Index ................................................................................................................ 189
Preface

The Oracle Solaris 11.1 Tunable Parameters Reference Manual provides reference information about Oracle Solaris OS kernel and network tunable parameters. This manual does not provide tunable parameter information about desktop systems or Java environments.

This manual contains information for both SPARC based and x86 based systems.

Note – This Oracle Solaris release supports systems that use the SPARC and x86 families of processor architectures. The supported systems appear in the Oracle Solaris Hardware Compatibility List at http://www.oracle.com/webfolder/technetwork/hcl/index.html. This document cites any implementation differences between the platform types.

Who Should Use This Book

This book is intended for experienced Oracle Solaris system administrators who might need to change kernel tunable parameters in certain situations. For guidelines on changing Oracle Solaris tunable parameters, refer to “Tuning an Oracle Solaris System” on page 19.

How This Book Is Organized

The following table describes the chapters and appendixes in this book.

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chapter 1, “Overview of Oracle Solaris System Tuning”</td>
<td>An overview of tuning an Oracle Solaris system. Also provides a description of the format used in the book to describe the kernel tunables.</td>
</tr>
<tr>
<td>Chapter 2, “Oracle Solaris Kernel Tunable Parameters”</td>
<td>A description of Oracle Solaris kernel tunables such as kernel memory, file system, process size, and paging parameters.</td>
</tr>
<tr>
<td>Chapter 3, “Oracle Solaris ZFS Tunable Parameters”</td>
<td>A description of Oracle Solaris ZFS tunable parameters. This chapter also includes ZFS tuning information for database products.</td>
</tr>
<tr>
<td>Chapter 4, “NFS Tunable Parameters”</td>
<td>A description of NFS tunables such as caching symbolic links, dynamic retransmission, and RPC security parameters.</td>
</tr>
</tbody>
</table>
Chapter 5, “Internet Protocol Suite Tunable Parameters”
A description of TCP/IP tunables such as IP forwarding, source routing, and buffer-sizing parameters.

Chapter 6, “System Facility Parameters”
A description of parameters used to set default values of certain system facilities. Changes are made by modifying files in the /etc/default directory.

Appendix A, "Tunable Parameters Change History"
A history of parameters that have changed or are now obsolete.

Appendix B, "Revision History for This Manual"
A history of this manual’s revisions including the current Oracle Solaris release.

Other Resources for Oracle Solaris Tuning Information
This table describes other resources for Oracle Solaris tuning information.

<table>
<thead>
<tr>
<th>Tuning Resource</th>
<th>For More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>In-depth technical white papers</td>
<td><a href="http://www.oracle.com/technetwork/server-storage/solaris/overview/index.html">http://www.oracle.com/technetwork/server-storage/solaris/overview/index.html</a></td>
</tr>
</tbody>
</table>

Access to Oracle Support
Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Typographic Conventions
The following table describes the typographic conventions that are used in this book.

<table>
<thead>
<tr>
<th>Typeface</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>AaBbCc123</td>
<td>The names of commands, files, and directories, and onscreen computer output</td>
<td>Edit your .login file.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use ls -a to list all files.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>machine_name% you have mail.</td>
</tr>
</tbody>
</table>
TABLE P–1  Typographic Conventions (Continued)

<table>
<thead>
<tr>
<th>Typeface</th>

</table>
Overview of Oracle Solaris System Tuning

This section provides overview information about the format of the tuning information in this manual. This section also describes the different ways to tune an Oracle Solaris system.

- “What’s New in Oracle Solaris System Tuning?” on page 17
- “Tuning an Oracle Solaris System” on page 19
- “Tuning Format of Tunable Parameters Descriptions” on page 19
- “Tuning the Oracle Solaris Kernel” on page 21
- “Special Oracle Solaris tune and var Structures” on page 23
- “Viewing Oracle Solaris System Configuration Information” on page 24
- “kstat Utility” on page 24

What’s New in Oracle Solaris System Tuning?

This section describes new or changed parameters in the Oracle Solaris 11.1 release.

- Oracle Solaris 11.1: Oracle Solaris ZFS tunable information is provided in Chapter 3, “Oracle Solaris ZFS Tunable Parameters.”
- Oracle Solaris 11.1: The maxusers, max_nprocs, ngroups_max, pidmax, and segkpsize parameters have been revised. For more information, see Chapter 2, “Oracle Solaris Kernel Tunable Parameters.”
- Oracle Solaris 11.1: The dnlc_dircache_percent parameter is new. For more information, see “dnlc_dircache_percent” on page 65.
- Oracle Solaris 11: The rstchown parameter that was previously set in the /etc/system file is obsolete. If you set this parameter in the /etc/system file, the following error message is displayed:

  sorry, variable ‘rstchown’ is not defined in the ‘kernel’

  This parameter has been replaced by the ZFS rstchown file system property and a general file system mount option. For more information, see Oracle Solaris 11.1 Administration: ZFS File Systems and mount(1M).
Oracle Solaris 11: The following system configuration parameters that were previously configured by editing files in the /etc/default directory have changed to SMF services:

- autofs
- init
- kbd
- nfs

For information about changing SMF service properties, see Chapter 6, “System Facility Parameters.”

Oracle Solaris 11: The `ipadm` command replaces the `ndd` command for setting network properties. TCP, IP, UDP, and SCTP properties are set as follows:

```
ipadm set-prop -p parameter ip|ipv4|ipv6|tcp|udp|sctp
```

In addition, most of the network tunable names have changed slightly to correlate better with the `ipadm` format.

For more information, see "Overview of Tuning IP Suite Parameters" on page 129.

Oracle Solaris 11: This release includes the `disp_rechoose_interval` parameter. For more information, see "disp_rechoose_interval" on page 73.

Oracle Solaris 11: This release includes the `ngroups_max` parameter description. For more information, see "ngroups_max" on page 38.

Oracle Solaris 11: This release includes the `zfs_arc_min` and `zfs_arc_max` parameter descriptions. For more information, see "zfs_arc_min" on page 82 and "zfs_arc_max" on page 83.

Oracle Solaris 11: This release includes several `igb` and `ixgbe` network driver parameters. For more information, see "igb Parameters" on page 56 and "ixgbe Parameters" on page 57.

Oracle Solaris 11: This release includes the `ddi_msix_alloc_limit` parameter that can be used to increase the number of MSI-X interrupts that a device instance can allocate. For more information, see "ddi_msix_alloc_limit" on page 55.

Oracle Solaris 11: This release includes the `kmem_stackinfo` parameter, which can be enabled to monitor kernel thread stack usage. For more information, see "kmem_stackinfo" on page 53.

Oracle Solaris 11: Memory locality group parameters are provided in this release. For more information about these parameters, see "Locality Group Parameters" on page 78.
The Oracle Solaris OS is a multi-threaded, scalable UNIX operating system that runs on SPARC and x86 processors. It is self-adjusting to system load and demands minimal tuning. In some cases, however, tuning is necessary. This book provides details about the officially supported kernel tuning options available for the Oracle Solaris OS.

The Solaris kernel is composed of a core portion, which is always loaded, and a number of loadable modules that are loaded as references are made to them. Many variables referred to in the kernel portion of this guide are in the core portion. However, a few variables are located in loadable modules.

A key consideration in system tuning is that setting system parameters (or system variables) is often the least effective action that can be done to improve performance. Changing the behavior of the application is generally the most effective tuning aid available. Adding more physical memory and balancing disk I/O patterns are also useful. In a few rare cases, changing one of the variables described in this guide will have a substantial effect on system performance.

Remember that one system’s /etc/system settings might not be applicable, either wholly or in part, to another system’s environment. Carefully consider the values in the file with respect to the environment in which they will be applied. Make sure that you understand the behavior of a system before attempting to apply changes to the system variables that are described here.

We recommend that you start with an empty /etc/system file when moving to a new Oracle Solaris release. As a first step, add only those tunables that are required by in-house or third-party applications. After baseline testing has been established, evaluate system performance to determine if additional tunable settings are required.

Caution – The tunable parameters described in this book can and do change from Oracle Solaris release to Oracle Solaris release. Publication of these tunable parameters does not preclude changes to the tunable parameters and their descriptions without notice.

Tuning Format of Tunable Parameters Descriptions

The format for the description of each tunable parameter is as follows:

- Parameter Name
- Description
- Data Type
- Default
- Range
- Units
- Dynamic?
- Validation

Tuning an Oracle Solaris System
### Tuning Format of Tunable Parameters Descriptions

- Implicit
- When to Change
- Zone Configuration
- Commitment Level
- Change History

**Parameter Name**

Is the exact name that is typed in the `/etc/system` file, or found in the `/etc/default/facility` file.

Most parameters names are of the form `parameter` where the parameter name does not contain a colon (:). These names refer to variables in the core portion of the kernel. If the name does contain a colon, the characters to the left of the colon reference the name of a loadable module. The name of the parameter within the module consists of the characters to the right of the colon. For example:

`module_name:variable`

**Description**

Briefly describes what the parameter does or controls.

**Data Type**

Indicates the signed or unsigned short integer or long integer. A long integer is twice the width in bits as an integer. For example, an unsigned integer = 32 bits, an unsigned long integer = 64 bits.

**Units**

(Optional) Describes the unit type.

**Default**

What the system uses as the default value.

**Range**

Specifies the possible range allowed by system validation or the bounds of the data type.

- **MAXINT** – A shorthand description for the maximum value of a signed integer (2,147,483,647)
- **MAXUINT** – A shorthand description for the maximum value of an unsigned integer (4,294,967,295)

**Dynamic?**

Yes, if the parameter can be changed on a running system with the `mdb` or `kmdb` debugger. No, if the parameter is a boot time initialization only.

**Validation**

Checks that the system applies to the value of the variable either as specified in the `/etc/system` file or the default value, as well as when the validation is applied.

**Implicit**

(Optional) Provides unstated constraints that might exist on the parameter, especially in relation to other parameters.

**When to Change**

Explains why someone might want to change this value. Includes error messages or return codes.
Zone Configuration Identifies whether the parameter can be set in a exclusive-IP zone or must be set in the global zone. None of the parameters can be set in shared-IP zones.

Commitment Level Identifies the stability of the interface. Many of the parameters in this manual are still evolving and are classified as unstable. For more information, see attributes(5).

Change History (Optional) Contains a link to the Change History appendix, if applicable.

Tuning the Oracle Solaris Kernel

The following table describes the different ways tunable parameters can be applied.

<table>
<thead>
<tr>
<th>Apply Tunable Parameters in These Ways</th>
<th>For More Information</th>

<td>Chapter 6, &quot;System Facility Parameters&quot;</td>
</tr>
</tbody>
</table>

/etc/system File

The /etc/system file provides a static mechanism for adjusting the values of kernel parameters. Values specified in this file are read at boot time and are applied. Any changes that are made to the file are not applied to the operating system until the system is rebooted.

One pass is made to set all the values before the configuration parameters are calculated.

Example-Setting a Parameter in /etc/system

The following /etc/system entry sets the ZFS ARC maximum (zfs_arc_max) to 30 GB.

```
set zfs:zfs_arc_max = 0x780000000
```
Recovering From an Incorrect Value

Make a copy of the /etc/system file before modifying it so that you can easily recover from incorrect value. For example:

```
# cp /etc/system /etc/system.good
```

If a value specified in the /etc/system file causes the system to become unbootable, you can recover with the following command:

```
ok boot -a
```

This command causes the system to ask for the name of various files used in the boot process. Press the Return key to accept the default values until the name of the /etc/system file is requested. When the Name of system file [/etc/system]: prompt is displayed, type the name of the good /etc/system file or /dev/null:

```
Name of system file [/etc/system]: /etc/system.good
```

If /dev/null is specified, this path causes the system to attempt to read from /dev/null for its configuration information. Because this file is empty, the system uses the default values. After the system is booted, the /etc/system file can be corrected.

For more information on system recovery, see Oracle Solaris Administration: Common Tasks.

**kmdm Command**

kmdm is an interactive kernel debugger with the same general syntax as mdb. An advantage of interactive kernel debugger is that you can set breakpoints. When a breakpoint is reached, you can examine data or step through the execution of kernel code.

kmdm can be loaded and unloaded on demand. You do not have to reboot the system to perform interactive kernel debugging, as was the case with kadb.

For more information, see kmdm(1).

**mdb Command**

The modular debugger, mdb, is unique among Solaris debuggers because it is easily extensible. A programming API is available that allows compilation of modules to perform desired tasks within the context of the debugger.

mdb also includes a number of desirable usability features, including command-line editing, command history, built-in output pager, syntax checking, and command pipelining. mdb is the recommended post-mortem debugger for the kernel.
For more information, see \texttt{mdb(1)}.

\textbf{Example—Using \texttt{mdb} to Display Information}

Display a high-level view of a system’s memory usage. For example:

```
# mdb -k
Loading modules: [ unix genunix specfs dtrace mac cpu.generic cpu.ms.AuthenticAMD.15
uppc pcplusmp scsi_vhci zfs mpt sd ip hook neti arp usba sockfs kssl qlc fctl stmf stmf_sbd md lofs random idm fcp crypto cpc smbsrv nfs fcip sppp ufs logindmux ptm nsmb scu
mpt_sas pmcs emlx]
> ::memstat
Page Summary Pages MB %Tot
------------ ---------------- ---------------- ----
Kernel 160876 628 16%
ZFS File Data 303401 1185 30%
Anon 25335 98 2%
Exec and libs 1459 5 0%
Page cache 5083 19 1%
Free (cachelist) 6616 25 1%
Free (freelist) 510870 1995 50%
Total 1013640 3959
Physical 1013639 3959
> $q
```

For more information on using the modular debugger, see the \textit{Oracle Solaris Modular Debugger Guide}.

When using either \texttt{kmdb} or \texttt{mdb} debugger, the module name prefix is not required. After a module is loaded, its symbols form a common name space with the core kernel symbols and any other previously loaded module symbols.

\textbf{Special Oracle Solaris \texttt{tune} and \texttt{var} Structures}

Oracle Solaris tunable parameters come in a variety of forms. The \texttt{tune} structure defined in the \texttt{/usr/include/sys/tuneable.h} file is the runtime representation of \texttt{tune_t_fsflushr}, \texttt{tune_t_minarmem}, and \texttt{tune_t_flkrec}. After the kernel is initialized, all references to these variables are found in the appropriate field of the \texttt{tune} structure.

The proper way to set parameters for this structure at boot time is to initialize the special parameter that corresponds to the desired field name. The system initialization process then loads these values into the \texttt{tune} structure.

A second structure into which various tunable parameters are placed is the \texttt{var} structure named \texttt{v}. You can find the definition of a \texttt{var} structure in the \texttt{/usr/include/sys/var.h} file. The runtime representation of variables such as \texttt{autoup} and \texttt{bufhwm} is stored here.

Do not change either the \texttt{tune} or \texttt{var} structure on a running system. Changing any field in these structures on a running system might cause the system to panic.
Viewing Oracle Solaris System Configuration Information

Several tools are available to examine system configuration information. Some tools require superuser privilege. Other tools can be run by a non-privileged user. Every structure and data item can be examined with the kernel debugger by using `mdb` on a running system or by booting under `kmdb`.

For more information, see `mdb(1)` or `kadb(1M)`.

### sysdef Command

The `sysdef` command provides the values of memory and process resource limits, and portions of the `tune` and `v` structures. For example, the `sysdef` “Tunable Parameters” section from a SPARC T3-4 system with 500 GB of memory is as follows:

```
280628904  maximum memory allowed in buffer cache (bufhwm)
  65546  maximum number of processes (v.v proc)
   99  maximum global priority in sys class (MAXCLSYSPRI)
  65541  maximum processes per user id (v.v maxup)
    30  auto update time limit in seconds (NAUTOUP)
    25  page stealing low water mark (GPGSLO)
     1  fsflush run rate (FSFLUSHR)
    25  minimum resident memory for avoiding deadlock (MINARMEM)
    25  minimum swapable memory for avoiding deadlock (MINASMEM)
```

For more information, see `sysdef(1M)`.

### kstat Utility

`kstats` are data structures maintained by various kernel subsystems and drivers. They provide a mechanism for exporting data from the kernel to user programs without requiring that the program read kernel memory or have superuser privilege. For more information, see `kstat(1M)` or `kstat(3KSTAT)`.
This chapter describes most of the Oracle Solaris kernel tunable parameters.

<td>NFS tunable parameters</td>
<td>Chapter 4, “NFS Tunable Parameters”</td>
</tr>
</tbody>
</table>
**General Kernel and Memory Parameters**

This section describes general kernel parameters that are related to physical memory and stack configuration. The ZFS-related memory parameters have moved to Chapter 3, "Oracle Solaris ZFS Tunable Parameters."

### phymem

**Description**
Modifies the system's configuration of the number of physical pages of memory after the Oracle Solaris OS and firmware are accounted for.

**Data Type**
Unsigned long

**Default**
Number of usable pages of physical memory available on the system, not counting the memory where the core kernel and data are stored

**Range**
1 to amount of physical memory on system

**Units**
Pages

**Dynamic?**
No

**Validation**
None

**When to Change**
Whenever you want to test the effect of running the system with less physical memory. Because this parameter does not take into account the memory used by the core kernel and data, as well as various other data structures allocated early in the startup process, the value of phymem should be less than the actual number of pages that represent the smaller amount of memory.

**Commitment Level**
Unstable

### default_stksize

**Description**
Specifies the default stack size of all threads. No thread can be created with a stack size smaller than default_stksize. If default_stksize is set, it overrides lwp_default_stksize. See also "lwp_default_stksize" on page 27.

**Data Type**
Integer
Default

- 3 x PAGESIZE on SPARC systems
- 5 x PAGESIZE on x64 systems

Range

Minimum is the default values:

- 3 x PAGESIZE on SPARC systems
- 5 x PAGESIZE on x64 systems

Maximum is 32 times the default value.

Units

Bytes in multiples of the value returned by the getpagesize parameter. For more information, see getpagesize(3).

Dynamic?

Yes. Affects threads created after the variable is changed.

Validation

Must be greater than or equal to 8192 and less than or equal to 262,144 (256 x 1024). Also must be a multiple of the system page size. If these conditions are not met, the following message is displayed:

Illegal stack size, Using N

The value of N is the default value of default_stksize.

When to Change

When the system panics because it has run out of stack space. The best solution for this problem is to determine why the system is running out of space and then make a correction.

Increasing the default stack size means that almost every kernel thread will have a larger stack, resulting in increased kernel memory consumption for no good reason. Generally, that space will be unused. The increased consumption means other resources that are competing for the same pool of memory will have the amount of space available to them reduced, possibly decreasing the system’s ability to perform work. Among the side effects is a reduction in the number of threads that the kernel can create. This solution should be treated as no more than an interim workaround until the root cause is remedied.

Commitment Level

Unstable

lwp_default_stksize

Description

Specifies the default value of the stack size to be used when a kernel thread is created, and when the calling routine does not provide an explicit size to be used.

Data Type

Integer
### General Kernel and Memory Parameters

#### Default
- 32,768 for SPARC platforms
- 20,480 for x64 platforms

#### Range
Minimum is the default values:
- 3 \times \text{PAGESIZE} on SPARC systems
- 5 \times \text{PAGESIZE} on x64 systems

Maximum is 32 times the default value.

#### Units
Bytes in multiples of the value returned by the `getpagesize` parameter. For more information, see `getpagesize(3C)`.

#### Dynamic?
Yes. Affects threads created after the variable is changed.

#### Validation
Must be greater than or equal to 8192 and less than or equal to 262,144 (256 \times 1024). Also must be a multiple of the system page size. If these conditions are not met, the following message is displayed:

```
Illegal stack size, Using N
```

The value of $N$ is the default value of `\text{lwp\_default\_stksize}`.

#### When to Change
When the system panics because it has run out of stack space. The best solution for this problem is to determine why the system is running out of space and then make a correction.

Increasing the default stack size means that almost every kernel thread will have a larger stack, resulting in increased kernel memory consumption for no good reason. Generally, that space will be unused. The increased consumption means other resources that are competing for the same pool of memory will have the amount of space available to them reduced, possibly decreasing the system’s ability to perform work. Among the side effects is a reduction in the number of threads that the kernel can create. This solution should be treated as no more than an interim workaround until the root cause is remedied.

#### Commitment Level
Unstable

---

### logevent_max_q_sz

<table>
<thead>
<tr>
<th>Description</th>
<th>Maximum number of system events allowed to be queued and waiting for delivery to the syseventd daemon. Once the size of the system event queue reaches this limit, no other system events are allowed on the queue.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
Default: 5000
Range: 0 to MAXINT
Units: System events
Dynamic?: Yes

Validation: The system event framework checks this value every time a system event is generated by ddi_log_sysevent and sysevent_post_event. For more information, see ddi_log_sysevent(9F) and sysevent_post_event(3SYSEVENT).

When to Change: When error log messages indicate that a system event failed to be logged, generated, or posted.

Commitment Level: Unstable

**segkpsize**

Description: Specifies the amount of kernel pageable memory available. This memory is used primarily for kernel thread stacks. Increasing this number allows either larger stacks for the same number of threads or more threads.

Data Type: Unsigned long
Default: 2 GB x the smaller result of nCPUs / 128 or the amount of physical memory / 256 GB

Range: 512 MB to 64 GB (SPARC)
200 MB to 8 GB (x86)

Units: Pages
Dynamic?: No

Validation: Value is compared to minimum and maximum sizes. If smaller than the minimum or larger than the maximum, it is reset to 2 GB. A message to that effect is displayed.

On SPARC systems, the segkpsize value cannot exceed twice the size of physical memory. On x86 systems, the value cannot exceed the size of physical memory.

When to Change: Required to support large numbers of processes on a system. The default size of 2 GB allows creation of 24-KB stacks for more than...
65,536 kernel threads. If more than this number is needed or the stack size needs to be increased, segkpsize can be increased, assuming sufficient physical memory exists.

Commitment Level: Unstable
Change History: For information, see “segkpsize” on page 178.

noexec_user_stack
Description: Enables the stack to be marked as nonexecutable, which helps make buffer-overflow attacks more difficult.

An Oracle Solaris system running a 64-bit kernel makes the stacks of all 64-bit applications nonexecutable by default. Setting this parameter is necessary to make 32-bit applications nonexecutable.

Data Type: Signed integer
Default: 0 (disabled)
Range: 0 (disabled) or 1 (enabled)
Units: Toggle (on/off)
Dynamic?: Yes. Does not affect currently running processes, only processes created after the value is set.
Validation: None
When to Change: Should be enabled at all times unless applications are deliberately placing executable code on the stack without using mprotect to make the stack executable. For more information, see mprotect(2).

Commitment Level: Unstable

fsflush and Related Parameters
This section describes fsflush and related tunables.

fsflush
The system daemon, fsflush, runs periodically to do three main tasks:
1. On every invocation, fsflush flushes dirty file system pages over a certain age to disk.
2. On every invocation, fsflush examines a portion of memory and causes modified pages to be written to their backing store. Pages are written if they are modified and if they do not meet one of the following conditions:

- Pages are kernel page
- Pages are free
- Pages are locked
- Pages are associated with a swap device
- Pages are currently involved in an I/O operation

The net effect is to flush pages from files that are mapped with mmap with write permission and that have actually been changed.

Pages are flushed to backing store but left attached to the process using them. This will simplify page reclamation when the system runs low on memory by avoiding delay for writing the page to backing store before claiming it, if the page has not been modified since the flush.

3. fsflush writes file system metadata to disk. This write is done every $n$th invocation, where $n$ is computed from various configuration variables. See "tune_t_fsflushr" on page 31 and "autoup" on page 32 for details.

The following features are configurable:

- Frequency of invocation (tune_t_fsflushr)
- Whether memory scanning is executed (dopageflush)
- Whether file system data flushing occurs (doiflush)
- The frequency with which file system data flushing occurs (autoup)

For most systems, memory scanning and file system metadata synchronizing are the dominant activities for fsflush. Depending on system usage, memory scanning can be of little use or consume too much CPU time.

**tune_t_fsflushr**

- **Description**: Specifies the number of seconds between fsflush invocations
- **Data Type**: Signed integer
- **Default**: 1
- **Range**: 1 to MAXINT
- **Units**: Seconds
- **Dynamic?**: No
Validation

If the value is less than or equal to zero, the value is reset to 1 and a warning message is displayed. This check is done only at boot time.

When to Change

See the autoup parameter.

Commitment Level

Unstable

**autoup**

Description

Along with tune_t_flushr, autoup controls the amount of memory examined for dirty pages in each invocation and frequency of file system synchronizing operations.

The value of autoup is also used to control whether a buffer is written out from the free list. Buffers marked with the B_DELWRI flag (which identifies file content pages that have changed) are written out whenever the buffer has been on the list for longer than autoup seconds. Increasing the value of autoup keeps the buffers in memory for a longer time.

Data Type

Signed integer

Default

30

Range

1 to MAXINT

Units

Seconds

Dynamic?

No

Validation

If autoup is less than or equal to zero, it is reset to 30 and a warning message is displayed. This check is done only at boot time.

Implicit

autoup should be an integer multiple of tune_t_flushr. At a minimum, autoup should be at least 6 times the value of tune_t_flushr. If not, excessive amounts of memory are scanned each time fsflush is invoked.

The total system pages multiplied by tune_t_flushr should be greater than or equal to autoup to cause memory to be checked if dopageflush is non-zero.

When to Change

Here are several potential situations for changing autoup, tune_t_flushr, or both:

- Systems with large amounts of memory – In this case, increasing autoup reduces the amount of memory scanned in each invocation of fsflush.
Systems with minimal memory demand—Increasing both autoup and tune_t_fsflushr reduces the number of scans made. autoup should be increased also to maintain the current ratio of autoup / tune_t_fsflushr.

Systems with large numbers of transient files (for example, mail servers or software build machines)–If large numbers of files are created and then deleted, fsflush might unnecessarily write data pages for those files to disk.

Commitment Level Unstable

dopageflush

Description Controls whether memory is examined for modified pages during fsflush invocations. In each invocation of fsflush, the number of physical memory pages in the system is determined. This number might have changed because of a dynamic reconfiguration operation. Each invocation scans by using this algorithm: total number of pages x tune_t_fsflushr / autoup pages

Data Type Signed integer
Default 1 (enabled)
Range 0 (disabled) or 1 (enabled)
Units Toggle (on/off)
Dynamic? Yes
Validation None
When to Change If the system page scanner rarely runs, which is indicated by a value of 0 in the sr column of vmstat output.

Commitment Level Unstable

doflush

Description Controls whether file system metadata syncs will be executed during fsflush invocations. This synchronization is done every Nth invocation of fsflush where N= (autoup / tune_t_fsflushr). Because this algorithm is integer division, if tune_t_fsflushr is greater than autoup, a synchronization is done on every invocation of fsflush because the code checks to see if its iteration counter is greater
than or equal to N. Note that N is computed once on invocation of fsflush. Later changes to tune_t_fsflushr or autoup have no effect on the frequency of synchronization operations.

<table>
<thead>
<tr>

<td>When files are frequently modified over a period of time and the load caused by the flushing perturbs system behavior.</td>
</tr>
</tbody>
</table>

Files whose existence, and therefore consistency of state, does not matter if the system reboots are better kept in a TMPFS file system (for example, /tmp). Inode traffic can be reduced on systems by using the mount -noatime option. This option eliminates inode updates when the file is accessed.

For a system engaged in realtime processing, you might want to disable this option and use explicit application file synchronizing to achieve consistency.

Commitment Level Unstable

**Process-Sizing Parameters**

Several parameters (or variables) are used to control the number of processes that are available on the system and the number of processes that an individual user can create. The foundation parameter is maxusers. This parameter drives the values assigned to max_procs and maxuprc.

**maxusers**

Description

Originally, maxusers defined the number of logged in users the system could support. When a kernel was generated, various tables were sized based on this setting. Current Oracle Solaris releases do much of its sizing based on the amount of memory on the system. Thus, much of the past use of maxusers has changed. A number of subsystems that are still derived from maxusers:
The maximum number of processes on the system
- The number of quota structures held in the system
- The size of the directory name look-up cache (DNLC)

**Data Type** Signed integer

**Default** Lesser of the amount of memory in MB or 2048, and the greater of that value and nCPUs x 8

**Range**
- 1 to the greater of 2048 or nCPUs x 8, based on the size of physical memory, if not set in the `/etc/system` file
- 1 to the greater of 4096 or the nCPUs x 8, if set in the `/etc/system` file

**Units** Users

**Dynamic?** No. After computation of dependent parameters is done, `maxusers` is never referenced again.

**Validation** If the value is greater than the maximum allowed, it is reset to the maximum. A message to that effect is displayed.

**When to Change** When the default number of user processes derived by the system is too low. This situation is evident when the following message displays on the system console:

```
out of processes
```

You might also change this parameter when the default number of processes is too high, as in these situations:

- Database servers that have a lot of memory and relatively few running processes can save system memory when the default value of `maxusers` is reduced.
- If file servers have a lot of memory and few running processes, you might reduce this value. However, you should explicitly set the size of the DNLC. See “ncsize” on page 63.

**Commitment Level** Unstable

**Change History** For information, see “maxusers” on page 178.

---

**reserved_procs**

**Description** Specifies the number of system process slots to be reserved in the process table for processes with a UID of root (0). For example, `fsflush` has a UID of root (0).

**Data Type** Signed integer
Process-Sizing Parameters

| Default | 5 |
| Range   | 5 to MAXINT |
| Units   | Processes |
| Dynamic? | No. Not used after the initial parameter computation. |
| Validation | Any /etc/system setting is honored. |
| Commitment Level | Unstable |
| When to Change | Consider increasing to 10 + the normal number of UID 0 (root) processes on system. This setting provides some cushion should it be necessary to obtain a root shell when the system is otherwise unable to create user-level processes. |

**pidmax**

Description  
Specifies the value of the largest possible process ID.

pidmax sets the value for the maxpid variable. Once maxpid is set, pidmax is ignored. maxpid is used elsewhere in the kernel to determine the maximum process ID and for validation checking.

Any attempts to set maxpid by adding an entry to the /etc/system file have no effect.

max_nprocs

Description
Specifies the maximum number of processes that can be created on a system. Includes system processes and user processes. Any value specified in /etc/system is used in the computation of maxuprc.

This value is also used in determining the size of several other system data structures. Other data structures where this parameter plays a role are as follows:
- Determining the size of the directory name lookup cache (if ncs_size is not specified)
- Verifying that the amount of memory used by configured system V semaphores does not exceed system limits
- Configuring Hardware Address Translation resources for x86 platforms

Data Type
Signed integer

Default
10 + (16 x maxusers) if maxusers is set in the /etc/system file

The larger of 30,000 or 10 + (128 x number of CPUs), if maxusers is not set in the /etc/system file

Range
26 to value of maxpid

Dynamic?
No

Validation
Yes. If the value exceeds maxpid, it is set to maxpid.

When to Change
Changing this parameter is one of the steps necessary to enable support for more than 30,000 processes on a system.

Commitment Level
Unstable

Change History
For information, see “max_nprocs” on page 178.

maxuprc

Description
Specifies the maximum number of processes that can be created on a system by any one user.

Data Type
Signed integer

Default
max_nprocs - reserved_procs

Range
1 to max_nprocs - reserved_procs

Units
Processes
| **Dynamic?**  | No |
| **Validation** | Yes. This value is compared to \texttt{max_nprocs - reserved_procs} and set to the smaller of the two values. |
| **When to Change** | When you want to specify a hard limit for the number of processes a user can create that is less than the default value of however many processes the system can create. Attempting to exceed this limit generates the following warning messages on the console or in the messages file: |
| | \texttt{out of per-user processes for uid N} |
| **Commitment Level** | Unstable |

### ngroups\textsubscript{max}:

**Description**: Specifies the maximum number of supplemental groups per process.

**Data Type**: Signed integer

**Default**: 16

**Range**: 0 to 1024

**Units**: Groups

**Dynamic?** | No |
| **Validation** | Yes. If \texttt{ngroups_max} is set to an invalid value, it is automatically reset to the closest legal value. For example, if it is set to less than zero, it is reset to 0. If it is set to greater than 1024, it is reset to 1024. |
| **When to Change** | Review the following considerations if you are using NFS \texttt{AUTH\_SYS} authentication and you want to increase the default \texttt{ngroups\_max} value: |
| | 1. If \texttt{ngroups\_max} is set to \texttt{16} or if the client's \texttt{AUTH\_SYS} credential that is provided has 15 or fewer groups, the client's group information is used. |
| | 2. If \texttt{ngroups\_max} is set to greater than \texttt{16} and the client's \texttt{AUTH\_SYS} credential from the name server contains exactly 16 groups, the maximum allowed, the NFS server consults the name server and matches the client's UID to a user name. Then, the name server computes a list of groups to which the user belongs. |
| **Commitment Level** | Unstable |
| **Change History** | For information, see “\texttt{ngroups\_max}” on page 178. |
Paging-Related Parameters

The Solaris OS uses a demand paged virtual memory system. As the system runs, pages are brought into memory as needed. When memory becomes occupied above a certain threshold and demand for memory continues, paging begins. Paging goes through several levels that are controlled by certain parameters.

The general paging algorithm is as follows:

- A memory deficit is noticed. The page scanner thread runs and begins to walk through memory. A two-step algorithm is employed:
  1. A page is marked as unused.
  2. If still unused after a time interval, the page is viewed as a subject for reclaim.

If the page has been modified, a request is made to the pageout thread to schedule the page for I/O. Also, the page scanner continues looking at memory. Pageout causes the page to be written to the page’s backing store and placed on the free list. When the page scanner scans memory, no distinction is made as to the origin of the page. The page might have come from a data file, or it might represent a page from an executable’s text, data, or stack.

- As memory pressure on the system increases, the algorithm becomes more aggressive in the pages it will consider as candidates for reclamation and in how frequently the paging algorithm runs. (For more information, see “fastscan” on page 46 and “slowscan” on page 47.) As available memory falls between the range lotsfree and minfree, the system linearly increases the amount of memory scanned in each invocation of the pageout thread from the value specified by slowscan to the value specified by fastscan. The system uses the desfree parameter to control a number of decisions about resource usage and behavior.

The system initially constrains itself to use no more than 4 percent of one CPU for pageout operations. As memory pressure increases, the amount of CPU time consumed in support of pageout operations linearly increases until a maximum of 80 percent of one CPU is consumed. The algorithm looks through some amount of memory between slowscan and fastscan, then stops when one of the following occurs:

- Enough pages have been found to satisfy the memory shortfall.
- The planned number of pages have been looked at.
- Too much time has elapsed.

If a memory shortfall is still present when pageout finishes its scan, another scan is scheduled for 1/4 second in the future.

The configuration mechanism of the paging subsystem was changed. Instead of depending on a set of predefined values for fastscan, slowscan, and handspreadpages, the system determines the appropriate settings for these parameters at boot time. Setting any of these parameters in the /etc/system file can cause the system to use less than optimal values.
Caution – Remove all tuning of the VM system from the /etc/system file. Run with the default settings and determine if it is necessary to adjust any of these parameters. Do not set either cache_free or priority_paging.

Dynamic reconfiguration (DR) for CPU and memory is supported. A system in a DR operation that involves the addition or deletion of memory recalculates values for the relevant parameters, unless the parameter has been explicitly set in /etc/system. In that case, the value specified in /etc/system is used, unless a constraint on the value of the variable has been violated. In this case, the value is reset.

lotsfree

Description Serves as the initial trigger for system paging to begin. When this threshold is crossed, the page scanner wakes up to begin looking for memory pages to reclaim.

Data Type Unsigned long

Default The greater of 1/64th of physical memory or 512 KB

Range The minimum value is 512 KB or 1/64th of physical memory, whichever is greater, expressed as pages using the page size returned by getpagesize. For more information, see getpagesize(3C).

The maximum value is the number of physical memory pages. The maximum value should be no more than 30 percent of physical memory. The system does not enforce this range, other than that described in the Validation section.

Units Pages

Dynamic? Yes, but dynamic changes are lost if a memory-based DR operation occurs.

Validation If lotsfree is greater than the amount of physical memory, the value is reset to the default.

Implicit The relationship of lotsfree being greater than desfree, which is greater than minfree, should be maintained at all times.

When to Change When demand for pages is subject to sudden sharp spikes, the memory algorithm might be unable to keep up with demand. One workaround is to start reclaiming memory at an earlier time. This solution gives the paging system some additional margin.
A rule of thumb is to set this parameter to 2 times what the system needs to allocate in a few seconds. This parameter is workload dependent. A DBMS server can probably work fine with the default settings. However, you might need to adjust this parameter for a system doing heavy file system I/O.

For systems with relatively static workloads and large amounts of memory, lower this value. The minimum acceptable value is 512 KB, expressed as pages using the page size returned by `getpagesize`.

Commitment Level: Unstable

**desfree**

Description: Specifies the preferred amount of memory to be free at all times on the system.

Data Type: Unsigned integer

Default: `lotsfree / 2`

Range: The minimum value is 256 KB or 1/128th of physical memory, whichever is greater, expressed as pages using the page size returned by `getpagesize`.

The maximum value is the number of physical memory pages. The maximum value should be no more than 15 percent of physical memory. The system does not enforce this range other than that described in the Validation section.

Units: Pages

Dynamic?: Yes, unless dynamic reconfiguration operations that add or delete memory occur. At that point, the value is reset to the value provided in the `/etc/system` file or calculated from the new physical memory value.

Validation: If `desfree` is greater than `lotsfree`, `desfree` is set to `lotsfree / 2`. No message is displayed.

Implicit: The relationship of `lotsfree` being greater than `desfree`, which is greater than `minfree`, should be maintained at all times.

Side Effects: Several side effects can arise from increasing the value of this parameter. When the new value nears or exceeds the amount of available memory on the system, the following can occur:
Asynchronous I/O requests are not processed, unless available memory exceeds `desfree`. Increasing the value of `desfree` can result in rejection of requests that otherwise would succeed.

- NFS asynchronous writes are executed as synchronous writes.
- The swapper is awakened earlier, and the behavior of the swapper is biased towards more aggressive actions.
- The system might not preload (prefault) as many executable pages as possible into the system. This side effect results in applications potentially running slower than they otherwise would.

**When to Change**

For systems with relatively static workloads and large amounts of memory, lower this value. The minimum acceptable value is 256 KB, expressed as pages using the page size returned by `getpagesize`.

**Commitment Level**

Unstable

---

**minfree**

**Description**

Specifies the minimum acceptable memory level. When memory drops below this number, the system biases allocations toward allocations necessary to successfully complete pageout operations or to swap processes completely out of memory. Either allocation denies or blocks other allocation requests.

**Data Type**

Unsigned integer

**Default**

desfree / 2

**Range**

The minimum value is 128 KB or 1/256th of physical memory, whichever is greater, expressed as pages using the page size returned by `getpagesize`.

The maximum value is the number of physical memory pages. The maximum value should be no more than 7.5 percent of physical memory. The system does not enforce this range other than that described in the Validation section.

**Units**

Pages

**Dynamic?**

Yes, unless dynamic reconfiguration operations that add or delete memory occur. At that point, the value is reset to the value provided in the `/etc/system` file or calculated from the new physical memory value.

**Validation**

If `minfree` is greater than `desfree`, `minfree` is set to `desfree` / 2. No message is displayed.
Implicit Therelationship of lotsfree being greater than desfree, which is greater than minfree, should be maintained at all times.

When to Change The default value is generally adequate. For systems with relatively static workloads and large amounts of memory, lower this value. The minimum acceptable value is 128 KB, expressed as pages using the page size returned by getpagesize.

Commitment Level Unstable

throttlefree

Description Specifies the memory level at which blocking memory allocation requests are put to sleep, even if the memory is sufficient to satisfy the request.

Data Type Unsigned integer

Default minfree

Range The minimum value is 128 KB or 1/256th of physical memory, whichever is greater, expressed as pages using the page size returned by getpagesize.

The maximum value is the number of physical memory pages. The maximum value should be no more than 4 percent of physical memory. The system does not enforce this range other than that described in the Validation section.

Units Pages

Dynamic? Yes, unless dynamic reconfiguration operations that add or delete memory occur. At that point, the value is reset to the value provided in the /etc/system file or calculated from the new physical memory value.

Validation If throttlefree is greater than desfree, throttlefree is set to minfree. No message is displayed.

Implicit The relationship of lotsfree is greater than desfree, which is greater than minfree, should be maintained at all times.

When to Change The default value is generally adequate. For systems with relatively static workloads and large amounts of memory, lower this value. The minimum acceptable value is 128 KB, expressed as pages using the page size returned by getpagesize. For more information, see getpagesize(3C).
pageout_reserve

Description: Specifies the number of pages reserved for the exclusive use of the pageout or scheduler threads. When available memory is less than this value, nonblocking allocations are denied for any processes other than pageout or the scheduler. Pageout needs to have a small pool of memory for its use so it can allocate the data structures necessary to do the I/O for writing a page to its backing store.

Data Type: Unsigned integer

Default: \texttt{throttlefree}/2

Range: The minimum value is 64 KB or 1/512th of physical memory, whichever is greater, expressed as pages using the page size returned by \texttt{getpagesize(3C)}.

The maximum is the number of physical memory pages. The maximum value should be no more than 2 percent of physical memory. The system does not enforce this range, other than that described in the Validation section.

Units: Pages

Dynamic?: Yes, unless dynamic reconfiguration operations that add or delete memory occur. At that point, the value is reset to the value provided in the /etc/system file or calculated from the new physical memory value.

Validation: If pageout\_reserve is greater than throttlefree / 2, pageout\_reserve is set to throttlefree / 2. No message is displayed.

Implicit: The relationship of lotsfree being greater than desfree, which is greater than minfree, should be maintained at all times.

When to Change: The default value is generally adequate. For systems with relatively static workloads and large amounts of memory, lower this value. The minimum acceptable value is 64 KB, expressed as pages using the page size returned by getpagesize.

Commitment Level: Unstable
pages_pp_maximum

Description: Defines the number of pages that must be unlocked. If a request to lock pages would force available memory below this value, that request is refused.

Data Type: Unsigned long

Default: The greater of (tune_t_minarmem + 100 and [4% of memory available at boot time + 4 MB])

Range: Minimum value enforced by the system is tune_t_minarmem + 100. The system does not enforce a maximum value.

Units: Pages

Dynamic?: Yes, unless dynamic reconfiguration operations that add or delete memory occur. At that point, the value is reset to the value provided in the /etc/system file or was calculated from the new physical memory value.

Validation: If the value specified in the /etc/system file or the calculated default is less than tune_t_minarmem + 100, the value is reset to tune_t_minarmem + 100.

No message is displayed if the value from the /etc/system file is increased. Validation is done only at boot time and during dynamic reconfiguration operations that involve adding or deleting memory.

When to Change: When memory-locking requests fail or when attaching to a shared memory segment with the SHARE_MMU flag fails, yet the amount of memory available seems to be sufficient.

Excessively large values can cause memory locking requests (mlock, mlockall, and memcntl) to fail unnecessarily. For more information, see mlock(3C), mlockall(3C), and memcntl(2).

Commitment Level: Unstable

tune_t_minarmem

Description: Defines the minimum available resident (not swappable) memory to maintain necessary to avoid deadlock. Used to reserve a portion of memory for use by the core of the OS. Pages restricted in this way are not seen when the OS determines the maximum amount of memory available.
Data Type: Signed integer  
Default: 25  
Range: 1 to physical memory  
Units: Pages  
Dynamic?: No  
Validation: None. Large values result in wasted physical memory.  
When to Change: The default value is generally adequate. Consider increasing the default value if the system locks up and debugging information indicates that no memory was available.  
Commitment Level: Unstable

**fastscan**

Description: Defines the maximum number of pages per second that the system looks at when memory pressure is highest.  
Data Type: Signed integer  
Default: The `fastscan` default value is set in one of the following ways:  
- The `fastscan` value set in the `/etc/system` file is used.  
- The `maxfastscan` value set in the `/etc/system` file is used.  
- If neither `fastscan` nor `maxfastscan` is set in the `/etc/system` file, `fastscan` is set to 64 MB when the system is booted. Then, after the system is booted for a few minutes, the `fastscan` value is set to the number of pages that the scanner can scan in one second using 10% of a CPU.  

In all three cases, if the derived value is more than half the memory in the system, the `fastscan` value is capped at the value of half the memory in the system.  
Range: 64 MB to half the system's physical memory  
Units: Pages  
Dynamic?: Yes, unless dynamic reconfiguration operations that add or delete memory occur. At that point, the value is reset to the value provided by `/etc/system` or calculated from the new physical memory value.  
Validation: The maximum value is the lesser of 64 MB and 1/2 of physical memory.
When to Change  When more aggressive scanning of memory is preferred during periods of memory shortfall, especially when the system is subject to periods of intense memory demand or when performing heavy file I/O.

Commitment Level  Unstable

**slowscan**

Description  Defines the minimum number of pages per second that the system looks at when attempting to reclaim memory.

Data Type  Signed integer

Default  The smaller of 1/20th of physical memory in pages and 100.

Range  1 to \( \text{fastscan} / 2 \)

Units  Pages

Dynamic?  Yes, unless dynamic reconfiguration operations that add or delete memory occur. At that point, the value is reset to the value provided in the `/etc/system` file or calculated from the new physical memory value.

Validation  If `slowscan` is larger than `fastscan` / 2, `slowscan` is reset to `fastscan` / 2. No message is displayed.

When to Change  When more aggressive scanning of memory is preferred during periods of memory shortfall, especially when the system is subject to periods of intense memory demand.

Commitment Level  Unstable

**min_percent_cpu**

Description  Defines the minimum percentage of CPU that `pageout` can consume. This parameter is used as the starting point for determining the maximum amount of time that can be consumed by the page scanner.

Data Type  Signed integer

Default  4

Range  1 to 80

Units  Percentage

Dynamic?  Yes
Validation: None

When to Change: Increasing this value on systems with multiple CPUs and lots of memory, which are subject to intense periods of memory demand, enables the pager to spend more time attempting to find memory.

Commitment Level: Unstable

**handspreadpages**

Description: The Oracle Solaris OS uses a two-handed clock algorithm to look for pages that are candidates for reclaiming when memory is low. The first hand of the clock walks through memory marking pages as unused. The second hand walks through memory some distance after the first hand, checking to see if the page is still marked as unused. If so, the page is subject to being reclaimed. The distance between the first hand and the second hand is handspreadpages.

Data Type: Unsigned long

Default: fastscan

Range: 1 to maximum number of physical memory pages on the system

Units: Pages

Dynamic?: Yes. This parameter requires that the kernel reset_hands parameter also be set to a non-zero value. Once the new value of handspreadpages has been recognized, reset_hands is set to zero.

Validation: The value is set to the lesser of either the amount of physical memory and the handspreadpages value.

When to Change: When you want to increase the amount of time that pages are potentially resident before being reclaimed. Increasing this value increases the separation between the hands, and therefore, the amount of time before a page can be reclaimed.

Commitment Level: Unstable

**pages_before_pager**

Description: Defines part of a system threshold that immediately frees pages after an I/O completes instead of storing the pages for possible reuse. The
threshold is \texttt{lotsfree + pages\_before\_pager}. The NFS environment also uses this threshold to curtail its asynchronous activities as memory pressure mounts.

- **Data Type**: Signed integer
- **Default**: 200
- **Range**: 1 to amount of physical memory
- **Units**: Pages
- **Dynamic?**: No
- **Validation**: None
- **When to Change**: You might change this parameter when the majority of I/O is done for pages that are truly read or written once and never referenced again. Setting this variable to a larger amount of memory keeps adding pages to the free list.

You might also change this parameter when the system is subject to bursts of severe memory pressure. A larger value here helps maintain a larger cushion against the pressure.

- **Commitment Level**: Unstable

### maxpgio

- **Description**: Defines the maximum number of page I/O requests that can be queued by the paging system. This number is divided by 4 to get the actual maximum number used by the paging system. This parameter is used to throttle the number of requests as well as to control process swapping.
- **Data Type**: Signed integer
- **Default**: 40
- **Range**: 1 to a variable maximum that depends on the system architecture, but mainly by the I/O subsystem, such as the number of controllers, disks, and disk swap size
- **Units**: I/Os
- **Dynamic?**: No
- **Validation**: None
Implicit

The maximum number of I/O requests from the pager is limited by the size of a list of request buffers, which is currently sized at 256.

When to Change

Increase this parameter to page out memory faster. A larger value might help to recover faster from memory pressure if more than one swap device is configured or if the swap device is a striped device. Note that the existing I/O subsystem should be able to handle the additional I/O load. Also, increased swap I/O could degrade application I/O performance if the swap partition and application files are on the same disk.

Commitment Level

Unstable

Swapping-Related Parameters

Swapping in the Oracle Solaris OS is accomplished by the swapfs pseudo file system. The combination of space on swap devices and physical memory is treated as the pool of space available to support the system for maintaining backing store for anonymous memory. The system attempts to allocate space from disk devices first, and then uses physical memory as backing store. When swapfs is forced to use system memory for backing store, limits are enforced to ensure that the system does not deadlock because of excessive consumption by swapfs.

swapfs_reserve

Description

Defines the amount of system memory that is reserved for use by system (UID = 0) processes.

Data Type

Unsigned long

Default

The smaller of 4 MB and 1/16th of physical memory

Range

The minimum value is 4 MB or 1/16th of physical memory, whichever is smaller, expressed as pages using the page size returned by getpagesize.

The maximum value is the number of physical memory pages. The maximum value should be no more than 10 percent of physical memory. The system does not enforce this range, other than that described in the Validation section.

Units

Pages

Dynamic?

No
Validation | None  
When to Change | Generally not necessary. Only change when recommended by a software provider, or when system processes are terminating because of an inability to obtain swap space. A much better solution is to add physical memory or additional swap devices to the system.  
Commitment Level | Unstable  

### `swapfs_minfree`

**Description**

Defines the desired amount of physical memory to be kept free for the rest of the system. Attempts to reserve memory for use as swap space by any process that causes the system’s perception of available memory to fall below this value are rejected. Pages reserved in this manner can only be used for locked-down allocations by the kernel or by user-level processes.

**Data Type** | Unsigned long  
**Default** | The larger of 2 MB and 12.5% of physical memory  
**Range** | 1 to amount of physical memory  
**Units** | Pages  
**Dynamic?** | No  
**Validation** | None  
**When to Change** | Consider reducing this parameter value when processes are failing because of an inability to obtain swap space, yet the system has memory available. For example, change this value to use no more than 6.25% of system memory, but do not reduce it below 5% of system memory. On SPARC systems, the value should be at least 2 times the value of `tsb_alloc_hiwater_factor`. For more information, see “`tsb_alloc_hiwater_factor`” on page 75.  
**Commitment Level** | Unstable  
**Change History** | For information, see “`swapfs_minfree`” on page 179.
Kernel Memory Allocator

The Oracle Solaris kernel memory allocator distributes chunks of memory for use by clients inside the kernel. The allocator creates a number of caches of varying size for use by its clients. Clients can also request the allocator to create a cache for use by that client (for example, to allocate structures of a particular size). Statistics about each cache that the allocator manages can be seen by using the `kstat -c kmem_cache` command.

Occasionally, systems might panic because of memory corruption. The kernel memory allocator supports a debugging interface (a set of flags), that performs various integrity checks on the buffers. The kernel memory allocator also collects information on the allocators. The integrity checks provide the opportunity to detect errors closer to where they actually occurred. The collected information provides additional data for support people when they try to ascertain the reason for the panic.

Use of the flags incurs additional overhead and memory usage during system operations. The flags should only be used when a memory corruption problem is suspected.

**kmem_flags**

**Description**

The Oracle Solaris kernel memory allocator has various debugging and test options.

Five supported flag settings are described here.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUDIT</td>
<td>0x1</td>
<td>The allocator maintains a log that contains recent history of its activity. The number of items logged depends on whether CONTENTS is also set. The log is a fixed size. When space is exhausted, earlier records are reclaimed.</td>
</tr>
<tr>
<td>TEST</td>
<td>0x2</td>
<td>The allocator writes a pattern into freed memory and checks that the pattern is unchanged when the buffer is next allocated. If some portion of the buffer is changed, then the memory was probably used by a client that had previously allocated and freed the buffer. If an overwrite is identified, the system panics.</td>
</tr>
<tr>
<td>Flag</td>
<td>Setting</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>REDZONE</td>
<td>0x4</td>
<td>The allocator provides extra memory at the end of the requested buffer and inserts a special pattern into that memory. When the buffer is freed, the pattern is checked to see if data was written past the end of the buffer. If an overwrite is identified, the kernel panics.</td>
</tr>
<tr>
<td>CONTENTS</td>
<td>0x8</td>
<td>The allocator logs up to 256 bytes of buffer contents when the buffer is freed. This flag requires that AUDIT also be set. The numeric value of these flags can be logically added together and set by the <code>/etc/system</code> file.</td>
</tr>
<tr>
<td>LITE</td>
<td>0x100</td>
<td>Does minimal integrity checking when a buffer is allocated and freed. When enabled, the allocator checks that the redzone has not been written into, that a freed buffer is not being freed again, and that the buffer being freed is the size that was allocated. Do not combine this flag with any other flags.</td>
</tr>
</tbody>
</table>

Data Type: Signed integer  
Default: 0 (disabled)  
Range: 0 (disabled) or 1 - 15 or 256 (0x100)  
Dynamic?: Yes. Changes made during runtime only affect new kernel memory caches. After system initialization, the creation of new caches is rare.  
Validation: None  
When to Change: When memory corruption is suspected  
Commitment Level: Unstable

**kmem_stackinfo**

Description: If the `kmem_stackinfo` variable is enabled in the `/etc/system` file at kernel thread creation time, the kernel thread stack is filled with a specific pattern instead of filled with zeros. During kernel thread execution, this kernel thread stack pattern is progressively overwritten. A simple count from the stack top until the pattern is not found gives a high watermark value, which is the maximum kernel stack space used by a kernel thread. This mechanism allows the following features:
General Driver Parameters

- Compute the percentage of kernel thread stack really used (a high watermark) for current kernel threads in the system
- When a kernel thread ends, the system logs the last kernel threads that have used the most of their kernel thread stacks before dying to a small circular memory buffer

<table>
<thead>
<tr>

Apr 20 17:18:04 neo genunix: [ID 943528 kern.notice] load 'sched/TS_DPTBL' id 15
loaded @ 0x7be1b2f8/0x19c8380 size 176/2096
Apr 20 17:18:04 neo genunix: [ID 131579 kern.notice] installing TS_DPTBL, module id 15.
- 0x40000000 – Prints detailed error messages. For every module loaded, messages such as the following appear on the console and in the `/var/adm/messages` file:

```
Apr 20 18:30:00 neo unix: Errno = 2
Apr 20 18:30:00 neo unix: kobj_open: vn_open of /platform/sun4v/kernel/exec/sparcv9/intpexec fails
Apr 20 18:30:00 neo unix: Errno = 2
Apr 20 18:30:00 neo unix: kobj_open: '/kernel/exec/sparcv9/intpexec'
Apr 20 18:30:00 neo unix: vp = 6001577760
Apr 20 18:30:00 neo unix: kobj_close: 0x6001577760
Apr 20 18:30:00 neo unix: kobj_open: vn_open of /platform/SUNW,Sun-Fire-T200/kernel/exec/sparcv9/intpexec fails,
Apr 20 18:30:00 neo unix: Errno = 2
Apr 20 18:30:00 neo unix: kobj_open: vn_open of /platform/sun4v/kernel/exec/sparcv9/intpexec fails
```

- 0x20000000 - Prints even more detailed messages. This value doesn’t print any additional information beyond what the 0x40000000 flag does during system boot. However, this value does print additional information about releasing the module when the module is unloaded.

These values can be added together to set the final value.

**Dynamic?** Yes

**Validation** None

**When to Change** When a module is either not loading as expected, or the system seems to hang while loading modules. Note that when 0x40000000 is set, system boot is slowed down considerably by the number of messages written to the console.

**Commitment Level** Unstable

---

**ddi_msix_alloc_limit**

**Description** x86 only: This parameter controls the number of Extended Message Signaled Interrupts (MSI-X) that a device instance can allocate. Due to an existing system limitation, the default value is 2. You can increase the number of MSI-X interrupts that a device instance can allocate by increasing the value of this parameter. This parameter can be set either by editing the `/etc/system` file or by setting it with `mdb` before the device driver attach occurs.

**Data Type** Signed integer

**Default** 2

**Range** 1 to 16
**Dynamic?** Yes  
**Validation** None  
**When to Change** To increase the number of MSI-X interrupts that a device instance can allocate. However, if you increase the number of MSI-X interrupts that a device instance can allocate, adequate interrupts might not be available to satisfy all allocation requests. If this happens, some devices might stop functioning or the system might fail to boot. Reduce the value or remove the parameter in this case.

**Commitment Level** Unstable

---

**Network Driver Parameters**

**igb Parameters**

**mr_enable**

**Description** This parameter enables or disables multiple receive and transmit queues that are used by the igb network driver. This parameter can be set by editing the `/etc/driver/drv/igb.conf` file before the igb driver attach occurs.

**Data Type** Boolean  
**Default** 1 (disable multiple queues)  
**Range** 0 (enable multiple queues) or 1 (disable multiple queues)  
**Dynamic?** No  
**Validation** None  
**When to Change** To enable or disable multiple receive and transmit queues that are used by the igb network driver.  
**Commitment Level** Unstable

**intr_force**

**Description** This parameter is used to force an interrupt type, such as MSI, MSI-X, or legacy, that is used by the igb network driver. This parameter can be set by editing the `/etc/driver/drv/igb.conf` file before the igb driver attach occurs.
### ixgbe Parameters

#### tx_queue_number

**Description:** This parameter controls the number of transmit queues that are used by the ixgbe network driver. You can increase the number of transmit queues by increasing the value of this parameter. This parameter can be set by editing the `/etc/driver/drv/ixgbe.conf` file before the ixgbe driver attach occurs.

<table>
<thead>
<tr>
<th>Data Type</th>

#### rx_queue_number

**Description:** This parameter controls the number of receive queues that are used by the ixgbe network driver. You can increase the number of receive
queues by increasing the value of this parameter. This parameter can be set by editing the `/etc/driver/drv/ixgbe.conf` file before the `ixgbe` driver attach occurs.

**Data Type**: Unsigned integer  
**Default**: 8  
**Range**: 1 to 64  
**Dynamic?**: No  
**Validation**: None  
**When to Change**: To change the number of receive queues that are used by the `ixgbe` network driver.  
**Commitment Level**: Unstable

**intr_throttling**

*Description*: This parameter controls the interrupt throttling rate of the `ixgbe` network driver. You can increase the rate of interrupt by decreasing the value of this parameter. This parameter can be set by editing the `/etc/driver/drv/ixgbe.conf` file before the `ixgbe` driver attach occurs.

**Data Type**: Unsigned integer  
**Default**: 200  
**Range**: 0 to 65535  
**Dynamic?**: No  
**Validation**: None  
**When to Change**: To change the interrupt throttling rate that is used by the `ixgbe` network driver.  
**Commitment Level**: Unstable

**rx_limit_per_intr**

*Description*: This parameter controls the maximum number of receive queue buffer descriptors per interrupt that are used by the `ixgbe` network driver. You can increase the number of receive queue buffer descriptors by increasing the value of this parameter. This parameter can be set by editing the `/etc/driver/drv/ixgbe.conf` file before the `ixgbe` driver attach occurs.

**tx_copy_threshold**

Description: This parameter controls the transmit buffer copy threshold that is used by the ixgbe network driver. You can increase the transmit buffer copy threshold by increasing the value of this parameter. This parameter can be set by editing the `/etc/driver/drv/ixgbe.conf` file before the ixgbe driver attach occurs.

Data Type: Unsigned integer

Default: 512

Range: 0 to 9126

Dynamic? No

Validation: None

When to Change: To change the transmit buffer copy threshold that is used by the ixgbe network driver.

Commitment Level: Unstable

**rx_copy_threshold**

Description: This parameter controls the receive buffer copy threshold that is used by the ixgbe network driver. You can increase the receive buffer copy threshold by increasing the value of this parameter. This parameter can be set by editing the `/etc/driver/drv/ixgbe.conf` file before the ixgbe driver attach occurs.

Data Type: Unsigned integer

Default: 128

Range: 0 to 9126

Dynamic? No

Validation: None

When to Change: To change the receive buffer copy threshold that is used by the ixgbe network driver.
General I/O Parameters

**maxphys**

Description: Defines the maximum size of physical I/O requests. If a driver encounters a request larger than this size, the driver breaks the request into `maxphys` sized chunks. File systems can and do impose their own limit.

Data Type: Signed integer

Default: 131,072 (sun4u or sun4v) or 57,344 (x86). The `sd` driver uses the value of 1,048,576 if the drive supports wide transfers. The `ssd` driver uses 1,048,576 by default.

Range: Machine-specific page size to MAXINT

Units: Bytes

Dynamic?: Yes, but many file systems load this value into a per-mount point data structure when the file system is mounted. A number of drivers load the value at the time a device is attached to a driver-specific data structure.

Validation: None

When to Change: When doing I/O to and from raw devices in large chunks. Note that a DBMS doing OLTP operations issues large numbers of small I/Os. Changing `maxphys` does not result in any performance improvement in that case.

Commitment Level: Unstable

**rlim_fd_max**

Description: Specifies the "hard" limit on file descriptors that a single process might have open. Overriding this limit requires superuser privilege.

Data Type: Signed integer

Default: 65,536

Range: 1 to MAXINT
### General I/O Parameters

<table>
<thead>
<tr>
<th>Units</th>
<th>File descriptors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic?</td>
<td>No</td>
</tr>
<tr>
<td>Validation</td>
<td>None</td>
</tr>
</tbody>
</table>
| When to Change         | When the maximum number of open files for a process is not enough. Other limitations in system facilities can mean that a larger number of file descriptors is not as useful as it might be. For example:

- A 32-bit program using standard I/O is limited to 256 file descriptors. A 64-bit program using standard I/O can use up to 2 billion descriptors. Specifically, standard I/O refers to the `stdio(3C)` functions in `libc(3LIB)`.

- `select` is by default limited to 1024 descriptors per `fd_set`. For more information, see `select(3C)`. A 32-bit application code can be recompiled with a larger `fd_set` size (less than or equal to 65,536). A 64-bit application uses an `fd_set` size of 65,536, which cannot be changed.

An alternative to changing this on a system wide basis is to use the `plimit(1)` command. If a parent process has its limits changed by `plimit`, all children inherit the increased limit. This alternative is useful for daemons such as `inetd`.

| Commitment Level       | Unstable         |

---

### rlim_fd_cur

**Description**

Defines the "soft" limit on file descriptors that a single process can have open. A process might adjust its file descriptor limit to any value up to the "hard" limit defined by `rlim_fd_max` by using the `setrlimit()` call or by issuing the `limit` command in whatever shell it is running. You do not require superuser privilege to adjust the limit to any value less than or equal to the hard limit.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Signed integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 to MAXINT</td>
</tr>
<tr>
<td>Units</td>
<td>File descriptors</td>
</tr>
<tr>
<td>Dynamic?</td>
<td>No</td>
</tr>
<tr>
<td>Validation</td>
<td>Compared to <code>rlim_fd_max</code>. If <code>rlim_fd_cur</code> is greater than <code>rlim_fd_max</code>, <code>rlim_fd_cur</code> is reset to <code>rlim_fd_max</code>.</td>
</tr>
</tbody>
</table>
When to Change

When the default number of open files for a process is not enough. Increasing this value means only that it might not be necessary for a program to use setrlimit to increase the maximum number of file descriptors available to it.

Commitment Level

Unstable

General File System Parameters

ncsize

Description

Defines the number of entries in the directory name look-up cache (DNLC). This parameter is used by UFS, NFS, and ZFS to cache elements of path names that have been resolved.

The DNLC also caches negative look-up information, which means it caches a name not found in the cache.

Data Type

Signed integer

Default

\[(4x(v.v\_proc + maxusers) + 320) + (4x(v.v\_proc + maxusers) + 320)/100\]

Range

0 to MAXINT

Units

DNLC entries

Dynamic?

No

Validation

None. Larger values cause the time it takes to unmount a file system to increase as the cache must be flushed of entries for that file system during the unmount process.

When to Change

You can use the kstat -n dnlcstats command to determine when entries have been removed from the DNLC because it was too small. The sum of the pick_heuristic and the pick_last parameters represents otherwise valid entries that were reclaimed because the cache was too small.

Excessive values of ncsie have an immediate impact on the system because the system allocates a set of data structures for the DNLC based on the value of ncsie. By default, a system allocates 64-byte structures for ncsie. The value has a further effect on UFS and NFS, unless ufs_ninode and nfs:ninode are explicitly set.

Commitment Level

Unstable
**dnlc_dir_enable**

Description: Enables large directory caching

*Note* – This parameter has no effect on NFS or ZFS file systems.

Data Type: Unsigned integer
Default: 1 (enabled)
Range: 0 (disabled) or 1 (enabled)
Dynamic?: Yes, but do not change this tunable dynamically. You can enable this parameter if it was originally disabled. Or, you can disable this parameter if it was originally enabled. However, enabling, disabling, and then enabling this parameter might lead to stale directory caches.
Validation: No
When to Change: Directory caching has no known problems. However, if problems occur, then set `dnlc_dir_enable` to 0 to disable caching.
Commitment Level: Unstable

**dnlc_dir_min_size**

Description: Specifies the minimum number of entries cached for one directory.

*Note* – This parameter has no effect on NFS or ZFS file systems.

Data Type: Unsigned integer
Default: 40
Range: 0 to MAXUINT (no maximum)
Units: Entries
Dynamic?: Yes, this parameter can be changed at any time.
Validation: None
When to Change: If performance problems occur with caching small directories, then increase `dnlc_dir_min_size`. Note that individual file systems might have their own range limits for caching directories.
Commitment Level: Unstable

**dnlc_dir_max_size**

Description: Specifies the maximum number of entries cached for one directory.

*Note* - This parameter has no effect on NFS or ZFS file systems.

Data Type: Unsigned integer
Default: MAXUINT (no maximum)
Range: 0 to MAXUINT
Dynamic?: Yes, this parameter can be changed at any time.
Validation: None
When to Change: If performance problems occur with large directories, then decrease dnlc_dir_max_size.

Commitment Level: Unstable

**dnlc_dircache_percent**

Description: Calculates the maximum percentage of physical memory that the DNLC directory cache can consume.

Data Type: Integer
Default: 100
Range: 0 to 100
Units: Percentage
Dynamic?: No
Validation: At boot time, the value range is checked and default value is enforced.
When to Change: When the system experiences a memory shortage and high kernel memory consumption, consider lowering this value. If performance issues are seen with the default value, consider increasing the value.
Note – The DNLC is used by UFS and ZFS file systems and NFS clients. Setting this tunable might be considered for better performance when there are memory shortages and high kernel memory consumption or when a memory is needed by the ARC or other kernel caches.

Commitment Level Unstable
Change History For information, see "dnlc_dircache_percent" on page 179.

TMPFS Parameters

**tmpfs:tmpfs_maxkmem**

**Description**
Defines the maximum amount of kernel memory that TMPFS can use for its data structures (tmpnodes and directory entries).

**Data Type**
Unsigned long

**Default**
One page or 4 percent of physical memory, whichever is greater.

**Range**
Number of bytes in one page (8192 for sun4u or sun4v systems, 4096 for all other systems) to 25 percent of the available kernel memory at the time TMPFS was first used.

**Units**
Bytes

**Dynamic?**
Yes

**Validation**
None

**When to Change**
Increase if the following message is displayed on the console or written in the messages file:

tmp_memalloc: tmpfs over memory limit

The current amount of memory used by TMPFS for its data structures is held in the tmp_kmemspace field. This field can be examined with a kernel debugger.

**Commitment Level**
Unstable
**tmpfs:minfree**

- **Description**: Defines the minimum amount of swap space that TMPFS leaves for the rest of the system.
- **Data Type**: Signed long
- **Default**: 512
- **Range**: 0 to maximum swap space size
- **Units**: Pages
- **Dynamic?**: Yes
- **Validation**: None
- **When to Change**: To maintain a reasonable amount of swap space on systems with large amounts of TMPFS usage, you can increase this number. The limit has been reached when the console or messages file displays the following message:

  \[fs-name: File system full, swap space limit exceeded\]

- **Commitment Level**: Unstable

---

**Pseudo Terminals**

Pseudo terminals, ptys, are used for two purposes in Oracle Solaris software:

- Supporting remote logins by using the `telnet`, `rlogin`, or `rsh` commands
- Providing the interface through which the X Window system creates command interpreter windows

The default number of pseudo-terminals is sufficient for a desktop workstation. So, tuning focuses on the number of ptys available for remote logins.

The default number of ptys is now based on the amount of memory on the system. This default should be changed only to restrict or increase the number of users who can log in to the system.

Three related variables are used in the configuration process:

- `pt_cnt` – Default maximum number of ptys.
- `pt_pctofmem` – Percentage of kernel memory that can be dedicated to pty support structures. A value of zero means that no remote users can log in to the system.
- `pt_max_pty` – Hard maximum for number of ptys.
pt_cnt has a default value of zero, which tells the system to limit logins based on the amount of memory specified in pt_pctofmem, unless pt_max_pty is set. If pt_cnt is non-zero, pty's are allocated until this limit is reached. When that threshold is crossed, the system looks at pt_max_pty. If pt_max_pty has a non-zero value, it is compared to pt_cnt. The pty allocation is allowed if pt_cnt is less than pt_max_pty. If pt_max_pty is zero, pt_cnt is compared to the number of pty's supported based on pt_pctofmem. If pt_cnt is less than this value, the pty allocation is allowed. Note that the limit based on pt_pctofmem only comes into play if both pt_cnt and ptms_pptymax have default values of zero.

To put a hard limit on pty's that is different than the maximum derived from pt_pctofmem, set pt_cnt and ptms_pptymax in /etc/system to the preferred number of pty's. The setting of ptms_pctofmem is not relevant in this case.

To dedicate a different percentage of system memory to pty support and let the operating system manage the explicit limits, do the following:

- Do not set pt_cnt or ptms_pptymax in /etc/system.
- Set pt_pctofmem in /etc/system to the preferred percentage. For example, set pt_pctofmem=10 for a 10 percent setting.

Note that the memory is not actually allocated until it is used in support of a pty. Once memory is allocated, it remains allocated.

**pt_cnt**

**Description**
The number of available /dev/pts entries is dynamic up to a limit determined by the amount of physical memory available on the system. pt_cnt is one of three variables that determines the minimum number of logins that the system can accommodate. The default maximum number of /dev/pts devices the system can support is determined at boot time by computing the number of pty structures that can fit in a percentage of system memory (see pt_pctofmem). If pt_cnt is zero, the system allocates up to that maximum. If pt_cnt is non-zero, the system allocates to the greater of pt_cnt and the default maximum.

**Data Type**
Unsigned integer

**Default**
0

**Range**
0 to maxpid

**Units**
Logins/windows

**Dynamic?**
No

**Validation**
None
When to Change  When you want to explicitly control the number of users who can remotely log in to the system.
Commitment Level  Unstable

**pt_pctofmem**

Description  Specifies the maximum percentage of physical memory that can be consumed by data structures to support /dev/pts entries. A system consumes 176 bytes per /dev/pts entry.
Data Type  Unsigned integer
Default  5
Range  0 to 100
Units  Percentage
Dynamic?  No
Validation  None
When to Change  When you want to either restrict or increase the number of users who can log in to the system. A value of zero means that no remote users can log in to the system.
Commitment Level  Unstable

**pt_max_pty**

Description  Defines the maximum number of ptys the system offers
Data Type  Unsigned integer
Default  0 (Uses system-defined maximum)
Range  0 to MAXUINT
Units  Logins/windows
Dynamic?  Yes
Validation  None
Implicit  Should be greater than or equal to pt_cnt. Value is not checked until the number of ptys allocated exceeds the value of pt_cnt.
When to Change: When you want to place an absolute ceiling on the number of logins supported, even if the system could handle more based on its current configuration values.

Commitment Level: Unstable

---

**STREAMS Parameters**

**nstrpush**

Description: Specifies the number of modules that can be inserted into (pushed onto) a STREAM.

Data Type: Signed integer

Default: 9

Range: 9 to 16

Units: Modules

Dynamic?: Yes

Validation: None

When to Change: At the direction of your software vendor. No messages are displayed when a STREAM exceeds its permitted push count. A value of EINVAL is returned to the program that attempted the push.

Commitment Level: Unstable

**strmsgs**

Description: Specifies the maximum number of bytes that a single system call can pass to a STREAM to be placed in the data part of a message. Any write exceeding this size is broken into multiple messages. For more information, see `write(2)`.

Data Type: Signed integer

Default: 65,536

Range: 0 to 262,144

Units: Bytes
Dynamic? Yes
Validation None
When to Change When putmsg calls return ERANGE. For more information, see putmsg(2).
Commitment Level Unstable

**strctlsz**

Description Specifies the maximum number of bytes that a single system call can pass to a STREAM to be placed in the control part of a message.

Data Type Signed integer
Default 1024
Range 0 to MAXINT
Units Bytes
Dynamic? Yes
Validation None
When to Change At the direction of your software vendor. putmsg(2) calls return ERANGE if they attempt to exceed this limit.
Commitment Level Unstable

**System V Message Queues**

System V message queues provide a message-passing interface that enables the exchange of messages by queues created in the kernel. Interfaces are provided in the Oracle Solaris environment to enqueue and dequeue messages. Messages can have a type associated with them. Enqueueing places messages at the end of a queue. Dequeueing removes the first message of a specific type from the queue or the first message if no type is specified.

For detailed information on tuning these system resources, see Chapter 6, “Resource Controls (Overview),” in Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management.
System V Semaphores

System V semaphores provide counting semaphores in the Oracle Solaris OS. A semaphore is a counter used to provide access to a shared data object for multiple processes. In addition to the standard set and release operations for semaphores, System V semaphores can have values that are incremented and decremented as needed (for example, to represent the number of resources available). System V semaphores also provide the ability to do operations on a group of semaphores simultaneously as well as to have the system undo the last operation by a process if the process dies.

System V Shared Memory

System V shared memory allows the creation of a segment by a process. Cooperating processes can attach to the memory segment (subject to access permissions on the segment) and gain access to the data contained in the segment. This capability is implemented as a loadable module. Entries in the /etc/system file must contain the shmsys: prefix.

A special kind of shared memory known as intimate shared memory (ISM) is used by DBMS vendors to maximize performance. When a shared memory segment is made into an ISM segment, the memory for the segment is locked. This feature enables a faster I/O path to be followed and improves memory usage. A number of kernel resources describing the segment are then shared between all processes that attach to the segment in ISM mode.

segspt_minfree

<table>
<thead>
<tr>
<th>Description</th>
<th>Identifies pages of system memory that cannot be allocated for ISM shared memory.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Type</td>
<td>Unsigned long</td>
</tr>
<tr>
<td>Default</td>
<td>5 percent of available system memory when the first ISM segment is created</td>
</tr>
<tr>
<td>Range</td>
<td>0 to 50 percent of physical memory</td>
</tr>
<tr>
<td>Units</td>
<td>Pages</td>
</tr>
<tr>
<td>Dynamic?</td>
<td>Yes</td>
</tr>
<tr>
<td>Validation</td>
<td>None. Values that are too small can cause the system to hang or performance to severely degrade when memory is consumed with ISM segments.</td>
</tr>
<tr>
<td>When to Change</td>
<td>On database servers with large amounts of physical memory using ISM, the value of this parameter can be decreased. If ISM segments are not</td>
</tr>
</tbody>
</table>
used, this parameter has no effect. A maximum value of 128 MB (0x4000) is almost certainly sufficient on large memory machines.

Commitment Level  Unstable

Scheduling

disp_rechoose_interval

Description  Similar to the previous rechoose_interval parameter, this parameter specifies the amount of time before a process is deemed to have lost all affinity for the last CPU it ran on. However, this parameter is set in more granular time increments. This parameter should be used instead of the deprecated rechoose_interval parameter, but the rechoose_interval parameter is still accepted if it is set in the /etc/system file.

After this interval expires, any CPU is considered a candidate for scheduling a thread. This parameter does not apply to threads in the real-time class, but applies to threads in all other scheduling classes.

Use mdb if you want to change the value of this parameter by using the following steps:

1. Convert nanoseconds to unscaled time. For example, to convert a 5000000 nanosecond based value to unscaled time, use the following syntax:

   # mdb -kw
   .
   .
   > 0t5000000::time -u
   0xb6a444

2. Set disp_rechoose_interval to the unscaled time value. For example, provide the value that was returned in preceding step.

   > disp_rechoose_interval /Z 0xb6a444
disp_rechoose_interval: 0x447d998 = 0xb6a444

3. Verify that disp_rechoose_interval has been set to the right value. For example:

   > disp_rechoose_interval::print
   0xb6a444

Data Type  Signed integer
Timers

hires_tick

Description When set, this parameter causes the Oracle Solaris OS to use a system clock rate of 1000 instead of the default value of 100.

Data Type Signed integer

Default 0

Range 0 (disabled) or 1 (enabled)

Validation None

When to Change When you want timeouts with a resolution of less than 10 milliseconds, and greater than or equal to 1 millisecond.

Commitment Level Unstable

Change History For information, see “disp_rechoose_interval” on page 178.

timer_max

Description Specifies the number of POSIX timers available.
**Data Type**: Signed integer  
**Default**: 1000  
**Range**: 0 to MAXINT  
**Dynamic?**: No. Increasing the value can cause a system crash.  
**Validation**: None  
**When to Change**: When the default number of timers offered by the system is inadequate. Applications receive an EAGAIN error when executing timer_create system calls.  
**Commitment Level**: Unstable

---

**SPARC System Specific Parameters**

The following parameters apply to sun4v and SPARC M-Series sun4u platforms.

### **tsb_alloc_hiwater_factor**

**Description**: Initializes tsb_alloc_hiwater to impose an upper limit on the amount of physical memory that can be allocated for translation storage buffers (TSBs) as follows:

\[
\text{tsb\_alloc\_hiwater} = \frac{\text{physical memory (bytes)}}{\text{tsb\_alloc\_hiwater\_factor}}
\]

When the memory that is allocated to TSBs is equal to the value of tsb_alloc_hiwater, the TSB memory allocation algorithm attempts to reclaim TSB memory as pages are unmapped.

Exercise caution when using this factor to increase the value of tsb_alloc_hiwater. To prevent system hangs, the resulting high water value must be considerably lower than the value of swapfs_minfree and segspt_minfree.

**Data Type**: Integer  
**Default**: 32  
**Range**: 1 to MAXINIT
Note that a factor of 1 makes all physical memory available for allocation to TSBs, which could cause the system to hang. A factor that is too high will not leave memory available for allocation to TSBs, decreasing system performance.

Dynamic? Yes
Validation None
When to Change Change the value of this parameter if the system has many processes that attach to very large shared memory segments. Under most circumstances, tuning of this variable is not necessary.
Commitment Level Unstable

**default_tsb_size**

Description Selects size of the initial translation storage buffers (TSBs) allocated to all processes.

Data Type Integer
Default Default is 0 (8 KB), which corresponds to 512 entries
Range Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8 KB</td>
</tr>
<tr>
<td>1</td>
<td>16 KB</td>
</tr>
<tr>
<td>3</td>
<td>32 KB</td>
</tr>
<tr>
<td>4</td>
<td>128 KB</td>
</tr>
<tr>
<td>5</td>
<td>256 KB</td>
</tr>
<tr>
<td>6</td>
<td>512 KB</td>
</tr>
<tr>
<td>7</td>
<td>1 Mbyte</td>
</tr>
</tbody>
</table>

Dynamic? Yes
Validation None
When to Change Generally, you do not need to change this value. However, doing so might provide some advantages if the majority of processes on the system have a larger than average working set, or if resident set size (RSS) sizing is disabled.

Commitment Level Unstable

**enable_tsb_rss_sizing**

Description Enables a resident set size (RSS) based TSB sizing heuristic.

Data Type Boolean

Default 1 (TSBs can be resized)

Range 0 (TSBs remain at tsb_default_size) or 1 (TSBs can be resized)

If set to 0, then tsb_rss_factor is ignored.

Dynamic? Yes

Validation Yes

When to Change Can be set to 0 to prevent growth of the TSBs. Under most circumstances, this parameter should be left at the default setting.

Commitment Level Unstable

**tsb_rss_factor**

Description Controls the RSS to TSB span ratio of the RSS sizing heuristic. This factor divided by 512 yields the percentage of the TSB span which must be resident in memory before the TSB is considered as a candidate for resizing.

Data Type Integer

Default 384, resulting in a value of 75%. Thus, when the TSB is 3/4 full, its size will be increased. Note that some virtual addresses typically map to the same slot in the TSB. Therefore, conflicts can occur before the TSB is at 100% full.

Range 0 to 512

Dynamic? Yes

Validation None
When to Change

If the system is experiencing an excessive number of traps due to TSB misses, for example, due to virtual address conflicts in the TSB, you might consider decreasing this value toward 0.

For example, changing tsb_rss_factor to 256 (effectively, 50%) instead of 384 (effectively, 75%) might help eliminate virtual address conflicts in the TSB in some cases, but will use more kernel memory, particularly on a heavily loaded system.

TSB activity can be monitored with the trapsstat -T command.

Commitment Level

Unstable

Locality Group Parameters

This section provides generic memory tunables, which apply to any SPARC or x86 system that uses a Non-Uniform Memory Architecture (NUMA).

lp_alloc_prefer

Description

Controls a heuristic for allocation of large memory pages when the requested page size is not immediately available in the local memory group, but could be satisfied from a remote memory group.

By default, the Oracle Solaris OS allocates a remote large page if local free memory is fragmented, but remote free memory is not. Setting this parameter to 1 indicates that additional effort should be spent attempting to allocate larger memory pages locally, potentially moving smaller pages around to coalesce larger pages in the local memory group.

Data Type

Boolean

Default

0 (Prefer remote allocation if local free memory is fragmented and remote free memory is not)

Range

0 (Prefer remote allocation if local free memory is fragmented and remote free memory is not)

1 (Prefer local allocation whenever possible, even if local free memory is fragmented and remote free memory is not)

Dynamic?

No

Validation

None
When to Change

This parameter might be set to 1 if long-running programs on the system tend to allocate memory that is accessed by a single program, or if memory that is accessed by a group of programs is known to be running in the same locality group (lgroup). In these circumstances, the extra cost of page coalesce operations can be amortized over the long run of the programs.

This parameter might be left at the default value (0) if multiple programs tend to share memory across different locality groups, or if pages tend to be used for short periods of time. In these circumstances, quick allocation of the requested size tends to be more important than allocation in a particular location.

TLB miss activity might be observed by using the `trapstat -T` command.

Commitment Level

Uncommitted

**lgrp_mem_pset_aware**

Description

If a process is running within a user processor set, this variable determines whether randomly placed memory for the process is selected from among all the lgroups in the system or only from those lgroups that are spanned by the processors in the processor set.

For more information about creating processor sets, see `psrset(1M)`.

Data Type

Boolean

Default

0, the Oracle Solaris OS selects memory from all the lgroups in the system

Range

- 0, the Oracle Solaris OS selects memory from all the lgroups in the system (default)
- 1, try selecting memory only from those lgroups that are spanned by the processors in the processor set. If the first attempt fails, memory can be allocated in any lgroup.

Dynamic?

No

Validation

None

When to Change

Setting this value to a value of one (1) might lead to more reproducible performance when processor sets are used to isolate applications from one another.

</table>
Tuning ZFS Considerations

Review the following considerations before tuning ZFS:

- Default values are generally the best value. If a better value exists, it should be the default. While alternative values might help a given workload, it could quite possibly degrade some other aspects of performance. Occasionally, catastrophically so.

- The ZFS best practices should be followed before ZFS tuning is applied. These practices are a set of recommendations that have been shown to work in different environments and are expected to keep working in the foreseeable future. So, before turning to tuning, make sure you've read and understood the best practices. For more information, see Chapter 12, “Recommended Oracle Solaris ZFS Practices,” in Oracle Solaris 11.1 Administration: ZFS File Systems.

- Unless noted otherwise, the tunable parameters are global and impact ZFS behavior across the system.

ZFS ARC Parameters

This section describes parameters related to ZFS ARC behavior.

**zfs_arc_min**

Description: Determines the minimum size of the ZFS Adaptive Replacement Cache (ARC). See also “zfs_arc_max” on page 83.

Data Type: Unsigned Integer (64-bit)

Default: 64 MB

Range: 64 MB to zfs_arc_max

Units: Bytes

Dynamic?: No

Validation: Yes, the range is validated.

When to Change: When a system’s workload demand for memory fluctuates, the ZFS ARC caches data at a period of weak demand and then shrinks at a period of strong demand. However, ZFS does not shrink below the value of zfs_arc_min. Generally, you do not need to change the default value.

Commitment Level: Unstable

Change History: For information, see “zfs_arc_min” on page 177.
**zfs_arc_max**

**Description**
Determines the maximum size of the ZFS Adaptive Replacement Cache (ARC). See also “zfs_arc_min” on page 82.

**Data Type**
Unsigned Integer (64-bit)

**Default**
75% of memory on systems with less than 4 GB of memory

physmem minus 1 GB on systems with greater than 4 GB of memory

**Range**
64 MB to physmem

**Units**
Bytes

**Dynamic?**
No

**Validation**
Yes, the range is validated.

**When to Change**
If a future memory requirement is significantly large and well defined, you might consider reducing the value of this parameter to cap the ARC so that it does not compete with the memory requirement. For example, if you know that a future workload requires 20% of memory, it makes sense to cap the ARC such that it does not consume more than the remaining 80% of memory.

**Commitment Level**
Unstable

**Change History**
For information, see “zfs_arc_max” on page 177.

---

**ZFS File-Level Prefetch**

**zfs_prefetch_disable**

**Description**
This parameter determines a file-level prefetching mechanism called zprefetch. This mechanism looks at the patterns of reads to files and anticipates on some reads, thereby reducing application wait times. The current behavior suffers from two drawbacks:

- Sequential read patterns made of small reads very often hit in the cache. In this case, the current behavior consumes a significant amount of CPU time trying to find the next I/O to issue, whereas performance is governed more by the CPU availability.
- The zprefetch code has been observed to limit scalability of some loads. CPU profiling can be done by using the lockstat -I command or er_kernel as described here:
http://developers.sun.com/prodtech/cc/articles/perftools.html

You can disable prefetching by setting zfs_prefetch_disable in the /etc/system file.

Device-level prefetching is disabled when zfs_vdev_cache_size is disabled. This means that tuning vdev cache shift is no longer necessary if zfs_vdev_cache_size is disabled.

**Data Type**: Boolean  
**Default**: 0 (enabled)  
**Range**: 0 (enabled) or 1 (disabled)  
**Dynamic?**: Yes  
**Validation**: No  
**When to Change**: If the results of er_kernel show significant time in zfetch_* functions, or if lock profiling with lockstat shows contention around zfetch locks, then disabling file level prefetching should be considered.

**Commitment Level**: Unstable

---

**ZFS Device I/O Queue Depth**

**zfs_vdev_max_pending**

**Description**: This parameter controls the maximum number of concurrent I/Os pending to each device.

**Data Type**: Integer  
**Default**: 10  
**Range**: 0 to MAXINT  
**Dynamic?**: Yes  
**Validation**: No  
**When to Change**: In a storage array where LUNs are made of a large number of disk drives, the ZFS queue can become a limiting factor on read IOPS. This behavior is one of the underlying reasoning for the best practice of presenting as many LUNS as there are backing spindles to the ZFS storage pool. That is, if you create LUNS from a 10 disk-wide array level
raid-group, then using 5 to 10 LUNs to build a storage pool allows ZFS to manage enough of an I/O queue without the need to set this specific tunable.

However, when no separate intent log is in use and the pool is made of JBOD disks, using a small zfs_vdev_max_pending value, such as 10, can improve the synchronous write latency as those are competing for the disk resource. Using separate intent log devices can alleviate the need to tune this parameter for loads that are synchronously write intensive since those synchronous writes are not competing with a deep queue of non-synchronous writes.

Tuning this parameter is not expected to be effective for NVRAM-based storage arrays in the case where volumes are made of small number of spindles. However, when ZFS is presented with a volume made of a large (greater than 10) number of spindles, then this parameter can limit the read throughput obtained on the volume. The reason is that with a maximum of 10 or 35 queued I/Os per LUN, this can translate into less than 1 I/O per storage spindle, which is not enough for individual disks to deliver their IOPS. This issue would appear in iostat active queue output approaching the value of zfs_vdev_max_pending.

Device drivers may also limit the number of outstanding I/Os per LUN. If you are using LUNs on storage arrays that can handle large numbers of concurrent IOPS, then the device driver constraints can limit concurrency. Consult the configuration for the drivers your system uses. For example, the limit for the QLogic ISP2200, ISP2300, and SP212 family FCI HBA (qlc) driver is described as the execution-throttle parameter in /kernel/drv/qlc.conf.

Commitment Level  Unstable

**Tuning ZFS When Using Flash Storage**

The following information applies to Flash SSDs, F20 PCIe Accelerator Card, F40 PCIe Accelerator Card, and F5100 Flash Storage Array.

Review the following general comments when using ZFS with Flash storage:

- Consider using LUNs or low latency disks that are managed by a controller with persistent memory, if available, for the ZIL (ZFS intent log). This option can be considerably more cost effective than using flash for low latency commits. The size of the log devices must only be
large enough to hold 10 seconds of maximum write throughput. Examples would include a storage array based LUN, or a disk connected to an HBA with a battery protected write cache.

If no such device is available, segment a separate pool of flash devices for use as log devices in a ZFS storage pool.

- The F40 and F20 Flash Accelerator cards contain and export 4 independent flash modules to the OS. The F5100 contains up to 80 independent flash modules. Each flash module appear to the operating system as a single device. SSDs are viewed as a single device by the OS. Flash devices may be used as ZFS log devices to reduce commit latency, particularly if used in an NFS server. For example, a single flash module of a flash device used as a ZFS log device can reduce latency of single lightly threaded operations by 10x. More flash devices can be striped together to achieve higher throughput for large amounts of synchronous operations.

- Log devices should be mirrored for reliability. For maximum protection, the mirrors should be created on separate flash devices. In the case of F20 and F40 PCIe accelerator cards, maximum protection is achieved by ensuring that mirrors reside on different physical PCIe cards. Maximum protection with the F5100 storage array is obtained by placing mirrors on separate F5100 devices.

- Flash devices that are not used as log devices may be used as second level cache devices. This serves to both offload IOPS from primary disk storage and also to improve read latency for commonly used data.

Adding Flash Devices as ZFS Log or Cache Devices

Review the following recommendations when adding flash devices as ZFS log or cache devices.

- A ZFS log or cache device can be added to an existing ZFS storage pool by using the `zpool add` command. Be very careful with `zpool add` commands. Mistakenly adding a log device as a normal pool device is a mistake that will require you to destroy and restore the pool from scratch. Individual log devices themselves can be removed from a pool.

- Familiarize yourself with the `zpool add` command before attempting this operation on active storage. You can use the `zpool add -n` option to preview the configuration without creating the configuration. For example, the following incorrect `zpool add` preview syntax attempts to add a device as a log device:

```bash
# zpool add -n tank c4t1d0
vdev verification failed: use -f to override the following errors:
mismatched replication level: pool uses mirror and new vdev is disk
Unable to build pool from specified devices: invalid vdev configuration
```

This is the correct `zpool add` preview syntax for adding a log device to an existing pool:

```bash
# zpool add -n tank log c4t1d0
would update 'tank' to the following configuration:
  tank
```
If multiple devices are specified, they are striped together. For more information, see the examples below or *zpool* *(1M)*.

A flash device, `c4t1d0`, can be added as a ZFS log device:

```
# zpool add pool log c4t1d0
```

If 2 flash devices are available, you can add mirrored log devices:

```
# zpool add pool log mirror c4t1d0 c4t2d0
```

Available flash devices can be added as a cache device for reads.

```
# zpool add pool cache c4t3d0
```

You can’t mirror cache devices, they will be striped together.

```
# zpool add pool cache c4t3d0 c4t4d0
```

### Ensuring Proper Cache Flush Behavior for Flash and NVRAM Storage Devices

ZFS is designed to work with storage devices that manage a disk-level cache. ZFS commonly asks the storage device to ensure that data is safely placed on stable storage by requesting a cache flush. For JBOD storage, this works as designed and without problems. For many NVRAM-based storage arrays, a performance problem might occur if the array takes the cache flush request and actually does something with it, rather than ignoring it. Some storage arrays flush their large caches despite the fact that the NVRAM protection makes those caches as good as stable storage.

ZFS issues infrequent flushes (every 5 second or so) after the uberblock updates. The flushing infrequency is fairly inconsequential so no tuning is warranted here. ZFS also issues a flush every time an application requests a synchronous write (*O_DSYNC*, *fsync*, NFS commit, and so on). The completion of this type of flush is waited upon by the application and impacts performance. Greatly so, in fact. From a performance standpoint, this neutralizes the benefits of having an NVRAM-based storage.

Cache flush tuning was recently shown to help flash device performance when used as log devices. When all LUNs exposed to ZFS come from NVRAM-protected storage array and procedures ensure that no unprotected LUNs will be added in the future, ZFS can be tuned to
not issue the flush requests by setting `zfs_nocacheflush`. If some LUNs exposed to ZFS are not protected by NVRAM, then this tuning can lead to data loss, application level corruption, or even pool corruption. In some NVRAM-protected storage arrays, the cache flush command is a no-op, so tuning in this situation makes no performance difference.

A recent OS change is that the flush request semantic has been qualified to instruct storage devices to ignore the requests if they have the proper protection. This change requires a fix to our disk drivers and for the NVRAM device to support the updated semantics. If the NVRAM device does not recognize this improvement, use these instructions to tell the Solaris OS not to send any synchronize cache commands to the array. If you use these instructions, make sure all targeted LUNS are indeed protected by NVRAM.

Occasionally, flash and NVRAM devices do not properly advertise to the OS that they are non-devices, and that caches do not need to be flushed. Cache flushing is an expensive operation. Unnecessary flushes can drastically impede performance in some cases.

Review the following `zfs_nocacheflush` syntax restrictions before applying the tuning entries below:

- The tuning syntax below can be included in `sd.conf` but there must be only a single `sd-config-list` entry per vendor/product.
- If multiple devices entries are desired, multiple pairs of vendor IDs and `sd` tuning strings can be specified on the same line by using the following syntax:

  ```
  # "012345670123456789012345","tuning ",
  sd-config-list="][-VID1-][-----PID1-----]","param1:val1, param2:val2",
  ][-VIDN-][-----PIDN-----]","param1:val1, param3:val3"
  
  Make sure the vendor ID (VID) string is padded to 8 characters and the product ID (PID) string is padded to 16 characters as described in the preceding example.
  ```

Caution – All cache sync commands are ignored by the device. Use at your own risk.

1. Use the `format` utility to run the `inquiry` subcommand on a LUN from the storage array. For example:

   ```
   # format
   .
   .
   Specify disk (enter its number): x
   format> inquiry
   Vendor: ATA
   Product: Marvell
   Revision: XXXX
   format>
   ```

2. Select one of the following based on your architecture:
For F40 flash devices, add the following entry to `/kernel/drv/sd.conf`. In the entry below, ensure that "ATA" is padded to 8 characters, and "3E128-TS2-550B01" contains 16 characters. Total string length is 24.

```
sd-config-list="ATA  3E128-TS2-550B01","disksort:false, cache-non:true"
```

For F20 and F5100 flash devices, choose one of the following based on your architecture. In the entries below, "ATA" is padded to 8 characters, and "MARVELL SD88SA02" contains 16 characters. The total string length is 24.

```
ssd-config-list = "ATA MARVELL SD88SA02","throttle-max:32, disksort:false, cache-non:true"
```

Many SPARC architectures – Add the following entry to `/kernel/drv/ssd.conf`:

```
ssd-config-list="ATA MARVELL SD88SA02","throttle-max:32, disksort:false, cache-non:true"
```

3. Carefully add whitespace to make the vendor ID (VID) 8 characters long (here ATA) and Product ID (PID) 16 characters long (here MARVELL) in the `sd-config-list` entry as illustrated.

4. Reboot the system.

You can tune `zfs_nocacheflush` back to its default value (0) with no adverse effect on performance.

### SCSI Unmap Considerations for Flash Devices

The Solaris 11.1 OS has a problem that resulted in excessive calls to SCSI unmap routines. This particular problem is detrimental to flash performance. The workaround is to disable the unmap feature as follows:

- Include the following entry in the `/etc/system` file.

```
set zfs:zfs_unmap_ignore_size=0
```

- Reboot the system.

### Tuning ZFS for Database Products

Review the following considerations when using ZFS with a database product.

- If the database uses a fixed disk block or record size for I/O, set the ZFS `recordsize` property to match it. You can do this on a per-file system basis, even though multiple file systems might share a single pool.

- With ZFS’s copy-on-write design, tuning down the `recordsize` is a way to improve OLTP performance at the expense of batch reporting queries.
ZFS checksums every block stored on disk. This alleviates the need for the database layer to checksum data an additional time. If checksums are computed by ZFS instead of at the database layer, any discrepancy can be caught and fixed before the data is returned to the application.

UFS direct I/O is used to overcome some of the design deficiencies of UFS and to eliminate double buffering of data. In ZFS, the UFS design deficiencies do not exist and ZFS uses the primarycache and secondarycache properties to manage buffering data in the ARC. Note that using the secondarycache (L2ARC) property to improve random reads also requires the primarycache property to be enabled.

Keep pool space under 90% utilization to maintain pool performance.

Tuning ZFS for an Oracle Database

ZFS is recommended for any Oracle database version in single instance mode. ZFS can be used with an Oracle RAC database when it is available as a NFS-shared file system.

Review the following recommendations below for tuning ZFS for an Oracle database:

- **Verify that you are running the latest Solaris release**
  Start with the latest Solaris 10 or Solaris 11 release, with the Solaris 10 9/10 release as a minimum starting point.

- **Create LUNs for your ZFS storage pools, if needed**
  Use your storage array tools to create LUNs that will be presented to the ZFS storage pool. Or, consider using whole disks for your mirrored ZFS storage pools. For more information, see Chapter 3, "Managing Oracle Solaris ZFS Storage Pools," in Oracle Solaris 11.1 Administration: ZFS File Systems.

- **Create a storage pool for data files for tables, index, undo and temp data**
  Consider creating a mirrored storage pool to provide a higher level of data redundancy. For example:

  ```
  # zpool status dbpool
  pool: dbpool
  state: ONLINE
  scan: none requested
  config:

  NAME       STATE READ WRITE CKSUM
  dbpool     ONLINE 0  0  0
  mirror-0   ONLINE 0  0  0
  c0t5000C500335F95E3d0 ONLINE 0  0  0
  c0t5000C500335F907Fd0 ONLINE 0  0  0
  mirror-1   ONLINE 0  0  0
  c0t5000C500335BD117d0 ONLINE 0  0  0
  c0t5000C500335DC60Fd0 ONLINE 0  0  0
  ```
For databases with high redo log activity, such as a typical OLTP database with many commits, use a separate LUN for a separate log device.

- **Create a storage pool for the archive log**
  
  If available, a system's internal disk can handle this type of load. The archive log file system can also be a file system in the dbpool.
  
  ```
  # zpool create archivepool c0t5000c500335e106bd0
  ```

- **Create the ZFS file systems and set the specific file system properties by using the following guidelines.**

  Create separate file systems for redo, archive, undo, and temp database components using the default record size of 128 KB. The general rule is to set the file system recordsize = db_block_size for the file systems that contains Oracle data files. For table data and index components, create a file system with an 8 KB record size. Also consider providing metadata caching hints for your database file systems by using the primarycache property. For more information about ZFS file system properties, see “Introducing ZFS Properties” in *Oracle Solaris 11.1 Administration: ZFS File Systems.*

  - Create file systems for the table data files and index data files with an 8 KB recordsize. Use the default value for primarycache.

    ```
    # zfs create -o recordsize=8k -o mountpoint=/my_db_path/index dbpool/index
    # zfs set logbias=throughput dbpool/index
    # zfs get primarycache,recordsize,logbias dbpool/index
    NAME PROPERTY VALUE SOURCE
    dbpool/index primarycache all default
    dbpool/index recordsize 8K local
    dbpool/index logbias throughput local
    ```

  - Create file systems for temporary and undo table spaces, using the default recordsize and primarycache values.

    ```
    # zfs create -o mountpoint=/my_db_path/temp dbpool/temp
    # zfs set logbias=throughput dbpool/temp
    # zfs create -o mountpoint=/my_db_path/undo dbpool/undo
    # zfs set logbias=throughput dbpool/undo
    ```

  - **Create a storage pool for redo logs with a separate log device.** For databases with high redo log activity, such as a typical OLTP database with many commits, use a separate log device LUN.

    Partition the disk into two slices, a small slice, s0, in the 64 to 150 MB range, for the separate log device. The s1 slice contains the remaining disk space for the redo log.

    ```
    # zpool create redopool c0t50015179594b6f11d0s1 log c0t50015179594b6f11d0s0
    # zpool status redopool
    pool: redopool
    state: ONLINE
    scan: none requested
    config:
    ```
Create a filesystem for redo logs in the redo pool. Use default filesystem values for recordsize and primarycache.

```
# zfs create -o mountpoint=/my_db_path/redo redopool/redo
# zfs set logbias=latency redopool/redo
```

Create a filesystem for archivelog files in the archive pool, enabling compression, use the default value for recordsize and set primarycache to metadata.

```
# zfs create -o compression=on -o primarycache=metadata -o mountpoint=/my_db_admin_path/archive archivepool/archive
# zfs get primarycache,recordsize,compressratio,compression,available,used,quota archivepool/archive
```

```
NAME PROPERTY VALUE SOURCE
archivepool/archive primarycache metadata local
archivepool/archive recordsize 128K default
archivepool/archive compressratio 1.32x -
archivepool/archive compression on local
archivepool/archive available 40.0G -
archivepool/archive used 10.0G -
archivepool/archive quota 50G local
```

Consider tuning storage array I/O queues (for systems with HDS or EMC storage arrays)

ZFS aggregates read and write I/O and manages the priority of I/O before sending it to the driver level, which handles the device. The zfs_vdev_max_pending parameter defines the maximum number of I/Os that ZFS sends to any storage pool device.

In a legacy storage environment, the ssd_max_throttle and sd_max_throttle parameters define the maximum number of concurrent I/Os that the driver can send to the storage. By setting the zfs_vdev_max_pending default value equal to the value of the [s]sd_max_throttle parameter, we prevent ZFS from queuing I/O to yet another unnecessary SD layer.

If you have ssd:ssd_max_throttle or sd:sd_max_throttle in the /etc/system file in your existing environment, then set zfs:zfs_vdev_max_pending at the same value. For example, if the storage array administrator asked for the following setting:

```
set ssd:ssd_max_throttle=20
```

Then, also set this parameter as follows:

```
set ssd:ssd_max_throttle=20
set zfs:zfs_vdev_max_pending=20
```

Setting this parameter allows ZFS to control each LUN queue. This means that the total number of pending I/Os in the storage can grow as follows:

"
number of LUNs * ZFS_VDEV_MAX_PENDING

- **Allocate sufficient memory and swap resources**
  You can reduce ZFS memory consumption by tuning the `zfs_arc_max` parameter to a low value, but we still recommend provisioning enough memory to cache metadata for the actively used portion of the database, which is estimated at 1.5% with an 8 KB ZFS record size and proportionately less or more with larger or smaller records. The file system that hold index files is the one that has the largest benefit from file system caching because it is the last one to invalidate in case of lack of memory. The `zfs_arc_max` parameter is in bytes and accepts decimal or hexadecimal values. The following example sets this parameter to 2 GB:

  set zfs:zfs_arc_max=2147483648
  or
  set zfs:zfs_arc_max=0x80000000

  To prevent applications from failing due to lack of memory, you must configure some amount of swap space. The amount of swap equivalent to all of system memory is always enough for this purpose. This swap space is not expected to be used, but is needed as a reservation area. For information about increasing swap space, see "Managing Your ZFS Swap and Dump Devices" in *Oracle Solaris 11.1 Administration: ZFS File Systems*.

**Using ZFS with MySQL Considerations**

Review the following considerations when using ZFS with MySQL.

- **ZFS recordsize**
Match the ZFS `recordsize` property to the storage engine block size for better OLTP performance.

- **InnoDB**
  - With a known application memory footprint, such as for a database application, you might cap the ARC size so that the application will not need to reclaim its necessary memory from the ZFS cache.
  - Create a separate pool for the logs.
  - Set a different path for data and log in the `my.cnf` file.
  - Set the ZFS `recordsize` property to 16K for the InnoDB data files, and use the default `recordsize` value for InnoDB logs, prior to creating data files.
NFS Tunable Parameters

This section describes the NFS tunable parameters.

- “Tuning the NFS Environment” on page 95
- “NFS Module Parameters” on page 96
- “rpcmod Module Parameters” on page 123

Where to Find Tunable Parameter Information

</tbody>
</table>

Tuning the NFS Environment

You can define NFS parameters in the /etc/system file, which is read during the boot process. Each parameter includes the name of its associated kernel module. For more information, see “Tuning an Oracle Solaris System” on page 19.

Caution – The names of the parameters, the modules that they reside in, and the default values can change between releases. Check the documentation for the version of the active SunOS release before making changes or applying values from previous releases.
NFS Module Parameters

This section describes parameters related to the NFS kernel module.

**nfs:nfs3_pathconf_disable_cache**

Description: Controls the caching of `pathconf` information for NFS Version 3 mounted file systems.

Data Type: Integer (32-bit)

Default: 0 (caching enabled)

Range: 0 (caching enabled) or 1 (caching disabled)

Units: Boolean values

Dynamic?: Yes

Validation: None

When to Change: The `pathconf` information is cached on a per file basis. However, if the server can change the information for a specific file dynamically, use this parameter to disable caching. There is no mechanism for the client to validate its cache entry.

Commitment Level: Unstable

**nfs:nfs4_pathconf_disable_cache**

Description: Controls the caching of `pathconf` information for NFS Version 4 mounted file systems.

Data Type: Integer (32-bit)

Default: 0 (caching enabled)

Range: 0 (caching enabled) or 1 (caching disabled)

Units: Boolean values

Dynamic?: Yes

Validation: None

When to Change: The `pathconf` information is cached on a per file basis. However, if the server can change the information for a specific file dynamically, use this parameter to disable caching. There is no mechanism for the client to validate its cache entry.
Commitment Level Unstable

**nfs:nfs_allow_preepoch_time**

Description Controls whether files with incorrect or negative time stamps should be made visible on the client.

Historically, neither the NFS client nor the NFS server would do any range checking on the file times being returned. The over-the-wire timestamp values are unsigned and 32-bits long. So, all values have been legal.

The timestamp values on the 64-bit Solaris kernel are signed and 64-bits long. It is impossible to determine whether a time field represents a full 32-bit time or a negative time, that is, a time prior to January 1, 1970.

It is impossible to determine whether to sign extend a time value when converting from 32 bits to 64 bits. The time value should be sign extended if the time value is truly a negative number. However, the time value should not be sign extended if it does truly represent a full 32-bit time value. This problem is resolved by simply disallowing full 32-bit time values.

Data Type Integer (32-bit)
Default 0 (32-bit time stamps disabled)
Range 0 (32-bit time stamps disabled) or 1 (32-bit time stamps enabled)
Units Boolean values
Dynamic? Yes
Validation None
When to Change Even during normal operation, it is possible for the timestamp values on some files to be set very far in the future or very far in the past. If access to these files is preferred using NFS mounted file systems, set this parameter to 1 to allow the timestamp values to be passed through unchecked.

Commitment Level Unstable
**nfs:nfs_cots_timeo**

**Description**
Controls the default RPC timeout for NFS version 2 mounted file systems using connection-oriented transports such as TCP for the transport protocol.

**Data Type**
Signed integer (32-bit)

**Default**
600 (60 seconds)

**Range**
0 to $2^{31} - 1$

**Units**
10th of seconds

**Dynamic?**
Yes, but the RPC timeout for a file system is set when the file system is mounted. To affect a particular file system, unmount and mount the file system after changing this parameter.

**Validation**
None

**When to Change**
TCP does a good job ensuring requests and responses are delivered appropriately. However, if the round-trip times are very large in a particularly slow network, the NFS version 2 client might time out prematurely.

Increase this parameter to prevent the client from timing out incorrectly. The range of values is very large, so increasing this value too much might result in situations where a retransmission is not detected for long periods of time.

**Commitment Level**
Unstable

---

**nfs:nfs3_cots_timeo**

**Description**
Controls the default RPC timeout for NFS version 3 mounted file systems using connection-oriented transports such as TCP for the transport protocol.

**Data Type**
Signed integer (32-bit)

**Default**
600 (60 seconds)

**Range**
0 to $2^{31} - 1$

**Units**
10th of seconds

**Dynamic?**
Yes, but the RPC timeout for a file system is set when the file system is mounted. To affect a particular file system, unmount and mount the file system after changing this parameter.
### Validation
None

### When to Change
TCP does a good job ensuring requests and responses are delivered appropriately. However, if the round-trip times are very large in a particularly slow network, the NFS version 3 client might time out prematurely.

Increase this parameter to prevent the client from timing out incorrectly. The range of values is very large, so increasing this value too much might result in situations where a retransmission is not detected for long periods of time.

### Commitment Level
Unstable

---

### nfs:nfs4_cots_timeo

**Description**
Controls the default RPC timeout for NFS version 4 mounted file systems using connection-oriented transports such as TCP for the transport protocol.

The NFS Version 4 protocol specification disallows retransmission over the same TCP connection. Thus, this parameter primarily controls how quickly the client responds to certain events, such as detecting a forced unmount operation or detecting how quickly the server fails over to a new server.

**Data Type**
Signed integer (32-bit)

**Default**
600 (60 seconds)

**Range**
0 to $2^{31} - 1$

**Units**
10th of seconds

**Dynamic?**
Yes, but this parameter is set when the file system is mounted. To affect a particular file system, unmount and mount the file system after changing this parameter.

**Validation**
None

**When to Change**
TCP does a good job ensuring requests and responses are delivered appropriately. However, if the round-trip times are very large in a particularly slow network, the NFS version 4 client might time out prematurely.
Increase this parameter to prevent the client from timing out incorrectly. The range of values is very large, so increasing this value too much might result in situations where a retransmission is not detected for long periods of time.

Commitment Level  Unstable

**nfs:nfs_do_symlink_cache**

Description  Controls whether the contents of symbolic link files are cached for NFS version 2 mounted file systems.

Data Type  Integer (32-bit)
Default  1 (caching enabled)
Range  0 (caching disabled) or 1 (caching enabled)
Units  Boolean values
Dynamic?  Yes
Validation  None

When to Change  If a server changes the contents of a symbolic link file without updating the modification timestamp on the file or if the granularity of the timestamp is too large, then changes to the contents of the symbolic link file might not be visible on the client for extended periods. In this case, use this parameter to disable the caching of symbolic link contents. Doing so makes the changes immediately visible to applications running on the client.

Commitment Level  Unstable

**nfs:nfs3_do_symlink_cache**

Description  Controls whether the contents of symbolic link files are cached for NFS version 3 mounted file systems.

Data Type  Integer (32-bit)
Default  1 (caching enabled)
Range  0 (caching disabled) or 1 (caching enabled)
Units  Boolean values
Dynamic?  Yes
Validation None
When to Change If a server changes the contents of a symbolic link file without updating the modification timestamp on the file or if the granularity of the timestamp is too large, then changes to the contents of the symbolic link file might not be visible on the client for extended periods. In this case, use this parameter to disable the caching of symbolic link contents. Doing so makes the changes immediately visible to applications running on the client.

Commitment Level Unstable

**nfs:nfs4_do_symlink_cache**

Description Controls whether the contents of symbolic link files are cached for NFS version 4 mounted file systems.

Data Type Integer (32-bit)
Default 1 (caching enabled)
Range 0 (caching disabled) or 1 (caching enabled)
Units Boolean values
Dynamic? Yes
Validation None

In this case, use this parameter to disable the caching of symbolic link contents. Doing so makes the changes immediately visible to applications running on the client.

Commitment Level Unstable

**nfs:nfs_dynamic**

Description Controls whether a feature known as *dynamic retransmission* is enabled for NFS version 2 mounted file systems using connectionless transports such as UDP. This feature attempts to reduce retransmissions by monitoring server response times and then adjusting RPC timeouts and read- and write- transfer sizes.
NFS Module Parameters

**nfs:nfs3_dynamic**

Description: Controls whether a feature known as *dynamic retransmission* is enabled for NFS version 3 mounted file systems using connectionless transports such as UDP. This feature attempts to reduce retransmissions by monitoring server response times and then adjusting RPC timeouts and read- and write- transfer sizes.

</tbody>
</table>

### `nfs:nfs3_lookup_neg_cache`

| Description | Controls whether a negative name cache is used for NFS version 3 read-only mounted file systems. This negative name cache records file names that were looked up, but were not found. The cache is used to avoid over-the-network look-up requests made for file names that are already known to not exist. |
| Data Type   | Integer (32-bit) |
| Default     | 1 (enabled)      |
| Range       | 0 (disabled) or 1 (enabled) |
| Units       | Boolean values  |
Dynamic? Yes
Validation None
When to Change For the cache to perform correctly, negative entries must be strictly verified before they are used. This consistency mechanism is relaxed slightly for read-only mounted file systems. It is assumed that the file system on the server is not changing or is changing very slowly, and that it is okay for such changes to propagate slowly to the client. The consistency mechanism becomes the normal attribute cache mechanism in this case.

Negative cache entries are used only for read-only mounted file system. By assuming that the file system on the server is not changing or is changing very slowly, it is okay for such changes to propagate slowly to the client. The consistency mechanism becomes the normal attribute cache mechanism in this case.

If file systems are mounted read-only on the client, but are expected to change on the server and these changes need to be seen immediately by the client, use this parameter to disable the negative cache.

If you disable the `nfs:nfs_disable_rddir_cache` parameter, you should probably also disable this parameter. For more information, see “nfs:nfs_disable_rddir_cache” on page 113.

Commitment Level Unstable

**nfs:nfs4_lookup_neg_cache**

Description Controls whether a negative name cache is used for NFS version 4 mounted file systems. This negative name cache records file names that were looked up, but were not found. The cache is used to avoid over-the-network look-up requests made for file names that are already known to not exist.

Data Type Integer (32-bit)
Default 1 (enabled)
Range 0 (disabled) or 1 (enabled)
Units Boolean values
Dynamic? Yes
Validation None
When to Change For the cache to perform correctly, negative entries must be strictly verified before they are used. This consistency mechanism is relaxed slightly for read-only mounted file systems. It is assumed that the file system on the server is not changing or is changing very slowly, and that it is okay for such changes to propagate slowly to the client. The consistency mechanism becomes the normal attribute cache mechanism in this case.

If file systems are mounted read-only on the client, but are expected to change on the server and these changes need to be seen immediately by the client, use this parameter to disable the negative cache.

If you disable the `nfs:nfs_disable_rddir_cache` parameter, you should probably also disable this parameter. For more information, see “nfs:nfs_disable_rddir_cache” on page 113.

Commitment Level Unstable

### nfs:nfs_max_threads

**Description** Controls the number of kernel threads that perform asynchronous I/O for the NFS version 2 client. Because NFS is based on RPC and RPC is inherently synchronous, separate execution contexts are required to perform NFS operations that are asynchronous from the calling thread.

The operations that can be executed asynchronously are read for read-ahead, readdir for readdir read-ahead, write for putpage and pageio operations, commit, and inactive for cleanup operations that the client performs when it stops using a file.

**Data Type** Unsigned short

**Default** 8

**Range** 0 to \(2^{15} - 1\)

**Units** Threads

**Dynamic?** Yes, but this parameter is set per file system at mount time. To affect a particular file system, unmount and mount the file system after changing this parameter.

**Validation** None

**When to Change** To increase or reduce the number of simultaneous I/O operations that are outstanding at any given time. For example, for a very low bandwidth network, you might want to decrease this value so that the
NFS client does not overload the network. Alternately, if the network is very high bandwidth, and the client and server have sufficient resources, you might want to increase this value. Doing so can more effectively utilize the available network bandwidth, and the client and server resources.

Commitment Level Unstable

**nfs:nfs3_max_threads**

Description Controls the number of kernel threads that perform asynchronous I/O for the NFS version 3 client. Because NFS is based on RPC and RPC is inherently synchronous, separate execution contexts are required to perform NFS operations that are asynchronous from the calling thread.

The operations that can be executed asynchronously are read for read-ahead, readdir for readdir read-ahead, write for putpage and pageio requests, and commit.

Data Type Unsigned short

Default 8

Range 0 to $2^{15} - 1$

Units Threads

Dynamic? Yes, but this parameter is set per file system at mount time. To affect a particular file system, unmount and mount the file system after changing this parameter.

Validation None

When to Change To increase or reduce the number of simultaneous I/O operations that are outstanding at any given time. For example, for a very low bandwidth network, you might want to decrease this value so that the NFS client does not overload the network. Alternately, if the network is very high bandwidth, and the client and server have sufficient resources, you might want to increase this value. Doing so can more effectively utilize the available network bandwidth, and the client and server resources.

Commitment Level Unstable
**nfs:nfs4_max_threads**

**Description**
Controls the number of kernel threads that perform asynchronous I/O for the NFS version 4 client. Because NFS is based on RPC and RPC is inherently synchronous, separate execution contexts are required to perform NFS operations that are asynchronous from the calling thread. The operations that can be executed asynchronously are read for read-ahead, write-behind, directory read-ahead, and cleanup operations that the client performs when it stops using a file.

**Data Type**
Unsigned short

**Default**
8

**Range**
0 to $2^{15} - 1$

**Units**
Threads

**Dynamic?**
Yes, but this parameter is set per file system at mount time. To affect a particular file system, unmount and mount the file system after changing this parameter.

**Validation**
None

**When to Change**
To increase or reduce the number of simultaneous I/O operations that are outstanding at any given time. For example, for a very low bandwidth network, you might want to decrease this value so that the NFS client does not overload the network. Alternately, if the network is very high bandwidth, and the client and server have sufficient resources, you might want to increase this value. Doing so can more effectively utilize the available network bandwidth, and the client and server resources.

**Commitment Level**
Unstable

**nfs:nfs_nra**

**Description**
Controls the number of read-ahead operations that are queued by the NFS version 2 client when sequential access to a file is discovered. These read-ahead operations increase concurrency and read throughput. Each read-ahead request is generally for one logical block of file data.

**Data Type**
Integer (32-bit)

**Default**
4
nfs:nfs3_nra

Description Controls the number of read-ahead operations that are queued by the NFS version 3 client when sequential access to a file is discovered. These read-ahead operations increase concurrency and read throughput. Each read-ahead request is generally for one logical block of file data.

Data Type Integer (32-bit)
Default 4
Range 0 to $2^{31} - 1$
Units Logical blocks. (See "nfs:nfs3_bsize" on page 114.)
Dynamic? Yes
Validation None
When to Change To increase or reduce the number of read-ahead requests that are outstanding for a specific file at any given time. For example, for a very low bandwidth network or on a low memory client, you might want to decrease this value so that the NFS client does not overload the network or the system memory. Alternately, if the network is very high bandwidth, and the client and server have sufficient resources, you might want to increase this value. Doing so can more effectively utilize the available network bandwidth, and the client and server resources.

Commitment Level Unstable
**nfs:nfs4_nra**

**Description**
Controls the number of read-ahead operations that are queued by the NFS version 4 client when sequential access to a file is discovered. These read-ahead operations increase concurrency and read throughput. Each read-ahead request is generally for one logical block of file data.

**Data Type**
Integer (32-bit)

**Default**
4

**Range**
0 to \(2^{31} - 1\)

**Units**
Logical blocks. (See "nfs:nfs4_bsize" on page 114.)

**Dynamic?**
Yes

**Validation**
None

**When to Change**
To increase or reduce the number of read-ahead requests that are outstanding for a specific file at any given time. For example, for a very low bandwidth network or on a low memory client, you might want to decrease this value so that the NFS client does not overload the network or the system memory. Alternately, if the network is very high bandwidth, and the client and server have sufficient resources, you might want to increase this value. Doing so can more effectively utilize the available network bandwidth, and the client and server resources.

**Commitment Level**
Unstable

---

**nfs:nrnode**

**Description**
Controls the size of the rnode cache on the NFS client.

The rnode, used by both NFS version 2, 3, and 4 clients, is the central data structure that describes a file on the NFS client. The rnode contains the file handle that identifies the file on the server. The rnode also contains pointers to various caches used by the NFS client to avoid network calls to the server. Each rnode has a one-to-one association with a vnode. The vnode caches file data.

The NFS client attempts to maintain a minimum number of rnodes to attempt to avoid destroying cached data and metadata. When an rnode is reused or freed, the cached data and metadata must be destroyed.

**Data Type**
Integer (32-bit)
Default

The default setting of this parameter is 0, which means that the value of \texttt{nrnode} should be set to the value of the \texttt{ncsize} parameter. Actually, any non positive value of \texttt{nrnode} results in \texttt{nrnode} being set to the value of \texttt{ncsize}.

Range

1 to \(2^{31} - 1\)

Units

\texttt{rnodes}

Dynamic?

No. This value can only be changed by adding or changing the parameter in the \texttt{/etc/system} file, and then rebooting the system.

Validation

The system enforces a maximum value such that the \texttt{rnode} cache can only consume 25 percent of available memory.

When to Change

Because \texttt{rnodes} are created and destroyed dynamically, the system tends to settle upon a \texttt{nrnode}-size cache, automatically adjusting the size of the cache as memory pressure on the system increases or as more files are simultaneously accessed. However, in certain situations, you could set the value of \texttt{nrnode} if the mix of files being accessed can be predicted in advance. For example, if the NFS client is accessing a few very large files, you could set the value of \texttt{nrnode} to a small number so that system memory can cache file data instead of \texttt{rnodes}. Alternately, if the client is accessing many small files, you could increase the value of \texttt{nrnode} to optimize for storing file metadata to reduce the number of network calls for metadata.

Although it is not recommended, the \texttt{rnode} cache can be effectively disabled by setting the value of \texttt{nrnode} to 1. This value instructs the client to only cache 1 \texttt{rnode}, which means that it is reused frequently.

Commitment Level

Unstable

\textbf{nfs:nfs\_shrinkreaddir}

Description

Some older NFS servers might incorrectly handle NFS version 2 \texttt{READDIR} requests for more than 1024 bytes of directory information. This problem is due to a bug in the server implementation. However, this parameter contains a workaround in the NFS version 2 client.

When this parameter is enabled, the client does not generate a \texttt{READDIR} request for larger than 1024 bytes of directory information. If this parameter is disabled, then the over-the-wire size is set to the lesser of either the size passed in by using the \texttt{getdents} system call or by using \texttt{NFS_MAXDATA}, which is 8192 bytes. For more information, see \texttt{getdents(2)}.
### nfs:nfs3_shrinkreaddir

**Description**
Some older NFS servers might incorrectly handle NFS version 3 READDIR requests for more than 1024 bytes of directory information. This problem is due to a bug in the server implementation. However, this parameter contains a workaround in the NFS version 3 client.

When this parameter is enabled, the client does not generate a READDIR request for larger than 1024 bytes of directory information. If this parameter is disabled, then the over-the-wire size is set to the minimum of either the size passed in by using the getdents system call or by using MAXBSIZE, which is 8192 bytes. For more information, see [getdents](2).

</tbody>
</table>
### nfs:nfs_write_error_interval

**Description**: Controls the time duration in between logging `ENOSPC` and `EDQUOT` write errors received by the NFS client. This parameter affects NFS version 2, 3, and 4 clients.

**Data Type**: Long integer (64-bit)

**Default**: 5 seconds

**Range**: 0 to $2^{63} - 1$

**Units**: Seconds

**Dynamic?**: Yes

**Validation**: None

**When to Change**: Increase or decrease the value of this parameter in response to the volume of messages being logged by the client. Typically, you might want to increase the value of this parameter to decrease the number of out of space messages being printed when a full file system on a server is being actively used.

### nfs:nfs_write_error_to_cons_only

**Description**: Controls whether NFS write errors are logged to the system console and `syslog` or to the system console only. This parameter affects messages for NFS version 2, 3, and 4 clients.

**Data Type**: Integer (32-bit)

**Default**: 0 (system console and `syslog`)

**Range**: 0 (system console and `syslog`) or 1 (system console)

**Units**: Boolean values

**Dynamic?**: Yes

**Validation**: None

**When to Change**: Examine the value of this parameter to avoid filling up the file system containing the messages logged by the `syslogd` daemon. When this
parameter is enabled, messages are printed on the system console only and are not copied to the syslog messages file.

Commitment Level Unstable

**nfs:nfs_disable_rddir_cache**

**Description** Controls the use of a cache to hold responses from `READDIR` and `READDIRPLUS` requests. This cache avoids over-the-wire calls to the server to retrieve directory information.

**Data Type** Integer (32-bit)

**Default** 0 (caching enabled)

**Range** 0 (caching enabled) or 1 (caching disabled)

**Units** Boolean values

**Dynamic?** Yes

**Validation** None

**When to Change** Examine the value of this parameter if interoperability problems develop due to a server that does not update the modification time on a directory when a file or directory is created in it or removed from it. The symptoms are that new names do not appear in directory listings after they have been added to the directory or that old names do not disappear after they have been removed from the directory.

This parameter controls the caching for NFS version 2, 3, and 4 mounted file systems. This parameter applies to all NFS mounted file systems, so caching cannot be disabled or enabled on a per file system basis.

If you disable this parameter, you should also disable the following parameters to prevent bad entries in the DNLC negative cache:

- “nfs:nfs_lookup_neg_cache” on page 102
- “nfs:nfs3_lookup_neg_cache” on page 103
- “nfs:nfs4_lookup_neg_cache” on page 104

Commitment Level Unstable
nfs:nfs3_bsize

Description Controls the logical block size used by the NFS version 3 client. This block size represents the amount of data that the client attempts to read from or write to the server when it needs to do an I/O.

Data Type Unsigned integer (32-bit)

Default 32,768 (32 KB)

Range 0 to $2^{31} - 1$

Units Bytes

Dynamic? Yes, but the block size for a file system is set when the file system is mounted. To affect a particular file system, unmount and mount the file system after changing this parameter.

Validation None. Setting this parameter too low or too high might cause the system to malfunction. Do not set this parameter to anything less than PAGESIZE for the specific platform. Do not set this parameter too high because it might cause the system to hang while waiting for memory allocations to be granted.

When to Change Examine the value of this parameter when attempting to change the maximum data transfer size. Change this parameter in conjunction with the nfs:nfs3_max_transfer_size parameter. If larger transfers are preferred, increase both parameters. If smaller transfers are preferred, then just reducing this parameter should suffice.

Commitment Level Unstable

nfs:nfs4_bsize

Description Controls the logical block size used by the NFS version 4 client. This block size represents the amount of data that the client attempts to read from or write to the server when it needs to do an I/O.

Data Type Unsigned integer (32-bit)

Default 32,768 (32 KB)

Range 0 to $2^{31} - 1$

Units Bytes

Dynamic? Yes, but the block size for a file system is set when the file system is mounted. To affect a particular file system, unmount and mount the file system after changing this parameter.
Validation
None. Setting this parameter too low or too high might cause the system to malfunction. Do not set this parameter to anything less than PAGESIZE for the specific platform. Do not set this parameter too high because it might cause the system to hang while waiting for memory allocations to be granted.

When to Change
Examine the value of this parameter when attempting to change the maximum data transfer size. Change this parameter in conjunction with the nfs:nfs4_max_transfer_size parameter. If larger transfers are preferred, increase both parameters. If smaller transfers are preferred, then just reducing this parameter should suffice.

Commitment Level
Unstable

nfs:nfs_async_clusters

Description
Controls the mix of asynchronous requests that are generated by the NFS version 2 client. The four types of asynchronous requests are read-ahead, putpage, pageio, and readdir-ahead. The client attempts to round-robin between these different request types to attempt to be fair and not starve one request type in favor of another.

However, the functionality in some NFS version 2 servers such as write gathering depends upon certain behaviors of existing NFS Version 2 clients. In particular, this functionality depends upon the client sending out multiple WRITE requests at about the same time. If one request is taken out of the queue at a time, the client would be defeating this server functionality designed to enhance performance for the client.

Thus, use this parameter to control the number of requests of each request type that are sent out before changing types.

Data Type
Unsigned integer (32-bit)

Default
1

Range
0 to $2^{31} - 1$

Units
Asynchronous requests

Dynamic?
Yes, but the cluster setting for a file system is set when the file system is mounted. To affect a particular file system, unmount and mount the file system after changing this parameter.
### nfs:nfs3_async_clusters

**Description**
Controls the mix of asynchronous requests that are generated by the NFS version 3 client. The five types of asynchronous requests are read-ahead, putpage, pageio, readdir-ahead, and commit. The client attempts to round-robin between these different request types to attempt to be fair and not starve one request type in favor of another.

However, the functionality in some NFS version 3 servers such as write gathering depends upon certain behaviors of existing NFS version 3 clients. In particular, this functionality depends upon the client sending out multiple WRITE requests at about the same time. If one request is taken out of the queue at a time, the client would be defeating this server functionality designed to enhance performance for the client.

Thus, use this parameter to control the number of requests of each request type that are sent out before changing types.

<td>None. However, setting the value of this parameter to 0 causes all of the queued requests of a particular request type to be processed before moving on to the next type. This value effectively disables the fairness portion of the algorithm.</td>
</tr>
</tbody>
</table>
When to Change

To increase the number of each type of asynchronous operation that is
generated before switching to the next type. Doing so might help with
server functionality that depends upon clusters of operations coming
from the client.

Commitment Level

Unstable

**nfs:nfs4_async_clusters**

Description

Controls the mix of asynchronous requests that are generated by the
NFS version 4 client. The six types of asynchronous requests are
read-ahead, putpage, pageio, readdir-ahead, commit, and inactive. The
client attempts to round-robin between these different request types to
attempt to be fair and not starve one request type in favor of another.

However, the functionality in some NFS version 4 servers such as write
gathering depends upon certain behaviors of existing NFS version 4
clients. In particular, this functionality depends upon the client sending
out multiple WRITE requests at about the same time. If one request is
taken out of the queue at a time, the client would be defeating this
server functionality designed to enhance performance for the client.

Thus, use this parameter to control the number of requests of each
request type that are sent out before changing types.

Data Type

Unsigned integer (32-bit)

Default

1

Range

0 to \(2^{31} - 1\)

Units

Asynchronous requests

Dynamic?

Yes, but the cluster setting for a file system is set when the file system is
mounted. To affect a particular file system, unmount and mount the file
system after changing this parameter.

Validation

None. However, setting the value of this parameter to 0 causes all of the
queued requests of a particular request type to be processed before
moving on to the next type. This effectively disables the fairness
portion of the algorithm.

When to Change

To increase the number of each type of asynchronous request that is
generated before switching to the next type. Doing so might help with
server functionality that depends upon clusters of requests coming
from the client.
**nfs:nfs_async_timeout**

**Description**
Controls the duration of time that threads, which execute asynchronous I/O requests, sleep with nothing to do before exiting. When there are no more requests to execute, each thread goes to sleep. If no new requests come in before this timer expires, the thread wakes up and exits. If a request does arrive, a thread is woken up to execute requests until there are none again. Then, the thread goes back to sleep waiting for another request to arrive, or for the timer to expire.

**Data Type**
Integer (32-bit)

**Default**
6000 (1 minute expressed as 60 sec * 100Hz)

**Range**
0 to $2^{31} - 1$

**Units**
Hz. (Typically, the clock runs at 100Hz.)

**Dynamic?**
Yes

**Validation**
None. However, setting this parameter to a non positive value causes these threads exit as soon as there are no requests in the queue for them to process.

**When to Change**
If the behavior of applications in the system is known precisely and the rate of asynchronous I/O requests can be predicted, it might be possible to tune this parameter to optimize performance slightly in either of the following ways:

- By making the threads expire more quickly, thus freeing up kernel resources more quickly
- By making the threads expire more slowly, thus avoiding thread create and destroy overhead

**nfs:nacache**

**Description**
Tunes the number of hash queues that access the file access cache on the NFS client. The file access cache stores file access rights that users have with respect to files that they are trying to access. The cache itself is dynamically allocated. However, the hash queues used to index into the cache are statically allocated. The algorithm assumes that there is one access cache entry per active file and four of these access cache
entries per hash bucket. Thus, by default, the value of this parameter is set to the value of the \texttt{nnode} parameter.

**Data Type**  
Integer (32-bit)

**Default**  
The default setting of this parameter is 0. This value means that the value of \texttt{nacache} should be set to the value of the \texttt{nnode} parameter.

**Range**  
1 to $2^{31} - 1$

**Units**  
Access cache entries

**Dynamic?**  
No. This value can only be changed by adding or changing the parameter in the `/etc/system` file, and then rebooting system.

**Validation**  
None. However, setting this parameter to a negative value will probably cause the system to try to allocate a very large set of hash queues. While trying to do so, the system is likely to hang.

**When to Change**  
Examine the value of this parameter if the basic assumption of one access cache entry per file would be violated. This violation could occur for systems in a timesharing mode where multiple users are accessing the same file at about the same time. In this case, it might be helpful to increase the expected size of the access cache so that the hashed access to the cache stays efficient.

**Commitment Level**  
Unstable

---

**nfs:nfs3_jukebox delay**

**Description**  
Controls the duration of time that the NFS version 3 client waits to transmit a new request after receiving the \texttt{NFS3ERR_JUKEBOX} error from a previous request. The \texttt{NFS3ERR_JUKEBOX} error is generally returned from the server when the file is temporarily unavailable for some reason. This error is generally associated with hierarchical storage, and CD or tape jukeboxes.

**Data Type**  
Long integer (64-bit)

**Default**  
1000 (10 seconds expressed as 10 sec * 100Hz)

**Range**  
0 to $2^{63} - 1$ on 64-bit platforms

**Units**  
Hz. (Typically, the clock runs at 100Hz.)

**Dynamic?**  
Yes

**Validation**  
None
When to Change
Examine the value of this parameter and perhaps adjust it to match the behaviors exhibited by the server. Increase this value if the delays in making the file available are long in order to reduce network overhead due to repeated retransmissions. Decrease this value to reduce the delay in discovering that the file has become available.

Commitment Level
Unstable

**nfs:nfs3_max_transfer_size**

Description
Controls the maximum size of the data portion of an NFS version 3 READ, WRITE, READDIR, or READDIRPLUS request. This parameter controls both the maximum size of the request that the server returns as well as the maximum size of the request that the client generates.

Data Type
Integer (32-bit)

Default
1,048,576 (1 Mbyte)

Range
0 to $2^{31}$ - 1

Units
Bytes

Dynamic?
Yes, but this parameter is set per file system at mount time. To affect a particular file system, unmount and mount the file system after changing this parameter.

Validation
None. However, setting the maximum transfer size on the server to 0 is likely to cause clients to malfunction or just decide not to attempt to talk to the server.

There is also a limit on the maximum transfer size when using NFS over the UDP transport. UDP has a hard limit of 64 KB per datagram. This 64 KB must include the RPC header as well as other NFS information, in addition to the data portion of the request. Setting the limit too high might result in errors from UDP and communication problems between the client and the server.

When to Change
To tune the size of data transmitted over the network. In general, the nfs:nfs3_bsize parameter should also be updated to reflect changes in this parameter.

For example, when you attempt to increase the transfer size beyond 32 KB, update nfs:nfs3_bsize to reflect the increased value. Otherwise, no change in the over-the-wire request size is observed. For more information, see "nfs:nfs3_bsize" on page 114.
If you want to use a smaller transfer size than the default transfer size, use the `mount` command’s `-wsize` or `-rsize` option on a per-file system basis.

**Commitment Level** Unstable

### `nfs:nfs4_max_transfer_size`

**Description** Controls the maximum size of the data portion of an NFS version 4 READ, WRITE, READDIR, or READDIRPLUS request. This parameter controls both the maximum size of the request that the server returns as well as the maximum size of the request that the client generates.

**Data Type** Integer (32-bit)

**Default** 32,768 (32 KB)

**Range** 0 to $2^{31} - 1$

**Units** Bytes

**Dynamic?** Yes, but this parameter is set per file system at mount time. To affect a particular file system, unmount and mount the file system after changing this parameter.

**Validation** None. However, setting the maximum transfer size on the server to 0 is likely to cause clients to malfunction or just decide not to attempt to talk to the server.

There is also a limit on the maximum transfer size when using NFS over the UDP transport. For more information on the maximum for UDP, see “`nfs:nfs3_max_transfer_size`” on page 120.

**When to Change** To tune the size of data transmitted over the network. In general, the `nfs:nfs4_bsize` parameter should also be updated to reflect changes in this parameter.

For example, when you attempt to increase the transfer size beyond 32 KB, update `nfs:nfs4_bsize` to reflect the increased value. Otherwise, no change in the over-the-wire request size is observed. For more information, see “`nfs:nfs4_bsize`” on page 114.

If you want to use a smaller transfer size than the default transfer size, use the `mount` command’s `-wsize` or `-rsize` option on a per-file system basis.

**Commitment Level** Unstable
**nfs:nfs3_max_transfer_size_clts**

Description: Controls the maximum size of the data portion of an NFS version 3 READ, WRITE, READDIR, or READDIRPLUS request over UDP. This parameter controls both the maximum size of the request that the server returns as well as the maximum size of the request that the client generates.

Data Type: Integer (32-bit)

Default: 32,768 (32 KB)

Range: 0 to $2^{31} - 1$

Units: Bytes

Dynamic?: Yes, but this parameter is set per file system at mount time. To affect a particular file system, unmount and mount the file system after changing this parameter.

Validation: None. However, setting the maximum transfer size on the server to 0 is likely to cause clients to malfunction or just decide not to attempt to talk to the server.

When to Change: Do not change this parameter.

Commitment Level: Unstable

**nfs:nfs3_max_transfer_size_cots**

Description: Controls the maximum size of the data portion of an NFS version 3 READ, WRITE, READDIR, or READDIRPLUS request over TCP. This parameter controls both the maximum size of the request that the server returns as well as the maximum size of the request that the client generates.

Data Type: Integer (32-bit)

Default: 1,048,576 bytes

Range: 0 to $2^{31} - 1$

Units: Bytes

Dynamic?: Yes, but this parameter is set per file system at mount time. To affect a particular file system, unmount and mount the file system after changing this parameter.
Validation  None. However, setting the maximum transfer size on the server to 0 is likely to cause clients to malfunction or just decide not to attempt to talk to the server.

When to Change  Do not change this parameter unless transfer sizes larger than 1 Mbyte are preferred.

Commitment Level  Unstable

### rpcmod Module Parameters

This section describes NFS parameters for the rpcmod module.

**rpcmod:clnt_max_conns**

**Description**  Controls the number of TCP connections that the NFS client uses when communicating with each NFS server. The kernel RPC is constructed so that it can multiplex RPCs over a single connection. However, multiple connections can be used, if preferred.

**Data Type**  Integer (32-bit)

**Default**  1

**Range**  1 to $2^{31} - 1$

**Units**  Connections

**Dynamic?**  Yes

**Validation?**  None

**When to Change**  In general, one connection is sufficient to achieve full network bandwidth. However, if TCP cannot utilize the bandwidth offered by the network in a single stream, then multiple connections might increase the throughput between the client and the server.

Increasing the number of connections doesn’t come without consequences. Increasing the number of connections also increases kernel resource usage needed to keep track of each connection.

**Commitment Level**  Unstable
**rpcmod:clnt_idle_timeout**

Description: Controls the duration of time on the client that a connection between the client and server is allowed to remain idle before being closed.

Data Type: Long integer (64-bit)

Default: 300,000 milliseconds (5 minutes)

Range: 0 to \(2^{63} - 1\)

Units: Milliseconds

Dynamic?: Yes

Validation: None

When to Change: Use this parameter to change the time that idle connections are allowed to exist on the client before being closed. You might want to close connections at a faster rate to avoid consuming system resources.

Commitment Level: Unstable

---

**rpcmod:svc_idle_timeout**

Description: Controls the duration of time on the server that a connection between the client and server is allowed to remain idle before being closed.

Data Type: Long integer (64-bit)

Default: 360,000 milliseconds (6 minutes)

Range: 0 to \(2^{63} - 1\)

Units: Milliseconds

Dynamic?: Yes

Validation: None

When to Change: Use this parameter to change the time that idle connections are allowed to exist on the server before being closed. You might want to close connections at a faster rate to avoid consuming system resources.

Commitment Level: Unstable

---

**rpcmod:svc_default_stksize**

Description: Sets the size of the kernel stack for kernel RPC service threads.
**Data Type**  Integer (32-bit)

**Default**  The default value is 0. This value means that the stack size is set to the system default.

**Range**  0 to $2^{31} - 1$

**Units**  Bytes

**Dynamic?**  Yes, for all new threads that are allocated. The stack size is set when the thread is created. Therefore, changes to this parameter do not affect existing threads but are applied to all new threads that are allocated.

**Validation**  None

**When to Change**  Very deep call depths can cause the stack to overflow and cause red zone faults. The combination of a fairly deep call depth for the transport, coupled with a deep call depth for the local file system, can cause NFS service threads to overflow their stacks.

Set this parameter to a multiple of the hardware page size on the platform.

**Commitment Level**  Unstable

---

**rpcmod:maxdupreqs**

**Description**  Controls the size of the duplicate request cache that detects RPC-level retransmissions on connectionless transports. This cache is indexed by the client network address and the RPC procedure number, program number, version number, and transaction ID. This cache avoids processing retransmitted requests that might not be idempotent.

**Data Type**  Integer (32-bit)

**Default**  8192

**Range**  1 to $2^{31} - 1$

**Units**  Requests

**Dynamic?**  The cache is dynamically sized, but the hash queues that provide fast access to the cache are statically sized. Making the cache very large might result in long search times to find entries in the cache.

Do not set the value of this parameter to 0. This value prevents the NFS server from handling non idempotent requests.

**Validation**  None
rpcmod Module Parameters

**rpcmod:cotsmaxdupreqs**

**Description**
Controls the size of the duplicate request cache that detects RPC-level retransmissions on connection-oriented transports. This cache is indexed by the client network address and the RPC procedure number, program number, version number, and transaction ID. This cache avoids processing retransmitted requests that might not be idempotent.

**Data Type**
Integer (32-bit)

**Default**
8192

**Range**
1 to $2^{31} - 1$

**Units**
Requests

**Dynamic?**
Yes

**Validation**
The cache is dynamically sized, but the hash queues that provide fast access to the cache are statically sized. Making the cache very large might result in long search times to find entries in the cache.

Do not set the value of this parameter to 0. It prevents the NFS server from handling non-idempotent requests.

**When to Change**
Examine the value of this parameter if false failures are encountered by NFS clients. For example, if an attempt to create a directory fails, but the directory is actually created, perhaps that retransmitted *MKDIR* request was not detected by the server.

The size of the cache should match the load on the server. The cache records non-idempotent requests and so only needs to track a portion of the total requests. The cache does need to hold the information long enough to be able to detect a retransmission by the client. Typically, the client timeout for connectionless transports is relatively short, starting around 1 second and increasing to about 20 seconds.
of the total requests. It does need to hold the information long enough to be able to detect a retransmission on the part of the client. Typically, the client timeout for connection oriented transports is very long, about 1 minute. Thus, entries need to stay in the cache for fairly long times.

| Commitment Level | Unstable |
Internet Protocol Suite Tunable Parameters

This chapter describes various Internet Protocol suite properties.

- “IP Tunable Parameters” on page 130
- “TCP Tunable Parameters” on page 136
- “UDP Tunable Parameters” on page 154
- “IPQoS Tunable Parameter” on page 156
- “SCTP Tunable Parameters” on page 157
- “Per-Route Metrics” on page 168

Where to Find Tunable Parameter Information

<table>
<thead>
<tr>
<th>Tunable Parameter</th>
<th>For Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle Solaris kernel tunable parameters</td>
<td>Chapter 2, “Oracle Solaris Kernel Tunable Parameters”</td>
</tr>
<tr>
<td>Oracle Solaris ZFS tunable parameters</td>
<td>Chapter 3, “Oracle Solaris ZFS Tunable Parameters”</td>
</tr>
<tr>
<td>NFS tunable parameters</td>
<td>Chapter 4, “NFS Tunable Parameters”</td>
</tr>
</tbody>
</table>

Overview of Tuning IP Suite Parameters

You can set all of the tuning parameters described in this chapter by using the `ipadm` command except for the following parameters:

- “ipcl_conn_hash_size” on page 149
- “ip_squeue_worker_wait” on page 149
- “ip_squeue_fanout” on page 134

These parameters can only be set in the `/etc/system` file.
Use the following syntax to set TCP/IP parameters by using the `ipadm` command:

```bash
# ipadm set-prop -p parameter ip|ipv4|ipv6|tcp|udp|sctp
```

For example:

```bash
# ipadm set-prop -p extra_priv_ports=1047 tcp
# ipadm show-prop -p extra_priv_ports tcp
```

<table>
<thead>
<tr>
<th>PROTO</th>
<th>PROPERTY</th>
<th>PERM</th>
<th>CURRENT</th>
<th>PERSISTENT</th>
<th>DEFAULT</th>
<th>POSSIBLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>tcp</td>
<td>extra_priv_ports</td>
<td>rw</td>
<td>1047</td>
<td>1047</td>
<td>2049,4045</td>
<td>1-65535</td>
</tr>
</tbody>
</table>

For more information, see `ipadm(1M)`.

Use the following syntax to set TCP/IP parameters by using the `ndd` command:

```bash
# ndd -set driver parameter value
```

For more information, see `ndd(1M)`.

**IP Suite Parameter Validation**

All parameters described in this section are checked to verify that they fall in the parameter range. The parameter’s range is provided with the description for each parameter.

**Internet Request for Comments (RFCs)**

Internet protocol and standard specifications are described in RFC documents. You can review RFCs from the following site:

[https://www.ietf.org/rfc.html](https://www.ietf.org/rfc.html)

At this site, you can browse RFC topics by entering an RFC number or an internet-draft file name in the IETF Repository Retrieval search field.

**IP Tunable Parameters**

**_icmp_err_interval and _icmp_err_burst**

**Description**

Controls the rate of IP in generating ICMP error messages. IP generates only up to _icmp_err_burst IP error messages in any _icmp_err_interval.

The _icmp_err_interval parameter protects IP from denial of service attacks. Setting this parameter to 0 disables rate limiting. It does not disable the generation of error messages.
### Default

100 milliseconds for `_icmp_err_interval`

10 error messages for `_icmp_err_burst`

### Range

0 – 99,999 milliseconds for `_icmp_err_interval`

1 – 99,999 error messages for `_icmp_err_burst`

### Dynamic?

Yes

### When to Change

If you need a higher error message generation rate for diagnostic purposes.

### Commitment Level

Unstable

### Change History

For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

---

### `_respond_to_echo_broadcast` and `_respond_to_echo_multicast (ipv4 or ipv6)`

**Description**

Controls whether IP responds to a broadcast ICMPv4 echo request or a IPv6 multicast ICMPv6 echo request.

**Default**

1 (enabled)

**Range**

0 (disabled) or 1 (enabled)

**Dynamic?**

Yes

**When to Change**

If you do not want this behavior for security reasons, disable it.

**Commitment Level**

Unstable

**Change History**

For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

---

### `_send_redirects (ipv4 or ipv6)`

**Description**

Controls whether IPv4 or IPv6 sends out ICMPv4 or ICMPv6 redirect messages.

**Default**

1 (enabled)

**Range**

0 (disabled) or 1 (enabled)

**Dynamic?**

Yes

**When to Change**

If you do not want this behavior for security reasons, disable it.
### Commitment Level
Unstable

### Change History
For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

## forwarding (ipv4 or ipv6)

**Description** Controls whether IPv4 or IPv6 forwards packets with source IPv4 routing options or IPv6 routing headers.

**Default** 0 (disabled or off)

**Range** 0 (disabled or off) or 1 (enabled or on)

**Dynamic?** Yes

**When to Change** Keep this parameter disabled to prevent denial of service attacks.

**Commitment Level** Unstable

**Change History** For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

## ttl

**Description** Controls the time to live (TTL) value in the IPv4 header for the outbound IPv4 packets on an IP association.

**Default** 255

**Range** 1 to 255

**Dynamic?** Yes

**When to Change** Generally, you do not need to change this value.

**Commitment Level** Unstable

**Change History** For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

## hoplimit (ipv6)

**Description** Sets the value of the hop limit in the IPv6 header for the outbound IPv6 packets on an IP association.

**Default** 255
Range 0 to 255
Dynamic? Yes
When to Change Generally, you do not need to change this value.
Commitment Level Unstable
Change History For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

_addrs_per_if
Description Defines the maximum number of logical IP interfaces associated with a real interface.
Default 256
Range 1 to 8,192
Dynamic? Yes
When to Change Do not change the value. If more logical interfaces are required, you might consider increasing the value. However, recognize that this change might have a negative impact on IP’s performance.
Commitment Level Unstable
Change History For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

hostmodel (ipv4 or ipv6)
Description Controls send and receive behavior for IPv4 or IPv6 packets on a multi-homed system. This property can have the following values: weak, strong, and src-priority. The default value is weak.
Default weak
Range weak, strong, or src-priority
- weak
  - Outgoing packets - The source address of the packet going out need not match the address configured on the outgoing interface.
- **Incoming packets** - The destination address of the incoming packet need not match the address configured on the incoming interface.

- **strong**
  - **Outgoing packets** - The source address of the packet going out must match the address configured on the outgoing interface.

- **Incoming packets** - The destination address of the incoming packet must match the address configured on the incoming interface.

- **src-priority**
  - **Outgoing packets** - If multiple routes for the IP destination in the packet are available, the system prefers routes where the IP source address in the packet is configured on the outgoing interface.

  If no such route is available, the system falls back to selecting the best route, as with the weak $ES$ case.

  - **Incoming packets** - The destination address of the incoming packet must be configured on any one of the host’s interface.

Dynamic? Yes
When to Change If a machine has interfaces that cross strict networking domains (for example, a firewall or a VPN node), set this parameter to strong.
Commitment Level Unstable
Change History For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

### ip_queue_fanout

**Description**
Determines the mode of associating TCP/IP connections with queues.

A value of 0 associates a new TCP/IP connection with the CPU that creates the connection. A value of 1 associates the connection with multiple queues that belong to different CPUs.

**Default**
1

**Range**
0 or 1

**Dynamic?** Yes
When to Change Consider setting this parameter to 1 to spread the load across all CPUs in certain situations. For example, when the number of CPUs exceed the number of NICs, and one CPU is not capable of handling the network load of a single NIC, change this parameter to 1.

This property can only be set in the /etc/system file.

Zone Configuration This parameter can only be set in the global zone.

Commitment Level Unstable

**IP Tunable Parameters With Additional Cautions**

Changing the following parameters is not recommended.

### _pathmtu_interval_

- **Description**: Specifies the interval in milliseconds when IP flushes the path maximum transfer unit (PMTU) discovery information, and tries to rediscover PMTU.
- **Default**: 1200 milliseconds (20 minutes)
- **Range**: 2.999999999
- **Dynamic?**: Yes
- **When to Change**: Do not change this value.
- **Commitment Level**: Unstable
- **Change History**: For information, see “IP Parameter Name Changes (Oracle Solaris 11)” on page 180.

### _icmp_return_data_bytes (ipv4 or ipv6)_

- **Description**: When IPv4 or IPv6 sends an ICMPv4 or ICMPv6 error message, it includes the IP header of the packet that caused the error message. This parameter controls how many extra bytes of the packet beyond the IPv4 or IPv6 header are included in the ICMPv4 or ICMPv6 error message.
- **Default**: 64 for IPv4
  1280 for IPv6
TCP Tunable Parameters

<table>
<thead>
<tr>

<th>Dynamic?</th>
<th>When to Change</th>
<th>Commitment Level</th>
<th>Change History</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>deferred_ack_interval</em></td>
<td>Specifies the time-out value for the TCP-delayed acknowledgment (ACK) timer for hosts that are not directly connected.</td>
<td>100 milliseconds</td>
<td>1 millisecond to 1 minute</td>
<td>Yes</td>
<td>Do not increase this value to more than 500 milliseconds. Increase the value under the following circumstances:</td>
<td>Unstable</td>
<td>For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.</td>
</tr>
</tbody>
</table>
_local_dack_interval_

**Description**
Specifies the time-out value for TCP-delayed acknowledgment (ACK) timer for hosts that are directly connected.

Refer to RFC 1122, 4.2.3.2.

**Default**
50 milliseconds

**Range**
10 milliseconds to 500 milliseconds

**Dynamic?**
Yes

**When to Change**
Do not increase this value to more than 500 milliseconds.

Increase the value under the following circumstances:
- Slow network links (less than 57.6 Kbps) with greater than 512 bytes maximum segment size (MSS)
- The interval for receiving more than one TCP segment is short

**Commitment Level**
Unstable

**Change History**
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

_deferred_ack_max_

**Description**
Specifies the maximum number of TCP segments received from remote destinations (not directly connected) before an acknowledgment (ACK) is generated. TCP segments are measured in units of maximum segment size (MSS) for individual connections. If set to 0 or 1, no ACKs are delayed, assuming all segments are 1 MSS long. The actual number is dynamically calculated for each connection. The value is the default maximum.

**Default**
2

**Range**
0 to 16

**Dynamic?**
Yes

**When to Change**
Do not change the value. In some circumstances, when the network traffic becomes very bursty because of the delayed ACK effect, decrease the value. Do not decrease this value below 2.

**Commitment Level**
Unstable
_local_dacks_max

**Description**
Specifies the maximum number of TCP segments received from directly connected destinations before an acknowledgment (ACK) is generated. TCP segments are measured in units of maximum segment size (MSS) for individual connections. If set to 0 or 1, it means no ACKs are delayed, assuming all segments are 1 MSS long. The actual number is dynamically calculated for each connection. The value is the default maximum.

**Default**
8

**Range**
0 to 16

**Dynamic?**
Yes

**When to Change**
Do not change the value. In some circumstances, when the network traffic becomes very bursty because of the delayed ACK effect, decrease the value. Do not decrease this value below 2.

**Commitment Level**
Unstable

**Change History**
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

_wsacle_always

**Description**
When this parameter is enabled, which is the default setting, TCP always sends a SYN segment with the window scale option, even if the window scale option value is 0. Note that if TCP receives a SYN segment with the window scale option, even if the parameter is disabled, TCP responds with a SYN segment with the window scale option. In addition, the option value is set according to the receive window size.

Refer to RFC 1323 for the window scale option.

**Default**
1 (enabled)

**Range**
0 (disabled) or 1 (enabled)

**Dynamic?**
Yes
When to Change
If there is an interoperability problem with an old TCP stack that does not support the window scale option, disable this parameter.

Commitment Level
Unstable

Change History
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

_tstamp_always
Description
If set to 1, TCP always sends a SYN segment with the timestamp option. Note that if TCP receives a SYN segment with the timestamp option, TCP responds with a SYN segment with the timestamp option even if the parameter is set to 0.

Default
0 (disabled)

Range
0 (disabled) or 1 (enabled)

Dynamic?
Yes

When to Change
If getting an accurate measurement of round-trip time (RTT) and TCP sequence number wraparound is a problem, enable this parameter.

Refer to RFC 1323 for more reasons to enable this option.

Commitment Level
Unstable

Change History
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

send_buf
Description
Defines the default send window size in bytes. Refer to “Per-Route Metrics” on page 168 for a discussion of setting a different value on a per-route basis. See also “max_buf” on page 140.

Default
49,152

Range
4,096 to the current value of ”max_buf” on page 140

Dynamic?
Yes

When to Change
An application can use setsockopt(3XNET) SO_SNDBUF to change the individual connection’s send buffer.

Commitment Level
Unstable
TCP Tunable Parameters

Change History
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

**recv_buf**

Description
Defines the default receive window size in bytes. Refer to “Per-Route Metrics” on page 168 for a discussion of setting a different value on a per-route basis. See also "max_buf" on page 140 and "recv_hiwat_minmss" on page 153.

Default
128,000

Range
2,048 to the current value of “max_buf” on page 140

Dynamic?
Yes

When to Change
An application can use setsockopt(3XNET) SO_RCVBUF to change the individual connection’s receive buffer.

Commitment Level
Unstable

Change History
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

**max_buf**

Description
Defines the maximum send and receive buffer size in bytes. This parameter controls how large the send and receive buffers are set to by an application that uses setsockopt(3XNET).

Default
1,048,576

Range
128,000 to 1,073,741,824

Dynamic?
Yes

When to Change
If TCP connections are being made in a high-speed network environment, increase the value to match the network link speed.

Commitment Level
Unstable

Change History
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.
### _cwnd_max

**Description**

Defines the maximum value of the TCP congestion window (cwnd) in bytes.

For more information on the TCP congestion window, refer to RFC 1122 and RFC 2581.

**Default**

1,048,576

**Range**

128 to 1,073,741,824

**Dynamic?**

Yes

**When to Change**

Even if an application uses `setsockopt(3XNET)` to change the window size to a value higher than `_cwnd_max`, the actual window used can never grow beyond `_cwnd_max`. Thus, `_max_buf` should be greater than `_cwnd_max`.

**Commitment Level**

Unstable

**Change History**

For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

### _slow_start_initial

**Description**

Defines the maximum initial congestion window (cwnd) size in the maximum segment size (MSS) of a TCP connection.

Refer to RFC 2414 on how the initial congestion window size is calculated.

**Default**

10

**Range**

1 to 10

**Dynamic?**

Yes

**When to Change**

Do not change the value.

If the initial cwnd size causes network congestion under special circumstances, decrease the value.

**Commitment Level**

Unstable

**Change History**

For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.
**_local_slow_start_initial_**

**Description**
Defines the initial congestion window (cwnd) size in the maximum segment size (MSS) of a TCP connection between directly connected hosts.

**Default**
10

**Range**
1 to 16,384

**Dynamic?**
Yes

**When to Change**
Consider increasing this parameter value if applications would benefit from a larger initial window.

**Commitment Level**
Unstable

**Change History**
For information, see “_local_slow_start_initial_” on page 180.

**_slow_start_after_idle_**

**Description**
The congestion window size in the maximum segment size (MSS) of a TCP connection after it has been idled (no segment received) for a period of one retransmission timeout (RTO).

Refer to RFC 2414 on how the initial congestion window size is calculated.

**Default**
4

**Range**
1 to 16,384

**Dynamic?**
Yes

**When to Change**
For more information, see “_slow_start_initial_” on page 141.

**Commitment Level**
Unstable

**Change History**
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

**sack**

**Description**
If set to 2, TCP always sends a SYN segment with the selective acknowledgment (SACK) permitted option. If TCP receives a SYN segment with a SACK-permitted option and this parameter is set to 1, TCP responds with a SACK-permitted option. If the parameter is set to
TCP does not send a SACK-permitted option, regardless of whether the incoming segment contains the SACK permitted option. Refer to RFC 2018 for information on the SACK option.

**Default** 2 (active enabled)

**Range** 0 (disabled), 1 (passive enabled), or 2 (active enabled)

**Dynamic?** Yes

**When to Change** SACK processing can improve TCP retransmission performance so it should be actively enabled. Sometimes, the other side can be confused with the SACK option actively enabled. If this confusion occurs, set the value to 1 so that SACK processing is enabled only when incoming connections allow SACK processing.

**Commitment Level** Unstable

**Change History** For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

---

**rev_src_routes**

**Description** If set to 0, TCP does not reverse the IP source routing option for incoming connections for security reasons. If set to 1, TCP does the normal reverse source routing.

**Default** 0 (disabled)

**Range** 0 (disabled) or 1 (enabled)

**Dynamic?** Yes

**When to Change** If IP source routing is needed for diagnostic purposes, enable it.

**Commitment Level** Unstable

**Change History** For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

---

**time_wait_interval**

**Description** Specifies the time in milliseconds that a TCP connection stays in TIME-WAIT state.

For more information, refer to RFC 1122, 4.2.2.13.
### ecn

**Description** Controls Explicit Congestion Notification (ECN) support.

If this parameter is set to 0, TCP does not negotiate with a peer that supports the ECN mechanism.

If this parameter is set to 1 when initiating a connection, TCP does not tell a peer that it supports ECN mechanism.

However, TCP tells a peer that it supports ECN mechanism when accepting a new incoming connection request if the peer indicates that it supports ECN mechanism in the SYN segment.

If this parameter is set to 2, in addition to negotiating with a peer on the ECN mechanism when accepting connections, TCP indicates in the outgoing SYN segment that it supports the ECN mechanism when TCP makes active outgoing connections.

Refer to RFC 3168 for information on ECN.

<table>
<thead>
<tr>
<th>Default</th>
<th>1 (passive enabled)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0 (disabled), 1 (passive enabled), or 2 (active enabled)</td>
</tr>
<tr>
<td>Dynamic?</td>
<td>Yes</td>
</tr>
<tr>
<td>When to Change</td>
<td>ECN can help TCP better handle congestion control. However, there are existing TCP implementations, firewalls, NATs, and other network devices that are confused by this mechanism. These devices do not comply to the IETF standard.</td>
</tr>
</tbody>
</table>
Because of these devices, the default value of this parameter is set to 1. In rare cases, passive enabling can still cause problems. Set the parameter to 0 only if absolutely necessary.

Commitment Level: Unstable

Change History: For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

_conn_req_max_q

Description: Specifies the default maximum number of pending TCP connections for a TCP listener waiting to be accepted by accept(3SOCKET). See also “_conn_req_max_q” on page 146.

Default: 128

Range: 1 to 4,294,967,295

Dynamic?: Yes

When to Change: For applications such as web servers that might receive several connection requests, the default value might be increased to match the incoming rate.

Do not increase the parameter to a very large value. The pending TCP connections can consume excessive memory. Also, if an application cannot handle that many connection requests fast enough because the number of pending TCP connections is too large, new incoming requests might be denied.

Note that increasing _conn_req_max_q does not mean that applications can have that many pending TCP connections. Applications can use listen(3SOCKET) to change the maximum number of pending TCP connections for each socket. This parameter is the maximum an application can use listen() to set the number to. Thus, even if this parameter is set to a very large value, the actual maximum number for a socket might be much less than _conn_req_max_q, depending on the value used in listen().

Commitment Level: Unstable

Change History: For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.
### _conn_req_max_q0

**Description**

Specifies the default maximum number of incomplete (three-way handshake not yet finished) pending TCP connections for a TCP listener.

For more information on TCP three-way handshake, refer to RFC 793. See also “_conn_req_max_q” on page 145.

**Default**

1,024

**Range**

0 to 4,294,967,295

**Dynamic?**

Yes

**When to Change**

For applications such as web servers that might receive excessive connection requests, you can increase the default value to match the incoming rate.

The following explains the relationship between _conn_req_max_q0 and the maximum number of pending connections for each socket.

When a connection request is received, TCP first checks if the number of pending TCP connections (three-way handshake is done) waiting to be accepted exceeds the maximum (N) for the listener. If the connections are excessive, the request is denied. If the number of connections is allowable, then TCP checks if the number of incomplete pending TCP connections exceeds the sum of N and _conn_req_max_q0. If it does not, the request is accepted. Otherwise, the oldest incomplete pending TCP request is dropped.

**Commitment Level**

Unstable

**Change History**

For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

### _conn_req_min

**Description**

Specifies the default minimum value for the maximum number of pending TCP connection requests for a listener waiting to be accepted. This is the lowest maximum value of listen(3SOCKET) that an application can use.

**Default**

1

**Range**

1 to 1,024

**Dynamic?**

Yes
When to Change
This parameter can be a solution for applications that use listen(3SOCKET) to set the maximum number of pending TCP connections to a value too low. Increase the value to match the incoming connection request rate.

Commitment Level
Unstable

Change History
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

_rst_sent_rate_enabled

Description
If this parameter is set to 1, the maximum rate of sending a RST segment is controlled by the ipmadm parameter, _rst_sent_rate. If this parameter is set to 0, no rate control when sending a RST segment is available.

Default
1 (enabled)

Range
0 (disabled) or 1 (enabled)

Dynamic?
Yes

When to Change
This tunable helps defend against denial of service attacks on TCP by limiting the rate by which a RST segment is sent out. The only time this rate control should be disabled is when strict conformance to RFC 793 is required.

Commitment Level
Unstable

Change History
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

_rst_sent_rate

Description
Sets the maximum number of RST segments that TCP can send out per second.

Default
40

Range
0 to 4,294,967,295

Dynamic?
Yes

When to Change
In a TCP environment, there might be a legitimate reason to generate more RSTs than the default value allows. In this case, increase the default value of this parameter.
Commitment Level: Unstable

**Change History**
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

---

**smallest_anon_port**

**Description**
This parameter controls the smallest port number TCP can select as an ephemeral port. An application can use an ephemeral port when it creates a connection with a specified protocol and it does not specify a port number. Ephemeral ports are not associated with a specific application. When the connection is closed, the port number can be reused by a different application.

**Unit**
Port number

**Default**
32,768

**Range**
1,024 to 65,535

**Dynamic?**
Yes

**When to Change**
When a larger ephemeral port range is required.

---

**largest_anon_port**

**Description**
This parameter controls the largest port number TCP can select as an ephemeral port. An application can use an ephemeral port when it creates a connection with a specified protocol and it does not specify a port number. Ephemeral ports are not associated with a specific application. When the connection is closed, the port number can be reused by a different application.

**Unit**
Port number

**Default**
65,535

**Range**
32,768 to 65,535

**Dynamic?**
Yes

**When to Change**
When a larger ephemeral port range is required.

---

**Commitment Level**
Unstable

**Change History**
For information, see “[tcp,sctp,udp]_smallest_anon_port and [tcp,sctp,udp]_largest_anon_port” on page 180.
TCP/IP Parameters Set in the /etc/system File

The following parameters can be set only in the /etc/system file. After the file is modified, reboot the system.

For example, the following entry sets the ipcl_conn_hash_size parameter:

```
set ip:ipcl_conn_hash_size=value
```

**ipcl_conn_hash_size**

**Description** Controls the size of the connection hash table used by IP. The default value of 0 means that the system automatically sizes an appropriate value for this parameter at boot time, depending on the available memory.

**Data Type** Unsigned integer

**Default** 0

**Range** 0 to 82,500

**Dynamic?** No. The parameter can only be changed at boot time.

**When to Change** If the system consistently has tens of thousands of TCP connections, the value can be increased accordingly. Increasing the hash table size means that more memory is wired down, thereby reducing available memory to user applications.

**Commitment Level** Unstable

**ip_queue_worker_wait**

**Description** Governs the maximum delay in waking up a worker thread to process TCP/IP packets that are enqueued on a queue. An *queue* is a serialization queue that is used by the TCP/IP kernel code to process TCP/IP packets.

**Default** 10 milliseconds

**Range** 0 – 50 milliseconds

**Dynamic?** Yes
When to Change  
Consider tuning this parameter if latency is an issue, and network traffic is light. For example, if the machine serves mostly interactive network traffic.

The default value usually works best on a network file server, a web server, or any server that has substantial network traffic.

Zone Configuration  
This parameter can only be set in the global zone.

Commitment Level  
Unstable

**TCP Parameters With Additional Cautions**

Changing the following parameters is not recommended.

**_keepalive_interval**

Description  
This `ipadm` parameter sets a probe interval that is first sent out after a TCP connection is idle on a system-wide basis.

Solaris supports the TCP keep-alive mechanism as described in RFC 1122. This mechanism is enabled by setting the `SO_KEEPALIVE` socket option on a TCP socket.

If `SO_KEEPALIVE` is enabled for a socket, the first keep-alive probe is sent out after a TCP connection is idle for two hours, the default value of the `tcp_keepalive_interval` parameter. If the peer does not respond to the probe after eight minutes, the TCP connection is aborted. For more information, refer to “_rexmit_interval_initial” on page 151.

You can also use the `TCP_KEEPALIVE_THRESHOLD` socket option on individual applications to override the default interval so that each application can have its own interval on each socket. The option value is an unsigned integer in milliseconds. See also `tcp(7P)`.

Default  
2 hours

Range  
10 seconds to 10 days

Units  
Unsigned integer (milliseconds)

Dynamic?  
Yes

When to Change  
Do not change the value. Lowering it may cause unnecessary network traffic and might also increase the chance of premature termination of the connection because of a transient network problem.
<table>
<thead>
<tr>
<th>Commitment Level</th>
<th>Unstable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change History</td>
<td>For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.</td>
</tr>
</tbody>
</table>

### _ip_abort_interval

**Description**

Specifies the default total retransmission timeout value for a TCP connection. For a given TCP connection, if TCP has been retransmitting for _ip_abort_interval period of time and it has not received any acknowledgment from the other endpoint during this period, TCP closes this connection.

For TCP retransmission timeout (RTO) calculation, refer to RFC 1122, 4.2.3. See also “_rexmit_interval_max” on page 152.

<table>
<thead>
<tr>
<th>Default</th>
<th>5 minutes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>500 milliseconds to 1193 hours</td>
</tr>
<tr>
<td>Dynamic?</td>
<td>Yes</td>
</tr>
<tr>
<td>When to Change</td>
<td>Do not change this value. See “_rexmit_interval_max” on page 152 for exceptions.</td>
</tr>
<tr>
<td>Commitment Level</td>
<td>Unstable</td>
</tr>
<tr>
<td>Change History</td>
<td>For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.</td>
</tr>
</tbody>
</table>

### _rexmit_interval_initial

**Description**

Specifies the default initial retransmission timeout (RTO) value for a TCP connection. Refer to “Per-Route Metrics” on page 168 for a discussion of setting a different value on a per-route basis.

<table>
<thead>
<tr>
<th>Default</th>
<th>1000 milliseconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>1 millisecond to 20000 milliseconds</td>
</tr>
<tr>
<td>Dynamic?</td>
<td>Yes</td>
</tr>
<tr>
<td>When to Change</td>
<td>Do not change this value. Lowering the value can result in unnecessary retransmissions.</td>
</tr>
<tr>
<td>Commitment Level</td>
<td>Unstable</td>
</tr>
<tr>
<td>Change History</td>
<td>For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.</td>
</tr>
</tbody>
</table>
### _rexmit_interval_max_

**Description**
Defines the default maximum retransmission timeout value (RTO). The calculated RTO for all TCP connections cannot exceed this value. See also "_ip_abort_interval" on page 151.

**Default**
6000 milliseconds

**Range**
1 millisecond to 7200000 milliseconds

**Dynamic?**
Yes

**When to Change**
Do not change the value in a normal network environment.

If, in some special circumstances, the round-trip time (RTT) for a connection is about 10 seconds, you can increase this value. If you change this value, you should also change the _ip_abort_interval parameter. Change the value of _ip_abort_interval to at least four times the value of _rexmit_interval_max_.

**Commitment Level**
Unstable

**Change History**
For information, see "TCP Parameter Name Changes (Oracle Solaris 11)" on page 181.

### _rexmit_interval_min_

**Description**
Specifies the default minimum retransmission time out (RTO) value. The calculated RTO for all TCP connections cannot be lower than this value. See also "_rexmit_interval_max" on page 152.

**Default**
200 milliseconds

**Range**
1 millisecond to 7200000 milliseconds

**Dynamic?**
Yes

**When to Change**
Do not change the value in a normal network environment.

TCP’s RTO calculation should cope with most RTT fluctuations. If, in some very special circumstances, the round-trip time (RTT) for a connection is about 10 seconds, increase this value. If you change this value, you should change the _rexmit_interval_max parameter. Change the value of _rexmit_interval_max to at least eight times the value of _rexmit_interval_min_.

**Commitment Level**
Unstable

**Change History**
For information, see "TCP Parameter Name Changes (Oracle Solaris 11)" on page 181.
### _rexmit_interval_extra_

**Description**
Specifies a constant added to the calculated retransmission time out value (RTO).

**Default**
0 milliseconds

**Range**
0 to 7200000 milliseconds

**Dynamic?**
Yes

**When to Change**
Do not change the value.

When the RTO calculation fails to obtain a good value for a connection, you can change this value to avoid unnecessary retransmissions.

**Commitment Level**
Unstable

**Change History**
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

### _tstamp_if_wscale_

**Description**
If this parameter is set to 1, and the window scale option is enabled for a connection, TCP also enables the timestamp option for that connection.

**Default**
1 (enabled)

**Range**
0 (disabled) or 1 (enabled)

**Dynamic?**
Yes

**When to Change**
Do not change this value. In general, when TCP is used in high-speed network, protection against sequence number wraparound is essential. Thus, you need the timestamp option.

**Commitment Level**
Unstable

**Change History**
For information, see “TCP Parameter Name Changes (Oracle Solaris 11)” on page 181.

### _recv_hiwat_minmss_

**Description**
Controls the default minimum receive window size. The minimum is _recv_hiwat_minmss times the size of maximum segment size (MSS) of a connection.

**Default**
8

**Range**
1 to 65,536
## UDP Tunable Parameters

<tr>
<td>When to Change</td>
<td>Note that an application can use setsockopt(3XNET) SO_RCVBUF to change the size for an individual socket. In general, you do not need to change the default value.</td>
</tr>
</tbody>
</table>
Commitment Level | Unstable
--- | ---
Change History | For information, see “UDP Parameter Name Changes (Oracle Solaris 11)” on page 183.

**max_buf**

Description | Defines the maximum send and receive buffer size for a UDP socket. It controls how large the send and receive buffers are set to by an application that uses `getsockopt` (3SOCKET).
--- | ---
Default | 2,097,152
Range | 65,536 to 1,073,741,824
Dynamic? | Yes
When to Change | Increase the value of this parameter to match the network link speed if associations are being made in a high-speed network environment.
Commitment Level | Unstable
Change History | For information, see “UDP Parameter Name Changes (Oracle Solaris 11)” on page 183.

**smallest_anon_port**

Description | This parameter controls the smallest port number UDP can select as an ephemeral port. An application can use an ephemeral port when it creates a connection with a specified protocol and it does not specify a port number. Ephemeral ports are not associated with a specific application. When the connection is closed, the port number can be reused by a different application.
--- | ---
Unit | Port number
Default | 32,768
Range | 1,024 to 65,535
Dynamic? | Yes
When to Change | When a larger ephemeral port range is required.
Commitment Level | Unstable
Change History | For information, see “[tcp,sctp,udp]_smallest_anon_port and [tcp,sctp,udp]_largest_anon_port” on page 180.
**largest_anon_port**

**Description**
This parameter controls the largest port number UDP can select as an ephemeral port. An application can use an ephemeral port when it creates a connection with a specified protocol and it does not specify a port number. Ephemeral ports are not associated with a specific application. When the connection is closed, the port number can be reused by a different application.

**Unit**    Port number
**Default** 65,535
**Range** 32,768 to 65,535
**Dynamic?** Yes
**When to Change** When a larger ephemeral port range is required.
**Commitment Level** Unstable
**Change History** For information, see "[tcp,sctp,udp]_smallest_anon_port and [tcp,sctp,udp]_largest_anon_port" on page 180.

**IPQoS Tunable Parameter**

**_policy_mask**

**Description**
Enables or disables IPQoS processing in any of the following callout positions: forward outbound, forward inbound, local outbound, and local inbound. This parameter is a bitmask as follows:

<table>
<thead>
<tr>
<th>Not Used</th>
<th>Not Used</th>
<th>Not Used</th>
<th>Forward Outbound</th>
<th>Forward Inbound</th>
<th>Local Outbound</th>
<th>Local Inbound</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>X</td>
<td>X</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

A 1 in any of the position masks or disables IPQoS processing in that particular callout position. For example, a value of 0x01 disables IPQoS processing for all the local inbound packets.

**Default**
The default value is 0, meaning that IPQoS processing is enabled in all the callout positions.
Range 0 (0x00) to 15 (0x0F). A value of 15 indicates that IPQoS processing is disabled in all the callout positions.

Dynamic? Yes

When to Change If you want to enable or disable IPQoS processing in any of the callout positions.

Commitment Level Unstable

### SCTP Tunable Parameters

#### _max_init_retr_

**Description**  
Controls the maximum number of attempts an SCTP endpoint should make at resending an INIT chunk. The SCTP endpoint can use the SCTP initiation structure to override this value.

**Default** 8

**Range** 0 to 128

**Dynamic?** Yes

**When to Change** The number of INIT retransmissions depend on “_pa_max_retr_” on page 157. Ideally, _max_init_retr_ should be less than or equal to _pa_max_retr_.

**Commitment Level** Unstable

**Change History** For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

#### _pa_max_retr_

**Description**  
Controls the maximum number of retransmissions (over all paths) for an SCTP association. The SCTP association is aborted when this number is exceeded.

**Default** 10

**Range** 1 to 128

**Dynamic?** Yes

**When to Change** The maximum number of retransmissions over all paths depend on the number of paths and the maximum number of retransmission over
each path. Ideally, `sctp_pa_max_retr` should be set to the sum of
`_pp_max_retr` on page 158 over all available paths. For example, if
there are 3 paths to the destination and the maximum number of
retransmissions over each of the 3 paths is 5, then `pa_max_retr`
should be set to less than or equal to 15. (See the Note in Section 8.2,
RFC 2960.)

Commitment Level Unstable
Change History For information, see "SCTP Parameter Name Changes (Oracle Solaris
11)" on page 183.

**_pp_max_retr**

Description Controls the maximum number of retransmissions over a specific path.
When this number is exceeded for a path, the path (destination) is
considered unreachable.

Default 5
Range 1 to 128
Dynamic? Yes
When to Change Do not change this value to less than 5.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris
11)” on page 183.

**_cwnd_max**

Description Controls the maximum value of the congestion window for an SCTP
association.

Default 1,048,576
Range 128 to 1,073,741,824
Dynamic? Yes
When to Change Even if an application uses `setsockopt(3XNET)` to change the window
size to a value higher than `_cwnd_max`, the actual window used can
never grow beyond `_cwnd_max`. Thus, "max_buf" on page 163 should be
greater than `_cwnd_max`.

Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

`ipv4_ttl`

Description Controls the time to live (TTL) value in the IP version 4 header for the outbound IPv4 packets on an SCTP association.

Default 64
Range 1 to 255
Dynamic? Yes
When to Change Generally, you do not need to change this value.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

`ipv6_hoplimit`

Description Sets the value of the hop limit in the IPv6 header for the outbound IPv6 packets on an SCTP association.

Default 60
Range 0 to 255
Dynamic? Yes
When to Change Generally, you do not need to change this value.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

`heartbeat_interval`

Description Computes the interval between HEARTBEAT chunks to an idle destination, that is allowed to heartbeat.

An SCTP endpoint periodically sends an HEARTBEAT chunk to monitor the reachability of the idle destinations transport addresses of its peer.

Default 30 seconds
### _new_secret_interval_

**Description**
Determines when a new secret needs to be generated. The generated secret is used to compute the MAC for a cookie.

- **Default**: 2 minutes
- **Range**: 0 to 1,440 minutes
- **Dynamic?**: Yes
- **When to Change**: Refer to RFC 2960, section 5.1.3.
- **Commitment Level**: Unstable
- **Change History**: For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

### _initial_mtu_

**Description**
Determines the initial maximum send size for an SCTP packet including the length of the IP header.

- **Default**: 1500 bytes
- **Range**: 68 to 65,535
- **Dynamic?**: Yes
- **When to Change**: Increase this parameter if the underlying link supports frame sizes that are greater than 1500 bytes.
- **Commitment Level**: Unstable
- **Change History**: For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.
**_deferred_ack_interval_**

Description: Sets the time-out value for SCTP delayed acknowledgment (ACK) timer in milliseconds.

Default: 100 milliseconds

Range: 1 to 60,000 milliseconds

Dynamic?: Yes

When to Change: Refer to RFC 2960, section 6.2.

Commitment Level: Unstable

Change History: For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

**_ignore_path_mtu_**

Description: Enables or disables path MTU discovery.

Default: 0 (disabled)

Range: 0 (disabled) or 1 (enabled)

Dynamic?: Yes

When to Change: Enable this parameter if you want to ignore MTU changes along the path. However, doing so might result in IP fragmentation if the path MTU decreases.

Commitment Level: Unstable

Change History: For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

**_initial_ssthresh_**

Description: Sets the initial slow start threshold for a destination address of the peer.

Default: 1,048,576

Range: 1,024 to 4,294,967,295

Dynamic?: Yes

When to Change: Refer to RFC 2960, section 7.2.1.

Commitment Level: Unstable
### send_buf

<table>
<thead>
<tr>
<th>Description</th>
<th>Defines the default send buffer size in bytes. See also “max_buf” on page 163.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>102,400</td>
</tr>
<tr>
<td>Range</td>
<td>8,192 to the current value of “max_buf” on page 163</td>

### recv_buf

<table>
<thead>
<tr>
<th>Description</th>
<th>Defines the default receive buffer size in bytes. See also “max_buf” on page 163.</th>
</tr>
</thead>
</table>

---

SCTPTunableParameters

Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.
### max_buf

**Default**
102,400  

**Range**
8,192 to the current value of "max_buf" on page 163  

**Dynamic?**
Yes  

**When to Change**
An application can use `setsockopt(3XNET) SO_RCVBUF` to change the individual connection’s receive buffer.  

**Commitment Level**
Unstable  

**Change History**
For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

---

### _rto_min

**Description**
Sets the lower bound for the retransmission timeout (RTO) in milliseconds for all the destination addresses of the peer.  

**Default**
1,000  

**Range**
500 to 60,000  

**Dynamic?**
Yes  

**When to Change**
Refer to RFC 2960, section 6.3.1.  

**Commitment Level**
Unstable  

**Change History**
For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.
**_rto_max_**

Description: Controls the upper bound for the retransmission timeout (RTO) in milliseconds for all the destination addresses of the peer.

Default: 60,000
Range: 1,000 to 60,000,000
Dynamic?: Yes
When to Change: Refer to RFC 2960, section 6.3.1.
Commitment Level: Unstable
Change History: For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

**_rto_initial_**

Description: Controls the initial retransmission timeout (RTO) in milliseconds for all the destination addresses of the peer.

Default: 3,000
Range: 1,000 to 60,000,000
Dynamic?: Yes
When to Change: Refer to RFC 2960, section 6.3.1.
Commitment Level: Unstable
Change History: For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

**_cookie_life_**

Description: Sets the lifespan of a cookie in milliseconds.

Default: 60,000
Range: 10 to 60,000,000
Dynamic?: Yes
When to Change: Generally, you do not need to change this value. This parameter might be changed in accordance with “_rto_max_” on page 164.
Commitment Level: Unstable
Change History
For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

_max_in_streams
Description Controls the maximum number of inbound streams permitted for an SCTP association.
Default 32
Range 1 to 65,535
Dynamic? Yes
When to Change Refer to RFC 2960, section 5.1.1.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

_initial_out_streams
Description Controls the maximum number of outbound streams permitted for an SCTP association.
Default 32
Range 1 to 65,535
Dynamic? Yes
When to Change Refer to RFC 2960, section 5.1.1.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

_shutack_wait_bound
Description Controls the maximum time, in milliseconds, to wait for a SHUTDOWN ACK after having sent a SHUTDOWN chunk.
Default 60,000
Range 0 to 300,000
Dynamic? Yes
When to Change Generally, you do not need to change this value. This parameter might be changed in accordance with "_rto_max" on page 164.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

_maxburst
Description Sets the limit on the number of segments to be sent in a burst.
Default 4
Range 2 to 8
Dynamic? Yes
When to Change You do not need to change this parameter. You might change it for testing purposes.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

_addip_enabled
Description Enables or disables SCTP dynamic address reconfiguration.
Default 0 (disabled)
Range 0 (disabled) or 1 (enabled)
Dynamic? Yes
When to Change The parameter can be enabled if dynamic address reconfiguration is needed. Due to security implications, enable this parameter only for testing purposes.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

_prsctp_enabled
Description Enables or disables the partial reliability extension (RFC 3758) to SCTP.
Default 1 (enabled)
Range 0 (disabled) or 1 (enabled)
Dynamic? Yes
When to Change Disable this parameter if partial reliability is not supported in your SCTP environment.
Commitment Level Unstable
Change History For information, see “SCTP Parameter Name Changes (Oracle Solaris 11)” on page 183.

**smallest_anon_port**

Description This parameter controls the smallest port number SCTP can select as an ephemeral port. An application can use an ephemeral port when it creates a connection with a specified protocol and it does not specify a port number. Ephemeral ports are not associated with a specific application. When the connection is closed, the port number can be reused by a different application.

Unit Port number
Default 32,768
Range 1,024 to 65,535
Dynamic? Yes
When to Change When a larger ephemeral port range is required.
Commitment Level Unstable
Change History For information, see “[tcp,sctp,udp] _smallest_anon_port and [tcp,sctp,udp] _largest_anon_port” on page 180.

**largest_anon_port**

Description This parameter controls the largest port number SCTP can select as an ephemeral port. An application can use an ephemeral port when it creates a connection with a specified protocol and it does not specify a port number. Ephemeral ports are not associated with a specific application. When the connection is closed, the port number can be reused by a different application.

Unit Port number
Per-Route Metrics

You can use per-route metrics to associate some properties with IPv4 and IPv6 routing table entries.

For example, a system has two different network interfaces, a fast Ethernet interface and a gigabit Ethernet interface. The system default `recv_maxbuf` is 128,000 bytes. This default is sufficient for the fast Ethernet interface, but may not be sufficient for the gigabit Ethernet interface.

Instead of increasing the system’s default for `recv_maxbuf`, you can associate a different default TCP receive window size to the gigabit Ethernet interface routing entry. By making this association, all TCP connections going through the route will have the increased receive window size.

For example, the following is in the routing table (`netstat -rn`), assuming IPv4:

```
192.123.123.0 192.123.123.4 U 1 4 hme0
192.123.124.0 192.123.124.4 U 1 4 ge0
default 192.123.123.1 UG 1 8
```

In this example, do the following:

```
# route change -net 192.123.124.0 -recvpipe x
```

Then, all connections going to the 192.123.124.0 network, which is on the `ge0` link, use the receive buffer size `x`, instead of the default 128,000 receive window size.

If the destination is in the `a.b.c.d` network, and no specific routing entry exists for that network, you can add a prefix route to that network and change the metric. For example:

```
# route add -net a.b.c.d 192.123.123.1 -netmask w.x.y.z
# route change -net a.b.c.d -recvpipe y
```
Note that the prefix route's gateway is the default router. Then, all connections going to that network use the receive buffer size \( y \). If you have more than one interface, use the `-ifp` argument to specify which interface to use. This way, you can control which interface to use for specific destinations. To verify the metric, use the `route(1M)` get command.
This chapter describes most of the parameters default values for various system facilities.

- “autofs” on page 172
- “cron” on page 172
- “devfsadm” on page 172
- “dhcpcagent” on page 172

- “login” on page 175
- “mpathd” on page 175
- “nfs” on page 175
- “nfslogd” on page 175
- “nss” on page 175
- “passwd” on page 175
- “su” on page 176
- “syslog” on page 176
- “tar” on page 176
- “telnetd” on page 176
- “utmpd” on page 176
System Default Parameters

The functioning of various system facilities is governed by a set of values that are read by each facility on startup. The values for each facility might be stored in a file for the facility located in the /etc/default directory, or in properties of a service instance in the Service Management Facility (SMF) configuration repository. For more information on SMF services and properties, see “Managing SMF Services” in Managing Services and Faults in Oracle Solaris 11.1.

For information about setting power management properties, see Chapter 5, “Managing the System Console, Terminal Devices, and Power Services (Tasks),” in Managing System Information, Processes, and Performance in Oracle Solaris 11.1.

autofs

You can display or configure SMF autofs properties by using the sharectl command. For example:

```
# sharectl get autofs
timeout=600
automount verbose=false
automountd verbose=false
nobrowse=false
trace=0
environment=
# sharectl set -p timeout=200 autofs
```

For details, see sharectl(1M).

cron

This facility enables you to disable or enable cron logging.

devfsadm

This file is not currently used.

dhcpagent

Client usage of DHCP is provided by the dhcpagent daemon. When ipadm is used to create a DHCP address object, or when ipadm identifies an interface that has been configured to receive its network configuration from DHCP, dhcpagent is started to manage an address on that interface.
For more information, see the /etc/default/dhcpagent information in the FILES section of dhcpagent(1M).

**fs**

File system administrative commands have a generic and file system-specific portion. If the file system type is not explicitly specified with the -F option, a default is applied. The value is specified in this file. For more information, see the Description section of default_fs(4).

**ftp**

This facility enables you to set the ls command behavior to the RFC 959 NLST command. The default ls behavior is the same as in the previous Solaris release.

For details, see ftp(4).

**inetinit**

This facility enables you to configure TCP sequence numbers and to enable or disable support for 6to4 relay routers.

**init**

System initialization properties are now part of the following SMF service:

```
svc:/system/environment:init
```

You can display and configure system initialization properties, such as TZ and LANG, by using similar syntax:

```
# svcadm -s svc:/system/environment:init
svc:/system/environment:init> setprop
Usage: setprop pg/name = [type:] value
       setprop pg/name = [type:] ([value...])

Set the pg/name property of the currently selected entity. Values may be enclosed in double-quotes. Value lists may span multiple lines.
```

```
svc:/system/environment:init> listprop
umask
umask/value_authorization application
umask/umask application 022
upgrade
upgrade/skip_init_upgrade boolean false
```

System Default Parameters

Chapter 6 • System Facility Parameters 173
For more information, see the FILES section of init(1M).

**ipsec**

This facility enables you to configure parameters, such as IKE daemon debugging information and the ikeadm privilege level.

**kbd**

Keyboard configuration properties are now part of the following SMF service:

```
svc:/system/keymap:default
```

You display and configure keyboard properties by using similar syntax:

```
# svc_cfg -s svc:/system/keymap:default
svc:/system/keymap:default> setprop
Usage: setprop pg/name = [type:] value
       setprop pg/name = [type:] ([value...])
```

Set the pg/name property of the currently selected entity. Values may be enclosed in double-quotes. Value lists may span multiple lines.

```
svc:/system/keymap:default> listprop
general          framework
   general/complete   astring
   general/enabled    boolean  false
keymap            system
   keymap/console_beeper_freq integer  900
   keymap/kbd_beeper_freq integer  2000
   keymap/keyboard_abort astring  enable
   keymap/keyclick    boolean  false
```

For more information, see kbd(1).

**keyserv**

For details, see the /etc/default/keyserv information in the FILES section of keyserv(1M).
login

For details, see the /etc/default/login information in the FILES section of login(1).

mpathd

This facility enables you to set in.mpathd configuration parameters.

For details, see in.mpathd(1M).

nfs

You can display or configure SMF NFS properties by using the sharectl command. For example:

```
# sharectl get nfs
servers=1024
lockd_listen_backlog=32
lockd_servers=1024
lockd_retransmit_timeout=5
grace_period=90
server_versmin=2
server_versmax=4
client_versmin=2
client_versmax=4
server_delegation=on
nfsmapid_domain=
# sharectl set -p grace_period=60 nfs
```

For details, see nfs(4).

nfslogd

For details, see the Description section of nfslogd(1M).

nss

This facility enables you to configure initgroups (3C) lookup parameters.

For details, see nss(4).

passwd

For details, see the /etc/default/passwd information in the FILES section of passwd(1).
su
For details, see the /etc/default/su information in the FILES section of su(1M).

syslog
For details, see the /etc/default/syslogd information in the FILES section of syslogd(1M).

tar
For a description of the -f function modifier, see tar(1).

If the TAPE environment variable is not present and the value of one of the arguments is a number and -f is not specified, the number matching the archiveN string is looked up in the /etc/default/tar file. The value of the archiveN string is used as the output device with the blocking and size specifications from the file.

For example:

% tar -c 2 /tmp/*
This command writes the output to the device specified as archive2 in the /etc/default/tar file.

telnetd
This file identifies the default BANNER that is displayed upon a telnet connection.

utmpd
The utmpd daemon monitors /var/adm/utmpx (and /var/adm/utmp in earlier Solaris versions) to ensure that utmp entries inserted by non-root processes by pututxline(3C) are cleaned up on process termination.

Two entries in /etc/default/utmpd are supported:

- SCAN_PERIOD – The number of seconds that utmpd sleeps between checks of /proc to see if monitored processes are still alive. The default is 300.
- MAX_FDS – The maximum number of processes that utmpd attempts to monitor. The default value is 4096 and should never need to be changed.
This chapter describes the change history of specific tunable parameters. If a parameter is in this section, it has changed from a previous release. Parameters whose functionality has been removed are listed also.

- "Kernel Parameters" on page 177
- "TCP/IP Tunable Parameters (Oracle Solaris 11 and 11.1)" on page 180
- "Parameters That Are Obsolete or Have Been Removed (Oracle Solaris 11 and 11.1)" on page 184

Kernel Parameters

General Kernel and Memory Parameters (Oracle Solaris 11 and 11.1)

zfs_arc_min
This parameter description is newly documented in the Oracle Solaris 11 release. For more information, see “zfs_arc_min” on page 82.

In Oracle Solaris 11.1, the zfs_arc_min parameter information has moved to Chapter 3, "Oracle Solaris ZFS Tunable Parameters."

zfs_arc_max
This parameter description is newly documented in the Oracle Solaris 11 release. For more information, see “zfs_arc_max” on page 83.

In Oracle Solaris 11.1, the zfs_arc_max parameter information has moved to Chapter 3, "Oracle Solaris ZFS Tunable Parameters."
disp_rechoose_interval
This parameter is new in the Oracle Solaris 11 release. For more information, see “disp_rechoose_interval” on page 73.

Paging-Related Parameters (Oracle Solaris 11)

fastscan
The default value of fastscan was clarified. For more information, see “fastscan” on page 46.

Process-Sizing Tunables (Oracle Solaris 11.1)

ngroups_max
This parameter is newly documented in the Oracle Solaris 11 release.
In the Oracle Solaris 11.1 release, the When to Change description was revised to include interaction information for AUTH_SYS authentication when this parameter is set to greater than 16. For more information, see “ngroups_max” on page 38.

max_nprocs
The default value of this parameter was updated in the Oracle Solaris 11.1 release. For more information, see “max_nprocs” on page 37.

maxusers
The default value of this parameter was updated in the Oracle Solaris 11.1 release. For more information, see “maxusers” on page 34.

pidmax
The default value of this parameter was updated in the Oracle Solaris 11.1 release. For more information, see “pidmax” on page 36.

segkpsize
The default value of this parameter was updated in the Oracle Solaris 11.1 release. For more information, see “segkpsize” on page 29.
Swapping-Related Parameter (Oracle Solaris 11.1)

**swapfs_minfree**
The When to Change section of this parameter information was updated in the Oracle Solaris 11.1 release. For more information, see "swapfs_minfree" on page 51.

General File System Parameter (Oracle Solaris 11.1)

**dnlc_dircache_percent**
This parameter is new in the Oracle Solaris 11.1 release. For more information, see "dnlc_dircache_percent" on page 65.

General Driver Parameter (Oracle Solaris 11)

**ddi_msix_alloc_limit**
This parameter is newly documented in the Oracle Solaris 11 release. For more information, see "ddi_msix_alloc_limit" on page 55.

Network Driver Parameters (Oracle Solaris 11)

**igb Parameters**
The igb network driver parameters are provided in the Oracle Solaris 11 release. For more information, see “igb Parameters” on page 56.

**ixgbe Parameters**
The ixgbe network driver parameters are provided in the Oracle Solaris 11 release. For more information, see “ixgbe Parameters” on page 57.
TCP/IP Tunable Parameters (Oracle Solaris 11 and 11.1)

[tcp,sctp,udp]_smallest_anon_port and [tcp,sctp,udp]_largest_anon_port

These parameters are newly documented in the Oracle Solaris 11 release.

- “smallest_anon_port” on page 167
- “largest_anon_port” on page 167
- “smallest_anon_port” on page 148
- “largest_anon_port” on page 148
- “smallest_anon_port” on page 155
- “largest_anon_port” on page 156

_local_slow_start_initial

This parameter is newly documented in the Oracle Solaris 11.1 release. For more information, see “_local_slow_start_initial” on page 142.

IP Parameter Name Changes (Oracle Solaris 11)

The following IP parameters have been renamed to IP properties.

You can set an IP property by using syntax similar to the following:

```bash
# ipadm set-prop -p _icmp_err_interval=100 ip
```

You can display IP property information by using syntax similar to the following:

```bash
# ipadm show-prop -p _icmp_err_interval ip
```

UDP Parameter Name Changes (Oracle Solaris 11)

The following UDP parameters have been renamed to UDP properties. You can set a UDP property by using syntax similar to the following:

```
# ipadm set-prop -p send_buf=57344 udp
```

You can display UDP property information by using syntax similar to the following:

```
# ipadm show-prop -p send_buf udp
```

<table>
<thead>
<tr>

</table>

SCTP Parameter Name Changes (Oracle Solaris 11)

The following SCTP parameters have been renamed to SCTP properties. You can set an SCTP property by using syntax similar to the following:

```
# ipadm set-prop -p _max_init_retr=8 sctp
```

You can display SCTP property information by using syntax similar to the following:

```
# ipadm show-prop -p _max_init_retr sctp
```

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
NCA Parameters

The network cache accelerator (NCA) parameter information is obsolete and has been removed.

**consistent_coloring**

This parameter is obsolete starting in the Oracle Solaris 11.1 release.

**rstchown**

This parameter is obsolete starting in the Oracle Solaris 11 release.

<table>
<thead>
<tr>
<th>Description</th>
<th>Indicates whether the POSIX semantics for the chown system call are in effect. POSIX semantics are as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>■ A process cannot change the owner of a file, unless it is running with UID 0.</td>
</tr>
<tr>
<td></td>
<td>■ A process cannot change the group ownership of a file to a group in which it is not currently a member, unless it is running as UID 0.</td>
</tr>
</tbody>
</table>

For more information, see `chown(2)`.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Signed integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1, indicating that POSIX semantics are used</td>
</tr>
<tr>
<td>Range</td>
<td>0 = POSIX semantics not in force or 1 = POSIX semantics used</td>
</tr>
<tr>
<td>Units</td>
<td>Toggle (on/off)</td>
</tr>
<tr>
<td>Dynamic?</td>
<td>Yes</td>
</tr>
<tr>
<td>Validation</td>
<td>None</td>
</tr>
<tr>
<td>When to Change</td>
<td>When POSIX semantics are not wanted. Note that turning off POSIX semantics opens the potential for various security holes. Doing so also opens the possibility of a user changing ownership of a file to another user and being unable to retrieve the file without intervention from the user or the system administrator.</td>
</tr>
<tr>
<td>Commitment Level</td>
<td>Obsolete</td>
</tr>
</tbody>
</table>
Obsolete TCP/IP Module Parameters (Oracle Solaris 11)

**ip_multidata_outbound**
This parameter is obsolete in the Oracle Solaris 11 release.

**tcp_mdt_max_pbufs**
This parameter is obsolete in the Oracle Solaris 11 release.
Revision History for This Manual

This section describes the revision history for this manual.

- “Current Version: Oracle Solaris 11.1 Release” on page 187
- “New or Changed Parameters in the Oracle Solaris Release” on page 187

Current Version: Oracle Solaris 11.1 Release

The current version of this manual applies to the Oracle Solaris 11.1 release.

New or Changed Parameters in the Oracle Solaris Release

The following sections describe new, changed, or obsolete kernel tunables.

- Oracle Solaris 11.1: Oracle Solaris ZFS tunable information is provided in Chapter 3, “Oracle Solaris ZFS Tunable Parameters.”
- Oracle Solaris 11.1: The maxusers, max_nprocs, ngroups_max, pidmax, and segksize parameters have been revised in the Oracle Solaris 11.1 release. For more information, see Chapter 2, “Oracle Solaris Kernel Tunable Parameters.”
- Oracle Solaris 11.1: The dnlc_dircache_percent parameter is new in the Oracle Solaris 11.1 release. For more information, see “dnlc_dircache_percent” on page 65.
- Oracle Solaris 11: The rstchown parameter is obsolete. For more information, see “What’s New in Oracle Solaris System Tuning?” on page 17.
- Oracle Solaris 11: The ipadm command replaces the ndd command for setting TCP, IP, UDP, and SCTP properties. In addition, the names of the network parameters have changed to better correlate to the ipadm format. For more information, see “Overview of Tuning IP Suite Parameters” on page 129.
- Oracle Solaris 11: This release includes the disp_rechoose_interval parameter. For more information, see “disp_rechoose_interval” on page 73.
Oracle Solaris 11: This release includes the `ngroups_max` parameter description. For more information, see "ngroups_max" on page 38.

Oracle Solaris 11: This release includes the `zfs_arc_min` and `zfs_arc_max` parameter descriptions. For more information, see "zfs_arc_min" on page 82 and "zfs_arc_max" on page 83.

Oracle Solaris 11: This release includes several `igb` and `ixgbe` network driver parameters. For more information, see "igb Parameters" on page 56 and "ixgbe Parameters" on page 57.

Oracle Solaris 11: This release includes the `ddi_msix_alloc_limit` parameter that can be used to increase the number of MSI-X interrupts that a device instance can allocate. For more information, see "ddi_msix_alloc_limit" on page 55.

Oracle Solaris 11: This release includes the `kmem_stackinfo` parameter, which can be enabled to monitor kernel thread stack usage. For more information, see "kmem_stackinfo" on page 53.

Oracle Solaris 11: Memory locality group parameters are provided in this release. For more information about these parameters, see "Locality Group Parameters" on page 78.

Oracle Solaris 11: Parameter information was updated to include sun4v systems. For more information, see the following references:

- "maxphys" on page 61
- "tmpfs:tmpfs_maxkmem" on page 66
- "SPARC System Specific Parameters" on page 75
