Preface

*Oracle Solaris Cluster Data Service for SAP liveCache Guide* explains how to install and configure Oracle Solaris Cluster data services.

**Note** – This Oracle Solaris Cluster release supports systems that use the SPARC and x86 families of processor architectures. In this document, “x86” refers to the larger family of x86 compatible products. Information in this document pertains to all platforms unless otherwise specified.

This document is intended for system administrators with extensive knowledge of Oracle software and hardware. Do not use this document as a planning or presales guide. Before reading this document, you should have already determined your system requirements and purchased the appropriate equipment and software.

The instructions in this book assume knowledge of the Oracle Solaris Operating System and expertise with the volume-manager software that is used with Oracle Solaris Cluster software.

Bash is the default shell for Oracle Solaris 11. Machine names shown with the Bash shell prompt are displayed for clarity.

**Using UNIX Commands**

This document contains information about commands that are specific to installing and configuring Oracle Solaris Cluster data services. The document does not contain comprehensive information about basic UNIX commands and procedures, such as shutting down the system, booting the system, and configuring devices. Information about basic UNIX commands and procedures is available from the following sources:

- Online documentation for the Oracle Solaris Operating System
- Oracle Solaris Operating System man pages
- Other software documentation that you received with your system
Typographic Conventions

The following table describes the typographic conventions that are used in this book.

<table>
<thead>
<tr>
<th>Typeface</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>AaBbCc123</td>
<td>The names of commands, files, and directories, and onscreen computer output</td>
<td>Edit your .login file. Use ls -a to list all files. machine_name% you have mail.</td>
</tr>
<tr>
<td>AaBbCc123</td>
<td>What you type, contrasted with onscreen computer output</td>
<td>machine_name% su</td>
</tr>
<tr>
<td>aabbcc123</td>
<td>Placeholder: replace with a real name or value</td>
<td>Password:</td>
</tr>
<tr>
<td>AaBbCc123</td>
<td>Book titles, new terms, and terms to be emphasized</td>
<td>Read Chapter 6 in the User’s Guide. A cache is a copy that is stored locally. Do not save the file. Note: Some emphasized items appear bold online.</td>
</tr>
</tbody>
</table>

Shell Prompts in Command Examples

The following table shows UNIX system prompts and superuser prompts for shells that are included in the Oracle Solaris OS. In command examples, the shell prompt indicates whether the command should be executed by a regular user or a user with privileges.

<table>
<thead>
<tr>
<th>Shell</th>
<th>Prompt</th>
</tr>

Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.
Getting Help

If you have problems installing or using Oracle Solaris Cluster, contact your service provider and provide the following information.

- Your name and email address (if available)
- Your company name, address, and phone number
- The model number and serial number of your systems
- The release number of the operating environment (for example, Oracle Solaris 11)
- The release number of Oracle Solaris Cluster (for example, Oracle Solaris Cluster 4.1)

Use the following commands to gather information about your system for your service provider.

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>prtconf -v</code></td>
<td>Displays the size of the system memory and reports information about peripheral devices</td>
</tr>
<tr>
<td><code>psrinfo -v</code></td>
<td>Displays information about processors</td>
</tr>
<tr>
<td><code>pkg list</code></td>
<td>Reports which packages are installed</td>
</tr>
<tr>
<td><code>prtdiag -v</code></td>
<td>Displays system diagnostic information</td>
</tr>
<tr>
<td><code>/usr/cluster/bin/clnode show-rev -v</code></td>
<td>Displays Oracle Solaris Cluster release and package version information for each node</td>
</tr>
</tbody>
</table>

Also have available the contents of the `/var/adm/messages` file.
Installing and Configuring HA for SAP liveCache

This chapter contains explains how to install and configure HA for SAP liveCache.

This chapter contains the following sections.

- “HA for SAP liveCache Overview” on page 9
- “Installing and Configuring HA for SAP liveCache” on page 11
- “Planning the HA for SAP liveCache Installation and Configuration” on page 12
- “Preparing the Nodes and Disks” on page 14
- “Installing and Configuring liveCache” on page 15
- “Verifying the liveCache Installation and Configuration” on page 17
- “Installing the HA for SAP liveCache Package” on page 18
- “Registering and Configuring the HA for SAP liveCache” on page 19
- “Verifying the HA for SAP liveCache Installation and Configuration” on page 22
- “Tuning HA for SAP liveCache Fault Monitors” on page 24

HA for SAP liveCache Overview

Use the information in this section to understand how Oracle Solaris Cluster HA for SAP liveCache (HA for SAP liveCache) makes liveCache highly available.

For conceptual information on scalable services, see the Oracle Solaris Cluster Concepts Guide.

To eliminate a single point of failure in an SAP Advanced Planner & Optimizer (APO) System, HA for SAP liveCache provides fault monitoring and automatic failover for liveCache and fault monitoring and automatic restart for SAP xserver. The following table lists the data services that best protect SAP Supply Chain Management (SCM) components in an Oracle Solaris Cluster configuration. Figure 1–1 also illustrates the data services that best protect SAP SCM components in an Oracle Solaris Cluster configuration.
### Protection of liveCache Components

**Installing and Configuring HA for SAP liveCache**

R/3<br>Oracle Solaris Cluster<br>HA for SAP NetWeaver<br>liveCache<br>RDBMS<br>Oracle Solaris Cluster data service for your RDBMS

FIGURE 1–1  Protection of liveCache Components
Planning the HA for SAP liveCache Installation and Configuration

This section contains the information you need to plan your HA for SAP liveCache installation and configuration.

Note – If you have not already done so, read your SAP documentation before you begin planning your HA for SAP liveCache installation and configuration because your SAP documentation includes configuration restrictions and requirements that are not outlined in Oracle Solaris Cluster documentation or dictated by Oracle Solaris Cluster software.

Configuration Requirements

Caution – Your data service configuration might not be supported if you do not adhere to these requirements.

Use the requirements in this section to plan the installation and configuration of HA for SAP liveCache. These requirements apply to HA for SAP liveCache only. You must meet these requirements before you proceed with your HA for SAP liveCache installation and configuration.

For requirements that apply to all data services, see Oracle Solaris Cluster Data Services Planning and Administration Guide.

- Use SAP liveCache versions 7.7.04.38 or 7.7.07.10, or another compatible version.

Standard Data Service Configurations

Use the standard configurations in this section to plan the installation and configuration of HA for SAP liveCache. HA for SAP liveCache supports the standard configurations in this section. HA for SAP liveCache might support additional configurations. However, you must contact your Oracle service provider for information on additional configurations.
Figure 1–2 illustrates a four-node cluster with SAP APO Central Instance, APO application servers, a database, and liveCache. APO Central Instance, the database, and liveCache are configured as failover data services. SAP xserver can be configured only as a multiple master data service. APO application servers can be configured as scalable or failover data services.

**Configuration Considerations**

Use the information in this section to plan the installation and configuration of HA for SAP liveCache. The information in this section encourages you to think about the impact your decisions have on the installation and configuration of HA for SAP liveCache.

- Install liveCache on its own global device group, separate from the global device group for the APO Oracle database and SAP R/3 software. This separate global device group for liveCache ensures that the liveCache resource can depend on the HA Storage Plus resource for liveCache only.
- If you want to run SAP xserver as any user other than user root, create that user on all nodes on which SAP xserver runs, and define this user in the Xserver_User extension property. SAP xserver starts and stops based on the user you identify in this extension property. The default for this extension property is user root.

**Configuration Planning Questions**

Use the questions in this section to plan the installation and configuration of HA for SAP liveCache. See "Configuration Considerations" on page 13 for information that might apply to these questions.

- What resource groups will you use for network addresses and application resources and the dependencies between them?
- What is the logical hostname (for liveCache resource) for clients that will access the data service?
- Where will the system configuration files reside?

See Oracle Solaris Cluster Data Services Planning and Administration Guide for the advantages and disadvantages of placing the liveCache binaries on the local file system as opposed to the cluster file system.
Preparing the Nodes and Disks

This section contains the procedures you need to prepare the nodes and disks.

▼ How to Prepare the Nodes

Use this procedure to prepare for the installation and configuration of liveCache.

1 Assume a root role on all of the nodes.

2 Configure the svc:/system/name-service/switch:default SMF service.
   a. On each node or zone that can master the liveCache resource, include one of the following entries for group, project, an passwd database entries in the svc:/system/name-service/switch:default SMF service.

      config/database:
      config/database: files
      config/database: files [NOTFOUND=return] nis
      config/database: files [NOTFOUND=return] nisplus
      config/database: files [NOTFOUND=return] ldap

      Example:

      # svcconfig -s name-service/switch
      svc/system/name-service/switch> \
      setprop config/passwd = astring: "files [NOTFOUND=return] nis"
      svc/system/name-service/switch> exit
      # svcadmin refresh name-service/switch
      # svcadmin restart name-service/switch

   b. On each node or zone that can master the liveCache resource, ensure that files appears first for the protocols database entry in the svc:/system/name-service/switch:default SMF service.

      Example:

      protocols: files nis

HA for SAP liveCache uses the su - user command and the dbmcli command to start and stop liveCache.

The network information name service might become unavailable when a cluster node’s public network fails. Implementing the preceding changes to the svc:/system/name-service/switch:default SMF service file ensures that the su(1M) command and the dbmcli command do not refer to the NIS/NIS+/ldap name services.
Installing and Configuring liveCache

This section contains the procedures that you need to install and configure liveCache.

▼ How to Install and Configure liveCache

Use this procedure to install and configure liveCache.

1 Install and configure SAP APO System.

See Oracle Solaris Cluster Data Service for SAP Guide for the procedures on how to install and configure SAP APO System on Oracle Solaris Cluster software.

2 Install liveCache.

Note – Install liveCache by using the physical hostname if you have not already created the required logical host.

For more information, see your SAP documentation.

3 Ensure that the liveCache administrator user is in the sdb group user group.

The format of the liveCache administrator user’s user ID is lc-nameadm.

If you are creating the liveCache administrator user manually, add the following entry to the /etc/group file:

```
sdba:::group-id::lc-nameadm
```

- **group-id**: The group’s unique numerical ID (GID) within the system
- **lc-name**: Lowercase name of liveCache database instance

For more information about the /etc/group file, see the group(4) man page.

4 Become liveCache administrator user, create the .XUSER. 62 file for the SAP APO administrator user and the liveCache administrator user by using the following command.

Note – This user whose home directory contains the .XUSER. 62 file is an internal database user who has permissions to start, stop, and query the database.

```
$ dbmcli -d LC-NAME -n logical-hostname-ususername.passwd
```

- **LC-NAME**: Uppercase name of liveCache database instance
- **logical-hostname**: Logical hostname that is used with the liveCache resource
Caution – Neither SAP APO transaction LC10 nor HA for SAP liveCache functions properly if you do not create this file correctly.

5 Copy /usr/spool/sql if it exists, from the node or zone, on which you installed liveCache, to all the nodes that will run the liveCache resource.

Ensure that the ownership of these files is the same on all nodes as it is on the node or zone on which you installed liveCache.

Example:

```bash
# tar cfB /tmp/usr-spool.tar /usr/spool/sql
Log in to the destination zone.
# scp root@source:/tmp/usr-spool.tar /tmp
# cd /
# tar xfb /tmp/usr-spool.tar
```

```
source Specifies the node or zone where you installed SAP liveCache
```

6 Copy the /etc/opt/sdb directory and its contents from the node on which you installed liveCache, to all the nodes or zones where resources for liveCache will run.

Ensure that the ownership of these files is the same on all nodes as it is on the node or zone on which you installed liveCache.

```bash
# tar cfB /tmp/opt-sdb.tar /etc/opt/sdb
Log in to the target zone.
# scp root@source:/tmp/opt-sdb.tar /tmp
# cd /
# tar xfb /tmp/opt-sdb.tar
```

```
source Specifies the node or zone where you installed SAP liveCache.
```

7 Create a link from the /sapdb/LCA/db/wrk directory to the /sapdb/data/wrk directory as follows:

```bash
# ln -s /sapdb/data/wrk /sapdb/LCA/db/wrk
```

8 Ensure that all the required system files have been copied from the install node or zone to all the nodes or zones that will run the liveCache resource.

The required files include /etc/group, /etc/passwd, /etc/project, and /etc/user_attr.

▼ How to Enable liveCache to Run in a Cluster

During a standard SAP installation, liveCache is installed with a physical hostname. You must modify liveCache to use a logical hostname so that liveCache works in a Oracle Solaris Cluster environment. Use this procedure to enable liveCache to run in a cluster.
Verifying the liveCache Installation and Configuration

Before You Begin

Ensure that the /etc/netmasks file has IP-address subnet and netmask entries for all logical hostnames. If necessary, edit the /etc/netmasks file to add any missing entries.

1. Create the failover resource group to hold the network and liveCache resource.
   
   # clresourcegroup create [-n node-zone-list] livecache-resource-group

2. Verify that you added all the network resources you use to your name service database.

3. Add a network resource (logical hostname) to the failover resource group.
   
   # clreslogicalhostname create -g livecache-resource-group
   # -h lc-logical-hostname lc-logical-hostname

   **Note** – If you require a fully qualified hostname, you must specify the fully qualified name with the -h option and you cannot use the fully qualified form in the resource name.

4. Enable the failover resource group.
   
   # clresourcegroup online -M livecache-resource-group

5. Enable the network resource (logical hostname).
   
   # clresource enable lc-logical-hostname

6. Log on to the node or zone that hosts the liveCache resource group.

7. As the liveCache administrator user, start SAP xserver manually on the node or zone that hosts the liveCache resource group.
   
   # su - lc-nameadm
   $ x_server start
   
   lc-name Lowercase name of liveCache database instance

8. Log on to SAP APO System by using your SAP GUI with user DDIC.

9. Go to transaction LC10 and change the liveCache host to the logical hostname you defined in Step 3.
   
   liveCache host: lc-logical-hostname

Verifying the liveCache Installation and Configuration

This section contains the procedure that you need to verify the liveCache installation and configuration.
How to Verify the liveCache Installation and Configuration

Use this procedure to verify the liveCache installation and configuration. This procedure does not verify that your application is highly available because you have not installed your data service yet.

1. Log on to SAP APO System by using your SAP GUI with user DDIC.

2. Go to transaction LC10.

3. Ensure that you can check the state of liveCache.

4. Ensure that the following `dbmcli` commands work as user `lc-nameadm`.

   $ dbmcli -d LC-NAME -n logical-hostname -U DEFAULT db_state
   $ dbmcli -d LC-NAME -n logical-hostname db_enum

5. Confirm that the liveCache administrator user can run the `lcinit restart` command.

   a. Become the liveCache administrator user.

      # su - lc-nameadm

      lc-name   Lowercase name of liveCache database instance

   b. Run the `lcinit restart` command

      $ lcinit lc-name restart

Installing the HA for SAP liveCache Package

If you did not install the HA for SAP liveCache package during your initial Oracle Solaris Cluster installation, perform this procedure to install the package.

How to Install the HA for SAP liveCache Package

Perform this procedure on each cluster node where you want the HA for SAP liveCache software to run.

1. On the cluster node where you are installing the data service package, assume the root role.
2 Ensure that the solaris and ha-cluster publishers are valid.

```
# pkg publisher
PUBLISHER     TYPE STATUS    URI
solaris        origin online solaris-repository
ha-cluster     origin online ha-cluster-repository
```

For information about setting the solaris publisher, see "Set the Publisher Origin to the File Repository URI" in Copying and Creating Oracle Solaris 11.1 Package Repositories.

3 Install the HA for SAP liveCache software package.

```
# pkg install ha-cluster/data-service/sap-livecache
```

4 Verify that the package installed successfully.

```
$ pkg info ha-cluster/data-service/sap-livecache
```

Installation is successful if output shows that State is Installed.

5 Perform any necessary updates to the Oracle Solaris Cluster software.

For instructions on updating single or multiple packages, see Chapter 11, "Updating Your Software," in Oracle Solaris Cluster System Administration Guide.

Registering and Configuring the HA for SAP liveCache

This section contains the procedures that you need to configure HA for SAP liveCache.

Setting HA for SAP liveCache Extension Properties

Use the extension properties in Appendix A, "HA for SAP liveCache Extension Properties," to create your resources. Use the following command line to configure extension properties when you create your resource.

```
clresource create -g resource-group -t resource-type -p property=value resource
```

Use the procedure in "Changing Resource Type, Resource Group, and Resource Properties" in Oracle Solaris Cluster Data Services Planning and Administration Guide to configure the extension properties if you have already created your resources. You can update some extension properties dynamically. You can update others, however, only when you create or disable a resource. The Tunable fields in Appendix A, "HA for SAP liveCache Extension Properties," indicate when you can update each property. See Chapter 1, "Planning for Oracle Solaris Cluster Data Services," in Oracle Solaris Cluster Data Services Planning and Administration Guide for a list of Oracle Solaris Cluster properties.
How to Register and Configure HA for SAP liveCache

Use this procedure to configure HA for SAP liveCache as a failover data service for the liveCache database and SAP xserver as a multiple master data service. This procedure assumes that you installed the data service packages. If you did not install the HA for SAP liveCache packages as part of your initial Oracle Solaris Cluster installation, go to “Installing the HA for SAP liveCache Package” on page 18 to install the data service packages. Otherwise, use this procedure to configure the HA for SAP liveCache.

Caution – Do not configure more than one SAP xserver resource on the same cluster because one SAP xserver serves multiple liveCache instances in the cluster. More than one SAP xserver resource that runs on the same cluster causes conflicts between the SAP xserver resources. These conflicts cause all SAP xserver resources to become unavailable. If you attempt to start the SAP xserver twice, you receive an error message that says Address already in use.

1 Assume a root role on one of the nodes or zones in the cluster that will host the liveCache resource.

2 Copy the lccluster file to the same location as the lcinit file.

   `cp /opt/SUNWsclc/livecache/bin/lccluster /sapdb/LC-NAME/db/sap`   
   `LC-NAME` Uppercase name of liveCache database instance

3 Edit the lccluster file to substitute the value for put-LC_NAME-here.

   a. Open the lccluster file.

      `# vi /sapdb/LC-NAME/db/sap/lccluster`   

   b. Replace put-LC_NAME-here with the liveCache instance name.

      The liveCache instance name is the value you defined in the Livecache_Name extension property.

      `LC_NAME="liveCache-instance-name"`

4 Add the HAStragePlus resource to the liveCache resource group.

   `# cresource type register SUNW.HAStoragePlus`   
   `# cresource create -g livecache-resource-group`   
   `-t SUNW.HAStoragePlus -p filesystemmountpoints=mountpoint,...`   
   `-p globaldevicepaths=livecache-device-group`   
   `-p affinityon=TRUE livecache-storage-resource`

   The resource is created in the enabled state.
Note – AffinityOn must be set to TRUE and the local file system must reside on global disk
groups to be failover.

For the procedure on how to set up an HAStoragePlus resource, see Oracle Solaris Cluster Data
Services Planning and Administration Guide.

5 Register the resource type for liveCache database.
   # clresourcetype register SUNW.sap_livecache

6 Register the resource type for SAP xserver.
   # clresourcetype register SUNW.sap_xserver

7 Create a multiple master resource group for SAP xserver. Configure SAP xserver to run on all the
   potential nodes or zones that liveCache will run on.

   **Note** – Configure SAP xserver so that SAP xserver starts on all nodes or zones that the liveCache
   resources can fail over to. To implement this configuration, ensure that the node-zone-list
   parameter of the SAP xserver resource group contains all the nodes or zones listed in the
   liveCache resource groups’ node-zone-list. Also, the value of desired_primaries and
   maximum_primaries of the SAP xserver resource group must be equal to each other.

   # clresourcegroup create -n node-zone-list
   -p Maximum_primaries=value
   -p Desired_primaries=value xserver-resource-group

8 Add the HAStoragePlus resource to the SAP xserver resource group.
   # clresource create
   -g xserver-resource-group
   -t SUNW.HAStoragePlus
   -p filesystemmountpoints=mountpoints
   -p affinityon=false xserver-storage-resource

   The resource is created in the enabled state.

   For more information about setting up an HAStoragePlus resource, see “Enabling Highly
   Available Local File Systems” in Oracle Solaris Cluster Data Services Planning and
   Administration Guide.

9 Create an SAP xserver resource in this multiple master resource group.
   # clresource create
   -g xserver-resource-group
   -t SUNW.sap_xserver
   -p resource_dependencies_offline_restart= xserver-storage-resource
   -xserver-storage-resource[LOCAL_NODE] xserver-resource

   The resource is created in the enabled state.
See "Setting HA for SAP liveCache Extension Properties" on page 19 for a list of extension properties.

10 Create the liveCache resource.

```
# clresource create -g livecache-resource-group \
-t SUNW.sap_livecache \
-p livecache_name=LC-NAME \
-p resource_dependenciesOffline_restart=livecache-storage-resource, livecache-resource
```

The resource is created in the enabled state.

11 Ensure that the liveCache resource group is brought online only on the node or zone where the SAP xserver resource group is online.

To meet this requirement, create on the liveCache resource group a strong positive affinity for the SAP xserver resource group.

```
# clresourcegroup set \
-p rg_affinities=++xserver-resource-group livecache-resource-group
```

12 Enable the liveCache failover resource group.

```
# clresourcegroup online -M livecache-resource-group
```

13 (Optional) Consider configuring your cluster to prevent the APO application server resource group from being brought online on the same node or zone as the liveCache resource group.

You might plan to run the APO application server on a node or zone to which the liveCache resource can fail over. In this situation, consider using resource group affinities to shut down the APO application server when the liveCache resource fails over to the node or zone.

To specify this behavior, create on the APO application server resource group a strong negative affinity for the liveCache resource group.

```
# clresourcegroup set \
-p rg_affinities=--liveCache-resource-group apo-resource-group
```

Verifying the HA for SAP liveCache Installation and Configuration

This section contains the procedure you need to verify that you installed and configured your data service correctly.
How to Verify the HA for SAP liveCache Installation and Configuration

Use this procedure to verify that you installed and configured HA for SAP liveCache correctly. You need the information in the following table to understand the various states of the liveCache database.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFLINE</td>
<td>liveCache is not running.</td>
</tr>
<tr>
<td>COLD</td>
<td>liveCache is available for administrator tasks.</td>
</tr>
<tr>
<td>WARM</td>
<td>liveCache is online.</td>
</tr>
<tr>
<td>STOPPED INCORRECTLY</td>
<td>liveCache stopped incorrectly. This is also one of the interim states while liveCache starts or stops.</td>
</tr>
<tr>
<td>ERROR</td>
<td>Cannot determine the current state. This is also one of the interim states while liveCache starts or stops.</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>This is one of the interim states while liveCache starts or stops.</td>
</tr>
</tbody>
</table>

Log on to the node or zone that hosts the resource group that contains the liveCache resource, and verify that the fault monitor functionality works correctly.

a. **Terminate liveCache abnormally by stopping all liveCache processes.**

   Oracle Solaris Cluster software restarts liveCache.

   If you do not see this behavior, you might not have correctly performed Step 2 and Step 3 in “How to Register and Configure HA for SAP liveCache” on page 20.

   ```bash
   # ps -ef|grep sap|grep kernel
   # kill -9 livecache-processes
   ```

b. **Terminate liveCache by using the Stop liveCache button in LC10 or by running the lcinit command.**

   Oracle Solaris Cluster software does not restart liveCache. However, the liveCache resource status message reflects that liveCache stopped outside of Oracle Solaris Cluster software through the use of the Stop liveCache button in LC10 or the lcinit command. The state of the liveCache resource is UNKNOWN. When the user successfully restarts liveCache by using the Start liveCache button in LC10 or the lcinit command, the HA for SAP liveCache Fault Monitor updates the resource state and status message to indicate that liveCache is running under the control of Oracle Solaris Cluster software.

   If you do not see this behavior, you might not have correctly performed Step 2 and Step 3 in “How to Register and Configure HA for SAP liveCache” on page 20.
2 Log on to SAP APO by using your SAP GUI with user DDIC, and verify that liveCache starts correctly by using transaction LC10.

3 As user root, switch the liveCache resource group to another node or zone.
   
   ```
   # clresourcegroup switch -n node2 livecache-resource-group
   ```

4 Repeat Step 1 through Step 3 for each potential node or zone on which the liveCache resource can run.

5 Log on to the nodes or zones that host the SAP xserver resource, and verify that the fault monitor functionality works correctly.
   
   Terminate SAP xserver abnormally by stopping all SAP xserver processes.
   
   ```
   # ps -ef|grep xserver
   # kill -9 xserver-process
   ```

   Verify that the SAP xserver agent restarts the SAP xserver.

## Tuning HA for SAP liveCache Fault Monitors

Fault monitoring for the HA for SAP liveCache data service is provided by the following fault monitors:

- The SAP liveCache fault monitor
- The SAP xserver fault monitor

Each fault monitor is contained in a resource whose resource type is shown in the following table.

<table>
<thead>
<tr>
<th>Fault Monitor</th>
<th>Resource Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAP liveCache</td>
<td>SUNW.sap_livecache</td>
</tr>
<tr>
<td>SAP xserver</td>
<td>SUNW.sap_xserver</td>
</tr>
</tbody>
</table>

System properties and extension properties of these resources control the behavior of the fault monitors. The default values of these properties determine the preset behavior of the fault monitors. The preset behavior should be suitable for most Oracle Solaris Cluster installations. Therefore, you should tune the HA for SAP liveCache fault monitors only if you need to modify this preset behavior.

Tuning the HA for SAP liveCache fault monitors involves the following tasks:

- Setting the interval between fault monitor probes
- Setting the timeout for fault monitor probes
Defining the criteria for persistent faults
Specifying the failover behavior of a resource

For more information, see "Tuning Fault Monitors for Oracle Solaris Cluster Data Services" in Oracle Solaris Cluster Data Services Planning and Administration Guide. Information about the HA for SAP liveCache fault monitors that you need to perform these tasks is provided in the subsections that follow.

Tune the HA for SAP liveCache fault monitors when you register and configure HA for SAP liveCache. For more information, see “Registering and Configuring the HA for SAP liveCache” on page 19.

Factors That Affect the Interval Between Fault Monitor Probes

To determine whether SAP xserving and SAP liveCache are operating correctly, the HA for SAP liveCache fault monitors probe these resources periodically. The optimum interval between fault monitor probes depends on the time that is required to respond to a fault in a resource. This time depends on how the complexity of the resource affects the time that is required for operations such as restarting the resource.

Operations by the HA for SAP liveCache Fault Monitors During a Probe

The optimum timeout for fault monitor probes depends on the operations that a fault monitor performs to probe the resource.

Operations by the SAP liveCache Fault Monitor During a Probe

During a probe, the SAP liveCache fault monitor performs the following operations:

1. The SAP liveCache fault monitor determines whether SAP liveCache is online.
2. If liveCache is online, the SAP liveCache fault monitor determines whether the liveCache parent process is running.
3. If liveCache is not online, the SAP liveCache fault monitor determines whether a user stopped liveCache outside the control of Oracle Solaris Cluster.
   A user can stop liveCache by using the \texttt{Stop liveCache} button in LC10 or the \texttt{lcinit} command.
4. If a user did not stop liveCache outside the control of Oracle Solaris Cluster, the SAP liveCache fault monitor determines whether SAP xserving is available.
Operations by the SAP xserver Fault Monitor During a Probe

During a probe, the SAP xserver fault monitor determines whether SAP xserver is available.

Faults Detected by the HA for SAP liveCache Fault Monitors

Faults that each HA for SAP liveCache fault monitor detects are described in the subsections that follow.

Faults Detected by the SAP liveCache Fault Monitor

The SAP liveCache fault monitor detects the following faults in SAP liveCache:

- Unexpected termination of liveCache

  Note – The liveCache fault monitor also detects the expected termination of liveCache, which is not a fault. For more information, see “Monitoring the Termination of liveCache by a User” on page 27.

- Unexpected termination of the liveCache parent process

- System failures

SAP liveCache can be stopped or restarted only if SAP xserver is available. Therefore, the SAP liveCache fault monitor also detects the unavailability of SAP xserver. This fault monitoring supplements the fault monitoring that the SAP xserver fault monitor provides. This additional fault monitoring enforces the cross-resource group resource dependency between SAP xserver and SAP liveCache.

Faults Detected by the SAP xserver Fault Monitor

The SAP xserver fault monitor detects following faults:

- **Unavailability of SAP xserver.** Unavailability of SAP xserver is also detected by the SAP liveCache fault monitor.

- **System errors.** The SAP xserver fault monitor treats a system error as a partial failure.

- **Persistent system errors.** A persistent system error is a system error that occurs four times within the retry interval. If a persistent system error occurs, the fault monitor restarts SAP xserver.
Recovery Actions in Response to Detected Faults

To minimize the disruption that transient faults in a resource cause, a fault monitor restarts the resource in response to such faults. For persistent faults, more disruptive action than restarting the resource is required:

- For the SAP liveCache resource, the fault monitor fails over the resource to another node or zone. The SAP liveCache resource is a failover resource.
- For the SAP xserver resource, the fault monitor takes the resource offline. The SAP xserver is a multiple master data resource.

Monitoring the Termination of liveCache by a User

The SAP liveCache fault monitor detects when a user stops liveCache outside the control of Oracle Solaris Cluster. A user can stop liveCache by using the `Stop liveCache` button in LC10 or the `lcinit` command.

In this situation, the liveCache fault monitor updates the status of the liveCache resource to indicate that liveCache is stopped. However, the liveCache fault monitor performs no recovery action.

If a user restarts liveCache, the liveCache fault monitor updates the status of the liveCache resource to indicate that liveCache is running again.
Extension properties for HA for SAP liveCache resource types are described in the following sections.

- "SUNW.sap_livecache Extension Properties" on page 29
- "SUNW.sap_xserver Extension Properties" on page 30

For details about system-defined properties, see the `r_properties(5)` man page and the `rg_properties(5)` man page.

**SUNW.sap_livecache Extension Properties**

The `SUNW.sap_livecache` resource type represents the SAP liveCache application in a Oracle Solaris Cluster configuration. The extension properties of this resource type are as follows:

**Confdir_list (optional)**
- The directory for liveCache software and the instance directory.
  - **Data type**: String
  - **Default**: `/sapdb`
  - **Range**: Not applicable
  - **Tunable**: At creation

**Livecache_name (required)**
- Name of liveCache database instance.
  - **Data type**: String
  - **Default**: None
  - **Range**: Not applicable
  - **Tunable**: At creation
Monitor_retry_count
Number of PMF restarts that are allowed for the fault monitor.

**Data type** Integer

**Default** 4

**Range** No range defined

**Tunable** Any time

Monitor_retry_interval
Time interval in minutes for fault monitor restarts.

**Data type** Integer

**Default** 2

**Range** No range defined

**Tunable** Any time

Probe_timeout
Timeout value in seconds for the probes.

**Data type** Integer

**Default** 90

**Range** No range defined

**Tunable** Any time

---

**SUNW.sap_xserver Extension Properties**

The SUNW.sap_xserver resource type represents SAP xserver in an Oracle Solaris Cluster configuration. The extension properties of this resource type are as follows:

Confdir_List
The full path to the directory that contains the SAP liveCache software and SAP liveCache database instance.

**Data type** String

**Default** /sapdb

**Range** Not applicable

**Tunable** At creation
Independent_Program_Path
The full path to the directory that contains the following programs and libraries for SAP xserver:

- Programs that are independent of the database software version
- Libraries for the client runtime environment

HA for SAP liveCache determines the path to the x_server command from the value of this property. The x_server command resides in the bin subdirectory of the directory that this property specifies.

Data type: String
Default: No default defined
Range: Not applicable
Tunable: When disabled
Introduced in release: 3.1 4/04

Monitor_retry_count
The maximum number of restarts by the PMF that are allowed for the fault monitor.

Data type: Integer
Default: 4
Range: No range defined
Tunable: Any time

Monitor_retry_interval
The period of time in minutes during which the PMF counts restarts of the fault monitor.

Data type: Integer
Default: 2
Range: No range defined
Tunable: Any time

Probe_timeout
The timeout value in seconds for fault monitor probes.

Data type: Integer
Default: 120
Range: No range defined
Tunable: Any time
**Soft_Stop_Pct**

The percentage of the Stop method timeout that is used to stop SAP xserver by using the SAP utility `x_server stop`. If this timeout is exceeded, the SIGKILL signal is used to stop all SAP xserver processes.

- **Data type**: Integer
- **Default**: 50
- **Range**: 1–100
- **Tunable**: When disabled

**Xserver_User**

The UNIX user identity of the OS user who administers SAP xserver.

- **Data type**: String
- **Default**: root
- **Range**: Not applicable
- **Tunable**: At creation
