This guide describes how to deploy Oracle Coherence*Web (Coherence*Web), an HTTP session management module, to GlassFish Server, WebLogic Server and other application servers. It also describes the different session management features that you can configure.

This guide also describes how you can integrate Coherence*Web with WebLogic Portal, to provide session state management based on Oracle Coherence caches.

**Audience**

This guide is intended for application developers who want to be able to manage session state in clustered environments.

**Documentation Accessibility**

**Access to Oracle Support**

Introduction to Coherence*Web

This chapter contains the following sections:

- Understanding Coherence*Web
- Supported Web Containers
- Installation and Deployment Road Map

Understanding Coherence*Web

Coherence*Web is an HTTP session management module dedicated to managing session state in clustered environments. Built on top of Oracle Coherence (Coherence), Coherence*Web:

- brings Coherence data grid’s data scalability, availability, reliability, and performance to in-memory session management and storage.
- can configure fine-grained session and session attribute scoping by way of pluggable policies (see "Session and Session Attribute Scoping" on page 5-7).
- can be deployed to many mainstream application servers such as Oracle GlassFish Server, Oracle WebLogic Server, IBM WebSphere, Tomcat, and so on (see "Supported Web Containers" on page 1-1).
- can be deployed to many portal containers, including Oracle WebLogic Portal (see Chapter 10, "Using Coherence*Web with WebLogic Portal").
- allows storage of session data outside of the Java EE application server, freeing application server heap space and enabling server restarts without session data loss (see "Deployment Topologies" on page 5-16).
- enables session sharing and management across different Web applications, domains and heterogeneous application servers (see "Session and Session Attribute Scoping" on page 5-7).
- can be used in advanced session models (that is, Monolithic, Traditional, and Split Session) that define how the session state is serialized or deserialized in the cluster (see "Session Models" on page 5-2).

Supported Web Containers

To install the Coherence*Web session management module on Oracle WebLogic Server 9.2.1, 9.2.3, 10.3.1, and later, you can use the Coherence*Web Service Provider Interface (SPI)-based installation. For instructions on installing the Management Module on WebLogic Server 10.3.4, see Chapter 2, "Using Coherence*Web with WebLogic Server."
For third-party application servers and a few legacy versions of Oracle WebLogic Server (9.2.1, 9.2.3, 10.3, 10.3.1), Coherence*Web provides a generic installer, the WebInstaller, that transparently instruments your Web applications. Chapter 4, "Using Coherence*Web on Other Application Servers," describes how to use the WebInstaller to install Coherence*Web on these servers.

Table 1–1 summarizes the Web containers supported by the Coherence*Web session management module. It also provides links to the information required to install Coherence*Web. Notice that all of the Web containers (except Oracle WebLogic Server 10.3.4) share the same general installation instructions. A few, such as Caucho Resin, and WebLogic 10.3, require extra, container-specific steps that you must complete before starting the general installation instructions.

---

**Note:** The value in the Server Type Alias column is used only by the Coherence*Web WebInstaller installation. The value is passed to the WebInstaller through the -server command-line option.

---
There are deployment decisions you should make before you configure and deploy Coherence*Web. Coherence*Web is supported on many different application servers. Regardless of which application server you are using, you might have to change some Coherence*Web configuration options to meet your particular requirements, such as packaging considerations, session model, session locking mode, and deployment topology.

### Choose Your Cluster Node Isolation

Cluster node isolation refers to the scope of the Coherence nodes that are created within each application server JVM. Several different isolation modes are supported. For example: you might be deploying multiple applications to the container that require the use of the same cluster (or one Coherence node); you might have multiple Web applications packaged in a single EAR file that use a single cluster; or you might have Web applications that must keep their session data separate and must be deployed to their own individual Coherence cluster. These choices and the deployment descriptors and elements that must be configured are described in "Cluster Node Isolation" on page 5-10.

### Choose Your Locking Mode

Locking mode refers to the behavior of HTTP sessions when they are accessed concurrently by multiple Web container threads. Coherence*Web offers several different session locking options. For example, you can allow multiple nodes in a cluster to access an HTTP session simultaneously, or allow only one thread at a time to access an HTTP session. You can also allow multiple threads to access the same Web application instance while prohibiting concurrent access by threads in different Web application instances. These choices, and the deployment descriptors and elements that must be configured, are described in "Session Locking Modes" on page 5-13.

### Choose How to Scope Sessions and Session Attributes

Session and session attribute scoping refers to the fine-grained control over how both session data and session attributes are scoped (or shared) across application boundaries. Coherence*Web supports sharing sessions across Web applications and restricts which session attributes are shared across the application boundaries. These choices, and the deployment descriptors and elements that must be configured, are described in "Session and Session Attribute Scoping" on page 5-7.

Choose When to Clean Up Expired HTTP Sessions

Coherence*Web provides a session reaper, which invalidates sessions that have expired. Chapter 7, "Cleaning Up Expired HTTP Sessions," describes the session reaper.

Choose the Installation Method

The installation procedure that you follow depends on your application server. "Supported Web Containers" on page 1-1 provides a list of the application servers and the corresponding instructions for installing Coherence*Web.

If you are installing Coherence*Web on a recent release of WebLogic Server (WebLogic Server 11gR1 and later), use the native WebLogic Server SPI-based installation procedure described in Chapter 2, "Using Coherence*Web with WebLogic Server."

For other application servers, use the generic Java EE WebInstaller described in Chapter 4, "Using Coherence*Web on Other Application Servers."

Note that the installation of Coherence*Web on WebLogic Portal is completely independent of WebLogic Server; that is, you do not have to install Coherence*Web on WebLogic Server to install it on WebLogic Portal. See Chapter 10, "Using Coherence*Web with WebLogic Portal."
Using Coherence*Web with WebLogic Server

This chapter contains the following sections:

■ Overview of the Coherence*Web SPI
■ Configuring and Deploying Coherence*Web—Main Steps
■ Scoping the Session Cookie Path
■ Sharing Coherence*Web Sessions with Other Application Servers

Coherence*Web provides session state persistence and management. It is a session management module that uses Coherence caches for storing and managing session data. This chapter describes how to set up and deploy Coherence*Web so that it can be used by applications running on WebLogic Server.

Coherence*Web is an alternative to the WebLogic Server in-memory HTTP state replication services. Consider using Coherence*Web if you are encountering any of these situations:

■ Your application works with large HTTP session state objects
■ You run into memory constraints, due to storing HTTP session object data
■ You want to offload HTTP session storage to an existing Coherence cluster
■ You want to share session state across enterprise applications and Web modules

New for 3.7.1: The session-cache-config.xml file has been moved from the coherence-web-spi.war file to the coherence-web.jar file. The coherence-web.jar file can be found in the coherence\lib directory.

Overview of the Coherence*Web SPI

The Coherence*Web Service Provider Interface (SPI) consists of the coherence-web-spi.war file. To use functionality provided by the coherence-web-spi.war, the coherence.jar classes must also be available to the Web application.

In Coherence*Web, the following default cache configurations are defined:

■ The Coherence*Web SPI for WebLogic Server is configured with local-storage disabled. The server will serve requests and will not be used to host data. This
means a Coherence cache server must be running in its own JVM, separate from
the JVM running WebLogic Server.

■ The timeout for requests to the cache server to respond is 30 seconds. If a request
to the cache server has not responded in 30 seconds, a com.tangosol.net.
RequestTimeoutException exception is thrown.

Coherence cache configurations and services used by Coherence*Web SPI are defined
in the session-cache-config.xml file, which can be found in the coherence-
web.jar file. The default cache and services configuration defined in the session-
cache-config.xml file should satisfy most Web applications.

Coherence*Web provides several session locking modes to control concurrent access of
sessions. Both Coherence*Web and the Coherence*Web SPI employ Last Write Wins
locking by default. See "Session Locking Modes" on page 5-13 for more information
about locking modes.

By itself, the Coherence*Web SPI does not require a load balancer to run in front of the
WebLogic Server tier. However, a load balancer will improve performance. It is
required if the same session will be used concurrently and locking is not enabled. The
default load balancer enforces HTTP session JVM affinity, however, other load
balancing alternatives are available. WebLogic Server ships with several different
proxy plug-ins which enforce JVM session stickiness. Documentation for configuring
the WebLogic Server proxy plug-in is available at this URL:

1111/e13709/load_balancing.htm

Configuring and Deploying Coherence*Web—Main Steps

Coherence*Web includes a deployable shared library that contains a native plug-in to
the WebLogic Server HTTP Session Management interface. The following steps
summarize how to prepare your deployments to use Coherence*Web with applications
running on WebLogic Server:

1. Download Oracle Coherence to your file system. See "Download Oracle
   Coherence" on page 2-2.

2. Modify the web.xml file in the WAR deployment if your application requires
   advanced configuration for Coherence*Web. "Configure Coherence*Web" on
   page 2-3 describes the parameters that can be configured for Web applications. The
   entire set of Coherence*Web parameters are described in Appendix A,
   "Coherence*Web Context Parameters."

3. (Optional) Configure the WebLogic-generated HTTP session cookie parameters in
   the weblogic.xml or weblogic-application.xml file. See "Configure the
   Session Cookies" on page 2-5.

4. (Optional for testing; strongly suggested for production) Start a Cache Server Tier
   in a separate JVM from the one running WebLogic Server. See "Start a Cache
   Server" on page 2-8.

5. Determine the appropriate packaging based on your deployment requirements
   and follow the packaging instructions. Depending on your version of WebLogic
   Server, see "Configure Cluster Nodes" on page 2-10.

Download Oracle Coherence

All of the files needed by Coherence*Web, including the coherence-web-spi.war
file, are included in the Coherence distribution.
By default, Coherence 3.6 is installed with WebLogic Server 10.3.4. The default location of the Coherence directory is C:\Oracle\Middleware\coherence_3.6. If you are using WebLogic Server 10.3.4, you can download Coherence 3.7 and save it to your file system. Ensure that your applications reference coherence-web-spi.war, coherence.jar, and other library files that are in the Coherence 3.7 distribution.

Similarly, if you are working with WebLogic Server 10.3.3, you might already have Coherence installed in a coherence_3.5 directory. Again, you can download Coherence 3.7 and save it to your file system. Ensure that your applications reference coherence-web-spi.war, coherence.jar, and other library files that are in the Coherence 3.7 distribution.

If you are using WebLogic Server 10.3.2 or earlier, simply download the Coherence distribution to your file system.

### Applying Required Software Patches

Some older versions of WebLogic Server require you to apply software patches before you can work with Coherence and Coherence*Web. Table 2–1 identifies the versions of WebLogic Server and their associated patches.

| Table 2–1 Required Software Patches for WebLogic Server |
|---------------------------------|---------------------------------|---------------------------------|---------------------------------|
| WebLogic Server 9.2 MP1         | WebLogic Server 9.2 MP3         | WebLogic Server 10.3            | WebLogic Server 11g (10.3.1 and later) |
| WebLogic Smart Update          | Patch ID: 616G                  | Patch ID: LP7B                   | Patch ID: 6W2W                   | No Patch Required               |

You can obtain the patches either through the Smart Update utility in the WebLogic Server Administration Console or by going to My Oracle Support.

To use Smart Update, see the instructions in the WebLogic Server Administration Console. For production environments, you should review the Smart Update production installation notes.

To use My Oracle Support, go to the My Oracle Support web site.

https://support.oracle.com/

Select the Patches tab, click on the Simple Search link, and on the subsequent screen submit a search for a Patch Number/Name with the appropriate value (for example, 11399293). Download the patch zip file from the displayed results. Instructions for applying the Coherence patch are located in the README.txt included in the patch zip file.

### Configure Coherence*Web

The Coherence*Web SPI provides a default configuration that should satisfy most Web applications. Table 2–2 describes only those Coherence*Web context parameters where the default for the SPI version is different from the non-SPI version. Table 2–3 describes the compatibility mode context parameter which is supplied by the SPI. For complete descriptions of all Coherence*Web parameters, see Appendix A, "Coherence*Web Context Parameters."

You can also configure the context parameters on the command line as system properties. The system properties have the same name as the context parameters, but the dash (-) is replaced with a period (.). For example, to declare a value for the context parameter coherence-enable-sessioncontext on the command line, enter it like this:

-Dcoherence.enable.sessioncontext=true
If both a system property and the equivalent context parameter are configured, the value from the system property is used.

### Table 2-2  Coherence*Web Context Parameters Configured by the SPI

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| coherence-application-name      | Coherence*Web uses the value of this parameter to determine the name of the application that uses the ApplicationScopeController interface to scope attributes. The value for this parameter should be provided in the following format: *application name* + ! + *Web module name*

  The *application name* is the name of the application that uses the ApplicationScopeController interface and *Web module name* is the name of the Web module in which it appears.

  For example, if you have an EAR file named test.ear and a Web-module named app1 defined in the EAR file, then the default value for the coherence-application-name parameter would be test!app1.

  If this parameter is not configured, then Coherence*Web uses the name of the class loader instead. Also, if the parameter is not configured and the ApplicationScopeController interface is configured, then a warning is logged saying that the application name was not configured. See “Session Attribute Scoping” on page 5-9 for more information. |
| coherence-reaperdaemon-assume-locality | This setting allows the session reaper to assume that the sessions that are stored on this node (for example, by a distributed cache service) are the only sessions that this node must check for expiration. The default is false. |
| coherence-scopecontroller-class | This value specifies the class name of the optional com.tangosol.coherence.servlet.HttpSessionCollection$AttributeScopeController interface implementation.

  Valid values include:

  - com.tangosol.coherence.servlet.AbstractHttpSessionCollection$ApplicationScopeController (default)
  - com.tangosol.coherence.servlet.AbstractHttpSessionCollection$GlobalScopeController

  The default set by the Coherence*Web SPI is com.tangosol.coherence.servlet.AbstractHttpSessionCollection$ApplicationScopeController. |

Table 2-3 describes the coherence-session-weblogic-compatibility-mode context parameter which is specifically provided by the Coherence*Web SPI.
Using Coherence*Web with WebLogic Server

Table 2–3   Context Parameter Provided by the Coherence*Web SPI

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-session-weblogic-compatibility-mode</td>
<td>This parameter is provided by the SPI version of Coherence<em>Web. If its value is set to true, it determines that a single session ID (with the cookie path set to &quot;/&quot;) will map to a unique Coherence</em>Web session instance in each Web application. If it is false, then the standard behavior will apply: a single session ID will map to a single session instance using the Coherence*Web SPI in WebLogic Server. All other session persistence mechanisms in WebLogic use a single session ID in each Web application to refer to different session instances. This parameter defaults to true unless the global scope controller is specified. If this controller is specified, then the parameter defaults to false.</td>
</tr>
</tbody>
</table>

Table 2–4 describes the coherence-factory-class context parameter. The default value, which is set by the Coherence*Web SPI, should not be changed.

Table 2–4   Context Parameter Value that Should Not be Changed

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-factory-class</td>
<td>The fully qualified name of the class that implements the SessionHelper.Factory factory class. The Coherence*Web SPI sets the default value to weblogic.servlet.internal.session.WebLogicSPIFactory. This value should not be changed.</td>
</tr>
</tbody>
</table>

Configure the Session Cookies

If you are using Coherence*Web SPI, then WebLogic Server generates and parses the session cookie. In this case, any native Coherence*Web session cookie configuration parameters will be ignored. To configure the session cookies, use the WebLogic-generated HTTP session cookie parameters in the weblogic.xml or weblogic-application.xml files. Table 2–5 describes these parameters.

In this table, Updatable? indicates whether the value of the parameter can be changed while the server is running. Not applicable indicates that there is no corresponding Coherence session cookie parameter.
<table>
<thead>
<tr>
<th>This Session Cookie Parameter...</th>
<th>Replaces this Coherence*Web Cookie Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cookie-comment</td>
<td>Not applicable</td>
<td>Specifies the comment that identifies the session tracking cookie in the cookie file. The default is null. Updatable? Yes</td>
</tr>
<tr>
<td>cookie-domain</td>
<td>coherence-session-cookie-domain</td>
<td>Specifies the domain for which the cookie is valid. For example, setting cookie-domain to .mydomain.com returns cookies to any server in the *.mydomain.com domain. The domain name must have at least two components. Setting a name to *.com or *.net is not valid. If not set, this attribute defaults to the server that issued the cookie. For more information, see Cookie.setDomain() in the Servlet specification. The default is null. Updatable? Yes</td>
</tr>
<tr>
<td>cookie-max-age-secs</td>
<td>coherence-session-max-age</td>
<td>Sets the life span of the session cookie, in seconds, after which it expires on the client. For more information about cookies, see &quot;Using Sessions and Session Persistence&quot; in Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server. The default value is -1 (unlimited). Updatable? Yes</td>
</tr>
<tr>
<td>cookie-name</td>
<td>coherence-session-cookie-name</td>
<td>Defines the session-tracking cookie name. Defaults to JSESSIONID if not set. You can set this to a more specific name for your application. The default is JSESSIONID. Updatable? Yes</td>
</tr>
<tr>
<td>cookie-path</td>
<td>coherence-session-cookie-path</td>
<td>Defines the session-tracking cookie path. If not set, this attribute defaults to a slash (/) where the browser sends cookies to all URLs served by WebLogic Server. You can set the path to a narrower mapping, to limit the request URLs to which the browser sends cookies. The default is null. Updatable? Yes</td>
</tr>
<tr>
<td>cookie-secure</td>
<td>coherence-session-cookie-secure</td>
<td>Tells the browser that the cookie can be returned only over an HTTPS connection. This ensures that the cookie ID is secure and should be used only on Web sites that use HTTPS. Session cookies sent over HTTP will not work if this feature is enabled. Disable the url-rewriting-enabled element if you intend to use this feature. WebLogic Server generates the session cookie. The default is false. Updatable? Yes</td>
</tr>
</tbody>
</table>
### Table 2–5  (Cont.) WebLogic-Generated HTTP Session Cookie Parameters

<table>
<thead>
<tr>
<th>This Session Cookie Parameter</th>
<th>Replaces this Coherence*Web Cookie Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cookies-enabled</td>
<td>coherence-session-cookies-enabled</td>
<td>Enables use of session cookies by default and is recommended, but you can disable them by setting this property to false. You might turn this option off for testing purposes. The default is true. Updatable? Yes</td>
</tr>
<tr>
<td>debug-enabled</td>
<td>Not applicable</td>
<td>Enables the debugging feature for HTTP sessions. Support it by enabling HttpSessionDebug logging and the WebLogic Server trace logger. The default value is false. Updatable? Yes</td>
</tr>
<tr>
<td>encode-session-id-in-query-params</td>
<td>Not applicable</td>
<td>Is set to true if the latest servlet specification requires containers to encode the session ID in path parameters. Certain Web servers do not work well with path parameters. In such cases, the encode-session-id-in-query-params element should be set to true. WebLogic Server generates the HTTP response. The default value is false. Updatable? Yes</td>
</tr>
<tr>
<td>http-proxy-caching-of-cookies</td>
<td>Not applicable</td>
<td>When set to false, WebLogic Server adds the following header and response to indicate that the proxy caches are not caching the cookies: “Cache-control: no-cache=set-cookie” WebLogic Server generates the HTTP response. The default value is true. Updatable? Yes</td>
</tr>
<tr>
<td>id-length</td>
<td>coherence-session-id-length</td>
<td>Sets the size of the session ID. The minimum value is 8 bytes and the maximum value is Integer.MAX_VALUE. If you are writing a Wireless Application Protocol (WAP) application, you must use URL rewriting because the WAP protocol does not support cookies. Also, some WAP devices have a 128-character limit on URL length (including attributes), which limits the amount of data that can be transmitted using URL rewriting. To allow more space for attributes, use this attribute to limit the size of the session ID that is randomly generated by WebLogic Server. You can also limit the length to a fixed 52 characters, and disallow special characters, by setting the WAPEnabled attribute. For more information, see &quot;URL Rewriting and Wireless Access Protocol&quot; in Developing Web Applications for WebLogic Server. The default is 52. Updatable? No</td>
</tr>
</tbody>
</table>
Start a Cache Server

A Coherence cache server (also known as a data node) is responsible for storing and managing all cached data. It can be either a dedicated JVM or run within a WebLogic Server instance. The senior node (which is the first node) in a Coherence data cluster can take several seconds to start; the startup time required by subsequent nodes is minimal.

Whether you start the cache servers first or the WebLogic Server instances first, depends on the server topology you are employing:

- If you are using an In-Process topology (all storage-enabled WebLogic Server instances), then it does not matter if you start the cache servers first or WebLogic Server instances first.
- If you are using an Out-of-Process topology (storage-disabled WebLogic Server instances and standalone Coherence cache servers), then start the cache servers first, followed by the WebLogic Server instances. This will ensure that there is minimal (measured in milliseconds) startup time for applications using...
Coherence. Any additional Web applications that use Coherence are guaranteed not to be the senior data member, so they will have minimal impact on WebLogic Server startup.

In this topology, if you do not start the cache servers first, Coherence will respond with an error message similar to the following:

No storage-enabled nodes exist for service ...

To Start a Standalone Coherence Data Node

Follow these steps to start a standalone Coherence data node:

1. Create a script for starting a Coherence data node. The following is a very simple example of a script that starts a storage-enabled cache server. This example assumes that you are using a Sun JVM. See "JVM Tuning" in Developer's Guide for Oracle Coherence for more information.

   ```
   java -server -Xms512m -Xmx512m -cp <Coherence installation dir>/lib/coherence-web.jar:<Coherence installation dir>/lib/coherence.jar -Dtangosol.coherence.management.remote=true -Dtangosol.coherence.cacheconfig=cache_configuration_file -Dtangosol.coherence.session.localstorage=true com.tangosol.net.DefaultCacheServer
   
   You must include coherence-web.jar and coherence.jar on the classpath. The cache_configuration_file represents the absolute path to the cache configuration file on your file system. For Coherence*Web, this will be the session-cache-config.xml file. Note that the cache configuration defined for the cache server must match the cache configuration defined for the application servers which run on the same Coherence cluster.

   If you have additional Coherence caches running on Coherence*Web, then you must merge the cache configuration information (typically defined in the coherence-cache-config.xml file) with the session configuration contained in the session-cache-config.xml file. The cache and session configuration must be consistent across WebLogic Server and Coherence cache servers.

   For more information on merging these files, see "Merging Coherence Cache and Session Information" in Integration Guide for Oracle Coherence.

2. Start one or more Coherence data nodes using the script described in the previous step.

To Start a Storage-Enabled or -Disabled WebLogic Server Instance

By default, a Coherence*Web-enabled WebLogic Server instance starts in storage-disabled mode. To start the WebLogic Server instance in storage-enabled mode, follow these steps:

1. Create a script for starting a Coherence data node. This can be similar to the script described in the previous section.

2. Include the command-line property to enable local storage, -Dtangosol.coherence.session.localstorage=true, in the server startup command.

For more information about working with WebLogic Server through the command line, see "weblogic.Server Command-Line Reference" in Oracle Fusion Middleware Command Reference for Oracle WebLogic Server.
Configure Cluster Nodes

The session management provided by Coherence*Web can have application server-scope, EAR-scope, or WAR-scope. Like Coherence clusters, scoping of Coherence*Web depends on the placement of the coherence.jar file in the classloader’s hierarchy. You can find detailed information about each of the scopes in "Cluster Node Isolation" on page 5-10.

WebLogic Server, versions 10.3.3 and later, provides several features, collectively known as ActiveCache, that allow your applications to more easily interact with the Coherence cache. For a complete discussion of these features see the Using ActiveCache guide.

Some earlier versions of WebLogic Server (such as version 10.3.1 and earlier) might need a software patch to use Coherence and Coherence*Web. To find out if your version of WebLogic Server requires a patch, see "Applying Required Software Patches" on page 2-3.

The following sections describe how you can configure the different cluster node configurations to run Coherence*Web:

■ Configuring Application Server-Scoped Cluster Nodes
■ Configuring EAR-Scoped Cluster Nodes
■ Configuring WAR-Scoped Cluster Nodes

---

**Note:** Consider the use of the application server-scoped cluster configuration very carefully. Do not use it in environments where application interaction is unknown or unpredictable.

An example of such an environment might be a deployment where multiple application teams are deploying applications written independently, without carefully coordinating and enforcing their conventions and naming standards. With this configuration, all applications are part of the same cluster—the likelihood of collisions between namespaces for caches, services, and other configuration settings is quite high and could lead to unexpected results.

For these reasons, Oracle Coherence strongly recommends that you use EAR-scoped and WAR-scoped cluster node configurations. If you are in doubt regarding which deployment topology to choose, or if this warning applies to your deployment, then do not choose the application server-scoped cluster node configuration.

---

Configuring Application Server-Scoped Cluster Nodes

If you are adding Coherence*Web for session management to a Coherence cluster, follow these steps:

1. Edit your WebLogic Server system classpath to include the coherence.jar file or copy the JAR file to your $DOMAIN_HOME/lib directory.

2. Use the WebLogic Server Administration Console or the command line to deploy coherence-web-spi.war file as a shared library.

3. Enable Coherence*Web in your Web application.

Add the library reference code illustrated in Example 2-1 to the weblogic.xml file in each WAR file deployed in the WebLogic Server that intends to use Coherence*Web.
**Example 2-1  Library Reference for a WAR File**

```xml
<weblogic-web-app>
  ...
  <library-ref>
    <library-name>coherence-web-spi</library-name>
  </library-ref>
  ...
</weblogic-web-app>
```

**Configuring EAR-Scoped Cluster Nodes**

If you are using Coherence*Web for session management in EAR-scoped cluster nodes, and your applications are running on WebLogic Server 10.3.2 or earlier, follow these steps:

1. Use the WebLogic Server Administration Console to deploy the coherence.jar and coherence-web-spi.war files as shared libraries to all of the target servers where the application will be deployed. See “Install a Java EE Library” in Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help for more information.

   If you receive an error when you attempt to deploy coherence.jar through the WebLogic Server Administration Console, you can use WLST commands. See Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help for more information.

2. Reference the coherence.jar file in the weblogic-application.xml file. Store the file in the EAR’s META-INF directory.

   Example 2–2 illustrates a weblogic-application.xml file.

   **Example 2–2  Coherence JAR Referenced in weblogic-application.xml**

   ```xml
   <weblogic-application ...>
     ...
     <library-ref>
       <library-name>coherence</library-name>
     </library-ref>
     ...
   </weblogic-application>
   ```

3. Reference the coherence-web-spi.war file in the weblogic.xml file.

   Example 2–3 illustrates a weblogic.xml file.

   **Example 2–3  Coherence Web SPI WAR Referenced in weblogic.xml**

   ```xml
   <weblogic-web-app>
     ...
     <library-ref>
       <library-name>coherence-web-spi</library-name>
     </library-ref>
     ...
   </weblogic-web-app>
   ```

**Configuring WAR-Scoped Cluster Nodes**

If you are using Coherence*Web for session management in WAR-scoped cluster nodes, follow these steps:

1. Use the WebLogic Server Administration Console or the command line to deploy the coherence-web-spi.war file as a shared library to all of the target servers.
Scoping the Session Cookie Path

where the application will be deployed. See "Install a Java EE Library" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

2. Add the coherence.jar file to the application. You can do this in any of the following ways:
   - Import coherence.jar file as an optional package in the manifest.mf file of each module that will be using Coherence. Example 2–4 illustrates a manifest.mf file.

   **Example 2–4 Manifest File that References the Coherence JAR File**
   
   Manift-Version: 1.0
   Extension-List: coherence
   coherence-Extension-Name: coherence
   
   - Copy the coherence.jar file to the WAR file's WEB-INF/lib directory.

3. If you deploy the coherence-web-spi.war file as a shared library, you must also create a shared library reference by adding the stanza illustrated in Example 2–5 to the weblogic.xml file in the WAR file's WEB-INF directory.

   **Example 2–5 Library Reference for a Web Application**
   
   <weblogic-web-app ...>
   ...
   <library-ref>
     <library-name>coherence-web-spi</library-name>
   </library-ref>
   ...
   </weblogic-web-app>

Scoping the Session Cookie Path

WebLogic Server and Coherence*Web handle session scoping and the session lifecycle in different ways. This can impact your decision to implement a single sign-on (SSO) strategy for your applications.

By default, WebLogic Server uses the same session ID in every Web application for a given client, and sets the session cookie path to a slash (/). This is a requirement of the WebLogic Server default thin SSO implementation, which is enabled by default. By generating a session cookie with a path of "/", clients always return the same session ID in every request to the server. In WebLogic Server, a single session ID can be mapped to multiple session objects. Each Web application will have a different session object instance even though the session ID is identical (unless session sharing is enabled).

In contrast, Coherence*Web maps a session ID to a single session instance. This means that the behavior of having multiple session instances mapped to the same ID is not replicated by default if an application uses Coherence*Web. Because the session cookie is mapped to "/" by default, a single Coherence*Web session is shared across all Web applications. The default configuration in Coherence*Web is that all session attributes are scoped to a Web application. For most purposes, this single session approach is transparent. The major difference of having a single session across all Web applications is the impact of session invalidation. If Coherence*Web is enabled and you invalidate a session in one Web application, then you invalidate that session in all Web applications that use that session instance. If your Web applications do not use thin SSO, then you can avoid this issue by scoping the session cookie to the Web application path.

Therefore, you have the following options regarding SSO:
■ Enable "WebLogic Server session compatibly mode". This configuration is set with the coherence-session-weblogic-compatibility-mode parameter and mirrors all of the native WebLogic Server session persistence types: memory (single-server, non-replicated), file system persistence, JDBC persistence, cookie-based session persistence, and in-memory replication (across a cluster). By default, this mode is enabled. See "Using Sessions and Session Persistence" in Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server for more information.

■ Enable thin SSO functionality. Clients will use a single session across all Web applications. This means that the session life cycle will be inconsistent with all other session persistence types.

■ Disable the thin SSO functionality by scoping the session cookie path to the Web application context path. This will allow the session life cycle to be consistent with all other session persistence types.

One advantage of enabling thin SSO with Coherence*Web is that it will work across all Web applications that are using the same Coherence cluster for Coherence*Web. The Coherence cluster is completely independent from the WebLogic Server cluster. The thin SSO functionality can even span multiple domains by enabling cross-domain trust in the WebLogic Server security layer.

Sharing Coherence*Web Sessions with Other Application Servers

If you are running Coherence*Web on WebLogic Server and on other application servers within a single cluster, then the session cookies created by WebLogic Server will not be decoded correctly by Coherence*Web on the other servers. This is because WebLogic Server adds a session affinity suffix to the cookie which is not part of the session ID stored in Coherence*Web. The other application servers must remove the WebLogic session affinity suffix from the session cookie value for Coherence*Web to be able to retrieve the session from the Coherence cache.

To strip the WebLogic session affinity suffix from the session cookie, add the coherence-session-affinity-token context parameter to the web.xml file used in the other application servers. Set the parameter value to an exclamation point (!), as illustrated in Example 2–6. The session affinity suffix will be removed from the session cookie when it is processed by the other application server.

Example 2–6 Removing Session Affinity Suffix

```xml
...<context-param>
  <param-name>coherence-session-affinity-token</param-name>
  <param-value>!</param-value>
</context-param>
...```

See Appendix A, "Coherence*Web Context Parameters" for more information on the coherence-session-affinity-token context parameter.
Using Coherence*Web with GlassFish Server

Oracle GlassFish Server delivers a flexible, lightweight and extensible Java EE 6 platform. It provides a small footprint, fully featured Java EE application server that is completely supported for commercial deployment and is available as a standalone offering. Oracle GlassFish Server is best suited for applications requiring lightweight infrastructure and the most recent implementations of Java Enterprise Edition. This chapter describes how to set up and deploy Coherence*Web so that it can be used by applications running on GlassFish Server.

Starting with Coherence 3.7 and Oracle GlassFish Server 3.1, there is a Coherence*Web feature called ActiveCache for GlassFish. ActiveCache for GlassFish provides Coherence*Web functionality in Web applications deployed on Oracle GlassFish Servers. In previous releases, the Coherence*Web WebInstaller was required to preprocess applications before they could use Coherence*Web for session storage. With ActiveCache for GlassFish, the WebInstaller pre-processing step is not required for GlassFish 3.1 applications.

**Overview of ActiveCache for GlassFish**

ActiveCache for GlassFish functionality is provided in the coherence-web.jar file which can be found in the coherence/lib folder. Coherence cache configurations and services used by ActiveCache for GlassFish are defined in the session-cache-config.xml file, which can be found in the coherence-web.jar file. The default cache and services configuration defined in the session-cache-config.xml file should satisfy most Web applications.

Since Coherence*Web uses Coherence caches to store session data, the coherence.jar file must also be available to the Web application’s classloader. See "Configure Cluster Nodes" on page 3-7 for more information on configuring ActiveCache for GlassFish to run on EAR-scoped or WAR-scoped cluster nodes.

By default, the Coherence node running on GlassFish Server is configured as storage-disabled. A separate Coherence cache server must be running for the Web application to work.

Coherence*Web provides several session locking modes to control concurrent access of sessions. ActiveCache for GlassFish employs Last Write Wins Locking by default. This
allows concurrent access to a session by multiple threads in a single JVM or multiple JVMs while prohibiting concurrent modification. See "Session Locking Modes" on page 5-13 for more information about locking modes.

The split session model (SplitHttpSessionModel), where small session attributes are stored as a single cache entry, and large attributes are stored as individual cache entries, is the default session model used by ActiveCache for GlassFish. See "Session Models" on page 5-2 for more information.

Heap space is made available in GlassFish Server by storing session data in the Coherence data grid. Storing session data outside of GlassFish Server allows the Web application and the server to be restarted without any loss of session data. It also allows sessions to be shared across different web applications. Coherence*Web can run on GlassFish Server in either EAR-scoped or WAR-scoped cluster nodes. Application Server-scope is not supported.

### Configuring And Deploying Coherence*Web on GlassFish Server—Main Steps

The following steps summarize how to prepare your deployments to use Coherence*Web with applications running on GlassFish Server:

1. Download Oracle Coherence to your file system. See "Download Oracle Coherence".

2. Set the session persistence type to coherence-web for the Web application in glassfish-web.xml file. See "Set the Session Persistence Type" on page 3-3.

3. (Optional) If you must override the default Coherence*Web cache or cluster configuration, edit the session-cache-config.xml file. See "Override the Default Coherence*Web Cache or Cluster Configuration" on page 3-3.

4. Make the coherence-web.jar file available to the Web application. See "Copy the ActiveCache for GlassFish and Session Cache Files to the Application" on page 3-3.

5. Edit the web.xml file to make your Web application available to a server cluster. See "Make Your Web Applications Distributable" on page 3-3.

6. (Optional) Edit the web.xml file in the WAR deployment if your application requires advanced configuration for Coherence*Web. See "Configure Coherence*Web".

7. (Optional for testing; strongly suggested for production) Start a Cache Server Tier in a JVM that is separate from the one running GlassFish Server. See "Start a Cache Server" on page 3-6.

8. Package the application. Coherence*Web can be configured for EAR-scoped or WAR-scoped cluster nodes on GlassFish Server. See "Configure Cluster Nodes" on page 3-7.

### Download Oracle Coherence

All of the files supporting Coherence*Web, including ActiveCache for GlassFish, are included in the Coherence distribution. You can get the latest release of Oracle Coherence at this URL:

http://www.oracle.com/technetwork/middleware/coherence/overview/index.html
Set the Session Persistence Type

Create or edit the *glassfish-web.xml* file in the WEB-INF directory of the Web application. Set the session persistence type for the Web application to be *coherence-web*, for example:

```
<glassfish-web-app>
  <session-config>
    <session-manager persistence-type="coherence-web"/>
  </session-config>
</glassfish-web-app>
```

Override the Default Coherence*Web Cache or Cluster Configuration

The *session-cache-config.xml* file provides the default definition of the session caches and services which Coherence*Web uses to implement HTTP session management. The *coherence-web.jar* file contains a default *session-cache-config.xml* file which should satisfy most Web applications. If necessary, you can provide an alternate cache and cluster configuration in your own custom *session-cache-config.xml* and *tangosol-coherence-override.xml* file. You must include the file in the WEB-INF/classes directory in the Web application.

Copy the ActiveCache for GlassFish and Session Cache Files to the Application

The *coherence-web.jar* file provides the functionality for ActiveCache for GlassFish. You must make the *coherence-web.jar* file available to the applications that you want to run on GlassFish Server.

Copy the *coherence-web.jar* file to the /WEB-INF/lib/ directory of each Web application that you intend to deploy on GlassFish Server.

Make Your Web Applications Distributable

Your Web application must be configured to run in a distributed environment, such as a server cluster. Add the `<distributable/>` element to the *web.xml* deployment descriptor of your Web application. The `<distributable/>` element is a child of the root `<web-app>` element. The *web.xml* file is located in the WEB-INF directory of your Web application.

Configure Coherence*Web

ActiveCache for GlassFish provides a default Coherence*Web configuration that should satisfy most Web applications. The Coherence*Web configuration is defined using `<context-param>` elements in the *web.xml* file. The default values can be overridden by adding or editing `<context-params>` elements in the *web.xml* file.

```
<context-param>
  <param-name>context-param-name</param-name>
  <param-value>context-param-value</param-value>
</context-param>
```

**Note:** If you make any changes to the Coherence*Web configuration after a Web application has been started, then you must restart the Web application. There are no dynamically updatable configuration options in Coherence*Web.

Table 3–1 describes the default values which ActiveCache for GlassFish provides for Coherence*Web. See Appendix A, “Coherence*Web Context Parameters” for more information about these parameters.
Coherence*Web context parameters that configure the session cookie are not honored because GlassFish Server generates and parses the session cookie. Even though Coherence*Web can be configured to enable servlet contexts to be clustered, ActiveCache for GlassFish does not support this functionality.

Table 3–2 describes the Coherence*Web context parameters that are not valid when used with ActiveCache for GlassFish. ActiveCache for GlassFish will return a warning log if these context parameters are present. See Appendix A, "Coherence*Web Context Parameters" for more information about these parameters.

### Table 3–1 Default Context Parameter Values Provided by ActiveCache for GlassFish

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description and Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-application-name</td>
<td>The default is ServletContext + ServletContext name. A consistent and unique string to represent the Web application name.</td>
</tr>
<tr>
<td>coherence-cluster-owned</td>
<td>The default is false. Because all Coherence nodes start when the Web application starts, they should also shutdown the Coherence node when the Web application stops.</td>
</tr>
<tr>
<td>coherence-reaperdaemon-assume-locality</td>
<td>The default is false. Sessions can be stored on standalone cache servers.</td>
</tr>
<tr>
<td>coherence-scopecontroller-class</td>
<td>The default is com.tangosol.coherence.servlet.AbstractHttpSessionCollection$ApplicationScopeController</td>
</tr>
<tr>
<td>coherence-session-locking</td>
<td>The default is false. Session locking is disabled by default. This configuration enables a &quot;last writer wins&quot; policy.</td>
</tr>
<tr>
<td>coherence-sessioncollection-class</td>
<td>The default is com.tangosol.coherence.servlet.SplitHttpSessionCollection. SplitHttpSessionCollection is the recommended default model.</td>
</tr>
</tbody>
</table>

### Table 3–2 Coherence*Web Context Parameters that are not Valid for the GlassFish Server

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Reason Why it is Not Valid</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-distributioncontroller-class</td>
<td>The value for GlassFish Server is com.tangosol.coherence.servlet.glassfish31.GlassFishHybridController.</td>
</tr>
<tr>
<td>coherence-preserve-attributes</td>
<td>GlassFish Server caches nonserializable user data in the session.</td>
</tr>
<tr>
<td>coherence-session-cookie-domain</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie.</td>
</tr>
<tr>
<td>coherence-session-cookie-max-age</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie.</td>
</tr>
<tr>
<td>coherence-session-cookie-name</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie.</td>
</tr>
<tr>
<td>coherence-session-cookie-path</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie.</td>
</tr>
<tr>
<td>coherence-session-cookies-enabled</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie, as well as encoding URLs with session id.</td>
</tr>
<tr>
<td>coherence-eventlisteners</td>
<td>This parameter is not valid because ActiveCache for GlassFish automatically registers session event listeners registered in web.xml.</td>
</tr>
</tbody>
</table>
Configuring And Deploying Coherence*Web on GlassFish Server—Main Steps

**Table 3–3** describes the valid session configuration parameters in the *glassfish-web.xml* file. They are valid because GlassFish creates the session cookie and performs URL encoding in servlets.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Reason Why it is Valid</th>
</tr>
</thead>
<tbody>
<tr>
<td>session-config/cookie-properties/cookieComment</td>
<td>GlassFish generates the session cookie.</td>
</tr>
<tr>
<td>session-config/cookie-properties/cookieMaxAgeSeconds</td>
<td>GlassFish generates the session cookie.</td>
</tr>
<tr>
<td>session-config/cookie-properties/cookiePath</td>
<td>GlassFish generates the session cookie.</td>
</tr>
<tr>
<td>session-config/cookie-properties/cookieSecure</td>
<td>GlassFish generates the session cookie.</td>
</tr>
<tr>
<td>session-config/cookie-properties/cookieDomain</td>
<td>GlassFish generates the session cookie.</td>
</tr>
<tr>
<td>session-config/session-properties/enableCookies</td>
<td>GlassFish Server generates the session cookie.</td>
</tr>
<tr>
<td>session-config/session-properties/enableURLRewriting</td>
<td>GlassFish Server generates the session cookie.</td>
</tr>
<tr>
<td>session-config/session-manager/persistence-type</td>
<td>This parameter must be set to coherence-web to enable Coherence*Web.</td>
</tr>
<tr>
<td>session-config/session-manager/manager-properties/reap-interval-in-seconds</td>
<td>This value sets the coherence-reaperdaemon-cycle-seconds Coherence*Web configuration parameter. The default for the GlassFish Server is 60 seconds.</td>
</tr>
<tr>
<td>session-config/session-properties/timeoutSeconds</td>
<td>This value sets the coherence-session-expire-seconds Coherence*Web configuration parameter. It overrides the equivalent parameter in the <em>web.xml</em> file.</td>
</tr>
</tbody>
</table>

**Table 3–4** describes the configuration parameters in the *glassfish-web.xml* file which are not valid when using ActiveCache for GlassFish. If these parameters are configured in the *glassfish-web.xml* file, then they are ignored.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Reason Why it is Not Valid</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-servletcontext-clustered</td>
<td>This parameter is not valid because Oracle Coherence*Web does not support a clustered ServletContext in ActiveCache for GlassFish.</td>
</tr>
<tr>
<td>coherence-session-id-length</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie.</td>
</tr>
<tr>
<td>coherence-session-urldecode-bycontainer</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie, as well as encoding and decoding URLs.</td>
</tr>
<tr>
<td>coherence-session-urlencode-enabled</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie, as well as encoding URLs with session id.</td>
</tr>
<tr>
<td>coherence-session-urlencode-name</td>
<td>This parameter is not valid because GlassFish Server is responsible for generating and parsing the session cookie, as well as encoding URLs with session id.</td>
</tr>
</tbody>
</table>
Start a Cache Server

A Coherence data node (also known as a cache server) is responsible for storing and managing all cached data. It can be run either in a dedicated JVM (out-of-process) or within a GlassFish Server instance (in-process). The senior node (which is the first node) in a Coherence data cluster can take several seconds to start up; the start-up time required by subsequent nodes is minimal.

If you are using an out-of-process topology (storage-disabled GlassFish Server instances and stand alone Coherence cache servers), then start the cache servers first, followed by the GlassFish Server instances. This will ensure that there is minimal (measured in milliseconds) startup time for applications using Coherence. Any additional Web applications that use Coherence are guaranteed not to be the senior data member, so they will have minimal impact on GlassFish Server startup.

To Start a Stand-Alone Coherence Data Node

1. Create a script for starting a Coherence data node.

   The following is a sample script that starts a cache server. This example assumes that you are using a Sun JVM. See "JVM Tuning" in the Developer's Guide for Oracle Coherence for more information.

   ```bash
   java -server -Xms512m -Xmx512m
   -cp <Coherence installation dir>/lib/coherence-web.jar:<Coherence installation dir>/lib/coherence.jar
   -Dtangosol.coherence.management.remote=true
   -Dtangosol.coherence.cacheconfig=session-cache-config.xml
   -Dtangosol.coherence.session.localstorage=true
com.tangosol.net.DefaultCacheServer
   ```

   You must include coherence-web.jar and coherence.jar on the classpath. For Coherence*Web, use the session-cache-config.xml file as the cache configuration file. This is the file you obtained in "Copy the ActiveCache for GlassFish and Session Cache Files to the Application" on page 3-3. Note that the cache configuration defined for the cache server must match the cache configuration defined for the application servers which run on the same Coherence cluster.

### Table 3-4 GlassFish Context Parameters that are not Valid for Coherence*Web in glassfish.web.xml

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Reason Why it is Not Valid</th>
</tr>
</thead>
<tbody>
<tr>
<td>session-config/session-manager/manager-</td>
<td>Coherence*Web controls session management. Because sessions can be shared across applications, it is not possible to count the number of sessions for a specific application.</td>
</tr>
<tr>
<td>manager/manager-properties/maxSessions</td>
<td></td>
</tr>
<tr>
<td>session-config/session-manager/manager-</td>
<td>Coherence*Web always flushes session data to the cache at the end of a request (although it might do so asynchronously).</td>
</tr>
<tr>
<td>manager/manager-properties/persistenceFrequency</td>
<td></td>
</tr>
<tr>
<td>session-config/session-manager/manager-</td>
<td>This parameter is relevant only for the file session persistence type.</td>
</tr>
<tr>
<td>manager/manager-properties/sessionFilename</td>
<td></td>
</tr>
<tr>
<td>session-config/session-manager/store-</td>
<td>This parameter is relevant only for the file session persistent type.</td>
</tr>
<tr>
<td>properties/directory</td>
<td></td>
</tr>
<tr>
<td>session-config/session-manager/store-</td>
<td>This parameter is relevant only for the GlassFish Server native replicated session persistent type.</td>
</tr>
<tr>
<td>properties/persistenceScope</td>
<td></td>
</tr>
</tbody>
</table>
If you have additional Coherence caches running on Coherence*Web, then you must merge the cache configuration information (typically defined in the coherence-cache-config.xml file) with the session configuration contained in the session-cache-config.xml file. The cache and session configuration must be consistent for the GlassFish Server and the Coherence cache servers.

For more information on merging these files, see "Merging Coherence Cache and Session Information" in Integration Guide for Oracle Coherence.

2. Start one or more Coherence data nodes using the script described in the previous step.

To Start a Storage-Enabled or -Disabled GlassFish Server Instance

By default, a Coherence*Web-enabled GlassFish Server instance starts in storage-disabled mode.

There are several ways to start the GlassFish Server instance in storage-enabled mode. One way is to include the command line property -Dtangosol.coherence.session.localstorage=true in the server startup command.

Another way is to set the local-storage element in the session-cache-config.xml file to true, for example:

```xml
...<local-storage system-property="tangosol.coherence.session.localstorage">true</local-storage>
...
```

Configure Cluster Nodes

On the GlassFish Server, Coherence*Web can be configured only for EAR- or WAR-scoped cluster nodes. Because of the way that GlassFish Server class loaders work, it is not possible to configure application server-scoped cluster nodes. See "Cluster Node Isolation" on page 5-10 for more information on application server-, EAR-, and WAR-scoped cluster nodes.

Configuring EAR-Scoped Cluster Nodes

To use Coherence*Web in EAR-scoped cluster nodes:

1. Copy the coherence.jar and coherence-web.jar files to the WEB-INF/lib directory of each WAR in the EAR file.

2. Set the session persistence type to coherence-web in the glassfish-web.xml file, as illustrated in Example 3–2.

Example 3–2 Setting the Persistence Type in the glassfish-web.xml File

```xml
<glassfish-web-app>
  ...
  <session-config>
    <session-manager persistence-type="coherence-web"/>
  </session-config>
  ...
</glassfish-web-app>
```

3. Copy the session cache configuration file session-cache-config.xml to the /WEB-INF/classes/ directory of each WAR file in the EAR file.
Configuring WAR-Scoped Cluster Nodes

To use Coherence*Web in WAR-scoped cluster nodes:

1. Copy the coherence.jar and coherence-web.jar files to the /WEB-INF/lib/ directory of each Web application that you intend to deploy on GlassFish Server.

2. Set the session persistence type to coherence-web in the glassfish-web.xml file. See Example 3–2.

3. Copy the session cache configuration file session-cache-config.xml to the /WEB-INF/classes/ directory of each Web application that you intend to deploy on GlassFish Server.

This packaging means that each deployed WAR file will create a Coherence node in the cluster. If you package multiple WAR files in an EAR file, then each WAR file will create a Coherence node in the cluster.
This chapter provides instructions on how to use the Coherence*Web WebInstaller to install Coherence*Web for Java EE applications on a variety of different application servers.

This chapter contains the following sections:

- Installing Coherence*Web Using the WebInstaller
- Coherence*Web WebInstaller Ant Task
- Testing HTTP Session Management
- How the Coherence*Web WebInstaller Instruments a Java EE Application
- Installing Coherence*Web into Applications Using Java EE Security

**Installing Coherence*Web Using the WebInstaller**

Coherence*Web can be enabled for Java EE applications on several different Web containers. To do this, you must run the ready-to-deploy application through the automated Coherence*Web WebInstaller before deploying it. The automated installer prepares the application for deployment. It performs the installation process in two discrete steps: an inspection step and an installation step. For more information about what the installer does during these steps, see "How the Coherence*Web WebInstaller Instruments a Java EE Application" on page 4-10.
The installer can be run either from the Java command line or from Ant tasks. The following sections describe the Java command-line method. For Ant task-based installation, see "Coherence*Web WebInstaller Ant Task" on page 4-6.

Application Server-Specific Installation Instructions

All of the Web containers listed in "Supported Web Containers" on page 1-1 that can be installed with the WebInstaller share the same general installation instructions. These instructions are described in "General Instructions for Installing Coherence*Web Session Management Module" on page 4-2.

A few of the Web containers, such as Caucho Resin, and WebLogic 10.*n, require extra, container-specific steps that you must complete before starting the general installation procedure. The following sections describe application server-specific installation steps:

- Installing on Oracle WebLogic Server 10.*n
- Installing on Caucho Resin 3.1.*n

Installing on Oracle WebLogic Server 10.*n

Complete the following steps to install the Coherence*Web Session Management Module into Oracle WebLogic Server release 10 to 10.2:

1. Obtain the coherence-web.jar file from the coherence/lib directory.
2. For each WebLogic Server 10.*n installation that will be running in the server cluster, update the libraries using the following command:
   
   java -cp coherence.jar;coherence-web.jar com.tangosol.coherence.servlet.WebPluginInstaller <wls-home-path> -install

3. Follow the instructions described in "General Instructions for Installing Coherence*Web Session Management Module" on page 4-2 to complete the installation. Use the value WebLogic/10.x for the server type.

Installing on Caucho Resin 3.1.*n

Complete the following steps to install the Coherence*Web Session Management Module into a Caucho Resin 3.1.*n server:

1. Obtain the coherence-web.jar file from the coherence/lib directory.
2. For each Caucho Resin installation that will be running in the server cluster, update the libraries using the following command:
   
   java -cp coherence.jar;coherence-web.jar com.tangosol.coherence.servlet.WebPluginInstaller <resin-home-path> -install

3. Follow the instructions described in "General Instructions for Installing Coherence*Web Session Management Module" on page 4-2 to complete the installation. Use the value Resin/3.1.x for the server type.

General Instructions for Installing Coherence*Web Session Management Module

Complete the following steps to install Coherence*Web for a Java EE application on any of the Web containers listed under "Supported Web Containers" on page 1-1.

If you are installing Coherence*Web for a Java EE application on an Apache Tomcat Server, see also "Enabling Sticky Sessions for Apache Tomcat Servers" on page 4-6 for additional instructions.
If you are installing Coherence*Web for a Java EE application on IBM WebSphere Server, see also "Decoding URL Session IDs for IBM WebSphere 7.n Servers" on page 4-6 for additional instructions.

**To install Coherence*Web for the Java EE application you are deploying:**

1. Ensure that the application directory and the EAR file or WAR file are not being used or accessed by another process.

2. Change the current directory to the Coherence library directory (\%COHERENCE_HOME\lib on Windows and $COHERENCE_HOME/lib on UNIX).

3. Ensure that the paths are configured so that Java commands will run.

4. Complete the application inspection step by running the following command. Specify the full path to your application and the name of your server found in Table 1–1 (replacing the <app-path> and <server-type> with them in the following command line):

   ```
   java -jar webInstaller.jar <app-path> -inspect -server:<server-type>
   ```

   The system will create (or update, if it already exists) the coherence-web.xml configuration descriptor file for your Java EE application in the directory where the application is located. This configuration descriptor file contains the default Coherence*Web settings for your application as recommended by the installer.

5. If necessary, review and modify the Coherence*Web settings based on your requirements.

   You can modify the Coherence*Web settings by editing the coherence-web.xml descriptor file. Appendix A, "Coherence*Web Context Parameters," describes the Coherence*Web settings that can be modified. Use the param-name and param-value subelements of the context-param parameter to enable the features you want. Table 4–1 describes some examples of different settings.

   **Table 4–1  Example Context Parameter Settings for Coherence*Web**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-servletcontext-clustered</td>
<td>true</td>
<td>Clusters all ServletContext (global) attributes so that servers in a cluster share the same values for those attributes, and also receive the events specified by the Servlet Specification when those attributes change.</td>
</tr>
<tr>
<td>coherence-enable-sessioncontext</td>
<td>true</td>
<td>Allows an application to enumerate all of the sessions that exist within the application, or to obtain any one of those sessions to examine or manipulate.</td>
</tr>
<tr>
<td>coherence-session-id-length</td>
<td>32</td>
<td>Enables you to increase the length of the HttpSession ID, which is generated using a SecureRandom algorithm; the length can be any value, although in practice it should be small enough to fit into a cookie or a URL (depending on how session IDs are maintained.) Increasing the length can decrease the chance of a session being purposely hijacked.</td>
</tr>
<tr>
<td>coherence-urlencode-enabled</td>
<td>true</td>
<td>By default, the HttpSession ID is managed in a cookie. If the application supports URL encoding, this option enables it.</td>
</tr>
</tbody>
</table>

6. Complete the Coherence*Web application installation step by running the following command, replacing <app-path> with the full path to your application:

   ```
   java -jar webInstaller.jar <app-path> -install
   ```
The installer requires a valid `coherence-web.xml` configuration descriptor file to reside in the same directory as the application. The command creates a `session-cache-config.xml` file in the `WEB-INF\classes` directory of the application archive file. This file contains the session and cache configuration information.

7. Deploy the updated application and verify that everything functions as expected, using the lightweight load balancer provided with the Coherence distribution. Remember that the lightweight load balancer is not a production-ready utility, in contrast to the load balancer provided by WebLogic Server.

The application can be deployed and run in any of the deployment topologies supported by Coherence: in-process, out-of-process, or out-of-process with Coherence*Extend. See the following sections for information on deploying and running your applications under these topologies. For more information on the topologies themselves, see "Deployment Topologies" on page 5-16.

**Deploying and Running Applications In Process**

Coherence*Web can be run **in-process** with the application server. This is where session data is stored with the application server. See "In-Process Topology" on page 5-16 for more information on this topology.

**For the application server:**

1. Start the application server in storage-enabled mode. Add the system property `tangosol.coherence.session.localstorage=true` to the Java options of your application server startup script.

2. Deploy the `coherence.jar` and `coherence-web.jar` files as shared libraries.

3. Deploy and run your application.

**Deploying and Running Applications Out-of-Process**

In the out-of-process deployment topology, a stand-alone cache server stores the session data and the application server is configured as a cache client. See "Out-of-Process Topology" on page 5-17 for more information on this topology.

The cache server and the application server must use the same cache and session configuration. This configuration is generated in the `session-cache-config.xml` file by the Coherence*Web WebInstaller. The WebInstaller generates the file in the `WEB-INF\classes` directory of the instrumented application.

**For the cache server:**

1. Add the `tangosol.coherence.cacheconfig` system property to the cache server startup script to locate the file configuration file. You must also include the system property `tangosol.coherence.session.localstorage=true` to enable storage for the cache server.

2. Add the `coherence.jar` and `coherence-web.jar` files to the classpath in the cache server startup script.

Following is a sample startup script:

```bash
java -server -Xms512m -Xmx512m
```
For the application server (cache client):
1. Deploy the coherence.jar and coherence-web.jar files as shared libraries.
2. The session-cache-config.xml file should already be present in the WEB-INF/classes directory of the instrumented application.
   By default, the file should specify that local storage is disabled (if you are not sure, you can either inspect the file to confirm that the local-storage element is set to false or add the system property tangosol.coherence.session.localtimeing=false to the startup script).
3. Deploy the application to the server.

Migrating to Out-of-Process Topology
If you have been running and testing your application with Coherence*Web in-process, you can easily migrate to the out-of-process topology. Simply set up your cache server and application server as described in "Deploying and Running Applications Out-of-Process" on page 4-4.

Deploying and Running Applications Out-of-Process with Coherence*Extend
The out-of-process with Coherence*Extend topology is similar to the out-of-process topology except that the communication between the application server tier and the cache server tier is over Coherence*Extend (TCP/IP). Coherence*Extend consists of two components: an extend client (or proxy) running outside the cluster and an extend proxy service running in the cluster hosted by one or more cache servers. See "Out-of-Process with Coherence*Extend Topology" on page 5-18 for more information on this topology.

In these deployments, there are three types of participants:
- Cache servers (storage servers), which are used to store the actual session data in memory.
- Web (application) servers, which are the Extend clients in this topology. They are not members of the cluster; instead, they connect to a proxy node in the cluster that will issue requests to the cluster on their behalf.
- Proxy servers, which are storage-disabled members (nodes) of the cluster that accept and manage TCP/IP connections from Extend clients. Requests that arrive from clients will be sent into the cluster, and responses will be sent back through the TCP/IP connections.

For the cache server:
Follow the instructions for configuring the cache server in "Deploying and Running Applications Out-of-Process" on page 4-4. Also, edit the cache server’s copy of the session-cache-config.xml file to add the system properties tangosol.coherence.session.proxy=false and tangosol.coherence.session.localtimeing=true.
See "Configure the Cache for Proxy and Storage JVMs" on page 5-19 for more information and an example of a session-cache-config.xml file with these context parameters.

For the Web tier (application) server:
Follow the instructions for configuring the application server in "Deploying and Running Applications Out-of-Process" on page 4-4. Also, complete these steps:
1. Ensure that Coherence*Web is configured to use the Optimistic Locking mode. Optimistic locking is the default locking mechanism for Coherence*Web (see "Optimistic Locking" on page 5-14).

2. Edit the application server’s copy of the session-cache-config.xml file to add the proxy JVM host names, IP addresses and ports. To do this, add a <remote-addresses> section to the file. In most cases, you should include the host name and IP address, and port of all proxy JVMs for load balancing and failover.

See "Configure the Cache for Web Tier JVMs" on page 5-22 for more information and an example of a session-cache-config.xml file with a <remote-addresses> section.

For the proxy server:
With a few changes, the proxy server can use the same cache and session configuration as the application server and the cache server. Edit the session-cache-config.xml file to add these system properties:

- tangosol.coherence.session.localstorage=false to disable local storage.
- tangosol.coherence.session.proxy=true to indicate that a proxy service is being used.
- tangosol.coherence.session.proxy.localhost to indicate the host name or IP address of the NIC to which the proxy will bind.
- tangosol.coherence.session.proxy.localport to indicate a unique port number to which the proxy will bind.

See "Configure the Cache for Proxy and Storage JVMs" on page 5-19 for more information and an example of a session-cache-config.xml file with these context parameters.

Enabling Sticky Sessions for Apache Tomcat Servers
If you want to employ sticky sessions for the Apache Tomcat Server, you must configure the jvmRoute attribute in the server’s server.xml file. You can find more information on this attribute at this URL:

Decoding URL Session IDs for IBM WebSphere 7.n Servers
If set to true, the coherence-session-urldecode-by-container context parameter allows the container to decode the URL. This context parameter must be set to false if you are installing Coherence*Web for a Java EE application on release 7.n of the IBM WebSphere application server. Instead of the WebSphere application server, Coherence*Web will handle the decoding of session IDs.

The Coherence*Web WebInstaller, when run for the WebSphere 7.n application server type, will automatically set this parameter to false unless you explicitly set it to true.

Coherence*Web WebInstaller Ant Task
The Coherence*Web WebInstaller Ant task enables you to run the installer from within your existing Ant build files.
This section contains the following information:

- Using the Coherence*Web WebInstaller Ant Task
- Configuring the WebInstaller Ant Task
- WebInstaller Ant Task Examples

**Using the Coherence*Web WebInstaller Ant Task**

To use the Coherence*Web WebInstaller Ant task, add the task import statement illustrated in Example 4–1 to your Ant build file. In this example, `$(coherence.home)` refers to the root directory of your Coherence installation.

**Example 4–1  Task Import Statement for Coherence*Web WebInstaller**

```xml
<taskdef name="cwi" classname="com.tangosol.coherence.misc.CoherenceWebAntTask">
  <classpath>
    <pathelement location="$(coherence.home)/lib/webInstaller.jar"/>
  </classpath>
</taskdef>
```

The following procedure describes the basic process of installing Coherence*Web into a Java EE application from an Ant build:

1. Build your Java EE application as you ordinarily would.
2. Run the Coherence*Web Ant task with the operations attribute set to inspect.
3. Make any necessary changes to the generated Coherence*Web XML descriptor file.
4. Run the Coherence*Web Ant task with the operations attribute set to install.

**Performing Iterative Development**

If you are performing iterative development on your application, such as modifying JavaServer Pages (JSPs), Servlets, static resources, and so on, use the following installation process:

1. Run the Coherence*Web Ant task with the operations attribute set to uninstall, the failonerror attribute set to false, and the descriptor attribute set to the location of the previously generated Coherence*Web XML descriptor file (from Step 2 of “Using the Coherence*Web WebInstaller Ant Task”).
2. Build your Java EE application as you ordinarily would.
3. Run the Coherence*Web Ant task with the operations attribute set to inspect, and the install and descriptor attributes set to the location of the previously generated Coherence*Web XML descriptor file (from Step 2 of "Using the Coherence*Web WebInstaller Ant Task” on page 4-7).

**Changing the Coherence*Web Configuration Settings of a Java EE Application**

If you must change the Coherence*Web configuration settings of a Java EE application that is using Coherence*Web, follow these steps:

1. Run the Coherence*Web Ant task with the operations attribute set to uninstall and the descriptor attribute set to the location of the Coherence*Web XML descriptor file for the Java EE application.
2. Change the necessary configuration parameters in the Coherence*Web XML descriptor file.
3. Run the Coherence*Web Ant task with the operations attribute set to install and the descriptor attribute set to the location of the modified Coherence*Web XML descriptor file (from Step 2 of "Using the Coherence*Web WebInstaller Ant Task" on page 4-7).

Configuring the WebInstaller Ant Task

Table 4–2 describes the attributes that can be used with the Coherence*Web WebInstaller Ant task.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>app</td>
<td>Path to the target Java EE application. This can be a path to a WAR file, an EAR file, an expanded WAR directory, or an expanded EAR directory.</td>
<td>Yes, if the operations attribute is set to any value other than version.</td>
</tr>
<tr>
<td>backup</td>
<td>Path to a directory that holds a backup of the original target Java EE application. This attribute defaults to the directory that contains the Java EE application.</td>
<td>No</td>
</tr>
<tr>
<td>descriptor</td>
<td>Path to the Coherence*Web XML descriptor file. This attribute defaults to the coherence-web.xml file in the directory that contains the target Java EE application.</td>
<td>No</td>
</tr>
<tr>
<td>failonerror</td>
<td>Stops the Ant build if the Coherence*Web installer exits with a status other than 0. The default is true.</td>
<td>No</td>
</tr>
<tr>
<td>nowarn</td>
<td>Suppresses warning messages. This attribute can be either true or false. The default is false.</td>
<td>No</td>
</tr>
<tr>
<td>operations</td>
<td>A comma- or space-separated list of operations to perform; each operation must be one of inspect, install, uninstall, or version.</td>
<td>Yes</td>
</tr>
<tr>
<td>server</td>
<td>The alias of the target Java EE application server.</td>
<td>No</td>
</tr>
<tr>
<td>touch</td>
<td>Touches JSPs and TLDs that are modified by the Coherence*Web installer. This attribute can be either true, false, or M/d/y h:mm a. The default is false.</td>
<td>No</td>
</tr>
<tr>
<td>verbose</td>
<td>Displays verbose output. This attribute can be either true or false. The default is false.</td>
<td>No</td>
</tr>
</tbody>
</table>

WebInstaller Ant Task Examples

The following list provides sample commands for the WebInstaller Ant task.

- Inspect the myWebApp.war Web application and generate a Coherence*Web XML descriptor file called my-coherence-web.xml in the current working directory:

  `<cwi app="myWebApp.war" operations="inspect" descriptor="my-coherence-web.xml"/>
  
- Install Coherence*Web into the myWebApp.war Web application using the Coherence*Web XML descriptor file called my-coherence-web.xml found in the current working directory:

  `<cwi app="myWebApp.war" operations="install" descriptor="my-coherence-web.xml"/>
  
- Uninstall Coherence*Web from the myWebApp.war Web application:

  `<cwi app="myWebApp.war" operations="uninstall"/>
Testing HTTP Session Management

Coherence comes with a lightweight software load balancer; it is intended only for testing purposes. The load balancer is very easy to use and is very useful when testing functionality such as session management. Follow these steps to test HTTP session management with the lightweight load balancer:

1. Start multiple application server processes on one or more server machines, each running your application on a unique IP address and port combination.

2. Open a command (or shell) window.

3. Change the current directory to the Coherence library directory (%COHERENCE_HOME%/lib on Windows and $COHERENCE_HOME/lib on UNIX).

4. Ensure that paths are configured so that Java commands will run.

5. Start the software load balancer with the following command lines (each of these command lines makes the application available on the default HTTP port 80).

For example, to test load balancing locally on one machine with two application server instances on ports 7001 and 7002:

```
java -jar coherence-loadbalancer.jar localhost:80 localhost:7001 localhost:7002
```

To run the load balancer locally on a machine named server1 that load balances to port 7001 on server1, server2, and server3:

```
java -jar coherence-loadbalancer.jar server1:80 server1:7001 server2:7001 server3:7001
```

Assuming that you use the preceding command line, an application that previously was accessed with the URL http://server1:7001/my.jsp would now be accessed with the URL http://server1:80/my.jsp or just http://server1/my.jsp.
How the Coherence®Web WebInstaller Instruments a Java EE Application

During the inspection step, the Coherence®Web WebInstaller performs the following tasks:

1. Generates a template coherence-web.xml configuration file that contains basic information about the application and target Web container along with a set of default Coherence®Web configuration context parameters appropriate for the target Web container. See Appendix A, "Coherence®Web Context Parameters" for descriptions of all possible parameters.

   The WebInstaller sets the servlet container to start in storage-disabled mode (that is, it sets tangosol.coherence.session.localstorage to false).

   If an existing coherence-web.xml configuration file exists (for example, from a previous run of the Coherence®Web WebInstaller), the context parameters in the existing file are merged with those in the generated template.

2. Enumerates the JSP from each Web application in the target Java EE application and adds information about each JSP to the coherence-web.xml configuration file.

3. Enumerates the TLDs from each Web application in the target Java EE application and adds information about each TLD to the coherence-web.xml configuration file.

During the installation step, the Coherence®Web WebInstaller performs the following tasks:

1. Creates a backup of the original Java EE application so that it can be restored during the uninstallation step.

2. Adds the Coherence®Web configuration context parameters generated in Step 1 of the inspection step to the web.xml descriptor file of each Web application contained in the target Java EE application.

3. Unregisters any application-specific ServletContextListener, ServletContextAttributeListener, ServletRequestListener, ServletRequestAttributeListener, HttpSessionListener, and HttpSessionAttributeListener classes (including those registered by TLDs) from each Web application.

---

**Note:** Ensure that your application uses only relative redirections or the address of the load balancer.

---

**Table 4–3** describes the command-line options for the load balancer:

**Table 4–3  Load Balancer Command-Line Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>backlog</td>
<td>Sets the TCP/IP accept backlog option to the specified value, for example: -backlog=64</td>
</tr>
<tr>
<td>random</td>
<td>Specifies the use of a random load-balancing algorithm (default).</td>
</tr>
<tr>
<td>roundrobin</td>
<td>Specifies the use of a round-robin load-balancing algorithm</td>
</tr>
<tr>
<td>threads</td>
<td>Uses the specified number of request or response thread pairs (so the total number of additional daemon threads will be two times the specified value), for example: -threads=64.</td>
</tr>
</tbody>
</table>

---

How the Coherence®Web WebInstaller Instruments a Java EE Application

During the inspection step, the Coherence®Web WebInstaller performs the following tasks:

1. Generates a template coherence-web.xml configuration file that contains basic information about the application and target Web container along with a set of default Coherence®Web configuration context parameters appropriate for the target Web container. See Appendix A, "Coherence®Web Context Parameters" for descriptions of all possible parameters.

   The WebInstaller sets the servlet container to start in storage-disabled mode (that is, it sets tangosol.coherence.session.localstorage to false).

   If an existing coherence-web.xml configuration file exists (for example, from a previous run of the Coherence®Web WebInstaller), the context parameters in the existing file are merged with those in the generated template.

2. Enumerates the JSP from each Web application in the target Java EE application and adds information about each JSP to the coherence-web.xml configuration file.

3. Enumerates the TLDs from each Web application in the target Java EE application and adds information about each TLD to the coherence-web.xml configuration file.

During the installation step, the Coherence®Web WebInstaller performs the following tasks:

1. Creates a backup of the original Java EE application so that it can be restored during the uninstallation step.

2. Adds the Coherence®Web configuration context parameters generated in Step 1 of the inspection step to the web.xml descriptor file of each Web application contained in the target Java EE application.

3. Unregisters any application-specific ServletContextListener, ServletContextAttributeListener, ServletRequestListener, ServletRequestAttributeListener, HttpSessionListener, and HttpSessionAttributeListener classes (including those registered by TLDs) from each Web application.
4. Registers a Coherence*Web ServletContextListener class in each web.xml descriptor file. At run time, the Coherence*Web ServletContextListener class propagates each ServletContextEvent event to each application-specific ServletContextListener.

5. Registers a Coherence*Web ServletContextAttributeListener listener in each web.xml descriptor file. At run time, the Coherence*Web ServletContextAttributeListener propagates each ServletContextAttributeEvent event to each application-specific ServletContextAttributeListener.

6. Wraps each application-specific Servlet declared in each web.xml descriptor file with a Coherence*Web SessionServlet. At run time, each Coherence*Web SessionServlet delegates to the wrapped Servlet.

7. Adds the following directive to each JSP enumerated in Step 2 of the inspection step:

```html
<%@ page extends="com.tangosol.coherence.servlet.api22.JspServlet" %>
```

During the uninstallation step, the Coherence*Web WebInstaller replaces the instrumented Java EE application with the backup of the original version created in Step (1) of the installation process.

**Installing Coherence*Web into Applications Using Java EE Security**

**Note:** This section does not apply to the native WebLogic Server SPI implementation of Coherence*Web. It applies only if you are using the WebInstaller to install Coherence*Web into an application that uses Java EE security. For instructions on using the SPI implementation, see Chapter 2, "Using Coherence*Web with WebLogic Server."

To install Coherence*Web into an application that uses Java EE security, follow these additional steps during installation:

1. Enable Coherence*Web session cookies.

   See the coherence-session-cookies-enabled configuration element in Table A–1 for additional details.

2. Change the Coherence*Web session cookie name to a name that is different from the one used by the target Web container.

   By default, most containers use JSESSIONID for the session cookie name, so a good choice for the Coherence*Web session cookie name is CSESSIONID. See the coherence-session-cookie-name configuration element in Table A–1 for additional details.

3. Enable session replication for the target Web container.

   If session replication is not enabled, or the container does not support a form of session replication, then you will be forced to re-authenticate to the Web application during failover. See your Web container's documentation for instructions on enabling session replication.

This configuration causes two sessions to be associated with a given authenticated user:
- A Coherence*Web session that contains all session data created by the Web application
- A session created by the Web container during authentication that stores only information necessary to identify the user
You can configure Coherence*Web in many ways to meet the demands of your environment. Consequently, you might have to change some default configuration options. This chapter provides an in-depth look at the features that Coherence*Web supports so that you can make the appropriate configuration and deployment decisions.

- **Session Models**, which describes how Coherence*Web stores session state
- **Session and Session Attribute Scoping**, which allows fine-grained control over how both session data and session attributes are scoped (or *shared*) across application boundaries
- **Cluster Node Isolation**, which determines the number of Coherence nodes that are created within an application server JVM and where the Coherence library is deployed in the application’s classpath
- **Session Locking Modes**, which determines how applications will obtain concurrent access to HTTP sessions
- **Deployment Topologies**, which determines how the session data is stored and managed between the cache servers and application servers
- **Accessing Sessions with Lazy Acquisition**, which describes how to save processing time and power by directing Coherence*Web to acquire sessions only when the servlet or filter attempts to access it
- **Overriding the Distribution of HTTP Sessions and Attributes**, which describes how you can control whether a session or its attributes remain local (stored on the originating server’s heap and accessible only by that server) or distributed (stored within the Coherence grid, and thus, accessible to other server JVMs)
- **Detecting Changed Attribute Values**, which describes how Coherence*Web tracks attributes retrieved from the session that may have changed during the course of processing a request
- **Saving Non-Serializable Attributes Locally**, which describes how Coherence*Web can handle session attributes that are not serializable.
- **Securing Coherence*Web Deployments**, which describes how to prevent unauthorized Coherence TCMP cluster members from accessing HTTP session cache servers by enabling Secure Socket Layer (SSL).
Session Models

A session model describes how Coherence*Web stores the session state in Coherence. Session data is managed by an HttpSessionModel object while the session collection in a Web application is managed by an HttpSessionCollection object. You must configure only the collection type in the web.xml file—the model is implicitly derived from the collection type. Coherence*Web includes these different session model implementations:

- Traditional Model, which stores all session state as a single entity but serializes and deserializes attributes individually
- Monolithic Model, which stores all session state as a single entity, serializing and deserializing all attributes as a single operation
- Split Model, which extends the Traditional Model, but separates the larger session attributes into independent physical entities

---

**Note:** In general, Web applications that are part of the same Coherence cluster must use the same session model type. Inconsistent configurations could result in deserialization errors.

---

Figure 5–1 illustrates the three session models.

**Figure 5–1  Traditional, Monolithic, and Split Session Models**

![Session Models Diagram]

**Traditional Model**

The Traditional model is represented by the TraditionalHttpSessionModel and TraditionalHttpSessionCollectionView objects. They manage all of the HTTP session data for a particular session in a single Coherence cache entry, but manage each HTTP session attribute (particularly, its serialization and deserialization) separately.
This model is suggested for applications with relatively small HTTP session objects (10 KB or less) that do not have issues with object sharing between session attributes. Object sharing between session attributes occurs when multiple attributes of a session have references to the same exact object, meaning that separate serialization and deserialization of those attributes cause multiple instances of that shared object to exist when the HTTP session is later deserialized.

*Figure 5-2* illustrates the relationship between the logical representation of data and its physical representation in the session storage cache. In its logical representation session data consists of metadata, and various attributes. In its physical representation in the session storage cache, the metadata and attributes are converted to binaries, and a session ID is associated with them. Note that the attributes are serialized as separate entities in the session storage cache.

*Figure 5–2  Traditional Session Model*
Monolithic Model

The Monolithic model is represented by the MonolithicHttpSessionModel and MonolithicHttpSessionCollection objects. These are similar to the Traditional model, except that they solve the shared object issue by serializing and deserializing all attributes into a single object stream. As a result, the Monolithic model often does not perform as well as the Traditional model.

Figure 5–3 illustrates the relationship between the logical representation of data and its physical representation in the session storage cache. In its logical representation session data consists of metadata, and various attributes. In its physical representation in the session storage cache, the metadata and attributes are serialized into a single stream. A session ID is associated with the metadata and attributes.

Split Model

The Split model is represented by the SplitHttpSessionModel and SplitHttpSessionCollection objects. They store the core HTTP session metadata and all of the small session attributes in the same manner as the Traditional
model, thus ensuring high performance by keeping that block of binary session data small. All large attributes are split into separate cache entries to be managed individually, thus supporting very large HTTP session objects without unduly increasing the amount of data that must be accessed and updated within the cluster for each request. In other words, only the large attributes that are modified within a particular request incur any network overhead for their updates, and (because it uses near caching) the Split model generally does not incur any network overhead for accessing either the core HTTP session data or any of the session attributes.

Figure 5–4 illustrates the relationship between the logical representation of data and its physical representation in the session storage cache. In this model, large objects are stored as separate cache entries with their own session ID.
Session Model Recommendations

The following are recommendations on which session model to choose for your applications:

- The Split model is the recommended session model for most applications.
- The Traditional model might be more optimal for applications that are known to have small HTTP session objects.
The Monolithic model is designed to solve a specific class of problems related to multiple session attributes that have references to the same shared object, and that must maintain that object as a shared object.

"Session Management for Clustered Applications" in Getting Started with Oracle Coherence, provides information on the behavior of these models in a clustered environment.

---

**Note:** See Appendix A, "Coherence*Web Context Parameters" for descriptions of the parameters used to configure session models.

---

### Session and Session Attribute Scoping

Coherence*Web allows fine-grained control over how both session data and session attributes are scoped (or shared) across application boundaries:

#### Session Scoping

Coherence*Web allows session data to be shared by different Web applications deployed in the same or different Web containers. To do so, you must correctly configure the session cookie context parameters and make the classes of objects stored in session attributes available to each Web application.

If you are using cookies to store session IDs (that is, you are not using URL rewriting), you must set the session cookie path to a common context path for all Web applications that share session data. For example, to share session data between two Web applications registered under the context paths `/web/HRPortal` and `/web/InWeb`, you should set the `coherence-session-cookie-path` parameter to `/web`. On the other hand, if the two Web applications are registered under the context paths `/HRPortal` and `/InWeb`, you should set the `coherence-session-cookie-path` parameter to a slash (`/`).

If the Web applications that you would like to share session data are deployed on different Web containers running on different machines (that are not behind a common load balancer), you must also configure the session cookie domain to a domain shared by the machines. For example, to share session data between two Web applications running on `server1.mydomain.com` and `server2.mydomain.com`, you must set the `coherence-session-cookie-domain` context parameter to `.mydomain.com`.

To correctly serialize or deserialize objects stored in shared sessions, the classes of all objects stored in session attributes must be available to Web applications that share session data.

---

**Note:** For advanced use cases where EAR cluster node-scoping or application server JVM cluster scoping is employed and you do not want session data shared across individual Web applications, see "Preventing Web Applications from Sharing Session Data".

---

### Preventing Web Applications from Sharing Session Data

Sometimes you might want to explicitly prevent HTTP session data from being shared by different Java EE applications that participate in the same Coherence cluster. For example, assume you have two applications, `HRPortal` and `InWeb`, that share cached data in their Enterprise JavaBeans (EJB) tiers but use different session data. In this case, it is desirable for both applications to be part of the same Coherence cluster, but
undesirable for both applications to use the same clustered service for session data. One way to do this is to use the ApplicationScopeController interface to define the scope of an application’s attributes. “Session Attribute Scoping” on page 5-9 describes this technique. Another way is to specify a unique session cache service name for each application.

Follow these steps to specify a unique session cache service name for each application:

1. Locate the <service-name/> elements in each session-cache-config.xml file found in your application.
2. Set the elements to a unique value for each application.

   This forces each application to use a separate clustered service for session data.
3. Include the modified session-cache-config.xml file with the application.

Example 5–1 illustrates a sample session-cache-config.xml file for an HRPortal application. To prevent the HRPortal application from sharing session data with the InWeb application, rename the <service-name> element for the replicated scheme to ReplicationSessionsMiscHRP. Rename the <service-name> element for the distributed schemes to DistributedSessionsHRP.

Example 5–1   Configuration to Prevent Applications from Sharing Session Data
<replicated-scheme>
   <scheme-name>default-replicated</scheme-name>
   <service-name>ReplicatedSessionsMisc</service-name> // rename this to ReplicationSessionsMiscHRP
   <backing-map-scheme>
      <class-scheme>
         <scheme-ref>default-backing-map</scheme-ref>
      </class-scheme>
   </backing-map-scheme>
</replicated-scheme>

<distributed-scheme>
   <scheme-name>session-distributed</scheme-name>
   <service-name>DistributedSessions</service-name> // rename this to DistributedSessionsHRP
   <lease-granularity>member</lease-granularity>
   <backing-map-scheme>
      <class-scheme>
         <scheme-ref>default-backing-map</scheme-ref>
      </class-scheme>
   </backing-map-scheme>
</distributed-scheme>

<distributed-scheme>
   <scheme-name>session-certificate</scheme-name>
   <service-name>DistributedSessions</service-name> // rename this to DistributedSessionsHRP
   <lease-granularity>member</lease-granularity>
   <backing-map-scheme>
      <local-scheme>
         <scheme-ref>session-certificate-autoexpiring</scheme-ref>
      </local-scheme>
   </backing-map-scheme>
</distributed-scheme>
Working with Multiple Cache Configurations

If you are working with two or more applications running under Coherence*Web, then they could have multiple different cache configurations. In this case, the cache configuration on the cache server must contain the union of these cache configurations regardless of whether you run in storage-enabled or storage-disabled mode. This will allow the applications to be supported in the same cache cluster.

Keeping Session Cookies Separate

If you are using cookies to store session IDs, you must ensure that session cookies created by one application are not propagated to another application. To do this, you must set each application’s session cookie domain and path in their web.xml file. To prevent cookies from being propagated, ensure that no two applications share the same context path.

For example, assume you have two Web applications registered under the context paths /web/HRPortal and /web/InWeb. To prevent the Web applications from sharing session data through cookies, set the cookie path to /web/HRPortal in one application, and set the cookie path to /web/InWeb in the other application.

If your applications are deployed on different Web containers running on separate machines, then you can configure the cookie domain to ensure that they are not in the same domain.

For example, assume you have two Web applications running on server1.mydomain.com and server2.mydomain.com. To prevent session cookies from being shared between them, set the cookie domain in one application to server1.mydomain.com, and set the cookie domain in the other application to server2.mydomain.com.

Session Attribute Scoping

In the case where sessions are shared across Web applications there are many instances where the application might scope individual session attributes so that they are either globally visible (that is, all Web applications can see and modify these attributes) or scoped to an individual Web application (that is, not visible to any instance of another application).

Coherence*Web provides the ability to control this behavior by using the AttributeScopeController interface. This optional interface can selectively scope attributes in cases when a session might be shared across multiple applications. This allows different applications to potentially use the same attribute names for the application-scope state without accidentally reading, updating, or removing other applications’ attributes. In addition to having application-scoped information in the session, this interface allows the session to contain global (unscoped) information that can be read, updated, and removed by any of the applications that shares the session.

Two implementations of the AttributeScopeController interface are available: ApplicationScopeController and GlobalScopeController. The GlobalScopeController implementation does not scope attributes, while ApplicationScopeController scopes all attributes to the application by prefixing the name of the application to all attribute names.

Use the coherence-application-name context parameter to specify the name of the application (and the Web module in which the application appears). The ApplicationScopeController interface will use the name of the application to scope the attributes. If you do not configure this parameter, then Coherence*Web uses
the name of the class loader instead. For more information, see the description of coherence-application-name in Table 2–2.

---

**Note:** After a configured AttributeScopeController implementation is created, it is initialized with the name of the Web application, which it can use to qualify attribute names. Use the coherence-application-name context parameter to configure the name of your Web application.

---

### Sharing Session Information Between Multiple Applications

Coherence*Web allows multiple applications to share the same session object. To do this, the session attributes must be visible to all applications. You must also specify which URLs served by WebLogic Server will be able to receive cookies.

To allow the applications to share and modify the session attributes, reference the GlobalScopeController (com.tangosol.coherence.servlet.AbstractHttpSessionCollection$GlobalScopeController) interface as the value of the coherence-scopecontroller-class context parameter in the web.xml file. GlobalScopeController is an implementation of the com.tangosol.coherence.servlet.HttpSessionCollection$AttributeScopeController interface that allows individual session attributes to be globally visible.

**Example 5–2** illustrates the GlobalScopeController interface specified in the web.xml file.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<web-app>
  ...
  <context-param>
    <param-name>coherence-scopecontroller-class</param-name>
    <param-value>com.tangosol.coherence.servlet.AbstractHttpSessionCollection$GlobalScopeController</param-value>
  </context-param>
  ...
</web-app>
```

### Cluster Node Isolation

There are several different ways in which you can deploy Coherence*Web. One of the things to consider when deciding on a deployment option is cluster node isolation. Cluster node isolation considers:

- The number of Coherence nodes that are created within an application server JVM
- Where the Coherence library is deployed

Applications can be application server-scoped, EAR-scoped, or WAR-scoped. This section describes these considerations. For detailed information about the XML configuration for each of these options, see "Configure Cluster Nodes" on page 2-10.

### Application Server-Scoped Cluster Nodes

With this configuration, all deployed applications in a container using Coherence*Web become part of one Coherence node. This configuration produces the smallest number of Coherence nodes in the cluster (one for each Web container JVM) and, because the
Coherence library (coherence.jar) is deployed in the container's class path, only one copy of the Coherence classes is loaded into the JVM. This minimizes the use of resources. On the other hand, because all applications are using the same cluster node, all applications are affected if one application malfunctions.

Figure 5–5 illustrates an application server-scoped cluster with two cluster nodes (application server instances). Because Coherence*Web has been deployed to each instance’s class path, each instance can be considered to be a Coherence node. Each node contains two EAR files; each EAR file contains two WAR files. All of the application running in each instance share the same Coherence library and classes.

"Configuring Application Server-Scoped Cluster Nodes" on page 2-10 describes the XML configuration requirements for application server-scoped cluster nodes for WebLogic Server.

This configuration is not available for GlassFish Server.

Note: Consider the use of the application server-scoped cluster configuration very carefully. Do not use it in environments where application interaction is unknown or unpredictable.

An example of such an environment might be a deployment where multiple application teams are deploying applications written independently, without carefully coordinating and enforcing their conventions and naming standards. With this configuration, all applications are part of the same cluster—the likelihood of collisions between namespaces for caches, services, and other configuration settings is quite high and could lead to unexpected results.

For these reasons, Oracle Coherence strongly recommends that you use EAR-scoped and WAR-scoped cluster node configurations. If you are in doubt regarding which deployment topology to choose, or if this warning applies to your deployment, then do not choose the application server-scoped cluster node configuration.
**EAR-Scoped Cluster Nodes**

With this configuration, all deployed applications within each EAR file become part of one Coherence node. This configuration produces one Coherence node for each deployed EAR file that uses Coherence*Web. Because the Coherence library (coherence.jar) is deployed in the application’s classpath, only one copy of the Coherence classes is loaded for each EAR file. Since all Web applications in the EAR file use the same cluster node, all Web applications in the EAR file are affected if one of the Web applications malfunctions.

*Figure 5–6* illustrates four EAR-scoped cluster nodes. Since Coherence*Web has been deployed to each EAR file, each EAR file becomes a cluster node. All applications running inside each EAR file have access to the same Coherence libraries and classes.

**WAR-Scoped Cluster Nodes**

With this configuration, each deployed Web application becomes its own Coherence node. This configuration produces the largest number of Coherence nodes in the cluster (one for each deployed WAR file that uses Coherence*Web) and because the Coherence library (coherence.jar) is deployed in the Web application’s class path, there will be as many copies of the Coherence classes loaded as there are deployed WAR files. This results in the largest resource utilization of the three options. However, because each deployed Web application is its own cluster node, Web applications are completely isolated from other potentially malfunctioning Web applications.

WAR scoped cluster nodes reduce the deployment effort because no changes to the application server class path are required. This option is also ideal if you plan to deploy only one WAR file to an application server.
Figure 5–7 illustrates two different configurations of WAR files in application servers. Because each WAR file contains a copy of Coherence*Web (and Coherence), it can be considered a cluster node.

**Figure 5–7  WAR-Scoped Clusters**

For more information on XML configuration requirements for WAR-scoped cluster nodes, see these sections:

- For WebLogic Server, see "Configuring WAR-Scoped Cluster Nodes" on page 2-11
- For GlassFish Server, see "Configuring WAR-Scoped Cluster Nodes" on page 3-8

**Session Locking Modes**

Oracle Coherence provides the following configuration options for concurrent access to HTTP sessions.

- **Optimistic Locking**, which allows concurrent access to a session by multiple threads in a single member or multiple members, while prohibiting concurrent modification.

- **Last-Write-Wins Locking**, which is a variation of Optimistic Locking. This allows concurrent access to a session by multiple threads in a single member or multiple members. In this case, the last write is saved. This is the default locking mode.

- **Member Locking**, which allows concurrent access and modification of a session by multiple threads in the same member, while prohibiting concurrent access by threads in different members.

- **Application Locking**, which allows concurrent access and modification of a session by multiple threads in the same Web application instance, while prohibiting concurrent access by threads in different Web application instances.

- **Thread Locking**, which prohibits concurrent access and modification of a session by multiple threads in a single member.
For more information about the parameters described in this section, see Appendix A, "Coherence*Web Context Parameters."

**Optimistic Locking**

Coherence*Web and the Coherence*Web SPI are configured with Optimistic Locking by default. The Optimistic Locking mode allows multiple Web container threads in one or more members to access the same session concurrently. This setting does not use explicit locking; rather an optimistic approach is used to detect and prevent concurrent updates upon completion of an HTTP request that modifies the session. When Coherence*Web detects a concurrent modification, an exception, ConcurrentModificationException is thrown to the application. Therefore, an application must be prepared to handle this exception in an appropriate manner. To view the exception, set the weblogic.debug.DebugHttpSessions system property to true in the container's startup script (for example: -Dweblogic.debug.DebugHttpSessions=true).

The Optimistic Locking mode can be configured by setting the coherence-session-member-locking context parameter to false.

**Last-Write-Wins Locking**

Last-Write-Wins Locking mode is a variation on the Optimistic Locking mode. It allows multiple Web container threads in one or more members to access the same session concurrently. This setting does not use explicit locking; it does not prevent concurrent updates upon completion of an HTTP request that modifies the session. Instead, the last write, that is, the last modification made, is allowed to modify the session.

The Last-Write-Wins Locking mode can be configured by setting the coherence-session-locking parameter to false. This value will allow concurrent modification to sessions with the last update being applied. If the coherence-session-app-locking, coherence-session-member-locking, or coherence-session-thread-locking context parameter is set to true, this value is ignored (being logically true). The default is false.

**Member Locking**

The Member Locking mode allows multiple Web container threads in the same cluster node to access and modify the same session concurrently, but prohibits concurrent access by threads in different members. This is accomplished by acquiring a member-level lock for an HTTP session when the session is acquired. For more information about member-level locks, see <lease-granularity> in the "distributed-scheme" section of Developer's Guide for Oracle Coherence.

The Member Locking mode can be configured by setting the coherence-session-member-locking context parameter to true.

**Note:** Generally, Web applications that are part of the same cluster must use the same locking mode and sticky session optimizations setting. Inconsistent configurations could result in deadlock.
Session Locking Modes

Application Locking

The Application Locking mode restricts session access (and modification) to threads in a single Web application instance at a time. This is accomplished by acquiring both a member-level and application-level lock for an HTTP session when the session is acquired, and releasing both locks upon completion of the request. For more information about member-level locks, see <lease-granularity> in the "distributed-scheme" section of Developer’s Guide for Oracle Coherence.

The Application Locking mode can be configured by setting the coherence-session-app-locking context parameter to true. Note that setting this to true will imply a setting of true for coherence-session-member-locking.

Thread Locking

Thread Locking mode restricts session access (and modification) to a single thread in a single member at a time. This is accomplished by acquiring both a member level, application-level, and thread-level lock for an HTTP session when the session is acquired, and releasing all three locks upon completion of the request. For more information about member-level locks, see <lease-granularity> in the "distributed-scheme" section of the Developer’s Guide for Oracle Coherence.

The Thread Locking mode can be configured by setting the coherence-session-thread-locking context parameter to true. Note that setting this to true implies a setting of true for both coherence-session-member-locking and coherence-session-app-locking.

Troubleshooting Locking in HTTP Sessions

Enabling Member, Application, or Thread Locking for HTTP session access indicates that Coherence*Web will acquire a clusterwide lock for every HTTP request that requires access to a session. The exception to this is when sticky load balancing is available and the Coherence*Web sticky session optimization is enabled. By default, threads that attempt to access a locked session (locked by a thread in a different member) block access until the lock can be acquired. If you want to enable a timeout for lock acquisition, configure it with the coherence-session-get-lock-timeout context parameter, for example:

```xml
<context-param>
  <param-name>coherence-session-get-lock-timeout</param-name>
  <param-value>30</param-value>
</context-param>
```

Many Web applications do not have such a strict concurrency requirement. For these applications, using the Optimistic Locking mode has the following advantages:

- The overhead of obtaining and releasing clusterwide locks for every HTTP request is eliminated.
- Requests can be load-balanced away from failing or unresponsive members to active members without requiring the unresponsive member to release the clusterwide lock on the session.

Coherence*Web provides a diagnostic invocation service that is executed when a member cannot acquire the cluster lock for a session. You can control if this service is enabled by setting the coherence-session-log-threads-holding-lock context parameter. If this context parameter is set to true (default), then the
invocation service will cause the member that has ownership of the session to log the stack trace of the threads that are currently holding the lock.

Note that the `coherence-session-log-threads-holding-lock` context parameter is available only when the `coherence-sticky-sessions` context parameter is set to `true`. This requirement exists because Coherence Web will acquire a cluster-wide lock for every session access request unless sticky session optimization is enabled. By enabling sticky session optimization, frequent lock-holding, and the subsequent production of numerous log files, can be avoided.

Like all Coherence*Web messages, the `coherence-logging-config` operational configuration element controls how the message is logged. For more information on how to configure logging in Coherence, see the description of `logging-config`, in "Operation Configuration Elements" in Developer's Guide for Oracle Coherence.

Enabling Sticky Session Optimizations

If Member, Application, or Thread Locking is a requirement for a Web application that resides behind a sticky load balancer, Coherence*Web provides an optimization for obtaining the clusterwide lock required for HTTP session access. By definition, a sticky load balancer attempts to route each request for a given session to the same application server JVM that it previously routed requests to for that same session. This should be the same application server JVM that created the session. The sticky session optimization takes advantage of this behavior by retaining the clusterwide lock for a session until the session expires or until it is asked to release it. If, for whatever reason, the sticky load balancer sends a request for the same session to another application server JVM, that JVM will ask the JVM that owns the lock on the session to release the lock as soon as possible. For more information, see the `SessionOwnership` entry in Table C-2.

Sticky session optimization can be enabled by setting the `coherence-sticky-sessions` context parameter to `true`. This setting requires that Member, Application, or Thread Locking is enabled.

Deployment Topologies

Coherence*Web supports most of the same deployment topologies that Coherence does including in-process, out-of-process (that is, client/server deployment), and bridging clients and servers over Coherence*Extend. The major supported deployment topologies are described in the following sections.

- **In-Process Topology**, also known as **local storage enabled**, is where session data is stored **in-process** with the application server
- **Out-of-Process Topology**, also known as **local storage disabled**, is where the application servers are configured as cache clients and dedicated JVMs run as cache servers, physically storing and managing the clustered data.
- **Out-of-Process with Coherence*Extend Topology**, means communication between the application server tier and the cache server tier are over Coherence*Extend (TCP/IP).

**In-Process Topology**

The in-process topology is not recommended for production use and is supported mainly for development and testing. By storing the session data in-process with the application server, this topology is very easy to get up and running quickly for smoke
tests, developing and testing. In this topology, local storage is enabled (that is, tangosol.coherence.distributed.localstorage=true).

Figure 5–8 illustrates the in-process topology. All of the application servers communicate with the same session data cache.

**Figure 5–8 In-Process Deployment Topology**

![In-Process Deployment Topology Diagram](image)

### Out-of-Process Topology

For the out-of-process deployment topology, the application servers (that is, application server tier) are configured as cache clients (that is, tangosol.coherence.distributed.localstorage=false) and there are dedicated JVMs running as cache servers, physically storing and managing the clustered data.

This approach has these benefits:

- Session data storage is offloaded from the application server tier to the cache server tier. This reduces heap usage, garbage collection times, and so on.
- The application and cache server tiers can be scaled independently. If more application processing power is needed, just start more application servers. If more session storage capacity is needed, just start more cache servers.

The Out-of-Process topology is the default recommendation of Oracle Coherence due to its flexibility. Figure 5–9 illustrates the out-of-process topology. Each of the servers in the application tier maintain their own near cache. These near caches communicate with the session data cache which runs in a separate cache server tier.

**Figure 5–9 Out-of-Process Deployment Topology**

![Out-of-Process Deployment Topology Diagram](image)

### Migrating from In-Process to Out-of-Process Topology

You can easily migrate your application from an in-process to an out of process topology. To do this, you must run a cache server in addition to the application server. Start the cache server in storage-enabled mode and ensure that it references the same session and cache configuration file (session-cache-config.xml) that the
application server uses. Start the application server in storage-disabled mode. See "Migrating to Out-of-Process Topology" on page 4-5 for detailed information.

**Out-of-Process with Coherence*Extend Topology**

Coherence*Extend consists of two components: an extend client (or proxy) running outside the cluster and an extend proxy service running in the cluster hosted by one or more cache servers. The out-of-process with Coherence*Extend topology is similar to the out-of-process topology except that the communication between the application server tier and the cache server tier is over Coherence*Extend (TCP/IP). For information about configuring this scenario, see "Configuring Coherence*Web with Coherence*Extend" on page 5-18. For information about Coherence*Extend, see Client Guide for Oracle Coherence.

This approach has the same benefits as the out-of-process topology and the ability to divide the deployment of application servers and cache servers into segments. This is ideal in an environment where application servers are on a network that does not support UDP. The cache servers can be set up in a separate dedicated network, with the application servers connecting to the cluster by using TCP.

Figure 5–10 illustrates the out-of-process with Coherence*Extend topology. Near caches in the servers in the application server tier use an extend proxy to communicate with the session data cache in the cache server tier.

**Figure 5–10 Out-of-Process with Coherence*Extend Deployment Topology**

**Configuring Coherence*Web with Coherence*Extend**

One of the deployment options for Coherence*Web is to use Coherence*Extend to connect Web container JVMs to the cluster by using TCP/IP. This configuration should be considered if any of the following situations applies:

- The Web tier JVMs are in a DMZ while the Coherence cluster is behind a firewall.
- The Web tier is in an environment that does not support UDP.
- Web tier JVMs experience long or frequent garbage collection (GC) pauses.
- Web tier JVMs are restarted frequently.

In these deployments, there are three types of participants:
• Web tier JVMs, which are the Extend clients in this topology. They are not members of the cluster; instead, they connect to a proxy node in the cluster that will issue requests to the cluster on their behalf.

• Proxy JVMs, which are storage-disabled members (nodes) of the cluster that accept and manage TCP/IP connections from Extend clients. Requests that arrive from clients will be sent into the cluster, and responses will be sent back through the TCP/IP connections.

• Storage JVMs, which are used to store the actual session data in memory.

To Configure Coherence*Web to Use Coherence*Extend
1. Configure Coherence*Web to use the Optimistic Locking mode (see "Optimistic Locking" on page 5-14).
2. Configure a cache configuration file for the proxy and storage JVMs (see "Configure the Cache for Proxy and Storage JVMs" on page 5-19).
3. Modify the Web tier cache configuration file to point to one or more of the proxy JVMs (see "Configure the Cache for Web Tier JVMs" on page 5-22).

Configure the Cache for Proxy and Storage JVMs
The session cache configuration file (WEB-INF/classes/session-cache-config.xml) is an example Coherence*Web cache configuration file that uses Coherence*Extend.

Use this file for the proxy and server JVMs. It contains system property overrides that allow the same file to be used for both proxy and storage JVMs. When used by a proxy JVM, the system properties described in Table 5–1 should be specified.

Table 5–1 System Property Values for Proxy JVMs

<table>
<thead>
<tr>
<th>System Property Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tangosol.coherence.session.localstorage</td>
<td>false</td>
</tr>
<tr>
<td>tangosol.coherence.session.proxy</td>
<td>true</td>
</tr>
<tr>
<td>tangosol.coherence.session.proxy.localhost</td>
<td></td>
</tr>
<tr>
<td>tangosol.coherence.session.proxy.localport</td>
<td>The host name or IP address of the NIC to which the proxy will bind.</td>
</tr>
</tbody>
</table>

When used by a cache server, specify the system properties described in Table 5–2.

Table 5–2 System Property Values for Storage JVMs

<table>

Configure the Cache for Web Tier JVMs

The session cache configuration file illustrated in Example 5–4 is based on the session-cache-config.xml file that can be found in the coherence-web.jar file. The example illustrates a Coherence*Web cache configuration file that uses Coherence*Extend. The Web tier JVMs should use this cache configuration file. Follow these steps:

To Install the Session Cache Configuration File for the Web Tier:

1. Extract the session-cache-config.xml file from the coherence-web.jar file.

2. Add proxy JVM host names and IP addresses and ports to the <remote-addresses/> section of the file. In most cases, you should include the host name and IP address, and port of all proxy JVMs for load balancing and failover.
3. Rename the file to `session-cache-config-web-tier.xml`.

4. Place the file in the WEB-INF/classes directory of your Web application. If you used the WebInstaller to install Coherence*Web, replace the existing file that was added by the WebInstaller.

Example 5-4 illustrates the complete client-side session cache configuration file.

**Example 5-4  session-cache-config-web-tier.xml File**

```xml
<?xml version="1.0"?>
<cache-config xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns="http://xmlns.oracle.com/coherence/coherence-cache-config"
    xsi:schemaLocation="http://xmlns.oracle.com/coherence/coherence-cache-config coherence-cache-config.xsd">
    <!-- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -->
    <!--                                                                       -->
    <!-- Client-side cache configuration descriptor for Coherence*Web over     -->
    <!-- Coherence*Extend (see session-cache-config-server.xml).               -->
    <!--                                                                       -->
    <!-- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -->
    <caching-scheme-mapping>
        <!-- The clustered cache used to store Session management data. -->
        <cache-mapping>
            <cache-name>session-management</cache-name>
            <scheme-name>session-near</scheme-name>
        </cache-mapping>
        <!-- The clustered cache used to store ServletContext attributes. -->
        <cache-mapping>
            <cache-name>servletcontext-storage</cache-name>
            <scheme-name>session-near</scheme-name>
        </cache-mapping>
        <!-- The clustered cache used to store Session attributes. -->
        <cache-mapping>
            <cache-name>session-storage</cache-name>
            <scheme-name>session-near</scheme-name>
        </cache-mapping>
        <!-- The clustered cache used to store the "overflowing" (split-out due to size) -->
        <!-- Session attributes. Only used for the "Split" model. -->
        <cache-mapping>
```

**Note:** The `<remote-addresses>` element contains the proxy server(s) to which the Web container will connect. By default, the Web container will pick an address at random (if there is more than one address in the configuration). If the connection between the Web container and the proxy is broken, the container will connect to another proxy in the list.
<!-- The clustered cache used to store IDs of "recently departed" Sessions. -->

      <remote-addresses>
        <!-- The following list of addresses should include the hostname and port of all running proxy JVMs. This is for both load balancing and failover of requests from the Web tier. -->
      </remote-addresses>
    </tcp-initiator>
  </initiator-config>
</remote-cache-scheme>
Accessing Sessions with Lazy Acquisition

By default, Web applications instrumented with the WebInstaller will always acquire a session whenever a servlet or filter is called. The session is acquired regardless of whether the servlet or filter actually needs a session. This can be expensive in terms of time and processing power if you run many servlets or filters that do not require a session.

To avoid this behavior, enable lazy acquisition by setting the `coherence-session-lazy-access` context parameter to `true` in the web.xml file. The session will be acquired only when the servlet or filter attempts to access it.

Overriding the Distribution of HTTP Sessions and Attributes

The Coherence*Web Session Distribution Controller, described by the `HttpSessionCollection.SessionDistributionController` interface, enables you to override the default distribution of HTTP sessions and attributes in a Web application. You override the default distribution by setting the `coherence-distributioncontroller-class` context parameter (see "Registering a Session Distribution Controller Implementation" on page 5-27). The value of the context parameter indicates an implementation of the `SessionDistributionController` interface.

An implementation of the `SessionDistributionController` interface can identify sessions or attributes in any of the following ways:

- **Distributed**, where a distributed session or attribute is stored within the Coherence data grid, and thus, accessible to other server JVMs. All sessions (and their attributes) are managed in a distributed manner. This is the default behavior and is provided by the `com.tangosol.coherence.servlet.AbstractHttpSessionCollection$DistributedController` implementation of the `SessionDistributionController` interface.

- **Local**, where a local session or attribute is stored on the originating server's heap, and thus, only accessible by that server. The `com.tangosol.coherence.servlet.AbstractHttpSessionCollection$LocalController` class provides this behavior. This option is not recommended for production purposes, but it can be useful for testing the difference in scalable performance between local-only and fully distributed implementations.

- **Hybrid**, which is similar to distributed in that all sessions and serializable attributes are managed in a distributed manner. However, unlike distributed, session attributes that do not implement the `Serializable` interface will be kept local. The `com.tangosol.coherence.servlet`
AbstractHttpSessionCollection$HybridController class provides this behavior.

At any point during the life of a session, the session or attributes for that session can change from local or distributed. However, when a session or attribute is distributed it cannot change back to local.

You can use the Session Distribution Controller in any of the following ways:

- You can allow new sessions to remain local until you add an attribute (for example, when you add the first item to an online shopping cart); the idea is that a session must be fault-tolerant only when it contains valuable data.
- Some Web frameworks use session attributes to store the UI rendering state. Often, this data cannot be distributed because it is not serializable. Using the Session Distribution Controller, these attributes can be kept local while allowing the rest of the session attributes to be distributed.
- The Session Distribution Controller can assist in the conversion from nondistributed to distributed systems, especially when the cost of distributing all sessions and all attributes is a consideration.

**Implementing a Session Distribution Controller**

Example 5–5 illustrates a sample implementation of the HttpSessionCollection.SessionDistributionController interface. In the sample, sessions are tested to see if they have a shopping cart attached (only these sessions will be distributed). Next, the session is tested whether it contains a certain attribute. If the attribute is found, then it is not distributed.

**Example 5–5  Sample Session Distribution Controller Implementation**

```java
import com.tangosol.coherence.servlet.HttpSessionCollection;
import com.tangosol.coherence.servlet HttpSessionModel;

/**
 * Sample implementation of SessionDistributionController
 */

public class CustomSessionDistributionController
    implements HttpSessionCollection.SessionDistributionController
{
    public void init(HttpSessionCollection collection)
    {
    }

    /**
     * Only distribute sessions that have a shopping cart.
     *
     * @param model Coherence representation of the HTTP session
     * @return true if the session should be distributed
     */
    public boolean isSessionDistributed(HttpSessionModel model)
    {
        return model.getAttribute("shopping-cart") != null;
    }

    /**
     * If a session is 'distributed', then distribute all attributes with the
     * exception of the 'ui-rendering' attribute.
     */
```
Securing Coherence*Web Deployments

**Registering a Session Distribution Controller Implementation**

After you have written your SessionDistributionController implementation, you can register it with your application by using the coherence-distributioncontroller-class context parameter. See Appendix A, "Coherence*Web Context Parameters" for more information about this parameter.

**Detecting Changed Attribute Values**

By default, Coherence*Web tracks if attributes retrieved from the session have changed during the course of processing a request. This is done by caching the initial serialized binary form of the attribute when it is retrieved from the session. At the end of processing a request, Coherence*Web will compare the current binary value of the attribute with the "old" version of the binary. If the values do not match, then the current value is written to the cache.

If you know that your application does not mutate session attributes without doing a corresponding set, then you should set the coherence-enable-suspect-attributes context parameter to false. This will improve memory use and near-cache optimization.

**Saving Non-Serializable Attributes Locally**

By default, Coherence*Web attempts to serialize all session attributes. If you are working with any session attributes that are not serializable, you can store them locally by setting the coherence-preserve-attributes parameter to true. This parameter requires you to use a load balancer to retrieve non-serializable attributes for a session.

Note that if the client (application server) fails, then the attributes will be lost. Your application must be able to recover from this.

The default for this parameter is false. If you are using ActiveCache for GlassFish, then this value will be set to true because the GlassFish Server requires local sessions to be available.

See Appendix A, "Coherence*Web Context Parameters" for more information about the coherence-preserve-attributes parameter.

**Securing Coherence*Web Deployments**

To prevent unauthorized Coherence TCMP cluster members from accessing HTTP session cache servers, Coherence provides a Secure Socket Layer (SSL) implementation. This implementation can be used to secure TCMP communication between cluster nodes and TCF communication between Coherence*Extend clients.
Securing Coherence*Web Deployments

and proxies. Coherence allows you to use the Transport Layer Security (TLS) 1.0 protocol which is the next version of the SSL 3.0 protocol; however, the term SSL is used since it is the more widely recognized term.

This section provides only an overview of using SSL in a Coherence environment. For more information and sample configurations, see "Using SSL to Secure Communication" in Oracle Coherence Security Guide.

**Using SSL to Secure TCMP Communications**

A Coherence cluster can be configured to use SSL with TCMP. Coherence allows you to use both one-way and two-way authentication. Two-Way authentication is typically used more often than one-way authentication, which has fewer use cases in a cluster environment. In addition, it is important to realize that TCMP is a peer-to-peer protocol that generally runs in trusted environments where many cluster nodes are expected to remain connected with each other. The implications of SSL on administration and performance should be carefully considered.

In this configuration, you can use the pre-defined, out-of-the-box SSL socket provider that allows for two-way communication SSL connections based on peer trust, or you can define your own SSL socket provider.

**Using SSL to Secure Extend Client Communication**

Communication between extend clients and extend proxies can be secured using SSL. SSL requires configuration on both the client side as well as the cluster side. On the cluster side, you configure SSL in the cluster-side cache configuration file by defining a SSL socket provider for a proxy service. You can define the SSL socket provider either for all proxy services or for individual proxy services.

On the client side, you configure SSL in the client-side cache configuration file by defining a SSL socket provider for a remote cache scheme and, if required, for a remote invocation scheme. Like the cluster side, you can define the SSL socket provider either for all remote services or for individual remote services.
This chapter contains the following sections:

- Managing and Monitoring Applications with JMX
- Running Performance Reports

---

**Note:** To enable Coherence*Web JMX Management and Monitoring, this section assumes that you have first set up the Coherence Clustered JMX Framework. To set up this framework, see the configuration and installation instructions in "Using JMX to Manage Coherence" in *Management Guide for Oracle Coherence*.

### Managing and Monitoring Applications with JMX

The management attributes and operations for Web applications that use Coherence*Web for HTTP session management are visible through the `HttpSessionManagerMBean` MBean (`com.tangosol.coherence.servlet.management.HttpSessionManagerMBean`).

During startup, each Coherence*Web Web application registers a single instance of the `HttpSessionManager` class. You can use a monitoring tool, such as JConsole, to view the values of the MBean attributes. The MBean is unregistered when the Web application shuts down.

*Table 6–1* describes the object name that the MBean uses for registration.

<table>
<thead>
<tr>
<th>Managed Bean</th>
<th>Object Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>HttpSessionManager</td>
<td>type=HttpSessionManager,nodeId=cluster node id, appId=web application id</td>
</tr>
</tbody>
</table>

*Table 6–2* describes the information that `HttpSessionManager` provides. All of the names represent attributes, except `resetStatistics`, which is an operation.

Several of the MBean attributes use the following prefixes:

- **LocalSession**, which indicates a session that is not distributed to all members of the cluster. The session remains local to the originating server until a later point in the life of the session.
- **LocalAttribute**, which indicates a session attribute that is not distributed to all members of the cluster.
Overflow, a cache which stores the large session attributes when the Split Session model is used.

### Table 6–2 Information Returned by the HttpSessionManager

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AverageReapDuration</td>
<td>long</td>
<td>The average reap duration (the time it takes to complete a reap cycle) in milliseconds, since the statistic was reset. See &quot;Getting Session Reaper Performance Statistics&quot; on page 7-3.</td>
</tr>
<tr>
<td>CollectionClassName</td>
<td>String</td>
<td>The fully qualified class name of the HttpSessionCollection implementation in use. The HttpSessionCollection interface is an abstract model for a collection of HttpSessionModel objects. The interface is not at all affected by how the sessions communicate between the clients and the servers.</td>
</tr>
<tr>
<td>FactoryClassName</td>
<td>String</td>
<td>The fully-qualified class name of the Factory implementation being used. The SessionHelper.Factory class is used by the SessionHelper class to obtain objects that implement various important parts of the servlet specification. The Factory implementation can be placed in front of the application instead of the application server's own objects. This changes the apparent implementation of the application server itself (for example, adding clustering.)</td>
</tr>
<tr>
<td>LastReapDuration</td>
<td>long</td>
<td>The amount of time, in milliseconds, it took for the last reap cycle to finish. See &quot;Getting Session Reaper Performance Statistics&quot; on page 7-3.</td>
</tr>
<tr>
<td>LocalAttributeCacheName</td>
<td>String</td>
<td>The name of the local cache that stores non-distributed session attributes. If the attribute displays null then local session attribute storage is disabled.</td>
</tr>
<tr>
<td>LocalAttributeCount</td>
<td>Integer</td>
<td>The number of non-distributed session attributes stored in the local session attribute cache. If the attribute displays -1, then local session attribute storage is disabled.</td>
</tr>
<tr>
<td>LocalSessionCacheName</td>
<td>String</td>
<td>The name of the local cache that stores nondistributed sessions. If the attribute displays a null value, then local session storage is disabled.</td>
</tr>
<tr>
<td>LocalSessionCount</td>
<td>Integer</td>
<td>The number of nondistributed sessions stored in the local session cache. If the attribute displays a -1 value, then local session storage is disabled.</td>
</tr>
<tr>
<td>MaxReapedSessions</td>
<td>long</td>
<td>The maximum number of sessions reaped in a reap cycle since the statistic was reset. See &quot;Getting Session Reaper Performance Statistics&quot; on page 7-3.</td>
</tr>
<tr>
<td>NextReapCycle</td>
<td>java.lang.Date</td>
<td>The time, expressed as a java.lang.Date data type, for the next reap cycle. See &quot;Getting Session Reaper Performance Statistics&quot; on page 7-3.</td>
</tr>
<tr>
<td>OverflowAverageSize</td>
<td>Integer</td>
<td>The average size (in bytes) of the session attributes stored in the overflow clustered cache since the last time statistics were reset. If the attribute displays -1, then a SplitHttpSessionCollection model is not in use.</td>
</tr>
<tr>
<td>OverflowCacheName</td>
<td>String</td>
<td>The name of the clustered cache that stores the large attributes that exceed a certain size and thus are determined to be more efficiently managed as separate cache entries and not as part of the serialized session object itself. A null value is displayed if a SplitHttpSessionCollection model is not in use.</td>
</tr>
<tr>
<td>OverflowMaxSize</td>
<td>Integer</td>
<td>The maximum size (in bytes) of a session attribute stored in the overflow clustered cache since the last time statistics were reset. The attribute displays a -1 value if a SplitHttpSessionCollection model is not in use.</td>
</tr>
<tr>
<td>Attribute Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OverflowThreshold</td>
<td>Integer</td>
<td>The minimum length (in bytes) that the serialized form of an attribute value must be stored in the separate overflow cache that is reserved for large attributes. The attribute displays a -1 value if a SplitHttpSessionCollection model is not in use.</td>
</tr>
<tr>
<td>OverflowUpdates</td>
<td>Integer</td>
<td>The number of updates to session attributes stored in the overflow clustered cache since the last time statistics were reset. The attribute displays a -1 value if a SplitHttpSessionCollection model is not in use.</td>
</tr>
<tr>
<td>ReapedSessions</td>
<td>long</td>
<td>The number of sessions reaped during the last cycle. See &quot;Getting Session Reaper Performance Statistics&quot; on page 7-3.</td>
</tr>
<tr>
<td>ReapedSessionsTotal</td>
<td>long</td>
<td>The number of expired sessions that have been reaped since the statistic was reset. See &quot;Getting Session Reaper Performance Statistics&quot; on page 7-3.</td>
</tr>
<tr>
<td>ServletContextCacheName</td>
<td>String</td>
<td>The name of the clustered cache that stores javax.servlet.ServletContext attributes. The attribute displays null if ServletContext is not clustered.</td>

<tr>
<td>SessionMinSize</td>
<td>Integer</td>
<td>The minimum size (in bytes) of a session object placed in the session storage clustered cache since the last time statistics were reset.</td>
</tr>
<tr>
<td>SessionStickyCount</td>
<td>Integer</td>
<td>The number of session objects that belong to this instance of the Web application. The attribute displays -1 if sticky session optimizations are disabled.</td>
</tr>
<tr>
<td>SessionTimeout</td>
<td>Integer</td>
<td>The session expiration time (in seconds). The attribute displays -1 if sessions never expire.</td>
</tr>
<tr>
<td>SessionUpdates</td>
<td>Integer</td>
<td>The number of updates of session object stored in the session storage clustered cache since the last time statistics were reset.</td>
</tr>
</tbody>
</table>

Figure 6–1 illustrates the attributes of the HttpSessionManager MBean displayed in the JConsole monitoring tool.
Managing and Monitoring Applications on WebLogic Server

For WebLogic Server, management attributes and operations for Web applications that use Coherence*Web for HTTP session management are visible through the `WebLogicHttpSessionManagerMBean` MBean (com.tangosol.coherence.servlet.management.WebLogicHttpSessionManagerMBean).

Table 6–3 describes the object name that the MBean uses for registration.

<table>
<thead>
<tr>
<th>Managed Bean</th>
<th>Object Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebLogicHttpSessionManager</td>
<td>type=WebLogicHttpSessionManager, node=cluster node id, appId=web application id</td>
</tr>
</tbody>
</table>

The `WebLogicHttpSessionManager` class extends the `HttpSessionManager` class. In addition to the information described in Table 6–2, the `WebLogicHttpSessionManager` class also returns the information listed in Table 6–4. Enterprise Manager uses this information to correlate the Coherence*Web instances to the server.
Coherence includes a JMX-based reporting utility known as the `Reporter`. The Reporter provides several preconfigured reports that help administrators and developers manage capacity and troubleshoot problems. These reports are specially tuned for Coherence*Web:

- **Web Session Storage Report**, which records statistics about the activity between the cluster and the cache where the cluster’s session objects and data are stored.
- **Web Session Overflow Report**, which records statistics about the activity between the cluster and the cache where session objects and data are allowed to overflow from the Web session storage cache.
- **Web Report**, which records information about Coherence*Web activity for the cluster.
- **Web Service Report**, which records information about the service running the Coherence*Web application.

The Coherence*Web reports should be run as part of a batch report. They are defined in both the `report-web-group.xml` and the comprehensive `report-all.xml` batch reports. You can also include them in a custom batch report. The Coherence*Web reports are not defined in the default report group batch file, `report-group.xml`.

The Reporter runs the `report-group.xml` batch report by default. Use the `tangosol.coherence.management.report.configuration` system property to run `report-web-group.xml`, `report-all.xml`, or a custom batch report instead. Example 6–1 illustrates a command line where the property is used to change the report group batch file that is run to `report-web-group.xml`.

**Running Performance Reports**

**Note:** You can find a detailed discussion of the Reporter, including configuring the Reporter, running preconfigured reports, and creating custom reports, in the chapters under “Using JMX Reporting” in *Management Guide for Oracle Coherence*. 

---
Example 6–1  Specifying a Report Group on the Command Line

```
java -Dcom.sun.management.jmxremote
-Dtangosol.coherence.management=all
-Dtangosol.coherence.management.remote=true
-Dtangosol.coherence.management.report.autostart=false
-Dtangosol.coherence.management.report.distributed=false
-Dtangosol.coherence.management.report.configuration=reports/report-web-group.xml
-jar coherence.jar
```

The `report-web-group.xml`, `report-all.xml`, and `report-group.xml` report group batch files, can be found in the `reports` folder in the `coherence.jar` file.

Web Session Storage Report

The Web Session Storage report records statistics on the activity between the cluster and the cache where session objects and data are stored. The statistics include information about the number of put, get, and prune operations performed on the session storage cache, and the amount of time spent on these operations.

The report is a tab-delimited file that is prefixed with the date in `YYYYMMDDHH` format and appended with `-session-storage.txt`. For example, `2010013113-session-storage.txt` would be created on January 31, 2010 1:00 pm. Table 6–5 describes the contents of the Web Session Storage report.

</tr>
</tbody>
</table>
Web Session Overflow Report

The Web Session Overflow report records statistics on the activity between the cluster and the cache where the overflow of session objects and data is stored. The statistics include information about the number of put, get, and prune operations performed on the session overflow cache, and the amount of time spent on these operations.

The report is a tab-delimited file that is prefixed with the date in YYYYMMDDHH format and appended with-cache-session-overflow.txt. For example 2010013113-cache-session-overflow.txt would be created on January 31, 2010 1:00 pm. Table 6–6 describes the contents of the Web Session Overflow report.

Web Service Report

The Web Service report provides information about the service running the Coherence®Web application. The report records the requests processed, request failures, and request backlog, tasks processed, task failures, and task backlog. Request Count and Task Count are useful to determine performance and throughput of the service. RequestPendingCount and Task Backlog are useful in determining capacity issues or blocked processes. Task Hung Count, Task Timeout Count, Thread Abandoned Count, Request Timeout Count are the number of unsuccessful executions that have occurred in the system.
The report is a tab-delimited file that is prefixed with the date and hour in YYYYMMDDHH format and appended with -web-session-service.txt. For example 2009013102-web-session-service.txt would be created on January 1, 2009 at 2:00 am. Table 6–8 describes the contents of the Web Service Report.

Cleaning Up Expired HTTP Sessions

This chapter contains the following sections:

- Understanding the Session Reaper
- Configuring the Session Reaper
- Getting Session Reaper Performance Statistics
- Understanding Session Invalidation Exceptions for the Session Reaper

As part of Coherence*Web Session Management Module, HTTP sessions that have expired are eventually cleaned up by the Session Reaper. The Session Reaper provides a service similar to the JVM Garbage Collection (GC) capability: the Session Reaper is responsible for destroying any session that is no longer used, which is determined when that session has timed out.

Each HTTP session contains two pieces of information that determine when it has timed out. The first is the LastAccessedTime property of the session, which is the time stamp of the most recent activity involving the session. The second is the MaxInactiveInterval property of the session, which specifies how long the session is kept active without any activity; a typical value for this property is 30 minutes. The MaxInactiveInterval property defaults to the value configured for Coherence*Web, but it can be modified on a session-by-session basis.

Each time that an HTTP request is received by the server, if there is an HTTP session associated with that request, then the LastAccessedTime property of the session is automatically updated to the current time. As long as requests continue to arrive related to that session, it is kept active, but when a period of inactivity occurs longer than that specified by the MaxInactiveInterval property, then the session expires. Session expiration is passive—occurring only due to the passing of time. The Coherence*Web Session Reaper scans for sessions that have expired, and when it finds expired sessions it destroys them.

Understanding the Session Reaper

The Session Reaper configuration addresses three basic questions:

- On which servers will the Reaper run?
- How frequently will the Reaper run?
- When the Reaper runs, on which servers will it look for expired sessions?

Every application server running Coherence*Web runs the Session Reaper. That means that if Coherence is configured to provide a separate cache tier (made up of cache servers), then the Session Reaper does not run on those cache servers.
By default, the Session Reaper runs concurrently on all of the application servers, so that all of the servers share the workload of identifying and cleaning up expired sessions. The `coherence-reaperdaemon-cluster-coordinated` context parameter causes the cluster to coordinate reaping so that only one server at a time performs the actual reaping; the use of this option is not suggested, and it cannot be used with the Coherence*Web over Coherence*Extend topology.

The `coherence-reaperdaemon-cluster-coordinated` context parameter should not be used if sticky optimization (`coherence-sticky-sessions`) is also enabled. Because only one server at a time performs the reaping, sessions owned by other nodes cannot be reaped. This means that it will take longer for sessions to be reaped as more nodes are added to the cluster. Also, the reaping ownership does not circulate over the nodes in the cluster in a controlled way; one node can be the reaping node for a long time before it is taken over by another node. During this time, only its own sessions are reaped.

The Session Reaper is configured to scan the entire set of sessions over a certain period, called a reaping cycle, which defaults to five minutes. This length of the reaping cycle is specified by the `coherence-reaperdaemon-cycle-seconds` context parameter. This setting indicates to the Session Reaper how aggressively it must work. If the cycle length is configured too short, the Session Reaper uses additional resources without providing additional benefit. If the cycle length is configured too long, then expired sessions will use heap space in the Coherence caches unnecessarily. In most situations, it is far preferable to reduce resource usage than to ensure that sessions are cleaned up quickly after they expire. Consequently, the default cycle of five minutes is a good balance between promptness of cleanup and minimal resource usage.

During the reaping cycle, the Session Reaper scans for expired sessions. In most cases, the Session Reaper takes responsibility for scanning all of the HTTP sessions across the entire cluster, but there is an optimization available for the single tier topology. In the single tier topology, when all of the sessions are being managed by storage-enabled Coherence cluster members that are also running the application server, the session storage is colocated with the application server. Consequently, it is possible for the Session Reaper on each application server to scan only the sessions that are stored locally. This behavior can be enabled by setting the `coherence-reaperdaemon-assume-locality` configuration option to `true`.

Regardless of whether the Session Reaper scans only colocated sessions or all sessions, it does so in a very efficient manner by using these advanced capabilities of the Coherence data grid:

- The Session Reaper delegates the search for expired sessions to the data grid using a custom `ValueExtractor` implementation. This `ValueExtractor` takes advantage of the `BinaryEntry` interface so that it can determine if the session has expired without even deserializing the session. As a result, the selection of expired sessions can be delegated to the data grid just like any other parallel query, and can be executed by storage-enabled Coherence members in a very efficient manner.

- The Session Reaper uses the `com.tangosol.net.partition.PartitionedIterator` class to automatically query on a member-by-member basis, and in a random order that avoids harmonics in large-scale clusters.

Each storage-enabled member can very efficiently scan for any expired sessions, and it has to scan only one time per application server per reaper cycle. The result is a default Session Reaper configuration that works well for application server clusters with one or multiple servers.
The Session Reaper can invalidate sessions either in parallel or serially. By default, it invalidates sessions in parallel. This ensures that sessions are invalidated in a timely manner. However, if the application server JVM has a high system load due to a large number of concurrent threads then you have the option of invalidating serially. To configure the reaper to invalidate sessions serially, set the `coherence-reaperdaemon-parallel` context parameter to `false`.

To ensure that the Session Reaper does not impact the smooth operation of the application server, it breaks up its work into chunks and schedules that work in a manner that spreads the work across the entire reaping cycle. Because the Session Reaper has to know how much work it must schedule, it maintains statistics on the amount of work that it performed in previous cycles, and uses statistical weighting to ensure that statistics from recent reaping cycles count more heavily. There are several reasons why the Session Reaper breaks up the work in this manner:

- If the Session Reaper consumed a large number of CPU cycles simultaneously, it could cause the application to be less responsive to users. By doing a small portion of the work at a time, the application remains responsive.
- One of the key performance enablers for Coherence*Web is the near-caching feature of Coherence; because the sessions that are expired are accessed through that same near cache to clean them, expiring too many sessions too quickly could cause the cache to evict sessions that are being used on that application server, leading to performance loss.

The Session Reaper performs its job efficiently, even with the default configuration by:

- Delegating as much work as possible to the data grid
- Delegating work to only one member at a time
- Enabling the data grid to find expired sessions without deserializing them
- Restricting the usage of CPU cycles
- Avoiding cache-thrashing of the near caches that Coherence*Web relies on for performance

### Configuring the Session Reaper

The following are suggestions for tuning the default Session Reaper configuration:

- If the application is deployed with the in-process topology, then set the `coherence-reaperdaemon-assume-locality` configuration option to `true`.
- Because all of the application servers are responsible for scanning for expired sessions, it is reasonable to increase the `coherence-reaperdaemon-cycle-seconds` configuration option if the cluster is larger than 10 application servers. The larger the number of application servers, the longer the cycle can be; for example, with 200 servers, it would be reasonable to set the length of the reaper cycle as high as 30 minutes (that is, setting the `coherence-reaperdaemon-cycle-seconds` configuration option to 1800).

### Getting Session Reaper Performance Statistics

The `HttpSessionManagerMBeanWeb` provides several attributes that serve as performance statistics for the Session Reaper. These statistics, described in the following list, include the average time duration for a reap cycle, the number of sessions reaped, and the time until the next reap cycle.
AverageReapDuration, which is the average reap duration (the time it takes to complete a reap cycle), in milliseconds, since the statistic was reset

LastReapDuration, which is the time in milliseconds it took for the last reap cycle to finish

MaxReapedSessions, which is the maximum number of sessions reaped in a reap cycle since the statistic was reset

NextReapCycle, which is the time (as a java.lang.Date data type) for the next reap cycle

ReapedSessions, which is the number of sessions reaped during the last cycle

ReapedSessionsTotal, which is the number of expired sessions that have been reaped since the statistic was reset

These attributes are also described in Table 6–2 in the section "Managing and Monitoring Applications with JMX" on page 6-1.

You can access these attributes in a monitoring tool such as JConsole. However, you must set up the Coherence Clustered JMX Framework before you can access them. The configuration and installation instructions for the framework is provided in "Using JMX to Manage Coherence" in Management Guide for Oracle Coherence.

Understanding Session Invalidation Exceptions for the Session Reaper

Each Coherence*Web instance has a Session Reaper that will periodically iterate through all of the sessions in the session cache and check for expired sessions. If multiple Web applications are using Coherence*Web, then a reaper from one Web application can invalidate sessions used in a different application. Session listeners registered with the Web application that is reaping expired sessions will be executed.

Session attribute listeners will attempt to retrieve the session attribute values during invalidation. If the session attributes are dependent on classes that exist only in the original Web application, then a class not found exception will be thrown and logged in the Session Reaper. These exceptions will not cause any disruption in the Web application or the application server.

Coherence*Web provides a context parameter, coherence-session-log-invalidation-exceptions, to control whether these exceptions are logged. The default value, true, allows the exceptions to be logged. If you want to suppress the logging of these exceptions, set this context parameter to false.
ColdFusion is a rapid application development platform designed to make it easier to connect simple HTML pages to a database. ColdFusion applications can use Coherence*Web for session management regardless of whether the application server is running the SPI or non-SPI version of Coherence*Web.

This chapter contains the following sections:
- Configuring Coherence*Web SPI for ColdFusion Applications
- Configuring Coherence*Web (non-SPI) for ColdFusion Applications

## Configuring Coherence*Web SPI for ColdFusion Applications

If your ColdFusion applications run on WebLogic Server, you can use Coherence*Web for session management. To enable the SPI version of Coherence*Web for ColdFusion applications running on the WebLogic Server:

1. In the ColdFusion installer, create a WAR version of ColdFusion.
2. Follow the provided instructions for configuring WebLogic Server for ColdFusion.
3. Extract the WAR file into a directory for exploded directory deployment to WebLogic Server.
4. Create a `weblogic.xml` file in the `/WEB-INF` directory of the exploded ColdFusion WAR file. Specify the Coherence SPI as a `<library-ref>` attribute.

```xml
<?xml version="1.0"?>
<weblogic-web-app xmlns="http://www.bea.com/ns/weblogic/weblogic-web-app"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://www.bea.com/ns/weblogic/weblogic-web-app
http://www.bea.com/ns/weblogic/weblogic-web-app/1.0/weblogic-web-app.xsd">
  <library-ref>
    <library-name>coherence-web-spi</library-name>
  </library-ref>
</weblogic-web-app>
```

5. Copy the `coherence.jar` file to the `WEB-INF/lib` directory of the exploded application.
6. Copy the `cfusion.jar` file from the `WEB-INF/cfusion/lib` directory to the `WEB-INF/` directory.
7. Start the WebLogic Server instance. Deploy the Coherence*Web SPI to the WebLogic Server. The SPI is located at `coherence\lib\coherence-web-spi.war` in the Coherence distribution.
8. Deploy the ColdFusion application to the WebLogic Server instance.
9. Configure ColdFusion MX to use Java EE session management.
   a. Access the ColdFusion administration page at the following URL:
   b. Select Memory Variables under Server Sessions and enable the Use Java EE session variables checkbox.
10. Add your ColdFusion application under the exploded ColdFusion WAR file.

The application must have an Application.cfm file that specifies 
sessionmanagement="Yes", but should not configure the session using 
ColdFusion configuration (otherwise, exceptions are thrown). The 
Application.cfm file should contain the following line:
<capplication sessionmanagement="Yes">

---

**Configuring Coherence*Web (non-SPI) for ColdFusion Applications**

**Note:** This section applies only to application servers that do not use 
the SPI version of Coherence*Web.

---

To enable the non-SPI version of Coherence*Web with for your application server.

1. In the ColdFusion installer, create a WAR version of ColdFusion.
2. Follow the provided instructions for configuring your Java EE container for ColdFusion.

   If you run Caudo Resin as your application server, run the Coherence*Web WebInstaller on the container. See "Installing on Caudo Resin 3.1.n" on page 4-2 for more information.
3. Instrument the generated cfusion.war file using the Coherence*Web WebInstaller.

   See “General Instructions for Installing Coherence*Web Session Management Module” on page 4-2 for the additional steps to install Coherence*Web for a Java EE application.
4. Deploy the cfusion.war file to the Web container.
5. Configure ColdFusion MX to use Java EE session management:
   a. Access the ColdFusion administration page at the following URL:
      http://<host>:<port>/coldfusion-context-root/CFIDE/administrator
   b. Select Memory Variables under Server Sessions and enable the Use J2EE session variables check box.
6. Add your ColdFusion application.

   The application must have an Application.cfm file that specifies 
sessionmanagement="Yes", but should not configure the session using 
ColdFusion configuration (otherwise, exceptions are thrown). The 
Application.cfm file should contain the following line:
<capplication sessionmanagement="Yes">
JavaServer Faces (JSF) is a framework that enables you to build user interfaces for Web applications. MyFaces, from the Apache Software Foundation, provides JSF components that extend the JSF specification. MyFaces components are completely compatible with the JSF 1.1 Reference Implementation or any other compatible implementation.

For all JSF/MyFaces Web-Applications:
JSF and MyFaces attempts to cache the state of the view in the session object. This state data should be serializable by default, but there could be situations where this would not be the case. For example:

- If Coherence*Web reports `IllegalStateException` due to a non-serializable class, and all the attributes placed in the session by your Web-application are serializable, then you must configure JSF/MyFaces to store the state of the view in a hidden field on the rendered page.
- If the Web application puts non-serializable objects in the session object, you must set the `coherence-preserve-attributes` context parameter to `true`.

The JSF parameter `javax.faces.STATE_SAVING_METHOD` identifies where the state of the view is stored between requests. By default, the state is saved in the servlet session. Set the `STATE_SAVING_METHOD` parameter to `client` in the `context-param` stanza of the `web.xml` file, so that JSF stores the state of the entire view in a hidden field on the rendered page. If you do not, then JSF may attempt to cache that state, which is not serializable, in the session object.

Example 9–1 illustrates setting the `STATE_SAVING_METHOD` parameter in the `web.xml` file.

Example 9–1 Setting `STATE_SAVING_METHOD` in the `web.xml` File

```xml
...  
<context-param>  
  <param-name>javax.faces.STATE_SAVING_METHOD</param-name>  
  <param-value>client</param-value>  
</context-param>  
...  
```

For Instrumented Applications that use MyFaces
If you are deploying the MyFaces application with the Coherence*Web WebInstaller (that is, an instrumented application), then you might have to complete an additional step based on the version of MyFaces.
- If you are using Coherence*Web WebInstaller to deploy a Web-application built with a pre-1.1.1 version of MyFaces, then nothing more needs to be done.

- If you are using Coherence*Web WebInstaller to deploy a Web-application built with a 1.2.x version of MyFaces, then add the context parameter org.apache.myfaces.DELEGATE_FACES_SERVLET to the web.xml file. This parameter allows you to specify a custom servlet instead of the default javax.faces.webapp.FacesServlet.

  Example 9–2 illustrates setting the DELEGATE_FACES_SERVLET context parameter in the web.xml file.

  **Example 9–2 Setting DELEGATE_FACES_SERVLET in the web.xml File**

  ```xml
  ...
  <context-param>
    <param-name>org.apache.myfaces.DELEGATE_FACES_SERVLET</param-name>
    <param-value>com.tangosol.coherence.servlet.api23.ServletWrapper</param-value>
  </context-param>
  ...
  ```

For Instrumented Applications that Use the JSF Reference Implementation (Mojarra)

If you are using Coherence*Web WebInstaller to deploy a Web application based on the JSF Reference Implementation (Mojarra), then you must declare the FacesServlet class in the servlet stanza of the web.xml file.

**Example 9–3 Declaring the Faces Servlet in the web.xml File**

```xml
...
<servlet>
  <servlet-name>Faces Servlet (for loading config)</servlet-name>
  <servlet-class>javax.faces.webapp.FacesServlet</servlet-class>
</servlet>
...
```

For Non-Instrumented Applications that Use MyFaces and Coherence SPI

If you are using the Coherence SPI to deploy a Web application built with MyFaces, then nothing more needs to be done. This is the recommended method of running MyFaces with Coherence*Web.

For Non-Instrumented Applications that use the JSF Reference Implementation (Mojarra) and the Coherence SPI

If you are using the Coherence SPI to deploy a Web application based on the JSF Reference Implementation (Mojarra), then nothing needs to be done. This is the recommended method of running JSF with Coherence*Web.
Using Coherence*Web with WebLogic Portal

Coherence*Web can be used in a WebLogic Portal environment to provide session state management based on Coherence. Coherence*Web allows for more advanced deployment models, session models, and locking modes in a clustered environment. For more information about these features, see Chapter 5, "Coherence*Web Session Management Features."

This chapter contains the following sections:

- Downloading Required Patches (Optional)
- Using Coherence*Web with WebLogic Portal—Main Steps
- Using the Coherence Cache Provider with WebLogic Portal

**Downloading Required Patches (Optional)**

**Note:** Oracle WebLogic Server releases 10.3.1 or later do not require a patch. If you are using release 10.3.1 or later, you can skip this section.

If you are using WebLogic Server 10.3 or earlier, apply the appropriate software patch to all WebLogic Server instances that are hosting the Web applications that will use Coherence*Web. Table 10–1 lists the appropriate patches for your version of WebLogic Server and Coherence release level.

<table>
<thead>
<tr>
<th>WebLogic Server 9.2 MP1</th>
<th>WebLogic Server 10.3</th>
<th>WebLogic Server 10.3.1 and later</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebLogic Smart Update</td>
<td>Patch ID: AJQB</td>
<td>Patch ID: 6W2W</td>
</tr>
</tbody>
</table>

The patches can be downloaded by using either the MyOracleSupport Web site or the WebLogic Server’s Smart Update utility.

**To Download from MyOracleSupport:**

1. Go to the MyOracleSupport Web site to manually locate the patch.
   
   http://support.oracle.com/

2. Select the **Patches** tab and click the **Simple Search** link. On the subsequent screen, submit a search for a **Patch Number/Name** with the appropriate value (for example, 11399293).

3. Download the patch zip file from the displayed results.
4. See the README.txt included in the patch zip file for instructions for applying the Coherence patch.

**To Download Using Smart Update:**

1. Review the instructions in the Smart Update Guide for using Smart Update to install WebLogic Server patches.
   
   For production environments, Oracle recommends that you review the Smart Update production installation.
   
   You can find the Smart Update Guide at this URL:
   
   http://download.oracle.com/docs/cd/E14759_01/doc.32/e14143/toc.htm
   
2. Select **Start** then **All Programs** then **Oracle WebLogic** then **Smart Update** to open the login dialog box. Use your support ID and password to log in.

**Figure 10–1 Oracle Smart Update Login Dialog Box**

![Oracle Smart Update Login Dialog Box](image)

3. Download and apply the appropriate patch for your release of WebLogic Server. **Figure 10–2** illustrates the Oracle Smart Update browser.
Using Coherence*Web with WebLogic Portal—Main Steps

Follow these steps to use Coherence*Web with WebLogic Portal:

1. Start a Cache Server
2. Modify the Session Configuration (Optional)
3. Enable a P13N (Personalization) Cache Provider (Optional)
4. Locate the Coherence JAR File
5. Reference the SPI in the Portal Application
6. Enable Coherence*Web Sessions
7. Create and Deploy the Application

Start a Cache Server

A cache server JVM is a dedicated Coherence JVM that is responsible for storing and managing all cached data (in this case, the HTTP Session state). One or more cache server JVMs must be started before the WebLogic Server or WebLogic Portal JVMs can be started. Follow these steps to start a cache server:

1. Create a script for starting a Cache Server JVM. The following is an example of a script that starts a storage-enabled cache server for use with Coherence*Web. See "JVM Tuning" in *Developer's Guide for Oracle Coherence* for more information about tuning your particular JVM.
2. Start one or more cache server JVMs using the script described in the previous step.

**Modify the Session Configuration (Optional)**

Modify the `session-cache-config.xml` file (if necessary) to customize the cache topology for Coherence*Web.

This configuration file is located in the `coherence-web.jar` file. If you modify the `session-cache-config.xml` file, then you must replace it in the JAR file.

**Enable a P13N (Personalization) Cache Provider (Optional)**

If you want to use the Coherence P13N (Personalization) cache provider, then copy the `coherence-wlp.jar` file into the `APP-INF\lib` directory of the portal enterprise application.

See Integration Guide for Oracle Coherence for more information about the P13N CacheProvider SPI implementation and Web Services for Remote Portlets (WSRP)-federated portals.

If you want to use the Coherence P13N cache as the default cache provider, add the following line before the first `<cache>` element to the `META-INF\p13n-cache-config.xml` file in the portal enterprise application:

```
<default-provider-id>com.tangosol.coherence.weblogic</default-provider-id>
```

**Locate the Coherence JAR File**

Copy the `coherence.jar` file into the `APP-INF\lib` directory of the portal enterprise application.

**Reference the SPI in the Portal Application**

Reference the `coherence-web-spi.war` file by using a library reference (library-ref) in the `WEB-INF\weblogic.xml` file in the portal Web application:

```
<wls:library-ref>
  <wls:library-name>coherence-web-spi</wls:library-name>
</wls:library-ref>
```

**Enable Coherence*Web Sessions**

To enable Coherence*Web sessions, set the application parameter `coherence-web-sessions-enabled` to `true` in the `WEB-INF\web.xml` file in the portal Web application:

```
<context-param>
  <param-name>coherence-web-sessions-enabled</param-name>
  <param-value>true</param-value>
</context-param>
```
Create and Deploy the Application

1. In the portal domain, deploy the coherence-web-spi.war file as a library to the cluster.
2. Create an EAR file for the application.
3. In the portal domain, deploy the application EAR file to the cluster.

Using the Coherence Cache Provider with WebLogic Portal

The Coherence cache provider can be configured to provide caching services for enterprise applications that run on WebLogic Portal. To accomplish this, the cache providers and the WebLogic portal servers are set up to run in an out-of-process deployment topology.

In out-of-process topology, the WebLogic portal servers (or, WebLogic Portal server tier) are configured as cache clients with local storage disabled (that is, the tangosol.coherence.weblogic.localstorage, tangosol.coherence.distributed.localstorage, and tangosol.coherence.session.localstorage system properties are set to false) and there are dedicated JVMs running as cache servers, physically storing and managing the clustered data.

This approach has these benefits:

- Session data storage is offloaded from the WebLogic Portal tier to the cache server tier. This reduces heap usage, garbage collection times, and so on.
- The WebLogic Portal and cache server tiers can be scaled independently. If more application processing power is needed, start more WebLogic Portal servers. If more session storage capacity is needed, start more cache servers.

Out-of-process topology is the default recommendation of Oracle Coherence due to its flexibility. Figure 10–3 illustrates the out of process topology. Each of the WebLogic Portal servers in the portal tier maintain their own near cache. These near caches communicate with the session data cache which runs in a separate cache server tier.

See "Deploying Coherence Cache Provider for Out-of-Process Topology" on page 10-5 for instructions on how to configure this topology.

**Figure 10–3 Out-of-Process Deployment Topology for WebLogic Portal**

Deploying Coherence Cache Provider for Out-of-Process Topology

1. Obtain the session cache and portal cache configuration files:
To use the Coherence Cache Provider with WebLogic Portal:

1. **Extract the** session-cache-config.xml **file from the** coherence-web.jar **file.**
   
2. **Extract the** portal-cache-config.xml **file from the** coherence-wlp.jar **file.**
   
3. **Merge the contents of the** session-cache-config.xml **and portal-cache-config.xml** **files so that a set of Coherence grid nodes can support both types of objects: session and P13N cache.**
   
   You will need two copies of this file: one that will be used by the Coherence cache servers and one that will be used by the WebLogic Portal managed servers. The contents of the two files will be identical, except for the values of the local-storage properties in the portal cache and the session cache sections.

   Example D-1 in Appendix D, "Cache Configuration for WebLogic Portal and Oracle Coherence" illustrates a merged configuration file that can be used for the WebLogic Portal managed servers. The local-storage values for the session cache and portal cache are set to false. The configuration file for the Coherence cache server can be the same as Example D-1, except the values for the local-storage system property in the session cache configuration section and portal cache configuration section must be set to true.

4. **Use the merged configuration file for the WebLogic Portal managed server as the cache configuration file for the servers. For each application that will run on the WebLogic Portal managed server, copy the file to the application’s APP-INF/classes directory.**

5. **Set the merged configuration file as the cache configuration for the Coherence grid JVMs.** For example, in the following system property to locate the cache configuration file, portal-session-cache-config.xml represents the merged file:

   ```
   -Dtangosol.coherence.cacheconfig=D:\Coherence37\coherence\temp\portal-session-cache-config.xml
   ```

6. **Add the system properties to disable local storage for the WebLogic Portal managed servers.** For example, you can add the following properties to your Coherence cache server startup script:

   ```
   -Dtangosol.coherence.weblogic.localstorage=false -Dtangosol.coherence.distributed.localstorage=false -Dtangosol.coherence.session.localstorage=false
   ```

7. **Deploy the** coherence.jar, coherence-wlp.jar, and coherence-web-spi.war **files as shared libraries to all of the WebLogic Portal managed servers where the application will be deployed.**

   See the deployment instructions in "Using Coherence Web with WebLogic Portal—Main Steps" on page 10-3.

8. **Start the Coherence grid with the command line system properties for local storage and session storage set to true:**

   ```
   ... -Dtangosol.coherence.weblogic.localstorage=true -Dtangosol.coherence.session.localstorage=true ...
   ```

9. **Start the WebLogic Portal managed servers.**
This appendix describes the Coherence*Web context parameters. The parameters can be configured in the web.xml file or they can also be entered on the command line as system properties. The system properties have the same name as the context parameters, but the dash (-) is replaced with a period (.). For example, the context parameter coherence-enable-sessioncontext can be declared on the command line by:

-Dcoherence.enable.sessioncontext=true

If both a system property and the equivalent context parameter are configured, the value from the system property is honored.

Table A–1 describes the context parameters for Coherence*Web.
### Table A–1 Context Parameters for Coherence*Web

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| coherence-application-name         | Coherence*Web uses the value of this parameter to determine the name of the application that uses the ApplicationScopeController interface to scope attributes. The value for this parameter should be provided in the following format:  
  
  \[ \text{application name} + ! + \text{Web module name} \]  
  
  The application name is the name of the application that uses the ApplicationScopeController interface and Web module name is the name of the Web module in which it appears.  
  
  For example, if you have an EAR file named test.ear and a Web-module named appl defined in the EAR file, then the default value for the coherence-application-name parameter would be test!appl.  
  
  If this parameter is not configured, then Coherence*Web uses the name of the class loader instead. Also, if the parameter is not configured and the ApplicationScopeController interface is configured, then a warning is logged saying that the application name was not configured. See "Session Attribute Scoping" on page 5-9 for more information. |
| coherence-attribute-overflow-threshold | For the Split Model, described in "Session Models" on page 5-2, this value specifies the minimum length (in bytes) that the serialized form of an attribute value must be for it to be stored in the separate overflow cache that is reserved for large attributes.  
  
  If unspecified, this parameter defaults to 1024. |
| coherence-cluster-owned            | If true, Coherence*Web automatically shuts down the Coherence node when the Web application shuts down. You must use the WAR-scoped cluster node deployment model in this case. See "WAR-Scoped Cluster Nodes" on page 5-12 for more information.  
  
  If false, the Web application is responsible for shutting down the Coherence node (see com.tangosol.net.CacheFactory.shutdown() in the Javadoc). You must carefully consider a cluster node-scoping deployment model in this case and the circumstances under which the application shuts down the Coherence node and the side effects of doing so. See "Cluster Node Isolation" on page 5-10 for more information on cluster node scoping.  
  
  Note: When using the WebInstaller, a value of true instructs the WebInstaller to place the Coherence library in the WEB-INF/lib directory of each Web application found in your Java EE application.  
  
  If unspecified, this parameter defaults to false. |
| coherence-configuration-consistency | If true, Coherence*Web runs a configuration check at startup to determine whether all nodes in the Web tier have the same Coherence*Web configuration. If the configuration of a particular node is not consistent, then it will fail to start (which, in turn, prevents the application from starting).  
  
  If false, (there is no checking) and the configurations are not consistent, then the cluster members might exhibit inconsistent behavior in managing the session data.  
  
  If unspecified, this parameter defaults to false. |
Table A–1 (Cont.) Context Parameters for Coherence*Web

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-contextless-session-retain-millis</td>
<td>Specifies the number of milliseconds that a server holds a lock on a session while accessing it without the session being implied by the current request context. A session is implied by the current request context if and only if the current thread is processing a servlet request, and the request is associated with that session. All other access to a session object is out of context. For example, if a reference to an arbitrary session is obtained from a SessionContext object (if that option is enabled), or if the application has code that holds on to session object references to manage sessions directly. Because session access requires session ownership, out of context access to the session object automatically obtains ownership on behalf of the caller; that ownership will be retained for the number of milliseconds specified by this option so that repeated calls to the session do not individually obtain and release ownership, which is potentially an expensive operation. The valid range is 10 to 10000 (from 1/100th of a second up to 10 seconds). If unspecified, this parameter defaults to 200.</td>
</tr>
</tbody>
</table>
| coherence-distributioncontroller-class | This value specifies a class name of the com.tangosol.coherence.servlet.HttpSessionCollection$SessionDistributionController interface implementation. This feature requires coherence-sticky-sessions optimization to be enabled. Valid values include:  
- com.tangosol.coherence.servlet.AbstractHttpSessionCollection$DistributedController an implementation of the SessionDistributionController interface that forces all sessions (and thus their attributes) to be managed in a distributed manner. This is the default behavior, but by having an implementation that forces this, the raw overhead of using a HttpSessionController can be measured.  
- com.tangosol.coherence.servlet.AbstractHttpSessionCollection$HybridController an implementation of the SessionDistributionController interface that forces all sessions and serializable attributes to be managed in a distributed manner. All session attributes that do not implement the Serializable interface will be kept local.  
- com.tangosol.coherence.servlet.AbstractHttpSessionCollection$LocalController an implementation of the SessionDistributionController interface that forces all sessions (and thus their attributes) to be managed locally. This might not be useful for production purposes, but it can be useful for testing the difference in scalable performance between local-only and fully-distributed implementations. |
| coherence-enable-sessioncontext       | When set to true, this parameter allows the application to iterate sessions from the session context, thus disobeying the deprecation in the servlet specification. If unspecified, this parameter defaults to false. This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-eventlisteners              | This is the comma-delimited list of names of application classes that want to receive events from the Web container. This list comes from the application listeners declared in the listener elements of the web.xml file. This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
### Table A–1 (Cont.) Context Parameters for Coherence*Web

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-enable-suspect-attributes</td>
<td>If set to <code>true</code>, Coherence*Web attempts to detect whether the value of any session-related attributes have changed. Attributes that can be changed (determined with a simple check) and that can be accessed by a <code>get</code> method are deemed to be suspect. Changeable objects might have been changed by application code and must be re-serialized back into the cache. See &quot;Detecting Changed Attribute Values&quot; on page 5-27 for more information. If unspecified, this parameter defaults to <code>true</code>.</td>
</tr>
<tr>
<td>coherence-factory-class</td>
<td>This is the fully qualified name of the class that implements the <code>SessionFactory.Factory</code> factory class. This parameter defaults to <code>com.tangosol.coherence.servlet.api.DefaultFactory</code> where <code>nn</code> is 22, 23, 24, or 25 for Servlet 2.2, 2.3, 2.4, or 2.5 containers respectively.</td>
</tr>
<tr>
<td>coherence-local-session-cachename</td>
<td>This name overrides the name of the local cache that stores nondistributed sessions when the <code>coherence-distributioncontroller-class</code> parameter is specified. If unspecified, this parameter defaults to <code>local-session-storage</code>. Appendix C, &quot;Session Cache Configuration File&quot; describes this parameter.</td>
</tr>
<tr>
<td>coherence-local-attribute-cachename</td>
<td>This name overrides the name of the local cache that stores non-distributed sessions when either the <code>coherence-sessiondistributioncontroller-class</code> parameter is specified or the <code>coherence-preserve-attributes</code> parameter is <code>true</code>. If unspecified, this parameter defaults to <code>local-attribute-storage</code>. Appendix C, &quot;Session Cache Configuration File&quot; describes this parameter.</td>
</tr>
<tr>
<td>coherence-preserve-attributes</td>
<td>This value, if set to <code>true</code>, specifies that non-serializable attributes should be preserved as local ones. This parameter requires a load balancer to be present to retrieve non-serializable attributes for a session. These attributes will be lost if the client (application server) fails. The application would need to be able to recover from this. If you are using ActiveCache for GlassFish, this value will be set to <code>true</code> because the GlassFish Server requires local sessions to be available. If unspecified, this parameter defaults to <code>false</code>.</td>
</tr>
<tr>
<td>coherence-reaperdaemon-assume-locality</td>
<td>This setting allows the Session Reaper to assume that the sessions that are stored on this node (for example, by a distributed cache service) are the only sessions that this node must check for expiration. This value must be set to <code>false</code> if the session storage cache is being managed by nodes that are not running a reaper, for example if cache servers are being used to manage the session storage cache. If cache servers are being used, select the Split Model and run the session overflow storage in a separate distributed cache service that is managed entirely by the cache servers. Leave the session storage cache itself in a distributed cache service that is managed entirely by the application server JVMs so they can take advantage of this assume locality feature. See Chapter 7, &quot;Cleaning Up Expired HTTP Sessions&quot; for more information about the Session Reaper. If unspecified, this parameter defaults to <code>true</code>.</td>
</tr>
</tbody>
</table>
coherence-reaperdaemon-cluster-coordinated

If true, the Session Reaper coordinates reaping in the cluster such that only one server will perform reaping within a given reaping cycle, and it will be responsible for checking all of the sessions that are being managed in the cluster. See Chapter 7, “Cleaning Up Expired HTTP Sessions” for more information about the Session Reaper.

This option should not be used if sticky optimization (coherence-sticky-sessions) is also enabled. See "Understanding the Session Reaper" on page 7-1 for more information.

If unspecified, this parameter defaults to false.

coherence-reaperdaemon-cycle-seconds

This is the number of seconds that the daemon rests between reaping. For production clusters with long session timeout intervals, this can safely be set higher. For testing, particularly with short session timeout intervals, it can be set much lower. Setting it too low can cause more network traffic and use more processing cycles, and has benefit only if the application requires the sessions to be invalidated quickly when they have expired. See Chapter 7, “Cleaning Up Expired HTTP Sessions” for more information about the Session Reaper.

If unspecified, this parameter defaults to 300.

coherence-reaperdaemon-parallel

If set to true, the Session Reaper will invalidate expired sessions in parallel. When set to false, expired sessions will be invalidated serially. See "Understanding the Session Reaper" on page 7-1.

The default is true.

coherence-reaperdaemon-priority

This is the priority for the Session Reaper daemon. For more information, see Chapter 7, “Cleaning Up Expired HTTP Sessions” and the source for the java.lang.Thread class.

If unspecified, this parameter defaults to 5.

coherence-reaperdaemon-sweep-modulo

This parameter is deprecated as of Coherence Release 3.5.

coherence-scopecontroller-class

This value specifies a class name of the optional com.tangosol.coherence.servlet.HttpSessionCollection$AttributeScopeController interface implementation. See "Session Attribute Scoping" on page 5-9 for more information.

Valid values include:

- com.tangosol.coherence.servlet.AbstractHttpSessionCollection$ApplicationScopeController
- com.tangosol.coherence.servlet.AbstractHttpSessionCollection$GlobalScopeController

The default value for Coherence*Web SPI and ActiveCache for GlassFish is com.tangosol.coherence.servlet.AbstractHttpSessionCollection$ApplicationScopeController

For Coherence*Web WebInstaller, there is no declared default value.

coherence-servletcontext-clustered

This value is either true or false to indicate whether the attributes of the ServletContext will be clustered. If true, then all serializable ServletContext attribute values will be shared among all cluster nodes.

If unspecified, this parameter defaults to false, primarily because the servlet specification indicates that the ServletContext attributes are local to a JVM and should not be clustered.

This context parameter has no effect when used with the WebLogic SPI.
## Table A–1 (Cont.) Context Parameters for Coherence*Web

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-servletcontext-cachename</td>
<td>This specifies the name of the Coherence cache to be used to hold the servlet context data if the servlet context is clustered. When used with the Coherence*Web SPI, this parameter can be used to define a cache name, but the cache will not be used. If unspecified, this parameter defaults to servletcontext-storage. Appendix C, &quot;Session Cache Configuration File&quot; describes this parameter.</td>
</tr>
</tbody>
</table>
| coherence-session-affinity-token     | Configures the session affinity suffix token with a given value. For example, to set the session affinity suffix to abcd, add the following code to the Web application's web.xml file:  
```xml
<context-param>
  <param-name>coherence-session-affinity-token</param-name>
  <param-value>abcd</param-value>
</context-param>
```
To strip the session affinity suffix from the token, enter an exclamation point (!) as the parameter value. See "Sharing Coherence*Web Sessions with Other Application Servers" on page 2-13 for more information.                                                             |
| coherence-session-app-locking        | This value, if set to true, will prevent two threads in different applications from processing a request for the same session at the same time. If set to true the value of the coherence-session-member-locking parameter will be ignored, because application locking implies member locking. A value of false is incompatible with thread locking. If unspecified, this parameter defaults to false. See also coherence-session-member-locking, coherence-session-locking, and coherence-session-thread-locking parameter descriptions in this table and "Session Locking Modes" on page 5-13. |
| coherence-session-cachename          | This name overrides the name of the clustered cache that stores the sessions. If unspecified, this parameter defaults to session-storage. Appendix C, "Session Cache Configuration File" describes this parameter. |
| coherence-session-cookie-domain      | This specifies the domain of the session cookie as defined by Request for Comments 2109: HTTP State Management Mechanism (RFC 2109). By default, no domain is set explicitly by the session management implementation. See "Session and Session Attribute Scoping" on page 5-7 for more information. This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-cookie-name        | This specifies the name of the session cookie. If unspecified, this parameter defaults to JSESSIONID. This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-cookie-path        | This specifies the path of the session cookie as defined by RFC 2109. By default, no path is set explicitly by the session management implementation. See "Session and Session Attribute Scoping" on page 5-7 for more information. This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-cookie-max-age      | This specifies the maximum age in seconds of the session cookie as defined by RFC 2109. A value of -1 indicates that the cookie will not persist on the client; a positive value gives the maximum age that the cookie will be persistent for the client. Zero is not permitted. If unspecified, this parameter defaults to -1. This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
### Table A–1 (Cont.) Context Parameters for Coherence*Web

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| coherence-session-cookie-secure      | If true, this value ensures that the session cookie will be sent only from a Web client over a Secure Socket Layer (SSL) connection. If unspecified, the default is false.  
This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-cookies-enabled    | If unspecified, this parameter defaults to true to enable session cookies. This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation.                                  |
| coherence-session-deathcert-cachename| This name overrides the name of the clustered cache that stores the IDs of recently departed sessions. If unspecified, this parameter defaults to session-death-certificates. Appendix C, "Session Cache Configuration File" describes this parameter. |
| coherence-session-expire-seconds     | This value overrides the session expiration time, and is expressed in seconds. Setting it to -1 causes sessions to never expire. See Chapter 7, "Cleaning Up Expired HTTP Sessions" for more information.  
If unspecified, this parameter defaults to 1800. |
| coherence-session-get-lock-timeout   | This value configures a timeout for lock acquisition for Coherence*Web. See "Troubleshooting Locking in HTTP Sessions" on page 5-15 for more information.  
If unspecified, this parameter defaults to 1800. |
| coherence-session-id-length          | This is the length, in characters, of generated session IDs. The suggested absolute minimum length is 8. If unspecified, this parameter defaults to 12.  
This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-lazy-access        | This value enables lazy acquisition of sessions. A session will be acquired only when the servlet or filter attempts to access it. This is relevant only for instrumented Web applications—not when using the Coherence*Web SPI. See "Accessing Sessions with Lazy Acquisition" on page 5-25.  
If unspecified, this parameter defaults to false. |
| coherence-session-locking            | If false, concurrent modification to sessions, with the last update being saved, will be allowed. If coherence-session-app-locking, coherence-session-member-locking, or coherence-session-thread-locking are set to true, then this value is ignored (being logically true). See "Last-Write-Wins Locking" on page 5-14.  
If unspecified, this parameter defaults to false.  
See also coherence-session-app-locking, coherence-session-member-locking, and coherence-session-thread-locking in this table. |
| coherence-session-log-invalidation-exceptions | During session invalidation, many class not found exceptions might be thrown and logged in the session reaper. If this context parameter is set to false, then the exceptions will be suppressed. If set to true, then the exceptions will be logged.  
If unspecified, this parameter defaults to true.  
For more information on session invalidation and the cause of the class not found exceptions that might occur during operation of the session reaper, see "Understanding Session Invalidation Exceptions for the Session Reaper" on page 7-4. |
**Table A–1 (Cont.) Context Parameters for Coherence*Web**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-session-log-threads-holding-lock</td>
<td>If true, this value specifies if a diagnostic invocation service is executed when a member cannot acquire the cluster lock for a session. The invocation service will cause the member that has ownership of the session to log the stack trace of the threads that are currently holding the lock. The coherence-session-log-threads-holding-lock context parameter is available only when the coherence-sticky-sessions context parameter is set to true. If unspecified, this parameter defaults to true. See &quot;Troubleshooting Locking in HTTP Sessions&quot; on page 5-15 for more information.</td>
</tr>
<tr>
<td>coherence-session-management-cachename</td>
<td>This name overrides the name of the clustered cache that stores the management and configuration information for the session management implementation. Generally, it should be configured as a replicated cache. If unspecified, this parameter defaults to session-management. Appendix C, &quot;Session Cache Configuration File&quot; describes this parameter.</td>
</tr>
<tr>
<td>coherence-session-member-locking</td>
<td>If true, this value prevents two threads in different members from processing a request for the same session at the same time. See &quot;Optimistic Locking&quot; on page 5-14. If unspecified, this parameter defaults to false. See also coherence-session-thread-locking, coherence-session-locking, and coherence-session-app-locking in this table.</td>
</tr>
<tr>
<td>coherence.session.optimizeModifiedSessions</td>
<td>This JVM system property, if set to true, enables near cache optimizations which can improve performance with applications that use Last-Write-Wins locking. If unspecified, this value defaults to false. This parameter can be set only on the command line as a system property.</td>
</tr>
<tr>
<td>coherence-session-overflow-cachename</td>
<td>For the Split Model, this value overrides the name of the clustered cache that stores the large attributes that exceed a certain size and thus are determined to be more efficiently managed as separate cache entries and not as part of the serialized session object itself. If unspecified, this parameter defaults to session-overflow. Appendix C, &quot;Session Cache Configuration File&quot; describes this parameter.</td>
</tr>
<tr>
<td>coherence-session-strict-spec</td>
<td>If false, then the implementation will not be required to adhere to the servlet specification. The implementation will ignore certain types of exceptions and the application will not terminate. Setting, getting, and removing attributes, or invalidating sessions will not generate any callbacks to session listeners. Any ClassNotFoundException exceptions will not be propagated back to the caller if an attribute cannot be deserialized because the class does not exist in the invoking application. If true, then the implementation strictly adheres to the servlet specification. ClassNotFoundException exceptions must be handled by the application, and session listener events will be sent, even if retrieving the attribute value fails. If unspecified, this parameter defaults to true.</td>
</tr>
<tr>
<td>coherence-session-thread-locking</td>
<td>If true, this value prevents two threads in the same JVM from processing a request for the same session at the same time. If set to true, the value of the coherence-session-member-locking parameter is ignored, because thread locking implies member locking. If unspecified, this parameter defaults to false. See also coherence-session-app-locking, coherence-session-locking, and coherence-session-member-locking parameter descriptions in this table and &quot;Session Locking Modes&quot; on page 5-13.</td>
</tr>
</tbody>
</table>
Table A–1 (Cont.) Context Parameters for Coherence*Web

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| coherence-session-urldecode-bycontainer | If true, this value uses the container’s decoding of the URL session ID. If coherence-session-urlencode-name has been overridden, this must be set to false. Setting this to false will not work in some containers.  
If unspecified, this parameter defaults to true.  
This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-urlencode-bycontainer | If true, this value uses the container’s encoding of the URL session ID. Setting this to true could conflict with the setting for coherence-session-urlencode-name if it has been specified.  
If unspecified, this parameter defaults to false.  
This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-urlencode-enabled | If true, this value enables URL encoding of session IDs.  
If unspecified, this parameter defaults to true.  
This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-urlencode-name | This is the parameter name to encode the session ID into the URL. On some containers, this value cannot be overridden.  
If unspecified, this parameter defaults to jsessionid.  
This context parameter does not control Coherence*Web behavior when used with the WebLogic SPI implementation. |
| coherence-session-weblogic-compatibility-mode | If true, a single session ID (with the cookie path set to "/") will map to a unique Coherence*Web session instance in each Web application. If false, then the standard behavior will apply: that is, a single session ID will map to a single session instance using the Coherence*Web SPI in WebLogic Server. All other session persistence mechanisms in WebLogic Server use a single session ID in each Web application to refer to different session instances.  
If unspecified, this parameter defaults to true. An exception is when the application is configured to use the global scope controller. In this case, the default is false.  
See “Scoping the Session Cookie Path” on page 2-12. |
| coherence-sessioncollection-class | This is the fully-qualified class name of the HttpSessionCollection implementation to use. Possible values include:  
- com.tangosol.coherence.servlet.MonolithicHttpSessionCollection  
- com.tangosol.coherence.servlet.SplitHttpSessionCollection (default)  
- com.tangosol.coherence.servlet.TraditionalHttpSessionCollection  
A value must be specified for this parameter. |
<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coherence-shutdown-delay-seconds</td>
<td>This value determines how long the session management implementation waits before shutting down after receiving the last indication that the application has been stopped, either from ServletContextListener events (Servlet 2.3 or later) or by the destruction of Servlet and Filter objects. This value is expressed in seconds. A value of zero indicates synchronous shutdown; any positive value indicates asynchronous shutdown. If unspecified, this parameter defaults to 0, because some servers are not capable of asynchronous shutdown.</td>
</tr>
<tr>
<td>coherence-sticky-sessions</td>
<td>If true, this value specifies whether sticky session optimizations will be used. This should be enabled only if a sticky load balancer is being used. This feature requires member, application or thread locking to be enabled. See &quot;Enabling Sticky Session Optimizations&quot; on page 5-16. See also coherence-session-thread-locking, coherence-session-member-locking, and coherence-session-app-locking in this table. If unspecified, this parameter defaults to false.</td>
</tr>
<tr>
<td>coherence-web-sessions-enabled</td>
<td>Enables Coherence<em>Web sessions in WebLogic Portal applications. For more information, see &quot;Enable Coherence</em>Web Sessions&quot; on page 10-4.</td>
</tr>
</tbody>
</table>
This appendix will help you estimate the number of cache servers that an application will need. These equations will help you only to arrive at a reasonable estimate; they do not account for the effects of cache indexes, nonapplication objects that might reside on the cache server heap, failover headroom, and so on.

To find the number of cache servers that you will need, you must first calculate the application's heap requirements and the cache server's available tenured generation.

1. **Calculate your application's total heap requirements.**

   When trying to determine the number of cache servers that you will need for your application, a good starting point is to determine your application's total heap requirements. The total heap requirement can be calculated as the number of sessions that you will run, multiplied by the average number of cached objects per session, multiplied by average number of bytes per cached object. Because you typically make one backup copy per cache entry, multiply the total by 2. Written as an equation, this becomes:

   \[
   \text{Total}_\text{Heap}_\text{Requirement} = 2 \times (\text{Number}_\text{of}_\text{Sessions}) \times (\text{Average}_\text{Number}_\text{of}_\text{Cached}_\text{Objects}_\text{per}_\text{Session}) \times (\text{Average}_\text{Number}_\text{of}_\text{Bytes}_\text{per}_\text{Cached}_\text{Object})
   \]

   The units of measure for \(\text{Total}_\text{Heap}_\text{Requirement}\) are bytes. The \(\text{Average}_\text{Number}_\text{of}_\text{Bytes}_\text{per}_\text{Cached}_\text{Object}\), means the number of bytes in the serialized byte stream of primary copies only. Note that this equation does not address unserialized object size. Space requirements for backup copies are accounted for separately.

2. **Calculate the available tenured generation in a cache server JVM.**

   The available tenured generation is a function of the maximum heap size allocation and other user-specified JVM heap-sizing parameters. Another factor in the available tenured generation is the percentage of the heap that is available for storage. Typically, 66% is used as the maximum percentage of the heap available for storage, but this figure might be too low for your system. Thus, make it a variable:

   \[
   \text{Percent}_\text{of}_\text{Heap}_\text{Available}_\text{for}_\text{Storage} = 0.66
   \]

   \[
   \text{Available}_\text{Tenured}_\text{Generation} = (\text{Maximum}_\text{Heap}_\text{Size}) \times (\text{Percent}_\text{of}_\text{Heap}_\text{Available}_\text{for}_\text{Storage})
   \]

3. **Calculate the number of cache servers that will be needed.**

   To calculate the number of cache servers that will be needed, divide the total heap requirement by the available tenured generation.
Number of Cache Servers = (Total Heap Requirement / Available Tenured Generation)
Coherence*Web uses the caches and services defined in the session-cache-config.xml file to implement HTTP session management. This file is deployed in the WEB-INF/classes directory in either the instrumented Web application or shared WebLogic Coherence*Web SPI library. Table C–1 describes the default cache-related values used in the session-cache-config.xml file.

Table C–1 Cache-Related Values Used in session-cache-config.xml

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local-attribute-storage</td>
<td>This local cache is used to store attributes that are not distributed. This can happen under these conditions:</td>
</tr>
<tr>
<td></td>
<td>■ A coherence-distributioncontroller-class is configured. Attributes for local sessions will be stored in this cache.</td>
</tr>
<tr>
<td></td>
<td>■ A non-serializable attribute is set on a distributed session. If coherence-preserve-attributes is set to true, then non-serializable attributes will be placed in the cache. Table A–1 describes this parameter.</td>
</tr>
<tr>
<td>local-session-storage</td>
<td>This local cache is used to store session models that are considered to be local by the configured (if any) coherence-distributioncontroller-class parameter. Table A–1 describes this parameter.</td>
</tr>
<tr>
<td>servletcontext-storage</td>
<td>If ServletContext attribute clustering (see the coherence-servletcontext-clustered parameter in Table A–1) is enabled (it is disabled by default), this cache is used to store ServletContext attributes. This cache is replicated by default, because it is expected that there will a few read-mostly attributes.</td>
</tr>
<tr>
<td>session-death-certificates</td>
<td>Recently expired session IDs are stored in this cache to prevent reuse of a recently used session ID. By default, each storage node will hold up to 4000 session IDs, and session IDs will be evicted after 24 hours. This is configured as a distributed cache.</td>
</tr>
<tr>
<td>session-management</td>
<td>This cache is used to store internal configuration and management information for the session management implementation. This information is updated infrequently; therefore, it is a replicated cache by default.</td>
</tr>
<tr>
<td>session-overflow</td>
<td>If the coherence-sessioncollection-class parameter (described in Table A–1) is set to com.tangosol.coherence.servlet.SplitHttpSessionCollection, then this cache will hold large session attributes. By default, session attributes larger than 1 K will be stored in this cache. This is configured as a distributed cache.</td>
</tr>
<tr>
<td>session-storage</td>
<td>This cache is used to store session models. By default it is mapped to a near cache backed by a distributed cache because it is expected that a container will access and modify a subset of sessions multiple times (if sticky session load balancing is configured.) See &quot;Session Models&quot; on page 5-2 for more information.</td>
</tr>
</tbody>
</table>

Table C–2 describes the services-related values used in the session-cache-config.xml file.
Example C–1 illustrates the contents of the session-cache-config.xml file. The cache- and services-related values described in Table C–1 and Table C–2 appear in bold.

**Table C–2 Services-Related Values Used in session-cache-config.xml**

<table>

<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DistributedSessions</td>
<td>This distributed service is used by the following caches:</td>
</tr>
<tr>
<td></td>
<td>■ session-storage</td>
</tr>
<tr>
<td></td>
<td>■ session-overflow</td>
</tr>
<tr>
<td></td>
<td>■ session-death-certificates</td>
</tr>
<tr>
<td></td>
<td>The tangosol.coherence.session.localstorage system property controls if a JVM stores and manages data for these caches. Under most circumstances, this should be set to false for Web container JVMs. See “Deployment Topologies” on page 5-16 for more details.</td>
</tr>
<tr>
<td>ReplicatedSessionsMisc</td>
<td>This replicated service is used by the session-management and servletcontext-storage caches.</td>
</tr>
<tr>
<td>SessionOwnership</td>
<td>This invocation service is used by the sticky session optimization feature (if coherence-sticky-sessions is set to true).</td>
</tr>
</tbody>
</table>

**Example C–1 Contents of the session-cache-config.xml File**

```xml
<?xml version="1.0"?>
<cache-config xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
              xmlns="http://xmlns.oracle.com/coherence/coherence-cache-config"
              xsi:schemaLocation="http://xmlns.oracle.com/coherence/coherence-cache-config coherence-cache-config.xsd">
  <!--- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - --- -->
  <!--                                                                       -->
  <!--      Cache configuration descriptor for Coherence*Web                 -->
  <!--                                                                       -->
  <!-- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -->
  <caching-scheme-mapping>
    <!-- The clustered cache used to store Session management data. -->
    <cache-mapping>
      <cache-name>session-management</cache-name>
      <scheme-name>replicated</scheme-name>
    </cache-mapping>
  </caching-scheme-mapping>
  <!--- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - --- -->
  <!--                                                                       -->
  <!-- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -->
  <caching-scheme-mapping>
    <!-- The clustered cache used to store ServletContext attributes. -->
    <cache-mapping>
      <cache-name>servletcontext-storage</cache-name>
      <scheme-name>replicated</scheme-name>
    </cache-mapping>
  </caching-scheme-mapping>
  <!--- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - --- -->
  <!--                                                                       -->
  <!-- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -->
  <caching-scheme-mapping>
    <!-- The clustered cache used to store Session attributes. -->
    <cache-mapping>
      <cache-name>session-storage</cache-name>
      <scheme-name>session-near</scheme-name>
    </cache-mapping>
  </caching-scheme-mapping>
</cache-config>
```
The clustered cache used to store the "overflowing" (split-out due to size) Session attributes. Only used for the "Split" model.

```xml
<cache-mapping>
  <cache-name>session-overflow</cache-name>
  <scheme-name>session-distributed</scheme-name>
</cache-mapping>
```

The clustered cache used to store IDs of "recently departed" Sessions.

```xml
<cache-mapping>
  <cache-name>session-death-certificates</cache-name>
  <scheme-name>session-certificate</scheme-name>
</cache-mapping>
```

The local cache used to store Sessions that are not yet distributed (if there is a distribution controller).

```xml
<cache-mapping>
  <cache-name>local-session-storage</cache-name>
  <scheme-name>unlimited-local</scheme-name>
</cache-mapping>
```

The local cache used to store Session attributes that are not distributed (if there is a distribution controller or attributes are allowed to become local when serialization fails).

```xml
<cache-mapping>
  <cache-name>local-attribute-storage</cache-name>
  <scheme-name>unlimited-local</scheme-name>
</cache-mapping>
```

Replicated caching scheme used by the Session management and ServletContext attribute caches.

```xml
<replicated-scheme>
  <scheme-name>replicated</scheme-name>
  <service-name>ReplicatedSessionsMisc</service-name>
  <backing-map-scheme>
    <local-scheme>
      <scheme-ref>unlimited-local</scheme-ref>
    </local-scheme>
  </backing-map-scheme>
  <request-timeout>30s</request-timeout>
  <autostart>true</autostart>
</replicated-scheme>
```

Near caching scheme used by the Session attribute cache. The front cache uses a Local caching scheme and the back cache uses a Distributed caching scheme.

```xml
<near-scheme>
```
<scheme-name>session-near</scheme-name>
<front-scheme>
  <local-scheme>
    <scheme-ref>session-front</scheme-ref>
  </local-scheme>
</front-scheme>

When you are deploying the Coherence cache provider in an out-of-process topology, the WebLogic Portal managed servers (that is, the WebLogic Portal server tier) are configured as cache clients with local storage disabled. The Coherence caches operate as dedicated JVMs running as cache servers, physically storing and managing the portal and session data. See "Using the Coherence Cache Provider with WebLogic Portal" on page 10-5.

For this topology, you need two copies of the merged session and cache configuration files. One copy for the WebLogic Portal managed servers that has local storage disabled, and one copy for the Coherence cache servers which has local storage enabled.

Example D–1 illustrates a cache configuration file for a WebLogic Portal managed server. The configuration allows a WebLogic Portal managed server to store session data in a Coherence cache server. The configuration file combines the session cache configuration from session-cache-config.xml with the portal cache configuration from portal-cache-config.xml. The cache-mapping and \*-scheme sections for session management, taken from the session-cache-config.xml file, appear in bold font. The local-storage system property in the session cache configuration section is set to false. The local-storage system property in the portal cache configuration section for setting the WebLogic local storage to false, also appears in bold font.

The configuration file for the Coherence cache server can be the same as Example D–1, except the values for the local-storage system property in the session cache configuration section and portal cache configuration section must be set to true. See "Deploying Coherence Cache Provider for Out-of-Process Topology" on page 10-5 for more information.

**Example D–1  Cache Configuration for WebLogic Portal Managed Server**

```xml
<?xml version="1.0"?>
<!-- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -->
