 512-byte blocks.
  
  blocks
  The `swaplen` value for the area in 512-byte blocks.
  
  free
  The number of 512-byte blocks in this area that are not currently allocated.
  
  The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.
  
  If `swap -l` is run while `swapname` is in the process of being deleted (by `swap -d`), the string `INDEL` will appear in a sixth column of the swap stats.

- `s`
  Print summary information about total swap space usage and availability:

  ```bash
  allocated
  The total amount of swap space in bytes currently allocated for use as backing store.
```
reserved
The total amount of swap space in bytes not currently allocated, but claimed by memory
mappings for possible future use.

used
The total amount of swap space in bytes that is either allocated or reserved.

available
The total swap space in bytes that is currently available for future reservation and
allocation.

These numbers include swap space from all configured swap areas as listed by the -l
option, as well swap space in the form of physical memory.

Usage
On the 32-bit operating system, only the first 2 Gbytes -1 are used for swap devices greater
than or equal to 2 Gbytes in size. On the 64-bit operating system, a block device larger than 2
Gbytes can be fully utilized for swap up to \(2^{63} - 1\) bytes.

Environment
Variables
See environ(5) for descriptions of the following environment variables that affect the
execution of swap: LC_CTYPE and LC_MESSAGE.

Attributes
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

largefile(5)

Notes
For information about setting up a swap area with ZFS, see the ZFS Administration Guide.

Warnings
No check is done to determine if a swap area being added overlaps with an existing file system.
Name  sync – update the super block

Synopsis  sync

Description  sync executes the sync system primitive. If the system is to be stopped, sync must be called to ensure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See sync(2) for details.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  sync(2), attributes(5)
The `syncinit` utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package.

If run without options, `syncinit` reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.

**Options**

Options to `syncinit` normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, `loop=` and `loopback=` are equivalent.

The following options are supported:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>loop</code></td>
<td>yes</td>
<td>Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of <code>txc=baud</code> and <code>rxc=baud</code>.</td>
</tr>
<tr>
<td></td>
<td>no</td>
<td>Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of <code>txc=txc</code> and <code>rxc=rxc</code>.</td>
</tr>
<tr>
<td><code>echo</code></td>
<td>yes</td>
<td>Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.</td>
</tr>
<tr>
<td></td>
<td>no</td>
<td>Disable auto-echo mode.</td>
</tr>
<tr>
<td><code>nrzi</code></td>
<td>yes</td>
<td>Set the port to operate with NRZI data encoding.</td>
</tr>
<tr>
<td></td>
<td>no</td>
<td>Set the port to operate with NRZ data encoding.</td>
</tr>
<tr>
<td><code>txc</code></td>
<td><code>txc</code></td>
<td>Transmit clock source will be the TxC signal (pin 15).</td>
</tr>
<tr>
<td></td>
<td><code>rxc</code></td>
<td>Transmit clock source will be the RxC signal (pin 17).</td>
</tr>
<tr>
<td><code>baud</code></td>
<td></td>
<td>Transmit clock source will be the internal baud rate generator.</td>
</tr>
<tr>
<td><code>pll</code></td>
<td></td>
<td>Transmit clock source will be the output of the DPLL circuit.</td>
</tr>
</tbody>
</table>
There are also several single-word options that set one or more parameters at a time:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Equivalent to Options:</th>
</tr>
</thead>
<tbody>
<tr>
<td>external</td>
<td>txc=txc rxc=rxc loop=no</td>
</tr>
<tr>
<td>sender</td>
<td>txc=baud rxc=rxc loop=no</td>
</tr>
<tr>
<td>internal</td>
<td>txc=pll rxc=pll loop=no</td>
</tr>
<tr>
<td>stop</td>
<td>speed=0</td>
</tr>
</tbody>
</table>

### Examples

#### EXAMPLE 1 Using syncinit

The following command sets the first CPU port to loop internally, using internal clocking and operating at 38400 baud:

```bash
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```bash
example# syncinit zsh0 stop loop=no
device: /dev/zsh ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxc=rxc
```

### Attributes

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>

### Diagnostics

- **device** missing minor device number
  - The name device does not end in a decimal number that can be used as a minor device number.
bad speed: arg

The string arg that accompanied the speed= option could not be interpreted as a decimal integer.

Bad arg: arg

The string arg did not make sense as an option.

ioctl failure code = errno

An ioctl(2) system call failed. The meaning of the value of errno may be found in Intro(2).

Warnings
Do not use syncinit on an active serial link, unless needed to resolve an error condition. Do not use this command casually or without being aware of the consequences.
syncloop — synchronous serial loopback test program

/usr/sbin/syncloop [-cdlstv] device

The `syncloop` command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, `syncloop` opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the `device` argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, `syncloop` proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, `syncloop` attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an excoriating message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

```
CRC errors  Aborts  Overruns  Underruns  In<-Drops->  Out
0          0          0          0          0          0
```

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.

**Options**

The options for `syncloop` are described in the following table:
<table>
<thead>
<tr>
<th>Option</th>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>packet_count</td>
<td>100</td>
<td>Specifies the number of packets to be sent in the multiple-packet phase.</td>
</tr>
<tr>
<td>-d</td>
<td>hex_data_byte</td>
<td>random</td>
<td>Specifies that each packet will be filled with bytes with the value of hex_data_byte.</td>
</tr>
<tr>
<td>-l</td>
<td>packet_length</td>
<td>100</td>
<td>Specifies the length of each packet in bytes.</td>
</tr>
<tr>
<td>-s</td>
<td>line_speed</td>
<td>9600</td>
<td>Bit rate in bits per second.</td>
</tr>
<tr>
<td>-v</td>
<td></td>
<td></td>
<td>Sets verbose mode. If data errors occur, the expected and received data is displayed.</td>
</tr>
<tr>
<td>-t</td>
<td>test_type</td>
<td>none</td>
<td>A number, from 1 to 4, that specifies which test to perform. The values for test_type are as follows: 1: Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator). 2: External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test. 3: External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration. 4: Test using predefined parameters. User defines hardware configuration and may select port parameters using the syncinit(1M) command.</td>
</tr>
</tbody>
</table>

All numeric options except -d are entered as decimal numbers (for example, -s 19200). If you do not provide the -t test_type option, syncloop prompts for it.

**Examples**

**EXAMPLE 1** A sample display of using the syncloop command.

In the following command syncloop uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, syncloop prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

**Attributes** See attributes(5) for descriptions of the following attributes:
### Diagnostics

- **device missing minor device number**
  - The name `device` does not end in a decimal number that can be used as a minor device number.

- **invalid packet length: `nnn`**
  - The packet length was specified to be less than zero or greater than 4096.

- **poll: nothing to read**

- **poll: nothing to read or write.**
  - The `poll(2)` system call indicates that there is no input pending and/or that output would be blocked if attempted.

- **len `xxx` should be `yyy`**
  - The packet that was sent had a length of `yyy`, but was received with a length of `xxx`.

- **`nnn` packets lost in outbound queueing**
  - A discrepancy has been found between the number of packets sent by `syncloop` and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.

- **`nnn` packets lost in inbound queueing**

### Warnings

To allow its tests to run properly, as well as prevent disturbance of normal operations, `syncloop` should only be run on a port that is not being used for any other purpose at that time.
The `syncstat` command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver.

Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver's entry points is first called.

The `device` argument is the name of the serial device as it appears in the `/dev` directory. For example, `zsh0` specifies the first on-board serial device.

The following is a breakdown of `syncstat` output:

<table>
<thead>
<tr>
<th>speed</th>
<th>The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipkts</td>
<td>The total number of input packets.</td>
</tr>
<tr>
<td>opkts</td>
<td>The total number of output packets.</td>
</tr>
<tr>
<td>undrun</td>
<td>The number of transmitter underrun errors.</td>
</tr>
<tr>
<td>ovrrun</td>
<td>The number of receiver overrun errors.</td>
</tr>
<tr>
<td>abort</td>
<td>The number of aborted received frames.</td>
</tr>
<tr>
<td>crc</td>
<td>The number of received frames with CRC errors.</td>
</tr>
<tr>
<td>isize</td>
<td>The average size (in bytes) of input packets.</td>
</tr>
<tr>
<td>osize</td>
<td>The average size (in bytes) of output packets.</td>
</tr>
</tbody>
</table>

**Options**

- `-c` Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.

- `interval` `syncstat` samples the statistics every `interval` seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.
Examples

Sample output from the syncstat command:

example# syncstat zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600 15716 17121 0 0 1 3 98 89

example# syncstat -c zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600 0 0 0 0 0 0 0 0

In the following sample output a new line of output is generated every five seconds:

example# syncstat zsh0 5

ipkts opkts undrun ovrrun abort crc iutil outil
12 10 0 0 0 0 5% 4%
22 60 0 0 0 0 3% 90%
36 14 0 0 0 1 51% 2%

Attributes

See Also  syncinit(1M), syncloop(1M), attributes(5), zsh(7D)

Diagnostics  

diag interval: arg  
The argument arg is expected to be an interval and could not be understood.

device missing minor device number  
The name device does not end in a decimal number that can be used as a minor device number.

baud rate not set  
The interval option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics.

Warnings  

Underrun, overrun, frame-abort, and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as
cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the interval option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.
sysdef(1M)

**Name**
sysdef – output system definition

**Synopsis**
```
/usr/sbin/sysdef [-i] [-n namelist]
/usr/sbin/sysdef [-h] [-d] [-i] [-D]
```

**Description**
The `sysdef` utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters.

It generates the output by analyzing the named bootable operating system file (`namelist`) and extracting the configuration information from it.

The default system `namelist` is `/dev/kmem`.

**Options**
- `--`
  - `i`
    - Prints the configuration information from `/dev/kmem`. This is the default and only needs to be specified if the configuration information from both `/dev/kmem` and the system file specified with the `--namelist` option is needed.
  - `--namelist` (`namelist`)
    - Specifies a `namelist` other than the default (`/dev/kmem`). The `namelist` specified must be a valid bootable operating system.
  - `--h`
    - Prints the identifier of the current host in hexadecimal. If `sysdef --h` is executed within a non-global zone and the zone emulates a host identifier, then the zone's host identifier is printed. This numeric value is not guaranteed to be unique.
  - `--d`
    - The output includes the configuration of system peripherals formatted as a device tree.
  - `--D`
    - For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.

**Examples**

**EXAMPLE 1**  Sample output format

The following example displays the format of the `sysdef --d` output:

```
example% sysdef --d
Node 'SUNW,Ultra-5' 10, unit #1
  Node 'packages', unit #1 (no driver)
    Node 'terminal-emulator', unit #1 (no driver)
    Node 'debloaker', unit #1 (no driver)
    Node 'obp-tftp', unit #1 (no driver)
    Node 'disk-label', unit #1 (no driver)
    Node 'SUNW,builtin-drivers', unit #1 (no driver)

The `syseventadm` command is an administrative front-end to add, remove and list `sysevent` event handlers. You can also restart the `sysevent` daemon by use of the `restart` command. `syseventadm` can only be run by root.

The `syseventadm add` command adds a handler for a `sysevent` event specified by at least one of vendor, publisher or class. If `class` is specified, it may be qualified with a `sub-class`. Only the values specified for `vendor, publisher, class and sub-class` when adding the handler are matched against `sysevent` events to determine if the specification matches the event and the handler should be run. `path` is the full pathname of the command to be run in response to matching events, with optional arguments (`args`). If `username` is specified, the command is invoked as user `username`, otherwise as root.

The `syseventadm remove` command removes handlers for matching `sysevent` event specifications. Event specifications may be matched by specifying at least one of `vendor, publisher, class, username or path`. If `class` is specified, it may be qualified with a `sub-class`. Any of `vendor, publisher, class, sub-class, username, path or args` not specified match the corresponding fields of all events. Handlers for all matching specifications are removed.

The `syseventadm list` command lists the handlers for matching `sysevent` event specifications using the same match criteria as the `remove` command but without the requirement that at least one of `vendor, publisher, class, username or path` be specified. With no match criteria, all specifications are listed. The list command output format is: `vendor=pvendor] [publisher=publisher] [class=class] [subclass=subclass] [username=username] path [args]` where each of `class, sub-class, vendor, publisher and username` is listed only if part of the match criteria for the listed specification.

The `syseventadm restart` command informs the `syseventd` daemon to reread the `sysevent` registry after a change has been made by adding or removing one or more `sysevent` handler specifications.

The `sysevent` handling facility provides extensive macro capability for constructing the command line arguments to be executed in response to an event. Macro expansion applies only to the command line `args` specified for an event handler, with macros expanded with data from the event itself. Pre-defined macros are provided for the event `class, subclass, publisher` and `vendor` information. Macros not matching one of the pre-defined macro names cause the
attribute list attached to the event to be searched for an attribute of that name, with the value of the matching attribute substituted on the command line.

Macros are introduced by the $ character, with the macro name being the following token separated by a SPACE or TAB character. If the macro name is embedded in text, it may be delineated by ${ and }. A \ before the $ causes macro expansion not to occur.

$class$ The class string defining the event
$publisher$ The publisher string defining the event
$sequence$ The sequence number of the event.
$subclass$ The subclass string defining the event
$timestamp$ The timestamp of the event.
/vendor$ The vendor string defining the event

Macro names other than those pre-defined are compared against the attribute list provided with the event. An attribute with name matching the macro name causes the value of the attribute to be substituted as ASCII text on the generated command line.

Use of a macro for which no attribute with that name is defined, or for which multiple attributes with that name are provided, cause an error and the command is not invoked.

Attributes with signed data types (DATA_TYPE_INT16, DATA_TYPE_INT32 and DATA_TYPE_INT64) are expanded as decimal digits.

Attributes with unsigned data types (DATA_TYPE_BYTE, DATA_TYPE_UINT16, DATA_TYPE_UINT32, DATA_TYPE_UINT64 and DATA_TYPE_HTTIME) are expanded as hexadecimal digits with a 0x prefix.

Attributes with string data type (DATA_TYPE_STRING) are expanded with the string data. The data is not quoted. If it desired that the quoted strings be generated on the command line, put quotes around the macro call in the arguments.

Array types are expanded with each element expanded as defined for that scalar type, with a space separating each element substitution.

**Options** The add, list and remove subcommands support the following options:

- `-c class` Specify the event class, class.
- `-p publisher` Specify the event publisher, publisher.
- `-R rootdir` Specify an alternate root path, rootdir.

**Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone’s file system,
might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

- s subclass Specify the event subclass, subclass.
- u username Specify the username (username) to invoke the command.
- v vendor Specify the vendor (vendor) that defines the event. Events defined by third-party software should specify the company's stock symbol as vendor. Sun-defined events use SUNW.

**Operands**

The add, list and remove subcommands support the following options:

- **args** Command arguments
- **path** Full path of command to be run in response to event

**Examples**

**EXAMPLE 1** Adding an Event Handler

The following example adds an event handler for an event defined by vendor MYCO ("My Company"), class EC_ENV and sub-class ESC_ENV_TEMP. The command to be run is /opt/MYCOenv/bin/ec_env_temp, with arguments being the class name, sub-class name and pathname derived from the event attributes. The $ characters are preceded by a backslash to circumvent shell interpretation. There is no need to restart the service after the change since the registry is maintained on $ALTROOT.

```
# syseventadm add -R $ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
   /opt/MYCOenv/bin/ec_env_temp $class $subclass $pathname
```

Note the caveat on the use of the -R option in the description of that option, above.

**EXAMPLE 2** Removing an Event Handler

The following example removes the event handler added in Example 1.

```
# syseventadm remove -R $ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \ 
   /opt/MYCOenv/bin/ec_env_temp $class $subclass $pathname
```

Note the caveat on the use of the -R option in the description of that option, above.

**EXAMPLE 3** Listing Event Handlers

The following example lists all event handlers for events of class EC_ENV, subclass ESC_ENV_TEMP, as defined by vendor MYCO:

```
# syseventadm list -v MYCO -c EC_ENV -s ESC_ENV_TEMP \ 
   vendor=MYCO class=EC_ENV subclass=ESC_ENV_TEMP \ 
   /opt/MYCOenv/bin/ec_env_temp $class $subclass $pathname
```
EXAMPLE 4  Listing Event Handlers
The following example lists all event handlers defined by vendor VRTS.

# syseventadm list -v VRTS

EXAMPLE 5  Removing Event Handlers
The following example removes all event handlers defined by vendor VRTS, and restarts service.

# syseventadm remove -v VRTS
# syseventadm restart

EXAMPLE 6  Listing All Event Handlers Specified to Run a Command
The following example lists all event handlers specified to run the command /opt/MYCOenv/bin/ec_env_temp:

# syseventadm list /opt/MYCOenv/bin/ec_env_temp

EXAMPLE 7  Removing Event Handlers and Restarting Service
The following example removes all event handlers specified to run the command /opt/MYCOenv/bin/ec_env_temp, and restarts service:

# syseventadm remove /opt/MYCOenv/bin/ec_env_temp
# syseventadm restart

Exit Status  The following exit values are returned:

0  Successful completion.
1  No matching event specification found (remove or list commands only).
2  Incorrect command usage.
3  Permission denied.
4  Command failed.
5  Out of memory.

Notes  To avoid upgrade problems, packages delivering a sysevent event handler should install the event handler by running `syseventadm` from the package's postinstall script. The event handler can then be removed by running `syseventadm` from the package's preremove script using the same arguments as when added.
syseventconfd(1M)

Name  syseventconfd – kernel system event command invocation daemon

Synopsis  /usr/lib/sysevent/syseventconfd [-r rootdir]

Description  syseventconfd is the user-level daemon that invokes user-level commands in response to
kernel system events received from syseventd(1M).

Options  The following options are supported:

-  `-r rootdir`  Cause syseventconfd to use an alternate root path when creating its door. The
root path must match the root path used to invoke syseventd.

Files  /etc/sysevent/syseventconfd_event_service
       syseventconfd event service door file

       /usr/lib/sysevent/modules/sysevent_conf_mod.so
       syseventd loadable module (SLM) managing sysevent.conf files

Notes  The syseventconfd service is managed by the service management facility, smf(5), under the
service identifier:

svc:/system/sysevent:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
Name  syseventd – kernel system event notification daemon

Synopsis  /usr/lib/sysevent/syseventd [-d debug_level] [-r rootdir]

Description  syseventd is a user-level daemon that accepts delivery of system event buffers from the kernel. Once an event buffer has been delivered to syseventd, it, in turn, attempts to propagate the event to all interested end event subscribers.

Event subscribers take the form of a syseventd loadable module (SLM). syseventd passes the event buffer to each of its subscribers and in return expects a notification as to the successful or unsuccessful delivery attempt.

Upon successful delivery of the event buffer to all interested event subscribers, syseventd frees the event buffer from the kernel event queue.

Options  The following options are supported:

- `-d debug_level`  Enable debug mode. Messages are printed to the invoking user’s terminal.
- `-r rootdir`  Cause syseventd to use an alternate root path when creating its door and lock files. Modules continue to be loaded from the standard module directories.

Exit Status  The following exit values are returned:

0  Successful completion.
non-zero  An error occurred.

Files  /etc/sysevent/syseventd_daemon.lock

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using \texttt{svcadm(1M)}. The service's status can be queried using the \texttt{svcs(1)} command.
**Name**  
`sysidconfig` – execute system configuration applications, or define set of system configuration applications

**Synopsis**  
`sysidconfig [-lv] [-a application] [-b basedir]`  
`[-r application]`

**Description**  
Invoked without any options, the `sysidconfig` program executes a list of applications. An application on this list is referred to as a "system configuration application." Every application on this list will be passed one command-line argument, `-c`. This flag will cause the system configuration application to perform its configuration function. Without options, `sysidconfig` should only be invoked by startup scripts, which occurs during the initial installation and during a reconfigure reboot.

All applications on the list will be executed, if possible. All activity taken by the `sysidconfig` program is logged in the `sysidconfig log` file, `/var/log/sysidconfig.log`. If one or more of the applications on the list are either not present at execution time, are not executable, or execute but return a failure code upon completion, then that information will be logged as well. Successful completion of the program can be assumed if no error message is present in the log file. Programs are executed sequentially, with only one configuration application active at a time.

Executed with the `-l`, `-a`, or `-r` options, the `sysidconfig` program allows the super-user to list the defined configuration applications, and to add items to or remove items from that list. Running `sysidconfig` with options is the only way to view or manipulate the list. Only the super-user can execute the `sysidconfig` program with options.

The `-b` and `-v` options change the behavior of `sysidconfig`, and can be used with or without the list manipulation options discussed above. The `-b basedir` option is used to specify a reference root directory other than the default, `/`. The `-v` option duplicates the log file output on stdout.

By default, no SPARC based applications exist on this list. However, the x86 based systems are delivered with one application, `kdmconfig(1M)`, on the list. `kdmconfig` is not delivered on SPARC based systems.

This application is an extension of the `sysidtool(1M)` suite of programs. It is executed during initial installation and during a reconfigure reboot, before the window system has been started. Graphical User Interface (GUI) applications will not execute successfully if they are added to the list of configuration applications via `sysidconfig -a`.

This program is referenced, but not fully described, in the `sysidtool(1M)` manual page.

**Options**  
The valid options are:

- `-a application`  
  Add the named application to the list of defined applications. When next invoked without arguments, `sysidconfig` will run this newly added application after all previously defined applications. `application` must be a fully qualified path name that is not currently on the list of applications to execute.
Specify an alternate base directory (/ is defined as the default base directory if no other is specified). The specified directory is used as the root directory when adding, listing, removing, or executing configuration applications. The log file where information is recorded is in /var/log, relative to the specified basedir. In the log file, the basedir is not noted. This means, for example, that if the super-user on a diskless client's server executes:

```
sysidconfig -b /export/root/client -a /sbin/someapp
```

then the diskless client client would have /sbin/someapp executed upon reconfigure reboot. The diskless client's log file would note that /sbin/someapp was added, not /export/root/client/sbin/someapp.

Note – The root file system of any non-global zones must not be referenced with the -b option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

- l
List defined configuration applications. Applications will be executed one at a time, in the order shown in the list.

- r application
Remove the named application from the list of defined applications. application must be a fully qualified path name and it must be on the existing list of applications to execute.

- v
Verbose mode. This option echoes all information sent to the log file to stdout. Such information includes timestamp information about when the program was executed, the names of applications being executed, and results of those executions.

Return Values
The sysidconfig program will return 0 if it completes successfully.

When executed with the -r or -a options, error conditions or warnings will be reported on stdout. If the requested action completes successfully, an exit code of 0 will be returned.

Errors
EPERM The program was executed by a user other than the super-user.
EINVAL Option -l, -a, or -r was passed and the action could not be completed successfully.

Files
/var/log/sysidconfig.log sysidconfig log file

sysidconfig(1M)  

See Also  sys-unconfig(1M), sysidtool(1M), attributes(5)  
x86 Only  kdmconfig(1M)  

Diagnostics  When run without options, a log of the sysidconfig program's activity can be found in /var/log/sysidconfig.log. This file contains a timestamp log of each program executed, its resulting stderr output, and its exit code. If an application in the list was not found or is not executable, that will also be noted.
**Description**

`sysidtool` is a suite of programs that configure a new system, or one that has been unconfigured with `sys-unconfig(1M)`.

The `sysidtool` programs run automatically at system installation, or during the first boot after a machine has been successfully unconfigured.

These programs have no effect except at such times, and should never be run manually.

The `sysidtool` programs set up the appropriate information in the machine's configuration files, in the kernel, and on the machine's network interface. The following list shows the available commands and the information for which each of the commands lists.

- **sysidnet**: network configuration
  - Machine's default locale.
  - Machine's console type.
  - Machine's hostname.
  - Machine's IP address.

- **sysidns**: name service configuration
  - Name service choice: NIS, NIS+, DNS, LDAP, or none.
  - Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network).
  - Domain name for chosen name service.
  - Hostname and IP address of name server(s).
  - DNS search list (DNS name service only)

- **sysidsys**: miscellaneous system configuration
  - Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network).
  - Machine's time zone.
  - Date and time.

- **sysidroot**: control superuser information
  - Machine's root password.

- **sysidpm**: power management configuration
  - Auto-shutdown confirmation if the system is EnergyStar-V2 compliant, that is, a new system model shipped after October 1, 1995.

- **sysidnfs4**: NFSv4 domain configuration
  - Domain name to be used by NFSv4 client(s) and server(s) to transmit user and group id's as strings of the general form "[user|group]@domain".
sysidkbd: keyboard layout configuration
The corresponding keytable is loaded into the kernel according to the configured keyboard layout.

sysidconfig: host– or platform-specific configuration
This command controls specification and execution of custom configuration applications that can be specified for a particular host or a particular platform. See sysidconfig(1M).

The sysidtool programs attempt to obtain system configuration information from various name service databases, for example, NIS, or from the sysidcfg(4) file, and you are prompted to provide the information if it cannot be found. However, you can avoid one or more of the prompts by preconfiguring the appropriate configuration information in the name service databases or in the sysidcfg(4) file.

To preconfigure the information in the name service databases, you must use the name service commands or the Solstice AdminSuite tools. See Oracle Solaris 10 08/11 Installation Guide: Basic Installations for more details about how to preconfigure the system configuration information.

The machine’s configuration information is set up in its /etc and /var files.

If a system has more than one network interface, you can use sysidtool to configure all interfaces on the system.

You cannot use the name service databases or the sysidcfg(4) file to suppress the Power Management configuration prompt. However, you can suppress it by creating either the /autoshutdown or /noautoshutdown file before installation reboot. Accordingly, the auto-shutdown feature is silently configured. The /autoshutdown or /noautoshutdown files are removed by sysidpm before it exits.

If you have non-global zones installed and the nfs4_domain keyword exists in the sysidcfg file, the first boot of a non-global zone sets the domain. Otherwise, the Solaris interactive installation program comes up and you are prompted to provide a domain name before the boot process completes. See sysidcfg(4) and Oracle Solaris 10 8/11 Installation Guide: Custom JumpStart and Advanced Installations.

sysidkbd prompts for the keyboards with zero- countryCode and then sets the keyboard layout string in the /etc/default/kbd file. If the sysidkbd gets the valid keyboard layout string, the string will be set into the entry "LAYOUT=" in the file.

Files
/etc/.UNCONFIGURED
/etc/nodename
/etc/hostname.??[0-9]
/etc/default/init
/etc/defaultdomain

/etc/passwd password file. See passwd(4).
/etc/shadow  shadow password file. See `shadow(4)`.

Oracle Solaris 10 8/11 Installation Guide: Custom JumpStart and Advanced Installations

Notes  NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit [http://www.sun.com/directory/nisplus/transition.html](http://www.sun.com/directory/nisplus/transition.html).
syslogd reads and forwards system messages to the appropriate log files or users, depending on the priority of a message and the system facility from which it originates. The configuration file /etc/syslog.conf (see syslog.conf(4)) controls where messages are forwarded. syslogd logs a mark (timestamp) message every markinterval minutes (default 20) at priority LOG_INFO to the facility whose name is given as mark in the syslog.conf file.

A system message consists of a single line of text, which may be prefixed with a priority code number enclosed in angle-brackets (< >); priorities are defined in <sys/syslog.h>.

syslogd reads from the STREAMS log driver, /dev/log, and from any transport provider specified in /etc/netconfig, /etc/net/transport/hosts, and /etc/net/transport/services.

syslogd reads the configuration file when it starts up, and again whenever it receives a HUP signal (see signal.h(3HEAD), at which time it also closes all files it has open, re-reads its configuration file, and then opens only the log files that are listed in that file. syslogd exits when it receives a TERM signal.

As it starts up, syslogd creates the file /var/run/syslog.pid, if possible, containing its process identifier (PID).

If message ID generation is enabled (see log(7D)), each message will be preceded by an identifier in the following format: [ID msgid facility priority]. msgid is the message's numeric identifier described in msgid(1M), facility and priority are described in syslog.conf(4). [ID 123456 kern.notice] is an example of an identifier when message ID generation is enabled.

If the message originated in a loadable kernel module or driver, the kernel module's name (for example, ufs) will be displayed instead of unix. See EXAMPLES for sample output from syslogd with and without message ID generation enabled.

In an effort to reduce visual clutter, message IDs are not displayed when writing to the console; message IDs are only written to the log file. See Examples.

The /etc/default/syslogd file contains the following default parameter settings, which are in effect if neither the -t nor -T option is selected. See FILES.

The recommended way to allow or disallow message logging is through the use of the service management facility (smf(5)) property:

svc:/system/system-log/config/log_from_remote

This property specifies whether remote messages are logged. log_from_remote=true is equivalent to the -t command-line option and false is equivalent to the -T command-line option. The default value for log_from_remote is false. See NOTES, below.
**LOG_FROM_REMOTE**

Specifies whether remote messages are logged. **LOG_FROM_REMOTE=NO** is equivalent to the `-t` command-line option. The default value for **LOG_FROM_REMOTE** is **YES**.

**Options**

The following options are supported:

- `-d`
  Turn on debugging. This option should only be used interactively in a root shell once the system is in multi-user mode. It should not be used in the system start-up scripts, as this will cause the system to hang at the point where syslogd is started.

- `-f configfile`
  Specify an alternate configuration file.

- `-m markinterval`
  Specify an interval, in minutes, between mark messages.

- `-p path`
  Specify an alternative log device name. The default is `/dev/log`.

- `-T`
  Enable the syslogd UDP port to turn on logging of remote messages. This is the default behavior. See Files.

- `-t`
  Disable the syslogd UDP port to turn off logging of remote messages. See Files.

**Examples**

**EXAMPLE 1**  
**syslogd Output Without Message ID Generation Enabled**

The following example shows the output from syslogd when message ID generation is not enabled:

```
Sep 29 21:41:18 cathy unix: alloc /: file system full
```

**EXAMPLE 2**  
**syslogd Output with ID generation Enabled**

The following example shows the output from syslogd when message ID generation is enabled. The message ID is displayed when writing to log file `var/adm/messages`.

```
Sep 29 21:41:18 cathy ufs: [ID 845546 kern.notice] alloc /: file system full
```

**EXAMPLE 3**  
**syslogd Output with ID Generation Enabled**

The following example shows the output from syslogd when message ID generation is enabled when writing to the console. Even though message ID is enabled, the message ID is not displayed at the console.

```
Sep 29 21:41:18 cathy ufs: alloc /: file system full
```
EXAMPLE 4 Enabling Acceptance of UDP Messages from Remote Systems

The following commands enable syslogd to accept entries from remote systems.

```
# svccfg -s svc:/system/system-log setprop config/log_from_remote = true
# svcadm restart svc:/system/system-log
```

**Files**
- `/etc/syslog.conf`
  - Configuration file
- `/var/run/syslog.pid`
  - Process ID
- `/etc/default/syslogd`
  - Contains default settings. You can override some of the settings by command-line options.
- `/dev/log`
  - STREAMS log driver
- `/etc/netconfig`
  - Transport providers available on the system
- `/etc/net/transport/hosts`
  - Network hosts for each transport
- `/etc/net/transport/services`
  - Network services for each transport

**Attributes**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

**See Also**
- `logger(1)`, `svcs(1)`, `msgid(1M)`, `svcadm(1M)`, `svccfg(1M)`, `syslog(3C)`, `syslog.conf(4)`, `attributes(5)`, `signal.h(3HEAD)`, `smf(5)`, `log(7D)`

**Notes**
The mark message is a system time stamp, and so it is only defined for the system on which syslogd is running. It can not be forwarded to other systems.

When syslogd receives a HUP signal, it attempts to complete outputting pending messages, and close all log files to which it is currently logging messages. If, for some reason, one (or more) of these files does not close within a generous grace period, syslogd discards the pending messages, forcibly closes these files, and starts reconfiguration. If this shutdown procedure is disturbed by an unexpected error and syslogd cannot complete reconfiguration, syslogd sends a mail message to the superuser on the current system stating that it has shut down, and exits.

Care should be taken to ensure that each window displaying messages forwarded by syslogd (especially console windows) is run in the system default locale (which is syslogd’s locale). If
this advice is not followed, it is possible for a syslog message to alter the terminal settings for that window, possibly even allowing remote execution of arbitrary commands from that window.

The syslogd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/system-log:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

When syslogd is started by means of svcadm(1M), if a value is specified for LOG_FROM_REMOTE in the /etc/defaults/syslogd file, the SMF property svc:/system/system-log/config/log_from_remote is set to correspond to the LOG_FROM_REMOTE value and the /etc/default/syslogd file is modified to replace the LOG_FROM_REMOTE specification with the following comment:

```
# LOG_FROM_REMOTE is now set using svccfg(1m), see syslogd(1m).
```

If neither LOG_FROM_REMOTE nor svc:/system/system-log/config/log_from_remote are defined, the default is to log remote messages.

On installation, the initial value of svc:/system/system-log/config/log_from_remote is false.
sys-unconfig(1M)

Name       sys-unconfig – undo a system’s configuration
Synopsis    /usr/sbin/sys-unconfig
Description The sys-unconfig command is used to restore a system’s configuration to an “as-manufactured” state, ready to be reconfigured again. The system’s configuration consists of hostname, Network Information Service (NIS) domain name, timezone, IP address, IP subnet mask, and root password. This operation is the inverse of those performed by the sysidnet(1M), sysdns(1M), and sysidsys(1M) programs run at boot. See sysidtool(1M).

sys-unconfig does the following:

- Saves current /etc/inet/hosts file information in /etc/inet/hosts.saved.
- If the current /etc/vfstab file contains NFS mount entries, saves the /etc/vfstab file to /etc/vfstab.orig.
- Restores the default /etc/inet/hosts file.
- Removes the default hostname in /etc/hostname. interface files for all interfaces configured when this command is run. To determine which interfaces are configured, run the command ‘ifconfig -a’. The /etc/hostname. interface files corresponding to all of the interfaces listed in the resulting output, with the exception of the loopback interface (lo0), will be removed.
- Removes the default domain name in /etc/defaultdomain.
- Restores the timezone to PST8PDT in /etc/TIMEZONE.
- Disables the Network Information Service (NIS) and Network Information Service Plus (NIS+) if either NIS or NIS+ was configured.
- Removes the file /etc/inet/netmasks.
- Removes the file /etc/defaultrouter.
- Removes the password set for root in /etc/shadow.
- Removes the file /etc/.rootkey.
- Executes all system configuration applications. These applications are defined by prior executions of a sysidconfig -a application. (See sysidconfig(1M)). When sys-unconfig is run, all system configuration applications are passed one argument, -u.
- Removes the file /etc/resolv.conf.
- Removes the file /etc/sysidcfg.
- Regenerates keys for sshd(1M).

When sys-unconfig is finished, it performs a system shutdown. sys-unconfig is a potentially dangerous utility and can only be run by the super user.
sys-unconfig(1M)

**Files**
- `/etc/default/init` process control initialization
- `/etc/defaultdomain` determines host’s domain name
- `/etc/defaultrouter` specifies an IPv4 host’s default router
- `/etc/hostname/interface` identifies symbolic host name associated with network interface `interface`
- `/etc/inet/hosts` host name database
- `/etc/inet/netmasks` network mask database
- `/etc/nodename` local source for system name
- `/etc/.rootkey` super-user’s secret key
- `/etc/shadow` shadow password file
- `/etc/sysidcfg` system identification configuration file for diskless booting
- `/etc/vfstab` virtual file system table
- `/var/nis/NIS_COLD_START` list of NIS+ servers that serve a host’s default domain
- `/var/yp/binding/*/ypservers` identifies NIS servers to which the client is allowed to bind

**Attributes**

**Notes**
`sys-unconfig` is not available on diskless clients.
tapes – creates /dev entries for tape drives attached to the system

/usr/sbin/tapes [-r root_dir]

devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of tapes.

tapes creates symbolic links in the /dev/rmt directory to the actual tape device special files under the /devices directory tree. tapes searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed:

1. The /dev/rmt directory is searched for a /dev/rmt/n entry that is a symbolic link to the /devices special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive.

2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added.

3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive.

tapes does not remove links to non-existent devices; these must be removed by hand.

tapes is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed.

Notice to Driver Writers tapes(1M) considers all devices with the node type DDI_NT_TAPE to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [ l,m,h,c,u ][ b ][ n ].

The first character set is used to specify the tape density of the device, and are named low (l), medium (m), high (h), compressed (c), and ultra (u). These specifiers only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where l means 800 BPI, m means 1600 BPI, and h means 6250 BPI, whereas 4mm DAT tapes defines l as standard format, and m, h, c and u as compressed format. Drivers may choose to implement any or all of these format types.

During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. b instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file.

n or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See mtio(7I).
The minor number for tape devices should be created by encoding the device's instance number using the tape macro MTMINOR and ORing in the proper combination of density, BSD behavior, and no-rewind flags. See mtio(7I).

To prevent tapes from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string DDI_NT_TAPE when calling ddi_create_minor_node(9F).

**Options**

The following options are supported:

- `-r root_dir` Causes tapes to presume that the /dev/rmt directory tree is found under `root_dir`, not directly under `/`.

**Errors**

If tapes finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the /dev directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

**Examples**

**EXAMPLE 1** Creating Tape Device Nodes From Within the Driver's attach() Function

This example demonstrates creating tape device nodes from within the xktape driver's `attach(9E)` function.

```c
#include <sys/mtio.h>

struct tape_minor_info {
    char *minor_name;
    int minor_mode;
};

/*
 * create all combinations of logical tapes
 */
static struct tape_minor_info example_tape[] = {
    "", 0,    /* default tape */
    "t", MT_DENSITY1,
    "tb", MT_DENSITY1 | MT_BSD,
    "tbn", MT_DENSITY1 | MT_BSD | MT_NOREWIND,
    "m", MT_DENSITY2,
    "mb", MT_DENSITY2 | MT_BSD,
    "mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND,
    "h", MT_DENSITY3,
    "hb", MT_DENSITY3 | MT_BSD,
    "hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND,
    "c", MT_DENSITY4,
    "cb", MT_DENSITY4 | MT_BSD,
    "cbn", MT_DENSITY4 | MT_BSD | MT_NOREWIND,
    NULL, 0,
};
```
Creating Tape Device Nodes From Within the Driver’s attach() Function (Continued)

```c
int xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance;
    struct tape_minor_info *mdp;
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);

    for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
        ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
            (MTMINOR(instance) | mdp->minor_mode), DDI_NT_TAPE, 0);
    }
}
```

Installing the xktape driver on a Sun Fire 4800, with the driver controlling a SCSI tape (target 4 attached to an `isp(7D)` SCSI HBA) and performing a reconfiguration-boot creates the following special files in `/devices`.

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isptwo@4
crw-rw-rw- 1 root sys 33,136 Aug 29 00:02 xktape@4,0:
```

```
# ls -l /dev/rmt
/dev/rmt/0 -> ../../devices/[....]/xktape@4,0:
/dev/rmt/0b -> ../../devices/[....]/xktape@4,0:b
/dev/rmt/0bn -> ../../devices/[....]/xktape@4,0:bn
```

/dev/rmt will contain the logical tape devices (symbolic links to tape devices in `/devices`).
EXAMPLE 1  Creating Tape Device Nodes From Within the Driver’s attach() Function  (Continued)

/dev/rmt/0c  -> ../../devices/[...]/xktape@4,0:c
/dev/rmt/0cb -> ../../devices/[...]/xktape@4,0:cb
/dev/rmt/0cbn -> ../../devices/[...]/xktape@4,0:cbn
/dev/rmt/0cn -> ../../devices/[...]/xktape@4,0:cn
/dev/rmt/0h  -> ../../devices/[...]/xktape@4,0:h
/dev/rmt/0hb -> ../../devices/[...]/xktape@4,0:hb
/dev/rmt/0hbn -> ../../devices/[...]/xktape@4,0:hbn
/dev/rmt/0hn -> ../../devices/[...]/xktape@4,0:hn
/dev/rmt/0l  -> ../../devices/[...]/xktape@4,0:l
/dev/rmt/0lb -> ../../devices/[...]/xktape@4,0:lb
/dev/rmt/0ln -> ../../devices/[...]/xktape@4,0:ln
/dev/rmt/0m  -> ../../devices/[...]/xktape@4,0:m
/dev/rmt/0mb -> ../../devices/[...]/xktape@4,0:mb
/dev/rmt/0mbn -> ../../devices/[...]/xktape@4,0:mbn
/dev/rmt/0mn -> ../../devices/[...]/xktape@4,0:mn
/dev/rmt/0n  -> ../../devices/[...]/xktape@4,0:n

Writing Device Drivers

Bugs  tapes silently ignores malformed minor device names.
**Name**  
taskstat – prints ASET tasks status

**Synopsis**  
/usr/aset/util/taskstat  [-d  aset_dir]

**Description**  
taskstat is located in the /usr/aset/util directory. /usr/aset is the default operating directory of the Automated Security Enhancement Tool (ASET). An alternative working directory can be specified by the administrators through the aset -d command or the ASETDIR environment variable. See aset(1M). Because aset dispatches its tasks to run in the background, when it returns, these tasks may or may not have completed. taskstat prints the status of the tasks, listing those that are completed and those that are still executing.

The ASET reports, which are located in the /usr/aset/reports directory (see the -d option), are not complete until all the tasks finish executing.

**Options**  
- d aset_dir  
Specify the working directory for ASET. By default, this directory is /usr/aset. With this option, the reports directory will be located under aset_dir.

*System Administration Guide: Basic Administration*
tcxconfig(1M)

**Name**
tcxconfig – configure default linearity of 24-bit TrueColor Visual for OpenWindows

**Synopsis**
/usr/sbin/tcxconfig [linear | nonlinear]

**Description**
The `tcxconfig` script changes the default linearity of a 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer. When the S24 graphics driver for OpenWindows is installed, the default 24-bit TrueColor Visual is nonlinear. You can run `tcxconfig` with an argument that specifies the setting you want.

OpenWindows should not be running when you execute the `tcxconfig` script with an option. Start OpenWindows after `tcxconfig` has set the linearity you desire.

**Options**
If you specify no option, `tcxconfig` displays the current default setting.

You must become superuser before you can execute `tcxconfig` with one of the following options.

- `linear` Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.
- `nonlinear` Set nonlinear visual to be the default 24-bit TrueColor Visual.

**Exit Status**
The following exit values are returned:

<table>
<thead>
<tr>

System Administration Commands - Part 3
Name  th_define – create fault injection test harness error specifications

Synopsis  th_define [-n name -i instance -P path] [-a acc_types]
           [-r reg_number] [-l offset [length]]
           [-c count [failcount]] [-o operator [operand]]
           [-f acc_chk] [-w max_wait_period [report_interval]]

or

th_define [-n name -i instance -P path]
           [-a log [acc_types] [-r reg_number] [-l offset [length]]]
           [-c count [failcount]] [-s collect_time] [-p policy]
           [-x flags] [-C comment_string]
           [-e fixup_script [args]]

or

th_define [-h]

Description  The th_define utility provides an interface to the bus_ops fault injection bofi device driver for defining error injection specifications (referred to as errdefs). An errdef corresponds to a specification of how to corrupt a device driver’s accesses to its hardware. The command line arguments determine the precise nature of the fault to be injected. If the supplied arguments define a consistent errdef, the th_define process will store the errdef with the bofi driver and suspend itself until the criteria given by the errdef become satisfied (in practice, this will occur when the access counts go to zero).

You use the th_manage(1M) command with the start option to activate the resulting errdef. The effect of th_manage with the start option is that the bofi driver acts upon the errdef by matching the number of hardware accesses—specified in count, that are of the type specified in acc_types, made by instance number instance—of the driver whose name is name, (or by the driver instance specified by path) to the register set (or DMA handle) specified by reg_number, that lie within the range offset to offset + length from the beginning of the register set or DMA handle. It then applies operator and operand to the next failcount matching accesses.

If acc_types includes log, th_define runs in automatic test script generation mode, and a set of test scripts (written in the Korn shell) is created and placed in a sub-directory of the current directory with the name <driver>.test.<id> (for example, glm.test.978177106). A separate, executable script is generated for each access handle that matches the logging criteria. The log of accesses is placed at the top of each script as a record of the session. If the current directory is not writable, file output is written to standard output. The base name of each test file is the driver name, and the extension is a number that discriminates between different access handles. A control script (with the same name as the created test directory) is generated that will run all the test scripts sequentially.

Executing the scripts will install, and then activate, the resulting error definitions. Error definitions are activated sequentially and the driver instance under test is taken offline and brought back online before each test (refer to the -e option for more information). By default, logging applies to all PIO accesses, all interrupts, and all DMA accesses to and from areas
mapped for both reading and writing. You can constrain logging by specifying additional
acc_types, reg_number, offset and length. Logging will continue for count matching accesses,
with an optional time limit of collect_time seconds.

Either the -n or -P option must be provided. The other options are optional. If an option
(other than -a) is specified multiple times, only the final value for the option is used. If an
option is not specified, its associated value is set to an appropriate default, which will provide
maximal error coverage as described below.

Options

The following options are available:

-n name
  Specify the name of the driver to test. (String)

-i instance
  Test only the specified driver instance (-1 matches
  all instances of driver). (Numeric)

-P path
  Specify the full device path of the driver to test. (String)

-r reg_number
  Test only the given register set or DMA handle (-1
  matches all register sets and DMA handles). (Numeric)

-a acc_types
  Only the specified access types will be matched.
  Valid values for the acc_types argument are log, pio, pio_r, pio_w, dma, dma_r, dma_w and intr.
  Multiple access types, separated by spaces, can be
  specified. The default is to match all hardware
  accesses.

  If acc_types is set to log, logging will match all PIO
  accesses, interrupts and DMA accesses to and
  from areas mapped for both reading and writing.
  log can be combined with other acc_types, in
  which case the matching condition for logging
  will be restricted to the specified additional
  acc_types. Note that dma_r will match only DMA
  handles mapped for reading only; dma_w will
  match only DMA handles mapped for writing
  only; dma will match only DMA handles mapped
  for both reading and writing.

-l offset [length]
  Constrain the range of qualifying accesses. The
  offset and length arguments indicate that any
  access of the type specified with the -a option, to
  the register set or DMA handle specified with the
  -r option, lie at least offset bytes into the register
  set or DMA handle and at most offset + length
The default for `offset` is 0. The default for `length` is the maximum value that can be placed in an `offset_t` C data type (see `types.h`). Negative values are converted into unsigned quantities. Thus, `th_define -l 0 -1` is maximal.

Wait for `count` number of matching accesses, then apply an operator and operand (see the `-o` option) to the next `failcount` number of matching accesses. If the access type (see the `-a` option) includes logging, the number of logged accesses is given by `count + failcount - 1`. The `-1` is required because the last access coincides with the first faulting access.

Note that access logging may be combined with error injection if `failcount` and `operator` are nonzero and if the access type includes logging and any of the other access types (pio, dma and intr). See the description of access types in the definition of the `-a` option, above.

When the `count` and `failcount` fields reach zero, the status of the erdef is reported to standard output. When all active erdefs created by the `th_define` process complete, the process exits. If `acc_types` includes `log`, `count` determines how many accesses to log. If `count` is not specified, a default value is used. If `failcount` is set in this mode, it will simply increase the number of accesses logged by a further `failcount - 1`.

For qualifying PIO read and write accesses, the value read from or written to the hardware is corrupted according to the value of `operator`:

- `EQ` `operand` is returned to the driver.
- `OR` `operand` is bitwise ORed with the real value.
- `AND` `operand` is bitwise ANDed with the real value.
- `XOR` `operand` is bitwise XORed with the real value.
For PIO write accesses, the following operator is allowed:

**NO**  Simply ignore the driver's attempt to write to the hardware.

Note that a driver performs PIO via the ddi_getX(), ddi_putX(), ddi_rep_getX() and ddi_rep_putX() routines (where X is 8, 16, 32 or 64). Accesses made using ddi_getX() and ddi_putX() are treated as a single access, whereas an access made using the ddi_rep_*() routines are broken down into their respective number of accesses, as given by the repcount parameter to these DDI calls. If the access is performed via a DMA handle, operator and value are applied to every access that comprises the DMA request. If interference with interrupts has been requested then the operator may take any of the following values:

**DELAY**  After count accesses (see the -c option), delay delivery of the next failcount number of interrupts for operand number of microseconds.

**LOSE**  After count number of interrupts, fail to deliver the next failcount number of real interrupts to the driver.

**EXTRA**  After count number of interrupts, start delivering operand number of extra interrupts for the next failcount number of real interrupts.

The default value for operand and operator is to corrupt the data access by flipping each bit (XOR with -1).

If the acc_chk parameter is set to 1 or pio, then the driver's calls to ddi_check_acc_handle(9F) return DDI_FAILURE when the access count goes to 1. If the acc_chk parameter is set to 2 or dma, then the driver's calls to ddi_check_dma_handle(9F) return DDI_FAILURE when the access count goes to 1.
Constrain the period for which an error definition will remain active. The option applies only to non-logging errdefs. If an error definition remains active for \textit{max\_wait\_period} seconds, the test will be aborted. If \textit{report\_interval} is set to a nonzero value, the current status of the error definition is reported to standard output every \textit{report\_interval} seconds. The default value is zero. The status of the errdef is reported in parsable format (eight fields, each separated by a colon (:) character, the last of which is a string enclosed by double quotes and the remaining seven fields are integers):

\texttt{ft:mt:ac:fc:chk:ec:s:\"message\"} which are defined as follows:

- \texttt{ft} The UTC time when the fault was injected.
- \texttt{mt} The UTC time when the driver reported the fault.
- \texttt{ac} The number of remaining non-faulting accesses.
- \texttt{fc} The number of remaining faulting accesses.
- \texttt{chk} The value of the \texttt{acc\_chk} field of the errdef.
- \texttt{ec} The number of fault reports issued by the driver against this errdef (\texttt{mt} holds the time of the initial report).
- \texttt{s} The severity level reported by the driver.
- \texttt{\"message\"} Textual reason why the driver has reported a fault.

- \texttt{-h} Display the command usage string.

- \texttt{-s collect\_time} If \texttt{acc\_types} is given with the \texttt{-a} option and includes \texttt{log}, the errdef will log accesses for \texttt{collect\_time} seconds (the default is to log until the log becomes full). Note that, if the errdef
specification matches multiple driver handles, multiple logging errdefs are registered with the \texttt{bofi} driver and logging terminates when all logs become full or when \texttt{collect\_time} expires or when the associated errdefs are cleared. The current state of the log can be checked with the \texttt{th\_manage(1M)} command, using the \texttt{broadcast} parameter. A log can be terminated by running \texttt{th\_manage(1M)} with the \texttt{clear\_errdefs} option or by sending a \texttt{SIGALRM} signal to the \texttt{th\_define} process. See \texttt{alarm(2)} for the semantics of \texttt{SIGALRM}.

\texttt{-p policy}

Applicable when the \texttt{acc\_types} option includes \texttt{log}. The parameter modifies the policy used for converting from logged accesses to errdefs. All policies are inclusive:

- Use \texttt{rare} to bias error definitions toward rare accesses (default).
- Use \texttt{operator} to produce a separate error definition for each operator type (default).
- Use \texttt{common} to bias error definitions toward common accesses.
- Use \texttt{median} to bias error definitions toward median accesses.
- Use \texttt{maximal} to produce multiple error definitions for duplicate accesses.
- Use \texttt{unbiased} to create unbiased error definitions.
- Use \texttt{on-byte}, \texttt{two-byte}, \texttt{four-byte}, or \texttt{eight-byte} to select errdefs corresponding to 1, 2, 4 or 8 byte accesses (if chosen, the \texttt{\_xr} option is enforced in order to ensure that \texttt{ddi\_rep\_\*()} calls are decomposed into \texttt{multiple single accesses}).
- Use \texttt{multibyte} to create error definitions for multibyte accesses performed using \texttt{ddi\_rep\_get\*()} and \texttt{ddi\_rep\_put\*()}.

Policies can be combined by adding together these options. See the NOTES section for further information.
- x flags

Applicable when the acc_types option includes log. The flags parameter modifies the way in which the bof1 driver logs accesses. It is specified as a string containing any combination of the following letters:

- **w** Continuous logging (that is, the log will wrap when full).
- **t** Timestamp each log entry (access times are in seconds).
- **r** Log repeated I/O as individual accesses (for example, a ddi_rep_get16(9F) call which has a repcount of N is logged N times with each transaction logged as size 2 bytes. Without this option, the default logging behavior is to log this access once only, with a transaction size of twice the repcount).

-C comment_string

Applicable when the acc_types option includes log. It provides a comment string to be placed in any generated test scripts. The string must be enclosed in double quotes.

-e fixup_script [args]

Applicable when the acc_types option includes log. The output of a logging errdefs is to generate a test script for each driver access handle. Use this option to embed a command in the resulting script before the errors are injected. The generated test scripts will take an instance offline and bring it back online before injecting errors in order to bring the instance into a known fault–free state. The executable fixup_script will be called twice with the set of optional args—once just before the instance is taken offline and again after the instance has been brought online. The following variables are passed into the environment of the called executable:

- DRIVER_PATH Identifies the device path of the instance.
- DRIVER_INSTANCE Identifies the instance number of the device.
DRIVER_UNCONFIGURE  Has the value 1 when the instance is about to be taken offline.

DRIVER_CONFIGURE  Has the value 1 when the instance has just been brought online.

Typically, the executable ensures that the device under test is in a suitable state to be taken offline (unconfigured) or in a suitable state for error injection (for example configured, error free and servicing a workload). A minimal script for a network driver could be:

```bash
#!/bin/ksh

driver=xyznetdriver
ifnum=$driver$DRIVER_INSTANCE

if [[ $DRIVER_CONFIGURE = 1 ]]; then
    ifconfig $ifnum plumb
    ifconfig $ifnum ...
    ifworkload start $ifnum
elif [[ $DRIVER_UNCONFIGURE = 1 ]]; then
    ifworkload stop $ifnum
    ifconfig $ifnum down
    ifconfig $ifnum unplumb
fi

exit $?
```

The -e option must be the last option on the command line.

If the -a log option is selected but the -e option is not given, a default script is used. This script repeatedly attempts to detach and then re-attach the device instance under test.

Examples

```
th_define -n foo -i 1 -a log
```

Logs all accesses to all handles used by instance 1 of the foo driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -a log pio
```
Logs PIO accesses to each PIO handle used by instance 1 of the foo driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```bash
th_define -n foo -i 1 -p onebyte median -e fixup arg -now
```

Logs all accesses to all handles used by instance 1 of the foo driver while running the workload defined in the fixup script `fixup` with arguments `arg` and `-now`. Then generates a set of test scripts to inject appropriate errdefs while running that workload. The resulting error definitions are requested to focus upon single byte accesses to locations that are accessed a `median` number of times with respect to frequency of access to I/O addresses.

```bash
th_define -n se -l 0x20 1 -a pio_r -o OR 0x4 -c 10 1000
```

Simulates a stuck serial chip command by forcing 1000 consecutive read accesses made by any instance of the `se` driver to its command status register, thereby returning status busy.

```bash
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -f 1 -o OR 0x100
```

Causes 0x100 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```bash
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -o OR 0x0
```

Causes 0x0 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. This is of course a no-op.

```bash
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_r -c 0 10 -o EQ 0x70003
```

Causes the next ten next physical I/O reads from the register at offset 0x8100 in register set 1 of instance 3 of the foo driver to return 0x70003.

```bash
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_w -c 100 3 -o AND 0xfffffffffffffffff
```

The next 100 physical I/O writes to the register at offset 0x8100 in register set 1 of instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared.

```bash
th_define -n foo -i 3 -r 1 -l 0x8100 0x10 -a pio_r -c 0 1 -f 1 -o XOR 7
```

Causes the bottom three bits to have their values toggled for the next physical I/O read access to registers with offsets in the range 0x8100 to 0x8110 in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```bash
th_define -n foo -i 3 -a pio_w -c 0 1 -o NO 0
```
Prevents the next physical I/O write access to any register in any register set of instance 3 of the foo driver from going out on the bus.

```
th_define -n foo -i 3 -l 0 8192 -a dma_r -c 0 1 -o OR 7
```

Causes 0x7 to be ORed into each long long in the first 8192 bytes of the next DMA read, using any DMA handle for instance 3 of the foo driver.

```
th_define -n foo -i 3 -r 2 -l 0 8 -a dma_r -c 0 1 -o OR 0x7070707070707070
```

Causes 0x70 to be ORed into each byte of the first long long of the next DMA read, using the DMA handle with sequential allocation number 2 for instance 3 of the foo driver.

```
th_define -n foo -i 3 -l 256 256 -a dma_w -c 0 1 -f 2 -o OR 7
```

Causes 0x7 to be ORed into each long long in the range from offset 256 to offset 512 of the next DMA write, using any DMA handle for instance 3 of the foo driver. Subsequent calls in the driver to `ddi_check_dma_handle()` return DDI_FAILURE.

```
th_define -n foo -i 3 -r 0 -l 0 8 -a dma_w -c 100 3 -o AND 0xffffffffffffefff
```

The next 100 DMA writes using the DMA handle with sequential allocation number 0 for instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared in the first long long of the transfer.

```
th_define -n foo -i 3 -a intr -c 0 6 -o LOSE 0
```

Causes the next six interrupts for instance 3 of the foo driver to be lost.

```
th_define -n foo -i 3 -a intr -c 30 1 -o EXTRA 10
```

When the thirty-first subsequent interrupt for instance 3 of the foo driver occurs, a further ten interrupts are also generated.

```
th_define -n foo -i 3 -a intr -c 0 1 -o DELAY 1024
```

Causes the next interrupt for instance 3 of the foo driver to be delayed by 1024 microseconds.

**Notes**
The policy option in the `th_define -p` syntax determines how a set of logged accesses will be converted into the set of error definitions. Each logged access will be matched against the chosen policies to determine whether an error definition should be created based on the access.

Any number of policy options can be combined to modify the generated error definitions.

**Bytewise Policies** These select particular I/O transfer sizes. Specifying a byte policy will exclude other byte policies that have not been chosen. If none of the byte type policies is selected, all transfer sizes are treated equally. Otherwise, only those specified transfer sizes will be selected.
The frequency of access to a location is determined according to the access type, location and transfer size (for example, a two-byte read access to address A is considered distinct from a four-byte read access to address A). The algorithm is to count the number of accesses (of a given type and size) to a given location, and find the locations that were most and least accessed (let \( maxa \) and \( mina \) be the number of times these locations were accessed, and \( mean \) the total number of accesses divided by total number of locations that were accessed). Then a rare access is a location that was accessed less than

\[
\frac{(mean - mina) + mina}{3}
\]

times. Similarly for the definition of common accesses:

\[
maxa - \frac{(maxa - mean) + mean}{3}
\]

A location whose access patterns lies within these cutoffs is regarded as a location that is accessed with median frequency.

rare Create errdefs for locations that are rarely accessed.
common Create errdefs for locations that are commonly accessed.
median Create errdefs for locations that are accessed with median frequency.

If a transaction is duplicated, either a single or multiple errdefs will be written to the test scripts, depending upon the following two policies:

maximal Create multiple errdefs for locations that are repeatedly accessed.
unbiased Create a single errdef for locations that are repeatedly accessed.
operators For each location, a default operator and operand is typically applied. For maximal test coverage, this default may be modified using the operators policy so that a separate errdef is created for each of the possible corruption operators.

See Also kill(1), th_manage(1M), alarm(2), ddi_check_acc_handle(9F), 
ddi_check_dma_handle(9F)
Name  th_manage – manage the fault injection test harness

Synopsis  th_manage name instance command
          th_manage path command

Description  th_manage applies the action specified by command to the instance specified by instance of the
driver specified by name (or the driver instance specified by path). The driver instance must be
running fault injection specifications (errdefs) defined by th_define(1M).

th_manage supports several commands that operate on the driver instance specified by name
and instance (or path). The commands are:

  broadcast  Awaken all th_define processes, causing them to display their current
             status and exit if the errdef is now defunct (that is, if count, failcount, and
             acc_chk are all zero).

  clear_acc_chk  Awaken all th_define processes. If count and failcount are already zero,
                 then set acc_chk to zero, so that th_define exits once it has displayed its
                 status.

  clear_errdefs  Awaken all th_define processes. count, failcount and acc_chk are all set
                 to zero so that all th_define commands exit once they have displayed
                 their status.

  clear_errors  Awaken all th_define processes. If count is already zero, set failcount and
               acc_chk to zero, so that th_define exits once it has displayed its status.

  get_handles  List all the access handles.

  start  Begin or resume execution of all errdefs.

  stop  Suspend all errdefs for this name and instance (or path).

Examples  EXAMPLE 1  Useful Commands

To begin the tests, enter:

  # th_manage foo 0 start

To check the status of the errdefs, enter:

  # th_manage foo 0 broadcast

This causes each th_define process to print out its current status.

If the driver has reported a fatal error, you can take the driver offline using libdevice, clear
the error condition by entering:

  # th_manage foo 0 clear_acc_chk
or

```
# th_manage foo 0 clear_errors
```

and bring the driver online again using libdevice.

To terminate testing, enter:

```
# th_manage foo 0 clear_errdefs
```

```
th_define(1M)
```
tic – terminfo compiler

Synopsis
tic [-v [n]] [-c] file

Description
The command tic translates a terminfo file from the source format into the compiled format. The results are placed in the directory /usr/share/lib/terminfo. The compiled format is necessary for use with the library routines in curses(3CURSES).

If the environment variable TERMINFO is set, the compiled results are placed there instead of /usr/share/lib/terminfo.

Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.

Options
The following options are supported:

- c
  Specifies to check only file for errors. Errors in use= links are not detected.

- v[n]
  Specify that (verbose) output be written to standard error trace information showing tic’s progress. The optional integer n is a number from 1 to 10, indicating the desired level of detail of information. If n is omitted, the default level is 1. If n is specified and greater than 1, the level of detail is increased.

Operands
file
  Contains one or more terminfo terminal descriptions in source format [see terminfo(4)]. Each description in the file describes the capabilities of a particular terminal. When a use=entry-name field is discovered in a terminal entry currently being compiled, tic reads in the binary from /usr/share/lib/terminfo to complete the entry. (Entries created from file will be used first. If the environment variable TERMINFO is set, that directory is searched instead of /usr/share/lib/terminfo.) tic duplicates the capabilities in entry-name for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.

Files
/usr/share/lib/terminfo/?/*  Compiled terminal description database

Notes
When an entry, for example, entry_name_1, contains a use=entry_name_2 field, any canceled capabilities in entry_name_2 must also appear in entry_name_1 before use= for these capabilities to be canceled in entry_name_1.
tnchkdb(1M)

Name

tnchkdb – check file syntax of trusted network databases

Synopsis

/usr/sbin/tnchkdb [-h path] [-t path] [-z path]

Description

tnchkdb checks the syntax of the tnrhtp, trnrdb, and tnzonecfg databases. By default, the path for each file is:

- /etc/security/tsol/tnrhtp
- /etc/security/tsol/trnrdb
- /etc/security/tsol/tnzonecfg

You can specify an alternate path for any or all of the files by specifying that path on the command line by using the -h (tnrhdb), -t (tnrhtp) and -z (tnzonecfg) options. The options are useful when testing a set of modified files before installing the files as new system databases.

All three database files are checked for integrity. tnchkdb returns an exit status of 0 if all of the files are syntactically and, to the extent possible, semantically correct. If one or more files have errors, then an exit status of 1 is returned. If there are command line problems, such as an unreadable file, an exit status of 2 is returned. Errors are written to standard error.

To avoid cascading errors, when there are errors in tnrhtp, the template names in trnrdb are not validated.

tnchkdb can be run at any label, but the standard /etc/security/tsol files are visible only in the global zone.

Options

- h [ path ] Check path for proper trnrdb syntax. If path is not specified, then check /etc/security/tsol/tnrhtp.
- t [ path ] Check path for proper tnrhtp syntax. If path is not specified, then check /etc/security/tsol/tnrhtp.
- z [ path ] Check path for proper tnzonecfg syntax. If path is not specified, then check /etc/security/tsol/tnzonecfg.

Examples

EXAMPLE 1 Sample Error Message

The tnchkdb command checks for CIPSO errors. In this example, the admin_low template has an incorrect value of ADMIN_HIGH for its default label.

# tnchkdb
checking /etc/security/tsol/tnrhtp ...
 tnchkdb: def_label classification 7fff is invalid for cipso labels:
 line 14 entry admin_low
 tnchkdb: def_label compartments 241-256 must be zero for cipso labels:
 line 14 entry admin_low

“How to Check the Syntax of Trusted Network Databases” in Oracle Solaris Trusted Extensions Administrator's Procedures

Notes
The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

It is possible to have inconsistent but valid configurations of tnrhtp and tnrhdb when LDAP is used to supply missing templates.
tnctl(1M)

Name

`tnctl` – configure TrusteXtensions network parameters

Synopsis

```
/usr/sbin/tnctl [-dfv] [-h host [prefix] [:template]]
[-m zone:mlp:shared-mlp] [-t template [:key=val [;key=val]]]
[[-HTz] file]
```

Description

`tnctl` provides an interface to manipulate trusted network parameters in the Solaris kernel.

As part of Solaris Trusted Extensions initialization, `tnctl` is run in the global zone by an `smf(5)` script during system boot. The `tnctl` command is not intended to be used during normal system administration. Instead, if a local trusted networking database file is modified without using the Solaris Management Console, the administrator first issues `tnchkdb(1M)` to check the syntax, and then refreshes the kernel copy with this command:

```
# svcadm restart svc:/network/tnctl
```

See **WARNINGS** about the risks of changing remote host and template information on a running system.

Options

- `-d`
  Delete matching entries from the kernel. The default is to add new entries.

  When deleting MLPs, the MLP range must match exactly. MLPs are specified in the form:

  `port[-port]/protocol`

  Where `port` can be a number in the range 1 to 65535, or any known service (see `services(4)`), and `protocol` can be a number in the range 1 to 255, or any known protocol (see `protocols(4)`).

- `-f`
  Flush all kernel entries before loading the entries that are specified on the command line. The flush does not take place unless at least one entry parsed successfully.

- `-v`
  Turn on verbose mode.

- `-h host[/prefix]:[template]`
  Update the kernel remote-host cache on the local host for the specified `host` or, if a template name is given, change the kernel’s cache to use the specified `template`. If `prefix` is not specified, then an implied prefix length is determined according to the rules used for interpreting the `tnrhdb`. If `-d` is specified, then a template name cannot be specified.

- `-m zone:mlp:shared-mlp`
  Modify the kernel’s multilevel port (MLP) configuration cache for the specified `zone`. `zone` specifies the zone to be updated. `mlp` and `shared-mlp` specify the MLPs for the zone-specific and shared IP addresses. The `shared-mlp` field is effective in the global zone only.
-t template[key=val;key=val]
  Update the kernel template cache for template or, if a list of key=val pairs is given, change
  the kernel’s cache to use the specified entry. If -d is specified, then key=val pairs cannot be
  specified.

-T file
  Load all template entries in file into the kernel cache.

-H file
  Load all remote host entries in file into the kernel cache.

-z file
  Load just the global zone’s MLPs from file into the kernel cache. To reload MLPs for a
  non-global zone, reboot the zone:

  # zoneadm -z non-global zone reboot

“How to Synchronize the Kernel Cache With Trusted Network Databases” in Oracle Solaris
Trusted Extensions Administrator’s Procedures

Warnings Changing a template while the network is up can change the security view of an undetermined
number of hosts.

Notes The functionality described on this manual page is available only if the system is configured
with Trusted Extensions.

The tnctl service is managed by the service management facility, smf(5), under the service
identifier:

svc:/network/tnctl
The service's status can be queried by using `svcs(1)`. Administrative actions on this service, such as refreshing the kernel cache, can be performed using `svcadm(1M)`, as in:

```
svcadm refresh svc:/network/tnctl
```
**Name**  
tnd – trusted network daemon

**Synopsis**  
/usr/sbin/tnd  [-p poll-interval]

**Description**  
The tnd (trusted network daemon) initializes the kernel with trusted network databases and also reloads the databases on demand from an LDAP server and local files. tnd follows the order specified in the nsswitch.conf(4) file when loading configuration databases. tnd is started at the beginning of the boot process.

Tnd loads two databases into the kernel: the remote host database, tnrhdb and the remote-host template database, tnrhttp. These databases and their effect on the trusted network are described in their respective man pages. When the associated LDAP database or local databases are changed, tnd also updates the local kernel cache at the predetermined interval.

If a local trusted networking database file is modified, the administrator should run `tnchkdb(1M)` to check the syntax, and should also run `svcadm refresh svc:/network/tnd` to initiate an immediate database scan by tnd.

Tnd is intended to be started from an smf(5) script and to run in the global zone. The following signals cause specific svcadm actions:

- **SIGHUP**  
  Causes `svcadm refresh svc:/network/tnd` to be run.
  Initiates a rescan of the local and LDAP tnrhdb and tnrhttp databases. tnd updates the kernel database with any changes found.

- **SIGTERM**  
  Causes `svcadm disable svc:/network/tnd` to be run.
  Terminates the tnd daemon. No changes are made to the kernel database.

Running tnd in debug mode is determined by the value of the following service management facility (SMF) property:

```
tnd/debug_level = 0
```

A value of 0, as above, prevents debug information from being collected; 1 turns on debugging. The default value is 0. Debug output is sent to the /var/tsol/tnd/log log file.

**Options**  
- **-p poll-interval**  
  Set poll interval to `poll-interval` seconds. The default `poll-interval` is 1800 seconds (30 minutes).

**Examples**  
**EXAMPLE 1**  
Changing the Poll Interval

The following command changes the polling interval to one hour, and puts this interval in the SMF repository. At the next boot, the tnd poll interval will be one hour.

```
# svccfg -s network/tnd setprop tnd/poll_interval=3600
```

The following command changes the polling interval, but does not update the repository. At the next boot, the tnd poll interval remains the default, 30 minutes.
EXAMPLE 1 Changing the Poll Interval (Continued)

# tnd -p 3600

"How to Synchronize the Kernel Cache With Trusted Network Databases" in Oracle Solaris Trusted Extensions Administrator's Procedures

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

The tnd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/tnd

The service's status can be queried by using svc(1). Administrative actions on this service, such as requests to restart the daemon, can be performed using svcadm(1M), as in:

svcadm restart svc:/network/tnd
### tninfo — print kernel-level network information and statistics

#### Synopsis

```
/usr/sbin/tninfo [-h hostname] [-m zone-name] [-t template]
```

#### Description

**tninfo** provides an interface to retrieve and display kernel-level network information and statistics.

- **-h hostname**
  - Display the security structure for the specified host in the remote-host cache. The output should reflect what is specified in the `tnrhdb` database.

- **-m zone-name**
  - Display the MLP configuration associated with the specified zone. The output should reflect what is specified in the `tnzonecfg` database.

- **-t template**
  - Display the structure associated with the specified *template*. The output should reflect what is specified in the `tnrhtp` database.

#### Examples

**EXAMPLE 1**

Displaying Remote Host Structures Cached in the Kernel

This example shows the remote host structures cached in the kernel. The output reflects the definition in the `tnrhdb` database.

```plaintext
# tninfo -h machine1
IP address= 192.168.8.61
Template = cipso
```

**EXAMPLE 2**

Displaying Multilevel Ports for the Global Zone

This example shows the kernel-cached MLPs for the global zone. The output reflects the definition in the `tnzonecfg` database, plus any dynamically allocated MLPs. `private` indicates zone-specific MLPs.

```plaintext
# tninfo -m global
private:23/tcp;111/tcp;111/udp;515/tcp;2049/tcp;6000-6003/tcp;
    32812/tcp;36698/ip;38634/tcp;64365/ip
shared: 6000-6003/tcp
```

**EXAMPLE 3**

Displaying the *cipso* Template Definition

This example shows the kernel-cached *cipso* template definition. The output reflects the definition in the `tnrhtp` database.

```plaintext
# tninfo -t cipso
```

### Description
The Internet is a large and complex aggregation of network hardware, connected by gateways. Tracking the route a packet follows can be difficult. The utility traceroute traces the route that an IP packet follows to another internet host.

The traceroute utility utilizes both the IPv4 and IPv6 protocols. Use the `-A` option to override the default behavior. traceroute uses the IPv4 protocol `ttl` (time to live) field or the IPv6 field `hop limit`. It attempts to elicit an ICMP or ICMPv6 `TIME_EXCEEDED` response from each gateway along the path, and a `PORT_UNREACHABLE` (or `ECHO_REPLY` if `-I` is used) response from the destination host. It starts by sending probes with a `ttl` or `hop limit` of 1 and increases by 1 until it either gets to the host, or it hits the maximum `max_hop`. The default maximum `max_hop` is 30 hops, but this can be set by the `-m` option.

Three probes are sent at each `ttl` (`hop limit`) setting, and a line is printed showing the `ttl` (`hop limit`), the hostname and the address of the gateway, and the `rtt` (round trip time) of each probe. The number of probes may be specifically set using the `-q` option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, an asterisk (*) is displayed for that probe. The `-w` option may be used to set the timeout interval. Other possible annotations that may appear after the time are:

- `!` the `ttl` (`hop limit`) value in the received packet is <= 1.
- `!H` host unreachable.
- `!X` communication administratively prohibited.
- `<!N>` ICMP (ICMPv6) unreachable code N.

The following annotations appear only for IPv4:

- `!F` fragmentation needed. This should never occur. If this is seen, the associated gateway is broken.
- `!N` network unreachable.
Protocol unreachable.

Source route failed. It is likely that the gateway does not support source routing.

Unreachable for the specified tos (type-of-service).

Source host isolated or precedence problem.

The following annotations appear only for IPv6:

Host unreachable for a reason other than lack of an entry in the routing table.

Packet too big.

Destination is not a neighbor.

Unrecognized next header.

If almost all the probes result in some kind of unreachable code, then traceroute gives up and exits.

The destination host is not supposed to process the UDP probe packets, so the destination port default is set to an unlikely value. However, if some application on the destination is using that value, the value of port can be changed with the -p option.

The only mandatory parameter is the destination host name or IP number. The default probe datagram length is 40 bytes (60 bytes for IPv6), but this may be increased by specifying a packet length (in bytes) after the destination host name.

All integer arguments to traceroute can be specified in either decimal or hexadecimal notation. For example, packetlen can be specified either as 256 or 0x100.

Options

-A addr_family

Specify the address family of the target host. addr_family can be either inet or inet6. Address family determines which protocol to use. For an argument of inet, IPv4 is used. For inet6, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, traceroute will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.
Specify the address family \texttt{inet} or \texttt{inet6} to override the default behavior. If the argument specified is \texttt{inet}, \texttt{traceroute} will use the IPv4 address associated with the hostname. If none exists, \texttt{traceroute} will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.

If the specified argument is \texttt{inet6}, \texttt{traceroute} will use the IPv6 address that is associated with the hostname. If none exists, \texttt{traceroute} will state that the host is unknown and exit.

\texttt{-a}

Probe all of the addresses of a multi-homed destination. The output looks like \texttt{traceroute} has been run once for each IP address of the destination. If this option is used together with \texttt{-A}, \texttt{traceroute} probes only the addresses that are of the specified address family. While probing one of the addresses of the destination, user can skip to the next address by sending a SIGINT, or exit \texttt{traceroute} by sending a SIGQUIT signal. See \texttt{signal(3C)}

\texttt{-c traffic_class}

Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of \texttt{traffic_class} set in the probe packet. This option is valid only on IPv6.

\texttt{-d}

Set the \texttt{SO_DEBUG} socket option.

\texttt{-F}

Set the “don’t fragment” bit. This option is valid only on IPv4. When specified from within a shared-IP zone, this option has no effect as the “don’t fragment” bit is always set in this case.

\texttt{-f first_hop}

Set the starting \texttt{ttl (hop limit)} value to \texttt{first_hop}, to override the default value 1. \texttt{traceroute} skips processing for those intermediate gateways which are less than \texttt{first_hop} hops away.

\texttt{-g gateway}

Specify a loose source route \texttt{gateway}. The user can specify more than one \texttt{gateway} by using \texttt{-g} for each gateway. The maximum number of gateways is 8 for IPv4 and 127 for IPv6.

Note that some factors such as the link MTU can further limit the number of gateways for IPv6. This option cannot be used with the \texttt{-r} option.

Only users with the \{PRIV\_NET\_RAWACCESS\} privilege can specify a loose source route with this option.

\texttt{-I}

Use ICMP (ICMP6) \texttt{ECHO} instead of UDP datagrams.

\texttt{-i iface}

For IPv4, this option specifies a network interface to obtain the source IP address. This is normally only useful on a multi-homed host. The \texttt{-S} option is also another way to do this.
For IPv6, it specifies the network interface on which probe packets are transmitted. The argument can be either an interface index, for example, 1, 2, or an interface name, for example, er10, hme0.

- L flow_label
  Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

- l
  Print the value of the ttl (hop limit) field in each packet received.

- m max_hop
  Set the maximum ttl (hop limit) used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.

- n
  Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.

- P pause_sec
  Specify a delay, in seconds, to pause between probe packets. This may be necessary if the final destination does not accept undeliverable packets in bursts. By default, traceroute sends the next probe as soon as it has received a reply. Note that pause_sec is a real number.

- p port
  Set the base UDP port number used in probes. The default is 33434. traceroute hopes that nothing is listening on UDP ports (base+((nhops - 1)*nqueries) to (base+((nhops*nqueries)-1)) at the destination host, so that an ICMP (ICMP6) PORT_UNREACHABLE message will be returned to terminate the route tracing. If something is listening on a port in the default range, this option can be used to select an unused port range. nhops is defined as the number of hops between the source and the destination.

- Q max_timeout
  Stop probing this hop after max_timeout consecutive timeouts are detected. The default value is 5. Useful in combination with the -q option if you have specified a large nqueries probe count.

- q nqueries
  Set the desired number of probe queries. The default is 3.

- r
  Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router daemon. See in. routed(1M). You cannot use this option if the -g option is used.

- S
  Display a summary of how many probes were not answered for each hop.
-s src_addr
Use the following address, which usually is given as a literal IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address traceroute picks by default. If the IP address is not one of this machine’s interface addresses, an error is returned and nothing is sent. For IPv4, when used together with the -1 option, the given IP address should be configured on the specified interface. Otherwise, an error will be returned. In the case of IPv6, the interface name and the source address do not have to match.

-t tos
Set the tos (type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the tos value set in the probe packet. This option is valid only on IPv4.

-v
Verbose output. For each hop, the size and the destination of the response packets is displayed. Also ICMP (ICMP6) packets received other than TIME_EXCEEDED and UNREACHABLE are listed as well.

-w waittime
Set the time, in seconds, to wait for a response to a probe. The default is 5 seconds.

-x
Prevent traceroute from calculating checksums. Checksums are usually required for the last hop when using ICMP ECHO probes. This option is valid only on IPv4. See the -I option.

When specified from within a shared-IP zone, this option has no effect as the checksum is always calculated by the operating system in this case.

Operands
The following operands are supported:

host
The network host.

Examples
EXAMPLE 1  Sample Output From the traceroute Utility
Some sample output from the traceroute utility might be:

```
istanbul% traceroute london
traceroute: Warning: london has multiple addresses; \ 
using 4::114:a00:20ff:ab3d:83ed
traceroute: Warning: Multiple interfaces found; \ 
using 4::56:a00:20ff:fe93:8dde @ eri0:2
traceroute to london (4::114:a00:20ff:ab3d:83ed), 30 hops max, \ 
60 byte packets
1  frbldg7c-86 (4::56:a00:20ff:fe1f:65a1)  1.786 ms  1.544 ms  1.719 ms
```
EXAMPLE 1  Sample Output From the traceroute Utility  (Continued)

2  frbldg7b-77 (4::255::0:c0a8:517)  2.587 ms  3.001 ms  2.988 ms
3  london (4::114:a00:20ff:ab3d:83ed)  3.122 ms  2.744 ms  3.356 ms

The target host, london, has both IPv4 and IPv6 addresses in the name service database. According to the default behavior, traceroute uses IPv6 address of the destination host.

EXAMPLE 2  Using the traceroute Utility For a Host Which has Only IPv4 Addresses

In the following examples, traceroute is tracking the route to host sanfrancisco, which has only IPv4 addresses in the name service database. Therefore traceroute uses only IPv4 addresses. The following shows the 7-hop path that a packet would follow from the host istanbul to the host sanfrancisco.

istanbul% traceroute sanfrancisco
traceroute: Warning: Multiple interfaces found; using 172.31.86.247 @eri0
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 40 byte packets
1  frbldg7c-86 (172.31.86.1) 1.516 ms 1.283 ms 1.362 ms
2  flrbldg7u (172.31.17.131) 2.277 ms 1.773 ms 2.186 ms
3  bldg4-bldg1 (172.30.4.42) 1.978 ms 1.986 ms 13.996 ms
4  bldg6-bldg4 (172.30.4.49) 2.655 ms 3.042 ms 2.344 ms
5  ferbldg11a-001 (172.29.1.236) 2.636 ms 3.432 ms 3.830 ms
6  frbldg12b-153 (172.29.153.72) 3.452 ms 3.146 ms 2.962 ms
7  sanfrancisco (172.29.64.39) 3.430 ms 3.312 ms 3.451 ms

EXAMPLE 3  Using the traceroute Utility With Source Routing

The following example shows the path of a packet that goes from istanbul to sanfrancisco through the hosts cairo and paris, as specified by the -g option. The -I option makes traceroute send ICMP ECHO probes to the host sanfrancisco. The -i option sets the source address to the IP address configured on the interface qe0.

istanbul% traceroute -g cairo -g paris -i qe0 -q 1 -I sanfrancisco
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 56 byte packets
1  frbldg7c-86 (172.31.86.1) 2.012 ms
2  flrbldg7u (172.31.17.131) 4.960 ms
3  cairo (192.168.163.175) 4.894 ms
4  flrbldg7u (172.31.17.131) 3.475 ms
5  frbldg7c-017 (172.31.17.83) 4.126 ms
6  paris (172.31.86.31) 4.086 ms

Warnings  This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use traceroute(1M) during normal operations or from automated scripts.
The `trapstat` utility gathers and displays run-time trap statistics on UltraSPARC-based systems. The default output is a table of trap types and CPU IDs, with each row of the table denoting a trap type and each column of the table denoting a CPU. If standard output is a terminal, the table contains as many columns of data as can fit within the terminal width; if standard output is not a terminal, the table contains at most six columns of data. By default, data is gathered and displayed for all CPUs; if the data cannot fit in a single table, it is printed across multiple tables. The set of CPUs for which data is gathered and displayed can be optionally specified with the `-c` or `-C` option.

Unless the `-r` option or the `-a` option is specified, the value displayed in each entry of the table corresponds to the number of traps per second. If the `-r` option is specified, the value corresponds to the number of traps over the interval implied by the specified sampling rate; if the `-a` option is specified, the value corresponds to the accumulated number of traps since the invocation of `trapstat`.

By default, `trapstat` displays data once per second, and runs indefinitely; both of these behaviors can be optionally controlled with the `interval` and `count` parameters, respectively. The `interval` is specified in seconds; the `count` indicates the number of intervals to be executed before exiting. Alternatively, `command` can be specified, in which case `trapstat` executes the provided command and continues to run until the command exits. A positive integer is assumed to be an `interval`; if the desired `command` cannot be distinguished from an integer, the full path of `command` must be specified.

UltraSPARC I (obsolete), II, and III handle translation lookaside buffer (TLB) misses by trapping to the operating system. TLB miss traps can be a significant component of overall system performance for some workloads; the `-t` option provides in-depth information on these traps. When run with this option, `trapstat` displays both the rate of TLB miss traps and the percentage of time spent processing those traps. Additionally, TLB misses that hit in the translation storage buffer (TSB) are differentiated from TLB misses that further miss in the TSB. (The TSB is a software structure used as a translation entry cache to allow the TLB to be quickly filled; it is discussed in detail in the *UltraSPARC II User's Manual*.) The TLB and TSB miss information is further broken down into user- and kernel-mode misses.

Workloads with working sets that exceed the TLB reach may spend a significant amount of time missing in the TLB. To accommodate such workloads, the operating system supports multiple page sizes: larger page sizes increase the effective TLB reach and thereby reduce the number of TLB misses. To provide insight into the relationship between page size and TLB miss rate, `trapstat` optionally provides in-depth TLB miss information broken down by page size using the `-T` option. The information provided by the `-T` option is a superset of that provided by the `-t` option; only one of `-t` and `-T` can be specified.
Options

- The following options are supported:
  
  - **-a**
    
    Displays the number of traps as accumulating, monotonically increasing values instead of per-second or per-interval rates.

  - **-c cpulist**
    
    Enables `trapstat` only on the CPUs specified by `cpulist`.
    
    `cpulist` can be a single processor ID (for example, 4), a range of processor IDs (for example, 4-6), or a comma separated list of processor IDs or processor ID ranges (for example, 4, 5, 6 or 4, 6-8).

  - **-C processor_set_id**
    
    Enables `trapstat` only on the CPUs in the processor set specified by `processor_set_id`.
    
    `trapstat` modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, `trapstat` modifies its output to include the added CPU; if a CPU is removed from the set, `trapstat` modifies its output to exclude the removed CPU. At most one processor set can be specified.

  - **-e entrylist**
    
    Enables `trapstat` only for the trap table entry or entries specified by `entrylist`. A trap table entry can be specified by trap number or by trap name (for example, the level-10 trap can be specified as 74, 0x4A, 0x4a, or level-10).
    
    `entrylist` can be a single trap table entry or a comma separated list of trap table entries. If the specified trap table entry is not valid, `trapstat` prints a table of all valid trap table entries and values. A list of valid trap table entries is also found in The SPARC Architecture Manual, Version 9 and the Sun Microelectronics UltraSPARC II User's Manual. If the parsable option (`-P`) is specified in addition to the `-e` option, the format of the data is as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Timestamp (nanoseconds since start)</td>
</tr>
<tr>
<td>2</td>
<td>CPU ID</td>
</tr>
<tr>
<td>3</td>
<td>Trap number (in hexadecimal)</td>
</tr>
<tr>
<td>4</td>
<td>Trap name</td>
</tr>
<tr>
<td>5</td>
<td>Trap rate per interval</td>
</tr>
</tbody>
</table>

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; exant fields will remain unchanged.
Lists trap table entries. By default, a table is displayed containing all valid trap numbers, their names and a brief description. The trap name is used in both the default output and in the entrylist parameter for the -e argument. If the parsable option (-P) is specified in addition to the -l option, the format of the data is as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Trap number in hexadecimal</td>
</tr>
<tr>
<td>2</td>
<td>Trap number in decimal</td>
</tr>
<tr>
<td>3</td>
<td>Trap name</td>
</tr>
<tr>
<td>Remaining</td>
<td>Trap description</td>
</tr>
</tbody>
</table>

Generates parsable output. When run without other data gathering modifying options (that is, -e, -t or -T), trapstat's the parsable output has the following format:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Timestamp (nanoseconds since start)</td>
</tr>
<tr>
<td>2</td>
<td>CPU ID</td>
</tr>
<tr>
<td>3</td>
<td>Trap number (in hexadecimal)</td>
</tr>
<tr>
<td>4</td>
<td>Trap name</td>
</tr>
<tr>
<td>5</td>
<td>Trap rate per interval</td>
</tr>
</tbody>
</table>

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; extant fields will remain unchanged.

Explicitly sets the sampling rate to be rate samples per second. If this option is specified, trapstat's output changes from a traps-per-second to traps-per-sampling-interval.

Enables TLB statistics.

A table is displayed with four principal columns of data: itlb-miss, itsb-miss, dttlb-miss, and dtstb-miss. The columns contain both the rate of the corresponding event and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs,
with each CPU consuming two rows: one row for user-mode events (denoted with u) and one row for kernel-mode events (denoted with k). For each row, the percentage of CPU time is totalled and displayed in the rightmost column. The CPUs are delineated with a solid line. If the parsable option (-P) is specified in addition to the -t option, the format of the data is as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Timestamp (nanoseconds since start)</td>
</tr>
<tr>
<td>2</td>
<td>CPU ID</td>
</tr>
<tr>
<td>3</td>
<td>Mode (k denotes kernel, u denotes user)</td>
</tr>
<tr>
<td>4</td>
<td>I-TLB misses</td>
</tr>
<tr>
<td>5</td>
<td>Percentage of time in I-TLB miss handler</td>
</tr>
<tr>
<td>6</td>
<td>I-TSB misses</td>
</tr>
<tr>
<td>7</td>
<td>Percentage of time in I-TSB miss handler</td>
</tr>
<tr>
<td>8</td>
<td>D-TLB misses</td>
</tr>
<tr>
<td>9</td>
<td>Percentage of time in D-TLB miss handler</td>
</tr>
<tr>
<td>10</td>
<td>D-TSB misses</td>
</tr>
<tr>
<td>11</td>
<td>Percentage of time in D-TSB miss handler</td>
</tr>
</tbody>
</table>

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 12; extant fields will remain unchanged.

- T

Enables TLB statistics, with page size information. As with the -t option, a table is displayed with four principal columns of data: itlb-miss, itsb-miss, dtlb-miss, and dtwb-miss. The columns contain both the absolute number of the corresponding event, and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two sets of rows: one set for user-level events (denoted with u) and one set for kernel-level events (denoted with k). Each set, in turn, contains as many rows as
there are page sizes supported (see `getpagesize(3C)`). For each row, the percentage of CPU time is totalled and displayed in the right-most column. The two sets are delineated with a dashed line; CPUs are delineated with a solid line. If the parsable option (`-P`) is specified in addition to the `-T` option, the format of the data is as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Timestamp (nanoseconds since start)</td>
</tr>
<tr>
<td>2</td>
<td>CPU ID</td>
</tr>
<tr>
<td>3</td>
<td>Mode <em>k</em> denotes kernel, <em>u</em> denotes user)</td>
</tr>
<tr>
<td>4</td>
<td>Page size, in decimal</td>
</tr>
<tr>
<td>5</td>
<td>I-TLB misses</td>
</tr>
<tr>
<td>6</td>
<td>Percentage of time in I-TLB miss handler</td>
</tr>
<tr>
<td>7</td>
<td>I-TSB misses</td>
</tr>
<tr>
<td>8</td>
<td>Percentage of time in I-TSB miss handler</td>
</tr>
<tr>
<td>9</td>
<td>D-TLB misses</td>
</tr>
<tr>
<td>10</td>
<td>Percentage of time in D-TLB miss handler</td>
</tr>
<tr>
<td>11</td>
<td>D-TSB misses</td>
</tr>
<tr>
<td>12</td>
<td>Percentage of time in D-TSB miss handler</td>
</tr>
</tbody>
</table>

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 13; extant fields will remain unchanged.

**Examples**

**EXAMPLE 1 Using `trapstat` Without Options**

When run without options, `trapstat` displays a table of trap types and CPUs. At most six columns can fit in the default terminal width; if (as in this example) there are more than six CPUs, multiple tables are displayed:

```
example# trapstat

```

<table>
<thead>
<tr>
<th>vct</th>
<th>name</th>
<th>cpu0</th>
<th>cpu1</th>
<th>cpu4</th>
<th>cpu5</th>
<th>cpu8</th>
<th>cpu9</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>cleanwin</td>
<td>6446</td>
<td>4837</td>
<td>6368</td>
<td>2153</td>
<td>2623</td>
<td>1321</td>
</tr>
<tr>
<td>41</td>
<td>level-1</td>
<td>100</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

EXAMPLE 3  Using *trapstat* with TLB Statistics

The *-t* option displays in-depth TLB statistics, including the amount of time spent performing TLB miss processing. The following example shows that the machine is spending 14.1 percent of its time just handling D-TLB misses:

```
example# trapstat -t
```

```
cpu m| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim

EXAMPLE 4  Using *trapstat* with TLB Statistics and Page Size Information

By specifying the *-T* option, *trapstat* shows TLB misses broken down by page size. In this example, CPU 0 is spending 7.9 percent of its time handling user-mode TLB misses on 8K pages, and another 2.3 percent of its time handling user-mode TLB misses on 64K pages.

```
example# trapstat -T -c 0
```

```
cpu m size| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
----------+-------------------------------+-------------------------------+----
 0 u 8k| 1300 0.1 15 0.0 | 104897 7.9 90 0.0 | 8.0
 0 u 64k| 0 0.0 0 0.0 | 29935 2.3 7 0.0 | 2.3
 0 u 512k| 0 0.0 0 0.0 | 3569 0.2 2 0.0 | 0.2
 0 u 4m| 0 0.0 0 0.0 | 233 0.0 2 0.0 | 0.0
----------+-------------------------------+-------------------------------+----
 0 k 8k| 13 0.0 0 0.0 | 21733 6.5 110 0.0 | 6.5
 0 k 64k| 0 0.0 0 0.0 | 0 0.0 0 0.0 | 0.0
 0 k 512k| 0 0.0 0 0.0 | 0 0.0 206 0.1 | 0.1
 0 k 4m| 0 0.0 0 0.0 | 0 0.0 0 0.0 | 0.0
==========+===============================+===============================+====
   ttl | 1313 0.1 15 0.0 | 210367 17.1 417 0.2 | 17.5
```
EXAMPLE 5  Using trapstat with Entry Filtering

By specifying the -e option, trapstat displays statistics for only specific trap types. Using this option minimizes the probe effect when seeking specific data. This example yields statistics for only the dtlb-prot and syscall-32 traps on CPUs 12 through 15:

```
example# trapstat -e dtlb-prot,syscall-32 -c 12-15
vct name | cpu12 cpu13 cpu14 cpu15
------------------------+------------------------------------
 6c dtlb-prot | 817 754 1018 560
108 syscall-32 | 1426 1647 2186 1142
```

EXAMPLE 6  Using trapstat with a Higher Sampling Rate

The following example uses the -r option to specify a sampling rate of 1000 samples per second, and filter only for the level-10 trap. Additionally, specifying the -P option yields parsable output.

Notice the timestamp difference between the level-10 events: 9,998,000 nanoseconds and 10,007,000 nanoseconds. These level-10 events correspond to the system clock, which by default ticks at 100 hertz (that is, every 10,000,000 nanoseconds).

```
example# trapstat -e level-10 -P -r 1000
1070400  0 4a level-10  0
2048600  0 4a level-10  0
3030400  0 4a level-10  1
4035800  0 4a level-10  0
5027200  0 4a level-10  0
6027200  0 4a level-10  0
7027400  0 4a level-10  0
8028200  0 4a level-10  0
9026400  0 4a level-10  0
10029600 0 4a level-10  0
11028600 0 4a level-10  0
12024000 0 4a level-10  0
13028400 0 4a level-10  1
14031200 0 4a level-10  0
15027200 0 4a level-10  0
16027600 0 4a level-10  0
17025000 0 4a level-10  0
18026000 0 4a level-10  0
19027800 0 4a level-10  0
20025600 0 4a level-10  0
21025200 0 4a level-10  0
22025000 0 4a level-10  0
```
EXAMPLE 6  Using `trapstat` with a Higher Sampling Rate  

(Continued)

<table>
<thead>
<tr>

<td>40-45% per TLB miss trap hitting in the TSB, 25-30% per TLB miss trap missing in the TSB</td>
</tr>
</tbody>
</table>

See Also `lockstat(1M), pmap(1), psrset(1M), psrinfo(1M), pbind(1M), ppksz(1), getpagesize(3C)`

Notes When enabled, `trapstat` induces a varying probe effect, depending on the type of information collected. While the precise probe effect depends upon the specifics of the hardware, the following table can be used as a rough guide:

These probe effects are per trap not for the system as a whole. For example, running `trapstat` with the default options on a system that spends 7% of total time handling traps induces a performance degradation of less than one half of one percent; running `trapstat` with the -t or -T option on a system spending 5% of total time processing TLB misses induce a performance degradation of no more than 2.5%.

When run with the -t or -T option, `trapstat` accounts for its probe effect when calculating the %tim fields. This assures that the %tim fields are a reasonably accurate indicator of the time a given workload is spending handling TLB misses — regardless of the perturbing presence of `trapstat`.

</tr>
</tbody>
</table>

System Administration Commands - Part 3  2569
While the $%tim$ fields include the explicit cost of executing the TLB miss handler, they do not include the implicit costs of TLB miss traps (for example, pipeline effects, cache pollution, etc). These implicit costs become more significant as the trap rate grows; if high $%tim$ values are reported (greater than 50%), you can accurately infer that much of the balance of time is being spent on the implicit costs of the TLB miss traps.

Due to the potential system wide degradation induced, only the super-user can run $\text{trapstat}$.

Due to the limitation of the underlying statistics gathering methodology, only one instance of $\text{trapstat}$ can run at a time.
**Name**
ttyadm – format and output port monitor-specific information

**Synopsis**

[-m modules] [-p prompt] [-t timeout] [-S y | n]
[-T termtype] -d device -l ttylabel -s service

/usr/sbin/ttyadm -V

**Description**
The `ttyadm` command is an administrative command that formats `ttymon(1M)`-specific information and writes it to standard output. The Service Access Facility (SAF) requires each port monitor to provide such a command. Note that the port monitor administrative file is updated by the Service Access Controller’s administrative commands, `sacadm(1M)` and `pmadm(1M)`. `ttyadm` provides a means of presenting formatted port monitor-specific (ttymon-specific) data to these commands.

**Options**
The following options are supported:

- **-b**
  Set the “bi-directional port” flag. When this flag is set, the line can be used in both directions. `ttymon` will allow users to connect to the service associated with the port, but if the port is free, `uucico(1M)`, `cu(1C)`, or `ct(1C)` can use it for dialing out.

- **-c**
  Set the connect-on-carrier flag for the port. If the `-c` flag is set, `ttymon` will invoke the port’s associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done).

- **-d device**
  `device` is the full pathname of the device file for the TTY port.

- **-h**
  Set the hangup flag for the port. If the `-h` flag is not set, `ttymon` will force a hangup on the line by setting the speed to 0 before setting the speed to the default or specified value.

- **-i message**
  Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the `ttymon` monitoring the port is disabled.

- **-I**
  Initialize only. If the `-I` option is used, `ttymon` will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.

- **-l ttylabel**
  Specify which `ttylabel` in the `/etc/ttydefs` file to use as the starting point when searching for the proper baud rate.

- **-m modules**
  Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. `modules` must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed.

- **-p prompt**
  Specify the prompt message, for example, “login:”. 
-r count  
When the -r option is invoked, ttymon will wait until it receives data from the port before it displays a prompt. If count is 0, ttymon will wait until it receives any character. If count is greater than 0, ttymon will wait until count newlines have been received.

-s service  
_service_ is the full pathname of the service to be invoked when a connection request is received. If arguments are required, the command and its arguments must be enclosed in double quotes (" ").

-S y|n  
Set the software carrier value. y will turn software carrier on. n will turn software carrier off.

-t timeout  
Specify that ttymon should close a port if the open on the port succeeds, and no input data is received in timeout seconds.

-T termttype  
Set the terminal type. The _TERM_ environment variable will be set to termttype.

-V  
Display the version number of the current /usr/lib/saf/ttymon command.

**Output**  
If successful, ttymon will generate the requested information, write it to standard output, and exit with a status of 0. If ttymon is invoked with an invalid number of arguments or invalid arguments, or if an incomplete option is specified, an error message will be written to standard error and ttymon will exit with a non-zero status.

**Files**  
/etc/ttydefs

_System Administration Guide: Basic Administration_
ttymon is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Normally, ttymon is configured to run under the Service Access Controller, sac(1M), as part of the Service Access Facility (SAF). It is configured using the sacadm(1M) command. Each instance of ttymon can monitor multiple ports. The ports monitored by an instance of ttymon are specified in the port monitor’s administrative file. The administrative file is configured using the pmadm(1M) and ttyadm(1M) commands. When an instance of ttymon is invoked by the sac command, it starts to monitor its ports. For each port, ttymon first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in /etc/logindevperm, device owner, group and permissions are set. (See logindevperm(4).) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the sttydefs(1M) command. Default line disciplines on ports are usually set up by the autopush(1M) command of the Autopush Facility.

ttymon then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, ttymon tries the next speed and writes the prompt again. When valid input is received, ttymon interprets the per-service configuration file for the port, if one exists, creates a utmpx entry if required (see utmpx(4)), establishes the service environment, and then invokes the service associated with the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return. After the service terminates, ttymon cleans up the utmpx entry, if one exists, and returns the port to its initial state.

If autobaud is enabled for a port, ttymon will try to determine the baud rate on the port automatically. Users must enter a carriage return before ttymon can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by autobaud are 110, 1200, 2400, 4800, and 9600.

If a port is configured as a bidirectional port, ttymon will allow users to connect to a service, and, if the port is free, will allow uucico(1M), cu(1C), or ct(1C) to use it for dialing out. If a port is bidirectional, ttymon will wait to read a character before it prints a prompt.

If the connect-on-carrier flag is set for a port, ttymon will immediately invoke the port’s associated service when a connection request is received. The prompt message will not be sent.

If a port is disabled, ttymon will not start any service on that port. If a disabled message is specified, ttymon will send out the disabled message when a connection request is received. If ttymon is disabled, all ports under that instance of ttymon will also be disabled.
The service `ttymon` invokes for a port is specified in the `ttymon` administrative file. `ttymon` will scan the character string giving the service to be invoked for this port, looking for a `%d` or a `%%` two-character sequence. If `%d` is found, `ttymon` will modify the service command to be executed by replacing those two characters by the full path name of this port (the device name). If `%%` is found, they will be replaced by a single `%`. When the service is invoked, file descriptors 0, 1, and 2 are opened to the port device for reading and writing. The service is invoked with the user ID, group ID and current home directory set to that of the user name under which the service was registered with `ttymon`. Two environment variables, `HOME` and `TTYPROMPT`, are added to the service's environment by `ttymon`. `HOME` is set to the home directory of the user name under which the service is invoked. `TTYPROMPT` is set to the prompt string configured for the service on the port. This is provided so that a service invoked by `ttymon` has a means of determining if a prompt was actually issued by `ttymon` and, if so, what that prompt actually was.

See `ttyadm(1M)` for options that can be set for ports monitored by `ttymon` under the Service Access Controller.

### Service Invocation

The invocation of `ttymon` on the system console is managed under `smf(5)` by the service `svc:/system/console-login`. It provides a number of properties within the property group `ttymon` to control the invocation, as follows:

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>TTYMON OPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>device</td>
<td>astring</td>
<td>[-d device]</td>
</tr>
<tr>
<td>nohangup</td>
<td>boolean</td>
<td>[-h]</td>
</tr>
<tr>
<td>label</td>
<td>astring</td>
<td>[-l label]</td>
</tr>
<tr>
<td>modules</td>
<td>astring</td>
<td>[-m module1,module2]</td>
</tr>
<tr>
<td>prompt</td>
<td>astring</td>
<td>[-p prompt]</td>
</tr>
<tr>
<td>timeout</td>
<td>count</td>
<td>[-t timeout]</td>
</tr>
<tr>
<td>terminal_type</td>
<td>astring</td>
<td>[-T termttype]</td>
</tr>
</tbody>
</table>

If any value is the empty string or an integer set to zero, then the option is not passed to the `ttymon` invocation. The `-g` option is always specified for this invocation. The `-d` option always defaults to `/dev/console` if it is not set.

See EXAMPLES.

### Security

`ttymon` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `ttymon`. Here is a partial `pam.conf` file with entries for `ttymon` using the UNIX session management module.

```
ttymon session required /usr/lib/security/pam_unix_session.so.1
```

If there are no entries for the `ttymon` service, then the entries for the "other" service will be used.
The following options are supported:

- **-g**
  A special invocation of *ttymon* is provided with the *-g* option. This form of the command should only be called by applications that need to set the correct baud rate and terminal settings on a port and then connect to *login* service, but that cannot be pre-configured under the SAC. The following combinations of options can be used with *-g*:

- **-device**
  *device* is the full path name of the port to which *ttymon* is to attach. If this option is not specified, file descriptor 0 must be set up by the invoking process to a TTY port.

- **-h**
  If the *-h* flag is not set, *ttymon* will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.

- **-ttylabel**
  *ttylabel* is a link to a speed and TTY definition in the *ttydefs* file. This definition tells *ttymon* at what speed to run initially, what the initial TTY settings are, and what speed to try next if the user indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.

- **-mmmodules**
  When initializing the port, *ttymon* will pop all modules on the port, and then push *modules* in the order specified. *modules* is a comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.

- **-ppprompt**
  Allows the user to specify a prompt string. The default prompt is *Login:*

- **-timeout**
  Specifies that *ttymon* should exit if no one types anything in *timeout* seconds after the prompt is sent.

- **-termtype**
  Sets the TERM environment variable to *termtype*.

### Examples

#### EXAMPLE 1  Setting the Terminal Type

The following example sets the value of the terminal type (*-T*) option for the system console *ttymon* invocation:

```bash
svccfg -s svc:/system/console-login setprop \ 
ttymon/terminal_type = "xterm"
svcadm refresh svc:/system/console-login:default
```

### Environment Variables

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see *environ*(5)) are not set in the environment, the operational behavior of *ttymon* for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how *ttymon* behaves.
LC_CTYPE  
Determines how ttymon handles characters. When LC_CTYPE is set to a valid value, ttymon can display and handle text and filenames containing valid characters for that locale. ttymon can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. ttymon can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

Files
/etc/logindevperm

System Administration Guide: Basic Administration

Notes
If a port is monitored by more than one ttymon, it is possible for the ttymons to send out prompt messages in such a way that they compete for input.

The pam_unix(5) module is no longer supported. Similar functionality is provided by pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).
tunefs – tune an existing UFS file system

tunefs [-a maxcontig] [-d rotdelay] [-e maxbpg]
       [-m minfree] [-o space | time] special | filesystem

Description

tunefs is designed to change the dynamic parameters of a file system that affect the layout policies. When using tunefs with filesystem, filesystem must be in /etc/vfstab. The parameters that can be changed are indicated by the options given below.

Options

The following options are supported:

- **a maxcontig**
  The maximum number of logical blocks, belonging to one file, that is allocated contiguously. The default is calculated as follows:

  \[
  \text{maxcontig} = \frac{\text{disk drive maximum transfer size}}{\text{disk block size}}
  \]

  If the disk drive’s maximum transfer size cannot be determined, the default value for maxcontig is calculated from kernel parameters as follows:

  If maxphys is less than ufs_maxmaxphys, which is 1 Mbyte, then maxcontig is set to maxphys. Otherwise, maxcontig is set to ufs_maxmaxphys.

  You can set maxcontig to any positive integer value.

  The actual value will be the lesser of what has been specified and what the hardware supports.

- **d rotdelay**
  This parameter is obsolete as of the Solaris 10 release. The value is always set to 0, regardless of the input value.

- **e maxbpg**
  Indicates the maximum number of contiguous logical blocks any single file can allocate from a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total contiguous logical blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group.

  The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher.

- **m minfree**
  Specifies the minimum free space threshold, or the percentage of space held back from normal users. This value can be set to 0. However, up to a factor of three in throughput will be lost over the performance obtained at a 10% threshold. Note: If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.
-o space | time  The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is time.

Generally, you should optimize for time unless the file system is over 90% full.

Usage  See largefile(5) for the description of the behavior of tunefs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

txzonemgr – Trusted Extensions Zone Manager Configuration Utility

**Name**

txzonemgr – Trusted Extensions Zone Manager Configuration Utility

**Synopsis**

/usr/sbin/txzonemgr

**Description**

The txzonemgr shell script provides a simple menu-based GUI wizard for creating, installing, initializing, and booting labeled zones on a system where Trusted Extensions is enabled. The script provides contextual menus with appropriate choices.

**Attributes**

**Solaris Trusted Extensions Administrator's Procedures**

**Notes**

If administering zones from JDS, use txzonemgr rather than CDE actions.

txzonemgr uses the zenity command. For details, see the zenity(1) man page.
Name  tzreload – notify timezone update

Synopsis  /usr/sbin/tzreload [-a]

Description  The tzreload command notifies active (running) processes to reread timezone information. The timezone information is cached in each process, absent a tzreload command, is never reread until a process is restarted. In response to a tzreload command, active processes reread the current timezone information at the next call to ctime(3C) and mktime(3C). By default, the tzreload notification is sent to the processes within the current zone.

In addition to notifying active processes, the tzreload command also notifies cron(1M), to reinitialize the job scheduler with the new timezone information.

Options  The following options are supported:

- a  Notify processes in all zones.

Files  /usr/share/lib/zoneinfo
Standard zone information directory.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcs</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>

See Also  cron(1M), zdump(1M), zic(1M), zoneadm(1M), ctime(3C), mktime(3C), attributes(5)  
rpc.cmsd(1M), part of the CDE man page set.

Notes  Although tzreload reinitializes cron(1M), applications that are affected by timezone changes still need to be restarted or reinitialized if they do not reread the new timezone information before timezone changes take place.
Name  tzselect – select a time zone

Synopsis  /usr/bin/tzselect

Description  The tzselect program asks you a series of questions about the current location and outputs the resulting time zone description to standard output. The output is suitable as a value for the TZ environment variable.

All user interaction is through standard input and standard error.

Options  The tzselect command has no options.

Exit Status  The following exit values are returned:

0  Timezone information was successfully obtained.

>0  An error occurred.

Files  /usr/share/lib/zoneinfo directory containing timezone data files

The `uadmin` command provides control for basic administrative functions. This command is tightly coupled to the system administration procedures and is not intended for general use. It may be invoked only by the super-user.

Both the `cmd` (command) and `fcn` (function) arguments are converted to integers and passed to the `uadmin` system call. The optional `mdep` (machine dependent) argument is only available for the `cmd` values of 1 (A_REBOOT), 2 (A_SHUTDOWN), or 5 (A_DUMP). For any other `cmd` value, no `mdep` command-line argument is allowed.

When passing an `mdep` value that contains whitespaces, the string must be grouped together as a single argument enclosed within quotes, for example:

```
uadmin 1 1 "-s kernel/unix"
```

### Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>

</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

### See Also

`halt(1M), reboot(1M), uadmin(2), attributes(5)`

### Warnings

Shutting down or halting the system by means of `uadmin` does not update the boot archive. Avoid using this command after

- editing of files such as `/etc/system`
- installing new driver binaries or kernel binaries
- updating existing driver binaries or kernel binaries.

Use `reboot(1M)` or `halt(1M)` instead.
### Name
ucodeadm – update processor microcode

### Synopsis
```
/usr/sbin/ucodeadm -v

/usr/sbin/ucodeadm -u microcode-text-file

/usr/sbin/ucodeadm -i [-R path] microcode-text-file
```

### Description
The ucodeadm utility can be used to report running microcode revision on the processors, update microcode, or install microcode on the target system to be used during the boot process.

The `microcode-text-file` can be obtained from processor vendors.

### Options
- `-v` Report microcode revision.
- `-u microcode-text-file` Update microcode on all cross-call interrupt ready processors.
- `-i microcode-text-file` Install microcode files on target system to be used during the next boot cycle. The text file name must have the vendor name prefix, such as “intel” or “amd”.

By default the microcode files will be installed at:
```
/platform/i86pc/ucode/$VENDORSTR/
```
where VENDORSTR is either “GenuineIntel” or “AuthenticAMD”.

- `-R alternate path` Install microcode path in the alternate path.

### Examples
**EXAMPLE 1** Reporting the Microcode Revision
The following example displays the microcode revision that is currently running:
```
# ucodeadm -v
```

**EXAMPLE 2** Updating the Processor Microcode
The following example updates the processor microcode to `intel-ucode.txt`:
```
# ucodeadm -u intel-ucode.txt
```

**EXAMPLE 3** Installing the Microcode on the Target System
The following example installs the microcode on the target system, `/export/ucode-path`:
```
# ucodeadm -i -R /export/ucode-path intel-ucode.txt
```

If an alternate path is used when installing the microcode on the target system, the installed microcode file is not used on the next boot cycle.

### Exit Status
The following exit values are returned:

- `0` Successful completion.
>0 An error occurred.

ufsdump – incremental filesystem dump

**Synopsis**

```
/usr/sbin/ufsdump [options] [arguments] files_to_dump
```

**Description**

`ufsdump` backs up all files specified by `files_to_dump` (usually either a whole file system or files within a file system changed after a certain date) to magnetic tape, diskette, or disk file.

The `ufsdump` command can only be used on unmounted file systems, or those mounted read-only. Attempting to dump a mounted, read-write file system might result in a system disruption or the inability to restore files from the dump. Consider using the `fssnap(1M)` command to create a file system snapshot if you need a point-in-time image of a file system that is mounted.

If a file system was mounted with the logging option, it is strongly recommended that you run `ufsdump` as the root user. Running the command as a non-root user might result in the creation of an inconsistent dump.

`options` is a single string of one-letter `ufsdump` options.

`arguments` may be multiple strings whose association with the options is determined by order. That is, the first argument goes with the first option that takes an argument; the second argument goes with the second option that takes an argument, and so on.

`files_to_dump` is required and must be the last argument on the command line. See `OPERANDS` for more information.

With most devices `ufsdump` can automatically detect the end-of-media. Consequently, the `d`, `s`, and `t` options are not necessary for multi-volume dumps, unless `ufsdump` does not understand the way the device detects the end-of-media, or the files are to be restored on a system with an older version of the `restore` command.

**Options**

The following options are supported:

- **0–9**
  The "dump level." All files specified by `files_to_dump` that have been modified since the last `ufsdump` at a lower dump level are copied to the `dump_file` destination (normally a magnetic tape device). For instance, if a "level 2" dump was done on Monday, followed by a "level 4" dump on Tuesday, a subsequent "level 3" dump on Wednesday would contain all files modified or added since the "level 2" (Monday) backup. A "level 0" dump copies the entire file system to the `dump_file`.

- **a** `archive_file`
  Archive file. Archive a dump table-of-contents in the specified `archive_file` to be used by `ufsrestore(1M)` to determine whether a file is in the dump file that is being restored.

- **b** `factor`
  Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge
tapes (c option) is 126. The highest blocking factor available with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with tar(1).

c Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since ufsdump can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is not specified, ufsdump will slightly miscompute the size of the tape. If the b, d, s or t options are specified with this option, their values will override the defaults set by this option.

d bpi Tape density. Not normally required, as ufsdump can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the c option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are:

1/2 inch tape
  6250 BPI

1/4 inch cartridge
  1000 BPI The tape densities and other options are documented in the st(7D) man page.

diskette. Dump to diskette.

f dump_file Dump file. Use dump_file as the file to dump to, instead of /dev/rmt/0. If dump_file is specified as -, dump to standard output.

If the name of the file is of the form machine:device, the dump is done from the specified machine over the network using rmt(1M). Since ufsdump is normally run by root, the name of the local machine must appear in the / .rhosts file of the remote machine. If the file is specified as user@machine:device, ufsdump will attempt to execute as the specified user on the remote machine. The specified user must have a .rhosts file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

l Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to two minutes for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.
L string
Sets the tape label to string, instead of the default none. string may be no more than sixteen
characters long. If it is longer, it is truncated and a warning printed; the dump will still be
done. The tape label is specific to the ufsdump tape format, and bears no resemblance to
IBM or ANSI-standard tape labels.

n
Notify all operators in the sys group that ufsdump requires attention by sending messages
to their terminals, in a manner similar to that used by the wall(1M) command. Otherwise,
such messages are sent only to the terminals (such as the console) on which the user
running ufsdump is logged in.

N device_name
Use device_name when recording information in /etc/dumpdates (see the u option) and
when comparing against information in /etc/dumpdates for incremental dumps. The
device_name provided can contain no white space as defined in scanf(3C) and is
case-sensitive.

o
Offline. Take the drive offline when the dump is complete or the end-of-media is reached
and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the
tape is removed from the drive automatically. This prevents another process which rushes
in to use the drive, from inadvertently overwriting the media.

s size
Specify the size of the volume being dumped to. Not normally required, as ufsdump can
detect end-of-media. When the specified size is reached, ufsdump waits for you to change
the volume. ufsdump interprets the specified size as the length in feet for tapes and
cartridges, and as the number of 1024-byte blocks for diskettes. The values should be a little
smaller than the actual physical size of the media (for example, 425 for a 450-foot
cartridge). Typical values for tape devices depend on the c option, for cartridge devices,
and the D option for diskettes:

1/2 inch tape
  2300 feet
60-Mbyte 1/4 inch cartridge
  425 feet
150-Mbyte 1/4 inch cartridge
  700 feet
diskette
  1422 blocks (Corresponds to a 1.44-Mbyte diskette, with one cylinder reserved for bad
  block information.)
S  Size estimate. Determine the amount of space that is needed to perform the dump without
actually doing it, and display the estimated number of bytes it will take. This is useful with
incremental dumps to determine how many volumes of media will be needed.

T tracks
  Specify the number of tracks for a cartridge tape. Not normally required, as ufsdump can
detect end-of-media. The default is 9 tracks. The t option is not compatible with the 0
option. Values for Sun-supported tape devices are:
  60-Mbyte 1/4 inch cartridge
    9 tracks
  150-Mbyte 1/4 inch cartridge
    18 tracks

T time_wait [hms]
  Sets the amount of time to wait for an autoload command to complete. This option is
ignored unless the t option has also been specified. The default time period to wait is two
minutes. Specify time units with a trailing h (for hours), m (for minutes), or s (for seconds).
The default unit is minutes.

U
  Update the dump record. Add an entry to the file /etc/dumpdates, for each file system
successfully dumped that includes the file system name (or device name as specified with
the N option), date, and dump level.

V
  Verify. After each tape or diskette is written, verify the contents of the media against the
source file system. If any discrepancies occur, prompt for new media, then repeat the
dump/verification process. The file system must be unmounted. This option cannot be
used to verify a dump to standard output.

W
  Warning. List the file systems that have not been backed up within a day. This information
is gleaned from the files /etc/dumpdates and /etc/vfstab. When the w option is used, all
other options are ignored. After reporting, ufsdump exits immediately.

W
  Warning with highlight. Similar to the w option, except that the W option includes all file
systems that appear in /etc/dumpdates, along with information about their most recent
dump dates and levels. File systems that have not been backed up within a day are
highlighted.

Operands
  The following operand is supported:

    files_to_dump
      Specifies the files to dump. Usually it identifies a whole file system by its raw device name
(for example, /dev/rdsk/c0t3d0s6). Incremental dumps (levels 1 to 9) of files changed
after a certain date only apply to a whole file system. Alternatively, files_to_dump can identify individual files or directories. All named directories that may be examined by the user running ufsdump, as well as any explicitly-named files, are dumped. This dump is equivalent to a level 0 dump of the indicated portions of the filesystem, except that /etc/dumpdates is not updated even if the -u option has been specified. In all cases, the files must be contained in the same file system, and the file system must be local to the system where ufsdump is being run.

files_to_dump is required and must be the last argument on the command line.

If no options are given, the default is 9uf /dev/rmt/0 files_to_dump.

Usage
See largefile(5) for the description of the behavior of ufsdump when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples
EXAMPLE 1 Using ufsdump

The following command makes a full dump of a root file system on c0t3d0, on a 150-MByte cartridge tape unit 0:

eexample# ufsdump 0cfu /dev/rmt/0 /dev/rdsk/c0t3d0s0

The following command makes and verifies an incremental dump at level 5 of the usr partition of c0t3d0, on a 1/2 inch reel tape unit 1,:

eexample# ufsdump 5fuv /dev/rmt/1 /dev/rdsk/c0t3d0s6

Exit Status
While running, ufsdump emits many verbose messages. ufsdump returns the following exit values:

0
Normal exit.

1
Startup errors encountered.

3
Abort – no checkpoint attempted.

Files
/dev/rmt/0
default unit to dump to

/etc/dumpdates
dump date record

/etc/group
to find group sys

/etc/hosts
to gain access to remote system with drive
/etc/vfstab
list of file systems

Notes

Read Errors  Fewer than 32 read errors on the file system are ignored.

Process Per Reel  Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.

Operator Intervention  ufsdump requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the n option, ufsdump interacts with the operator on ufsdump's control terminal at times when ufsdump can no longer proceed, or if something is grossly wrong. All questions ufsdump poses must be answered by typing yes or no, as appropriate.

Since backing up a disk can involve a lot of time and effort, ufsdump checkpoints at the start of each volume. If writing that volume fails for some reason, ufsdump will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.

Suggested Dump Schedule  It is vital to perform full, “level 0”, dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using shutdown(1M). While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.

Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.
Although the Tuesday through Friday incrementals contain “extra copies” of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day’s incremental dump.

**ufsdump uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run dump with a nice (process priority) of ‘−5’ or better will likely make ufsdump run slower instead of faster.**

**Overlapping Partitions**
Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places root on slice 0, swap on slice 1, /opt on slice 5 and /usr on slice 6.

It should be emphasized that ufsdump dumps one ufs file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing ufsdump on slice 2 with the intent of dumping the entire disk would instead dump only the root file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

**Bugs**
The /etc/vfstab file does not allow the desired frequency of backup for file systems to be specified (as /etc/fstab did). Consequently, the w and W options assume file systems should be backed up daily, which limits the usefulness of these options.
ufsrestore utility restores files from backup media created with the ufsdump command. ufsrestore’s actions are controlled by the key argument. The key is exactly one function letter (i, r, R, t, or x) and zero or more function modifiers (letters). The key string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the key string.

filename arguments which appear on the command line, or as arguments to an interactive command, are treated as shell glob patterns by the x and t functions; any files or directories matching the patterns are selected. The metacharacters *, ?, and [ ] must be protected from the shell if they appear on the command line. There is no way to quote these metacharacters to explicitly match them in a filename.

The temporary files rstdir* and rstmode* are placed in /tmp by default. If the environment variable TMPDIR is defined with a non-empty value, that location is used instead of /tmp.

You must specify one (and only one) of the function letters listed below. Note that i, x, and r are intended to restore files into an empty directory. The R function is intended for restoring into a populated directory.

i Interactive. After reading in the directory information from the media, ufsrestore invokes a shell-like interface that allows you to browse through the dump file’s directory hierarchy and select individual files to be extracted. Restoration has the same semantics as x (see below). See Interactive Commands, below, for a description of available commands.

r Recursive. Starting with an empty directory and a level 0 dump, the r function recreates the filesystem relative to the current working directory, exactly as it appeared when the dump was made. Information used to restore incremental dumps on top of the full dump (for example, restorestatable) is also included. Several ufsrestore runs are typical, one for each higher level of dump (0, 1, ..., 9). Files that were deleted between the level 0 and a subsequent incremental dump will not exist after the final restore. To completely restore a file system, use the r function restore the level 0 dump, and again for each incremental dump. Although this function letter is intended for a complete restore onto a new file system (one just created with newfs(1M)), if the file system contains files not on the backup media, they are preserved.

R Resume restoring. If an r-mode ufsrestore was interrupted, this function prompts for the volume from which to resume restoring and continues the restoration from where it was left off. Otherwise identical to r.
Table of contents. List each filename that appears on the media. If no filename argument is given, the root directory is listed. This results in a list of all files on the media, unless the h function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the a function modifier is used. The a function modifier is mutually exclusive with the x and r function letters.

Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system.

If the filename argument matches a directory whose contents were written onto the media, and the h modifier is not in effect, the directory is recursively extracted, relative to the current directory, which is expected to be empty. For each file, the owner, modification time, and mode are restored (if possible).

If you omit the filename argument or specify ., the root directory is extracted. This results in the entire tape being extracted, unless the h modifier is in effect. With the x function, existing files are overwritten and ufsrestore displays the names of the overwritten files. Overwriting a currently-running executable can have unfortunate consequences.

Use the x option to restore partial file system dumps, as they are (by definition) not entire file systems.

<table>
<thead>
<tr>
<th>Function Modifiers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>Read the table of contents from archive_file instead of the media. This function modifier can be used in combination with the t, i, or x function letters, making it possible to check whether files are on the media without having to mount the media. When used with the x and interactive (i) function letters, it prompts for the volume containing the file(s) before extracting them.</td>
</tr>
<tr>
<td>x</td>
<td>Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system.</td>
</tr>
<tr>
<td>a</td>
<td>Absolute path, list absolute paths.</td>
</tr>
<tr>
<td>b</td>
<td>Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.</td>
</tr>
<tr>
<td>c</td>
<td>Convert the contents of the media in 4.1 BSD format to the new ufs file system format.</td>
</tr>
<tr>
<td>d</td>
<td>Debug. Turn on debugging output.</td>
</tr>
<tr>
<td>f</td>
<td>Use dump_file instead of /dev/rmt/0 as the file to restore from. Typically dump_file specifies a tape or diskette drive. If dump_file is specified as ‘−’, ufsrestore reads from the standard input. This allows ufsdump(1M) and ufsrestore to be used in a pipeline to copy a file system:</td>
</tr>
</tbody>
</table>

```bash
ufsrestore -f /dev/rmt/0 /path/to/dump
```

```bash
ufsrestore -f - /path/to/backup
```
ufsrestore(1M)

example# ufsdump 0f /dev/rdsk/c0t0d0s7 \
  | (cd /home; ufsrestore xf -)

If the name of the file is of the form machine:device, the restore is done
from the specified machine over the network using rmt(1M). Since
ufsrestore is normally run by root, the name of the local machine must
appear in the .rhosts file of the remote machine. If the file is specified
as user@machine:device, ufsrestore will attempt to execute as the
specified user on the remote machine. The specified user must have a
.rhosts file on the remote machine that allows the user invoking the
command from the local machine to access the remote machine.

h Extract or list the actual directory, rather than the files that it references.
This prevents hierarchical restoration of complete subtrees from the
tape.

l Autoload. When the end-of-tape is reached before the restore is
complete, take the drive off-line and wait up to two minutes (the default,
see the T function modifier) for the tape drive to be ready again. This
gives autoloading (stackloader) tape drives a chance to load a new tape. If
the drive is ready within two minutes, continue. If it is not, prompt for
another tape and wait.

L label The label that should appear in the header of the dump file. If the labels
do not match, ufsrestore issues a diagnostic and exits. The tape label is
specific to the ufsdump tape format, and bears no resemblance to IBM or
ANSI-standard tape labels.

m Extract by inode numbers rather than by filename to avoid regenerating
complete pathnames. Regardless of where the files are located in the
dump hierarchy, they are restored into the current directory and
renamed with their inode number. This is useful if only a few files are
being extracted.

o Offline. Take the drive off-line when the restore is complete or the
end-of-media is reached and rewind the tape, or eject the diskette. In the
case of some autoloading 8mm drives, the tape is removed from the drive
automatically.

s n Skip to the nth file when there are multiple dump files on the same tape.
For example, the command:
example# ufsrestore xfs /dev/rmt/0hn 5

would position you to the fifth file on the tape when reading volume 1 of
the dump. If a dump extends over more than one volume, all volumes
except the first are assumed to start at position 0, no matter what “s n”
value is specified.
If "s n" is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward n-1 files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.

T timeout [hms] Sets the amount of time to wait for an autoload command to complete. This function modifier is ignored unless the l function modifier has also been specified. The default timeout period is two minutes. The time units may be specified as a trailing h (hours), m (minutes), or s (seconds). The default unit is minutes.

v Verbose. ufsrestore displays the name and inode number of each file it restores, preceded by its file type.

y Do not ask whether to abort the restore in the event of tape errors. ufsrestore tries to skip over the bad tape block(s) and continue as best it can.

Interactive Commands ufsrestore enters interactive mode when invoked with the i function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:

add [filename] Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the h modifier is in effect).

cd directory Change to directory (within the dump file).

delete [filename] Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the h modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.

extract Extract all files on the extraction list from the dump media. ufsrestore asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If "s n" is given on the command line, volume 1 will automatically be positioned to file n when it is read.

help Display a summary of the available commands.

ls [directory] List files in directory or the current directory, represented by a '. ' (period). Directories are appended with a '/' (slash). Entries marked for extraction are prefixed with a '*' (asterisk). If the verbose option is in effect, inode numbers are also listed.
marked [directory] Like ls, except only files marked for extraction are listed.

pager Toggle the pagination of the output from the ls and marked commands. The pager used is that defined by the PAGER environment variable, or more(1) if that env var is not defined. The PAGER env var may include white-space-separated arguments for the pagination program.

pwd Print the full pathname of the current working directory.

quit ufsrestore exits immediately, even if the extraction list is not empty.

setmodes Prompts: set owner/mode for ‘.’ (period). Type y for yes to set the mode (permissions, owner, times) of the current directory ‘.’ (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type n for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped.

setpager command Sets the command to use for paginating output instead of the default or that inherited from the environment. The command string may include arguments in addition to the command itself.

verbose Toggle the status of the v modifier. While v is in effect, the ls command lists the inode numbers of all entries, and ufsrestore displays information about each file as it is extracted.

what Display the dump header on the media.

Operands The following operands are supported.

filename Specifies the pathname of files (or directories) to be restored to disk. Unless the h function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. filename is associated with either the x or t function letters, and must come last.

Usage See largefile(5) for the description of the behavior of ufsrestore when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status The following exit values are returned:

0 Successful completion.
1 An error occurred. Verbose messages are displayed.

Environment Variables PAGER The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is more(1).
TMPDIR  Selects the directory for temporary files. Defaults to /tmp if not defined in the environment.

Files
/dev/rmt/0  the default tape drive
$TMPDIR/rstdir*  file containing directories on the tape
$TMPDIR/rstmode*  owner, mode, and timestamps for directories
./restoresymtable  information passed between incremental restores

Attributes

Diagnostics
ufsrestore complains about bad option characters.

Read errors result in complaints. If y has been specified, or the user responds y, ufsrestore will attempt to continue.

If the dump extends over more than one tape, ufsrestore asks the user to change tapes. If the x or i function letter has been specified, ufsrestore also asks which volume the user wishes to mount. If the s modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file.

There are numerous consistency checks that can be listed by ufsrestore. Most checks are self-explanatory or can “never happen”. Common errors are given below.

Converting to new file system format
A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename: not found on tape
The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, using a dump tape created on an active file system, or restoring a partial dump with the r function.

expected next file inumber, got inumber
A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

Incremental tape too low
When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.
Incremental tape too high
   When doing incremental restore, a tape that does not begin its coverage where the previous
   incremental tape left off, or one that has too high an incremental level has been loaded.

media read error: invalid argument
   Blocking factor specified for read is smaller than the blocking factor used to write data.

Tape read error while restoring
Tape read error while skipping over inode inumber
Tape read error while trying to resynchronize
   A tape read error has occurred
   If a file name is specified, then its contents are probably partially wrong. If an inode is being
   skipped or the tape is trying to resynchronize, then no extracted files have been corrupted,
   though files may not be found on the tape.

resync ufsrestore, skipped *num*
   After a tape read error, ufsrestore may have to resynchronize itself. This message lists the
   number of blocks that were skipped over.

Incorrect tape label. Expected ‘foo’, got ‘bar’.
   The L option was specified, and its value did not match what was recorded in the header of
   the dump file.

Notes ufsrestore can get confused when doing incremental restores from dump tapes that were
   made on active file systems.

A level 0 dump must be done after a full restore. Because ufsrestore runs in user mode, it
   has no control over inode allocation. This means that ufsrestore repositions the files,
   although it does not change their contents. Thus, a full dump must be done to get a new set of
   directories reflecting the new file positions, so that later incremental dumps will be correct.
The `unshare` command makes a shared local resource unavailable as file system type `FSType`. If the option `-F FSType` is omitted, then the first file system type listed in file `/etc/dfs/fstypes` will be used as the default. `Specific_options`, as well as the semantics of `resourcename`, are specific to particular distributed file systems.

### Options

- `-F FSType` Specify the file system type.
- `-o specific_options` Specify options specific to the file system provided by the `-F` option.

### Files

- `/etc/dfs/fstypes`
- `/etc/dfs/sharetab`

### Attributes

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

### See Also

`share(1M), shareall(1M), attributes(5)`

### Notes

If `pathname` or `resourcename` is not found in the shared information, an error message will be sent to standard error.

When an `unshare` command completes successfully, a client mounting a file system specified in that `unshare` command no longer has access to that file system.
The unshare command makes local filesystems unavailable for mounting by remote systems. The shared filesystem must correspond to a line with NFS as the FSType in the file /etc/dfs/sharetab.

The following options are supported:

-F This option may be omitted if NFS is the first file system type listed in the file /etc/dfs/fstypes.

If the files system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if /export/foo is a symbolic link to /export/bar (/export/foo -> /export/bar), the following unshare command will result in /export/bar as the unshared pathname (and not /export/foo):

eexample# unshare -F nfs /export/foo

Notes

For file systems that are accessed by NFS Version 4 clients, once the unshare is complete, all NFS Version 4 state (open files and file locks) are released and unrecoverable by the clients. If the intent is to share the file system after some administrative action, the NFS daemon (nfsd) should first be stopped and then the file system unshared. After the administrative action is complete, the file system would then be shared and the NFS daemon restarted. See nfsd(1M)
Name  update_drv – modify device driver attributes

Synopsis  update_drv [-f | -v] driver_module
          update_drv [-b basedir] [-f | -v] -a [-m 'permission']
          [-i 'identify-name'] [-P 'privilege'] [-p 'policy'] driver_module
          update_drv [-b basedir] [-f | -v] -d [-m 'permission']
          [-i 'identify-name'] [-P 'privilege'] [-p 'policy'] driver_module

Description  The update_drv command informs the system about attribute changes to an installed device driver. It can be used to re-read the driver.conf(4) file, or to add, modify, or delete a driver’s minor node permissions or aliases.

Without options, update_drv reloads the driver.conf file.

Upon successfully updating the aliases, the driver binding takes effect upon reconfig boot or hotplug of the device.

Upon successfully updating the permissions, only the new driver minor nodes get created with the modified set of file permissions. Existing driver minor nodes do not get modified.

Options  The following options are supported:

-a  Add a permission, aliases, privilege or policy entry.

With the -a option specified, a permission entry (using the -m option), or a driver’s aliases entry (using the -i option), a device privilege (using the -P option) or a device policy (using the -p option), can be added or updated. If a matching minor node permissions entry is encountered (having the same driver name and the minor node), it is replaced. If a matching aliases entry is encountered (having a different driver name and the same alias), an error is reported.

The -a and -d options are mutually exclusive.

-b basedir  Installs or modifies the driver on the system with a root directory of basedir rather than installing on the system executing update_drv.

Note – The root file system of any non-global zones must not be referenced with the -b option. Doing so might damage the global zone’s file system, might compromise the security of the global zone, and might damage the non-global zone’s file system. See zones(5).

-d  Delete a permission, aliases, privilege or policy entry.

The -m permission, -i identify-name, -P privilege or the -p policy option needs to be specified with the -d option.

The -d and -a options are mutually exclusive.
If the entry doesn't exist update_drv returns an error.

- f Force the system to reread the driver.conf file even if the driver module cannot be unloaded. See NOTES section for details.

- i 'identify-name' A white-space separated list of aliases for the driver. If -a or -d option is not specified then this option is ignored. The identify-name string is mandatory. If all aliases need to be removed, rem_drv(1M) is recommended.

- m 'permission' Specify a white-space separated list of file system permissions for the device node of the device driver. If -a or -d option is not specified then, this option is ignored. The permission string is mandatory.

- p 'policy' With the -a option, policy is a white-space separated list of complete device policies. For the -d option, policy is a white space separated list of minor device specifications. The minor device specifications are matched exactly against the entries in /etc/security/device_policy, that is, no wildcard matching is performed.

- P 'privilege' With the -a option, privilege is a comma separated list of additional driver privileges. For the -d option, privilege is a single privilege. The privileges are added to or removed from the /etc/security/extra_privs file.

- v Verbose.

Examples

EXAMPLE 1 Adding or Modifying an Existing Minor Permissions Entry

The following command adds or modifies the existing minor permissions entry of the clone driver:

    example# update_drv -a -m 'llc1 777 joe staff' clone

EXAMPLE 2 Removing All Minor Permissions Entries

The following command removes all minor permission entries of the usbprn driver, the USB printer driver:

    example# update_drv -d -m '* 0666 root sys' usbprn

EXAMPLE 3 Adding a Driver Aliases Entry

The following command adds a driver aliases entry of the ugen driver with the identity string of usb459,20:

    example# update_drv -a -i "usb459,20" ugen
EXAMPLE 4  Re-reading the driver.conf File For the ohci Driver

The following command re-reads the driver.conf(4) file.

```
example# update_drv ohci
```  

EXAMPLE 5  Requiring a Self-defined Privilege to Open a tcp Socket

The following command requires a self-defined privilege to open a tcp socket:

```
example# update_drv -a -P net_tcp -p
   'write_priv_set=net_tcp read_priv_set=net_tcp' tcp
```  

EXAMPLE 6  Establishing a Path-oriented Alias

The following command establishes a path-oriented alias to force a specific driver, qlt, to be used for a particular device path:

```
example# update_drv -a -i "'/pci@8,600000/SUNW,qlc@4'" qlt
```  

Exit Status  The following exit values are returned:

- **0**  Successful completion.
- **>0**  An error occurred.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  add_drv(1M), modunload(1M), rem_drv(1M), driver.conf(4), attributes(5), privileges(5)

Notes  If -a or -d options are specified, update_drv does not re-read the driver.conf file.

A forced update of the driver.conf file reloads the driver.conf file without reloading the driver binary module. In this case, devices which cannot be detached reference driver global properties from the old driver.conf file, while the remaining driver instances reference global properties in the new driver.conf file.

It is possible to add an alias, which changes the driver binding of a device already being managed by a different driver. A force update with the -a option tries to bind to the new driver and report error if it cannot. If you specify more than one of the -m, -i, -P or -p options, a force flag tries to modify aliases or permissions. This is done even if the other operation fails and vice-versa. A force update with the -d option tries to delete entries and report the error if it cannot.
updatehome(1M)

Name  updatehome - update the home directory copy and link files for the current label

Synopsis  /usr/bin/updatehome  [-cirs]

Description  updatehome reads the user's minimum-label copy and link-control files (.copy_files and .link_files). These files contain a list of files to be copied and symbolically linked from the user's minimum-label home directory to the user's home directory at the current label.

The Solaris Trusted Extensions dtsession program performs an updatehome whenever a newly labeled workspace is created so that the user's favorite files are available for use. For example, the user probably wants a symbolic link to such files as .profile, .login, .cshrc, .exrc, .mailrc, and ~/bin. The updatehome command provides a convenient mechanism for accomplishing this symlink. The user can add files to those to be copied (.copy_files) and to those to be symbolically linked (.link_files).

Options  -c  Replace existing home-directory copies at the current label. The default is to skip over existing copies.

-i  Ignore errors encountered. The default aborts on error.

-r  Replace existing home-directory copies or symbolic links at the current label. This option implies options -c and -s. The default is to skip over existing copies or symbolic links.

-s  Replace existing home-directory symbolic links at the current label. The default is to skip over existing symbolic links.

Exit Status  Upon success, updatehome returns 0. Upon failure, updatehome returns 1 and writes diagnostic messages to standard error.

Examples  EXAMPLE 1  A Sample .copy_files File

The files that are listed in .copy_files can be modified at every user's label.

.cshrc
.mailrc
.mozilla/bookmarks.html

EXAMPLE 2  A Sample .link_files File

The files that are listed in .link_files can be modified at the lowest label. The changes propagate to the other labels that are available to the user.

~/.bin
.mozilla/preferences
.xrc
.rhosts
EXAMPLE 3 Updating the Linked and Copied Files

The .copy_files and .link_files were updated by the user at the minimum label. At a higher label, the user refreshes the copies and the links. No privileges are required to run the command.

```
% updatehome -r
```

**Files**

- `$HOME/.copy_files` List of files to be copied
- `$HOME/.link_files` List of files to be symbolically linked

**Attributes**

updatemanager(1M)

Name  updatemanager – start the Sun Update Manager application

Synopsis  updatemanager

Description  The updatemanager command starts the Sun Update Manager application. The Sun Update Manager is a graphical user interface (GUI) that you can use to manage updates and patches on your Solaris system.

For more information about using this application, see the Sun Update Manager 1.0 Administration Guide in the Sun Update Connection, System Edition Collection on docs.sun.com.

You can also manage updates and patches on the command line by using the smpatch command. See the smpatch(1M) man page.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTETYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

<td>Unstable</td>
</tr>
</tbody>
</table>

See Also  smpatch(1M), attributes(5)
Name  updatemedia – modify Solaris media with patches and packages

Synopsis  
/usr/bin/updatemedia -d media-root [ -v ] [ -o iso ] [ -l label ]
  pkg_or_patch [ pkg_or_patch ...]

Description  The updatemedia utility takes a list of patches and packages as input and updates the install
miniroot in media-root (the root directory of an on-disk image of a Solaris installation media) to
include the specified patches and packages. These patches and packages are also placed in a
subdirectory called DU under the Solaris install image. For example:

media-root/Solaris_10/0U

When booting a system from the updated media, the patches and packages will be part of the
booted Solaris image. They will also be applied to the target system being installed at the end of
the installation process.

If -o is specified, a bootable ISO image is created in the file media.iso that contains the Solaris
install media. The ISO image can then be burned onto a CD/DVD with utilities such as
cdrw(1) or cdrecord(1). (The latter is not a SunOS man page.)

Options  The following options are supported:

- d media-root
  Top-level directory of on-disk image of Solaris installation media. This is option must be
  specified.

- o iso
  Create a Solaris ISO image of media-root.

- l label
  Label/volume name of the ISO image (if -o option is specified). If -o is not specified, the
  name of Solaris directory under media-root, for example, Solaris_10, will be used.

- v
  Verbose. Multiple -v options increase verbosity.

Operands  The following operands are supported:

pkg_or_patch [ pkg_or_patch ...]
  One or more patches or packages (you can have both patches and packages in a single
  command) with which the Solaris installation media media-root will be updated.

Examples  EXAMPLE 1  Updating a Solaris Install Image with Patch and Package

The following command updates the Solaris install image in s10u1 by adding patch
123456-07 and package SUNWfoo.

# /usr/bin/updatemedia -d s10u1 SUNWfoo 123456-07
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>

</tbody>
</table>

See Also  cdrw(1), mkbootmedia(1M), attributes(5)  

mkisofs(8), ( /usr/share/man/man8/mkisofs.8 ), in the SUNWfsman package (not a SunOS man page)
useradd

**Synopsis**

```
useradd [-c comment] [-d dir] [-e expire] [-f inactive] 
  [-g group] [-G group [ , group ...]] [-m [-k skel_dir]] 
  [-u uid [-o]] [-s shell] [-A authorization [ , authorization ...]] 
  [-P profile [ , profile ...]] [-R role [ , role ...]] 
  [-p projname] [-K key=value] login
```

```
useradd -D [-b base_dir] [-e expire] [-f inactive] 
  [-g group] [-A authorization [ , authorization ...]] 
  [-P profile [ , profile ...]] [-R role [ , role ...]] 
  [-p projname] [-K key=value]
```

**Description**

`useradd` adds a new user to the `/etc/passwd` and `/etc/shadow` and `/etc/user_attr` files. The `-A` and `-P` options respectively assign authorizations and profiles to the user. The `-R` option assigns roles to a user. The `-p` option associates a project with a user. The `-K` option adds a `key=value` pair to `/etc/user_attr` for the user. Multiple `key=value` pairs may be added with multiple `-K` options.

`useradd` also creates supplementary group memberships for the user (-G option) and creates the home directory (-m option) for the user if requested. The new login remains locked until the `passwd(1)` command is executed.

Specifying `useradd -D` with the `-g`, `-b`, `-f`, `-e`, `-A`, `-P`, `-p`, `-R` or `-K` option (or any combination of these options) sets the default values for the respective fields. See the `-D` option, below.

Subsequent `useradd` commands without the `-D` option use these arguments.

The system file entries created with this command have a limit of 2048 characters per line. Specifying long arguments to several options can exceed this limit.

`useradd` requires that usernames be in the format described in `passwd(4)`. A warning message is displayed if these restrictions are not met. See `passwd(4)` for the requirements for usernames.

**Options**

The following options are supported:

- **-A authorization**
  One or more comma separated authorizations defined in `auth_attr(4)`. Only a user or role who has grant rights to the authorization can assign it to an account.

- **-b base_dir**
  The default base directory for the system if `-d dir` is not specified. `base_dir` is concatenated with the account name to define the home directory. If the `-m` option is not used, `base_dir` must exist.

- **-c comment**
  Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.
The home directory of the new user. It defaults to base_dir/account_name, where base_dir is the base directory for new login home directories and account_name is the new login name.

-D
Display the default values for group, base_dir, skel_dir, shell, inactive, expire, proj, projname and key=value pairs. When used with the -g, -b, -f, -e, -A, -p, -R, or -K options, the -D option sets the default values for the specified fields. The default values are:

- group other (GID of 1)
- base_dir /home
- skel_dir /etc/skel
- shell /bin/sh
- inactive 0
- expire null
- auths null
- profiles null
- proj 3
- projname default
- key=value (pairs not present defined in user_attr(4))
- roles null

-e expire
Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

If the date format that you choose includes spaces, it must be quoted. For example, you can enter 10/6/90 or "October 6, 1990". A null value ("") defeats the status of the expired date. This option is useful for creating temporary logins.

-f inactive
The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.
-g group
   An existing group’s integer ID or character-string name. Without the -D option, it defines
   the new user’s primary group membership and defaults to the default group. You can reset
   this default value by invoking useradd -D -g group. GIDs 0-99 are reserved for allocation
   by the Solaris Operating System.

-G group
   An existing group’s integer ID or character-string name. It defines the new user’s
   supplementary group membership. Duplicates between group with the -g and -G options
   are ignored. No more than NGROUPS_MAX groups can be specified. GIDs 0-99 are reserved
   for allocation by the Solaris Operating System.

-K key=value
   A key=value pair to add to the user’s attributes. Multiple -K options may be used to add
   multiple key=value pairs. The generic -K option with the appropriate key may be used
   instead of the specific implied key options (-A, -P, -R, -p). See user_attr(4) for a list of
   valid key=value pairs. The “type” key is not a valid key for this option. Keys may not be
   repeated.

-k skel_dir
   A directory that contains skeleton information (such as .profile) that can be copied into a
   new user’s home directory. This directory must already exist. The system provides the
   /etc/skel directory that can be used for this purpose.

-m
   Create the new user’s home directory if it does not already exist. If the directory already
   exists, it must have read, write, and execute permissions by group, where group is the user’s
   primary group.

-o
   This option allows a UID to be duplicated (non-unique).

-P profile
   One or more comma-separated execution profiles defined in prof_attr(4).

-p projname
   Name of the project with which the added user is associated. See the projname field as
   defined in project(4).

-R role
   One or more comma-separated execution profiles defined in user_attr(4). Roles cannot
   be assigned to other roles.

-s shell
   Full pathname of the program used as the user’s shell on login. It defaults to an empty field
   causing the system to use /bin/sh as the default. The value of shell must be a valid
   executable file.
-u uid
The UID of the new user. This UID must be a non-negative decimal integer below MAXUID as defined in <sys/param.h>. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. UIDs 0-99 are reserved for allocation by the Solaris Operating System.

Files
/etc/datemsk
/etc/passwd
/etc/shadow
/etc/group
/etc/skel
/usr/include/limits.h
/etc/user_attr

Attributes

</tr>
</tbody>
</table>

See Also
passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), userdel(1M), usermod(1M), getdate(3C), auth_attr(4), passwd(4), prof_attr(4), project(4), user_attr(4), attributes(5)

Diagnostics
In case of an error, useradd prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:
UX: useradd: ERROR: login is already in use. Choose another.

The following indicates that the uid specified with the -u option is not unique:
UX: useradd: ERROR: uid uid is already in use. Choose another.

The following indicates that the group specified with the -g option is already in use:
UX: useradd: ERROR: group group does not exist. Choose another.

The following indicates that the uid specified with the -u option is in the range of reserved UIDs (from 0-99):
UX: useradd: WARNING: uid uid is reserved.

The following indicates that the uid specified with the -u option exceeds MAXUID as defined in <sys/param.h>:
UX: useradd: ERROR: uid uid is too big. Choose another.

The following indicates that the /etc/passwd or /etc/shadow files do not exist:
UX: useradd: ERROR: Cannot update system files - login cannot be created.

Notes The useradd utility adds definitions to only the local /etc/group, etc/passwd, /etc/passwd, /etc/shadow, /etc/project, and /etc/user_attr files. If a network name service such as NIS or NIS+ is being used to supplement the local /etc/passwd file with additional entries, useradd cannot change information supplied by the network name service. However useradd will verify the uniqueness of the user name (or role) and user id and the existence of any group names specified against the external name service.
Name  userdel – delete a user’s login from the system

Synopsis  userdel [-r] login

Description  The userdel utility deletes a user account from the system and makes the appropriate account-related changes to the system file and file system.

Options  The following options are supported:

-  r  Remove the user’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.

Operands  The following operands are supported:

login  An existing login name to be deleted.

Exit Status  The following exit values are returned:

0  Successful completion.
2  Invalid command syntax. A usage message for the userdel command is displayed.
6  The account to be removed does not exist.
8  The account to be removed is in use.
10  Cannot update the /etc/group or /etc/user_attr file but the login is removed from the /etc/passwd file.
12  Cannot remove or otherwise modify the home directory.

Files  /etc/passwd  system password file
/etc/shadow  system file contain users’ encrypted passwords and related information
/etc/group  system file containing group definitions
/etc/user_attr  system file containing additional user attributes

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  auths(1), passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M),
groupmod(1M), logins(1M), roleadd(1M), rolemod(1M), useradd(1M), userdel(1M),
usermod(1M), passwd(4), prof_attr(4), user_attr(4), attributes(5)
Notes  The `userdel` utility only deletes an account definition that is in the local `/etc/group`, `/etc/passwd`, `/etc/shadow`, and `/etc/user_attr` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `userdel` cannot change information supplied by the network name service.
### Synopsis

```bash
usermod [-u uid [-o]] [-g group] [-G group [ , group ... ]]
       [-d dir [-m] [ -s shell ] [ -c comment ] [ -l new_name ]
       [-f inactive] [-e expire]
       [-A authorization [ , authorization ]]
       [-P profile [ , profile ] ] [-R role [ , role ]]
       [ -K key=value ] login
```

### Description

The `usermod` utility modifies a user’s login definition on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options might exceed this limit.

### Options

The following options are supported:

- `-A authorization`

  One or more comma separated authorizations as defined in `auth_attr(4)`. Only a user or role who has `grant` rights to the authorization can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

- `-c comment`

  Specify a comment string. `comment` can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s `/etc/passwd` entry.

- `-d dir`

  Specify the new home directory of the user. It defaults to `base_dir/login`, where `base_dir` is the base directory for new login home directories, and `login` is the new login.

- `-e expire`

  Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datemsk`. See `getdate(3C)`.

  For example, you may enter `10/6/90` or `October 6, 1990`. A value of `''` defeats the status of the expired date.

- `-f inactive`

  Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

- `-g group`

  Specify an existing group’s integer ID or character-string name. It redefines the user’s primary group membership.
-G group
 Specify an existing group’s integer "ID"", or character string name. It redefines the user’s supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_UMAX groups may be specified as defined in <param.h>.

-K key=value
 Replace existing or add to a user’s key=value pair attributes. Multiple -K options can be used to replace or add multiple key=value pairs. However, keys must not be repeated. The generic -K option with the appropriate key can be used instead of the specific implied key options (-A, -P, -R, -p). See user_attr(4) for a list of valid keys. Values for these keys are usually found in man pages or other sources related to those keys. For example, see project(4) for guidance on values for the project key. Use the command ppriv(1) with the -v and -l options for a list of values for the keys defaultpriv and limitpriv.

The keyword type can be specified with the value role or the value normal. When using the value role, the account changes from a normal user to a role; using the value normal keeps the account a normal user.

As a role account, no roles (-R or roles=value) can be present.

-l new_logname
 Specify the new login name for the user. See passwd(4) for the requirements for usernames.

-m
 Move the user’s home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by group, where group is the user’s primary group.

-o
 This option allows the specified UID to be duplicated (non-unique).

-P profile
 One or more comma-separated rights profiles defined in prof_attr(4). This replaces any existing profile setting in user_attr(4). If an empty profile list is specified, the existing setting is removed.

-R role
 One or more comma-separated roles (see roleadd(1M)). This replaces any existing role setting. If no role list is specified, the existing setting is removed.

-s shell
 Specify the full pathname of the program that is used as the user’s shell on login. The value of shell must be a valid executable file.

-u uid
 Specify a new UID for the user. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the user’s home directory is not modified with this option; a user will not have access to their home directory until the UID is manually reassigned using chown(1).
The following operands are supported:

    login
    An existing login name to be modified.

Examples

EXAMPLE 1  Assigning Privileges to a User
The following command adds the privilege that affects high resolution times to a user's initial, inheritable set of privileges.

    # usermod -K defaultpriv=basic,proc_clock_highres jdoe

This command results in the following entry in user_attr:

    jdoe::::type=normal;defaultpriv=basic,proc_clock_highres

EXAMPLE 2  Removing a Privilege from a User's Limit Set
The following command removes the privilege that allows the specified user to create hard links to directories and to unlink directories.

    # usermod -K limitpriv=all,!sys_linkdir jdoe

This command results in the following entry in user_attr:

    jdoe::::type=normal;defaultpriv=basic,limitpriv=all,!sys_linkdir

EXAMPLE 3  Removing a Privilege from a User's Basic Set
The following command removes the privilege that allows the specified user to examine processes outside the user's session.

    # usermod -K defaultpriv=basic,!proc_session jdoe

This command results in the following entry in user_attr:

    jdoe::::type=normal;defaultpriv=basic,!proc_session;limitpriv=all

EXAMPLE 4  Assigning a Role to a User
The following command assigns a role to a user. The role must have been created prior to this command, either through use of the Solaris Management Console GUI or through roleadd(1M).

    # usermod -R mailadm jdoe

This command results in the following entry in user_attr:

    jdoe::::type=normal;roles=mailadm;defaultpriv=basic;limitpriv=all

EXAMPLE 5  Removing All Profiles from a User
The following command removes all profiles that were granted to a user directly. The user will still have any rights profiles that are granted by means of the PROFS_GRANTED key in policy.conf(4).
EXAMPLE 5  Removing All Profiles from a User  (Continued)

# usermod -P "" jdoe

Exit Status  In case of an error, usermod prints an error message and exits with one of the following values:

2  The command syntax was invalid. A usage message for the usermod command is displayed.

3  An invalid argument was provided to an option.

4  The uid given with the -u option is already in use.

5  The password files contain an error. pwconv(1M) can be used to correct possible errors. See passwd(4).

6  The login to be modified does not exist, the group does not exist, or the login shell does not exist.

8  The login to be modified is in use.

9  The new_logname is already in use.

10  Cannot update the /etc/group or /etc/user_attr file. Other update requests will be implemented.

11  Insufficient space to move the home directory (-m option). Other update requests will be implemented.

12  Unable to complete the move of the home directory to the new home directory.

Files  /etc/group  
     system file containing group definitions

/etc/datemsk  
     system file of date formats

/etc/passwd  
     system password file

/etc/shadow  
     system file containing users' encrypted passwords and related information
The usermod utility modifies passwd definitions only in the local /etc/passwd and /etc/shadow files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, usermod cannot change information supplied by the network nameservice. However usermod will verify the uniqueness of user name and user ID against the external nameservice.

The usermod utility uses the /etc/datemsk file, available with SUNWaccr, for date formatting.
### Name
utmpd – utmpx monitoring daemon

### Synopsis
```
utmpd [-debug]
```

### Description
The `utmpd` daemon monitors the `/var/adm/utmpx` file. See `utmpx(4)` (and `utmp(4)` for historical information).

`utmpd` receives requests from `pututxline(3C)` by way of a named pipe. It maintains a table of processes and uses `poll(2)` on `/proc` files to detect process termination. When `utmpd` detects that a process has terminated, it checks that the process has removed its `utmpx` entry from `/var/adm/utmpx`. If the process' `utmpx` entry has not been removed, `utmpd` removes the entry. By periodically scanning the `/var/adm/utmpx` file, `utmpd` also monitors processes that are not in its table.

### Options
- `-debug`
  Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.

### Exit Status
The following exit values are returned:

- `0`
  Successful completion.
- `>0`
  An error occurred.

### Files
- `/etc/default/utmpd`
  You can set default values for the flags listed below. For example: `SCAN_PERIOD=600`

  - `SCAN_PERIOD`
    The number of seconds that `utmpd` sleeps between checks of `/proc` to see if monitored processes are still alive. The default is 300.

  - `MAX_fds`
    The maximum number of processes that `utmpd` attempts to monitor. The default value is 4096.

  - `WTMPX_UPDATE_FREQ`
    The number of seconds that `utmpd` sleeps between read accesses of the `wtmpx` file. The `wtmpx` file's last access time is used by `init(1M)` on reboot to determine when the operating system became unavailable. The default is 60.

- `/var/adm/utmpx`
  File containing user and accounting information for commands such as `who(1)`, `write(1)`, and `login(1)`.

- `/proc`
  Directory containing files for processes whose `utmpx` entries are being monitored.
Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
</tbody>
</table>

See Also  svcs(1), init(1M), svcadm(1M), poll(2), pututxline(3C), proc(4), utmp(4), utmpx(4), attributes(5), smf(5)

Notes  If the filesystem holding /var/adm/wtmpx is mounted with options which inhibit or defer access time updates, an unknown amount of error will be introduced into the utmp DOWN_TIME record’s timestamp in the event of an uncontrolled shutdown (for example, a crash or loss of power). Controlled shutdowns will update the modify time of /var/adm/wtmpx, which will be used on the next boot to determine when the previous shutdown occurred, regardless of access time deferral or inhibition.

The utmpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/utmp/default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service’s status can be queried using the svcs(1) command.
uucheck(1M)

Name  uucheck – check the uucp directories and permissions file

Synopsis  /usr/lib/uucp/uucheck [-v] [-x debug-level]

Description  uucheck checks for the presence of the uucp system required files and directories. uucheck also does error checking of the Permissions file (/etc/uucp/Permissions).

uucheck is executed during package installation. uucheck can only be used by the super-user or uucp.

Options  The following options are supported:

- v  Give a detailed (verbose) explanation of how the uucp programs will interpret the Permissions file.

- x debug-level  Produce debugging output on the standard output. debug-level is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files  /etc/uucp/Devices
       /etc/uucp/Limits
       /etc/uucp/Permissions
       /etc/uucp/Systems
       /var/spool/locks/*

Bugs  The program does not check file/directory modes or some errors in the Permissions file such as duplicate login or machine name.
Name  uucico – file transport program for the uucp system

Synopsis  /usr/lib/uucp/uucico [-f] [-c type] [-d spool-directory]
            [-i interface] [-r role-number] [-s system-name]
            [-x debug-level]

Description  uucico is the file transport program for uucp work file transfers.

Options  The following options are supported:

- f  This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the /etc/uucp/Limits file.

- c type  The first field in the Devices file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network.

- d spool-directory  This option specifies the directory spool-directory that contains the uucp work files to be transferred. The default spool directory is /var/spool/uucp.

- i interface  This option defines the interface used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write).

- r role-number  The role-number 1 is used for master mode. role-number 0 is used for slave mode (default). When uucico is started by a program or cron, role-number 1 should be used for master mode.

- s system-name  The -s option defines the remote system (system-name) that uucico will try to contact. It is required when the role is master; system-name must be defined in the Systems file.

- x debug-level  Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uusched scheduler, for debugging purposes, and can be started manually. For example, the shell uutry starts uucico with debugging turned on. The debug-level is a number between 0 and 9. Higher numbers give more detailed debugging information.

uucp(1C), uustat(1C), uux(1C), Uutry(1M), cron(1M), uusched(1M), attributes(5)
Name uucleanup – uucp spool directory clean-up

Synopsis /usr/lib/uucp/uucleanup [-C time] [-D time] [-m string]
[-o time] [-s system] [-W time] [-x debug-level] [-X time]

Description uucleanup will scan the spool directories for old files and take appropriate action to remove them in a useful way:

- Inform the requester of send/receive requests for systems that can not be reached.
- Return undeliverable mail to the sender.
- Deliver rnews files addressed to the local system.
- Remove all other files.

In addition, there is a provision to warn users of requests that have been waiting for a given number of days (default 1 day). Note: uucleanup will process as if all option times were specified to the default values unless time is specifically set.

This program is typically started by the shell uudemon.cleanup, which should be started by cron(1M).

Options -C time Remove any C. files greater or equal to time days old and send appropriate information to the requester (default 7 days).
-D time Remove any D. files greater or equal to time days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days).
-m string Include string in the warning message generated by the -W option. The default line is "See your local administrator to locate the problem".
-o time Delete other files whose age is more than time days (default 2 days).
-s system Execute for system spool directory only.
-W time Any C. files equal to time days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the JOBID, and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (-m option) (default 1 day).
-xdebug-level Produce debugging output on standard output. debug-level is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)
-X time Any X. files greater or equal to time days old will be removed. The D. files are probably not present (if they were, the X. could get executed). But if there are D. files, they will be taken care of by D. processing (default 2 days).
Files

- /usr/lib/uucp: directory with commands used by uucleanup internally
- /var/spool/uucp: spool directory

Name  uusched – uucp file transport program scheduler

Synopsis  /usr/lib/uucp/uusched [-u debug-level] [-x debug-level]

Description  uusched is the uucp(1C) file transport scheduler. It is usually started by the daemon uudemon.hour that is started by cron(1M) from an entry in user uucp’s crontab file:

```
11,41 * * * /etc/uucp/uucp/uudemon.hour
```

Options  The options are for debugging purposes only. debug-level is a number between 0 and 9. Higher numbers give more detailed debugging information:

The following options are supported:
- u debug-level  Passes the -u debug-level option uucico(1M) as -x debug-level.
- x debug-level  Outputs debugging messages from uusched.

Files  /etc/uucp/Devices
       /etc/uucp/Permissions
       /etc/uucp/Systems
       /var/spool/locks/*
       /var/spool/uucp/*

Uutry is a shell script that is used to invoke uucico(1M) to call a remote site. Debugging is initially turned on and is set to the default value of 5. The debugging output is put in file /tmp/system-name.

The following options are supported:

- **-r**
  This option overrides the retry time that is set in file /var/uucp/.Status/system-name.

- **-c type**
  The first field in the Devices file is the "Type" field. The -c option forces uucico to use only entries in the "Type" field that match the user-specified type. The specified type is usually the name of a local area network.

- **-x debug-level**
  debug-level is a number from 0 to 9. Higher numbers give more detailed debugging information.

uuxqt(1M)

Name uuxqt – execute remote command requests

Synopsis /usr/lib/uucp/uuxqt [-s system] [-x debug-level]

Description uuxqt is the program that executes remote job requests from remote systems generated by the use of the uux command. (mail uses uux for remote mail requests). uuxqt searches the spool directories looking for execution requests. For each request, uuxqt checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The Permissions file is used to validate file accessibility and command execution permission.

There are two environment variables that are set before the uuxqt command is executed:
- UU_MACHINE is the machine that sent the job (the previous one).
- UU_USER is the user that sent the job.

These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.

Options The following options are supported:
- -s system Specifies the remote system name.
- -x debug-level debug-level is a number from 0 to 9. Higher numbers give more detailed debugging information.

Name  virtinfo – virtualization domain information

Synopsis  virtinfo [ -acdpstu ]

Description  The virtinfo utility provides virtualization information returned by libv12n(3LIB) about the current domain. When options are specified, symbols that represent one or more virtualization domain characteristics are written to standard output. If no options are specified, virtinfo shows only the virtualization domain type.

Options  The virtinfo command supports the following options:

- a  Shows all information that is currently available from the system.
- c  Shows the network node name of the control domain. This name is identical to the string shown by running the uname -n command on the control domain.
- d  Shows the domain name for this virtual domain.
- p  Shows information in a parseable format.
- s  Shows the platform serial number.
- t  Shows the domain type.

The parseable output for Logical Domains (LDoms) has the following format:

```
VERSION 1.0
DOMAINROLE|impl=LDoms|control={true|false}|
    io={true|false}|service={true|false}|
    root={true|false}
DOMAINNAME|name=domain-name
DOMAINUUID|uuid=uuid
DOMAINCONTROL|name=control-domain-nodename
DOMAINCHASSIS|serialno=serial-no
```

Note that the control and guest values are mutually exclusive.
-u  Shows the universally unique identifier (UUID) of the domain. See the `libuuid(3LIB)` man page.

**Exit Status**  The following exit values are returned:

- **0** Successful completion.
- **>0** An error occurred.

**Examples**

**EXAMPLE 1**  Viewing Default Information

The following example shows the default information about the domain:

```bash
$ virtinfo
Domain role: LDoms control I/O service root

The current domain is the control domain, which is also an I/O domain, the service domain and a root I/O domain.
```

**EXAMPLE 2**  Viewing All Information

The following example shows all available information about the domain:

```bash
$ virtinfo -a
Domain role: LDoms control I/O service root
Domain name: primary
Domain UUID: 8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
Control domain: san-t2k-6
Chassis serial#: 0704RB0280
```

**EXAMPLE 3**  Viewing All Information In a Parsable Format

The following example shows all available information about the domain in a parsable format:

```bash
$ virtinfo -ap
VERSION 1.0
DOMAINROLE|impl=LDoms|control=true|io=true|service=true|root=true
DOMAINNAME|name=primary
DOMAINUUID|uuid=8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
DOMAINCONTROL|name=san-t2k-6
DOMAINCHASSIS|serialno=0704RB0280
```

vmstat(1M)

Name
vmstat – report virtual memory statistics

Synopsis
vmstat [-c|pqjs] [disks] [interval [count]]

Description
vmstat reports virtual memory statistics regarding kernel thread, virtual memory, disk, trap, and CPU activity.

On MP (multi-processor) systems, vmstat averages the number of CPUs into the output. For per-processor statistics, see mpstat(1M).

vmstat only supports statistics for certain devices. For more general system statistics, use sar(1), iostat(1M), or sar(1M).

Without options, vmstat displays a one-line summary of the virtual memory activity since the system was booted.

During execution of the kernel status command, the state of the system can change. If relevant, a state change message is included in the vmstat output, in one of the following forms:

<<device added: sd0>>
<<device removed: sd0>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>

Options
The following options are supported:

- c   Report cache flushing statistics. This option is obsolete, and no longer meaningful. This option might be removed in a future version of Solaris.

- i   Report the number of interrupts per device. count and interval does not apply to the -i option.

- p   Report paging activity in details. This option will display the following, respectively:

  epi  Executable page-ins.
  epo  Executable page-outs.
  epf  Executable page-frees.
  api  Anonymous page-ins.
  apo  Anonymous page-outs.
  apf  Anonymous page-frees.
  fpi  File system page-ins.
  fpo  File system page-outs.
fpf File system page-frees.

When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone's pool.

- q Suppress messages related to state changes.

- s Display the total number of various system events since boot. count and interval does not apply to the - s option.

- S Report on swapping rather than paging activity. This option will change two fields in vmstat’s “paging” display: rather than the “re” and “mf” fields, vmstat will report “si” (swap-ins) and “so” (swap-outs).

Operands The following operands are supported:

count Specifies the number of times that the statistics are repeated. count does not apply to the - i and - s options.

disks Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are id, sd, xd, or xy, followed by a number (for example, sd2, xd0, and so forth).

interval Specifies the last number of seconds over which vmstat summarizes activity. This number of seconds repeats forever. interval does not apply to the - i and - s options.

Examples

EXAMPLE 1 Using vmstat

The following command displays a summary of what the system is doing every five seconds.

example% vmstat 5

The fields of vmstat's display are
Using `vmstat` (Continued)

**kthr**
Report the number of kernel threads in each of the three following states:
- `r` the number of kernel threads in run queue
- `b` the number of blocked kernel threads that are waiting for resources (I/O, paging, and so forth)
- `w` the number of swapped out lightweight processes (LWPs) that are waiting for processing resources to finish.

**memory**
Report on usage of virtual and real memory.
- `swap` available swap space (Kbytes)
- `free` size of the free list (Kbytes)

**page**
Report information about page faults and paging activity. The information on each of the following activities is given in units per second.
- `re` page reclaims — but see the `-S` option for how this field is modified.
- `mf` minor faults — but see the `-S` option for how this field is modified.
- `pi` kilobytes paged in
- `po` kilobytes paged out
- `fr` kilobytes freed
- `de` anticipated short-term memory shortfall (Kbytes)
- `sr` pages scanned by clock algorithm

When executed in a zone and if the pools facility is active, all of the above (except for “de”) only report activity on the processors in the processor set of the zone’s pool.

**disk**
Report the number of disk operations per second. There are slots for up to four disks, labeled with a single letter and number. The letter indicates the type of disk (`s` = SCSI, `i` = IPI, and so forth); the number is the logical unit number.

**faults**
Report the trap/interrupt rates (per second).
- `in` interrupts
- `sy` system calls
- `cs` CPU context switches

When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone’s pool.
EXAMPLE 1 Using vmstat (Continued)

cpu Give a breakdown of percentage usage of CPU time. On MP systems, this is an
average across all processors.
us user time
sy system time
id idle time

When executed in a zone and if the pools facility is active, all of the above only
report activity on the processors in the processor set of the zone's pool.

System Administration Guide: Basic Administration

System Administration Guide: Advanced Administration

Notes The sum of CPU utilization might vary slightly from 100 because of rounding errors in the
production of a percentage figure.

The -c option (Report cache flushing statistics) is not supported in this release.
The vntsd daemon is a server that supports connections to the Logical Domains (LDoms) console by using `telnet(1)`. When a `telnet` session starts, `vntsd` sends `telnet` options to the client indicating a willingness to remotely echo characters and to suppress go ahead.

Consoles are organized into groups by the LDoms Manager. Each console group is assigned a unique group name and TCP port number. `vntsd` uses the group's port number to export access to the consoles within that group. To establish a connection with a console or console group, a user starts a `telnet(1)` session with the corresponding group's port number. Depending on the number of consoles within that group, `vntsd` does one of two things:

- If there is only one console in the group, `vntsd` connects a session to that LDoms console.
- If there are multiple consoles in the group, `vntsd` prompts the user to select the console to which they would like to connect, as shown in "Multiple-Console Options," below.

For each console, `vntsd` provides write access only to the first user connecting to the console. Subsequent users connecting to the console are allowed only to read from the console and wait for write access. When the first user disconnects, write privileges are transferred to the next user waiting in the queue. If a user who does not have write privileges attempts to write to a console, the `vntsd` displays the following message:

```
You do not have write access
```

A user who has no write access can acquire write access forcibly by using the `~w` special console command, described in "Special Console Commands," below.

`vntsd` can be invoked only with superuser privileges or by someone in the Primary Administrator role.

### Options

The options for `vntsd` are divided into multiple-console options and console commands.

#### Multiple-Console Options

The options listed below are supported when there are multiple LDoms consoles in a group.

The syntax for the use of these options is:

```
<hostname>-vnts-<group-name>: <option>
```

For example:

```
myhost-vnts-salesgroup: h
```

The `h` option invokes help, as described below.

```
h -- this help
l -- list of consoles
q -- quit
c(id), n(name) -- connect to console of domain {id} or domain name
```
List all consoles in the group. For example:

<table>
<thead>
<tr>
<th>DOMAIN ID</th>
<th>DOMAIN NAME</th>
<th>DOMAIN STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ldg1</td>
<td>online</td>
</tr>
<tr>
<td>1</td>
<td>ldg2</td>
<td>connected</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

The two domain states and their meanings are:

- **online**
  - No one is connected to the console.
- **connected**
  - At least one user is already connected to the console.

`q`
Disconnect from `vntsd`.

`c[id], n[name]`
Connect to specified console. Upon connection, the following message is displayed:

**Connecting to console `<domain-name>` in group `<group-name>`**

Press `~?` for control options ....

A tilde (~) appearing as the first character of a line is an escape signal that directs `vntsd` to perform a special console command. The tilde-tilde (~~) sequence outputs a tilde. In conjunction with the initial tilde, `vntsd` accepts the following special console commands:

- `~`
  - Disconnect from the console or console group.
- `~w`
  - Force write access to the console.
- `~p`
  - Disconnect from this console, and connect to the console that precedes this console in the list of consoles.
- `~n`
  - Disconnect from this console, and connect to the console that follows this console in the list of consoles.
- `~#`
  - Send break.
- `~^B`
  - Send alternate break.
- `~?`
  - Display `vntsd` help, as follows:
vntsd(1M)

~# - Send break
~^B - Send alternate break
~. - Exit from this console
~w - Force write access
~n - Console next
~p - Console previous
~? - Help

Files  /usr/lib/ldoms/vntsd
       Binary executable vntsd file.
/usr/lib/ldoms/vntsd.xml
       Service management facility (smf) manifest file for vntsd.

Attributes  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWldoms</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Evolving</td>
</tr>
</tbody>
</table>

See Also  telnet(1), svccfg(1M), usermod(1M), auth_attr(4), attributes(5), smf(5)

Notes  The vntsd is managed by the service management facility, smf(5), under the service identifier:
svc:/ldoms/vntsd

You can change the following properties using the svccfg(1M) command:

vntsd/vcc_device
   Set an instance of the virtual console concentrator (vcc) driver to which vntsd is connected.

vntsd/listen_addr
   Set the IP address to which vntsd listens, using the following syntax:
   vntsd/listen_addr: "xxx.xxx.xxx.xxx"
   ...where xxx.xxx.xxx.xxx is a valid IP address. The default value of this property is to listen on IP address 127.0.0.1. Users can connect to a guest console over a network if the value is set to the IP address of the control domain.

   Note – Enabling network access to a console has security implications. Any user can connect to a console and for this reason it is disabled by default.

vntsd/timeout_minutes
   Set timeout in minutes. vntsd will timeout (close) telnet connection if there is no activity (input or output) on the console. The default value is 0, which disables timeout.
vntsd/authorization

Enable the authorization checking of users and roles for the domain console or consoles that are being accessed. The default value of this property is false to maintain backward compatibility. To enable authorization checking, use the `svccfg(1M)` command to set the property value to true. While this option is enabled, `vntsd` listens and accepts connections on localhost. If the `listen_addr` property specifies an alternate IP address when this option is enabled, `vntsd` ignores the alternate IP address and continues to listen on localhost. Connections that are initiated from other hosts will also fail. Authorizations are available to access all consoles or console groups, or to access specific consoles or console groups. When the `vntsd` service is enabled, the following authorization is added to the authorization description database, `auth_attr(4)`: 

```
solaris.vntsd.consoles:::Access All LDoms Guest Consoles::
```

Add any fine-grained authorizations based on the name of the console group. For example, if the name of the console group to be authorized is ldg1, add the following entry to the `auth_attr(4)` file:

```
solaris.vntsd.console-ldg1:::Access Specific LDoms Guest Console::
```

By default, the authorization to access all consoles is assigned to the root user or role. The Primary Administrator (superuser) can use the `usermod(1M)` command to assign the required authorization or authorizations to other users or roles.

The following example gives user user1 the authorization to access all domain consoles:

```
# usermod -A "solaris.vntsd.consoles" user1
```

The following example gives user user1 the authorization to access the console group named ldg1:

```
# usermod -A "solaris.vntsd.console-ldg1" user1
```
volcopy(1M)

**Name**
volcopy – make an image copy of file system

**Synopsis**
volcopy [-F FSType] [-V] [generic_options]
   [-o FSType-specific_options] operands

**Description**
volcopy makes a literal copy of the file system. This command may not be supported for all FSTypes.

**Options**
The following options are supported:

- **-F FSType**
  Specify the FSType on which to operate. The FSType should either be specified here or be determinable from /etc/vfstab by matching the operands with an entry in the table. Otherwise, the default file system type specified in /etc/default/fs will be used.

- **-V**
  Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option should be used to verify and validate the command line.

**generic_options**
Options that are commonly supported by most FSType-specific command modules. The following options are available:

- **-a**
  Require the operator to respond “yes” or “no” instead of simply waiting ten seconds before the copy is made.

- **-s**
  (Default) Invoke the DEL if wrong verification sequence.

- **-o FSType-specific_options**
  Specify FSType-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the FSType-specific module of the command.

**Operands**
The following operands are supported:

operands generally include the device and volume names and are file system specific. A detailed description of the operands can be found on the FSType-specific man pages of volcopy.

**Exit Status**
The following exit values are returned:

- 0  Successful file system copy
- 1  An error has occurred.
Files

/etc/vfstab list of default parameters for each file system
/etc/default/fs default local file system type. Default values can be set for the following
flags in /etc/default/fs. For example: LOCAL=ufs.

LOCAL: The default partition for a command if no FSType is
specified.

volcopy.
volcopy_ufs(1M)

Name
volcopy_ufs – make an image copy of a ufs file system

Synopsis
volcopy [-F ufs] [generic_options] fsname srcdevice volname1 destdevice volname2

Description
volcopy makes a literal copy of the ufs file system using a blocksize matched to the device.

Options
The following option is supported:

generic_options  options supported by the generic volcopy command. See volcopy(1M).

Operands
The following operands are supported:

fsname       represents the mount point (for example, root, u1, etc.) of the file system being copied.

srcdevice or destdevice the disk partition specified using the raw device (for example, /dev/rdsk/cld0s8, /dev/rdsk/cld1s8, etc.).

srcdevice and volname1 the device and physical volume from which the copy of the file system is being extracted.

destdevice and volname2 the target device and physical volume.

fsname and volname are limited to six or fewer characters and recorded in the superblock. volname may be ‘−’ to use the existing volume name.

Exit Status
The following exit values are returned:

0  Successful file system copy.

non-zero  An error has occurred.

Files
/var/adm/filesave.log  a record of file systems/volumes copied

Attributes
See attributes(5) for descriptions of the following attributes:

<table>

Notes
volcopy does not support copying to tape devices. Use dd(1M) for copying to and from tape devices.
vold – Volume Management daemon to manage removable media devices

**Synopsis**
```
[-d root-dir] [-L debug-level]
```

**Description**
The Volume Management daemon, vold, creates and maintains a file system image rooted at `root-dir` that contains symbolic names for removable media devices. These devices include CD-R, CD-RW, floppies, DVD, and USB and 1394 mass storage devices. The default `root-dir` is set to `/vol` if no directory is specified by the `-d` option.

vold reads the `/etc/vold.conf` configuration file upon startup. If the configuration file is modified later, vold must be told to reread the `/etc/vold.conf` file. Accomplish this rereading by entering:

```
example# svcadm refresh volfs
```

To tell vold to clean up and exit, enter:

```
example# svcadm disable volfs
```

To reenable:

```
example# svcadm enable volfs
```

To specify options (see OPTIONS):

```
example# svcfg
svc:/> select volfs
svc:/system/filesystem/volfs> listprop vold/*
vold/config_file astring
vold/log_debuglevel count 0
vold/log_file astring
vold/log_nfs_trace boolean false
vold/logVerbose boolean false
vold/never_writeback_label boolean false
vold/root_dir astring
svc:/system/filesystem/volfs> setprop vold/never_writeback_label=true
csvc:/system/filesystem/volfs> exit
```

```
# svcadm disable volfs
# svcadm enable volfs
```

vold is hotplug-aware for USB and 1394 mass storage devices, thus there is no need for stopping and restarting vold. It is recommended to `eject(1)` the “media” before hot-removing a device. The eject command unmounts any filesystems mounted from the media, making it safe to remove the device. (Note that all USB and 1394 devices, regardless of whether they contain removable media, are treated like removable media devices).
The following options are supported:

- **-n** Never writeback. Volume Management updates media labels with unique information if labels are not unique. This flag keeps Volume Management from changing your media. The default setting is FALSE.

- **-t** Dump NFS trace information to the log file. The default setting is FALSE.

- **-v** Provide lots of status information to the log file. The default setting is FALSE (do not provide status info to log file).

- **-d root-dir** Specify an alternate root directory. The default location is /vol. Setting this will also cause other Volume Management utilities to use this as the default root directory.

- **-f config-file** Specify an alternate configuration file. The default file is /etc/vold.conf.

- **-l log-file** Specify an alternate log file. The default log file is /var/adm/vold.log.

- **-L debug-level** Change the level (verbosity) of debug messages sent to the log file. The range is 0 to 99 where 0 is nothing and 99 is everything. The default level is 0.

**Environment Variables**

vold sets the following environment variables to aid programs which are called when events such as insert, notify, and eject occur:

- **VOLUME_ACTION** Event that caused this program to be executed.
- **VOLUME_PATH** Pathname of the matched regex from the vold.conf file.
- **VOLUME_DEVICE** Device (in /vol/dev) that applies to the media.
- **VOLUME_NAME** Name of the volume in question.
- **VOLUME_USER** User ID of the user causing the event to occur.
- **VOLUME_SYMNAME** Symbolic name of a device containing the volume.
- **VOLUME_MEDIATYPE** Name of the type of media (CD-ROM, floppy or rmdisk)

**Files**

- **/etc/vold.conf** Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes events to occur when specific criteria are met.
- **/usr/lib/vold/*.so.1** Shared objects called by Volume Management daemon when certain actions occur.
- **/var/adm/vold.log** the default log file location (see the -l option for a description).
- **/vol** the default Volume Management root directory.

System Administration Guide: Basic Administration

Notes  The Volume Management daemon and associated commands might not be included in a future Solaris release.
Wall reads its standard input until an end-of-file. It then sends this message to all currently logged-in users preceded by:

```
Broadcast Message from...
```

If `filename` is given, then the message is read in from that file. Normally, pseudo-terminals that do not correspond to login sessions are ignored. Thus, when using a window system, the message appears only on the console window. However, `-a` will send the message even to such pseudo-terminals.

It is used to warn all users, typically prior to shutting down the system.

The sender must be superuser to override any protections the users may have invoked. See `mesg(1)`.

`wall` runs `setgid()` to the group ID `tty`, in order to have write permissions on other user’s terminals. See `setuid(2)`.

`wall` will detect non-printable characters before sending them to the user’s terminal. Control characters will appear as a `"^"` followed by the appropriate ASCII character; characters with the high-order bit set will appear in “meta” notation. For example, `\003` is displayed as `^C` and `\372` as `'M–z'`.

The following options are supported:

- `-a` Broadcast message to the console and pseudo-terminals.
- `-g grpname` Broadcast to the users in a specified group only, per the group database (see `group(4)`).

**Environment Variables**

If the `LC_*` variables (`LC_CTYPE`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) are not set in the environment, the operational behavior of `wall` for each corresponding locale category is determined by the value of the `LANG` environment variable. See `environ(5)`. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `wall` behaves.

**Files**

`/dev/tty*`

Notes  wall displays "Cannot send to ..." when the open on a user's tty file fails.
wanboot_keygen(1M)

Name  wanboot_keygen – create and display client and server keys for WAN booting

Synopsis  
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=3des
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=aes
/usr/lib/inet/wanboot/keygen -m
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=sha1
/usr/lib/inet/wanboot/keygen -d -m
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=keytype

Description  The keygen utility has three purposes:

- Using the -c flag, to generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys.
- Using the -m flag, to generate and store a “master” HMAC SHA-1 key for WAN install, and to derive from the master key per-client HMAC SHA-1 hashing keys, in a manner described in RFC 3118, Appendix A.
- Using the -d flag along with either the -c or -m flag to indicate the key repository, to display a key of type specified by keytype, which must be one of 3des, aes, or sha1.

The net and cid arguments are used to identify a specific client. Both arguments are optional. If the cid option is not provided, the key being created or displayed will have a per-network scope. If the net option is not provided, then the key will have a global scope. Default net and code values are used to derive an HMAC SHA-1 key if the values are not provided by the user.

Options  The following options are supported:

- c  Generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys. Also generates and stores per-client HMAC SHA-1 keys. Used in conjunction with -o.
- d  Display a key of type specified by keytype, which must be one of 3des, aes, or sha1. Use -d with -m or with -c and -o.
- m  Generate and store a “master” HMAC SHA-1 key for WAN install.
- o  Specifies the WANboot client and/or keytype.

Examples  

EXAMPLE 1  Generate a Master HMAC SHA-1 Key

# keygen -m

EXAMPLE 2  Generate and Then Display a Client-Specific Master HMAC SHA-1 Key

# keygen -c -o net=172.16.174.0 ,cid=010003BA0E6A36 ,type=sha1
# keygen -d -c -o net=172.16.174.0 ,cid=010003BA0E6A36 ,type=sha1
EXAMPLE 3  Generate and Display a 3DES Key with a Per-Network Scope

# keygen -c -o net=172.16.174.0, type=3des
# keygen -d -o net=172.16.174.0, type=3des

Exit Status  0  Successful operation.
           >0  An error occurred.

wanboot_keymgmt utility

**Synopsis**

```
/usr/lib/inet/wanboot/keymgmt -i -k key_file -s keystore -o type=keytype
/usr/lib/inet/wanboot/keymgmt -x -f outfile -s keystore -o type=keytype
```

**Description**

The keymgmt utility has two purposes:

- To take a raw key, stored in `key_file`, and insert it in the repository specified by `keystore`.
- To extract a key of a specified type from the repository specified by `keystore`, depositing it in `outfile`.

`outfile` will be created if it does not already exist. The type of key being added or extracted is specified by `keytype` and may have one of four values: 3des, aes, rsa, or sha1 (the last used by HMAC SHA-1). When extracting a key, the first key with an OID matching the supplied type is used.

**Arguments**

The following arguments are supported:

- `-i` Used in conjunction with `-k` to insert a raw key in `keystore`.
- `-f outfile` Used to specify a file to receive an extracted key.
- `-k key_file` Used in conjunction with `-i` to specify the file in which a raw key is stored. This key will be inserted in `keystore`.
- `-o type=keytype` Specifies the type of key being inserted or extracted. Must be one of 3des, aes, rsa, or sha1.
- `-s keystore` Specifies a repository in which a key will be inserted or from which a key will be extracted.
- `-x` Used in conjunction with `-f` to extract a key of a specified type and deposit it in `outfile`.

**Exit Status**

- `0` Successful operation.
- `>0` An error occurred.

ITU-T Recommendation X.208
wanboot_p12split – split a PKCS #12 file into separate certificate and key files

### Synopsis

```
/usr/lib/inet/wanboot/p12split -i p12file -c out_cert -k out_key
[-t out_trust -l id] [-v]
```

### Description

The `p12split` utility extracts a certificate and private key from the repository specified by `p12file`, depositing the certificate in `out_cert` and the key in `out_key`. If supplied, the `-l` option specifies the value for the LocalKeyId that will be used in the new certificate and key files. `p12split` can optionally extract a trust certificate into the `out_trust` file if the `-t` option is specified. Use the `-v` option to get a verbose description of the split displayed to standard output.

### Options

The following arguments and options are supported:

- `-c out_cert` Specifies a repository that receives an extracted certificate.
- `-i p12file` Specifies a repository from which a certificate and private key is extracted.
- `-k out_key` Specifies a repository that receives an extracted private key.
- `-l id` Specifies the value for the LocalKeyId that will be used in the new certificate and key files.
- `-t out_trust` Specifies a file for receiving an extracted trust certificate.
- `-v` Displays a verbose description of the split to stdout.

### Exit Status

- `0` Successful operation.
- `>0` An error occurred.

wanbootutil(1M)

Name
wanbootutil – manage keys and certificates for WAN booting

Synopsis
wanbootutil [keygen] [option_specific_arguments]
wanbootutil [keymgmt] [option_specific_arguments]
wanbootutil [p12split] [option_specific_arguments]

Description
The wanbootutil command creates and manages WANboot encryption and hashing keys and manipulates PKCS#12 files for use by WAN boot.

wanbootutil has three subcommands, each covered in a separate man page:
wanboot_keygen(1M) Generates encryption and hashing keys.
wanboot_keymgmt(1M) Inserts and extracts keys from WAN boot key repositories.
wanboot_p12split(1M) Splits a PKCS#12 file into separate certificate and key files for use by WAN boot.

Options
The options are supported for wanbootutil are the use of keygen, keymgmt, or p12split. The options for these subcommands are described in their respective man pages.

Examples
EXAMPLE 1 Generate a 3DES Client Key
# wanbootutil keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=3des

EXAMPLE 2 Insert an RSA Private Client Key
wanbootutil keymgmt -i -k keyfile \n    -s /etc/netboot/172.16.174.0/010003BA0E6A36/keystore -o type=rsa

EXAMPLE 3 Split a PKCS#12 File into Certificate and Key Components
# wanbootutil p12split -i p12file -c out_cert -k out_key

Exit Status
0 Successful operation.
non-zero An error occurred. Writes an appropriate error message to standard error.

wbemadmin–start Sun WBEM User Manager

**Name**
wbemadmin – start Sun WBEM User Manager

**Synopsis**
/usr/sadm/bin/wbemadmin

**Description**
The `wbemadmin` utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment.

The `wbemadmin` utility allows you to perform the following tasks:

- **Manage user access rights**: Use the `wbemadmin` utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.

- **Manage namespace access rights**: Use the `wbemadmin` utility to add, delete, or modify access rights for all users to a namespace.

The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the `root\security` namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

All programming operations are performed within a namespace. Two namespaces are created by default during installation:

- `root\cimv2` — Contains the default CIM classes that represent objects on your system.
- `root\security` — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.
You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in to the root account, you can set the following types of access to CIM objects:

- Read Only — Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- Read/Write — Allows full read, write, and delete access to all CIM classes and instances.
- Write — Allows write and delete, but not read access to all CIM classes and instances.
- None — Allows no access to CIM classes and instances.

Context help is displayed in the left side of the wbemadmin dialog boxes. When you click on a field, the help content changes to describe the selected field. No context help is available on the main User Manager window.

The wbemadmin security administration tool updates the following Java classes in the root\security namespace:

- Solaris_UserAcl — Updated when access rights are granted or changed for a user.
- Solaris_namespaceAcl — Updated when access rights are granted or changed for a namespace.

Usage The wbemadmin utility is not the tool for a distributed environment. It is used for local administration on the machine on which the CIM Object Manager is running.

Exit Status The wbemadmin utility terminates with exit status 0.

Warning The root\security namespace stores access privileges. If you grant other users access to the root\security namespace, those users can grant themselves or other users rights to all other namespaces.

wbemconfig – convert a JavaSpaces datastore to the newer Reliable Log datastore format

**Synopsis**
```
/usr/sadm/lib/wbem/wbemconfig convert
```

**Description**
A Reliable Log directory is created that contains the converted data. This directory is named `/var/sadm/wbem/logr`.

The `convert` argument is the only supported option of this command. You should only run this command after stopping WBEM (CIM Object Manager) with the `init.wbem stop` command. Otherwise your data may be corrupted.

This command successfully converts any proprietary custom MOFs you have created in the datastore, but not any CIM or Solaris MOFs you have modified. These will be destroyed. To recompile any modified CIM or Solaris MOFs into the new datastore, run the `mofcomp` command on the MOF files containing the class definitions.

Because the `wbemconfig convert` command invokes the JVM (Java Virtual Machine) to perform conversion of the JavaSpaces datastore, you must be running the same version of the JVM as when the original JavaSpaces storage was created. After the `wbemconfig convert` command is completed, you can change to any version of the JVM you want.

To see what version of the JVM you are running, issue the `java -version` command.

**Options**
The following options are supported:

- `convert` Convert a JavaSpaces datastore to the newer Reliable Log datastore format.

**Attributes**

wbemlogviewer–startWBEMLogViewer

The wbemlogviewer utility startstheWBEMLogViewer graphical user interface, which enables administrators to view and maintain log records created by WBEM clients and providers. The WBEM Log Viewer displays a Login dialog box. You must log in as root or a user with write access to the root\cimv2 namespace to view and maintain log files. Namespaces are described in wbemadmin(1M).

Log events can have three severity levels.

- **Errors**
- **Warnings**
- **Informational**

The WBEM log file is created in the /var/sadm/wbem/log directory, with the name wbem_log. The first time the log file is backed up, it is renamed wbem_log.1, and a new wbem_log file is created. Each succeeding time the wbem_log file is backed up, the file extension number of each backup log file is increased by 1, and the oldest backup log file is removed if the limit, which in turn is specified in the log service settings, on the number of logfiles is exceeded. Older backup files have higher file extension numbers than more recent backup files.

The log file is renamed with a .1 file extension and saved when one of the following two conditions occur:

- The current file reaches the specified file size limit.
- A WBEM client application uses the clearLog() method in the Solaris_LogService class to clear the current log file.

A WBEM client application uses the clearLog() method in the Solaris_LogService class to clear the current log file.

A user chooses Action->Back Up Now in the Log Viewer application.

Help is displayed in the left panel of each dialog box. Context help is not displayed in the main Log Viewer window.

**Usage**
The WBEM Log Viewer is not the tool for a distributed environment. It is used for local administration.

The WBEM Log Viewer allows you to perform the following tasks:

**View the logs**

**Set properties of log files**

- Click Action->Log File Settings to specify log file parameters and the log file directory.

**Back up a log file**

- Click Action->Back Up Now to back up and close the current log file and start a new log file.
Open historical log files  
Click Action->Open Log File to open a backed-up log file.

Delete an old log file  
Open the file and then click Action->Delete Log File. You can only delete backed-up log files.

View log record details  
Double-click a log entry or click View->Log Entry Details to display the details of a log record.

Sort the logs  
Click View->Sort By to sort displayed entries. You can also click any column heading to sort the list. By default, the log entries are displayed in reverse chronological order (new logs first).

**Exit Status**  
The `wbemlogviewer` utility terminates with exit status 0.

**Files**  
/var/sadm/wbem/log/wbem_log  
WBEM log file

Name  wcadmin – manage the configuration of the Sun Java Web Console

Synopsis  
```
/usr/sbin/wcadmin subcommand options
/usr/sbin/wcadmin [-h|--help]
/usr/sbin/wcadmin [-V|--version]
```

Description  wcadmin is a Command Line Interface (CLI) — based tool for managing the configuration of the Sun Java Web Console.

Subcommands  The following subcommands are supported:

- **add**  The `wcadmin add` subcommand adds a new shared jar file, a new JAAS login module, or a new shared service property to the console configuration. An optional identifier may be specified; if omitted, the identifier is derived from the resource name. The resource is added when the console is next started.

  The format of the `add` subcommand is:

  ```
  add -l -a appname [-n id] jarpath
  add -m -a appname [-n id] -b behavior -s service [-o name=value] classname
  add -p -a appname name=value [... name=value]
  ```

- **deploy**  The `wcadmin deploy` subcommand deploys the specified web application into the console’s web server instance. Applications are deployed directly from their installation directories.

  The format of the `deploy` subcommand is:

  ```
  deploy [-D] -a appname -x context app_path
  ```

- **disable**  The `wcadmin disable` subcommand disables access to the specified web application in the console’s web server instance.

  The format of the `disable` subcommand is:

  ```
  disable -x context
  ```

- **enable**  The `wcadmin enable` subcommand enables access to the specified web application in the console’s web server instance.

  The format of the `enable` subcommand is:

  ```
  enable -x context
  ```

- **list**  The `wcadmin list` subcommand lists the resources currently configured for the console; including deployed web applications, shared jar files, login modules, and shared service properties. If no option is specified, all resources are listed.
The format of the `list` subcommand is:

```bash
list [-a] [-d] [-l] [-m] [-p]
```

**password**

The `wcadmin password` subcommand manages the administrator and security keystore passwords for the console. Keystore passwords should not be changed while the console is running.

The format of the `password` subcommand is:

```bash
password [-a] [-k] [-t]
password -f password_file
```

**reload**

The `wcadmin reload` subcommand unloads the specified web application from the console's web server instance and reloads the application from its original installation directory.

The format of the `reload` subcommand is:

```bash
reload -x context
```

**remove**

The `wcadmin remove` subcommand removes a shared jar file, a login module, or a shared service property from the console configuration. The resource may be specified by its identifier or by its full jarpath or classname. The resource is removed when the console is next started.

The format of the `remove` subcommand is:

```bash
remove -l -a appname [-n id] jarpath
remove -m -a appname [-n id] classname
remove -p -a appname property [...]```

**undeploy**

The `wcadmin undeploy` subcommand undeploys the specified web application from the console's web server instance.

The format of the `undeploy` subcommand is:

```bash
undeploy [-D] -a appname -x context
```

**Options**

The following options are supported:

- **-h** | **--help** | **-?**
  Display runtime help.

- **-V** | **--version**
  Display console version information.

- **-D** | **--defer**
  When used with the deploy and undeploy subcommands, defers the deployment or undeployment until the next console restart.
The operation is deferred by simply adding or removing the corresponding resource registration notification file. If defer is not specified, a runtime deployment or undeployment is performed, so that the application becomes available or unavailable in the running console. If the console instance is not currently running, the operation is automatically deferred.

-a | --adminpassword
Specify that the administrator password should be changed, when used with password subcommand. You are prompted for a new password, which must be 8 to 32 characters.

-a | --application
Specify the application name, when used with subcommands other than password subcommand.

-d | --detail
Specify that configuration details of each resource should be displayed.

-f
Specify the fully qualified path name to a file containing one or more password property values. See the description of the password_file argument.

-k | --keypassword
Specify that the keystore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.

-l | --library
Specify that the resource is a shared jar file.

-m | --module
Specify that the resource is a JAAS login module.

-n | --name
Specify the short-hand identifier name for the resource. If omitted, the identifier name is derived from the full resource name.

-o | --option
Specify the name and value of a login module option property, separated by the equals character.

-p | --property
Specify that the resource is one or more shared service properties.

-s | --service
Specify the name of the JAAS login service definition. If omitted, the default console login service definition is assumed.

-t | --trustpassword
Specify that the truststore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.

-x | --context
Specify the web application context path name under which the application is deployed.

Arguments

app_path
The fully qualified file system path to the web application installation directory.

appname
The application name. The name must be unique among all web applications registered with the console. It is also used as the name of the subdirectory under the console’s pre-registration directory which contains
all the resource registration notification files for that application. Typically, the application package name, plugin identifier, or context path name is specified for the application name.

**behavior**  
The JAAS login module control flag behavior. Must be one of “optional”, “required”, “requisite”, or “sufficient”.

**classname**  
The fully qualified Java package class name of the JAAS login module. The specified class must be included in a shared jar file added to the console.

**context**  
The web application context path name under which the application is deployed. With the .reg suffix, the context forms the file name of the registration notification file for that application.

**id**  
The short-hand identifier name for a jar file or login module resource to be added or removed. The identifier name must be unique among the resources shared for a given application name. With the .reg suffix, it forms the file name of the registration notification file for that resource.

**jarpath**  
The fully qualified file system path to the jar file resource. When the resource is added to the console, its path is included in the classpath of the console’s shared class loader.

**option**  
The JAAS login module option property name.

**property**  
The shared service property name.

**password_file**  
The fully qualified path to a password text file that contains the new administrator, keystore, and truststore passwords in property file format. The administrator password is specified using the “adminpassword” property. The keystore password is specified using the “keypassword” property. The truststore password is specified using the “trustpasswd” property. At least one password property must be contained in the password file.

**value**  
The login module option or shared service property value. If the value contains white space, it must be quoted.

### Examples

The following command adds a jar file to be shared in the console:

```
wcadmin add -l -a myapp_1.0 -n wbem /usr/sadm/lib/wbem.jar
```

The following command deploys a new web application:

```
wadmin deploy -a myapp_1.0 -x myapp /opt/SUNWmyapp/myapp
```

The following command reloads an existing web application:

```
wadmin reload -x myapp
```

The following command undeploys a web application at the next server restart:
The following command lists all the deployed web applications in the console. If the status field is "running", the web application is available. If the status field is "stopped", the web application is disabled and is not available. If all web applications are "stopped", this typically indicates the console web server instance is not running.

wcadmin list -a

The following command removes a shared jar file:

wcadmin remove -l -a myapp_1.0 -n wbem

The following command changes passwords that are specified in a file:

wcadmin password -f /home/mydir/console-passwords

**Exit Status**  
The following exit values are returned:

- **0**  Subcommand succeeded without error
- **1**  Usage error: missing or malformed arguments
- **2**  Fatal error: subcommand failed with one or more errors

smcwebserver(1M), smreg(1M), attributes(5), environ(5)
whodo(1M)

Name  whodo – who is doing what

Synopsis  /usr/sbin/whodo [-h] [-l] [user]

Description  The `whodo` command produces formatted and dated output from information in the
/var/adm/utmpx and /proc/pid files.

The display is headed by the date, time, and machine name. For each user logged in, device
name, user-ID and login time is shown, followed by a list of active processes associated with
the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used,
and process name.

If `user` is specified, output is restricted to all sessions pertaining to that user.

Options  The following options are supported:

- `-h`  Suppress the heading.

- `-l`  Produce a long form of output. The fields displayed are: the user’s login name, the
name of the tty the user is on, the time of day the user logged in (in `hours:minutes`), the
idle time — that is, the time since the user last typed anything (in `hours:minutes`), the
CPU time used by all processes and their children on that terminal (in `minutes:seconds`), the CPU time used by the currently active processes (in `minutes:seconds`), and the name and arguments of the current process.

Examples  **EXAMPLE 1**  Using the `whodo` Command

The command:

```
example% whodo
```

produces a display like this:

```
Tue Mar 12 15:48:03 1985
bailey
tty09  mcn   8:51
tty09  28158 0:29 sh

 tty52  bdr   15:23
tty52  21688 0:05 sh
tty52  22788 0:01 whodo
tty52  22017 0:03 vi
tty52  22549 0:01 sh

tty08  lee   10:20
tty08  6748  0:01 layers
xt162  6751  0:01 sh
xt163  6761  0:05 sh
tty08  6536  0:05 sh
```
Environment Variables

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of tar(1) for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the C (U.S. style) locale determines how whodo behaves.

LC_CTYPE
Determined how whodo handles characters. When LC_CTYPE is set to a valid value, whodo can display and handle text and filenames containing valid characters for that locale. The whodo command can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. whodo can also handle EUC characters of 1, 2, or more column widths. In the C locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES
Determined how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the C locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

LC_TIME
Determined how whodo handles date and time formats. In the C locale, date and time handling follow the U.S. rules.

Exit Status
The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

Files
/etc/passwd System password file
/var/adm/utmpx User access and administration information
/proc/pid PID information for individual users

**wracct(1M)**

**Name**  
wracct – write extended accounting records for active processes and tasks

**Synopsis**  
/usr/sbin/wracct -i id_list [-t record_type]  
(process | task)

**Description**  
The wracct utility allows the administrator to invoke the extended accounting system, if active, to write intermediate records representing the resource usage of a selected set of processes or tasks. For tasks, a record_type option is also supported, allowing the administrator to request the writing of:

- an interval record, which reflects task usage since a previous interval record (or since task creation if there is no interval record), or
- a partial record, which reflects usage since task creation.

**Options**  
The following options are supported:

- **-i id_list**  
  Select the IDs of the tasks or processes to write records for. Specify id_list as a comma- or space-separated list of IDs, presented as a single argument. For some shells, this requires appropriate quoting of the argument.

- **-t record_type**  
  Select type of record to write for the selected task or process. For tasks, record_type can be partial or interval. partial is the default type, and the only type available for process records.

**Operands**  
The following operands are supported:

- **process**  
  Treat the given ID as a process ID for the purposes of constructing and writing an extended accounting record.

- **task**  
  Treat the given ID as a task ID for the purposes of constructing and writing an extended accounting record.

**Examples**

**EXAMPLE 1**  
Writing a Partial Record

Write a partial record for all active sendmail processes.

# /usr/sbin/wracct -i "pgrep sendmail" process

**EXAMPLE 2**  
Writing an Interval Record

Write an interval record for the task with ID 182.

# /usr/sbin/wracct -t interval -i 182 task

**Exit Status**  
The following exit values are returned:

- 0  
  Successful completion.

- 1  
  An error occurred.

- 2  
  Invalid command line options were specified.
3  Pertinent components of extended accounting facility are not active.

**Files**  
/var/adm/exacct/task  
/var/adm/exacct/proc  Extended accounting data files.

**Attributes**

acctadm(1M), attributes(5)
wrsmconf - manage WCI RSM controller configurations

**Synopsis**
/usr/platform/sun4u/sbin/wrsmconf create -c controller_id -f config_file
wrsmconf initial -f config_file [-c controller_id]
wrsmconf remove [-c controller_id]
wrsmconf topology [-c controller_id]
wrsmconf dump -c controller_id -f config_file

**Description**
wrsmconf provides a means to create, install, retrieve, and remove configurations for WCI remote shared memory (RSM) controllers.

**Options**
The following options are supported:

- **create -c controller_id -f config_file**
  Create a set of per-node configurations for the specified controller and store them to the file `config_file`. The created file contains a per-node configuration for each node specified in the input for the specified controller. The file has a checksum on it and cannot be modified directly. This file can be used in a `wrsmconf initial` call on each node to install the node's configuration into the local driver.

  A list of nodes and WCI devices connected to those nodes is read from standard input. For each connected pair of links, specify the nodename (uname -n), safari port id, and link number on both sides of the connection. The format of the information looks like this:

  `<nodename>,<wrsm-portid>,<linkno>=<nodename>,<wrsm-portid>,<linkno>`
  `<nodename>,<wrsm-portid>,<linkno>=<nodename>,<wrsm-portid>,<linkno>`

  This interface is intended for installing configurations for testing (such as for SunVTS). Only direct-connect, non-striped configurations for 1 to 3 nodes can be specified. FM node ids and RSM hardware addresses are assigned to the specified nodes contiguously and in order starting from 0.

- **initial -f config_file [-c controller_id]**
  Install the configuration for the local node stored in the file `config_file` into the driver as the initial configuration for the specified controller. This command fails under the following circumstances:
- If controller_id is specified and the configuration in the file is not for the specified controller.
- If the file does not contain a valid configuration for the local node or if the checksum in the file shows it has been modified.
- If a configuration has already been installed for the controller. If this happens, use wrsmconf remove to remove the existing configuration.

`remove [-c controller_id]` Disable communication through the installed configuration for all controllers or the specified controller and remove the configuration(s) from the driver.

`topology -c controller_id` For each installed controller (or for the specified controller), print to stdout the set of nodes this controller is configured to reach, including the nodename, FM node id, and RSM hardware address for each node. The following is example output:

<table>
<thead>
<tr>
<th>FM Node ID</th>
<th>Node Name</th>
<th>Controller Instance</th>
<th>Controller HW Addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>hpc00</td>
<td>0</td>
<td>101</td>
</tr>
<tr>
<td>0</td>
<td>hpc00</td>
<td>1</td>
<td>333</td>
</tr>
<tr>
<td>1</td>
<td>hpc01</td>
<td>0</td>
<td>102</td>
</tr>
<tr>
<td>1</td>
<td>hpc01</td>
<td>1</td>
<td>54</td>
</tr>
<tr>
<td>1</td>
<td>hpc01</td>
<td>2</td>
<td>34</td>
</tr>
<tr>
<td>2</td>
<td>hpc03</td>
<td>0</td>
<td>103</td>
</tr>
<tr>
<td>2</td>
<td>hpc03</td>
<td>1</td>
<td>103</td>
</tr>
<tr>
<td>2</td>
<td>hpc03</td>
<td>2</td>
<td>103</td>
</tr>
</tbody>
</table>

`dump -c controller-id -f config_file` Fetch the installed configuration for the specified controller from the driver and store it into the file `config_file` along with a checksum to protect the data. This configuration can later be installed with the command `wrsmconf initial`.

**Exit Status** This command returns 0 on successful completion, and a non-zero value if an error occurred.

**Attributes** See `attributes(5)` for descriptions of the following attributes:
ATTRIBUTETYPE ATTRIBUTE VALUE

Availability      SUNWwrsm

See Also  kstat(1M), wrsmstat(1M), attributes(5)
Name
wrsmstat – report WCI RSM driver statistics

Synopsis
/usr/platform/sun4u/sbin/wrsmstat controller
    [-c controller_id]
wrsmstat wrsm [-i wrsm_instance_num] [-v]
wrsmstat route [-c controller_id]
    [-h node_hostname]
wrsmstat set [-i wrsm_instance_num] -c cmmu -s start -e end

Description
The wrsmstat command provides statistics on remote shared memory (RSM) controllers, routes to nodes, and WCI interfaces managed by the WCI RSM driver (wrsm). It also provides an interface for setting extended performance counter control registers that constrain the wrsm counters available through busstat(1M).

Options
The following options are supported:

controller [-c controller_id]
    Displays information describing the state of the specified controller, or of all controllers if none is specified. The following is sample output:

    $ wrsmstat controller -c 5 Controller 5 ------------ Controller state: up Local RSM
    Hardware address: 0x4 Exported segments: 0 # published: 0 # connections: 0 total bound memory: 0 Imported segments: 0 Send Queues: 0 Registered Handlers: 0 Assigned WCIs: 4 Available WCIs: 2

wrsm [-i wrsm_instance_num] [-v]
    Displays information describing the state of the specified RSM WCI, or of all RSM WCIs if none is specified. The following is sample output:

    $ wrsmstat wrsm -i 2
    WCI instance 2
    -------------
    Portid: 5
    Controller ID: 0
    Config Version: 5
    Link Error Shutdown Trigger: 40000
    Link #0 is not present.
    Link #1
    Link Enabled: yes
    Link State: up
    Remote RSM HW addr: 1
    Remote wnode ID: 1
    Remote link num: 1
    Remote WCI port ID: 3
    Error takedowns: 0
    Bad Config takedowns: 0
    Failed bringups: 0
Total link errors: 0
Maximum link errors: 0
Average link errors: 0
Auto shutdown enabled: yes
Link #2 is not present.

If you specify the -v option, the following additional information is displayed:

Cluster Error Count: 0
Uncorrectable SRAM ECC error: no
Maximum SRAM ECC errors: 0
Average SRAM ECC errors: 0

route [-c controller_id] [-h nodename]
Displays the route to the specified node through the specified controller. If no node is specified, displays the routes to all nodes. If no controller is specified, displays the specified node's route through all controllers. If neither is specified, displays the routes to all nodes through all controllers. The following is sample output:

$ wrsmstat -c 3 -h fred
Controller 3 - Route to fred
----------------------------
Config Version: 1
PM node id: 0x345543
RSM hardware address: 0x9

      link# 2, first hop RSM HW addr: 0x2
WCI #1
   Port ID: 13
   Instance: 1
   Num of hops: 2
   Num of links: 2
      link# 0, first hop RSM HW addr: 0x4
      link# 2, first hop RSM HW addr: 0x2

set [-i wrsm_instance_num] -c cmmu -s <start> -e <end>
For the specified WCI (or for each RSM WCI if none specified), configure the specified range of CMMU entries so that transactions through them are counted by wrsm busstat kstats. Each call will cause transactions to be counted through the new ranges of cmmu entries in addition to the previously specified ranges. To count transactions through all CMMUs, specify a start value of 0 and end value of 0. To clear all ranges (and not count
transactions through any cmu entries), specify a start value of 0 and end value of -1.

**Exit Status**  This command returns 0 on successful completion, and a non-zero value if an error occurred.

**Attributes**  See attributes(5) for descriptions of the following attributes:

xntpd is a daemon which sets and maintains a UNIX system time-of-day in agreement with Internet standard time servers. xntpd is a complete implementation of the Network Time Protocol (NTP) version 3 standard, as defined by RFC 1305. It also retains compatibility with version 1 and 2 servers as defined by RFC 1059 and RFC 1119, respectively. The computations done in the protocol and clock adjustment code are carried out with high precision and with attention to the details which might introduce systematic bias into the computations. This is done to try to maintain an accuracy suitable for synchronizing with even the most precise external time source.

Ordinarily, xntpd reads its configuration from a configuration file at startup time. The default configuration file name is /etc/inet/ntp.conf, although this may be overridden from the command line. It is also possible to specify a working, although limited, xntpd configuration entirely on the command line, obviating the need for a configuration file. This may be particularly appropriate when xntpd is to be configured as a broadcast or multicast client, with all peers being determined by listening to broadcasts at run time. Through the use of the ntpq(1M) program, various internal xntpd variables can be displayed and configuration options altered while the daemon is running.

The daemon can operate in any of several modes, including symmetric active/passive, client/server and broadcast/multicast. A broadcast/multicast client can automatically discover remote servers, compute one-way delay correction factors and configure itself automatically. This makes it possible to deploy a fleet of workstations without specifying a configuration file or configuration details specific to its environment.

Options

The following command line arguments are understood by xntpd. See Configuration Commands for a more complete functional description:

- **-a** Run in authentication mode.
- **-A** Disable authentication mode.
- **-b** Listen for broadcast NTP and sync to this if available.
- **-c conffile** Specify an alternate configuration file.
- **-d** Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.
- **-e authdelay** Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.
- **-f driftfile** Specify the location of the drift file.
-k keyfile
Specify the location of the file which contains the NTP authentication keys.

-l logfile
Specify a log file instead of logging to syslog.

-m
Listen for multicast messages and synchronize to them if available (requires multicast kernel).

-p pidfile
Specify the name of the file to record the daemon’s process id.

-r broadcast
Ordinarily, the daemon automatically compensates for the network delay between the broadcast/multicast server and the client; if the calibration procedure fails, use the specified default delay (in seconds).

-s statsdir
Specify the directory to be used for creating statistics files.

-t trustedkey
Add a key number to the trusted key list.

-v variable
Add a system variable.

-V variable
Add a system variable listed by default.

Usage
xntpd’s configuration file format is similar to other Unix configuration files. Comments begin with a ‘#’ character and extend to the end of the line. Blank lines are ignored. Configuration commands consist of an initial keyword followed by a list of arguments, separated by whitespace. Some arguments may be optional. These commands may not be continued over multiple lines. Arguments may be host names, host addresses written in dotted-decimal, integers, floating point numbers (when specifying times in seconds) and text strings.

In the following descriptions, optional arguments are delimited by ‘[ ]’, while alternatives are separated by ‘|’. The first three commands specify various time servers to be used and time services to be provided.

peer host_address [ key # ] [ version # ] [ prefer ]
Specifies that the local server is to operate in “symmetric active” mode with the remote server host_address named in the command. In this mode, the local server can be synchronized to the remote server. In addition, the remote server can be synchronized by the local server. This is useful in a network of servers where, depending on various failure scenarios, either the local or remote server host may be the better source of time. The peer command, and the server and broadcast commands that follow, can take the following arguments:
key Indicates that all packets sent to the address are to include authentication fields, encrypted using the specified key number. The range of this number is that of an unsigned 32 bit integer. By default, an encryption field is not included.

version Specifies the version number to be used for outgoing NTP packets. Versions 1, 2, and 3 are the choices; version 3 is the default.

prefer Marks the host as a preferred host. This host will be preferred for synchronization over other comparable hosts.

server host_address [ key # ] [ version f1# ] [ prefer ] [ mode f1# ] server Specifies that the local server is to operate in "client" mode with the remote server named in the command. In this mode the local server can be synchronized to the remote server, but the remote server can never be synchronized to the local server.

broadcast host_address [ key # ] [ version # ] [ ttl # ] Specifies that the local server is to operate in "broadcast" mode where the local server sends periodic broadcast messages to a client population at the broadcast/multicast address named in the command. Ordinarily, this specification applies only to the local server operating as a transmitter. For operation as a broadcast client, see broadcastclient or multicastclient commands elsewhere in this document. In
broadcast mode the host_address is usually the broadcast address on a local network or a multicast address assigned to NTP. The IANA has assigned the network, 224.0.1.1 to NTP. This is presently the only network that should be used. The following option is used only with the broadcast mode:

**ttl**

Specifies the time-to-live (TTL) to use on multicast packets. Selection of the proper value, which defaults to 127, is something of a black art and must be coordinated with the network administrator(s).

**broadcastclient**

Directs the local server to listen for broadcast messages on the local network, in order to discover other servers on the same subnet. Upon hearing a broadcast message for the first time, the local server measures the nominal network delay using a brief client/server exchange with the remote server. Then the server enters the "broadcastclient" mode, in which it listens for and synchronizes to succeeding broadcast messages. In order to avoid accidental or malicious disruption in this mode, both the local and remote servers must operate using authentication, with the same trusted key and key identifier.

**multicastclient**

[ IP address . . . ] Used in the same way as the broadcastclient command, but operates using IP multicasting. Support for this command requires the use of authentication. If one or more IP addresses are given, the server joins the respective multicast group(s).
If none are given, the IP address assigned to NTP (224.0.1.1) is assumed.

```
driftfile filename
```

Specifies the name of the file used to record the frequency offset of the local clock oscillator. If the file exists, it is read at startup in order to set the initial frequency offset. Then the file is updated once per hour with the current offset computed by the daemon. If the file does not exist or this command is not given, the initial frequency offset is assumed to be zero. In this case, it may take some hours for the frequency to stabilize and the residual timing errors to subside. The file contains a single floating point value equal to the offset in parts-per-million (ppm). The file is updated by first writing the current drift value into a temporary file and then using `rename(2)` to replace the old version. This implies that `xntpd` must have write permission for the directory the drift file is located in, and that file system links, symbolic or otherwise, should probably be avoided.

```
enable auth | bclient | pll | monitor | stats [...] 
```

Provides a way to enable or disable various server options. To do so, execute a two word command, where the first word is `enable` or `disable` and the second is the flag. Flags not mentioned are unaffected. Flags that can be changed are described below, along with their default values.
### Flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth</td>
<td>disable</td>
<td>Causes the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using a trusted key and key identifier.</td>
</tr>
<tr>
<td>bclient</td>
<td>disable</td>
<td>Causes the server to listen for a message from a broadcast or multicast server. After this occurs, an association is automatically instantiated for that server. Default for this flag is disable (off).</td>
</tr>
<tr>
<td>pll</td>
<td>enable</td>
<td>Enables the server to adjust its local clock. If not set, the local clock free-runs at its intrinsic time and frequency offset. This flag is useful in case the local clock is controlled by some other device or protocol and NTP is used only to provide synchronization to other clients.</td>
</tr>
<tr>
<td>monitor</td>
<td>disable</td>
<td>Enables the monitoring facility (see elsewhere).</td>
</tr>
<tr>
<td>stats</td>
<td>enable</td>
<td>Enables statistics facility filegen (see Monitoring Commands below).</td>
</tr>
</tbody>
</table>

#### slealways [yes|no]

Force xntpd to always slew the time.

#### keys filename

Specifies the name of a file which contains the encryption keys and key identifiers used by xntpd when operating in authenticated mode. The format of this file is described later in this document.

#### trustedkey  # [...]

Specifies the encryption key identifiers which are trusted for the purposes of authenticating peers suitable for synchronization. The
accesscontrolcommands

authentication procedures require that both the local and remote servers share the same key and key identifier, defined to be used for this purpose. However, different keys can be used with different servers. The arguments are 32 bit unsigned integers. Note, however, that key 0 is fixed and globally known. If meaningful authentication is to be performed, the 0 key should not be trusted.

controlkey #

Specifies the key identifier to use with the ntpq(1M) program, which is useful to diagnose and repair problems that affect xntpd operation. The operation of the ntpq program and xntpd conform to those specified in RFC 1305. Requests from a remote ntpq program which affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier. The argument to this command is a 32 bit unsigned integer. If no controlkey command is included in the configuration file, or if the keys don’t match. These requests are ignored.

restrict address [ mask numeric_mask ] [ flag ] [ ... ]

xntpd implements a general purpose address--and--mask based restriction list. The list is sorted by IP address and mask, and the list is searched in this order for matches, with the last match found defining the restriction flags associated with the incoming packets. The source address of incoming packets is used for the match, with the 32 bit address being logically and'ed with the mask associated with the restriction entry and then compared with the entry's address (which has also been and'ed with the mask) to look for a match. The "mask" argument defaults to 255.255.255.255, meaning that the "address" is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and, given the sort algorithm, is always the first entry in the list. Note that, while "address" is normally given in dotted--quad format, the text string "default", with no mask option, may be used to indicate the default entry. In the current implementation, flags always restrict access, i.e., an entry with no flags indicates that free access to the server is to be given. The flags are not orthogonal, in that more restrictive flags often make less restrictive ones redundant. The flags can generally be classed into two categories, those which restrict time service and those which restrict informational queries and attempts to do run time reconfiguration of the server. One or more of the following flags may be specified:

ignore  Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to.

noquery  Ignore all NTP mode 7 packets (i.e., information queries and configuration requests) from the source. Time service is not affected.
nomodify: Ignore all NTP mode 7 packets which attempt to modify the state of the server (i.e., run time reconfiguration). Queries which return information are permitted.

notrap: Decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the mode 6 control message protocol which is intended for use by remote event logging programs.

lowpriotraper: Declare traps set by matching hosts to be low priority. The number of traps a server can maintain is limited. The current limit is 3. Traps are usually assigned on a first come, first served basis, with later trap requestors being denied service. This flag modifies the assignment algorithm by allowing low priority traps to be overridden by later requests for normal priority traps.

noserve: Ignore NTP packets whose mode is other than 7. In effect, time service is denied, though queries may still be permitted.

nopeer: Provide stateless time service to polling hosts, but do not allocate peer memory resources to these hosts even if they otherwise might be considered useful as future synchronization partners.

notrust: Treat these hosts normally in other respects, but never use them as synchronization sources.

limited: These hosts are subject to a limitation on number of clients from the same net that will be accepted. Net in this context refers to the IP notion of net (class A, class B, class C, etc.). Only the first client_limit hosts that have shown up at the server and that have been active during the last client_limit_period seconds are accepted. Requests from other clients from the same net are rejected. Only time request packets are taken into account. "Private", "control", and "broadcast" packets are not subject to client limitation and therefore do not contribute to client count. A history of clients is kept using the monitoring capability of xntpd. Thus, monitoring is active as long as there is a restriction entry with the limited flag. The default value for client_limit is 3. The default value for client_limit_period is 3600 seconds. Currently both variables are not runtime configurable.

ntpport: This is actually a match algorithm modifier, rather than a restriction flag. Its presence causes the restriction entry to be matched only if the source port in the packet is the standard
NTP UDP port (123). Both ntpport and non-ntppport may be specified. The ntpport is considered more specific and is sorted later in the list.

Default restriction list entries, with the flags, ignore, ntpport, for each of the local host’s interface addresses are inserted into the table at startup to prevent the server from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured no flags are associated with the default entry (i.e., everything besides your own NTP server is unrestricted).

The restriction facility was added to allow the current access policies of the time servers running on the NSF net backbone to be implemented with xntpd as well. This facility may be useful for keeping unwanted or broken remote time servers from affecting your own. However, it should not be considered an alternative to the standard NTP authentication facility.

**clientlimit limit**
Sets `client_limit` to `limit`; allows configuration of client limitation policy. This variable defines the number of clients from the same network that are allowed to use the server.

**clientperiod period**
Sets `client_limit_period`; allows configuration of client limitation policy. This variable specifies the number of seconds after which a client is considered inactive and thus no longer is counted for client limit restriction.

**Monitoring Commands**

**statsdir /directory path/**
Indicates the full path of a directory where statistics files should be created (see below). This keyword allows the (otherwise constant) filegen filename prefix to be modified for file generation sets used for handling statistics logs (see filegen statement below).

**statistics name...**
Enables writing of statistics records. Currently, three kinds of statistics are supported. Each type is described below by giving its name, a sample line of data, and an explanation of each field:

**loopstats**
enables recording of loop filter statistics information. Each update of the local clock outputs a line of the following form to the file generation set named "loopstats":

<table>
<thead>
<tr>
<th>Field No.</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The date (Modified Julian day)</td>
</tr>
<tr>
<td>2</td>
<td>The time (seconds and fraction past UTC midnight)</td>
</tr>
</tbody>
</table>
### peerstats

enables recording of peer statistics information. This includes statistics records of all peers of a NTP server and of the 1-pps signal, where present and configured. Each valid update appends a line similar to the one below, to the current element of a file generation set named "peerstats":

```
48773 10847.650 127.127.4.1 9714 -0.001605 \
   0.00000 0.00142
```

<table>
<thead>
<tr>
<th>Field No.</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The date (Modified Julian Day)</td>
</tr>
<tr>
<td>1</td>
<td>The time (seconds and fraction past UTC midnight)</td>
</tr>
<tr>
<td>2</td>
<td>The peer address in dotted-quad notation</td>
</tr>
<tr>
<td>3</td>
<td>peer status. The status field is encoded in hex in the format described in Appendix B.2.2 of the NTP specification, RFC 1305.</td>
</tr>
<tr>
<td>4</td>
<td>Offset in seconds</td>
</tr>
<tr>
<td>5</td>
<td>Delay in seconds</td>
</tr>
<tr>
<td>6</td>
<td>Dispersion in seconds</td>
</tr>
</tbody>
</table>

### clockstats

enables recording of clock driver statistics information. Each update received from a clock driver outputs a line of the following form to the file generation set named "clockstats":

```
49213 525.624 127.127.4.1 93 226 \
   00:08:29.606 D
```

<table>
<thead>
<tr>
<th>Field No.</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The date (Modified Julian Day)</td>
</tr>
<tr>
<td>1</td>
<td>The time (seconds and fraction past UTC midnight)</td>
</tr>
<tr>
<td>2</td>
<td>The clock address in dotted-quad notation</td>
</tr>
<tr>
<td>3</td>
<td>The last timecode received from the clock in decoded ASCII format, where meaningful</td>
</tr>
<tr>
<td>4</td>
<td>In some clock drivers a good deal of additional information can be gathered and displayed as well.</td>
</tr>
<tr>
<td></td>
<td>Statistic files are managed using file generation sets (see <code>filegen</code> below).</td>
</tr>
<tr>
<td></td>
<td>The information obtained by enabling statistics recording allows analysis</td>
</tr>
</tbody>
</table>
of temporal properties of a xntpd server. It is usually only useful to primary servers or maybe main campus servers.

`filegen name [file filename] [type typename] [flag flagval] [link | nolink] [enable | disable]`

Configures setting of generation file set name. Generation file sets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation file sets provide access to a set of files used to store the actual data. At any time at most one element of the set is being written to. The type given specifies when and how data will be directed to a new element of the set. This way, information stored in elements of a file set that are currently unused are available for administrative operations without the risk of disturbing the operation of xntpd. (Most important: they can be removed to free space for new data produced.)

Filenames of set members are built from three elements:

- **prefix**: This is a constant filename path. It is not subject to modifications via the `filegen` statement. It is defined by the server, usually specified as a compile time constant. It may, however, be configurable for individual file generation sets via other commands. For example, the prefix used with “loopstats” and “peerstats” filegens can be configured using the `statdir` statement explained above.

- **filename**: This string is directly concatenated to the prefix mentioned above (no intervening '/' (slash)). This can be modified using the `file` argument to the `filegen` statement. No '.' elements are allowed in this component to prevent filenames referring to parts outside the filesystem hierarchy denoted by prefix.

- **suffix**: This part is reflects individual elements of a file set. It is generated according to the type of a file set as explained below.

A file generation set is characterized by its type. The following types are supported:

- **none**: The file set is actually a single plain file.

- **pid**: One element of file set is used per incarnation of a xntpd server. This type does not perform any changes to file set members during runtime. However it provides an easy way of separating files belonging to different xntpd server incarnations. The set member filename is built by appending a '.' (dot) to concatenated prefix and filename strings, and appending the decimal representation of the process id of the xntpd server process.

- **day**: One file generation set element is created per day. The term day is based on UTC. A day is defined as the period between 00:00 and 24:00 UTC. The file set member suffix consists of a '.' (dot) and a day specification in the form, YYYYMMDD. YYYY is a 4 digit year number (e.g., 1992). MM is a two digit month number. DD is a two digit day number. Thus, all information written at December 10th, 1992 would end up in a file named, PrefixFilename.19921210.
Any file set member contains data related to a certain week of a year. The term _week_ is defined by computing "day of year" modulo 7. Elements of such a file generation set are distinguished by appending the following suffix to the file set filename base: a dot, a four digit year number, the letter 'W', and a two digit week number. For example, information from January, 5th 1992 would end up in a file with suffix ".1992W1".

One generation file set element is generated per month. The file name suffix consists of a dot, a four digit year number, and a two digit month.

One generation file element is generated per year. The filename suffix consists of a dot and a 4 digit year number.

This type of file generation sets changes to a new element of the file set every 24 hours of server operation. The filename suffix consists of a dot, the letter ‘a’, and an eight digit number. This number is taken to be the number of seconds the server is running at the start of the corresponding 24 hour period.

Information is only written to a file generation set when this set is _enabled_. Output is prevented by specifying, _disabled_.

It is convenient to be able to access the current element of a file generation set by a fixed name. This feature is enabled by specifying _link_ and disabled using _nolink_. If _link_ is specified, a hard link from the current file set element to a file without suffix is created. When there is already a file with this name and the number of links of this file is one, it is renamed appending a dot, the letter ‘C’, and the pid of the _xntpd_ server process. When the number of links is greater than one, the file is unlinked. This allows the current file to be accessed by a constant name.

The broadcast and multicast modes require a special calibration to determine the network delay between the local and remote servers. Ordinarily, this is done automatically by the initial protocol exchanges between the local and remote servers. In some cases, the calibration procedure may fail due to, for example, network or server access controls. This command specifies the default delay to be used under these circumstances. Typically (for Ethernet), a number between 0.003 and 0.007 is appropriate for _seconds_. When this command is not used, the default is 0.004 seconds.

The _trap_ command configures a trap receiver at the given _host_address_ and _port_number_ for sending.
messages with the specified local
interface_address. If the port number is
unspecified, a value of 18447 is used. If the
interface address is not specified, the message is
sent with the source address of the local interface
the message is sent through. On a multi-homed
host, the interface used may change with routing
changes.

C information from the server in a log file. While
such monitor programs may also request their
own trap dynamically, configuring a trap receiver
ensures that no messages are lost when the server
is started.

setvar variable [ default ]

This command adds an additional system
variable. Variables like this can be used to
distribute additional information such as the
access policy. If the variable of the form,
variable_name=value is followed by the default
keyword, the variable will be listed as one of the
default system variables (see the ntpq(1M)
command). Additional variables serve
informational purposes only. They can be listed;
but they are not related to the protocol. The
known protocol variables always override any
variables defined via the setvar mechanism.

Three special variables contain the names of all
variable of the same group. sys_var_list holds the
names of all system variables. peer_var_list holds
the names of all peer variables. And clock_var_list
hold the names of the reference clock variables.

monitor [yes | no]
authenticate [yes | no]

These commands have been superseded by the
enable and disable commands. They are listed
here for historical purposes.

logconfig configkeyword

Controls the amount of output written to syslog
or the logfile. By default all output is turned on.
configkeyword is formed by concatenating the
message class with the event class. It is
permissible to use the prefix, all, instead of a
message class. A message class may also be
followed by the keyword, all, meaning to enable/disable all of the respective message class.
All config keywords can be prefixed with the symbols, ‘=’, ‘+’ and ‘−’. Here, ‘=’ sets the syslog mask, ‘+’ adds messages, and ‘−’ removes messages. Syslog messages can be controlled in four classes: sys, peer, clock, sync. Within these classes four types of messages can be controlled. Each is described below, along with its config keyword:

<table>
<thead>
<tr>
<th>Config keyword</th>
<th>Message type</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>Informational messages control configuration information.</td>
</tr>
<tr>
<td>events</td>
<td>Event messages control logging of events (reachability, synchronization, alarm conditions).</td>
</tr>
<tr>
<td>statistics</td>
<td>Statistical messages control statistical output.</td>
</tr>
<tr>
<td>status</td>
<td>Status messages describe mainly the synchronization status.</td>
</tr>
</tbody>
</table>

A minimal log configuration might look like this:

```
logconfig =syncstatus +sysevents
```

A configuration like this lists, just the synchronization state of xntpd and the major system events. For a simple reference server, the following minimum message configuration could be useful:

```
logconfig =syncall +clockall
```

This configuration lists all clock information and synchronization information. All other events and messages about peers, system events and so on, is suppressed.
The NTP standard specifies an extension to allow verification of the authenticity of received NTP packets, and to provide an indication of authenticity in outgoing packets. This is implemented in `xntpd` using the DES or MD5 algorithms to compute a digital signature, or message-digest. The specification allows any one of possibly 4 billion keys, numbered with 32 bit key identifiers, to be used to authenticate an association. The servers involved in an association must agree on the key and key identifier used to authenticate their data. However they must each learn the key and key identifier independently. In the case of DES, the keys are 56 bits long with, depending on type, a parity check on each byte. In the case of MD5, the keys are 64 bits (8 bytes). `xntpd` reads its keys from a file specified using the `-k` command line option or the `keys` statement in the configuration file. While key number 0 is fixed by the NTP standard (as 56 zero bits) and may not be changed, one or more of the keys numbered 1 through 15 may be arbitrarily set in the keys file.

The key file uses the same comment conventions as the configuration file. Key entries use a fixed format of the form, `keyno type key`. Here, `keyno` is a positive integer, `type` is a single character which defines the format the key is given in, and `key` is the key itself.

The `key` may be given in one of several different formats, controlled by the `type` character. The different key types, and corresponding formats, are described below:

**Key:** S

**Format:** A 64 bit hexadecimal number in DES format

In this format, the high order 7 bits of each octet are used to form the 56 bit key while the low order bit of each octet is given a value such that odd parity is maintained for the octet. Leading zeroes must be specified (i.e., the key must be exactly 16 hex digits long) and odd parity must be maintained. Hence a zero key in standard format would be given as: 0101010101010101.

**Key:** N

**Format:** A 64 bit hexadecimal number in NTP format

This format is the same as the DES format except the bits in each octet have been rotated one bit right so that the parity bit is now the high order bit of the octet. Leading zeroes must be specified and odd parity must be maintained. A zero key in NTP format would be specified as: 8080808080808080.

**Key:** A

**Format:** A 1–to–8 character ASCII string

A key is formed from this by using the lower order 7 bits of the ASCII representation of each character in the string. Zeroes are added on the right when necessary to form a full width 56 bit key.

**Key:** M
Format: A 1-to-8 character ASCII string, using the MD5 authentication scheme.

Note that both the keys and the authentication schemes (DES or MD5) must be identical between a set of peers sharing the same key number.

Primary Clock Support

xntpd has been built to be compatible with all supported types of reference clocks. A reference clock is generally (though not always) a radio timecode receiver which is synchronized to a source of standard time such as the services offered by the NRC in Canada and NIST in the U.S. The interface between the computer and the timecode receiver is device dependent and will vary, but it is often a serial port.

For the purposes of configuration, xntpd treats reference clocks in a manner analogous to normal NTP peers as much as possible. Reference clocks are referred to by address, much as a normal peer is. However, an invalid IP address is used to distinguish them from normal peers. Reference clock addresses are of the form 127.127.t.u where t is an integer denoting the clock type and u indicates the type-specific unit number. Reference clocks are configured using a server statement in the configuration file where the host_address is the clock address. The key, version and ttl options are not used for reference clock support. Some reference clocks require a mode option to further specify their operation. The prefer option can be useful to persuade the server to cherish a reference clock with somewhat more enthusiasm than other reference clocks or peers. Clock addresses may generally be used anywhere in the configuration file that a normal IP address can be used. For example, they can be used in restrict statements, although such use would normally be considered strange.

Reference clock support provides the fudge command, which can be used to configure reference clocks in special ways. The generic format that applies to this command is,

```
  fudge 127.127.t.u [ time1 secs ] [ time2 secs ]
    [ stratum int ] [ refid int ]
    [ flag1 0|1 ] [ flag2 0|1 ] [ flag3 0|1 ] [ flag4 0|1 ]
```

with options described as follows:

- **time1**
  - Are specified in fixed point seconds and used in some clock drivers as calibration constants. By convention, and unless indicated otherwise, time1 is used as a calibration constant to adjust the nominal time offset of a particular clock to agree with an external standard, such as a precision PPS signal. The specified offset is in addition to the propagation delay provided by other means, such as internal DIP switches.

- **time2**
  - Arespecifiedinfixedpointsecondsandusedinsomeclockdriverasanalgorithmconstant.

- **stratum**
  - Is a number in the range zero to 15 and is used to assign a nonstandard operating stratum to the clock.

- **refid**
  - Is an ASCII string in the range one to four characters and is used to assign a nonstandard reference identifier to the clock.
Are binary flags used for customizing the clock driver. The interpretation of these values, and whether they are used at all, is a function of the needs of the particular clock driver. However, by convention, and unless indicated otherwise, \texttt{flag3} invokes the TIOCSPPS ioctl, while \texttt{flag4} is used to enable recording verbose monitoring data to the clockstats file configured with the \texttt{filegen} command.

Ordinarily, the stratum of a reference clock is zero, by default. Since the \texttt{xntpd} daemon adds one to the stratum of each peer, a primary server ordinarily displays stratum one. In order to provide engineered backups, it is often useful to specify the reference clock stratum as greater than zero. The \texttt{stratum} option is used for this purpose. Also, in cases involving both a reference clock and a 1-pps discipline signal, it is useful to specify the reference clock identifier as other than the default, depending on the driver. The \texttt{refid} option is used for this purpose. Except where noted, these options apply to all clock drivers.

\texttt{xntpd} on Unix machines currently supports several different types of clock hardware. It also supports a special pseudo-clock used for backup or when no other clock source is available. In the case of most of the clock drivers, support for a 1-pps precision timing signal is available as described in the README file in the \texttt{./doc} directory of the xntp3 program distribution. The clock drivers, and the addresses used to configure them, are described in the file, README.refclocks, in the doc directory of the current program distribution.

Most variables used by the NTP protocol can be examined with \texttt{ntpq} (mode 6 messages). Currently very few variables can be modified via mode 6 messages. These variables are either created with the \texttt{setvar} directive or the leap warning variables. The leap warning bits that can be set in the \texttt{leapwarning} variable (up to one month ahead). Both, the \texttt{leapwarning} and in the \texttt{leapindication} variable, have a slightly different encoding than the usual leap bits interpretation:

- 00: The daemon passes the leap bits of its synchronization source (usual mode of operation).
- 01/10: A leap second is added/deleted (operator forced leap second).
- 11: Leap information from the synchronization source is ignored (thus LEAP_NOWARNING is passed on).

Files

- \texttt{/etc/inet/ntp.conf} Default name of the configuration file
- \texttt{/etc/ntp/ntp.drift} Conventional name of the drift file
- \texttt{/etc/inet/ntp.keys} Conventional name of the key file
- \texttt{/etc/inet/ntp.server} Sample server configuration file

Notes  The xntpd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/ntp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
**Name**

xntpd – special NTP query program

**Synopsis**

xntpd [-ilnps] [ -c *command* ] [ *host* ] [...]

**Description**

xntpd queries the xntpd daemon about its current state and requests changes in that state. You can run xntpd in interactive mode or in controlled using command line arguments.

Extensive state and statistics information is available through the xntpd interface. In addition, nearly all the configuration options which can be specified at start up using xntpd's configuration file may also be specified at run time using xntpd.

If one or more request options is included on the command line when xntpd is executed, each of the requests is sent to the NTP servers running on each of the hosts given as command line arguments, or on the local host by default. If no request options are given, xntpd attempts to read commands from the standard input and execute these on the NTP server running on the first host specified on the command line, again defaulting to the local host when no other host is specified. xntpd prompts for commands if the standard input is a terminal device.

xntpd uses NTP mode 7 packets to communicate with the NTP server, and can be used to query any compatible server on the network which permits it. As NTP is a UDP protocol, this communication is somewhat unreliable, especially over large distances. xntpd does not attempt to re-transmit requests, and times requests out if the remote host is not heard from within a suitable timeout time.

The operation of xntpd is specific to the particular implementation of the xntpd daemon. You can expect xntpd to work only with this and maybe some previous versions of the daemon. Requests from a remote xntpd program that affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier.

**Options**

xntpd reads interactive format commands from the standard input. If you specify the `-c`, `-l`, `-p` or `-s` option, the specified queries are sent to the hosts immediately.

The following command line options are supported:

- `-c *command*`...  
  Add *command* to the list of commands to execute on the specified hosts. *command* is interpreted as an interactive format command.

  Multiple `-c` options may be specified.

- `-i`  
  Force xntpd to operate in interactive mode.

  Prompts are written to the standard output. Commands are read from the standard input.

- `-l`  
  Obtain a list of peers which are known to the servers.

  This option is equivalent to `-c listpeers`. See listpeers in Control Message Commands.
-n  Output all host addresses in dotted-quad numeric format rather than converting to the canonical host names.

-p  Print a list of the peers known to the server as well as a summary of their state.

   This option is equivalent to -c peers. See peers in Control Message Commands.

-s  Print a list of the peers known to the server as well as a summary of their state, but in a slightly different format than the -p option. This option is equivalent to -c dmpeers. See dmpeers in Control Message Commands.

Operands The following operands are supported:

Usage Interactive Commands The interactive commands consist of a keyword (command_keyword) followed by zero to four arguments. You need to entry only enough characters of the command_keyword to uniquely identify it. The output of an interactive command is sent to the standard output by default. You can send the output of an interactive command to a file by appending a <, followed by a file name, to the command line.

A number of interactive format commands are executed entirely within the xntpd program itself and do not result in NTP mode.

The following interactive commands are supported:

?  [command_keyword] Without an argument, print a list of ntpq command keywords. If command_keyword is specified, print function and usage information about the command_keyword.

delay milliseconds Specify a time interval to add to timestamps included in requests which require authentication.

   This enables (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Because the server no longer requires timestamps in authenticated requests, this command may be obsolete.

help [command_keyword] Without an argument, print a list of ntpq command keywords. If command_keyword is specified, print function and usage information about the command_keyword.

host hostname Set the host (hostname) to which future queries are sent. Specify hostname as a host name or a numeric address.
hostnames [ yes | no ]

Print hostnames or numeric addresses in information displays.

Specify yes to print host names. Specify no to print numeric addresses.

The default is yes, unless the -n command line option is specified.

keyid keyid

Enable specification of a key number (keyid) to authenticate configuration requests. keyid must correspond to a key number the server has been configured to use for this purpose.

passwd

Allow the user to specify a password at the command line to authenticate configuration requests.

The password is not displayed, and must correspond to the key configured for use by the NTP server for this purpose. If the password does not correspond to the key configured for use by the NTP server, requests are not successful.

quit

Exit xntpd.

timeout milliseconds

Specify a timeout period for responses to server queries.

The default is approximately 8000 milliseconds. As xntpd retries each query once after a timeout, the total waiting time for a timeout is twice the timeout value set.

Control Message Commands

Query commands result in NTP mode 7 packets containing requests for information being sent to the server. These control message commands are read-only commands in that they make no modification of the server configuration state.

The following control message commands are supported:

clkbug

Obtain debugging information for a reference clock driver. This information is provided only by some clock drivers.

clockinfo clock_peer_address [...]

Obtain and print information concerning a peer clock.

The values obtained provide information on the setting of fudge factors and other clock performance information.

dmpeers

Obtain a list of peers for which the server is maintaining state, along with a summary of that state.
The peer summary list is identical to the output of the peers command, except for the character in the leftmost column. Characters only appear beside peers which were included in the final stage of the clock selection algorithm. A . indicates that this peer was cast off in the falseticker detection, while a + indicates that the peer made it through. A * denotes the peer with which the server is currently synchronizing.

iostats
Print statistics counters maintained in the input-output module.

kerninfo
Obtain and print kernel phase-lock loop operating parameters.
This information is available only if the kernel has been specially modified for a precision timekeeping function.

listpeers
Obtain and print a brief list of the peers for which the server is maintaining state.
These should include all configured peer associations as well as those peers whose stratum is such that they are considered by the server to be possible future synchronization candidates.

loopinfo [oneline | multiline]
Print the values of selected loop filter variables.
The loop filter is the part of NTP which deals with adjusting the local system clock.
The oneline and multiline options specify the format in which this information is printed. multiline is the default.
The offset is the last offset given to the loop filter by the packet processing code. The frequency is the frequency error of the local clock in parts-per-million (ppm). The time const controls the stiffness of the phase-lock loop and thus the speed at which it can adapt to oscillator drift. The watchdog timer value is the number of seconds which have elapsed since the last sample offset was given to the loop filter.

memstats
Print statistics counters related to memory allocation code.
monlist [version] Obtain and print traffic counts collected and maintained by the monitor facility. The version number should not normally need to be specified.

peers Obtain a list of peers for which the server is maintaining state, along with a summary of that state.

The following summary information is included:
■ Address of the remote peer.
■ Local interface address. If a local address has yet to be determined it is 0.0.0.0.
■ Stratum of the remote peer. A stratum of 16 indicates the remote peer is unsynchronized.
■ Polling interval, in seconds.
■ Reachability register, in octal.
■ Current estimated delay, offset and dispersion of the peer, in seconds.
■ Mode in which the peer entry is operating.

This is represented by the character in the left margin. A + denotes symmetric active, a - indicates symmetric passive, a = means the remote server is being polled in client mode, a ^ indicates that the server is broadcasting to this address, a ~ denotes that the remote peer is sending broadcasts and a * marks the peer the server is currently synchronizing to.

■ Host.

This field may contain a host name, an IP address, a reference clock implementation name with its parameter or REFCLK (implementation number, parameter). On hostnames no only IP-addresses is displayed.

pstats peer_address [...] Show the per-peer statistic counters associated with the specified peers.

reslist Obtain and print the server’s restriction list.

Generally, this list is printed in sorted order.
**showpeer peer_address […]**

Show a detailed display of the current peer variables for one or more peers. Most of these values are described in the NTP Version 2 specification.

**sysinfo**

Print a variety of system state variables that are related to the local server.

The output from `sysinfo` is described in NTP Version 3 specification, RFC-1305. All except the last four lines are described in the NTP Version 3 specification, RFC-1305.

The `system flags` show various system flags, some of which can be set and cleared by the `enable` and `disable` configuration commands, respectively. These are the `auth`, `bclient`, `monitor`, `pll`, `pps` and `stats` flags. See the `xntpd` documentation for the meaning of these flags. There are two additional flags which are read only, the `kernel_pll` and `kernel_pps`. These flags indicate the synchronization status when the precision time kernel modifications are in use. The `kernel_pll` indicates that the local clock is being disciplined by the kernel, while the `kernel_pps` indicates the kernel discipline is provided by the PPS signal. The stability is the residual frequency error remaining after the system frequency correction is applied and is intended for maintenance and debugging. In most architectures, this value initially decreases from as high as 500 ppm to a nominal value in the range .01 to .1 ppm. If it remains high for some time after starting the daemon, something may be wrong with the local clock, or the value of the kernel variable tick may be incorrect. The `broadcastdelay` shows the default broadcast delay, as set by the `broadcastdelay` configuration command. The `authdelay` shows the default authentication delay, as set by the `authdelay` configuration command.

**sysstats**

Print statistics counters maintained in the protocol module.

**timerstats**

Print statistics counters maintained in the timer/event queue support code.

The server authenticates all requests that cause state changes in the server. The server uses a configured NTP key to accomplish this. This facility can also be disabled by the server by not configuring a key).
You must make the key number and the corresponding key known to xntpd. Use the keyid or passwd commands to do so.

The passwd command prompts users for a password to use as the encryption key. It also prompts automatically for both the key number and password the first time a command which would result in an authenticated request to the server is given. Authentication provides verification that the requester has permission to make such changes. It also gives an extra degree of protection against transmission errors.

Authenticated requests always include a time stamp in the packet data. The time stamp is included in the computation of the authentication code. This timestamp is compared by the server to its receive time stamp. If the time stamps differ by more than a small amount the request is rejected.

Time stamps are rejected for two reasons. First, it makes simple replay attacks on the server, by someone who might be able to overhear traffic on your LAN, much more difficult. Second, it makes it more difficult to request configuration changes to your server from topologically remote hosts.

While the reconfiguration facility works well with a server on the local host, and may work adequately between time-synchronized hosts on the same LAN, it works very poorly for more distant hosts. If reasonable passwords are chosen, care is taken in the distribution and protection of keys and appropriate source address restrictions are applied, the runtime reconfiguration facility should provide an adequate level of security.

The following commands make authenticated requests.

`addpeer peer_address [ keyid ] [ version ] [ prefer ]`

Add a configured peer association at the given address and operating in symmetric active mode. An existing association with the same peer may be deleted when this command is executed, or may simply be converted to conform to the new configuration, as appropriate.

If the optional keyid is a non-zero integer, all outgoing packets to the remote server will have an authentication field attached encrypted with this key. If the keyid is 0 or omitted, no authentication is done.

Specify version as 1, 2 or 3. The default is 3.

The prefer keyword indicates a preferred peer. This keyword is used primarily for clock synchronisation if possible. The preferred peer also determines the validity of the PPS signal - if the preferred peer is suitable for synchronisation so is the PPS signal.

`addserver peer_address [ keyid ] [ version ] [ prefer ]`

Identical to the addpeer command, except that the operating mode is client.

`addtrap [ address [ port ] [ interface ]`

Set a trap for asynchronous messages.
authinfo
Return information concerning the authentication module, including known keys and
counts of encryptions and decryptions which have been done.

broadcast peer_address [ keyid ] [ version ] [ prefer ]
Identical to the addpeer command, except that the operating mode is broadcast. In this
case a valid key identifier and key are required. The peer_address parameter can be the
broadcast address of the local network or a multicast group address assigned to NTP. If a
multicast address, a multicast-capable kernel is required.

clrtrap [ address [ port ] [ interface]
Clear a trap for asynchronous messages.

delrestrict address mask [ ntpport ]
Delete the matching entry from the restrict list.

fudge peer_address [ time1 ] [ time2 ] [ stratum ] [ refid ]
Provide a way to set certain data for a reference clock.

readkeys
Cause the current set of authentication keys to be purged and a new set to be obtained by
re-reading the keys file. The keys file must have been specified in the xntpd configuration
file. This enables encryption keys to be changed without restarting the server.

restrict address mask flag [ flag ]
This command operates in the same way as the restrict configuration file commands of
xntpd.

reset
Clear the statistics counters in various modules of the server.

traps
Display the traps set in the server.

trustkey keyid [...] 
untrustkey keyid [...]
These commands operate in the same way as the trustedkey and untrustkey
configuration file commands of xntpd.

unconfig peer_address [...]
Cause the configured bit to be removed from the specified peers. In many cases this causes
the peer association to be deleted. When appropriate, however, the association may persist
in an unconfigured mode if the remote peer is willing to continue on in this fashion.

unrestrict address mask flag [ flag ]
Unrestrict the matching entry from the restrict list.

ypbind – NIS binder process

/ usr/ lib/ netsvc/ yp/ ypbind [-broadcast | -ypset | -ypsetme]

NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in ypclnt(3NSL). Administrative tools are described in ypinit(1M), ypwhich(1), and ypset(1M). Tools to see the contents of NIS maps are described in ypcat(1), and ypmatch(1).

ypbind is a daemon process that is activated at system startup time from the svc:/network/nis/client:default service. By default, it is invoked as ypbind - broadcast. ypbind runs on all client machines that are set up to use NIS. See sysidtool(1M). The function of ypbind is to remember information that lets all NIS client processes on a node communicate with some NIS server process. ypbind must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network. If the NIS server is a NIS+ server in NIS (YP) compatibility mode, see the NOTES section of the ypfiles(4) manpage for more information.

The information ypbind remembers is called a binding — the association of a domain name with a NIS server. The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the - broadcast option, the ypbind process broadcasts on the net trying to find an NIS server, either a ypserv process serving the domain or an rpc.nisd process in “YP-compatibility mode” serving NIS+ directory with name the same as (case sensitive) the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net. If started without the -broadcast option, ypbind process steps through the list of NIS servers that was created by ypinit -c for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. All the hosts in the NIS servers file must be listed in the /etc/hosts file along with their IP addresses. Once a domain is bound by ypbind, that same binding is given to every client process on the node. The ypbind process on the local node or a remote node may be queried for the binding of a particular domain by using the ypwhich(1) command.

If ypbind is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound, and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, ypbind will try to bind to another NIS server using the process described above. ypbind also accepts requests to set its binding for a particular domain. The request is usually generated by the ypset(1M) command. In order for ypset to work, ypbind must have been invoked with flags -ypset or -ypsetme.

Options

- broadcast Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server. This option is analogous to ypbind with no options in earlier Sun releases and is recommended for ease of use.
Allow users from any remote machine to change the binding by means of the ypset command. By default, no one can change the binding. This option is insecure.

-onlyrootme Only allow root on the local machine to change the binding to a desired server by means of the ypset command. ypbind can verify the caller is indeed a root user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

Files /var/yp/binding/ypdomain/ypservers
/etc/inet/hosts

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

See Also svcs(1), ypcat(1), ypmatch(1), ypwhich(1), ifconfig(1M), rpc.nisd(1M), svcadm(1M), ypinr(1M), ypset(1M), ypclnt(3NSL), hosts(4), ypfiles(4), attributes(5), smf(5)

Notes ypbind supports multiple domains. The ypbind process can maintain bindings to several domains and their servers, the default domain is the one specified by the domainname(1M) command at startup time.

The -broadcast option works only on the UDP transport. It is insecure since it trusts “any” machine on the net that responds to the broadcast request and poses itself as an NIS server.

The ypbind service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nis/client:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svc(1) command.
ypinit – setup NIS client

/usr/sbin/ypinit [-c] [-m] [-s master_server]

ypinit can be used to set up an NIS client system. You must be the superuser to run this command. This script need not be used at all if ypbind(1M) is started with the -broadcast option (it is invoked with this option from the svc:/network/nis/client:default service).

Normally, ypinit is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned.

ypinit prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. Each of these NIS servers must be listed in the /etc/hosts file along with its IP address. ypinit stores the list in file /var/yp/binding/domain/ypservers. This file is used by ypbind when run without the -broadcast option.

Options
- c Set up a ypclient system.
- m Build a master ypserver data base.
- s master_server Slave data base. master_server must be the same master configured in the YP maps and returned by the ypwhich -m command.

Files
/etc/hosts
/var/yp/binding/domain/ypservers

Attributes See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWnisu</td>
</tr>
</tbody>
</table>

See Also svcs(1), svcadm(1M), ypbind(1M), sysinfo(2), hosts(4), attributes(5), smf(5)

Notes The NIS client service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nis/client:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Bugs ypinit sets up the list of NIS servers only for the current domain on the system when it is run, that is, the domain returned by the SL_SRPC_DOMAIN command to sysinfo(2). Care should be taken to ensure that this is the same as the desired domain for NIS client processes.
ypmake(1M)

Name

ypmake – rebuild NIS database

Synopsis
cd /var/yp ; make [map]

Description

The file called Makefile in /var/yp is used by make(1S) to build the Network Information Service (NIS) database. With no arguments, make creates dbm databases for any NIS maps that are out-of-date, and then executes yppush(1M) to notify slave databases that there has been a change.

If you supply a map on the command line, make will update that map only. Typing make passwd will create and yppush the password database (assuming it is out of date). Likewise, make ipnodes and make networks will create and yppush the ipnodes and network files, $(INETDIR)/ipnodes and $(DIR)/networks.

There are four special variables used by make: DIR, which gives the directory of the source files; NOPUSH, which when non-null inhibits doing a yppush of the new database files; INETDIR, which gives the directory of the ipnodes source file; and DOM, which is used to construct a domain other than the master's default domain. The default for DIR is /etc, and the default for INETDIR is /etc/inet. The default for NOPUSH is the null string.

Refer to ypfiles(4) and ypserv(1M) for an overview of the NIS service.

If a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping, is present, the NIS server components run in N2L mode. In N2L mode, the server components use a new set of map files with an LDAP:prefix, based on the LDAP DIT. In N2L mode, authoritative NIS information is obtained from the DIT. The NIS source files and ypmake have no role, and they should not be used. If ypmake is accidentally run, then the server components will detect this, and will log a warning message. For additional information, see ypfiles(4).

Files

/var/yp Directory containing NIS configuration files.
/etc/inet/hosts System hosts file.
/etc Default directory for source files.

The NIS makefile is only used when running the `ypserv(1M)` server to provide NIS services. If these are being provided by the NIS+ server running in NIS compatibility mode, see `rpc.nisd(1M)`; this makefile is not relevant. See `ypfiles(4)` for more details.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.
ypmap2src(1M)

<table>
<thead>
<tr>
<th>Name</th>
<th>yppmap2src – convert NIS maps to NIS source files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synopsis</td>
<td>/usr/lib/netsvc/yp/ypmap2src [-t]</td>
</tr>
<tr>
<td></td>
<td>[-c custom-map-name] ... [-d domain] -o output-directory</td>
</tr>
</tbody>
</table>

| Description | Use the yppmap2src utility to convert standard NIS maps to approximations of the equivalent NIS source files. This utility functions like the reverse of ypmake(1M). |

The primary use for yppmap2src is to convert from a NIS server that uses the NIS to LDAP(N2L) transition mechanism, which does not use NIS source files, to traditional NIS, where source files are required. The yppmap2src utility is also used by NIS administrators who wish to discover the contents of NIS maps for which the sources are not available.

Generally, this operation is not necessary. More often, administrators will switch from traditional NIS to N2L in anticipation of the eventual transition to LDAP naming. When this switch is made, authoritative information is moved into the LDAP DIT, and the NIS sources have no further role. N2L supports NIS clients until such time as they can be converted to LDAP, and the NIS service suspended.

The yppmap2src utility does not guarantee that the files that are generated are identical to the original NIS source files. Some information might have been thrown away by ypmake and cannot be recovered. N2L also might have updated the maps to reflect changes made by LDAP clients. It is essential that the sources generated are checked to confirm no problems have occurred.

Per entry comment fields, from existing source files, are not merged into source files generated by yppmap2src. If a user wishes N2L to maintain comment information, then the NIS2LDAP mapping configuration file should be modified so that the comment fields are mapped into LDAP. This will ensure that the comments are visible to native LDAP clients and present in the N2L map files.

When yppmap2src is run, it will take up-to-date comments from the map file and insert them into the NIS source file generated.

Handling Custom Maps | yppmap2src only knows about the standard NIS maps and standard source to map conversion. If an advanced user has changed these, that is, the user has modified the NIS makefile, the equivalent changes must also be made to the yppmap2src script.

Options | yppmap2src supports the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>Specifies that custom-map-name should be converted to a source file by running makedbm -u on it. This is a shortcut so that simple custom maps can be handled without editing yppmap2src.</td>
</tr>
<tr>
<td>-d domain-name</td>
<td>Specifies the domain to convert. The domain-name can be a fully qualified file path, such as /var/yp/a.b.c, or just a domain name, a.b.c. In the latter case, yppmap2osrc looks in /var/yp for the domain directory.</td>
</tr>
</tbody>
</table>
-o dest  Specifies the destination directory for the converted files. A directory other than /etc should be specified. The maps generated are copied to the correct location, /etc, /etc/security or other source directory, as appropriate.

-t  Specifies that traditional NIS maps, without N2L's LDAP_ prefix, should be converted. By default, maps with the LDAP_prefix are converted.

Operands  ypmap2src supports the following operands:

source-file  Lists the standard source files to convert. If this option is not given, then all the standard source files, plus any custom files specified by the -c option, are converted.

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)
Name  yppoll – return current version of a NIS map at a NIS server host

Synopsis  /usr/sbin/yppoll [-d ypdomain] [-h host] mapname

Description  The yppoll command asks a ypserv() process what the order number is, and which host is the master NIS server for the named map.

Options  
- d ypdomain  Use ypdomain instead of the default domain.
- h host  Ask the ypserv process at host about the map parameters. If host is not specified, the NIS server for the local host is used. That is, the default host is the one returned by ypwhich(1).

yppush – force propagation of changed NIS map

**Synopsis**

```
```

**Description**

`yppush` copies a new version of a Network Information Service (NIS) map from the master NIS server to the slave NIS servers. It is normally run only on the master NIS server by the `Makefile` in `/var/yp` after the master databases are changed. It first constructs a list of NIS server hosts by reading the NIS `ypservers` map within the `domain`. Keys within the `ypservers` map are the ASCII names of the machines on which the NIS servers run.

A “transfer map” request is sent to the NIS server at each host, along with the information needed by the transfer agent (the program that actually moves the map) to call back the `yppush`. When the attempt has completed (successfully or not), and the transfer agent has sent `yppush` a status message, the results can be printed to `stdout`. Messages are also printed when a transfer is not possible, for instance, when the request message is undeliverable, or when the timeout period on responses has expired.

Refer to `ypfiles(4)` and `ypserv(1M)` for an overview of the NIS service.

**Options**

The following options are supported:

- `-d domain` Specifies a `domain`.
- `-h host` Propagates only to the named `host`.
- `-p #parallel-xfrs` Allows the specified number of map transfers to occur in parallel.
- `-v` Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.

**Files**

- `/var/yp` Directory where NIS configuration files reside.
- `/var/yp/domain/ypservers. (dir, pag)` Map containing list of NIS servers to bind to when running in server mode.

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

`ypserv(1M), ypxfr(1M), ypfiles(4), attributes(5)`

**Notes**

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.
Bugs  In the current implementation (version 2 NIS protocol), the transfer agent is `ypxfr(1M)`, which is started by the `ypserv` program. If `yppush` detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 YPPROC_GET request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. `yppush` prints a message saying that an “old-style” message has been sent. The system administrator should later check to see that the transfer has actually taken place.
ypserv, ypxfrd – NIS server and binder processes

**Synopsis**
/usr/lib/netsvc/yp/ypserv [-dv] [-i | -I] [-r | -R]
/usr/lib/netsvc/yp/ypxfrd

**Description**
The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are ndbm files in a directory tree rooted at /var/yp. See ndbm(3C). These files are described in ypfiles(4). The processes are /usr/lib/netsvc/yp/ypserv, the NIS database lookup server, and /usr/lib/netsvc/yp/ypbind, the NIS binder. The programmatic interface to the NIS service is described in ypclnt(3NSL). Administrative tools are described in yppoll(1M), yppush(1M), ypset(1M), ypxfr(1M), and ypwhich(1). Tools to see the contents of NIS maps are described in ypcat(1), and ypmatch(1). Database generation and maintenance tools are described in ypinit(1M), yppmake(1M), and makedbm(1M).

The ypserv utility is a daemon process typically activated at system startup from svc:/network/nis/server:default. Alternatively, you can, as the root user, start NIS services using ypstart(1M) from the command-line. ypserv runs only on NIS server machines with a complete NIS database. You can halt all NIS services using the ypstop(1M) command.

The ypxfrd utility transfers entire NIS maps in an efficient manner. For systems that use this daemon, map transfers are 10 to 100 times faster, depending on the map. To use this daemon, be sure ypxfrd is running on the master server. See /usr/lib/netsvc/yp/ypstart. ypxfr attempts to use ypxfrd first. If that fails, it prints a warning, then uses the older transfer method.

The ypserv daemon’s primary function is to look up information in its local database of NIS maps.

The operations performed by ypserv are defined for the implementor by the YP Protocol Specification, and for the programmer by the header file <rpcsvc/yp_prot.h>.

Communication to and from ypserv is by means of RPC calls. Lookup functions are described in ypclnt(3NSL), and are supplied as C-callable functions in the libnsl(3LIB) library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: yp_match(3NSL), yp_first(3NSL), yp_next(3NSL), and yp_all(3NSL). The yp_match operation takes a key, and returns the associated value. The yp_first operation returns the first key-value pair from the map, and yp_next can be used to enumerate the remainder. yp_all ships the entire map to the requester as the response to a single RPC request.

A number of special keys in the DBM files can alter the way in which ypserv operates. The keys of interest are:

**YP_INTERDOMAIN**
The presence of this key causes ypserv to forward to a DNS server host lookups that cannot be satisfied by the DBM files.
YP_SECURE

This key causes ypserve to answer only questions coming from clients on reserved ports.

YP_MULTI_hostname

This is a special key in the form, YP_MULTI_hostname addr1,...,addrN. A client looking for hostname receives the closest address.

Two other functions supply information about the map, rather than map entries: yp_order(3NSL), and yp_master(3NSL). In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with makedbm(1M), however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. These functions include do_you_serve_this_domain?, transfer_map, and reinitialize_internal_state.

On start up, ypserve checks for the existence of the NIS to LDAP (N2L) configuration file /var/yp/NISLDAPmapping. If it is present then a master server starts in N2L mode. If the file is not present it starts in “traditional” (non N2L) mode. Slave servers always start in traditional mode.

In N2L mode, a new set of map files, with an LDAP_prefix, are generated, based on the contents of the LDAP DIT. The old map files, NIS source files and ypmake(1M) are not used.

It is possible that ypmake(1M) can be accidentally run in N2L mode. If the occurs, the old style map files are overwritten. That the map files are overwritten is harmless. However, any resulting yppush(1M) operation will push information based on the DIT rather than the source files. The user may not expect information based on the DIT. ypserve keeps track of the last modification date of the old style map files. If the map files have been updated, a warning is logged that suggests that the user call yppush directly instead of ypmake.

If a server attempts to run in N2L mode and a LDAP server cannot be contacted, it behaves as follows:

1. When ypserve is started, a warning will be logged.
2. When a NIS read access is made and the TTL entry has expired, a warning is logged. Information that is returned from the cache has not been updated.
3. When a NIS write access is made, a warning is logged. The cache will not be updated, and a NIS failure will be returned.

If ypxfrd is running in N2L mode and is asked to transfer a map, ypxfrd first checks whether the map is out of date. If the map is out of date, ypxfrd initiates an update from the DIT. ypxfrd cannot wait for the update to complete. If ypxfrd waited, the client end ypxf operation could time out. To prevent ypxfrd from timing out, the existing map is transferred from the cache. The most up to date map will be transferred on subsequent ypxfrd operations.
The NIS service should go to the DNS for more host information. This requires the existence of a correct /etc/resolv.conf file pointing to a DNS server. This option turns on DNS forwarding regardless of whether or not the YP_INTERDOMAIN flag is set in the hosts maps. See makedbm(1M). In the absence of an /etc/resolv.conf file, ypserv complains, but ignores the -d option.

- i
If in N2L mode, initialize the NIS related parts of the DIT based on the current, non LDAP_prefixed, map files. The LDAP_prefixed maps are not created or updated. If you require that LDAP_prefixed maps be updated or created, then use the -ir option.

The -i option does not attempt to create any NIS domain or container objects. If any NIS domain or container objects have not already been created, then errors will occur, as entries are written to nonexistent containers.

- I
Identical to -i, except that any missing domain and container objects are created.

- r
If in N2L mode, then refresh the LDAP_prefixed map files based on the contents of the DIT.

- ir
If both -i and -r are specified in N2L mode, then the DIT will first be initialized from the current non LDAP_prefixed map files. A new set of LDAP_prefixed maps will then be generated from the contents of the DIT. A new set of LDAP_prefixed maps is required when moving from traditional NIS to N2L mode NIS.

- Ir
Identical to -ir, except that any missing domain and container objects are created.

-v
Operate in the verbose mode, printing diagnostic messages to stderr.

When run with the -i, -r, -I, -ir or -Ir options, the ypserv command runs in the foreground and exits once map initialization has been completed. Once the ypserv command exits, the user knows the maps are ready and can restart ypserv and the other yp daemons by running ypstart(1M).

If there is a requirement to initialize the DIT from the NIS source files, which may have been modified since the maps were last remade, run ypmake before running ypserv -i or ypserv -ir. ypmake regenerated old style NIS maps. Then ypserv -ir dumps them into the DIT. When the -ir option is used, the LDAP_prefixe maps are also generated or updated. Since these maps will be more recent than the old style maps, ypmake will not be reported as erroneous when it is run.

/var/yp/securenets
Defines the hosts and networks that are granted access to information in the served domain. It is read at startup time by both ypserv and yp xfrd.
If the /var/yp/ypserv.log file exists when ypServ starts up, log information is written to it when error conditions arise.

/var/yp/binding/domainname/ypservers

Lists the NIS server hosts that ypbind can bind to.

Network Interface Guide

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes

ypserv supports multiple domains. The ypServ process determines the domains it serves by looking for directories of the same name in the directory /var/yp. It replies to all broadcasts requesting yp service for that domain.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

NIS uses ndbm() files to store maps. Therefore, it is subject to the 1024 byte limitations described in the USAGE and NOTES sections of the ndbm(3C) man page.

The NIS server service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nis/server:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svc(1) command.
Name   ypset – point ypbind at a particular server

Synopsis  
/usr/sbin/ypset [-d ypdomain] [-h host] server

Description  In order to run ypset, ypbind must be initiated with the –ypset or –ypsetme options. See ypbind(1M). ypset tells ypbind to get NIS services for the specified ypdomain from the ypser process running on server. If server is down, or is not running ypser, this might not be discovered until an NIS client process tries to obtain a binding for the domain. At this point, the binding set by ypset is tested by ypbind. If the binding is invalid, ypbind attempts to rebind for the same domain.

ypset is useful for binding a client node that is not on a broadcast net, or is on a broadcast net that is not running an NIS server host. It is also useful for debugging NIS client applications, for instance, where an NIS map exists only at a single NIS server host.

Where several hosts on the local net are supplying NIS services, ypbind can rebind to another host, even while you attempt to find out if the ypset operation succeeded. For example, if you enter the ypset command below, you might get the subsequent response from ypwhich:

```
example% ypset host1
example% ypwhich
host2
```

The sequence shown above is a function of the NIS subsystem’s attempt to load-balance among the available NIS servers, and occurs when host1 does not respond to ypbind because it is not running ypser (or is overloaded), and host2, running ypser, obtains the binding.

server indicates which NIS server to bind to, and must be specified as a name or an IP address. This works only if the node has a current valid binding for the domain in question and ypbind has been set to allow use of ypset. In most cases, server should be specified as an IP address.

ypset tries to bind over a connectionless transport. The NIS library call, yp_all(), uses connection-oriented transport and derives the NIS server’s address based on the connectionless address supplied by ypset.

Refer to ypfiles(4) for an overview of the NIS name service.

Options
- -d ypdomain  Use ypdomain, instead of the default domain.
- -h host  Set ypbind’s binding on host, instead of locally. Specify host as a name.

System Administration Guide: Basic Administration

Notes

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.
The `ypxfr` command moves an NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory `/var/yp/ypdomain` (this directory must already exist; `ypdomain` is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real `name`.

If run interactively, `ypxfr` writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file `/var/yp/ypxfr.log` exists, it appends all its output to that file. Since `ypxfr` is most often run from the privileged user's `crontab` file, or by `ypserv`, the log file can retain a record of what was attempted, and what the results were.

For consistency between servers, `ypxfr` should be run periodically for every map in the NIS database. Different maps change at different rates: a map might not change for months at a time, for instance, and can therefore be checked only once a day. Some maps might change several times per day. In such a case, you might want to check hourly for updates. A `crontab` entry can be used to automatically perform periodic updates. Rather than having a separate `crontab` entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in `/usr/sbin/yp`: `ypxfr_1perday`, `ypxfr_2perday`, and `ypxfr_1perhour`.

Refer to `ypfiles(4)` for an overview of the NIS name service.

### Options

- `-c`
  Do not send a “Clear current map” request to the local `ypserv` process. Use this flag if `ypserv` is not running locally at the time you are running `ypxfr`. Otherwise, `ypxfr` complains that it cannot communicate with the local `ypserv`, and the transfer fails.

- `-f`
  Force the transfer to occur even if the version at the master is not more recent than the local version.

- `-C tid prog server`
  This option is for use only by `ypserv`. When `ypserv` starts `ypxfr`, it specifies that `ypxfr` should call back a `yppush` process at the host `server`, registered as program number `prog`, and waiting for a response to transaction `tid`.

- `-d ypdomain`
  Specify a domain other than the default domain.

- `-h host`
  Get the map from `host`, regardless of the master. If `host` is not specified, `ypxfr` asks the NIS service for the name of the master, and tries to get the map from there. `host` must be a valid host name.
- `s ypdomain`: Specify a source domain from which to transfer a map that should be the same across domains.

### Files

- `/var/yp/ypxfr.log`: Log file
- `/usr/lib/netsvc/yp/ypxfr_1perday`: Script to run one transfer per day, for use with `cron(1M)`
- `/usr/lib/netsvc/yp/ypxfr_2perday`: Script to run two transfer per day, for use with `cron(1M)`
- `/usr/lib/netsvc/yp/ypxfr_1perhour`: Script for hourly transfers of volatile maps
- `/var/yp/ypdomain`: NIS domain
- `/usr/spool/cron/crontabs/root`: Privileged user's crontab file

**Name**  zdb – ZFS debugger

**Synopsis**  

zdb pool

**Description**  The `zdb` command is used by support engineers to diagnose failures and gather statistics. Since the ZFS file system is always consistent on disk and is self-repairing, `zdb` should only be run under the direction by a support engineer.

If no arguments are specified, `zdb`, performs basic consistency checks on the pool and associated datasets, and report any problems detected.

Any options supported by this command are internal to Sun and subject to change at any time.

**Exit Status**  The following exit values are returned:

0      The pool is consistent.
1      An error was detected.
2      Invalid command line options were specified.

**Attributes**  See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWzfsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Unstable</td>
</tr>
</tbody>
</table>

**See Also**  `zfs(1M), zpool(1M), attributes(5)`
The `zdump` command prints the current time for each time zone (zonename) listed on the command line. Specify zonename as the name of the time zone database file relative to /usr/share/lib/zoneinfo.

Specifying an invalid time zone (zonename) to `zdump` does not return an error, rather `zdump` uses GMTO. This is consistent with the behavior of the library calls; `zdump` reflects the same behavior of the time routines in libc. See `ctime(3C)` and `mktime(3C)`.

The following options are supported:

- **--version** Outputs version information and exits.
- **-v** Displays the entire contents of the time zone database file for zonename. Prints the time at the lowest possible time value; the time one day after the lowest possible time value; the times both one second before and exactly at each time at which the rules for computing local time change; the time at the highest possible time value; and the time at one day less than the highest possible time value. See `mktime(3C)` and `ctime(3C)` for information regarding time value (time_t). Each line of output ends with isdst=1 if the given time is Daylight Saving Time, or isdst=0 otherwise.
- **-c [loyear],hiyear** Cuts off the verbose output near the start of the given year(s). By default, the program cuts off verbose output near the start of the years -500 and 2500.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**Files** /usr/share/lib/zoneinfo Standard zone information directory

Name  zfs – configures ZFS file systems

Synopsis  zfs [-?]
          zfs create [-p] [-o property=value] ... filesystem
          zfs create [-ps] [-b blocksize] [-o property=value] ... -V size volume
          zfs destroy [-rRf] filesystem|volume
          zfs destroy [-rRd] snapshot
          zfs snapshot [-r] [-o property=value]...
             filesystem@snapname|volume@snapname
          zfs rollback [-rRf] snapshot
          zfs clone [-p] [-o property=value] ... snapshot filesystem|volume
          zfs promote clone-filesystem
          zfs rename filesystem|volume|snapshot
             filesystem|volume|snapshot
          zfs rename [-p] filesystem|volume filesystem|volume
          zfs rename -r snapshot snapshot
          zfs list [-r|-d depth][-H][-o property[,...]] [-t type[,...]]
             [-s property] ... [-S property] ... [filesystem|volume|snapshot] ...
          zfs set [-r] property=value filesystem|volume|snapshot ...
          zfs get [-r|-d depth][-Hp][-o all | field[,...]] [-s source[,...]]
             all | property[,...] filesystem|volume|snapshot ...
          zfs inherit [-rS] property filesystem|volume|snapshot ...
          zfs upgrade
          zfs upgrade [-v]
          zfs upgrade [-r] [-V version] -a | filesystem
          zfs userspace [-niHp] [-o field[,...]] [-sS field] ...
             [-t type[,...]] filesystem|snapshot
          zfs groupspace [-niHp] [-o field[,...]] [-sS field] ...
             [-t type[,...]] filesystem|snapshot
          zfs mount
          zfs mount [-vO] [-o options] -a | filesystem
          zfs unmount [-f] -a | filesystem|mountpoint
          zfs share -a | filesystem
          zfs unshare -a filesystem|mountpoint
          zfs send [-DvRbp] [-[iI] snapshot] snapshot
The `zfs` command configures ZFS datasets within a ZFS storage pool, as described in `zpool(1M)`. A dataset is identified by a unique path within the ZFS namespace. For example:

```bash
pool/{filesystem, volume, snapshot}
```

where the maximum length of a dataset name is `MAXNAMELEN` (256 bytes).

A dataset can be one of the following:

**filesystem**

A ZFS dataset of type `filesystem` can be mounted within the standard system namespace and behaves like other file systems. While ZFS file systems are designed to be POSIX compliant, known issues exist that prevent compliance in some cases. Applications that depend on standards conformance might fail due to nonstandard behavior when checking file system free space.

**volume**

A logical volume exported as a raw or block device. This type of dataset should only be used under special circumstances. File systems are typically used in most environments.
A read-only version of a file system or volume at a given point in time. It is specified as `filesystem@name` or `volume@name`.

A ZFS storage pool is a logical collection of devices that provide space for datasets. A storage pool is also the root of the ZFS file system hierarchy.

The root of the pool can be accessed as a file system, such as mounting and unmounting, taking snapshots, and setting properties. The physical storage characteristics, however, are managed by the `zpool(1M)` command.

See `zpool(1M)` for more information on creating and administering pools.

A snapshot is a read-only copy of a file system or volume. Snapshots can be created extremely quickly, and initially consume no additional space within the pool. As data within the active dataset changes, the snapshot consumes more data than would otherwise be shared with the active dataset.

Snapshots can have arbitrary names. Snapshots of volumes can be cloned or rolled back, but cannot be accessed independently.

File system snapshots can be accessed under the `.zfs/snapshot` directory in the root of the file system. Snapshots are automatically mounted on demand and may be unmounted at regular intervals. The visibility of the `.zfs` directory can be controlled by the `snapdir` property.

A clone is a writable volume or file system whose initial contents are the same as another dataset. As with snapshots, creating a clone is nearly instantaneous, and initially consumes no additional space.

Clones can only be created from a snapshot. When a snapshot is cloned, it creates an implicit dependency between the parent and child. Even though the clone is created somewhere else in the dataset hierarchy, the original snapshot cannot be destroyed as long as a clone exists. The `origin` property exposes this dependency, and the `destroy` command lists any such dependencies, if they exist.

The clone parent-child dependency relationship can be reversed by using the `promote` subcommand. This causes the “origin” file system to become a clone of the specified file system, which makes it possible to destroy the file system that the clone was created from.

Creating a ZFS file system is a simple operation, so the number of file systems per system is likely to be numerous. To cope with this, ZFS automatically manages mounting and unmounting file systems without the need to edit the `/etc/vfstab` file. All automatically managed file systems are mounted by ZFS at boot time.

By default, file systems are mounted under `/path`, where `path` is the name of the file system in the ZFS namespace. Directories are created and destroyed as needed.
A file system can also have a mount point set in the `mountpoint` property. This directory is created as needed, and ZFS automatically mounts the file system when the `zfs mount -a` command is invoked (without editing `/etc/vfstab`). The `mountpoint` property can be inherited, so if `pool/home` has a mount point of `/export/stuff`, then `pool/home/user` automatically inherits a mount point of `/export/stuff/user`.

A file system `mountpoint` property of `none` prevents the file system from being mounted.

If needed, ZFS file systems can also be managed with traditional tools (`mount`, `umount`, `/etc/vfstab`). If a file system’s mount point is set to `legacy`, ZFS makes no attempt to manage the file system, and the administrator is responsible for mounting and unmounting the file system.

**Zones**

A ZFS file system can be added to a non-global zone by using the `zonecfg add fs` subcommand. A ZFS file system that is added to a non-global zone must have its `mountpoint` property set to `legacy`.

The physical properties of an added file system are controlled by the global administrator. However, the zone administrator can create, modify, or destroy files within the added file system, depending on how the file system is mounted.

A dataset can also be delegated to a non-global zone by using the `zonecfg add dataset` subcommand. You cannot delegate a dataset to one zone and the children of the same dataset to another zone. The zone administrator can change properties of the dataset or any of its children. However, the `quota` property is controlled by the global administrator.

A ZFS volume can be added as a device to a non-global zone by using the `zonecfg add device` subcommand. However, its physical properties can be modified only by the global administrator.

For more information about `zonecfg` syntax, see `zonecfg(1M)`.

After a dataset is delegated to a non-global zone, the zoned property is automatically set. A zoned file system cannot be mounted in the global zone, since the zone administrator might have to set the mount point to an unacceptable value.

The global administrator can forcibly clear the zoned property, though this should be done with extreme care. The global administrator should verify that all the mount points are acceptable before clearing the property.

**Native Properties**

Properties are divided into two types, native properties and user-defined (or “user”) properties. Native properties either export internal statistics or control ZFS behavior. In addition, native properties are either editable or read-only. User properties have no effect on ZFS behavior, but you can use them to annotate datasets in a way that is meaningful in your environment. For more information about user properties, see the “User Properties” section, below.
Every dataset has a set of properties that export statistics about the dataset as well as control various behaviors. Properties are inherited from the parent unless overridden by the child. Some properties apply only to certain types of datasets (file systems, volumes, or snapshots).

The values of numeric properties can be specified using human-readable suffixes (for example, k, KB, M, Gb, and so forth, up to Z for zettabyte). The following are all valid (and equal) specifications:

\[
1536M, \ 1.5g, \ 1.50GB
\]

The values of non-numeric properties are case sensitive and must be lowercase, except for mountpoint, sharenfs, and sharesmb.

The following native properties consist of read-only statistics about the dataset. These properties can be neither set, nor inherited. Native properties apply to all dataset types unless otherwise noted.

available
The amount of space available to the dataset and all its children, assuming that there is no other activity in the pool. Because space is shared within a pool, availability can be limited by any number of factors, including physical pool size, quotas, reservations, or other datasets within the pool.

This property can also be referred to by its shortened column name, avail.

compressratio
The compression ratio achieved for this dataset, expressed as a multiplier. Compression can be turned on by running: `zfs set compression=on dataset`. The default value is off.

creation
The time this dataset was created.

defer_destroy
This property is on if the snapshot has been marked for deferred destroy by using the `zfs destroy -d` command. Otherwise, the property is off.

groupused@group
The amount of space consumed by the specified group in this dataset. Space is charged to the group of each file, as displayed by `ls -l`. See the `userused@user` property for more information.

Unprivileged users can only access their own groups' space usage. The root user, or a user who has been granted the `groupused` privilege with `zfs allow`, can access all groups' usage.

mounted
For file systems, indicates whether the file system is currently mounted. This property can be either yes or no.
origin
For cloned file systems or volumes, the snapshot from which the clone was created. The
origin cannot be destroyed (even with the -r or -f options) so long as a clone exists.

referenced
The amount of data that is accessible by this dataset, which may or may not be shared with
other datasets in the pool. When a snapshot or clone is created, it initially references the
same amount of space as the file system or snapshot it was created from, since its contents
are identical.

This property can also be referred to by its shortened column name, refer.

type
The type of dataset: filesystem, volume, or snapshot.

used
The amount of space consumed by this dataset and all its descendents. This is the value that
is checked against this dataset’s quota and reservation. The space used does not include this
dataset’s reservation, but does take into account refreservation (through
usedbyrefreservation) and the reservations of any descendent datasets (through
usedbychildren). The amount of space that a dataset consumes from its parent, as well as
the amount of space that are freed if this dataset is recursively destroyed, is the greater of its
space used and its reservation.

When snapshots (see the “Snapshots” section) are created, their space is initially shared
between the snapshot and the file system, and possibly with previous snapshots. As the file
system changes, space that was previously shared becomes unique to the snapshot, and
counted in the snapshot’s space used. Additionally, deleting snapshots can increase the
amount of space unique to (and used by) other snapshots.

The amount of space used, available, or referenced does not take into account pending
changes. Pending changes are generally accounted for within a few seconds. Committing a
change to a disk using fsync(3C) or O_SYNC does not necessarily guarantee that the space
usage information is updated immediately.

usedby*
The usedby* properties decompose the used properties into the various reasons that space
is used. Specifically, used = usedbychildren + usedbydataset + usedbyrefreservation
+, usedbysnapshots. These properties are only available for datasets created on zpool
“version 13” pools.

usedbychildren
The amount of space used by children of this dataset, which would be freed if all the
dataset's children were destroyed.
usedbydataset
The amount of space used by this dataset itself, which would be freed if the dataset were
destroyed (after first removing any reservation and destroying any necessary
snapshots or descendents).

usedbyreservation
The amount of space used by a reservation set on this dataset, which would be freed if
the reservation was removed.

Space accounted for by this property represents potential consumption by future writes,
reserved in advance to prevent write allocation failures in this dataset. This can include
unwritten data, space currently shared with snapshots, and compression savings for
volumes (which may be lost when replaced with less compressible data). When allocations
for later writes increase usedbydataset or usedbysnapshots, usedbyreservation will
decrease accordingly.

usedbysnapshots
The amount of space consumed by snapshots of this dataset. In particular, it is the amount
of space that would be freed if all of this dataset’s snapshots were destroyed. Note that this is
not simply the sum of the snapshots’ used properties because space can be shared by
multiple snapshots.

userused@user
The amount of space consumed by the specified user in this dataset. Space is charged to the
owner of each file, as displayed by ls -l. The amount of space charged is displayed by du
and ls -s. See the zfs userspace subcommand for more information.

Unprivileged users can access only their own space usage. The root user, or a user who has
been granted the userused privilege with zfs allow, can access everyone’s usage.

The userused@... properties are not displayed by zfs get all. The user’s name must be
appended after the @ symbol, using one of the following forms:
- POSIX name (for example, joe)
- POSIX numeric ID (for example, 789)
- SID name (for example, joe.smith@mydomain)
- SID numeric ID (for example, S-1-123-456-789)

userrefs
This property is set to the number of user holds on this snapshot. User holds are set by
using the zfs hold command.

volblocksize=blocksize
For volumes, specifies the block size of the volume. The blocksize cannot be changed once
the volume has been written, so it should be set at volume creation time. The default
blocksize for volumes is 8 Kbytes. Any power of 2 from 512 bytes to 128 Kbytes is valid.

This property can also be referred to by its shortened column name, volblock.
The following native properties can be used to change the behavior of a ZFS dataset.

\texttt{aclinherit=discard|noallow|restricted|passthrough|passthrough-x}

Controls how ACL entries are inherited when files and directories are created. A file system with an aclinherit property of discard does not inherit any ACL entries. A file system with an aclinherit property value of noallow only inherits inheritable ACL entries that specify "deny" permissions. The property value restricted (the default) removes the \texttt{write acl} and \texttt{write owner} permissions when the ACL entry is inherited. A file system with an aclinherit property value of passthrough inherits all inheritable ACL entries without any modifications made to the ACL entries when they are inherited. A file system with an aclinherit property value of passthrough-x has the same meaning as passthrough, except that all ACEs inherit the execute permission only if the file creation mode also requests the execute bit.

When the property value is set to passthrough, files are created with a mode determined by the inheritable ACEs. If no inheritable ACEs exist that affect the mode, then the mode is set in accordance to the requested mode from the application.

\texttt{atime=on|off}

Controls whether the access time for files is updated when they are read. Turning this property off avoids producing write traffic when reading files and can result in significant performance gains, though it might confuse mailers and other similar utilities. The default value is on.

\texttt{canmount=on|off|noauto}

If this property is set to off, the file system cannot be mounted, and is ignored by \texttt{zfs mount -a}. Setting this property to off is similar to setting the mountpoint property to none, except that the dataset still has a normal mountpoint property, which can be inherited. Setting this property to off allows datasets to be used solely as a mechanism to inherit properties. One example of setting canmount=off is to have two datasets with the same mountpoint, so that the children of both datasets appear in the same directory, but might have different inherited characteristics.

When the noauto option is set, a dataset can only be mounted and unmounted explicitly. The dataset is not mounted automatically when the dataset is created or imported, nor is it mounted by the \texttt{zfs mount -a} command or unmounted by the \texttt{zfs unmount -a} command.

This property is not inherited.

\texttt{checksum=on|off|fletcher2,|fletcher4|sha256}

Controls the checksum used to verify data integrity. The default value is on, which automatically selects an appropriate algorithm (currently, fletcher4, but this may change in future releases). The value off disables integrity checking on user data. Disabling checksums is NOT a recommended practice.

Changing this property affects only newly-written data.
**compression=on|off|lzjb|gzip|gzip-N|zle**

Controls the compression algorithm used for this dataset. The lzjb compression algorithm is optimized for performance while providing decent data compression. Setting compression to on uses the lzjb compression algorithm. The gzip compression algorithm uses the same compression as the gzip(1) command. You can specify the gzip level by using the value gzip-N where N is an integer from 1 (fastest) to 9 (best compression ratio). Currently, gzip is equivalent to gzip-6 (which is also the default for gzip(1)).

This property can also be referred to by its shortened column name compress. Changing this property affects only newly-written data.

**copies=1|2|3**

Controls the number of copies of data stored for this dataset. These copies are in addition to any redundancy provided by the pool, for example, mirroring or RAID-Z. The copies are stored on different disks, if possible. The space used by multiple copies is charged to the associated file and dataset, changing the used property and counting against quotas and reservations.

Changing this property only affects newly-written data. Therefore, set this property at file system creation time by using the -o copies=N option.

**devices=on|off**

Controls whether device nodes can be opened on this filesystem. The default value is on.

**exec=on|off**

Controls whether processes can be executed from within this filesystem. The default value is on.

**groupquota@group=size|none**

Limits the amount of space consumed by the specified group. Group space consumption is identified by the userquota@user property.

Unprivileged users can access only their own groups’ space usage. The root user, or a user who has been granted the groupquota privilege with zfs allow, can get and set all groups’ quotas.

**logbias = latency|throughput**

Provides a hint to ZFS about handling of synchronous requests in this dataset. If logbias is set to latency (the default), ZFS uses the pool’s log devices (if configured) to handle the requests at low latency. If logbias is set to throughput, ZFS does not use the configured pool log devices. Instead, ZFS optimizes synchronous operations for global pool throughput and efficient use of resources.

**mountpoint=path|none|legacy**

Controls the mount point used for this filesystem. See the “Mount Points” section for more information on how this property is used.

When the mountpoint property is changed for a file system, the file system and any children that inherit the mount point are unmounted. If the new value is legacy, then they
remain unmounted. Otherwise, they are automatically remounted in the new location if the property was previously legacy or none, or if they were mounted before the property was changed. In addition, any shared file systems are unshared and shared in the new location.

**nbmand=on | off**
Controls whether the file system should be mounted with nbmand (Non Blocking mandatory locks). This is used for SMB clients. Changes to this property only take effect when the file system is umounted and remounted. See mount(1M) for more information on nbmand mounts.

**primarycache=all | none | metadata**
Controls what is cached in the primary cache (ARC). If this property is set to all, then both user data and metadata is cached. If this property is set to none, then neither user data nor metadata is cached. If this property is set to metadata, then only metadata is cached. The default value is all.

**quota=size | none**
Limits the amount of space a dataset and its descendents can consume. This property enforces a hard limit on the amount of space used. This includes all space consumed by descendents, including file systems and snapshots. Setting a quota on a descendent of a dataset that already has a quota does not override the ancestor’s quota, but rather imposes an additional limit.

Quotas cannot be set on volumes, as the volsize property acts as an implicit quota.

**readonly=on | off**
Controls whether this dataset can be modified. The default value is off.

This property can also be referred to by its shortened column name, rdonly.

**recordsize=size**
Specifies a suggested block size for files in the file system. This property is designed solely for use with database workloads that access files in fixed-size records. ZFS automatically tunes block sizes according to internal algorithms optimized for typical access patterns.

For databases that create very large files but access them in small random chunks, these algorithms may be suboptimal. Specifying a recordsize greater than or equal to the record size of the database can result in significant performance gains. Use of this property for general purpose file systems is strongly discouraged, and may adversely affect performance.

The size specified must be a power of two greater than or equal to 512 and less than or equal to 128 Kbytes.

Changing the file system’s recordsize affects only files created afterward; existing files and received data are unaffected.

This property can also be referred to by its shortened column name, recsize.
refquota=size | none
Limits the amount of space a dataset can consume. This property enforces a hard limit on the amount of space used. This hard limit does not include space used by descendents, including file systems and snapshots.

refreservation=size | none
The minimum amount of space guaranteed to a dataset, not including its descendents. When the usedbydataset space is below this value, the dataset is treated as if it were taking up the amount of space specified by refreservation. The usedbyrefreservation figure represents this extra space, adding to the total used space charged to the dataset, and in turn consuming from the parent datasets' usage, quotas, and reservations. This protects the dataset from overcommitment of pool resources, by ensuring that space for future writes is reserved in advance.

Space shared with snapshots can later be replaced with new data, and the snapshot represents a commitment to keep both copies. If refreservation is set, usedbyrefreservation must be increased to the full size of refreservation when taking a new snapshot, accounting for this commitment. If there is insufficient space available to the dataset for this increase, snapshot creation will be denied.

This property can also be referred to by its shortened column name, refreserv.

reservation=size | none
The minimum amount of space guaranteed to a dataset and its descendents. When the amount of space used is below this value, the dataset is treated as if it were taking up the amount of space specified by its reservation. Reservations are accounted for in the parent datasets' space used, and count against the parent datasets' quotas and reservations.

This property can also be referred to by its shortened column name, reserv.

rstchown=on | off
Indicates whether the file system restricts users from giving away their files by means of chown(1) or the chown(2) system call. The default is to restrict chown. When rstchown is off then chown will act as if the user has the PRIV_FILE_CHOWN_SELF privilege.

secondarycache=all | none | metadata
Controls what is cached in the secondary cache (L2ARC). If this property is set to all, then both user data and metadata is cached. If this property is set to none, then neither user data nor metadata is cached. If this property is set to metadata, then only metadata is cached. The default value is all.

setuid=on | off
Controls whether the set-UID bit is respected for the file system. The default value is on.

sharesmb=on | off | opts
Controls whether the file system is shared by using the Solaris SMB service, and what options are to be used. A file system with the sharesmb property set to off is managed
through traditional tools such as `share_nfs(1M)`. Otherwise, the file system is automatically shared and unshared with the `zfs share` and `zfs unshare` commands.

Because SMB shares requires a resource name, a unique resource name is constructed from the dataset name. The constructed name is a copy of the dataset name except that the characters in the dataset name, which would be illegal in the resource name, are replaced with underscore (_) characters. A pseudo property “name” is also supported that allows you to replace the data set name with a specified name. The specified name is then used to replace the prefix dataset in the case of inheritance. For example, if the dataset `data/home/john` is set to `name=john`, then `data/home/john` has a resource name of `john`. If a child dataset of `data/home/john/backups`, it has a resource name of `john_backups`.

When SMB shares are created, the SMB share name appears as an entry in the `.zfs/shares` directory. You can use the `ls` or `chmod` command to display the share-level ACLs on the entries in this directory.

When the `sharesmb` property is changed for a dataset, the dataset and any children inheriting the property are re-shared with the new options, only if the property was previously set to `off`, or if they were shared before the property was changed. If the new property is set to `off`, the file systems are unshared.

**Note** – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`sharenfs=on | off | opts`  
Controls whether the dataset is shared by using the NFS protocol. If the property is set to `on`, the `zfs share` command is invoked with no options. You can specify a comma-separated list of options as the contents of this property. See the EXAMPLES section. You can also share a ZFS file system by using the `zfs share` command. Setting the `sharenfs` property or using the `zfs share` command is preferred over using the legacy `share(1M)` command.

When the `sharenfs` property is changed for a dataset, the dataset and any children inheriting the property are re-shared with the new options, only if the property was previously `off`, or if they were shared before the property was changed. If the new property is `off`, the file systems are unshared.

`snapdir=hidden | visible`  
Controls whether the `.zfs` directory is hidden or visible in the root of the file system as discussed in the “Snapshots” section. The default value is `hidden`.

`sync=standard | always | disabled`  
Determines the degree to which file system transactions are synchronized. This property can be set when a dataset is created, or dynamically, and will take effect immediately. `sync` can have one of the following settings:
Thedefaultoption. Synchronous filersystemtransactionsarewritten to the intent log
and then all devices written are flushed to ensure the data is stable (that is, not cached by
device controllers).

Every filesystem transaction would be written and flushed to stable storage. This setting
should be used only where extreme caution is required, as there is a significant
performance penalty.

Synchronous requests are disabled. File system transactions commit to stable storage
only on the next DMU transaction group commit, which might be after many seconds.
This setting gives the highest performance. However, it is very dangerous as ZFS would
be ignoring the synchronous transaction demands of applications such as databases or
NFS. Furthermore, when this setting is in effect for the currently active root or /var
filesystem, out-of-spec behavior, application data loss, and increased vulnerability to
replay attacks can result. Administrators should only use this option only when these
risks are understood.

Limits the amount of space consumed by the specified user. Similar to the refquota
property, the userquota space calculation does not include space that is used by
descendent datasets, such as snapshots and clones. User space consumption is identified by
the userspace@user property.

Enforcement of user quotas may be delayed by several seconds. This delay means that a
user might exceed her quota before the system notices that she is over quota. The system
would then begin to refuse additional writes with the EDQUOT error message. See the zfs
userspace subcommand for more information.

Unprivileged users can only access their own groups' space usage. The root user, or a user
who has been granted the userquota privilege with zfs allow, can get and set everyone's
quota.

This property is not available on volumes, on file systems before version 4, or on pools
before version 15. The userquota@... properties are not displayed by zfs get all. The
user's name must be appended after the @ symbol, using one of the following forms:

- POSIX name (for example, joe)
- POSIX numeric ID (for example, 789)
- SID name (for example, joe.smith@mydomain)
- SID numeric ID (for example, S-1-123-456-789)

The on-disk version of this file system, which is independent of the pool version. This
property can only be set to later supported versions. See the zfs upgrade command.
volsize=size
Specifies the logical size of the volume. By default, creating a volume establishes a refreservation that is a somewhat larger than the actual logical volume size, to account for ZFS metadata overhead. Any changes to volsize are reflected in an equivalent change to the refreservation. The volsize can only be set to a multiple of volblocksize, and cannot be zero.

The refreservation is set on the volume to prevent unexpected behavior for consumers. Without the reservation, the volume could run out of space, resulting in undefined behavior or data corruption, depending on how the volume is used. These effects can also occur when the volume size is changed while it is in use (particularly when shrinking the size). Extreme care should be used when adjusting the volume size.

Though not recommended, a "sparse volume" (also known as "thin provisioning") can be created by specifying the -s option to the zfs create -V command, or by changing the reservation after the volume has been created. A "sparse volume" is a volume where the reservation is less than the volume size. Consequently, writes to a sparse volume can fail with ENOSPC when the pool is low on space. For a sparse volume, changes to volsize are not reflected in the reservation.

vsca...
case-insensitive matching behavior on a file system that supports mixed behavior is limited to the Solaris SMB server product. For more information about the mixed value behavior, see the *Oracle Solaris ZFS Administration Guide*.

**Note** – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

**normalization = none | formC | formD | formKC | formKD**

Indicates whether the file system should perform a Unicode normalization of file names whenever two file names are compared, and which normalization algorithm should be used. File names are always stored unmodified, names are normalized as part of any comparison process. If this property is set to a legal value other than none, the utf8only property was left unspecified, the utf8only property is automatically set to on. The default value of the normalization property is none. This property cannot be changed after the file system is created.

**Note** – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

**utf8only = on | off**

Indicates whether the file system should reject file names that include characters that are not present in the UTF-8 character code set. If this property is explicitly set to off, the normalization property must either not be explicitly set or be set to none. The default value for the utf8only property is off. This property cannot be changed after the file system is created.

**Note** – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

When a ZFS file system is mounted, either through the legacy `mount(1M)` command for legacy mounts or the `zfs mount` command, its mount options are set according to its properties. The correlation between properties and mount options is as follows:

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>MOUNT OPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>devices</td>
<td>devices/nodevices</td>
</tr>
<tr>
<td>exec</td>
<td>exec/noexec</td>
</tr>
<tr>
<td>readonly</td>
<td>ro/rw</td>
</tr>
<tr>
<td>setuid</td>
<td>setuid/nosetuid</td>
</tr>
<tr>
<td>xattr</td>
<td>xattr/noxattr</td>
</tr>
<tr>
<td>rstchown</td>
<td>rstchown/norstchown</td>
</tr>
</tbody>
</table>

In addition, these options can be set on a per-mount basis using the `-o` option, without affecting the property that is stored on disk. The values specified on the command line override the values stored in the dataset. The `-nosuid` option is an alias for `nodevices`, `nosetuid`. These properties are reported as “temporary” by the `zfs get` command. If the properties are changed while the dataset is mounted, the new setting overrides any temporary settings.
In addition to the standard native properties, ZFS supports arbitrary user properties. User properties have no effect on ZFS behavior, but applications or administrators can use them to annotate datasets (file systems, volumes, and snapshots).

User property names must contain a colon (:) character to distinguish them from native properties. They may contain lowercase letters, numbers, and the following punctuation characters: colon (:), dash (-), period (.), and underscore (_). The expected convention is that the property name is divided into two portions such as module:property, but this namespace is not enforced by ZFS. User property names can be at most 256 characters, and cannot begin with a dash (-).

When making programmatic use of user properties, it is strongly suggested to use a reversed DNS domain name for the module component of property names to reduce the chance that two independently-developed packages use the same property name for different purposes.

The values of user properties are arbitrary strings, are always inherited, and are never validated. All of the commands that operate on properties (zfs list, zfs get, zfs set, and so forth) can be used to manipulate both native properties and user properties. Use the zfs inherit command to clear a user property. If the property is not defined in any parent dataset, it is removed entirely. Property values are limited to 1024 characters.

During an initial installation or a live upgrade from a UFS file system, a swap device and dump device are created on ZFS volumes in the ZFS root pool. By default, the swap area size is based on 1/2 the size of physical memory up to 2 GB. The size of the dump device depends on the kernel's requirements at installation time. Separate ZFS volumes must be used for the swap area and dump devices. Do not swap to a file on a ZFS file system. A ZFS swap file configuration is not supported.

If you need to change your swap area or dump device after the system is installed or upgraded, use the swap(1M) and dumpadm(1M) commands. If you need to change the size of your swap area or dump device, see the Oracle Solaris ZFS Administration Guide

All subcommands that modify state are logged persistently to the pool in their original form.

zfs ?
   Displays a help message.

zfs create [-p] [-o property=value] ... filesystem
   Creates a new ZFS file system. The file system is automatically mounted according to the mountpoint property inherited from the parent.

   -p
   Creates all the non-existing parent datasets.Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. Any property specified on the command line using the -o option is ignored. If the target filesystem already exists, the operation completes successfully.
-o property=value
Sets the specified property as if the command zfs set property=value was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

zfs create [-ps] [-b blocksize] [-o property=value] ... -V size volume
Creates a volume of the given size. The volume is exported as a block device in /dev/zvol/(dsk,rsk)/path, where path is the name of the volume in the ZFS namespace. The size represents the logical size as exported by the device. By default, a reservation of equal size is created.

size is automatically rounded up to the nearest 128 Kbytes to ensure that the volume has an integral number of blocks regardless of blocksize.

-p
Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. Any property specified on the command line using the -o option is ignored. If the target filesystem already exists, the operation completes successfully.

-s
Creates a sparse volume with no reservation. See volsize in the Native Properties section for more information about sparse volumes.

-o property=value
Sets the specified property as if the zfs set property=value command was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

-b blocksize
Equivalent to -o voldblocksize=blocksize. If this option is specified in conjunction with -o voldblocksize, the resulting behavior is undefined.

zfs destroy [-rRf] filesystem|volume
Destroys the given dataset. By default, the command unshares any file systems that are currently shared, unmounts any file systems that are currently mounted, and refuses to destroy a dataset that has active dependents (children or clones).

-r
Recursively destroy all children.

-R
Recursively destroy all dependents, including cloned file systems outside the target hierarchy.
-f
For an unmount of any file systems using the `umount -f` command. This option has
no effect on non-file systems or unmounted file systems.

Extreme care should be taken when applying either the -r or the -f options, as they can
destroy large portions of a pool and cause unexpected behavior for mounted file systems in
use.

`zfs destroy [-rRd] snapshot`
The given snapshot is destroyed immediately if and only if the `zfs destroy` command
without the -d option would have destroyed it. Such immediate destruction would occur,
for example, if the snapshot had no clones and the user-initiated reference count were zero.

If the snapshot does not qualify for immediate destruction, it is marked for deferred
deletion. In this state, it exists as a usable, visible snapshot until both of the preconditions
listed above are met, at which point it is destroyed.

-d
Defer snapshot deletion.

-r
Destroy (or mark for deferred deletion) all snapshots with this name in descendent file
systems.

-R
Recursively destroy all dependents.

`zfs snapshot [-r] [-o property=value] ... filesystem@snapname|volume@snapname`
Creates a snapshot with the given name. All previous modifications by successful system
calls to the file system are part of the snapshot. See the “Snapshots” section for details.

-r
Recursively create snapshots of all descendent datasets. Snapshots are taken atomically,
so that all recursive snapshots correspond to the same moment in time.

-o property=value
Sets the specified property; see `zfs create` for details.

`zfs rollback [-rRf] snapshot`
Roll back the given dataset to a previous snapshot. When a dataset is rolled back, all data
that has changed since the snapshot is discarded, and the dataset reverts to the state at the
time of the snapshot. By default, the command refuses to roll back to a snapshot other than
the most recent one. In order to do so, all intermediate snapshots must be destroyed by
specifying the -r option.

The -rR options do not recursively destroy the child snapshots of a recursive snapshot.
Only the top-level recursive snapshot is destroyed by either of these options. To completely
roll back a recursive snapshot, you must rollback the individual child snapshots.
Recursively destroy any snapshots more recent than the one specified.

-R
Recursively destroy any more recent snapshots, as well as any clones of those snapshots.

-f
Used with the -R option to force an unmount of any clone file systems that are to be destroyed.

zfs clone [-p] [-o property=value] ... snapshot filesystem|volume
Creates a clone of the given snapshot. See the "Clones" section for details. The target dataset can be located anywhere in the ZFS hierarchy, and is created as the same type as the original.

-p
Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. If the target filesystem or volume already exists, the operation completes successfully.

-o property=value
Sets the specified property; see zfs create for details.

zfs promote clone filesystem
Promotes a clone filesystem to no longer be dependent on its "origin" snapshot. This makes it possible to destroy the file system that the clone was created from. The clone parent-child dependency relationship is reversed, so that the origin file system becomes a clone of the specified file system.

The snapshot that was cloned, and any snapshots previous to this snapshot, are now owned by the promoted clone. The space they use moves from the origin file system to the promoted clone, so enough space must be available to accommodate these snapshots. No new space is consumed by this operation, but the space accounting is adjusted. The promoted clone must not have any conflicting snapshot names of its own. The rename subcommand can be used to rename any conflicting snapshots.

zfs rename filesystem|volume|snapshot
filesystem|volume|snapshot
zfs rename [-p] filesystem|volume filesystem|volume
Renames the given dataset. The new target can be located anywhere in the ZFS hierarchy, with the exception of snapshots. Snapshots can only be renamed within the parent file system or volume. When renaming a snapshot, the parent file system of the snapshot does not need to be specified as part of the second argument. Renamed file systems can inherit new mount points, in which case they are unmounted and remounted at the new mount point.
-p
  Creates all the nonexistent parent datasets. Datasets created in this manner are
  automatically mounted according to the mountpoint property inherited from their
  parent.

\texttt{zfs\ rename -r\ snapshot\ snapshot}

Recursively rename the snapshots of all descendent datasets. Snapshots are the only dataset
that can be renamed recursively.

\texttt{zfs\ list [-r] [-d\ depth] [-H] [-o\ property[,...]] [-t\ type[,...]] [-s\ property] ... [-S\ property] ... [filesystem[volume|snapshot] ...}

Lists the property information for the given datasets in tabular form. If specified, you can
list property information by the absolute pathname or the relative pathname. By default, all
file systems and volumes are displayed. Snapshots are displayed if the \texttt{listsnaps} property
is on (the default is on). The following fields are displayed,
name, used, available, referenced, mountpoint.

-H
  Used for scripting mode. Do not print headers and separate fields by a single tab instead
  of arbitrary white space.

-r
  Recursively display any children of the dataset on the command line.

-d\ depth
  Recursively display any children of the dataset, limiting the recursion to \texttt{depth}. A depth
  of 1 will display only the dataset and its direct children.

-o\ property
  A comma-separated list of properties to display. The property must be:
  - One of the properties described in the “Native Properties” section
  - A user property
  - The value name to display the dataset name
  - The value space to display space usage properties on file systems and volumes. This
    is a shortcut for specifying
    -o\ name,avail,used,usedsnap,usedds,usedreserv,usedchild
    -t\ filesystem, volume\ syntax.

-s\ property
  A property for sorting the output by column in ascending order based on the value of
  the property. The property must be one of the properties described in the “Properties”
  section, or the special value name to sort by the dataset name. Multiple properties can be
  specified at one time using multiple -s property options. Multiple -s options are
  evaluated from left to right in decreasing order of importance.

  The following is a list of sorting criteria:
  - Numeric types sort in numeric order.
- String types sort in alphabetical order.
- Types inappropriate for a row sort that row to the literal bottom, regardless of the specified ordering.
- If no sorting options are specified the existing behavior of \texttt{zfs list} is preserved.

\texttt{-S property}

Same as the \texttt{-s} option, but sorts by property in descending order.

\texttt{-t type}

A comma-separated list of types to display, where \texttt{type} is one of filesystem, snapshot, volume, or all. For example, specifying \texttt{-t snapshot} displays only snapshots. The following aliases can be used in place of the type specifiers: \texttt{fs (filesystem)}, \texttt{snap (snapshot)}, and \texttt{vol (volume)}.

\texttt{zfs set [-r] property=value filesystem|volume|snapshot ...}

Sets the property to the given value for each dataset. Only some properties can be edited. See the “Properties” section for more information on what properties can be set and acceptable values. Numeric values can be specified as exact values, or in a human-readable form with a suffix of B, K, M, G, T, P, E, Z (for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, exabytes, or zettabytes, respectively). User properties can be set on snapshots. For more information, see the “User Properties” section.

\texttt{-r}

Recursively apply the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property.

\texttt{zfs get [-r|-d depth] [-Hp] [-o all | field[,...] [-s source[,...]] all | property[,...] filesystem|volume|snapshot ...}

Displays properties for the given datasets. If no datasets are specified, then the command displays properties for all datasets on the system. For each property, the following columns are displayed:

<table>
<thead>
<tr>
<th>name</th>
<th>Dataset name</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>Property name</td>
</tr>
<tr>
<td>value</td>
<td>Property value</td>
</tr>
<tr>
<td>source</td>
<td>Property source. Can either be local, default, temporary, inherited, or none (-).</td>
</tr>
</tbody>
</table>

All columns except the RECEIVED column are displayed by default; specify particular or all columns, using the \texttt{-o} option. This command takes a comma-separated list of properties as described in the “Native Properties” and “User Properties” sections.

The special value \texttt{all} can be used to display all properties that apply to the given dataset's type (filesystem, volume, or snapshot).

\texttt{-r}

Recursively display properties for any children.
-d depth
  Recursively display any children of the dataset, limiting the recursion to depth. A depth of 1 will display only the dataset and its direct children.

-H
  Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.

-o field
  Set of fields to display. One or more of:
  name,property,value,received,source

  Present multiple fields as a comma-separated list. The default value is:
  name,property,value,source

  The keyword all specifies all sources.

-s source
  A comma-separated list of sources to display. Those properties coming from a source other than those in this list are ignored. Each source must be one of the following:
  local,default,inherited,temporary,received,none

  The default value is all sources.

-p
  Display numbers in parseable (exact) values.

zfs inherit [-rS] property filesystem|volume|snapshot ...
  Clears the specified property, causing it to be inherited from an ancestor. If no ancestor has the property set, then the default value is used. See the "Properties" section for a listing of default values, and details on which properties can be inherited.

-r
  Recursively inherit the given property for all children.

-S
  Revert to the received property value, if any. If the property does not have a received value, the behavior of zfs inherit -S is the same as zfs inherit without -S. If the property does have a received value, zfs inherit masks the received value with the inherited value until zfs inherit -S reverts to the received value.

zfs upgrade
  Identifies a file system version, which determines available file system features in the currently running software release. You can continue to use older file system versions, but some features might not be available. A file system can be upgraded by using the zfs upgrade -a command. You will not be able to access a file system of a later version on a system that runs an earlier software version.
zfs upgrade [-v]
Displays ZFS file system versions that are supported by the current software. The current ZFS file system versions and all previously supported versions are displayed, along with an explanation of the features provided with each version.

zfs upgrade [-r] [-V version] [-a | filesystem]
Upgrades file systems to a new, on-disk version. Upgrading a file system means that it will no longer be accessible on a system running an older software version. A zfs send stream that is generated from a new file system snapshot cannot be accessed on a system that runs an older software version.

In general, the file system version is independent of the pool version. See zpool(1M) for information on the zpool upgrade command.

In some cases, the file system version and the pool version are interrelated and the pool version must be upgraded before the file system version can be upgraded.

- a
Upgrade all file systems on all imported pools.

filesystem
Upgrade the specified file system.

- r
Upgrade the specified file system and all descendent file systems

- V version
Upgrade to the specified version. If the -V flag is not specified, this command upgrades to the most recent version. This option can only be used to increase the version number, and only up to the most recent version supported by this software.

zfs userspace [-nHp] [-o field[...] [-sS field]... [-t type[...]] filesystem | snapshot
Displays space consumed by, and quotas on, each user in the specified filesystem or snapshot. This corresponds to the userused@user and userquota@user properties.

- n
Print numeric ID instead of user/group name.

- H
Do not print headers, use tab-delimited output.

- p
Use exact (parseable) numeric output.

- o field[...]
Display only the specified fields from the following set, type, name, used, quota. The default is to display all fields.

- s field
Sort output by this field. The s and S flags may be specified multiple times to sort first by one field, then by another. The default is -s type -s name.
-S field
    Sort by this field in reverse order. See -s.

-t type[,...]
    Print only the specified types from the following set,
    all, posixuser, smbuser, posixgroup, smbgroup.

    The default is -t posixuser, smbuser

    The default can be changed to include group types.

-i
    Translate SID to POSIX ID. The POSIX ID may be ephemeral if no mapping exists.
    Normal POSIX interfaces (for example, stat(2), ls -l) perform this translation, so the
    -i option allows the output from zfs userspace to be compared directly with those
    utilities. However, -i may lead to confusion if some files were created by an SMB user
    before a SMB-to-POSIX name mapping was established. In such a case, some files are
    owned by the SMB entity and some by the POSIX entity. However, the -i option will
    report that the POSIX entity has the total usage and quota for both.

zfs groupspace [-nHp] [-o field[,...]] [-S field][,...] [-t type[,...]] filesystem | snapshot
    Displays space consumed by, and quotas on, each group in the specified filesystem or
    snapshot. This subcommand is identical to zfs userspace, except that the default types to
    display are -t posixgroup, smbgroup.

zfs mount
    Displays all ZFS file systems currently mounted.

zfs mount [-vO] [-o options] -a | filesystem
    Mounts ZFS file systems. Invoked automatically as part of the boot process.

    -o options
        An optional, comma-separated list of mount options to use temporarily for the duration
        of the mount. See the “Temporary Mount Point Properties” section for details.

    -O
        Perform an overlay mount. See mount(1M) for more information.

    -v
        Report mount progress.

    -a
        Mount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem
    Mount the specified filesystem.
zfs unmount [-f] -a [filesystem|mountpoint]
Unmounts currently mounted ZFS file systems. Invoked automatically as part of the shutdown process.

- f
Forcefully unmount the file system, even if it is currently in use.

- a
Unmount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem|mountpoint
Unmount the specified filesystem. The command can also be given a path to a ZFS file system mount point on the system.

zfs share -a [filesystem]
Shares ZFS file systems that have the sharenfs or sharesmb property set. Sharing a file system with the NFS or SMB protocol means that the file system data is available over the network. ZFS file systems that have the sharenfs or sharesmb property set are automatically shared when a system is booted.

- a
Shares all ZFS file systems that have the sharenfs or sharesmb property set and according to the share property values.

filesystem
Shares the specified file system that has the sharenfs or sharesmb property set and according to the share property values.

zfs unshare -a [filesystem|mountpoint]
Unshares all ZFS file systems that have the sharenfs or sharesmb property set.

- a
Unshare all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem|mountpoint
Unshare the specified filesystem. The command can also be given a path to a ZFS file system shared on the system.

zfs send [-vRbp] [-[iI] snapshot] snapshot
Creates a stream representation of the second snapshot, which is written to standard output. The output can be redirected to a file or to a different system (for example, using ssh(1)). By default, a full stream is generated.

- b
Sends only received property values whether or not they are overridden by local settings, but only if the dataset has ever been received. Use this option when you want zfs receive to restore received properties backed up on the sent dataset and to avoid sending local settings that may have nothing to do with the source dataset, but only with how the data is backed up.
The format of the stream is committed. You will be able to receive your streams on future versions of ZFS.

```
zfs receive [-vnFu] [[-o property=value] | [-x property]] ... filesystem|volume|snapshot
zfs receive [-vnFu] [[-o property=value] | [-x property]] ... [-d | -e] filesystem
```

Creates a snapshot whose contents are as specified in the stream provided on standard input. If a full stream is received, then a new file system is created as well. Streams are created using the `zfs send` subcommand, which by default creates a full stream. `zfs recv` can be used as an alias for `zfs receive`.

If an incremental stream is received, then the destination file system must already exist, and its most recent snapshot must match the incremental stream’s source. For zvols, the destination device link is destroyed and recreated, which means the zvol cannot be accessed during the `receive` operation.
When a snapshot replication package stream that is generated by using the `zfs send -R` command is received, any snapshots that do not exist on the sending location are destroyed by using the `zfs destroy -d` command. If `-o property=value` or `-x property` is specified, it applies to the effective value of the property throughout the entire subtree of replicated datasets. Effective property values may be set or inherited, depending on the property and whether the dataset is the topmost in the replicated subtree. Received properties are retained in spite of being overridden and may be restored with `zfs inherit -rS` or `zfs send -Rb`.

The name of the snapshot (and file system, if a full stream is received) that this subcommand creates depends on the argument type and the `-d` or `-e` option.

If the argument is a snapshot name, the specified snapshot is created. If the argument is a file system or volume name, a snapshot with the same name as the sent snapshot is created within the specified file system or volume. If the `-d` or `-e` option is specified, the snapshot name is determined by appending the sent snapshot's name to the specified file system. If the `-d` option is specified, all but the pool name of the sent snapshot path is appended (for example, `b/c@1` appended from sent snapshot `a/b/c@1`), and if the `-e` option is specified, only the tail of the sent snapshot path is appended (for example, `c@1` appended from sent snapshot `a/b/c@1`). In the case of `-d`, any file systems needed to replicate the path of the sent snapshot are created within the specified file system.

- `-d`
  Use all but the first element of the sent snapshot path (all but the pool name) to determine the name of the new snapshot as described in the paragraph above.

- `-e`
  Use the last element of the sent snapshot path to determine the name of the new snapshot as described in the paragraph above.

- `-F`
  Force a rollback of the file system to the most recent snapshot before performing the receive operation. If receiving an incremental replication stream (for example, one generated by `zfs send -R -[iI]`), destroy snapshots and file systems that do not exist on the sending side.

- `-n`
  Do not actually receive the stream. This can be useful in conjunction with the `-v` option to verify the name the receive operation would use.

- `-o property=value`
  Sets the specified property as if the command `zfs set property=value` is invoked at the same time the received dataset is created from the non-incremental send stream or updated from the incremental send stream. Any editable ZFS property can also be set at receive time. Set-once properties bound to the received data, such as normalization and casesensitivity, cannot be set at receive time even when the datasets are newly created by `zfs receive`. Multiple `-o` options can be specified. An error results if the same property is specified in multiple `-o` or `-x` options.
-u
File system that is associated with the received stream is not mounted.

-v
Print verbose information about the stream and the time required to perform the receive operation.

-x property
Ensures that the effective value of the specified property after the receive is unaffected by the value of that property in the send stream (if any), as if the property had been excluded from the send stream. If the specified property is not present in the send stream, this option does nothing. If a received property needs to be overridden, the effective value can be set or inherited, depending on the property. In the case of an incremental update, -x leaves any existing local setting or explicit inheritance unchanged (since the received property is already overridden). All -o restrictions apply equally to -x.

zfs allow filesystem | volume
Displays permissions that have been delegated on the specified filesystem or volume. See the other forms of zfs allow for more information.

zfs allow [-ldug] everyone|user|group[,...] perm|@setname[,...] filesystem | volume
zfs allow [-ld] -e perm|@setname[,...] filesystem | volume
Delegates ZFS administration permission for the file systems to non-privileged users.

[-ug] everyone|user|group[,...]
Specifies to whom the permissions are delegated. Multiple entities can be specified as a comma-separated list. If neither of the -ug options are specified, then the argument is interpreted preferentially as the keyword everyone, then as a user name, and lastly as a group name. To specify a user or group named "everyone", use the -u or -g options. To specify a group with the same name as a user, use the -g options.

[-e] perm|@setname[,...]
Specifies that the permissions be delegated to everyone. Multiple permissions may be specified as a comma-separated list. Permission names are the same as ZFS subcommand and property names. See the property list below. Property set names, which begin with an at sign (@), may be specified. See the -s form below for details.

[-ld] filesystem | volume
Specifies where the permissions are delegated. If neither of the -ld options are specified, or both are, then the permissions are allowed for the file system or volume, and all of its descendents. If only the -l option is used, then is allowed "locally" only for the specified file system. If only the -d option is used, then is allowed only for the descendent file systems.

Permissions are generally the ability to use a ZFS subcommand or change a ZFS property. The following permissions are available:
<table>

</tbody>
</table>
Sets "create time" permissions. These permissions are granted (locally) to the creator of any newly-created descendent file system.

Defines or adds permissions to a permission set. The set can be used by other zfs allow commands for the specified file system and its descendants. Sets are evaluated dynamically, so changes to a set are immediately reflected. Permission sets follow the same naming restrictions as ZFS file systems, but the name must begin with an "at sign" (@), and can be no more than 64 characters long.

Removes permissions that were granted with the zfs allow command. No permissions are explicitly denied, so other permissions granted are still in effect. For example, if the permission is granted by an ancestor. If no permissions are specified, then all permissions for the specified user, group, or everyone are removed. Specifying everyone (or using the -e option) only removes the permissions that were granted to everyone, not all permissions for every user and group. See the zfs allow command for a description of the -ldudec options.

Removes permissions from a permission set. If no permissions are specified, then all permissions are removed, thus removing the set entirely.
zfs hold [-r] tag snapshot...
   Adds a single reference, named with the tag argument, to the specified snapshot or
   snapshots. Each snapshot has its own tag namespace, and tags must be unique within that
   space.

   If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy
   command return EBUSY.

   -r
   Specifies that a hold with the given tag is applied recursively to the snapshots of all
   descendent file systems.

zfs holds [-r] snapshot...
   Lists all existing user references for the given snapshot or snapshots.

   -r
   Lists the holds that are set on the named descendent snapshots, in addition to listing the
   holds on the named snapshot.

zfs release [-r] tag snapshot...
   Removes a single reference, named with the tag argument, from the specified snapshot or
   snapshots. The tag must already exist for each snapshot.

   If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy
   command return EBUSY.

   -r
   Recursively releases a hold with the given tag on the snapshots of all descendent file
   systems.

zfs diff [-FHt] snapshot snapshot | filesystem
   Gives a high-level description of the differences between a snapshot and a descendent
   dataset. The descendent can be either a snapshot of the dataset or the current dataset.

   For each file that has undergone a change between the original snapshot and the
   descendent, the type of change is described along with the name of the file. In the case of a
   rename, both the old and new names are shown. Whitespace characters, backslash
   characters, and other non-printable or non-7-bit ASCII characters found in file names are
   displayed as a backslash character followed by the three-digit octal representation of the
   byte value.

   If the -t option is specified, the first column of output from the command is the file's
   st_ctim value. For deleted files, this is the final st_ctim in the earlier snapshot.

   The type of change follows any timestamp displayed, and is described with a single
   character:
   +  Indicates the file was added in the later dataset.
   -  Indicates the file was removed in the later dataset.
M Indicates the file was modified in the later dataset.
R Indicates the file was renamed in the later dataset.

If the -F option is specified, the next column of output will be a single character describing the type of the file. The mappings are:

F regular file
/ directory
B block device
> door
| FIFO
@ symbolic link
P event portal
= socket

If the modification involved a change in the link count of a non-directory file, the change will be expressed as a delta within parentheses on the modification line. If the file was renamed, the old name will be separated from the new with the string "->".

If the -H option is selected, easier-to-parse output is produced. Fields are separated by a single tab, and no arrow string (->) is placed between the old and new names of a rename. No guarantees are made on the spacing between fields of non -H output.

Unless they already have the {PRIV_SYS_CONFIG} or {PRIV_SYS_MOUNT} privilege, users must be granted the diff permission with zfs allow to use this subcommand.

Examples

EXAMPLE 1 Creating a ZFS File System Hierarchy

The following commands create a file system named pool/home and a file system named pool/home/bob. The mount point /export/home is set for the parent file system, and is automatically inherited by the child file system.

```
# zfs create pool/home
# zfs set mountpoint=/export/home pool/home
# zfs create pool/home/bob
```

EXAMPLE 2 Creating a ZFS Snapshot

The following command creates a snapshot named yesterday. This snapshot is mounted on demand in the .zfs/snapshot directory at the root of the pool/home/bob file system.

```
# zfs snapshot pool/home/bob@yesterday
```
EXAMPLE 3  Creating and Destroying Multiple Snapshots

The following command creates snapshots named yesterday of pool/home and all of its
descendent file systems. Each snapshot is mounted on demand in the .zfs/snapshot
directory at the root of its file system. The second command destroys the newly created
snapshots.

```
# zfs snapshot -r pool/home@yesterday
# zfs destroy -r pool/home@yesterday
```

EXAMPLE 4  Disabling and Enabling File System Compression

The following command disables the compression property for all file systems under
pool/home. The next command explicitly enables compression for pool/home/anne.

```
# zfs set compression=off pool/home
# zfs set compression=on pool/home/anne
```

EXAMPLE 5  Listing ZFS Datasets

The following command lists all active file systems and volumes in the system. Snapshots are
displayed if the listsnaps property is on. The default is on. See zpool(1M) for more
information on pool properties.

```
# zfs list
NAME     USED   AVAIL  REFER MOUNTPOINT
pool      450K   457G   18K /pool
pool/home 315K   457G   21K /export/home
pool/home/anne 18K   457G   18K /export/home/anne
pool/home/bob  276K  457G  276K /export/home/bob
```

EXAMPLE 6  Setting a Quota on a ZFS File System

The following command sets a quota of 30 GB for pool/home/bob.

```
# zfs set quota=30G pool/home/bob
```

EXAMPLE 7  Listing ZFS Properties

The following command lists all properties for pool/home/bob.

```
# zfs get all pool/home/bob
NAME PROPERTY VALUE SOURCE
pool/home/bob type filesystem -
pool/home/bob creation Tue Apr 12 15:00 2011 -
pool/home/bob used 31K -
pool/home/bob available 30.0G -
pool/home/bob referenced 31K -
pool/home/bob compressratio 1.00x -
pool/home/bob mounted yes -
pool/home/bob quota 30G local
```

The following command gets a single property value.

```bash
# zfs get -H -o value compression pool/home/bob
```

The following command lists all properties with local settings for pool/home/bob.

```bash
# zfs get -r -s local -o name,property,value all pool/home/bob
```

**NAME** | **PROPERTY** | **VALUE**
---|---|---

EXAMPLE 7  Listing ZFS Properties  (Continued)

pool/home/bob  quota  30G
pool/home/bob  compression  on

EXAMPLE 8  Rolling Back a ZFS File System

The following command reverts the contents of pool/home/anne to the snapshot named yesterday, deleting all intermediate snapshots.

# zfs rollback -r pool/home/anne@yesterday

EXAMPLE 9  Creating a ZFS Clone

The following command creates a writable file system whose initial contents are the same as pool/home/bob@yesterday.

# zfs clone pool/home/bob@yesterday pool/clone

EXAMPLE 10  Promoting a ZFS Clone

The following commands illustrate how to test out changes to a file system, and then replace the original file system with the changed one, using clones, clone promotion, and renaming:

# zfs create pool/project/production
    populate /pool/project/production with data
# zfs snapshot pool/project/production@today
# zfs clone pool/project/production@today pool/project/beta
    make changes to /pool/project/beta and test them
# zfs promote pool/project/beta
# zfs rename pool/project/production pool/project/legacy
# zfs rename pool/project/beta pool/project/production
    once the legacy version is no longer needed, it can be destroyed
# zfs destroy pool/project/legacy

EXAMPLE 11  Inheriting ZFS Properties

The following command causes pool/home/bob and pool/home/anne to inherit the checksum property from their parent.

# zfs inherit checksum pool/home/bob pool/home/anne

EXAMPLE 12  Remotely Replicating ZFS Data

The following commands send a full stream and then an incremental stream to a remote machine, restoring them into poolB/received/fs@aand poolB/received/fs@b, respectively. poolB must contain the file system poolB/received, and must not initially contain poolB/received/fs.

# zfs send pool/fs@a | \
    ssh host zfs receive poolB/received/fs@a
EXAMPLE 12  Remotely Replicating ZFS Data  (Continued)

```bash
# zfs send -i a pool/fs@b | ssh host 
   zfs receive poolB/received/fs
```

EXAMPLE 13  Using the `zfs receive -d` Option

The following command sends a full stream of `poolA/fsA/fsB@snap` to a remote machine, receiving it into `poolB/received/fsA/fsB@snap`. The `fsA/fsB@snap` portion of the received snapshot’s name is determined from the name of the sent snapshot. `poolB` must contain the filesystem `poolB/received`. If `poolB/received/fsA` does not exist, it is created as an empty file system.

```bash
# zfs send poolA/fsA/fsB@snap | 
   ssh host zfs receive -d poolB/received
```

EXAMPLE 14  Setting User Properties

The following example sets the user–defined `com.example:department` property for a dataset.

```bash
# zfs set com.example:department=12345 tank/accounting
```

EXAMPLE 15  Performing a Rolling Snapshot

The following example shows how to maintain a history of snapshots with a consistent naming scheme. To keep a week’s worth of snapshots, the user destroys the oldest snapshot, renames the remaining snapshots, and then creates a new snapshot, as follows:

```bash
# zfs destroy -r pool/users@7daysago
# zfs rename -r pool/users@6daysago @7daysago
# zfs rename -r pool/users@5daysago @6daysago
# zfs rename -r pool/users@4daysago @5daysago
# zfs rename -r pool/users@3daysago @4daysago
# zfs rename -r pool/users@2daysago @3daysago
# zfs rename -r pool/users@yesterday @2daysago
# zfs rename -r pool/users@today @yesterday
# zfs snapshot -r pool/users@today
```

EXAMPLE 16  Setting `share nfs` Property Options on a ZFS File System

The following commands show how to set `share nfs` property options to enable `rw` access for a set of IP addresses and to enable root access for system `neo` on the `tank/home` file system.

```bash
# # zfs set share nfs="rw=@123.123.0.0/16,root=neo" tank/home
```

If you are using DNS for host name resolution, specify the fully qualified hostname.
EXAMPLE 17  Delegating ZFS Administration Permissions on a ZFS Dataset
The following example shows how to set permissions so that user anne can create, destroy, mount, and take snapshots on pool/home/anne. The permissions on pool/home/anne are also displayed.

```
# zfs allow anne create,destroy,mount,snapshot pool/home/anne
# zfs allow pool/home/anne
--- Permissions on pool/home/anne -------------------------------
Local+Descendent permissions:
          user anne create,destroy,mount,snapshot
```

Because the pool/home/anne mount point permission is set to 755 by default, user anne will be unable to mount file systems under pool/home/anne. Set an ACL similar to the following syntax to provide mount point access:

```
# chmod A+user:anne:add_subdirectory:allow /pool/home/anne
```

EXAMPLE 18  Delegating Create Time Permissions on a ZFS Dataset
The following example shows how to grant anyone in the group staff to create file systems in pool/home. This syntax also allows staff members to destroy their own file systems, but not destroy anyone else's file system. The permissions on pool/home are also displayed.

```
# zfs allow staff create,mount pool/home
# zfs allow -c destroy pool/home
# zfs allow pool/home
--- Permissions on pool/home -------------------------------
Create time permissions:
         destroy
Local+Descendent permissions:
          group staff create,mount
```

EXAMPLE 19  Defining and Granting a Permission Set on a ZFS Dataset
The following example shows how to define and grant a permission set on the pool/home file system. The permissions on pool/home are also displayed.

```
# zfs allow -s @pset create,destroy,snapshot,mount pool/home
# zfs allow staff @pset pool/home
# zfs allow pool/home
--- Permissions on pool/home -------------------------------
Permission sets:
 @pset create,destroy,snapshot,mount
Create time permissions:
         destroy
Local+Descendent permissions:
          group staff @pset,create,mount
```
EXAMPLE 20  Delegating Property Permissions on a ZFS Dataset

The following example shows how to grant the ability to set quotas and reservations on the tank/users file system. The permissions on tank/users are also displayed.

```
# zfs allow mark quota,reservation tank/users
# zfs allow tank/users

---- Permissions on tank/users ---------------------------------------
Local+Descendent permissions:
  user mark quota,reservation

mark% zfs set quota=10G tank/users/tim
mark% zfs get quota tank/users/tim
NAME PROPERTY VALUE SOURCE
  tank/users/tim quota 10G local
```

EXAMPLE 21  Removing ZFS Delegated Permissions on a ZFS Dataset

The following example shows how to remove the snapshot permission from the @pset permission set for the staff group on the pool/home file system. The permissions on pool/home are also displayed.

```
# zfs unallow -s @pset snapshot pool/home
# zfs allow pool/home

---- Permissions on pool/home ----------------------------------------
Permission sets:
  @pset create,destroy,mount
Create time permissions:
  destroy
Local+Descendent permissions:
  group staff @pset,create,mount
```

EXAMPLE 22  Displaying ZFS Snapshot Differences

The following command shows the output from a zfs diff command with the -F and -t options.

```
# zfs diff -Ft myfiles@snap1
 1269962501.206726811 M / /myfiles/
 1269962444.207369955 M F /myfiles/link_to_me (+1)
 1269962499.207519834 R /myfiles/ rename_me -> /myfiles/renamed
 1269962431.813566720 - F /myfiles/delete_me
 1269962518.666905544 + F /myfiles/new_file
 1269962501.393099817 + | /myfiles/new_pipe
```

Exit Status  The following exit values are returned:

0  Successful completion.
1
   An error occurred.

2
   Invalid command line options were specified.

Notes

A file described as modified by the diff subcommand might have been modified in multiple ways. Any action that causes a change in the st_ctim (see stat(2)) is a basis for reporting a modification.
Name  zic – time zone compiler

[-d directory] [-y yearistype] [filename]...

Description  zic reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a filename is ‘-’, the standard input is read.

Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment that extends to the end of the line. White space characters and pound signs can be enclosed within double quotes (“”) if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.

Rule  A rule line has the form:

For example:

Rule  NAME FROM TO TYPE IN ON AT SAVE LETTER/S

The fields that make up a rule line are:

Rule  USA 1969 1973 - Apr lastSun 2:00 1:00 D

NAME  Gives the (arbitrary) name of the set of rules this rule is part of.

FROM  Gives the first year in which the rule applies. The word minimum (or an abbreviation) means the minimum year with a representable time value. The word maximum (or an abbreviation) means the maximum year with a representable time value.

TO  Gives the final year in which the rule applies. In addition to minimum and maximum (as above), the word only (or an abbreviation) can be used to repeat the value of the FROM field.

TYPE  Gives the type of year in which the rule applies. If TYPE is:

‘-’  The rule applies in all years between FROM and TO, inclusive.

uspres  The rule applies in U.S. Presidential election years.

nonpres  The rule applies in years other than U.S. Presidential election years.

even  The rule applies to even-numbered years.

odd  The rule applies to odd-numbered years.

If TYPE is something else, then zic will attempt to execute the command

yearistype year type
to check the type of a year: an exit status of 0 means that the year is of the given type; an exit status of 1 means that the year is not of the given type. The `year1s type` command is not currently provided in the Solaris environment.

**IN**
Names the month in which the rule takes effect. Month names can be abbreviated.

**ON**
Gives the day on which the rule takes effect. Recognized forms include:
- `5` the fifth day of the month
- `lastSun` The last Sunday in the month
- `lastMon` The last Monday in the month
- `Sun>=8` First Sunday on or after the eighth
- `Sun<=25` Last Sunday on or before the 25th

Names of days of the week can be abbreviated or spelled out in full. Note: There cannot be spaces within the **ON** field.

**AT**
Gives the time of day at which the rule takes effect. Recognized forms include:
- `2` Time in hours
- `2:00` Time in hours and minutes
- `15:00` 24-hour format time (for times after noon)
- `1:28:14` Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.

Any of these forms can be followed by the letter w if the given time is local “wall clock” time; s if the given time is local “standard” time; or u (or g or z) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.

**SAVE**
Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the **AT** field (without the w and s suffixes).

**LETTER/S**
Gives the “variable part” (for example, the “S” or “D” in “EST” or “EDT” of time zone abbreviations to be used when this rule is in effect. If this field is ‘−’, the variable part is null.

**Zone**
A zone line has the form:
```
Zone  NAME  GMTOFF  RULES/SAVE  FORMAT  [UNTIL]
```

For example:
The fields that make up a zone line are:

**NAME**
- The name of the time zone. This is the name used in creating the time conversion information file for the zone.

**GMTOFF**
- The amount of time to add to UTC to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign to subtract time from UTC.

**RULES/SAVE**
- The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is ‘−’, then standard time always applies in the time zone.

**FORMAT**
- The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the “variable part” of the time zone abbreviation goes. Alternately, a slash (/) separates standard and daylight abbreviations.

**UNTIL**
- The time at which the UTC offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given UTC offset and rule change until the time specified.

The month, day, and time of day have the same format as the IN, ON, and AT columns of a rule; trailing columns can be omitted, and default to the earliest possible value for the missing columns.

The next line must be a “continuation” line. This line has the same form as a zone line except that the string “Zone” and the name are omitted. The continuation line places information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines can contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.

**Link**
- A link line has the form:

  Link  LINK-FROM  LINK-TO

  For example:

  Link  Europe/Istanbul  Asia/Istanbul

  The LINK-FROM field should appear as the NAME field in some zone line; the LINK-TO field is used as an alternate name for that zone.
Except for continuation lines, lines can appear in any order in the input.

**Options**

- **-version** Outputs version information and exits.
- **-d directory** Creates time conversion information files in the directory `directory` rather than in the standard directory `/usr/share/lib/zoneinfo`.
- **-l localtime** Uses the given time zone as local time `localtime`. `zic` acts as if the file contained a link line of the form:
  
  Link `localtime` `localtime`

- **-p posixrules** Uses the rules of the given time zone `posixrules` when handling POSIX-format time zone environment variables. `zic` acts as if the input contained a link line of the form:
  
  Link `posixrules` `posixrules`

  This option is not used by `ctime(3C)` and `mktime(3C)` in the Solaris environment.

- **-s** Limits time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.

  This option is obsolete and may be removed in a future release.

- **-v** Complains if a year that appears in a data file is outside the range of years representable by system time values (0:00:00 a.m. UTC, January 1, 1970, to 3:14:07 a.m. UTC, January 19, 2038). This option also complains if a time of 24:00 (which cannot be handled by pre-1998 versions of `zic`) appears in the input.

- **-y yearistype** Uses the given command `yearistype` rather than `yearistype` when checking year types (see Rules under DESCRIPTION).

**Operands**

- **filename** A file containing input lines that specify the time conversion information files to be created. If a `filename` is `−`, the standard input is read.

**Files**

- `/usr/share/lib/zoneinfo` Standard directory used for created files
- `/usr/share/lib/zoneinfo/src` Directory containing source files

**Attributes**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWcsu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed*</td>
</tr>
</tbody>
</table>
* The -s option is obsolete.

**See Also** `time(1), zdump(1M), ctime(3C), mktime(3C), attributes(5)`

**Notes** For areas with more than two types of local time, you might need to use local standard time in the AT field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

If the current `timezone` file is edited and compiled using the "zic" command, the changes will only be reflected in any new processes that are running. The most accurate way to reflect the changes for the whole system would be a reboot.
**Zoneadm**

**Name**
zoneadm – administer zones

**Synopsis**
zoneadm -z zonename [-u uuid-match] subcommand
  [subcommand_options]

zoneadm [-R root] [-z zonename] [-u uuid-match] list
  [list_options]

zoneadm [-R root] -z zonename [-u uuid-match] mark incomplete

**Description**
The zoneadm utility is used to administer system zones. A zone is an application container that is maintained by the operating system runtime.

**Security**
Once a process has been placed in a zone other than zone 0, the process or any of its children cannot change zones.

**Options**
The following options are supported:

- `-R root`
  Specify an alternate root (boot environment). This option can only be used in conjunction with the “list” and “mark” subcommands.

- `-u uuid-match`
  Unique identifier for a zone, as assigned by libuuid(3LIB). If this option is present and the argument is a non-empty string, then the zone matching the UUID is selected instead of the one named by the `-z` option, if such a zone is present.

- `-z zonename`
  String identifier for a zone.

**Subcommands**
Subcommands which can result in destructive actions or loss of work have a `-F` flag to force the action. If input is from a terminal device, the user is prompted if such a command is given without the `-F` flag; otherwise, if such a command is given without the `-F` flag, the action is disallowed, with a diagnostic message written to standard error. If a zone installation or uninstallation is interrupted, the zone is left in the incomplete state. Use uninstall to reset such a zone back to the configured state.

The following subcommands are supported:

**attach**
attach [-u] [-U] [-b patchid]... [-F] [-n path] [brand-specific options]

The attach subcommand takes a zone that has been detached from one system and attaches the zone onto a new system. Therefore, it is advised (though not required) that the detach subcommand should be run before the “attach” takes place. Once you have the new zone in the configured state, use the attach subcommand to set up the zone root instead of installing the zone as a new zone.

For native zones, zoneadm checks package and patch levels on the machine to which the zone is to be attached. If the packages/patches that the zone depends on from the global zone are different (have different revision numbers) from the dependent packages/patches on the source machine, zoneadm reports these conflicts and does not perform the attach. If
the destination system has only newer dependent packages/patches (higher revision numbers) than those on the source system, you can use the \texttt{-u} or \texttt{-U} options. The \texttt{-u} option updates the minimum number of packages within the attached zone to match the higher-revision packages and patches that exist on the new system. The \texttt{-U} option updates all packages in the attached zone that are also installed in the global zone. With \texttt{-u} or \texttt{-U}, as in the default behavior, \texttt{zoneadm} does not perform an attach if outdated packages/patches are found on the target system.

For native zones, one or more \texttt{-b} options can be used to specify a patch ID for a patch installed in the zone. These patches will be backed out before the zone is attached or, if \texttt{-u} was also specified, updated. If multiple \texttt{-b} options are specified, the patches will be removed in the order that they appear on the command line. Patches should be backed out in the reverse order in which they were installed.

The \texttt{-F} option can be used to force the zone into the “installed” state with no validation. This option should be used with care since it can leave the zone in an unsupportable state if it was moved from a source system to a target system that is unable to properly host the zone. The \texttt{-n} option can be used to perform a “dry run” of the \texttt{attach} subcommand. It uses the output of the “\texttt{detach -n}” subcommand as input and is useful to identify any conflicting issues, such as the network device being incompatible, and can also determine whether the host is capable of supporting the zone. The path can be “\texttt{-}”, to read the input from standard input.

The zone’s brand may include additional options that govern how the zone will be attached. See \texttt{brands(5)} for specific brand information.

The zone being attached must first be configured using the \texttt{zonecfg} (see \texttt{zonecfg(1M)}) command. This does not apply when running “\texttt{attach -n}”.

Use the following command to attach a zone:

\begin{verbatim}
# zoneadm -z my-zone attach
\end{verbatim}

Use the following command to attach and update a zone:

\begin{verbatim}
# zoneadm -z my-zone attach -u (or -U)
\end{verbatim}

In the absence of \texttt{-n} (as above), the source zone must be halted before this subcommand can be used.

\texttt{-n path}

Read the zone manifest and verify that the target machine has the correct configuration to host the zone without actually performing an attach. The zone on the target system does not have to be configured on the new host before doing a trial-run attach.

\texttt{-u} or \texttt{-U}

Update the attached zone as described above.
The following boot_options are supported:

- `i altinit`
  Select an alternative executable to be the primordial Process. `altinit` is a valid path to an executable. The default primordial process is `init(1M)`.

- `-m smf_options`
  The smf_options include two categories of options to control booting behavior of the service management facility: recovery options and messages options.

  Message options determine the type and amount of messages that `smf(5)` displays during boot. Service options determine the services which are used to boot the system. See `kernel(1M)` for a listing of the -m suboptions.

- `s`
  Boots only to milestone svc:/milestone/single-user:default. This milestone is equivalent to init level s. See `svc.startd(1M)` and `init(1M)`.

clone [-m copy] [-s zfs_snapshot] source_zone

Install a zone by copying an existing installed zone. This subcommand is an alternative way to install the zone.

- `-m copy`
  Force the clone to be a copy, even if a “ZFS clone” is possible.

- `-s zfs_snapshot`
  Specify the name of a ZFS snapshot to use as the source of the clone. The snapshot must be a snapshot of the source zone taken from a previous “zoneadm clone” installation.

  The source zone must be halted before this subcommand can be used.

detach [-n]

Detach the specified zone. Detaching a zone is the first step in moving a zone from one system to another. The full procedure to migrate a zone is that the zone is detached, the zonepath directory is moved to the new host, and then the zone is attached on the new host.

Once the zone is detached, it is left in the configured state. If you try to install or clone to a configured zone that has been detached, you will receive an error message and the install or clone subcommand will not be allowed to proceed. The -n option can be used to perform a “dry run” of the detach subcommand. This generates the information needed for running the “attach -n” subcommand, which is useful to identify any conflicting issues, such as the network device being incompatible or if the host is capable of supporting the zone. The information is sent to standard output and can be saved to a file or piped to the “attach -n” subcommand.

Use the following command to detach a zone:

```
# zoneadm -z my-zone detach
```
Unless the \texttt{-n} option is used, the source zone must be halted before this subcommand can be used.

\texttt{-n}

Generate a zone manifest on a running zone without actually detaching the zone. The state of the zone on the originating system is not changed. The zone manifest is sent to standard output. The global administrator can direct this output to a file or pipe it to a remote command to be immediately validated on the target host.

\texttt{halt}

Halt the specified zones. \texttt{halt} bypasses running the shutdown scripts inside the zone. It also removes run time resources of the zone.

\texttt{Use:}

\texttt{zlogin zone shutdown}

to cleanly shutdown the zone by running the shutdown scripts.

\texttt{help [subcommand]}

Display general help. If you specify \texttt{subcommand}, displays help on \texttt{subcommand}.

\texttt{install [-x nodataset] [brand-specific options]}

Install the specified zone on the system. This subcommand automatically attempts to verify first. It refuses to install if the verify step fails. See the \texttt{verify} subcommand.

The zone’s brand may include additional options that govern how the software will be installed in the zone. See \texttt{brands(5)} for specific brand information.

\texttt{-x nodataset}

Do not create a ZFS file system.

\texttt{list [list_options]}

Display the name of the current zones, or the specified zone if indicated.

By default, all running zones are listed. If you use this subcommand with the \texttt{zoneadm -z zonename} option, it lists only the specified zone, regardless of its state. In this case, the \texttt{-i} and \texttt{-c} options are disallowed.

If neither the \texttt{-i} or \texttt{-c} options are given, all running zones are listed.

The following \texttt{list_options} are supported:

\texttt{-c}

Display all configured zones. This option overrides the \texttt{-i} option.

\texttt{-i}

Expand the display to all installed zones.

\texttt{-p}

Request machine parsable output. The output format is a list of lines, one per zone, with colon-delimited fields. These fields are:
If the zonepath contains embedded colons, they can be escaped by a backslash ("\:"), which is parsable by using the shell `read(1)` function with the environmental variable IFS. The `uuid` value is assigned by `libuuid(3LIB)` when the zone is installed, and is useful for identifying the same zone when present (or renamed) on alternate boot environments. Any software that parses the output of the "zoneadm list -p" command must be able to handle any fields that may be added in the future.

The `-v` and `-p` options are mutually exclusive. If neither `-v` nor `-p` is used, just the zone name is listed.

```
-v
```
Display verbose information, including zone name, id, current state, root directory, brand type, ip-type, and options.

The `-v` and `-p` options are mutually exclusive. If neither `-v` nor `-p` is used, just the zone name is listed.

`mark incomplete`
Change the state of an installed zone to "incomplete." This command may be useful in cases where administrative changes on the system have rendered a zone unusable or inconsistent. This change cannot be undone (except by uninstalling the zone).

`move new_zonepath`
Move the zonepath to new_zonepath. The zone must be halted before this subcommand can be used. The new_zonepath must be a local file system and normal restrictions for zonepath apply.

`ready`
Prepares a zone for running applications but does not start any user processes in the zone.

`reboot`
Restart the zones. This is equivalent to a halt boot sequence. This subcommand fails if the specified zones are not active.

`uninstall [-F]`
Uninstall the specified zone from the system. Use this subcommand with caution. It removes all of the files under the zonepath of the zone in question. You can use the `-F` flag to force the action.

`verify`
Check to make sure the configuration of the specified zone can safely be installed on the machine. Following is a break-down of the checks by resource/property type:

```
zonepath
zonepath and its parent directory exist and are owned by root with appropriate modes.
The appropriate modes are that zonepath is 700, its parent is not group or world-writable and so forth. zonepath is not over an NFS mount. A sub-directory of the zonepath named “root” does not exist.
```
If `zonepath` does not exist, the `verify` does not fail, but merely warns that a subsequent install will attempt to create it with proper permissions. A `verify` subsequent to that might fail should anything go wrong.

`zonepath` cannot be a symbolic link.

**fs**

Any `fs` resources have their `type` value checked. An error is reported if the value is one of `proc`, `mntfs`, `autofs`, `cachefs`, or `nfs` or the filesystem does not have an associated mount binary at `/usr/lib/fs/<fstype>/mount`.

It is an error for the `directory` to be a relative path.

It is an error for the path specified by `raw` to be a relative path or if there is no `fsck` binary for a given filesystem type at `/usr/lib/fs/<fstype>/fsck`. It is also an error if a corresponding `fsck` binary exists but a `raw` path is not specified.

**net**

All physical network interfaces exist. All network address resources are one of:

- a valid IPv4 address, optionally followed by "/" and a prefix length;
- a valid IPv6 address, which must be followed by "/" and a prefix length;
- a host name which resolves to an IPv4 address.

Note that hostnames that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, both the physical and address properties must be set. For an exclusive-IP zone, the physical property must be set and the address property cannot be set.

**rcctl**

It also verifies that any defined resource control values are valid on the current machine. This means that the privilege level is `privileged`, the limit is lower than the currently defined system value, and that the defined action agrees with the actions that are valid for the given resource control.

**Examples**

**EXAMPLE 1** Using the `-m` Option

The following command illustrates the use of the `-m` option.

```
# zoneadm boot -- -m verbose
```

**EXAMPLE 2** Using the `-i` Option

The following command illustrates the use of the `-i` option.

```
# zoneadm boot -- -i /sbin/init
```
EXAMPLE 3   Using the -s Option

The following command illustrates the use of the -s option.

```
# zoneadm boot -- -s
```

**Exit Status**   The following exit values are returned:

0
  Successful completion.

1
  An error occurred.

2
  Invalid usage.

**Attributes**   See attributes(5) for descriptions of the following attributes:

```
<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>system/zones</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Committed</td>
</tr>
</tbody>
</table>
```

**See Also**   read(1), svcs(1), zlogin(1), zonename(1), init(1M), kernel(1M), svcadm(1M), svc.startd(1M), svc.startd(1M), zonecfg(1M), libuuid(3LIB), attributes(5), brands(5), native(5), smf(5), zones(5)

**Notes**   The zones(5) service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The act of installing a new non-global zone is a fresh installation of the Solaris operating system. A new installation of Solaris must not require interaction with the user (that is, it must be “hands off”). Because of this, packages installed in the global zone and all non-global zones cannot contain request scripts (see pkgask(1M)). If a package did have a request script, then the creation of a non-global zone could not be done without user intervention. Any package that contains a request script is added to the global zone only. See pkgadd(1M).
zoneadm(1M)

Name  
zoneadm – zone administration daemon

Synopsis  
/usr/lib/zones/zoneadm

Description  
zoneadm is a system daemon that is started when the system needs to manage a particular zone. Because each instance of the zoneadm daemon manages a particular zone, it is not unexpected to see multiple zoneadm daemons running.

This daemon is started automatically by the zone management software and should not be invoked directly. The daemon shuts down automatically when no longer in use. It does not constitute a programming interface, but is classified as a private interface.

Attributes  
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Availability</td>
<td>SUNWzoneu</td>
</tr>
<tr>
<td>Interface Stability</td>
<td>Private</td>
</tr>
</tbody>
</table>

See Also

Notes  
The zones(5) service is managed by the service management facility, smf(5), under the service identifier:
	svc:/system/zones:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.
### zonecfg(1M)

<table>
<thead>
<tr>
<th>Name</th>
<th>zonecfg – set up zone configuration</th>
</tr>
</thead>
</table>
| Synopsis | zonecfg -z zonename  
zonecfg -z zonename subcommand  
zonecfg -z zonename -f command_file  
zonecfg help |
| Description | The `zonecfg` utility creates and modifies the configuration of a zone. Zone configuration consists of a number of resources and properties. To simplify the user interface, `zonecfg` uses the concept of a scope. The default scope is global. The following synopsis of the `zonecfg` command is for interactive usage:  
`zonecfg -z zonename subcommand`  
Parameters changed through `zonecfg` do not affect a running zone. The zone must be rebooted for the changes to take effect.  
In addition to creating and modifying a zone, the `zonecfg` utility can also be used to persistently specify the resource management settings for the global zone.  
In the following text, "rctl" is used as an abbreviation for "resource control". See `resource_controls(5)`.  
Every zone is configured with an associated brand. The brand determines the user-level environment used within the zone, as well as various behaviors for the zone when it is installed, boots, or is shutdown. Once a zone has been installed the brand cannot be changed. The default brand is determined by the installed distribution in the global zone. Some brands do not support all of the `zonecfg` properties and resources. See the brand-specific man page for more details on each brand. For an overview of brands, see the `brands(5)` man page. |
| Resources | The following resource types are supported:  
attr  
Generic attribute.  
capped-cpu  
Limits for CPU usage.  
capped-memory  
Limits for physical, swap, and locked memory.  
dataset  
ZFS dataset.  
dedicated-cpu  
Subset of the system’s processors dedicated to this zone while it is running. |
In the administration of zones, it is useful to distinguish between the global zone and non-global zones. Within non-global zones, there are two zone root file system models: sparse and whole root. The sparse root zone model optimizes the sharing of objects. The whole root zone model provides the maximum configurability. Note that not all brands support the sparse zone model.

Sparse Root Zones

Non-global zones that have `inherit-pkg-dir` resources are called sparse root zones.

The sparse root zone model optimizes the sharing of objects in the following ways:

- Only a subset of the packages installed in the global zone are installed directly into the non-global zone.
- Read-only loopback file systems, identified as `inherit-pkg-dir` resources, are used to gain access to other files.

In this model, all packages appear to be installed in the non-global zone. Packages that do not deliver content into read-only loopback mount file systems are fully installed. There is no need to install content delivered into read-only loopback mounted file systems since that content is inherited (and visible) from the global zone.

- As a general guideline, a zone requires about 100 megabytes of free disk space per zone when the global zone has been installed with all of the standard Solaris packages.
- By default, any additional packages installed in the global zone also populate the non-global zones. The amount of disk space required might be increased accordingly, depending on whether the additional packages deliver files that reside in the `inherit-pkg-dir` resource space.
An additional 40 megabytes of RAM per zone are suggested, but not required on a machine with sufficient swap space.

A sparse zone inherits the following directories:

```
/lib
/platform
/sbin
/usr
```

Although `zonecfg` allows you to remove one of these as an inherited directory, you should not do so. You should either follow the whole-root model or the sparse model; a subset of the sparse model is not tested and you might encounter unexpected problems.

Adding an additional `inherit-pkg-dir` directory, such as `/opt`, to a sparse root zone is acceptable.

**Whole Root Zones**

The whole root zone model provides the maximum configurability. All of the required and any selected optional Solaris packages are installed into the private file systems of the zone. The advantages of this model include the capability for global administrators to customize their zones file system layout. This would be done, for example, to add arbitrary unbundled or third-party packages.

The disk requirements for this model are determined by the disk space used by the packages currently installed in the global zone.

**Note** – If you create a sparse root zone that contains the following `inherit-pkg-dir` directories, you must remove these directories from the non-global zone’s configuration before the zone is installed to have a whole root zone:

- `/lib`
- `/platform`
- `/sbin`
- `/usr`

Each resource type has one or more properties. There are also some global properties, that is, properties of the configuration as a whole, rather than of some particular resource.

The following properties are supported:

```plaintext
(global)
  zonename

(global)
  zonepath

(global)
  autoboot
```
(global)
  bootargs

(globals)
  pool

(globals)
  limitpriv

(globals)
  brand

(globals)
  cpu-shares

(globals)
  hostid

(globals)
  max-lwps

(globals)
  max-msg-ids

(globals)
  max-sem-ids

(globals)
  max-shm-ids

(globals)
  max-shm-memory

(globals)
  scheduling-class

fs
  dir, special, raw, type, options

inherit-pkg-dir
  dir

net
  address, physical, defrouter

device
  match

rctl
  name, value

attr
  name, type, value
dataset name
dedicated-cpu ncpus,importance
capped-memory physical,swap,locked
capped-cpu ncpus

As for the property values which are paired with these names, they are either simple, complex, or lists. The type allowed is property-specific. Simple values are strings, optionally enclosed within quotation marks. Complex values have the syntax:

\(<name>=<value>,<name>=<value>,\ldots\>

where each \(<value>\) is simple, and the \(<name>\) strings are unique within a given property.

Lists have the syntax:

\([<value>,\ldots]\)

where each \(<value>\) is either simple or complex. A list of a single value (either simple or complex) is equivalent to specifying that value without the list syntax. That is, "foo" is equivalent to "[foo]". A list can be empty (denoted by "[]").

In interpreting property values, zonecfg accepts regular expressions as specified in fnmatch(5). See EXAMPLES.

The property types are described as follows:

global: zonename
   The name of the zone.

global: zonepath
   Path to zone's file system.

global: autoboot
   Boolean indicating that a zone should be booted automatically at system boot. Note that if the zones service is disabled, the zone will not autoboot, regardless of the setting of this property. You enable the zones service with a svcadm command, such as:

   \# svcadm enable svc:/system/zones:default

   Replace enable with disable to disable the zones service. See svcadm(1M).

global: bootargs
   Arguments (options) to be passed to the zone bootup, unless options are supplied to the "zoneadm boot" command, in which case those take precedence. The valid arguments are described in zoneadm(1M).
global: pool
Name of the resource pool that this zone must be bound to when booted. This property is incompatible with the dedicated-cpu resource.

global: limitpriv
The maximum set of privileges any process in this zone can obtain. The property should consist of a comma-separated privilege set specification as described in priv_str_to_set(3C). Privileges can be excluded from the resulting set by preceding their names with a dash (-) or an exclamation point (!). The special privilege string "zone" is not supported in this context. If the special string "default" occurs as the first token in the property, it expands into a safe set of privileges that preserve the resource and security isolation described in zones(5). A missing or empty property is equivalent to this same set of safe privileges.

The system administrator must take extreme care when configuring privileges for a zone. Some privileges cannot be excluded through this mechanism as they are required in order to boot a zone. In addition, there are certain privileges which cannot be given to a zone as doing so would allow processes inside a zone to unduly affect processes in other zones. zoneadm(1M) indicates when an invalid privilege has been added or removed from a zone's privilege set when an attempt is made to either "boot" or "ready" the zone.

See privileges(5) for a description of privileges. The command "ppriv -l" (see ppriv(1)) produces a list of all Solaris privileges. You can specify privileges as they are displayed by ppriv. In privileges(5), privileges are listed in the form PRIV_privilege_name. For example, the privilege sys_time, as you would specify it in this property, is listed in privileges(5) as PRIV_SYS_TIME.

global: brand
The zone's brand type.

global: ip-type
A zone can either share the IP instance with the global zone, which is the default, or have its own exclusive instance of IP.

This property takes the values shared and exclusive.

global: hostid
A zone can emulate a 32-bit host identifier to ease system consolidation. A zone's hostid property is empty by default, meaning that the zone does not emulate a host identifier. Zone host identifiers must be hexadecimal values between 0 and FFFFFFFE. A 0x or 0X prefix is optional. Both uppercase and lowercase hexadecimal digits are acceptable.

fs: dir, special, raw, type, options
Values needed to determine how, where, and so forth to mount file systems. See mount(1M), mount(2), fsck(1M), and vfstab(4).

inherit-pkg-dir: dir
The directory path.
net: address, physical, defrouter

The network address and physical interface name of the network interface. The network address is one of:

- a valid IPv4 address, optionally followed by "/" and a prefix length;
- a valid IPv6 address, which must be followed by "/" and a prefix length;
- a host name which resolves to an IPv4 address.

Note that host names that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

The value for the optional default router is specified similarly to the network address except that it must not be followed by a / (slash) and a network prefix length. To enable correct use of the defrouter functionality, the zones that use the property must be on a different subnet from the subnet on which the global zone resides. Also, each zone (or set of zones) that uses a different defrouter setting must be on a different subnet.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, you must set both the physical and address properties; setting the default router is optional. The interface specified in the physical property must be plumbed in the global zone prior to booting the non-global zone. However, if the interface is not used by the global zone, it should be configured down in the global zone, and the default router for the interface should be specified here.

For an exclusive-IP zone, the physical property must be set and the address and default router properties cannot be set. Note that a single datalink cannot be shared among multiple exclusive-IP zones.

device: match

Device name to match.

crl: name, value

The name and priv-limit/action triple of a resource control. See prctl(1) and rctladm(1M). The preferred way to set crl values is to use the global property name associated with a specific crl.

attr: name, type, value

The name, type and value of a generic attribute. The type must be one of int, uint, boolean or string, and the value must be of that type. uint means unsigned, that is, a non-negative integer.

dataset: name

The name of a ZFS dataset to be accessed from within the zone. See zfs(1M).

global: cpu-shares

The number of Fair Share Scheduler (FSS) shares to allocate to this zone. This property is incompatible with the dedicated-cpu resource. This property is the preferred way to set the zone.cpushares rctl.
global: `max-lwps`
   The maximum number of LWPs simultaneously available to this zone. This property is the
   preferred way to set the zone's `max-lwps` rctl.

global: `max-msg-ids`
   The maximum number of message queue IDs allowed for this zone. This property is the
   preferred way to set the zone's `max-msg-ids` rctl.

global: `max-sem-ids`
   The maximum number of semaphore IDs allowed for this zone. This property is the
   preferred way to set the zone's `max-sem-ids` rctl.

global: `max-shm-ids`
   The maximum number of shared memory IDs allowed for this zone. This property is the
   preferred way to set the zone's `max-shm-ids` rctl.

global: `max-shm-memory`
   The maximum amount of shared memory allowed for this zone. This property is the
   preferred way to set the zone's `max-shm-memory` rctl. A scale (K, M, G, T) can be applied
to the value for this number (for example, 1M is one megabyte).

global: `scheduling-class`
   Specifies the scheduling class used for processes running in a zone. When this property is
   not specified, the scheduling class is established as follows:
   - If the `cpu-shares` property or equivalent rctl is set, the scheduling class FSS is used.
   - If neither `cpu-shares` nor the equivalent rctl is set and the zone's pool property
     references a pool that has a default scheduling class, that class is used.
   - Under any other conditions, the system default scheduling class is used.

dedicated-cpu: `ncpu, importance`
   The number of CPUs that should be assigned for this zone's exclusive use. The zone will
   create a pool and processor set when it boots. See `pooladm(1M)` and `poolcfg(1M)` for more
   information on resource pools. The `ncpu` property can specify a single value or a range (for
   example, 1-4) of processors. The `importance` property is optional; if set, it will specify the
   `pset.importance` value for use by `pooladm(1M)`. If this resource is used, there must be
   enough free processors to allocate to this zone when it boots or the zone will not boot. The
   processors assigned to this zone will not be available for the use of the global zone or other
   zones. This resource is incompatible with both the `pool` and `cpu-shares` properties. Only a
   single instance of this resource can be added to the zone.

capped-memory: `physical, swap, locked`
   The caps on the memory that can be used by this zone. A scale (K, M, G, T) can be applied
to the value for each of these numbers (for example, 1M is one megabyte). Each of these
   properties is optional but at least one property must be set when adding this resource. Only
   a single instance of this resource can be added to the zone. The `physical` property sets the
   `max-rss` for this zone. This will be enforced by `rcapd(1M)` running in the global zone. The
The swap property is the preferred way to set the zone.max-swap rctl. The locked property is the preferred way to set the zone.max-locked-memory rctl.

**capped-cpu: ncpus**
Sets a limit on the amount of CPU time that can be used by a zone. The unit used translates to the percentage of a single CPU that can be used by all user threads in a zone, expressed as a fraction (for example, .75) or a mixed number (whole number and fraction, for example, 1.25). An ncpu value of 1 means 100% of a CPU, a value of 1.25 means 125%, .75 means 75%, and so forth. When projects within a capped zone have their own caps, the minimum value takes precedence.

The capped-cpu property is an alias for zone.cpu-cap resource control and is related to the zone.cpu-cap resource control. See resource_controls(5).

</tbody>
</table>
To further specify things, the breakdown of the complex property "value" of the "rctl" resource type, it consists of three name/value pairs, the names being "priv", "limit" and "action", each of which takes a simple value. The "name" property of an "attr" resource is syntactically restricted in a fashion similar but not identical to zone names: it must begin with an alphanumeric, and can contain alphanumeric plus the hyphen (-), underscore (_), and dot (.) characters. Attribute names beginning with "zone" are reserved for use by the system. Finally, the "autoboot" global property must have a value of "true" or "false".

Using Kernel Statistics to Monitor CPU Caps

Using the kernel statistics (`kstat(3KSTAT)`) module caps, the system maintains information for all capped projects and zones. You can access this information by reading kernel statistics (`kstat(3KSTAT)`), specifying caps as the kstat module name. The following command displays kernel statistics for all active CPU caps:

```
# kstat caps::'cpucaps/
```

A `kstat(1M)` command running in a zone displays only CPU caps relevant for that zone and for projects in that zone. See EXAMPLES.

The following are cap-related arguments for use with `kstat(1M)`:

- **caps**
  - The kstat module.
- **project_caps or zone_caps**
  - kstat class, for use with the kstat -c option.
- **cpucaps_project_id or cpucaps_zone_id**
  - kstat name, for use with the kstat -n option. `id` is the project or zone identifier.

The following fields are displayed in response to a `kstat(1M)` command requesting statistics for all CPU caps.

- **module**
  - In this usage of kstat, this field will have the value caps.
- **name**
  - As described above, cpucaps_project_id or cpucaps_zone_id
- **above_sec**
  - Total time, in seconds, spent above the cap.
- **below_sec**
  - Total time, in seconds, spent below the cap.
maxusage
   Maximum observed CPU usage.

nwait
   Number of threads on cap wait queue.

usage
   Current aggregated CPU usage for all threads belonging to a capped project or zone, in terms of a percentage of a single CPU.

value
   The cap value, in terms of a percentage of a single CPU.

zonename
   Name of the zone for which statistics are displayed.

See EXAMPLES for sample output from a kstat command.

Options
   The following options are supported:

   -f command_file
     Specify the name of zonecfg command file. command_file is a text file of zonecfg subcommands, one per line.

   -z zonename
     Specify the name of a zone. Zone names are case sensitive. Zone names must begin with an alphanumeric character and can contain alphanumeric characters, the underscore (_), the hyphen (-), and the dot (.). The name global and all names beginning with SUNW are reserved and cannot be used.

Subcommands
   You can use the add and select subcommands to select a specific resource, at which point the scope changes to that resource. The end and cancel subcommands are used to complete the resource specification, at which time the scope is reverted back to global. Certain subcommands, such as add, remove and set, have different semantics in each scope.

   zonecfg supports a semicolon-separated list of subcommands. For example:

   # zonecfg -z myzone "add net; set physical=myvnic; end"

   Subcommands which can result in destructive actions or loss of work have an -F option to force the action. If input is from a terminal device, the user is prompted when appropriate if such a command is given without the -F option otherwise, if such a command is given without the -F option, the action is disallowed, with a diagnostic message written to standard error.

   The following subcommands are supported:

   add resource-type (global scope)
   add property-name property-value (resource scope)
   In the global scope, begin the specification for a given resource type. The scope is changed to that resource type.
In the resource scope, add a property of the given name with the given value. The syntax for property values varies with different property types. In general, it is a simple value or a list of simple values enclosed in square brackets, separated by commas ([foo, bar, baz]). See PROPERTIES.

**cancel**
End the resource specification and reset scope to global. Abandons any partially specified resources. cancel is only applicable in the resource scope.

**clear property-name**
Clear the value for the property.

**commit**
Commit the current configuration from memory to stable storage. The configuration must be committed to be used by zoneadm. Until the in-memory configuration is committed, you can remove changes with the revert subcommand. The commit operation is attempted automatically upon completion of a zonecfg session. Since a configuration must be correct to be committed, this operation automatically does a verify.

**create [-F] [-a path |-b | -t template]**
Create an in-memory configuration for the specified zone. Use create to begin to configure a new zone. See commit for saving this to stable storage.

If you are overwriting an existing configuration, specify the -F option to force the action. Specify the -t template option to create a configuration identical to template, where template is the name of a configured zone.

Use the -a path option to facilitate configuring a detached zone on a new host. The path parameter is the zonepath location of a detached zone that has been moved on to this new host. Once the detached zone is configured, it should be installed using the “zoneadm attach” command (see zoneadm(1M)). All validation of the new zone happens during the attach process, not during zone configuration.

Use the -b option to create a blank configuration. Without arguments, create applies the Sun default settings.

**delete [-F]**
Delete the specified configuration from memory and stable storage. This action is instantaneous, no commit is necessary. A deleted configuration cannot be reverted.

Specify the -F option to force the action.

**end**
End the resource specification. This subcommand is only applicable in the resource scope. zonecfg checks to make sure the current resource is completely specified. If so, it is added to the in-memory configuration (see commit for saving this to stable storage) and the scope reverts to global. If the specification is incomplete, it issues an appropriate error message.
export [-f output-file]
   Print configuration to standard output. Use the -f option to print the configuration to
   output-file. This option produces output in a form suitable for use in a command file.

help [usage] [subcommand] [syntax] [command-name]
   Print general help or help about given topic.

info zonename | zonepath | autoboott | brand | pool | limitpriv
info [resource-type {property-name=property-value}]*]
   Display information about the current configuration. If resource-type is specified, displays
   only information about resources of the relevant type. If any property-name value pairs are
   specified, displays only information about resources meeting the given criteria. In the
   resource scope, any arguments are ignored, and info displays information about the
   resource which is currently being added or modified.

remove resource-type{property-name=property-value}(global scope)
   In the global scope, removes the specified resource. The [] syntax means 0 or more of
   whatever is inside the square braces. If you want only to remove a single instance of the
   resource, you must specify enough property name-value pairs for the resource to be
   uniquely identified. If no property name-value pairs are specified, all instances will be
   removed. If there is more than one pair is specified, a confirmation is required, unless you
   use the -F option.

select resource-type {property-name=property-value}
   Select the resource of the given type which matches the given property-name property-value
   pair criteria, for modification. This subcommand is applicable only in the global scope. The
   scope is changed to that resource type. The {} syntax means 1 or more of whatever is inside
   the curly braces. You must specify enough property-name property-value pairs for the
   resource to be uniquely identified.

set property-name=property-value
   Set a given property name to the given value. Some properties (for example, zonename and
   zonepath) are global while others are resource-specific. This subcommand is applicable in
   both the global and resource scopes.

verify
   Verify the current configuration for correctness:
   ■ All resources have all of their required properties specified.
   ■ A zonepath is specified.

revert [-F]
   Revert the configuration back to the last committed state. The -F option can be used to
   force the action.

exit [-F]
   Exit the zonecfg session. A commit is automatically attempted if needed. You can also use
   an EOF character to exit zonecfg. The -F option can be used to force the action.
Creating the Environment for a New Zone

In the following example, `zonecfg` creates the environment for a new zone. `/usr/local` is loopback mounted from the global zone into `/opt/local`. `/opt/sfw` is loopback mounted from the global zone, three logical network interfaces are added, and a limit on the number of fair-share scheduler (FSS) CPU shares for a zone is set using the `rctl` resource type. The example also shows how to select a given resource for modification.

```
example# zonecfg -z my-zone3
my-zone3: No such zone configured
Use 'create' to begin configuring a new zone.
zonecfg:my-zone3> create
zonecfg:my-zone3> set zonepath=/export/home/my-zone3
zonecfg:my-zone3> set autoboot=true
zonecfg:my-zone3> add fs
zonecfg:my-zone3:fs> set dir=/usr/local
zonecfg:my-zone3:fs> set special=/opt/local
zonecfg:my-zone3:fs> set type=lofs
zonecfg:my-zone3:fs> add options [ro, nodevices]
zonecfg:my-zone3:fs> end
zonecfg:my-zone3> add fs
zonecfg:my-zone3:fs> set dir=/mnt
zonecfg:my-zone3:fs> set special=/dev/dsk/c0t0d0s7
zonecfg:my-zone3:fs> set raw=/dev/rdsk/c0t0d0s7
zonecfg:my-zone3:fs> set type=ufs
zonecfg:my-zone3:fs> end
zonecfg:my-zone3> add inherit-pkg-dir
zonecfg:my-zone3:inherit-pkg-dir> set dir=/opt/sfw
zonecfg:my-zone3:inherit-pkg-dir> end
zonecfg:my-zone3> add net
zonecfg:my-zone3:net> set address=192.168.0.1/24
zonecfg:my-zone3:net> set physical=eri0
zonecfg:my-zone3:net> end
zonecfg:my-zone3> add net
zonecfg:my-zone3:net> set address=192.168.1.2/24
zonecfg:my-zone3:net> set physical=eri0
zonecfg:my-zone3:net> end
zonecfg:my-zone3> add net
zonecfg:my-zone3:net> set address=192.168.2.3/24
zonecfg:my-zone3:net> set physical=eri0
zonecfg:my-zone3:net> end
zonecfg:my-zone3> set cpu-shares=5
zonecfg:my-zone3> add capped-memory
zonecfg:my-zone3:capped-memory> set physical=50m
zonecfg:my-zone3:capped-memory> set swap=100m
zonecfg:my-zone3:capped-memory> end
zonecfg:my-zone3> exit
```
**EXAMPLE 2**  Creating a Non-Native Zone

The following example creates a new Linux zone:

```bash
example# zonecfg -z lxzone
lxzone: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:lxzone> create -t SUNWlx
zonecfg:lxzone> set zonepath=/export/zones/lxzone
zonecfg:lxzone> set autoboot=true
zonecfg:lxzone> exit
```

**EXAMPLE 3**  Creating an Exclusive-IP Zone

The following example creates a zone that is granted exclusive access to bge1 and bge33000 and that is isolated at the IP layer from the other zones configured on the system.

The IP addresses and routing is configured inside the new zone using `sysidtool(1M)`.

```bash
example# zonecfg -z excl
excl: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:excl> create
zonecfg:excl> set zonepath=/export/zones/excl
zonecfg:excl> set ip-type=exclusive
zonecfg:excl> add net
zonecfg:excl:net> set physical=bge1
zonecfg:excl:net> end
zonecfg:excl> add net
zonecfg:excl:net> set physical=bge33000
zonecfg:excl:net> end
zonecfg:excl> exit
```

**EXAMPLE 4**  Associating a Zone with a Resource Pool

The following example shows how to associate an existing zone with an existing resource pool:

```bash
example# zonecfg -z myzone
zonecfg:myzone> set pool=mypool
zonecfg:myzone> exit
```

For more information about resource pools, see `pooladm(1M)` and `poolcfg(1M)`.

**EXAMPLE 5**  Changing the Name of a Zone

The following example shows how to change the name of an existing zone:

```bash
example# zonecfg -z myzone
zonecfg:myzone> set zonename=myzone2
zonecfg:myzone2> exit
```
EXAMPLE 6  Changing the Privilege Set of a Zone
The following example shows how to change the set of privileges an existing zone’s processes will be limited to the next time the zone is booted. In this particular case, the privilege set will be the standard safe set of privileges a zone normally has along with the privilege to change the system date and time:

example# zonecfg -z myzone
zonecfg:myzone> set limitpriv="default,sys_time"
zonecfg:myzone2> exit

EXAMPLE 7  Setting the zone.cpu-shares Property for the Global Zone
The following command sets the zone.cpu-shares property for the global zone:

example# zonecfg -z global
zonecfg:global> set cpu-shares=5
zonecfg:global> exit

EXAMPLE 8  Using Pattern Matching
The following commands illustrate zonecfg support for pattern matching. In the zone flexlm, enter:

zonecfg:flexlm> add device
zonecfg:flexlm:device> set match="/dev/cua/a00[2-5]"
zonecfg:flexlm:device> end

In the global zone, enter:

global# ls /dev/cua
a   a000 a001 a002 a003 a004 a005 a006 a007 b

In the zone flexlm, enter:

flexlm# ls /dev/cua
a002 a003 a004 a005

EXAMPLE 9  Setting a Cap for a Zone to Three CPUs
The following sequence uses the zonecfg command to set the CPU cap for a zone to three CPUs.

zonecfg:myzone> add capped-cpu
zonecfg:myzone:capped-cpu> set ncpus=3
zonecfg:myzone:capped-cpu:capped-cpu> end

The preceding sequence, which uses the capped-cpu property, is equivalent to the following sequence, which makes use of the zone.cpu-cap resource control.

zonecfg:myzone> add rctl
zonecfg:myzone:rctl> set name=zone.cpu-cap
zonecfg:myzone:rctl> add value (priv=privileged,limit=300,action=none)
EXAMPLE 9  Setting a Cap for a Zone to Three CPUs  (Continued)

zonecfg:myzone::rctl> end

EXAMPLE 10  Using kstat to Monitor CPU Caps

The following command displays information about all CPU caps.

```bash
# kstat -n /cpucaps/
```

EXAMPLE 11  Displaying CPU Caps for a Specific Zone or Project

Using the kstat -c and -i options, you can display CPU caps for a specific zone or project, as
below. The first command produces a display for a specific project, the second for the same
project within zone 1.

# kstat -c project_caps

# kstat -c project_caps -i 1

Exit Status  The following exit values are returned:

0
  Successful completion.

1
  An error occurred.

2
  Invalid usage.

  zpool status [-xv] [-T d|u] [pool] ... [interval[count]]  
  zpool upgrade  
  zpool upgrade -v  
  zpool upgrade [-V version] -a | pool ...
## Description
The `zpool` command configures ZFS storage pools. A storage pool is a collection of devices that provides physical storage and data replication for ZFS datasets.

All datasets within a storage pool share the same space. See `zfs(1M)` for information on managing datasets.

### Virtual Devices (vdevs)
A “virtual device” describes a single device or a collection of devices organized according to certain performance and fault characteristics. The following virtual devices are supported:

- **disk**
  A block device, typically located under `/dev/dsk`. ZFS can use individual slices or partitions, though the recommended mode of operation is to use whole disks. A disk can be specified by a full path, or it can be a shorthand name (the relative portion of the path under `"/dev/dsk"`). A whole disk can be specified by omitting the slice or partition designation. When given a whole disk, ZFS automatically labels the disk, if necessary.

- **file**
  A regular file. The use of files as a backing store is strongly discouraged. It is designed primarily for experimental purposes, as the fault tolerance of a file is only as good as the file system of which it is a part. A file must be specified by a full path.

- **mirror**
  A mirror of two or more devices. Data is replicated in an identical fashion across all components of a mirror. A mirror with \( N \) disks of size \( X \) can hold \( X \) bytes and can withstand \((N-1)\) devices failing before data integrity is compromised.

- **raidz**
- **raidz1**
- **raidz2**
- **raidz3**
  A variation on RAID-5 that allows for better distribution of parity and eliminates the “RAID-5 write hole” (in which data and parity become inconsistent after a power loss). Data and parity is striped across all disks within a raidz group.

  A raidz group can have single-, double-, or triple parity, meaning that the raidz group can sustain one, two, or three failures, respectively, without losing any data. The `raidz1 vdev` type specifies a single-parity raidz group; the `raidz2 vdev` type specifies a double-parity raidz group; and the `raidz3 vdev` type specifies a triple-parity raidz group. The `raidz vdev` type is an alias for `raidz1`.

  A raidz group with \( N \) disks of size \( X \) with \( P \) parity disks can hold approximately \((N-P)*X\) bytes and can withstand \( P \) device(s) failing before data integrity is compromised. The minimum number of devices in a raidz group is one more than the number of parity disks. The recommended number is between 3 and 9 to help increase performance.

- **spare**
  A special pseudo-vdev which keeps track of available hot spares for a pool. For more information, see the “Hot Spares” section.
log
A separate-intent log device. If more than one log device is specified, then writes are
load-balanced between devices. Log devices can be mirrored. However, raidz vdev types
are not supported for the intent log. For more information, see the “Intent Log” section.

cache
A device used to cache storage pool data. A cache device cannot be configured as a mirror
or raidz group. For more information, see the “Cache Devices” section.

Virtual devices cannot be nested, so a mirror or raidz virtual device can only contain files or
disks. Mirrors of mirrors (or other combinations) are not allowed.

A pool can have any number of virtual devices at the top of the configuration (known as “root
vdevs”). Data is dynamically distributed across all top-level devices to balance data among
devices. As new virtual devices are added, ZFS automatically places data on the newly available
devices.

Virtual devices are specified one at a time on the command line, separated by whitespace. The
keywords “mirror” and “raidz” are used to distinguish where a group ends and another begins.
For example, the following creates two root vdevs, each a mirror of two disks:

```
# zpool create mypool mirror c0t0d0 c0t1d0 mirror c1t0d0 c1t1d0
```

Device Failure and
Recovery

ZFS supports a rich set of mechanisms for handling device failure and data corruption. All
metadata and data is checksummed, and ZFS automatically repairs bad data from a good copy
when corruption is detected.

In order to take advantage of these features, a pool must make use of some form of
redundancy, using either mirrored or raidz groups. While ZFS supports running in a
non-redundant configuration, where each root vdev is simply a disk or file, this is strongly
discouraged. A single case of bit corruption can render some or all of your data unavailable.

A pool’s health status is described by one of three states: online, degraded, or faulted. An
online pool has all devices operating normally. A degraded pool is one in which one or more
devices have failed, but the data is still available due to a redundant configuration. A faulted
pool has corrupted metadata, or one or more faulted devices, and insufficient replicas to
continue functioning.

The health of the top-level vdev, such as mirror or raidz device, is potentially impacted by the
state of its associated vdevs, or component devices. A top-level vdev or component device is in
one of the following states:

DEGRADED
One or more top-level vdevs is in the degraded state because one or more component
devices are offline. Sufficient replicas exist to continue functioning.

One or more component devices is in the degraded or faulted state, but sufficient replicas
exist to continue functioning. The underlying conditions are as follows:
Thenumber of checksum errors exceeds acceptable levels and the device is degraded as an indication that something may be wrong. ZFS continues to use the device as necessary.

The number of I/O errors exceeds acceptable levels. The device could not be marked as faulted because there are insufficient replicas to continue functioning.

**FAULTED**

One or more top-level vdevs is in the faulted state because one or more component devices are offline. Insufficient replicas exist to continue functioning.

One or more component devices is in the faulted state, and insufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The device could be opened, but the contents did not match expected values.
- The number of I/O errors exceeds acceptable levels and the device is faulted to prevent further use of the device.

**OFFLINE**

The device was explicitly taken offline by the "zpool offline" command.

**ONLINE**

The device is online and functioning.

**REMOVED**

The device was physically removed while the system was running. Device removal detection is hardware-dependent and may not be supported on all platforms.

**UNAVAIL**

The device could not be opened. If a pool is imported when a device was unavailable, then the device will be identified by a unique identifier instead of its path since the path was never correct in the first place.

If a device is removed and later reattached to the system, ZFS attempts to put the device online automatically. Device attach detection is hardware-dependent and might not be supported on all platforms.

**Hot Spares**

ZFS allows devices to be associated with pools as “hot spares”. These devices are not actively used in the pool, but when an active device fails, it is automatically replaced by a hot spare. To create a pool with hot spares, specify a "spare" vdev with any number of devices. For example,

```
# zpool create pool mirror c0d0 c1d0 spare c2d0 c3d0
```

Spares can be added with the `zpool add` command and removed with the `zpool remove` command. Once a spare replacement is initiated, a new "spare" vdev is created within the configuration that will remain there until the original device is replaced. At this point, the hot spare becomes available again if another device fails.
If the original failed device is physically replaced, brought back online, or the errors are cleared, either through an FMA event or by using the zpool online command or zpool clear command, and the state of the original device becomes healthy, the INUSE spare device will become AVAIL again.

Spares cannot replace log devices.

**Intent Log**

The ZFS Intent Log (ZIL) satisfies POSIX requirements for synchronous transactions. For instance, databases often require their transactions to be on stable storage devices when returning from a system call. NFS and other applications can also use fsync() to ensure data stability. By default, the intent log is allocated from blocks within the main pool. However, it might be possible to get better performance using separate intent log devices such as NVRAM or a dedicated disk. For example:

```
# zpool create pool c0d0 c1d0 log c2d0
```

Multiple log devices can also be specified, and they can be mirrored. See the EXAMPLES section for an example of mirroring multiple log devices.

Log devices can be added, replaced, attached, detached, and imported, and exported as part of the larger pool. Mirrored log devices can be removed by specifying the top-level mirror for the log.

**Cache Devices**

Devices can be added to a storage pool as “cache devices.” These devices provide an additional layer of caching between main memory and disk. For read-heavy workloads, where the working set size is much larger than what can be cached in main memory, using cache devices allow much more of this working set to be served from low latency media. Using cache devices provides the greatest performance improvement for random read-workloads of mostly static content.

To create a pool with cache devices, specify a “cache” vdev with any number of devices. For example:

```
# zpool create pool c0d0 c1d0 cache c2d0 c3d0
```

Cache devices cannot be mirrored or part of a raidz configuration. If a read error is encountered on a cache device, that read I/O is reissued to the original storage pool device, which might be part of a mirrored or raidz configuration.

The content of the cache devices is considered volatile, as is the case with other system caches.

**Processes**

Each imported pool has an associated process, named zpool- poolname. The threads in this process are the pool’s I/O processing threads, which handle the compression, checksumming, and other tasks for all I/O associated with the pool. This process exists to provide visibility into the CPU utilization of the system’s storage pools. The existence of this process is an unstable interface.
Each pool has several properties associated with it. Some properties are read-only statistics while others are configurable and change the behavior of the pool. The following are read-only properties:

- **allocated**
  
  Amount of storage space within the pool that has been physically allocated. This property can also be referred to by its shortened column name, `alloc`.

- **capacity**
  
  Percentage of pool space used. This property can also be referred to by its shortened column name, “cap”.

- **free**
  
  Number of blocks within the pool that are not allocated.

- **guid**
  
  A unique identifier for the pool.

- **health**
  
  The current health of the pool. Health can be “ONLINE”, “DEGRADED”, or “FAULTED”.

- **size**
  
  Total size of the storage pool.

These space usage properties report actual physical space available to the storage pool. The physical space can be different from the total amount of space that any contained datasets can actually use. The amount of space used in a raidz configuration depends on the characteristics of the data being written. In addition, ZFS reserves some space for internal accounting that the `zfs(1M)` command takes into account, but the `zpool` command does not. For non-full pools of a reasonable size, these effects should be invisible. For small pools, or pools that are close to being completely full, these discrepancies may become more noticeable.

The following property can be set at creation time and import time:

- **altroot**
  
  Alternate root directory. If set, this directory is prepended to any mount points within the pool. This can be used when examining an unknown pool where the mount points cannot be trusted, or in an alternate boot environment, where the typical paths are not valid. `altroot` is not a persistent property. It is valid only while the system is up. Setting `altroot` defaults to using `cachedfile=none`, though this may be overridden using an explicit setting.

The following property can be set at import time:

- **readonly=on | off**
  
  Controls whether the pool can be modified. When enabled, any synchronous data that exists only in the intent log is not accessible until the pool is imported in read-write mode.

  Importing a pool in read-only mode has the following limitations:

  - Attempts to set additional pool properties during the import are ignored.
All file system mounts are converted to include the read-only (ro) mount option.

A pool that has been imported in read-only mode can be restored to read-write mode by exporting and importing the pool.

The following properties can be set at creation time and import time, and later changed with the `zpool set` command:

`autoexpand=on|off`
Controls automatic pool expansion when a larger device is added or attached to the pool or when a larger device replaces a smaller device in the pool. If set to on, the pool will be resized according to the size of the expanded device. If the device is part of a mirror or raidz then all devices within that mirror/raidz group must be expanded before the new space is made available to the pool. The default behavior is off. This property can also be referred to by its shortened column name, `expand`.

`autoreplace=on|off`
Controls automatic device replacement. If set to "off", device replacement must be initiated by the administrator by using the "zpool replace" command. If set to "on", any new device, found in the same physical location as a device that previously belonged to the pool, is automatically formatted and replaced. The default behavior is "off". This property can also be referred to by its shortened column name, "replace".

`bootfs=pool/dataset`
Identifies the default bootable dataset for the root pool. This property is expected to be set mainly by the installation and upgrade programs.

`cachefile=path|none`
Controls the location of where the pool configuration is cached. Discovering all pools on system startup requires a cached copy of the configuration data that is stored on the root file system. All pools in this cache are automatically imported when the system boots. Some environments, such as install and clustering, need to cache this information in a different location so that pools are not automatically imported. Setting this property caches the pool configuration in a different location that can later be imported with "zpool import -c". Setting it to the special value "none" creates a temporary pool that is never cached, and the special value "'" (empty string) uses the default location.

Multiple pools can share the same cache file. Because the kernel destroys and recreates this file when pools are added and removed, care should be taken when attempting to access this file. When the last pool using a cache file is exported or destroyed, the file is removed.

`delegation=on|off`
Controls whether a non-privileged user is granted access based on the dataset permissions defined on the dataset. See `zfs(1M)` for more information on ZFS delegated administration.
failmode=wait | continue | panic
Controls the system behavior in the event of catastrophic pool failure. This condition is typically a result of a loss of connectivity to the underlying storage device(s) or a failure of all devices within the pool. The behavior of such an event is determined as follows:

wait
Blocks all I/O access to the pool until the device connectivity is recovered and the errors are cleared. A pool remains in the wait state until the device issue is resolved. This is the default behavior.

continue
Returns EIO to any new write I/O requests but allows reads to any of the remaining healthy devices. Any write requests that have yet to be committed to disk would be blocked.

panic
Prints out a message to the console and generates a system crash dump.

lists snaps=on | off
Controls whether snapshot information associated with this pool is displayed when "zfs list" is run without the -t option. The default value is "on".

version=version
The current on-disk version of the pool. This can be increased, but never decreased. The preferred method of updating pools is with the zpool upgrade command, though this property can be used when a specific version is needed for backwards compatibility. This property can be any number between 1 and the current version reported by zpool upgrade -v.

Subcommands
All subcommands that modify state are logged persistently to the pool in their original form.

The zpool command provides subcommands to create and destroy storage pools, add capacity to storage pools, and provide information about the storage pools. The following subcommands are supported:

zpool -?
Displays a help message.

zpool add [-fn] pool vdev ...
Adds the specified virtual devices to the given pool. The vdev specification is described in the "Virtual Devices" section. The behavior of the -f option, and the device checks performed are described in the "zpool create" subcommand.

-f
Forces use of vdevs, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

-n
Displays the configuration that would be used without actually adding the vdevs. The actual pool creation can still fail due to insufficient privileges or device sharing.
Do not add a disk that is currently configured as a quorum device to a zpool. After a disk is in the pool, that disk can then be configured as a quorum device.

**zpool attach** [-f] pool device new_device

Attaches new_device to an existing zpool device. The existing device cannot be part of a raidz configuration. If device is not currently part of a mirrored configuration, device automatically transforms into a two-way mirror of device and new_device. If device is part of a two-way mirror, attaching new_device creates a three-way mirror, and so on. In either case, new_device begins to resilver immediately.

- f
  Forces use of new_device, even if it appears to be in use. Not all devices can be overridden in this manner.

**zpool clear** [-F [-n]] pool [device] ...

Clears device errors in a pool. If no arguments are specified, all device errors within the pool are cleared. If one or more devices is specified, only those errors associated with the specified device or devices are cleared.

- F
  Initiates recovery mode for an unopenable pool. Attempts to discard the last few transactions in the pool to return it to an openable state. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost.

- n
  Used in combination with the -F flag. Check whether discarding transactions would make the pool openable, but do not actually discard any transactions.

**zpool create** [-fn] [-o property=value] ... [-O file-system-property=value] ... [-m mountpoint] [-R root] pool vdev ...

Creates a new storage pool containing the virtual devices specified on the command line. The pool name must begin with a letter, and can only contain alphanumeric characters as well as underscore ("_"), dash ("-"), and period ("."). The pool names mirror, raidz, spare, and log are reserved, as are names beginning with the pattern c[0-9]. The vdev specification is described in the "Virtual Devices" section.

The command verifies that each device specified is accessible and not currently in use by another subsystem. There are some uses, such as being currently mounted, or specified as the dedicated dump device, that prevents a device from ever being used by ZFS. Other uses, such as having a preexisting UFS file system, can be overridden with the -f option.

The command also checks that the replication strategy for the pool is consistent. An attempt to combine redundant and non-redundant storage in a single pool, or to mix disks and files, results in an error unless -f is specified. The use of differently sized devices within a single raidz or mirror group is also flagged as an error unless -f is specified.
Unless the -R option is specified, the default mount point is “/pool”. The mount point must not exist or must be empty, or else the root dataset cannot be mounted. This can be overridden with the -m option.

- f
  Forces use of vdevs, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

- n
  Displays the configuration that would be used without actually creating the pool. The actual pool creation can still fail due to insufficient privileges or if a device is currently in use.

- o property=value [-o property=value] ...
  Sets the given pool properties. See the “Properties” section for a list of valid properties that can be set.

- O file-system-property=value
  [-O file-system-property=value] ...
  Sets the specified properties for the pool’s top-level file system. See the “Properties” section of `zfs(1M)` for a list of valid properties that can be set.

- R root
  Equivalent to “-o cachefile=none,altroot=root”

- m mountpoint
  Sets the mount point for the pool’s top-level file system. The default mount point is “/pool” or “altroot/pool” if `altroot` is specified. The mount point must be an absolute path, “legacy”, or “none”. For more information on dataset mount points, see `zfs(1M)`.

```
zpool destroy [-f] pool
```
Destroys the given pool, freeing up any devices for other use. This command tries to unmount any active datasets before destroying the pool.

- f
  Forces any active datasets contained within the pool to be unmounted.

```
zpool detach pool device
```
Detaches `device` from a mirror. The operation is refused if there are no other valid replicas of the data.

```
zpool export [-f] pool ...
```
Exports the given pools from the system. All devices are marked as exported, but are still considered in use by other subsystems. The devices can be moved between systems (even those of different endianness) and imported as long as a sufficient number of devices are present.

Before exporting the pool, all datasets within the pool are unmounted.
For pools to be portable, you must give the `zpool` command whole disks, not just slices, so that ZFS can label the disks with portable EFI labels. Otherwise, disk drivers on platforms of different endianness will not recognize the disks.

`-f`
Forcefully unmount all datasets, using the "unmount -f" command.

`zpool get "all" [property[,...]] pool ...

Retrieves the given list of properties (or all properties if "all" is used) for the specified storage pool(s). These properties are displayed with the following fields:

- name Name of storage pool
- property Property name
- value Property value
- source Property source, either 'default' or 'local'.

See the "Properties" section for more information on the available pool properties.

`zpool history [-il] [pool] ...

Displays the command history of the specified pools or all pools if no pool is specified.

- i
Displays internally logged ZFS events in addition to user initiated events.

- l
Displays log records in long format, which in addition to standard format includes, the user name, the hostname, and the zone in which the operation was performed.

`zpool import [-d dir] [-c cachefile] [-D]

Lists pools available to import. If the -d option is not specified, this command searches for devices in "/dev/dsk". The -d option can be specified multiple times, and all directories are searched. If the device appears to be part of an exported pool, this command displays a summary of the pool with the name of the pool, a numeric identifier, as well as the vdev layout and current health of the device for each device or file. Destroyed pools, pools that were previously destroyed with the "zpool destroy" command, are not listed unless the -D option is specified.

The numeric identifier is unique, and can be used instead of the pool name when multiple exported pools of the same name are available.

- c cachefile
Reads configuration from the given cachefile that was created with the "cachefile" pool property. This cachefile is used instead of searching for devices.

- d dir
Searches for devices or files in `dir`. The -d option can be specified multiple times.

- D
Lists destroyed pools only.

Imports all pools found in the search directories. Identical to the previous command, except that all pools with a sufficient number of devices available are imported. Destroyed pools, pools that were previously destroyed with the “zpool destroy” command, will not be imported unless the -D option is specified.

-o mntopts
Comma-separated list of mount options to use when mounting datasets within the pool. See zfs(1M) for a description of dataset properties and mount options.

-o property=value
Sets the specified property on the imported pool. See the “Properties” section for more information on the available pool properties.

c cachefile
Reads configuration from the given cachefile that was created with the “cachefile” pool property. This cachefile is used instead of searching for devices.

d dir
Searches for devices or files in dir. The -d option can be specified multiple times. This option is incompatible with the -c option.

-D
Imports destroyed pools only. The -f option is also required.

-f
Forces import, even if the pool appears to be potentially active.

-F
Recovery mode for a non-importable pool. Attempt to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.

-a
Searches for and imports all pools found.

-m
Allows a pool to import when a log device is missing.

-R root
Sets the “cachefile” property to “none” and the “altroot” property to “root”.

-N
Import the pool without mounting any file systems.

-n
Used with the -F recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the -F option, above.

Imports a specific pool. A pool can be identified by its name or the numeric identifier. If newpool is specified, the pool is imported using the persistent name newpool. Otherwise, it is imported with the same name as its exported name. Do not import a root pool with a new name. Otherwise, the system might not boot.

If a device is removed from a system without running “zpool export” first, the device appears as potentially active. It cannot be determined if this was a failed export, or whether the device is really in use from another host. To import a pool in this state, the -f option is required.

-o mntopts
Comma-separated list of mount options to use when mounting datasets within the pool. See zfs(1M) for a description of dataset properties and mount options.

-o property=value
Sets the specified property on the imported pool. See the “Properties” section for more information on the available pool properties.

-c cachefile
Reads configuration from the given cachefile that was created with the "cachefile" pool property. This cachefile is used instead of searching for devices.

-d dir
Searches for devices or files in dir. The -d option can be specified multiple times. This option is incompatible with the -c option.

-D
Imports destroyed pool. The -f option is also required.

-f
Forces import, even if the pool appears to be potentially active.

-F
Recovery mode for a non-importable pool. Attempt to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.

-R root
Sets the "cachefile" property to "none" and the "altroot" property to "root".

-n
Used with the -F recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the -F option, above.

-m
Allows a pool to import when a log device is missing.
zpool iostat [-T d|u] [-v] [pool] ... [interval][count]
Displays I/O statistics for the given pools. When given an interval, the statistics are printed every interval seconds until Ctrl-C is pressed. If no pools are specified, statistics for every pool in the system are shown. If count is specified, the command exits after count reports are printed.

- T d|u
  Display a time stamp.
  Specify d for standard date format. See date(1). Specify u for a printed representation of the internal representation of time. See time(2).

- v
  Verbose statistics. Reports usage statistics for individual vdevs within the pool, in addition to the pool-wide statistics.

zpool list [-H] [-o props[,...]] [-T d|u] [pool] ...
Lists the given pools along with a health status and space usage. When given no arguments, all pools in the system are listed.

When given an interval, the status and space usage are displayed every interval seconds until Ctrl-C is entered. If count is specified, the command exits after count reports are displayed.

- H
  Scripted mode. Do not display headers, and separate fields by a single tab instead of arbitrary space.

- o props
  Comma-separated list of properties to display. See the “Properties” section for a list of valid properties. The default list is name, size, allocated, free, capacity, health, altroot.

- T d|u
  Display a time stamp.
  Specify d for standard date format. See date(1). Specify u for a printed representation of the internal representation of time. See time(2).

zpool offline [-t] pool device ...
Takes the specified physical device offline. While the device is offline, no attempt is made to read or write to the device.

This command is not applicable to spares or cache devices.

- t
  Temporary. Upon reboot, the specified physical device reverts to its previous state.

zpool online [-e] pool device...
Brings the specified physical device online.
This command is not applicable to spares or cache devices.

-e
Expand the device to use all available space. If the device is part of a mirror or raidz then all devices must be expanded before the new space will become available to the pool.

zpool remove pool device ...
Removes the specified device from the pool. This command currently only supports removing hot spares, cache, and log devices. A mirrored log device can be removed by specifying the top-level mirror for the log. Non-log devices that are part of a mirrored configuration can be removed using the zpool detach command. Non-redundant and raidz devices cannot be removed from a pool.

zpool replace [-f] pool old_device [new_device]
Replaces old_device with new_device. This is equivalent to attaching new_device, waiting for it to resilver, and then detaching old_device.

The size of new_device must be greater than or equal to the minimum size of all the devices in a mirror or raidz configuration.

new_device is required if the pool is not redundant. If new_device is not specified, it defaults to old_device. This form of replacement is useful after an existing disk has failed and has been physically replaced. In this case, the new disk may have the same /dev/dsk path as the old device, even though it is actually a different disk. ZFS recognizes this.

In zpool status output, the old_device is shown under the word replacing with the string /old appended to it. Once the resilver completes, both the replacing and the old_device are automatically removed. If the new device fails before the resilver completes and a third device is installed in its place, then both failed devices will show up with /old appended, and the resilver starts over again. After the resilver completes, both /old devices are removed along with the word replacing.

-f
Forces use of new_device, even if its appears to be in use. Not all devices can be overridden in this manner.

zpool scrub [-s] pool ...
Begins a scrub. The scrub examines all data in the specified pools to verify that it checksums correctly. For replicated (mirror or raidz) devices, ZFS automatically repairs any damage discovered during the scrub. The “zpool status” command reports the progress of the scrub and summarizes the results of the scrub upon completion.

Scrubbing and resilvering are very similar operations. The difference is that resilvering only examines data that ZFS knows to be out of date (for example, when attaching a new device to a mirror or replacing an existing device), whereas scrubbing examines all data to discover silent errors due to hardware faults or disk failure.
Because scrubbing and resilvering are I/O-intensive operations, ZFS allows only one at a time. If a scrub is already in progress, a subsequent "zpool scrub" returns an error, with the advice to use zpool scrub -s to cancel the current scrub. If a resilver is in progress, ZFS does not allow a scrub to be started until the resilver completes.

-s
Stop scrubbing.

zpool set property=value pool
Sets the given property on the specified pool. See the "Properties" section for more information on what properties can be set and acceptable values.

zpool split [-R altroot] [-n] [-o mntopts] [-o property=value] pool newpool [device ...]
Splits off one disk from each mirrored top-level vdev in a pool and creates a new pool from the split-off disks. The original pool must be made up of one or more mirrors and must not be in the process of resilvering. The split subcommand chooses the last device in each mirror vdev unless overridden by a device specification on the command line.

When using a device argument, split includes the specified device(s) in a new pool and, should any devices remain unspecified, assigns the last device in each mirror vdev to that pool, as it does normally. If you are uncertain about the outcome of a split command, use the -n ("dry-run") option to ensure your command will have the effect you intend.

-R altroot
Automatically import the newly created pool after splitting, using the specified altroot parameter for the new pool’s alternate root. See the altroot description in the "Properties" section, above.

-n
Displays the configuration that would be created without actually splitting the pool. The actual pool split could still fail due to insufficient privileges or device status.

-o mntopts
Comma-separated list of mount options to use when mounting datasets within the pool. See zfs(1M) for a description of dataset properties and mount options. Valid only in conjunction with the -R option.

-o property=value
Sets the specified property on the new pool. See the "Properties" section, above, for more information on the available pool properties.

zpool status [-xv] [-T d|u] [pool] ... [interval[count]]
Displays the detailed health status for the given pools. If no pool is specified, then the status of each pool in the system is displayed. For more information on pool and device health, see the "Device Failure and Recovery" section.

When given an interval, the status and space usage are displayed every interval seconds until Ctrl-C is entered. If count is specified, the command exits after count reports are displayed.
If a scrub or resilver is in progress, this command reports the percentage done and the estimated time to completion. Both of these are only approximate, because the amount of data in the pool and the other workloads on the system can change.

-x
  Only display status for pools that are exhibiting errors or are otherwise unavailable.

-v
  Displays verbose data error information, printing out a complete list of all data errors since the last complete pool scrub.

-T d|u
  Display a timestamp.

Specify d for standard date format. See date(1). Specify u for a printed representation of the internal representation of time. See time(2).

zpool upgrade
  Identifies a pool’s on-disk version, which determines available pool features in the currently running software release. You can continue to use older pool versions, but some features might not be available. A pool can be upgraded by using the zpool upgrade -a command. You will not be able to access a pool of a later version on a system that runs an earlier software version.

zpool upgrade -v
  Displays ZFS pool versions supported by the current software. The current ZFS pool versions and all previous supported versions are displayed, along with an explanation of the features provided with each version.

zpool upgrade [-V version] -a | pool ...
  Upgrades the specified pool to the latest on-disk version. If this command reveals that a pool is out-of-date, the pool can subsequently be upgraded using the zpool upgrade -a command. A pool that is upgraded will not be accessible on a system that runs an earlier software release.

-a
  Upgrades all pools.

-V version
  Upgrade to the specified version, which must be higher than the current version. If the -V flag is not specified, the pool is upgraded to the most recent version.

Examples

EXAMPLE 1  Creating a RAID-Z Storage Pool

The following command creates a pool with a single raidz root vdev that consists of six disks.

# zpool create tank raidz c0t0d0 c0t1d0 c0t2d0 c0t3d0 c0t4d0 c0t5d0
EXAMPLE 2 Creating a Mirrored Storage Pool
The following command creates a pool with two mirrors, where each mirror contains two disks.

```
# zpool create tank mirror c0t0d0 c0t1d0 mirror c0t2d0 c0t3d0
```

EXAMPLE 3 Creating a ZFS Storage Pool by Using Slices
The following command creates an unmirrored pool using two disk slices.

```
# zpool create tank /dev/dsk/c0t0d0s1 c0t1d0s4
```

EXAMPLE 4 Adding a Mirror to a ZFS Storage Pool
The following command adds two mirrored disks to the pool "tank", assuming the pool is already made up of two-way mirrors. The additional space is immediately available to any datasets within the pool.

```
# zpool add tank mirror c1t0d0 c1t1d0
```

EXAMPLE 5 Listing Available ZFS Storage Pools
The following command lists all available pools on the system.

```
# zpool list
NAME SIZE ALLOC FREE CAP HEALTH ALTROOT
pool 136G 109M 136G 0% ONLINE -
rpool 67.5G 12.6G 54.9G 18% ONLINE -
```

EXAMPLE 6 Listing All Properties for a Pool
The following command lists all the properties for a pool.

```
% zpool get all pool

pool allocated 130K -
pool readonly off -
```
EXAMPLE 7  Destroying a ZFS Storage Pool

The following command destroys the pool “tank” and any datasets contained within.

```
# zpool destroy -f tank
```

EXAMPLE 8  Exporting a ZFS Storage Pool

The following command exports the devices in pool tank so that they can be relocated or later imported.

```
# zpool export tank
```

EXAMPLE 9  Importing a ZFS Storage Pool

The following command displays available pools, and then imports the pool “tank” for use on the system.

The results from this command are similar to the following:

```
# zpool import
  pool: tank
    id: 767868315469843843
    state: ONLINE
  action: The pool can be imported using its name or numeric identifier.
  config:
    tank ONLINE
    mirror-0 ONLINE
c1t2d0 ONLINE
c1t3d0 ONLINE
```

```
# zpool import tank
```

EXAMPLE 10  Upgrading All ZFS Storage Pools to the Current Version

The following command upgrades all ZFS Storage pools to the current version of the software.

```
# zpool upgrade -a
```

This system is currently running ZFS pool version 29.

All pools are formatted using this version.

EXAMPLE 11  Managing Hot Spares

The following command creates a new pool with an available hot spare:

```
# zpool create tank mirror c0t0d0 c0t1d0 spare c0t2d0
```

If one of the disks were to fail, the pool would be reduced to the degraded state. The failed device can be replaced using the following command:

```
# zpool replace tank c0t0d0 c0t3d0
```
EXAMPLE 11  Managing Hot Spares  (Continued)

After the device has been resilvered, the spare is automatically detached and is made available should another device fail. The hot spare can be permanently removed from the pool using the following command:

```
# zpool remove tank c0t2d0
```

EXAMPLE 12  Creating a ZFS Pool with Separate Mirrored Log Devices

The following command creates a ZFS storage pool consisting of two, two-way mirrors and mirrored log devices:

```
# zpool create pool mirror c0d0 c1d0 mirror c2d0 c3d0 log mirror c4d0 c5d0
```

EXAMPLE 13  Adding Cache Devices to a ZFS Pool

The following command adds two disks for use as cache devices to a ZFS storage pool:

```
# zpool add pool cache c2d0 c3d0
```

Once added, the cache devices gradually fill with content from main memory. Depending on the size of your cache devices, it could take over an hour for them to fill. Capacity and reads can be monitored using the `iostat` option as follows:

```
# zpool iostat -v pool 5
```

EXAMPLE 14  Removing a Mirrored Log Device

The following example shows how to remove the mirrored log device `mirror-2` in the pool `tank`.

```
pool: tank
state: ONLINE
scrub: none requested
config:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>READ</th>
<th>WRITE</th>
<th>CKSUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>tank</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>mirror-0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c6t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c6t1d0</td>
<td>ONLINE</td>
<td>0</td>

<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c4t0d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>c4t1d0</td>
<td>ONLINE</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

# zpool remove tank mirror-2
```
EXAMPLE 15  Recovering a Faulted ZFS Pool

If a pool is faulted but recoverable, a message indicating this state is provided by `zpool status` if the pool was cached (see `cachefile` above), or as part of the error output from a failed `zpool import` of the pool.

Recover a cached pool with the `zpool clear` command:

```bash
# zpool clear -F data
Pool data returned to its state as of Tue Sep 08 13:23:35 2009.
Discarded approximately 29 seconds of transactions.
```

If the pool configuration was not cached, use `zpool import` with the recovery mode flag:

```bash
# zpool import -F data
Pool data returned to its state as of Tue Sep 08 13:23:35 2009.
Discarded approximately 29 seconds of transactions.
```

EXAMPLE 16  Importing a ZFS Pool with a Missing Log Device

The following examples illustrate attempts to import a pool with a missing log device. The `-m` option is used to complete the import operation.

Additional devices are known to be part of this pool, though their exact configuration cannot be determined.

```bash
# zpool import tank
The devices below are missing, use `-m` to import the pool anyway:
  c5t0d0 [log]

cannot import 'tank': one or more devices is currently unavailable

# zpool import -m tank
# zpool status tank
  pool: tank
  state: DEGRADED
  status: One or more devices could not be opened. Sufficient replicas exist for
          the pool to continue functioning in a degraded state.
  action: Attach the missing device and online it using 'zpool online'.
          see: http://www.sun.com/msg/ZFS-8000-2Q
          scan: none requested
  config:

    NAME  STATE     READ  WRITE CKSUM
    tank  DEGRADED  0     0      0
    c7t0d0 ONLINE   0     0      0
    logs  UNAVAIL   0     0      0 was /dev/dsk/c5t0d0
```
EXAMPLE 16 Importing a ZFS Pool with a Missing Log Device

(Co ntinued)

errors: No known data errors

The following example shows how to import a pool with a missing \textit{mirrored} log device.

\texttt{# zpool import tank}
The devices below are missing, use \texttt{-m} to import the pool anyway:
\texttt{mirror-1 [log]}
\texttt{c5t0d0}
\texttt{c5t1d0}

\texttt{# zpool import -m tank}

\texttt{# zpool status tank}
\begin{verbatim}
pool: tank state: DEGRADED status: One or more devices could not be opened. Sufficient replicas exist for the pool to continue functioning in a degraded state. action: Attach the missing device and online it using 'zpool online'.
  see: http://www.sun.com/msg/ZFS-8000-2Q
current scan: none requested
config:

\begin{verbatim}
NAME    STATE     READ  WRITE  CKSUM
tank     DEGRADED  0     0     0
       c7t0d0 ONLINE  0     0     0
logs    UNAVAIL  0     0     0
       mirror-1 UNAVAIL  0     0     0
End
errors: No known data errors

Exit Status The following exit values are returned:
\begin{itemize}
  \item 0 Successful completion.
  \item 1 An error occurred.
  \item 2 Invalid command line options were specified.
\end{itemize}

Name  zuludaemon – load microcode for Sun XVR-4000 Graphics Accelerator device

Synopsis  
/usr/sbin/zuludaemon [-dev zulu_device]

Description  The zuludaemon is a daemon, started and stopped from a script in /etc/init.d, that loads the microcode and provides other support functions for the Sun XVR-4000 Graphics Acceleration device. Do not kill this process. This daemon is essential to the zulu(7d) driver.

The zuludaemon process is not configurable.

Options  
-dev zulu_device  name of the Sun XVR-4000 Graphics Accelerator device

Files  
/usr/sbin/zuludaemon  daemon executable
/usr/lib/zulu.ucode  file containing microcode used by zuludaemon
/etc/init.d/zulusinit  startup/kill script for zuludaemon
