## About Predictor

Forecasting is an important part of many business decisions. Every organization must set goals, try to predict future events, and then act to fulfill the goals. As the timeliness of market actions becomes more important, the need for accurate planning and forecasting throughout an organization is essential to get ahead. The difference between good and bad forecasting can affect the success of an entire organization.

Predictor is an easy-to-use, graphically oriented forecasting feature included in:

- Oracle Crystal Ball, Fusion Edition, including Student and Faculty Editions
- Oracle Crystal Ball Decision Optimizer, Fusion Edition
- Oracle Crystal Ball Enterprise Performance Management, Fusion Edition

If you have historical data in your spreadsheet model, Predictor analyzes the data for trends and seasonal variations. It then predicts future values based on this information. You can answer questions such as, “What are the likely sales figures for next quarter?” or, “How much material do we need to have on hand?” As an added benefit, you can automatically save Predictor forecasts as Crystal Ball assumptions for immediate use in powerful risk analysis models. See [Chapter 2, “Getting Started with Predictor,”](#) for an overview of how Predictor works and what it can do for you.

Predictor runs on several versions of Microsoft Windows and Microsoft Excel. For a list of required hardware and software, see the current *Oracle Crystal Ball Installation and Licensing Guide*.

# How This Guide Is Organized

This guide includes the following additional sections to help you use Predictor:

- [Chapter 2, “Getting Started with Predictor”](#)  
Procedures for starting Predictor and running basic forecasts using default settings
- [Chapter 3, “Setting Up Predictor Forecasts”](#)  
Procedures for running forecasts with customized settings
- [Chapter 4, “Analyzing Predictor Results”](#)  
Descriptions of Predictor results and how to analyze them
- [Appendix A, “Predictor Tutorials”](#)  
A basic tutorial that quickly introduces Predictor’s features and an advanced tutorial that uses multiple regression analysis
- [Appendix B, “Predictor Examples”](#)  
Forecasting examples from various fields
- [Appendix C, “Important Predictor Concepts”](#)  
Definitions of important forecasting and statistical terms as they are used in Predictor
- [Appendix D, “Bibliography”](#)  
A list of related publications for further study
- **Glossary**  
Definitions of terms specific to Predictor as well as statistical terms used in this manual

## Screen Capture Notes

The screen captures in this manual were taken in Microsoft Excel 2003 for Microsoft Windows XP Professional.

Because of round-off differences between various system configurations, you might notice calculated results that are slightly different from those in the examples.

## Example Files

Example names are listed in full wherever given.

► To open an example file:

- 1 Select **Help**, then **Crystal Ball**, and then **Examples Guide**.
- 2 Click its name in the **Model Name** list. (In Microsoft Excel 2007 or later, select **Resources** in the Help group, and then select **Examples Guide**.)

## Online Help

You can display online help for Predictor by pressing F1 or clicking Help in the Predictor wizard.

**Tip:** Click **Contents** at the top of the help window for a table of contents.

## Developer Kit

If you are familiar with Visual Basic for Applications (VBA) or other supported development systems, you can use the Predictor developer kit to automate a number of basic forecasting and analysis operations. For details, see the *Oracle Crystal Ball Developer's Guide*.

## Accessibility Notes

You do not need to enable keyboard accessibility specifically for Crystal Ball and its features; command access is always in accessible mode. Crystal Ball, including Predictor, follows Microsoft Windows conventions for accessing commands using the keyboard. When you press Alt, shortcut keys are underlined in menus and dialogs. Crystal Ball output can be extracted to Microsoft Excel spreadsheets and pasted into PowerPoint slides, which are accessible through Microsoft Office. Starting with Crystal Ball version 11.1.2.0.00, an optional Accessibility mode, available through the Options tab of the Run Preferences dialog, activates special features for people with visual or motor impairments. For example, default chart display includes distinction by patterns as well as colors. For additional information about Crystal Ball accessibility, see the *Oracle Crystal Ball User's Guide*. For information about Microsoft Excel or PowerPoint accessibility, refer to Microsoft Office product documentation.

## Additional Resources

Oracle offers technical support, training, and other services to help you use Crystal Ball most effectively.

For more information, see the Crystal Ball Web site at:

<http://www.oracle.com/crystalball>

# 2

## Getting Started with Predictor

### In This Chapter

|  |    |
|--|----|
| Forecasting Basics .....                         | 11 |
| Creating Spreadsheets with Historical Data ..... | 12 |
| Starting Predictor and Running a Forecast .....  | 13 |
| Analyzing Results at a Basic Level .....         | 14 |
| Learning More .....                              | 14 |

## Forecasting Basics

Most historical or time-based data contains an underlying trend or seasonal pattern. However, most historical data also contains random fluctuations (“noise”) that make it difficult to detect these trends and patterns without a computer. Predictor uses sophisticated time-series methods to analyze the underlying structure of the data. It then projects the trends and patterns to predict future values.

Predictor uses two types of forecasting:

- **“Classic Time-series Forecasting” on page 82** breaks historical data into components: level, trend, seasonality, and error. Predictor analyzes these components and then projects them into the future to predict likely results.
- **“Multiple Linear Regression” on page 92** works best when outside influences have an effect on the variable that you want to forecast. Regression takes historical data from the influencing variables and determines the mathematical relationship between these variables and the target variable. It then uses time-series forecasting methods to forecast the influencing variables and combines the results mathematically to forecast the target variable.

In Predictor, a data series is a set of historical data for a single variable. When you run Predictor, it uses each time-series method on each of the selected data series and calculates a mathematical measure of goodness-of-fit. Predictor selects the method with the best goodness-of-fit as the method that will yield the most accurate forecast. Predictor performs this selection automatically, but you can also select individual methods manually or override the method that Predictor recommends with a different one.

The final forecast shows the most likely continuation of the data. Keep in mind that all these methods assume that some aspects of the historical trend or pattern will continue into the future. However, the farther out you forecast, the greater the likelihood that events will diverge from past behavior, and the less confident you can be of the results. To help you gauge the reliability

of the forecast, Predictor provides a confidence interval indicating the degree of uncertainty regarding the forecast.

After finding the best forecast for the data, Predictor displays detailed output that can include statistics, charts, reports, and interactive Microsoft Excel PivotTables. Predictor can also paste the forecasted values into a spreadsheet and create Crystal Ball assumptions from forecasted values so you can perform a “what-if” simulation.

The following topics describe how to set up Predictor forecasts using default settings so you can generate results quickly for further analysis:

- [“Creating Spreadsheets with Historical Data” on page 12](#)
- [“Starting Predictor and Running a Forecast” on page 13](#)
- [“Analyzing Results at a Basic Level” on page 14](#)
- [“Learning More” on page 14](#)

Predictor basics are demonstrated in [“Tutorial 1—Shampoo Sales” on page 53](#). You may find it helpful to work through this tutorial now, or read through the following sections first and then try the tutorial. When you are ready to expand your forecasting skills, [Chapter 3, “Setting Up Predictor Forecasts,”](#) provides detailed instructions.

## Creating Spreadsheets with Historical Data

Before using Predictor, create a Microsoft Excel spreadsheet with historical data to analyze. The spreadsheet should include:

- **Optional:** A descriptive spreadsheet title.
- **Optional:** A date (or other time period, such as Q2-2004) column or row, either at the top or along the left side of the data (in the last column before the data). If you format the dates as Microsoft Excel dates, Predictor can find the dates, extend them with the forecasted values, and use them as chart labels.
- Historical data, spaced equal time periods apart, in columns or rows adjacent to the date column or row. To produce a reasonable forecast, you should have at least six historical data points. Other requirements:
  - Single moving average analysis requires that the number of historical data points be twice the number of points to forecast.
  - Double moving average analysis requires that the number of historical data points be three times the number of points to forecast (or at least six, whichever is higher).
  - To use seasonal methods, you must have at least two seasons (complete cycles) of historical data.
  - For multiple linear regression, the number of historical data points must be greater than or equal to the number of independent variables (counting the included constant as an independent variable).

- To lag an independent variable in multiple linear regression, lag must be less than the number of historical data points. For details on lags, see [“Notes about Autocorrelations” on page 23](#).
- For multiple linear regression with lags, the number of data points minus any lags and leading blanks must be greater than the number of independent variables, plus 1 if a constant is included in the regression equation.
- When values in the date series are not in Microsoft Excel date format, the intervals between the values must all be exactly the same. For example, you can use integers for weeks (1, 2, 3, and so on) but you cannot omit any. The following is not an acceptable data series: 1, 2, 3, 5, 7. Also consider the valid date series 01-Jan, 01-Feb, 01-Mar. This is no longer valid when converted into days expressed as integers: 1, 32, 60.
- **Optional:** Headings for each data column or row, such as SKU 23442, Gas Usage, or Interest Rate.

The Toledo Gas spreadsheet (Figure 1) has all these components.

Figure 1 Example Spreadsheet

|    | A                                   | B | C | D | E | F | G |
|----|-------------------------------------|---|---|---|---|---|---|
| 1  | <b>Toledo Residential Gas Usage</b> |   |   |   |   |   |   |
| 2  |                                     |   |   |   |   |   |   |
| 3  |                                     |   |   |   |   |   |   |
| 4  |                                     |   |   |   |   |   |   |
| 5  |                                     |   |   |   |   |   |   |
| 6  |                                     |   |   |   |   |   |   |
| 7  |                                     |   |   |   |   |   |   |
| 8  |                                     |   |   |   |   |   |   |
| 9  |                                     |   |   |   |   |   |   |
| 10 |                                     |   |   |   |   |   |   |
| 11 |                                     |   |   |   |   |   |   |
| 12 |                                     |   |   |   |   |   |   |
| 13 |                                     |   |   |   |   |   |   |
| 14 |                                     |   |   |   |   |   |   |
| 15 |                                     |   |   |   |   |   |   |
| 16 |                                     |   |   |   |   |   |   |
| 17 |                                     |   |   |   |   |   |   |
| 18 |                                     |   |   |   |   |   |   |
| 19 |                                     |   |   |   |   |   |   |

## Starting Predictor and Running a Forecast

➤ Before you start Predictor:

- 1 Open a model with historical data (see [“Creating Spreadsheets with Historical Data” on page 12](#)).
- 2 Select a cell within the range to analyze.

► To start Predictor:

**1 Select Run, and then Predictor.**

The first time you start Predictor, the Predictor wizard Welcome panel opens. After that, Input Data opens.

The Welcome panel introduces Predictor and provides an overview of how it works.

**2 If Welcome opens, click Next to advance to Input Data.**

**3 Set up a forecast following the instructions in [Chapter 3, “Setting Up Predictor Forecasts.”](#) To set up a basic forecast, see [“Guidelines for Setting Up a Forecast”](#) on page 15.**

**4 To run a forecast and produce results, click Run.**

The Predictor Results window opens.

**Note:** You can click Run from any of the wizard panels except Welcome at any time, as long as the data range has been properly defined on the Input Data panel.

To use forecasted results, see [“Analyzing Results at a Basic Level”](#) on page 14.

## Analyzing Results at a Basic Level

Predictor simplifies the forecasting process, but you must understand the results it produces.

For a detailed description of all results and how to analyze them, see [Chapter 4, “Analyzing Predictor Results.”](#) At a basic level, you can view results for different series and paste results into the spreadsheet model:

- [“Understanding the Predictor Results Window”](#) on page 41
- [“Entering the Number of Time Periods to Forecast”](#) on page 43
- [“Selecting How to Display and Analyze Results”](#) on page 44

## Learning More

This chapter introduced Predictor at a basic level and suggested topics with more advanced content. If you have not already done so, you may find it helpful to:

- Work through [“Tutorial 1—Shampoo Sales”](#) on page 53
- Consider reviewing [Chapter 3, “Setting Up Predictor Forecasts,”](#) to learn procedures for increasing the accuracy of Predictor forecasting and analysis

# 3

## Setting Up Predictor Forecasts

### In This Chapter

|   |    |
|---|----|
| Guidelines for Setting Up a Forecast .....                      | 15 |
| Selecting the Location and Arrangement of Historical Data ..... | 17 |
| Selecting Data Attributes—Seasonality, Events, Screening .....  | 19 |
| Selecting a Forecasting Method .....                            | 29 |
| Setting Forecast Options .....                                  | 39 |

## Guidelines for Setting Up a Forecast

**Tip:** To preview these steps, work through [“Tutorial 1—Shampoo Sales”](#) on page 53.

➤ Follow these steps to set up a Predictor forecast and generate results:

- 1 **Create and open a spreadsheet model with historical data** as described in [“Creating Spreadsheets with Historical Data”](#) on page 12.
- 2 **Select a data cell and start Predictor** (see [“Starting Predictor and Running a Forecast”](#) on page 13).

**Note:** You can select an entire data range or a single cell and let Predictor determine the range. If columns or rows of data are separated by blank columns or rows, you can use Ctrl+click to select one cell in each data series. For details, see [“Selecting Discontiguous Data”](#) on page 18.

- 3 **Display the Input Data panel of the Predictor wizard.**

If Welcome opens, click Next to display Input Data.

- 4 **In Input Data, confirm that:**

- The appropriate data range is selected, including any row labels and column headers
- Column Header and Label settings are correct

For details, click Help or see [“Selecting the Location and Arrangement of Historical Data”](#) on page 17.

- 5 **Click Next to display Data Attributes.**

- 6 **In Data Attributes, indicate the time period for the data.**

For example, if the data points represent monthly numbers, select months.

7 For **Seasonality**, select **AutoDetect** so Predictor will use statistical algorithms to determine whether the data is seasonal. Findings appear in a statement to the right of the list box. To fine-tune seasonality settings or use optional events and screening settings, see [“Selecting Data Attributes—Seasonality, Events, Screening” on page 19](#).

8 **Optional:** If you are analyzing more than one data series with AutoDetect, click **View Seasonality** to chart the seasonality for each series.

For more information, see [“Viewing Historical Data by Seasonality” on page 20](#).

9 Click **Next** to open the **Methods** panel, and select forecasting methods.

10 Depending on the Data Attributes Seasonality setting, select one or more of these:

- **Non-seasonal Methods**—Work best on data that does not show a pattern that repeats regularly over a certain number of time periods, but can show a trend of decreasing or increasing over time
- **Seasonal Methods**—Work best on data that shows a pattern that repeats regularly over a certain number of time periods and can also show a trend of decreasing or increasing over time
- **ARIMA**—Useful in a variety of situations, particularly when there are many historical values and very few outlier values
- **Multiple Linear Regression**—Useful when independent variables affect another variable of interest

**Tip:** If **Non-seasonal Methods** and **Seasonal Methods** are available, select both.

If you have selected several series and one of them is controlled by the other, it is a dependent variable. In that case, select **Multiple Linear Regression** and see [“Using Multiple Linear Regression” on page 37](#).

11 When settings are complete, click **Next** to review or change forecasting options.

12 Select an error measure and a forecasting technique.

[“Time-series Forecasting Accuracy Measures” on page 88](#) describes these settings. For basic forecasting, use the defaults: RMSE and standard forecasting.

13 When all Options settings are complete, click **Run** to run the forecast and produce results. For more information, see [“Starting Predictor and Running a Forecast” on page 13](#).

The following topics describe how to customize Predictor settings to more closely reflect the historical data and provide more accurate forecast results:

- [“Selecting the Location and Arrangement of Historical Data” on page 17](#)
- [“Selecting Data Attributes—Seasonality, Events, Screening” on page 19](#)
- [“Selecting a Forecasting Method” on page 29](#)
- [“Setting Forecast Options” on page 39](#)

# Selecting the Location and Arrangement of Historical Data

Use the Input Data panel of the Predictor wizard to select the location and arrangement of historical data to analyze.

**Tip:** After you start Predictor the first time, Input Data opens automatically whenever you start Predictor, or click Input Data in the navigation pane of the Predictor wizard.

► To select the location and arrangement of historical data:

- 1 **Open a model with historical data, select a data cell in the range to analyze, and start Predictor as described in [“Starting Predictor and Running a Forecast” on page 13](#).**

Input Data shows a possible data selection in the Location of Data Series text box and the illustration at the right side of the panel.

- 2 **Location of data series** indicates the cells that contain data to analyze. If the data series have headers or labels at the beginning of the rows or columns of data, include them in the selection and select the appropriate **Headers** settings. If necessary, select a different data range.

**Note:** If you select one cell before you start the wizard, the data range is selected automatically, based on the continuously filled cells around the selected cell. If you select a range of cells before you start the wizard, that range is selected. If you do not select a cell, or if you select an empty cell before you start the wizard, you can select the range using the cell selector. You can have discontinuous data series with blank columns or rows between them. For selection rules, see [“Selecting Discontinuous Data” on page 18](#).

- 3 **Confirm that the Orientation, Headers, and Labels settings are correct:**

- **Orientation**—Specifies whether data series are in rows or columns: Data in rows indicates that historical data is in horizontal rows; Data in columns indicates that historical data is in vertical columns.
- **First row (or column) has headers**—Indicates whether the selected data has a title or header cell at the top of each column (if the data is in columns) or to the left of each row (if the data is in rows).
- **First column (or row) has dates**—Indicates whether the data range has a first row or column for dates. Predictor recognizes dates only in cells that are formatted as Microsoft Excel dates.
- **Back**—Opens the Welcome panel
- **Next**—Opens the Data Attributes panel
- **Run**—Runs Predictor if all required settings are complete, using the current method selections
- **Close**—Closes the Predictor wizard
- **Help**—Displays online help for the current panel

- 4 When settings are complete, click **Next** to open **Data Attributes** and set seasonality and optional events and screening options. For instructions, see [“Selecting Data Attributes—Seasonality, Events, Screening” on page 19](#).

**Note:** If the data range has empty cells in the middle of a data series, by default Predictor fills in the missing data (see [“Viewing Screened Data” on page 28](#)). If you select multiple data series, the data series are not required to start at the same time period. However, all the data series must end at the same time period.

**Tip:** For a quick forecast, complete the Input Data settings and click Run. Logical defaults on the remaining panels help ensure accurate results after you select a range of historical data to analyze.

## Selecting Discontiguous Data

If a model is formatted with blank rows or columns between the data series, you can still select multiple series for forecasting. Alternative ways for selecting such discontiguous series, either before you start Predictor or by using the cell selector tool in the Input Data panel, are as follows:

- You can use the Ctrl key to select a complete discontiguous range. The entire selected range is then used in Predictor.
- You can also select multiple discontiguous cells. In that case, each one of these cells is used as a starting point for autodetecting a series range and the results of the autodetection are combined and used in Predictor. If data is in columns and you select a few discontiguous blocks from right to left, Predictor sorts the resulting ranges and ensures that they are ordered from left to right. Data in rows is ordered from top to bottom.

The individual ranges that make up the discontiguous range must be aligned. If data is in rows, the left and right column of each range must be aligned. If data is in columns, the top and the bottom row must be aligned. If multiple ranges are detected but they are not aligned, an error message is displayed and only the first selected range is used.

# Selecting Data Attributes—Seasonality, Events, Screening

## Subtopics

- [Viewing Historical Data by Seasonality](#)
- [Viewing and Managing Events](#)
- [Viewing Screened Data](#)
- [Setting Screening Options](#)

Seasonality, also known as cyclical data, means that data for some unit of time repeats in a regular pattern. For example, if you have 24 monthly data points, and the data has peaks every December, the seasonality (repeating pattern) has a period of one year or 12 months.

Use the Data Attributes panel of the Predictor wizard to perform the following tasks:

- Specify time-period and seasonality information for historical data
- Define events that influenced data values
- Apply optional screening to replace missing values and locate and replace data outliers

## Specifying Time Periods and Seasonality

► To specify time periods and seasonality:

### 1 Display the **Data Attributes** panel of the Predictor wizard.

To display Data Attributes, click Next in Input Data or click Data Attributes in the navigation pane of the Predictor wizard.

### 2 For **Data is in**, identify the time period for the data.

For example, if the data points represent monthly numbers, select months.

### 3 For **Seasonality**, indicate whether the data is seasonal:

- **AutoDetect**—Uses statistical algorithms to determine whether the data is seasonal. Findings appear in a statement to the right of the list box.
- **Non-seasonal**—Indicates that data is treated as non-seasonal; seasonal methods will not be applied.
- **Seasonal**—Indicates that seasonal and non-seasonal methods are used by default. You must have at least two seasons (complete cycles) of data to use the seasonal methods.

### 4 **Optional:** If you are analyzing more than one data series click **View Seasonality** to review seasonality for each series.

For more information, see [“Viewing Historical Data by Seasonality” on page 20](#).

### 5 Specify how to treat missing values and outliers (historical values that differ extremely from other values):

- Select **Fill-in missing values** to fill in missing data values using settings in the **Data Screening Options** dialog.

- Select **Adjust outliers** to eliminate extreme values from the data before the time-series forecasting methods are run.

Note that the default values (filling in missing values but not adjusting outliers) are appropriate for most cases. For details, see [“Viewing Screened Data” on page 28](#).

- 6 **Optional:** Click **View Events** to define and manage events—time periods where data could have been affected by unusual occurrences such as promotions, weather, holidays, and strikes.

If you have defined an event, you can check **Include Events** to incorporate event definitions into forecasts. For details, see [“Viewing and Managing Events” on page 24](#).

- 7 **Optional:** Click **View Screened Data** to view a chart of filled-in values and adjusted outliers. For more information, see [“Viewing Screened Data” on page 28](#).

- 8 When settings are complete, click **Next** to open the **Methods** panel.

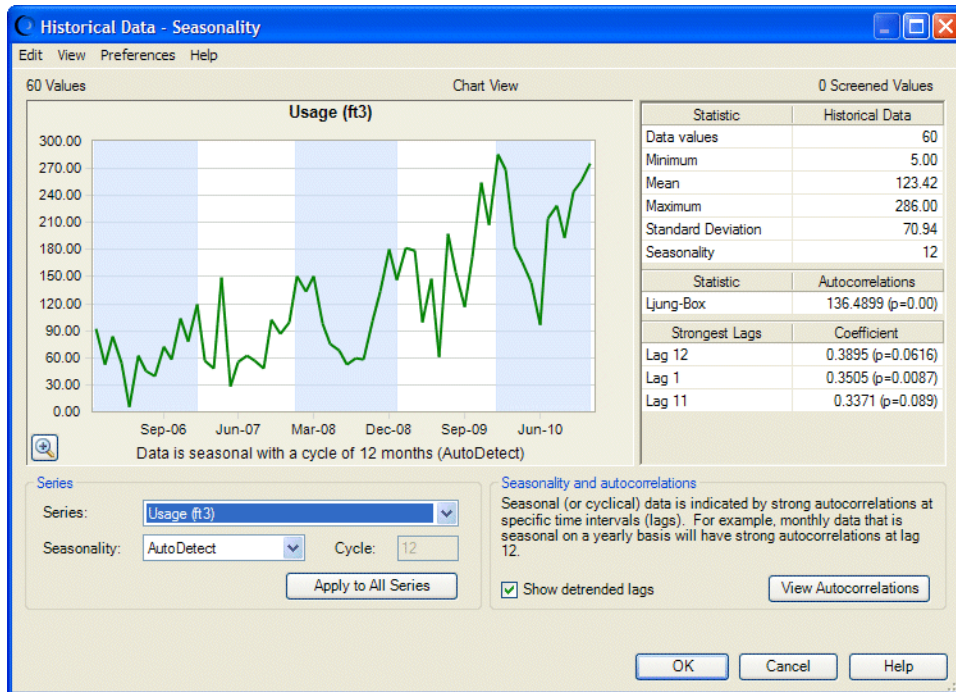

## Viewing Historical Data by Seasonality

As you progress through the Predictor wizard, you need to know if the data is seasonal (increases and decreases in a regular cycle) and, if so, what the season or cycle is. You can select **AutoDetect** in the **Input Data** panel, but you still may want to view charts of historical data to confirm seasonality selections before you run Predictor. In the **Data Attributes** panel of the Predictor wizard, you can choose to view charts of data values and autocorrelations for each series of historical data.

**Note:** If you selected **Fill-in missing values** in the **Input Data** panel, the missing values are already filled in when you view charts of historical data and autocorrelations. Data counts include the filled-in values. However, if you selected **Adjust outliers**, these charts do not include outlier adjustments and data counts. To view adjusted data, including data counts adjusted to include outliers, select **View Screened Data**.

- To view historical data values by series, in Data Attributes, click **View Seasonality**. The **Historical Data - Seasonality** dialog opens (Figure 2).

Figure 2 Historical Data – Seasonality Dialog

Historical Data - Seasonality contains:

- Series chart, upper-left corner—By default, plots historical data values for the selected series; can also display autocorrelation coefficients (see [“Identifying Seasonality with Autocorrelations”](#) on page 22 for details). In both views, seasonality is indicated by a repeating pattern.
- Series group, lower-left corner—Lists all the data series in the selected spreadsheet cell range. The currently selected series appears in the chart. Contains:
  - Series—The selected series
  - Seasonality—Seasonality setting for the current series
  - Cycle—Number of time periods in each season or cycle for the current series
  - Apply to All Series—Applies the current settings to all series
- Statistics, upper-right corner—Lists:
  - Statistics for seasonal data: number of data values, minimum value, mean value, maximum value, standard deviation of values, and the number of time periods in a cycle, such as 12 months in a year
  - Ljung-Box statistic for evaluating autocorrelations and the probability that data is not seasonal ([“Ljung-Box Statistic”](#) on page 97)
  - The three most significant autocorrelation coefficients (up to a lag of one-half of the number of data points)

- Menus that enable you to perform these actions:
  - Copy and print the chart (Edit menu)
  - Switch between the historical data chart, chart of data autocorrelations, and a data table (View menu)
  - Show and hide statistics (View menu)
  - Set chart preferences (Preferences menu)
  - Open Predictor help (Help menu)
- To show or remove trend corrections from the chart and statistics tables, select or clear **Show detrended lags**.
- To confirm seasonality using autocorrelations between data at different time lags, click **View Autocorrelations**.

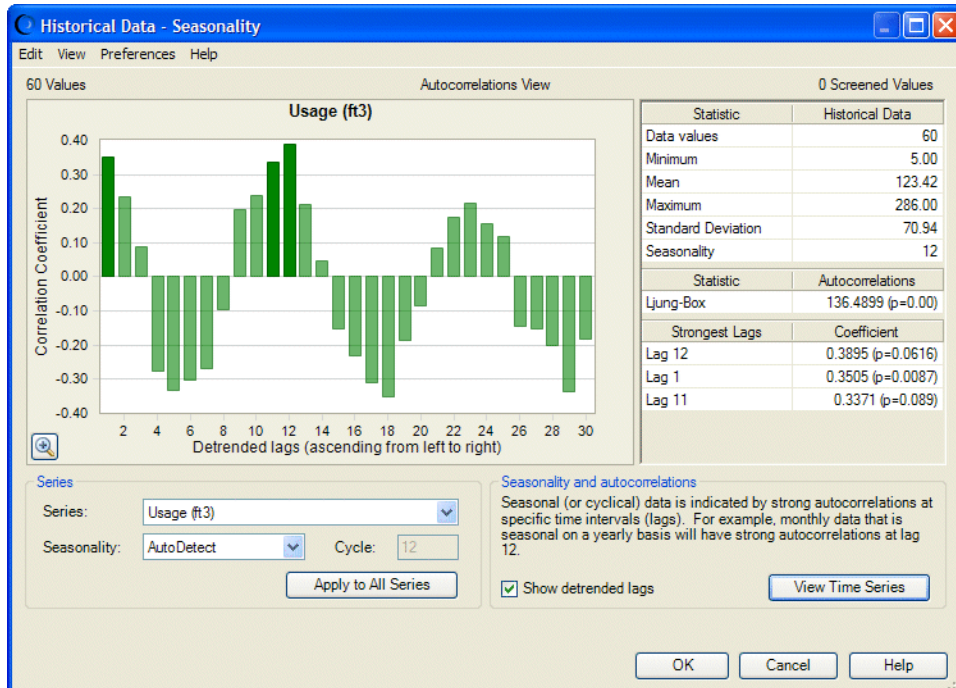

The seasonality chart changes to Autocorrelations view. For more information, see [“Identifying Seasonality with Autocorrelations” on page 22](#).

**Tip:** If you selected more than one historical data series, change the graph to view another data series by selecting it from the Series list.

## Identifying Seasonality with Autocorrelations

The Autocorrelations view of the Historical Data dialog displays a chart of autocorrelations—correlations of values of the same series separated by varying time lags—to indicate whether the historical data values have seasonality ([Figure 3](#)).

Figure 3 Historical Data – Seasonality Dialog – Autocorrelations View

**Note:** “[Viewing Historical Data by Seasonality](#)” on page 20 describes the Historical Data - Seasonality dialog.

Other dialog features:

- In Autocorrelations View, the series chart plots autocorrelation coefficients at different lags for the selected series (three greatest lags are plotted with darker bars); seasonality is indicated by strong lags at certain time periods.
- To show or remove trend corrections from the chart and statistics tables, select or clear **Show detrended lags** . For more information about lags and the Ljung-Box statistic, see “[Notes about Autocorrelations](#)” on page 23.
- To enlarge the chart, click + in the lower-left corner and move the sliders to show different levels of detail.
- To view seasonality in terms of historical data values for each series, click View Time Series. The seasonality chart changes to Chart View, a plot of historical data values over time. For more information, see “[Viewing Historical Data by Seasonality](#)” on page 20.

If you selected more than one historical data series, change the graph to view another data series by selecting it from the Series list.

### Notes about Autocorrelations

- The lag represents the number of data periods that the data is offset with the original data before calculating the correlation coefficient. For example, a lag of 12 corresponds with

correlating the data with itself, offset by 12 periods; in other words, the correlation of the first data item with the thirteenth data item, the second data item with the fourteenth data item, and so on. The  $p$ -value (value of Prob) in the statistics table indicates the significance of the lag and is detrended or not, depending on the check box selection in Autocorrelations View.

- A seasonal series has alternating patterns of positive and negative lags. The seasonality (cycle) is usually determined by the strongest lag in the set of positive lags following the first set of negative lags.
- Seasonality is always calculated on detrended lags to remove the effect that trending data has on autocorrelations. You can select or clear **Show detrended lags** to view autocorrelation information with or without detrending.
- If the probability of the Ljung-Box statistic is less than 0.05, the set of autocorrelations is significant, and the data is probably seasonal. The seasonality is indicated by the autocorrelation lag. For example, if one of the top three lags is 12 and has a probability of less than 0.001, the data probably have a seasonality of 12 periods.

## Viewing and Managing Events

### Subtopics

- [Adding Events](#)
- [Editing Events](#)
- [Deleting Events](#)
- [Setting Event Dates](#)

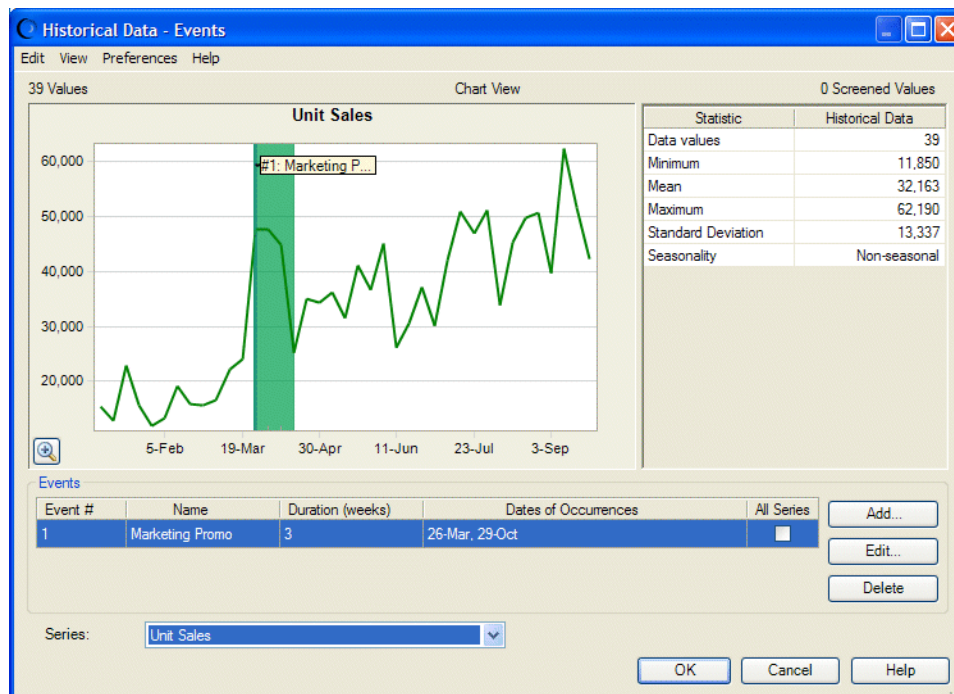

You can use the events feature of Predictor to define identifiable occurrences that have affected historical data and could affect predicted data. These events can be one-time occurrences, such as a storm, or events that repeat on a regular basis, such as quarterly sales promotions. You can also define events that repeat at irregular intervals, such as assembly-line lockouts or tagouts. Note that these events are different from unusual values without a known cause discussed in [“Viewing Screened Data” on page 28](#).

You can define events for historical and predicted data. If an event is defined only for historical data, Predictor calculates changes produced by a defined event and uses that information to minimize the effect of the event on data predictions. If an event is defined for historical and predicted data ranges, historical data is used to predict data for the same event in the future.

- To use defined events in Predictor calculations, in **Data Attributes**, select **Include Events**.
- To add, edit, delete, and view events, in **Data Attributes**, click **View Events**. The **Historical Data - Events** dialog opens (Figure 4).

Figure 4 Historical Data - Events Dialog with an Event Added

Historical Data - Events contains:

- Series chart, upper-left corner—Plots historical data values for the selected series; defined events are indicated by vertical bars.  
Click the Zoom button at the bottom of the chart beneath the y-axis to contract and expand the x-axis and show more or fewer time periods per unit of length.
- Events list—Lists events by number, name, duration, and date. A check box indicates whether the event applies to all series or just the selection. Use the buttons to add, edit, or delete events. For details, see the following:
  - [“Adding Events” on page 26](#)
  - [“Editing Events” on page 27](#)
  - [“Deleting Events” on page 27](#)

**Note:** Events cannot overlap. At least one time period must not be defined as an event. If more than 10 percent of the historical values are defined as events, predictive accuracy can be affected. A warning message is displayed, but you can still choose to complete the forecast.

- Series list, lower-left corner—Lists all the data series in the selected spreadsheet cell range. The currently selected series appears in the chart.
- Statistics, upper-right corner—Lists the following: number of historical data values, minimum value, mean value, maximum value, standard deviation of values, and the number of time periods in a cycle, such as 12 months in a year.
- Menus that enable you to:
  - Copy and print the chart (Edit menu)
  - Switch among the historical data chart and a data table (View menu)
  - Show and hide statistics (View menu)
  - Set chart preferences (Preferences menu)
  - Open Predictor help (Help menu)

**Tip:** You can view information for another data series by selecting it from the Series list.

After you define at least one event and check Include Events in Data Attributes, you can include events data in reports and extract events data. For instructions, see [“Creating Reports” on page 49](#) and [“Extracting Results Data” on page 50](#).

## Adding Events

► To add an event:

- 1 In **Data Attributes**, click **View Events**.
- 2 In **Historical Data – Events**, click **Add** (Alt+a).
- 3 In the **Add Event** dialog, provide the following requested information:
  - **Name**—A label to identify the event
  - **Apply to all series**—When selected, applies the new event to all series, not just to the current series
  - **Start date**—The date the event or the first occurrence of the event began ([“Setting Event Dates” on page 27](#))
  - **Duration**—The number of time periods that include a single occurrence of the effects of the event; this number must be a whole number, not a decimal, greater than 0
  - **Repeats**—Whether the event never repeats, repeats continuously at regular intervals, or repeats at custom (irregular) intervals

To enter additional irregular intervals after the “Start date” entry (including intervals in the future), select **at custom intervals** and follow the instructions in [“Setting Event Dates” on page 27](#).

If you select **every**, intervals are assumed to repeat in future predicted data as well as in past historical data.

- 4 When settings are complete, click OK.

For a description of the Historical Data – Events dialog, see [“Viewing and Managing Events” on page 24](#).

## Editing Events

- To edit an event:

- 1 In **Data Attributes**, click **View Events**.
- 2 In **Historical Data – Events**, select an event and click **Edit (Alt+t)**.
- 3 In **Edit Event**, edit the displayed information.

For a description of each edit box, see [“Adding Events” on page 26](#). For information on the start date and custom date settings, see [“Setting Event Dates” on page 27](#).

- 4 When settings are complete, click OK.

For a description of the Historical Data – Events dialog, see [“Viewing and Managing Events” on page 24](#).

## Deleting Events

- To delete an event:

- 1 In **Data Attributes**, click **View Events**.
- 2 In **Historical Data – Events**, select the event to delete and click **Delete (Alt+d)**.
- 3 Select **Yes** to delete the event and **No** to keep it.
- 4 When settings are complete, click **OK**.

For a description of the Historical Data – Events dialog, see [“Viewing and Managing Events” on page 24](#).

## Setting Event Dates

**Note:** The following settings are in **Add Event** and **Edit Event**. See [“Adding Events” on page 26](#) and [“Editing Events” on page 27](#).

- To set the start date of the first or only occurrence of an event, click **Select (Alt+S)** to display a calendar. You can enter text in the Filter box to narrow the search. For example, if the time

period is months, enter M to display May and March for all years. An asterisk (\*) is a “wildcard” symbol that matches any characters.

► To set additional start dates for irregular occurrences after the first “Start date” entry:

- 1 Select **at custom intervals**, and then click **Select (Alt+I)** to display the **Select Custom Dates** dialog.
- 2 Use the arrow buttons to move dates from **Available Dates** to **Selected Dates**. These are start dates for other occurrences of that event that happen later than the start date entered in **Add Events**.

The duration is assumed to be the same as the duration entered in **Add Events**. You can use **Filteras** described for “Start date” earlier in this list.

- 3 To define start dates for event occurrences in the future, enter a number for **Show Future Periods**.

This setting is only for entering start dates. It is different from **Periods to Forecast**, shown in **Predictor Results**.

## Viewing Screened Data

You can use the Predictor data screening features to:

- Fill in values that should exist in historical data but do not, such as data missing for one month in a five-year series (see [“Selecting Data Attributes—Seasonality, Events, Screening” on page 19](#))
- Screen (exclude) outliers, values that differ significantly from the normal range of historical data
- Specify the statistical algorithms used to fill in or screen data (see [“Setting Screening Options” on page 28](#))

► To examine the effects of filling in or screening data, and to change screening settings:

- 1 Click **View Screened Data** in the **Data Attributes** panel.

The Historical Data - Data Screening dialog opens. Any screened data values are highlighted in the chart.

- 2 **Optional:** Select **Show screened data only** to gray out unscreened data in the chart.
- 3 **Optional:** Click **Screening Options** to specify data filling and screening options. For details, see [“Setting Screening Options” on page 28](#).

## Setting Screening Options

You can choose from among several statistical methods to identify and adjust outliers and fill in missing values.

► To select an outlier detection method:

- 1 In the **Data Attributes** panel, click **View Screened Data**.

The Historical Data - Data Screening dialog opens.

## 2 In **Historical Data – Data Screening**, click **Screening Options**.

The Data Screening Options dialog opens.

## 3 Select a detection method and enter an associated threshold value.

You can select outliers using the mean and standard deviation, the median and median absolute deviation (MAD), or the median and interquartile deviation (IQD). For a description of each method, see [“Outlier Detection Methods” on page 97](#). The default is Mean and Standard Deviation with a standard deviation of 3.

➤ To select a method for adjusting outliers and filling in missing values:

### 1 Display the **Data Screening Options** dialog as described in steps 1 and 2 above.

### 2 Select a method:

- **Cubic spline interpolation** calculates a smooth, continuous curve that passes through each data point. It evaluates the entire data set.
- **Neighbor interpolation** examines values on each side of the value to be adjusted or filled in and calculates that value based on the mean or median of the specified neighbors.

For more information about each method, see [“Outlier and Missing Value Adjustment Methods” on page 99](#).

### 3 If you select **Neighbor interpolation**, indicate the number of neighbors to evaluate on each side of the target value and select a statistic.

### 4 When settings are complete, click **OK**.

## Selecting a Forecasting Method

Use the Methods panel of the Predictor wizard to select a forecasting method.

➤ To display **Methods**, click **Next** in **Data Attributes** or click **Methods** in the navigation pane of the Predictor wizard.

➤ To select one or more forecasting methods:

### 1 Depending on the Data Attributes **Seasonality** setting and the nature of the data, select one or more of the following:

- **Non-seasonal Methods**—Work best on data that do not show a pattern that repeats regularly over a certain number of time periods, but can show a trend of decreasing or increasing over time
- **Seasonal Methods**—Work best on data that show a pattern that repeats regularly over a certain number of time periods and can also show a trend of decreasing or increasing over time
- **ARIMA**—Useful in a variety of situations, particularly when there are many historical values and very few outlier values

- **Multiple Linear Regression**—Useful when independent variables affect another variable of interest

**Note:** Shortcut keys for selecting or clearing each method group are as follows: **Ctrl+n**, Non-seasonal Methods; **Ctrl+s**, Seasonal Methods; **Ctrl+a**, ARIMA; and **Ctrl+m**, Multiple Linear Regression.

## 2 Optional: Disable any individual method or override the default settings:

- For **Non-seasonal Methods** and **Seasonal Methods**, see [“Using Classic Time-series Forecasting Methods” on page 30](#) for help with selecting only a few methods or using all of them (recommended). Note that you can double-click any method to change its parameters and override the defaults.
- For **ARIMA** (autoregressive integrated moving average) methods), see [“Using ARIMA Time-series Forecasting Methods” on page 33](#).
- For **Multiple Linear Regression**, see [“Using Multiple Linear Regression” on page 37](#).

## 3 When settings are complete, click **Next** to review and change forecasting options.

# Using Classic Time-series Forecasting Methods

**Note:** This section describes non-seasonal and seasonal time-series forecasting methods that do not include Box-Jenkins ARIMA methods. For information on those methods, see [“Using ARIMA Time-series Forecasting Methods” on page 33](#).

You can forecast historical data using many different time-series forecasting methods. Some methods are designed to work best for certain types of data:

- Seasonal data (increasing or decreasing in a regularly recurring pattern over time; [Figure 5](#), left side)
- Trend data (consistently increasing or decreasing over time; [Figure 5](#), right side)
- Data with no trend or seasonality

**Figure 5** Seasonal Data (Left) and Data with a Trend (Right)

In addition to these categories, there are two types of seasonal methods: additive and multiplicative. Additive seasonality has a steady pattern amplitude, and multiplicative

seasonality has the pattern amplitude increasing or decreasing over time. Figure 6 illustrates these different curves.

Figure 6 Different Seasonal Curves

For time-series forecasting, any of the classic time-series forecasting methods should work with different amounts of success. However, each method has its own purpose, as described in Table 1 and the summary paragraphs that follow it. For more information about each classic method, see “Classic Non-seasonal Forecasting Methods” on page 83 and “Classic Seasonal Forecasting Methods” on page 85.

Table 1 Choosing a Classic Time-series Forecasting Method

| No Trend or Seasonality      | Trend Only, No Seasonality   | Seasonality Only, No Trend | Both Trend and Seasonality   |
|------------------------------|------------------------------|----------------------------|------------------------------|
| Single exponential smoothing | Double exponential smoothing | Seasonal additive          | Holt-Winters' additive       |
| Single moving average        | Double moving average        | Seasonal multiplicative    | Holt-Winters' multiplicative |

To summarize selection guidelines:

- Moving average methods—These methods help to smooth out short-term fluctuations and highlight longer-term trends or cycles. They are used when the time series does not have a trend. When the time series has a trend, using the double moving average method computes a second moving average from the original moving average to track the trend better.
- Exponential smoothing methods—While the moving averages give equal weights to included values, single exponential smoothing assigns exponentially decreasing weights as the observation get older, a more reasonable approach. When a time series has a trend, double exponential smoothing is useful and is computed by smoothing the series twice.

- To determine whether you have trend or seasonal data, click **View Seasonality** on the **Input Data** panel. For details, see [“Viewing Historical Data by Seasonality” on page 20](#).
- Tip:** Viewing seasonality can help you decide which methods to select. However, selecting all the classic time-series forecasting methods available for either Non-seasonal Methods or Seasonal Methods does not significantly slow down the calculations unless you are forecasting thousands of values at once, so you can consider trying them all (the default).
- For forecasting method selection procedures, see [“Selecting a Forecasting Method” on page 29](#).
- To manually set the parameters for any method, see [“Setting Classic Time-series Forecasting Method Parameters” on page 32](#), following.

## Setting Classic Time-series Forecasting Method Parameters

**Note:** This section describes classic non-seasonal and seasonal time-series forecasting methods and does not include Box-Jenkins ARIMA methods. For information on those methods, see [“Using ARIMA Time-series Forecasting Methods” on page 33](#).

- To manually set the parameters for any classic time-series forecasting method, overriding the automatic calculation of parameters:
  - 1 **Double-click in the method area.**  
The method’s Parameters dialog opens.
  - 2 **Optional: Select Optimize** to automatically optimize the parameters using error measures.
  - 3 **Optional: Select Lock Parameters** to enter new parameter values in the parameter fields.  
For more information on these parameters, see [“Classic Non-seasonal Forecasting Method Parameters” on page 85](#) and [“Classic Seasonal Forecasting Method Parameters” on page 87](#).
  - 4 **Click OK.**

**Note:** The user-defined settings remain for the current data selection until you reset them. Click **Set Default** to restore default settings for future data selection.

# Using ARIMA Time-series Forecasting Methods

## Subtopics

- [Selecting an ARIMA Model Selection Criterion](#)
- [Using ARIMA Custom Models](#)
- [Adding Custom ARIMA Models](#)
- [Editing Custom ARIMA Models](#)
- [Setting ARIMA Options](#)

Autoregressive integrated moving average (ARIMA) forecasting methods were popularized by G. E. P. Box and G. M. Jenkins in the 1970s. These techniques, often called the Box-Jenkins forecasting methodology, have the following steps:

1. Model identification and selection
2. Estimation of autoregressive (AR), integration or differencing (I), and moving average (MA) parameters
3. Model checking

ARIMA is a univariate process. Current values of a data series are correlated with past values in the same series to produce the AR component, also known as  $p$ . Current values of a random error term are correlated with past values to produce the MA component,  $q$ . Mean and variance values of current and past data are assumed to be stationary, unchanged over time. If necessary, an I component (symbolized by  $d$ ) is added to correct for a lack of stationarity through differencing.

In a non-seasonal ARIMA( $p,d,q$ ) model,  $p$  indicates the number or order of AR terms,  $d$  indicates the number or order of differences, and  $q$  indicates the number or order of MA terms. The  $p$ ,  $d$ , and  $q$  parameters are integers equal to or greater than 0.

Cyclical or seasonal data values are indicated by a seasonal ARIMA model of the format

$\text{SARIMA}(p,d,q)(P,D,Q)(t)$

The second group of parameters in parentheses are the seasonal values. Seasonal ARIMA models consider the number of time periods in a cycle as defined in the Historical Data – Seasonality dialog ([Figure 2 on page 21](#)). For a year, the number of time periods ( $t$ ) is 12.

**Note:** In the Predictor user interface, seasonal ARIMA models do not include the ( $t$ ) component, although it is still used in calculations. See the Bibliography for references that describe this methodology in more detail.

Crystal Ball ARIMA models do not fit to constant datasets or datasets that can be transformed to constant datasets by non-seasonal or seasonal differencing. Because of that feature, all constant series, or series with absolute regularity such as data representing a straight line or a saw-tooth plot, do not return an ARIMA model fit.

► To use ARIMA methods:

- 1 In the Predictor wizard **Methods** panel, select **ARIMA**.
- 2 In the **Autoregressive Integrated Moving Average (ARIMA) Details** panel, select **Automatic** (the default) or **Custom models**.

**Note:** Unless you are thoroughly acquainted with ARIMA methodology and intend to construct or use existing custom ARIMA models, select **Automatic**.

- 3 **Optional:** If you selected **Automatic**, select a model selection criterion, **Minimize information criterion** (the default) or **Minimize selected error measure**. The default generally provides a better ARIMA estimate. Minimizing the error measure selected elsewhere for Predictor forecasting can result in overfitting.
- 4 **Optional:** Click **Select Information Criterion (Alt+e)** to indicate which information criterion to use. For details, see [“Selecting an ARIMA Model Selection Criterion” on page 34](#). Unless you have good reason to select another, BIC (the default) is usually appropriate.
- 5 **Optional:** Select **Perform extended model search** to compare more models to the historical data. Results may be somewhat more accurate, but the analysis can take noticeably more time.
- 6 **Optional:** If you selected **Custom models** in [step 2](#), build a list of models to use. For instructions, see [“Using ARIMA Custom Models” on page 35](#).
- 7 **Optional:** Click **ARIMA Options (Alt+o)** to indicate whether to include a constant in the ARIMA equation and whether to perform a Box-Cox transformation. The default, **AutoSelect** or **None**, is usually appropriate for both options. For more information, see [“Setting ARIMA Options” on page 36](#).

**Note:** If **Automatic** is selected, any displayed models are fitted to each series. Custom seasonal models are not fitted to non-seasonal series, but non-seasonal models will be fitted to seasonal series.

If **Custom models** is selected, models apply only to the currently selected Predictor series and must be defined for each series separately.

## Selecting an ARIMA Model Selection Criterion

► To select an ARIMA model selection criterion:

- 1 In the Predictor wizard **Methods** panel, select **ARIMA**.
- 2 In the **Autoregressive Integrated Moving Average (ARIMA) Details** panel, select **Automatic** (the default).
- 3 Select **Minimize Information Criterion**, and then click **Select Information Criterion (Alt+e)**.
- 4 In the **Select Information Criterion** dialog, select a setting:
  - Bayesian Information Criterion (BIC)
  - Akaike's Information Criterion (AIC)
  - Corrected AIC (AICc)

**Note:** See the Bibliography for references that discuss the differences among these criteria. The three criteria differ in the way that they penalize overfitting. The differences are small, and the chosen criterion typically does not lead to a change in the ARIMA model selected as the best fit.

## Using ARIMA Custom Models

While automatic selection of an ARIMA model should be completely adequate, if results are different from what you expect and you are familiar with ARIMA methodology and model construction, you can create and edit ARIMA models in Predictor.

► To use custom models for ARIMA forecasting:

- 1 In the Predictor wizard **Methods** panel, select **ARIMA**.
- 2 In the **Autoregressive Integrated Moving Average (ARIMA) Details** panel, select **Custom models**.
- 3 Click a button to add, edit, or remove a model:
  - **Add (Alt+d)**, enables you to create a new model, as described in [“Adding Custom ARIMA Models” on page 35](#).
  - **Edit (Alt+e)**, enables you to modify the selected model, as described in [“Editing Custom ARIMA Models” on page 36](#).
  - **Remove (Alt+v)**, permanently deletes the selected model.

**Note:** Displayed models are fitted to each series. Custom seasonal models are not fitted to non-seasonal series, but non-seasonal models are fitted to seasonal series.

## Adding Custom ARIMA Models

► To add a custom model for ARIMA forecasting:

- 1 Follow steps 1 and 2 in [“Using ARIMA Custom Models” on page 35](#).
- 2 Click **Add (Alt+d)**.
- 3 In the **Add ARIMA Model** dialog, indicate the orders for each parameter of the non-seasonal and, optionally, seasonal model, and then click **OK**.

Follow these rules for entering model orders:

- Non-seasonal component orders can be 0 to 10. Seasonal component orders can be 0 to 2.
- Orders must be integers.
- At least one parameter of the non-seasonal or seasonal model component must be non-zero.
- As with standard ARIMA notation, the  $p$  portion of the model definition goes in the AR field, the  $q$  portion in the MA field, and the  $d$  portion in the I field.

- The time-period portion of a seasonal model is taken from the existing Predictor information for that series but is not included in the **Custom models** list.

4 When the definition is complete, click **OK**.

The new model is displayed in the Custom models list. Seasonal models are preceded by S —SARIMA (2, 0, 3) (1, 0, 2), for example.

## Editing Custom ARIMA Models

► To edit a custom model for ARIMA forecasting:

- 1 Follow steps 1 and 2 in [“Using ARIMA Custom Models” on page 35](#).
- 2 Click **Edit (Alt+e)**.
- 3 In the **Edit ARIMA Model** dialog, indicate the orders for each part of the non-seasonal and, optionally, seasonal model, and then click **OK**.

For model rules, see [“Adding Custom ARIMA Models” on page 35](#).

4 When the definition is complete, click **OK**.

## Setting ARIMA Options

ARIMA equations can include a constant that represents the intercept if the AR portion of a model is not 0; otherwise, it represents the mean of the series. You can set ARIMA options to indicate whether to include the constant in ARIMA equations. The ARIMA options can also be used to provide variance stationarity in data using the Box-Cox transformation. If you choose to apply the Box-Cox transformation, you can select from among several lambda (  $\lambda$  ) options. For more information, see the *Oracle Crystal Ball Statistical Guide*.

The ARIMA options settings apply to both automatic and custom-model ARIMA forecasts.

**AutoSelect** is the default for the constant option; **None** is the default for the Box-Cox option.

► To set ARIMA options:

- 1 In the Predictor wizard **Methods** panel, select **ARIMA**.
- 2 In the **Autoregressive Integrated Moving Average (ARIMA) Details** panel, click **ARIMA Options (Alt +o)**.
- 3 In the **ARIMA Options** dialog, indicate whether to:
  - Include the constant in ARIMA equations by selecting **AutoSelect** (the default), **Always**, or **Never**
  - Perform no Box-Cox transformation (**None**); or perform a Box-Cox transformation with an **Optimized value** for lambda or a **Square root**, **Logarithmic**, or **Custom lambda** value (between -5 and +5, inclusive)

**Note:** If you select AutoSelect for constant inclusion, Predictor includes a constant in the ARIMA equation only when the model does not include a non-seasonal or seasonal difference term.

## Using Multiple Linear Regression

If you know that some independent variables affect another variable of interest (the dependent variable), use multiple linear regression as the forecasting method for that variable. For example, summer temperatures affect electricity usage because, as it gets hotter, more people run their air conditioning. This means that electricity usage (the dependent variable) is dependent on the temperature (an independent variable).

Predictor follows this process to forecast a dependent variable with regression:

1. Creates an equation that defines the mathematical relationship between the independent variables and a dependent variable. This is the regression equation.
2. Forecasts each independent variable by running all the selected time-series forecasting methods for each one and using the best method for each.
3. Calculates the regression equation with the forecasted independent variable values to create the forecast for the dependent variable.

► To use multiple linear regression:

- 1 **On the Predictor wizard **Methods** panel, select **Multiple Linear Regression**.**
- 2 **In the **Regression Variables** dialog, select dependent and independent variables. For instructions, see [“Selecting Regression Variables” on page 38](#).**
- 3 **Select the regression method to use: **Standard**, **Forward stepwise**, or **Iterative stepwise**. For descriptions, see [“Regression Methods” on page 93](#).**
- 4 **If you selected a stepwise regression, you can select associated settings.**  
For instructions, see [“Setting Stepwise Regression Options” on page 38](#).
- 5 **Select or clear the remaining settings:**
  - **Include constant in regression equation**—Includes the y-intercept constant in the regression equation; if not selected, the regression equation passes through the origin. This setting is selected by default.
  - **Run only regression method for dependent variables**—If selected, forecasting methods other than regression are not run on dependent variables. By default, this setting is not selected and all the forecasting methods run on these variables along with linear regression.
  - **Calculate variance inflation factor (VIF) for independent variables**—Calculates the Variance Inflation Factor (VIF) of each independent variable included in the regression equation, where VIF is a measure of the strength of multicollinearity (amount of correlation) between the independent variables. Calculating the VIF requires additional time. By default, this setting is not selected.

**Note:** For rules concerning minimum number of data points required for multiple linear regression, see [“Creating Spreadsheets with Historical Data” on page 12](#).

## Selecting Regression Variables

The **Regression Variables** dialog opens when you select **Multiple Linear Regression** in the **Methods** panel of the Predictor wizard.

► To select dependent and independent variables for regression analysis:

**1** In the **Regression Variables** dialog, move the dependent variables into the **Dependent variables (Y's)** list:

a. Select the name of a dependent variable in the **Independent variables (X's)** list.

You can have more than one dependent variable. Predictor forecasts them all, one at a time, as functions of all the same independent variables.

b. Click  between the lists.

The variable moves to **Dependent variables (Y's)**.

**2** Confirm that all variables are included in the appropriate list.

**3** To lag independent variable data by a number of time periods:

a. Select a variable in **Independent variables (X's)**.

b. Enter the number of time periods to lag the variable in the **Lag** text box below the list.

c. Repeat for any other independent variables you want to lag.

**4** Clear the check box for any variables you do not want to include in the regression.

**5** Click **OK**.

The Methods panel is displayed again (see “Using Multiple Linear Regression” on page 26).

## Setting Stepwise Regression Options

The Stepwise Options dialog opens when you select one of the stepwise regression methods in the Methods panel of the Predictor wizard.

► To set appropriate stepwise method options:

**1** In the **Stepwise Options** dialog, select **R-Squared** and **Partial F-Test** settings.

Fields, settings, and buttons in the **Stepwise Options** dialog:

- **R-Squared**—Stops the stepwise regression if the difference between a specified statistic (either R-Squared or Adjusted R-Squared) for the previous and new regression solution is below a threshold value. When this happens, Predictor does not use the new regression solution. By default, this stopping criterion is selected and uses R-Squared as the statistic. If this setting and the Partial F-Test Significance are selected, the stepwise regression stops when it reaches either criterion's threshold value.

- **Threshold**—Sets the minimum increment required between the R-Squared or Adjusted R-Squared of the last step and the R-Squared or Adjusted R-Squared of the new step to continue with the stepwise regression. The default is 0.001.
- **Partial F-Test Significance**—Stops the stepwise regression if the probability of the F statistic for a new solution is above a maximum value. By default, this stopping criterion is not selected. If this setting and the R-Squared setting are selected, the stepwise regression stops when it reaches either criterion's threshold value.
- **Probability to add**—Sets the maximum probability of the correlation (partial F statistic) of the independent variable required to add the variable to the regression equation. The default is 0.05. When dealing with statistical tests, smaller probabilities indicate more significance.
- **Probability to remove**—Sets the minimum probability of the correlation (partial F statistic) of the independent variable required to remove the variable from the regression equation. The default is 0.05. This setting is only available with iterative stepwise regression. The Probability to remove setting must be at least 0.05 higher than the Probability to add setting.

2 Click **OK**.

The Methods panel is displayed again (see [“Using Multiple Linear Regression” on page 37](#)).

## Setting Forecast Options

Use the Options panel of the Predictor wizard to select an error measure and a forecasting technique. To display Options, click Next in Methods or click Options in the navigation pane of the Predictor wizard.

The following topics describe how to set the forecast options:

- [“Selecting Error Measures” on page 39](#)
- [“Selecting Forecasting Techniques” on page 40](#)

When all Options settings are complete, click Run to run the forecast and produce results. For more information, see [“Starting Predictor and Running a Forecast” on page 13](#).

## Selecting Error Measures

Predictor uses one of three error measures to determine which time-series forecasting method works best. When determining the best method, Predictor calculates the selected error measure when fitting each method to the historical data. The method with the lowest error measure is considered best, and the rest of the methods are ranked accordingly.

By default, Predictor uses RMSE to select the best method.

➤ To change which error measure Predictor uses:

1 On the **Options** panel, select the error measure you want Predictor to use to determine the best method:

- RMSE - Root Mean Squared Error
- MAD - Mean Absolute Deviation
- MAPE - Mean Absolute Percentage Error

For more information on these error measures, see [“Time-series Forecasting Accuracy Measures” on page 88](#).

- 2 Follow the instructions in [“Selecting Forecasting Techniques” on page 40](#) to complete the Options settings and prepare to run the forecasts.

## Selecting Forecasting Techniques

Predictor uses one of four forecasting techniques for time-series forecasting: Standard, Simple lead, Weighted lead, and Holdout. By default, Predictor uses Standard forecasting to select the best method.

► To change which forecasting technique Predictor uses:

- 1 On the **Options** panel, select the forecasting technique to use for time-series:

- **Standard forecasting**—Error measure between the fit values and the historical data for the same period; the default
- **Simple lead**—Error measure between the historical data and the fit offset by a specified number of periods (lead)
- **Weighted lead**—Average error measure between the historical data and the fit offset by 0, 1, 2, etc. periods, up to the specified number of periods (weighted lead)
- **Holdout**—Error measure between a set of excluded data and the forecasting values. Predictor does not use the excluded data to calculate the forecasting parameters

For more information about each technique, see [“Time-series Forecasting Techniques” on page 90](#).

- 2 If you select **Simple lead**, **Weighted lead**, or **Holdout**, enter the appropriate lead or holdout in the box.
- 3 If all settings in the Predictor wizard are complete, click **Run** to run the forecast and produce results.

## Understanding the Predictor Results Window

### Subtopics

- [Entering the Number of Time Periods to Forecast](#)
- [Selecting a Confidence Interval](#)

The Predictor Results window ([Figure 7](#)) is similar to the Historical Data dialog described in “[Viewing Historical Data by Seasonality](#)” on page 20.

Figure 7 Predictor Results Window with Shampoo Sales Results Including Events

- The Series group determines which data series is displayed. If you forecasted results for more than one series, look at all results by selecting each series in the Series list.
- By default, the displayed information is calculated using the forecasting method listed as BEST. You can view a different method for each series if you want. The methods are ordered from best to worst.

You can override the best method to calculate results using the new “best” method. This change only affects the current series. The other series remain unchanged unless you select one and override its method also.

If you change the method selection for a given series and then select another series and come back to the original series, it is the best method for the original series that is selected (not any non-best selection that might have been active when the series was changed). To always view a particular method when a particular series is selected, the best method should be overridden for that series.

- The chart of series data values includes historical and predicted, or forecasted, data. Plots of raw data values and fitted values are displayed for historical data. Forecasted data values are enclosed by lines that show the upper and lower confidence intervals (described in [“Selecting a Confidence Interval” on page 43](#)). You can use **Ctrl+p** to display and hide confidence interval lines on the chart.
- In the case of a dependent regression variable, the forecasted values are a function of the best forecast methods (or overridden best forecasting methods) of the independent variables.
- If you have defined at least one event and selected **Include events** in the Data Attributes panel, a shaded vertical bar displays through historical and predicted data defined as events. You

can select **Preferences**, and then **Highlight Events** to hide these bars and display them again (see [Figure 7 on page 42](#)).

**Note:** You can also select **Highlight Seasonality** and **Highlight Screened Data** to show or hide indications of seasonal cycles or filtered data if those features if they are selected in the Predictor wizard and included within displayed data.

- In the upper-right is a table of statistics for the raw historical data. For more information about these statistics, see [“Historical Data Statistics” on page 96](#).
- Below the historical statistics are error statistics for the forecasted data values. These statistics are described in [“Time-series Forecasting Accuracy Measures” on page 88](#).
- At the bottom of the statistics table are parameter values for the currently selected forecasting method. See [“Classic Non-seasonal Forecasting Method Parameters” on page 85](#) and [“Classic Seasonal Forecasting Method Parameters” on page 87](#).
- The Forecasts group is used to change the number of time periods to forecast and to select confidence interval boundaries. See [“Entering the Number of Time Periods to Forecast” on page 43](#) and [“Selecting a Confidence Interval” on page 43](#).

You can also use the Adjust and Paste buttons to adjust missing values and outliers (extreme values) and paste forecasted values into the Predictor model ([“Adjusting Forecasted Data” on page 44](#) and [“Pasting Predictor Forecasts” on page 46](#)).

- You can right-click within the Predictor Results window to display a menu with related commands.

For additional information, see [“Selecting How to Display and Analyze Results” on page 44](#).

## Entering the Number of Time Periods to Forecast

After Predictor determines the method that best fits the historical data, it can use that same method to forecast future values. You need to decide how many time periods to forecast.

Consider these factors:

- The first few values are fairly reliable. Forecast only as many values as you need.
  - The farther out you try to forecast, the less reliable the forecasted values are. The confidence interval of any forecast grows to reflect this decrease in reliability.
- To indicate how many time periods to forecast, enter the number in **Periods to forecast** in the lower-right corner of the **Predictor Results** window.

## Selecting a Confidence Interval

The confidence interval defines the range above and below a forecasted value where the value has some probability of occurring. For example, a confidence interval of 10% and 90% gives two points for each forecasted value. The lower point represents the 10th percentile. The higher point

represents the 90th percentile. There is an 80% chance the predicted value will fall within this range. The farther out the forecast is, the larger this range is.

- To select a confidence interval, select from the **Confidence interval** list in the lower right corner of the Predictor Results window or choose **Custom** to enter the desired confidence interval in the **Custom Confidence Interval** dialog.

## Selecting How to Display and Analyze Results

You can use Predictor results in several ways:

- Adjust the forecasted data, including rounding it
- Paste the forecasted data anywhere on the worksheet or into a new worksheet
- View, copy, and print charts that can show historical data, fitted values, forecasted data, and associated confidence intervals
- Generate a report summarizing the findings
- Create an interactive table of all the historical data, fitted values, forecasted data, and confidence intervals
- Create an interactive table of some or all the method information for each forecast, including the errors, parameters, and statistics for each method tried

For instructions:

- [“Adjusting Forecasted Data” on page 44](#)
- [“Pasting Predictor Forecasts” on page 46](#)
- [“Viewing Charts” on page 47](#)
- [“Creating Reports” on page 49](#)
- [“Extracting Results Data” on page 50](#)

## Adjusting Forecasted Data

After you run a Predictor forecast, you can adjust the forecasted data to customize it for your particular situation. For example, you could add 50 to each forecasted value, or you could round each value to the nearest hundreds. Adjustments are applied to all methods for that series.

- To adjust forecasted data:

- 1 Run a Predictor forecast and display the **Predictor Results** window.
- 2 Click **Adjust**.
- 3 In the **Adjust Forecast for Series** dialog, change any or all settings in the listed order:
  - 1. Percentile of forecast range—See the note below for an explanation; select **Custom** to enter a percentile into the **Custom Percentile** dialog (Default = Median)

- **2. Adjust values by**—Increases or decreases each value by the specified amount (Default = 0.00)
- **3. Round values to**—Rounds values to the specified numeric place; for example Integer rounds to the nearest number in units place (Default = No rounding; select **Custom** to specify a decimal place as described in “Custom Rounding” on page 45)
- **4. Restrict values to range**—Limits adjusted values to the specified range (Default = –Infinity to Infinity)

**Note:** When a time-series forecast is pasted into a model as a Crystal Ball assumption, each forecast value is assumed to be the median, or 50th percentile, of a normal distribution assumption. The percentile adjustment is ignored in this case.

- 4 Optional:** Click **Apply to All Series** to apply the settings to all data series, except for dependent variables in a regression analysis.
- 5 Optional:** Click **Defaults** to restore all the default settings.
- 6** When setting changes are complete, click **OK**.

## Custom Rounding

Several rounding settings are available in the **Adjust Forecast for Series** dialog; you can also specify custom rounding levels.

➤ To specify a custom rounding level:

**1** In the **Adjust Forecast for Series** dialog, select **Custom** for **3. Round values to**.

**2** In the **Custom Rounding** dialog, specify a rounding level:

- 0 = first place to the left of the decimal (units place)
- 1 = second place to the left of the decimal (tens)
- 2 = third place to the left of the decimal (hundreds)
- 3 = fourth place to the left of the decimal (thousands)
- –1 = first place to the right of the decimal (tenths)
- –2 = second place to the right of the decimal (hundredths)
- –3 = third place to the right of the decimal (thousandths)

Increased positive and negative values continue this pattern. The default is 0. The valid range of entries is –15 to 15, inclusive.

# Pasting Predictor Forecasts

## Subtopics

- [Time-series Forecast Method Results](#)
- [Multiple Linear Regression Results](#)

► To paste forecasted values into a Microsoft Excel worksheet:

- 1 In the **Predictor Results** window, set **Periods to forecast** to the number of time periods to paste into the worksheet.
- 2 Click **Paste**.
- 3 Select from among these settings in the **Paste Forecasts to Spreadsheet** dialog:
  - **Location:**
    - **At end of historical data**—Pastes forecasted data after the historical data
    - **Starting at cell**—Pastes data in the specified cell and following cells; select a range to paste multiple data series
  - **Note:** Data is pasted below or to the right of the specified cell, depending on the **Orientation** selection.
  - **Options:**
    - **Include date series**—Pastes date labels next to forecasted values
    - **Paste forecasts as Crystal Ball assumptions**—Creates pasted cells as Crystal Ball assumptions defined as normal distributions with a mean that is the forecasted value and a standard deviation that is based on the RMSE of the fitted data
  - **Note:** Predictor does not create assumptions if the variation in the data is zero or approaches infinity.
  - **Formatting:**
    - **AutoFormat**—Formats data to match the numerical formatting of the data series and highlights forecasts in **bold**

- 4 Click **OK**.

The results paste at the specified location. They are forecasted using the currently selected BEST method shown in the Predictor Results window.

Although Predictor tried all the methods you selected in the Method Gallery, it generates the pasted values using the best method, unless you overrode the best method, which is then used instead.

**Note:** Of the eight classic time-series forecasting methods, two result in flat lines: single moving average and single exponential smoothing. The forecasted values for these are all the same. This result is not an error. It is the best possible forecast for volatile or patternless data.

When you paste regression results, the independent variable forecast values are pasted as simple value cells. The dependent variable forecasted values are created as formula cells with the regression equation as the formula. The regression equation coefficients appear below the pasted values.

## Time-series Forecast Method Results

For data series forecasted using time-series methods, Predictor creates the assumptions as normal distributions with a mean equal to the forecasted value in the cell and a standard deviation calculated using the RMSE.

## Multiple Linear Regression Results

For multiple linear regression, Predictor creates assumptions for the independent variable forecast values only. This is because the independent variable values are simple value cells, but the dependent variable values are formula cells that are a function of the independent variables.

To see the variability of the dependent variable, select the pasted formula cells and define them as Crystal Ball forecast cells. (To do this, select Define, and then Define Forecast.) More likely, you will want to create one formula cell that represents the sum of the data in the dependent variable cells and define that formula cell as a Crystal Ball forecast.

## Viewing Charts

### Subtopics

- [Customizing Charts](#)
- [Copying and Printing Charts](#)

By default, the Predictor Results window contains a chart of historical and forecasted values in the upper left.

➤ To control the chart view, use these settings:

- **Periods to forecast**—Determines the number of forecasted values that appear in the chart
- **Confidence interval**—Indicates which confidence interval to calculate and plot
- **Series**—Selects the data series to display in the chart
- **Method**—Selects the method to use for calculating forecasted values
- **View menu**—**View, Table** changes the chart display to a table; **View, Chart** changes it back; and **View, Show Statistics** hides and displays the statistics tables to enlarge the chart

**Note:** If **Include events** is selected in the Data Attributes panel of the Predictor wizard, and at least one event is defined, Table View includes an Event column with the name and number of each event defined for the selected series.

- **Preferences menu**—**Preferences, Chart** displays the Chart Preferences dialog (see “Customizing Charts” on page 48, following); **Preferences, Show All Error Measures** hides and shows error measures that are not selected in the Options panel of the Predictor wizard; **Preferences, Highlight Seasonality** graphically emphasizes seasonal data cycles if present; **Preferences, Highlight Screened Data** emphasizes filled-in or adjusted-outlier data if these are present and you selected at least one of the **Data Screening** settings in the Data Attributes panel; and **Preferences, Highlight Events** emphasizes data defined as events if you have defined at least one event and selected **Include events** in the Data Attributes panel.

### Chart Notes

- As shown in the chart legend, the green line represents the historical data, the blue lines represent fitted and forecasted values, and the red dotted lines above and below the forecasted values represent the upper and lower confidence interval. A gap between the historical and forecasted values delineates the past and future values.
- Of the eight classic time-series forecasting methods, four result in straight lines: single moving average, single exponential smoothing, double moving average, and double exponential smoothing. Only the seasonal methods and multiple linear regression result in curves that approximate repeated data patterns.

## Customizing Charts

You can customize Predictor charts in many ways:

- Change the colors of lines and line types in the chart
- Display and hide the grid lines and legend
- Show the chart in perspective for a 3D effect
- Make the chart lines transparent

► To customize Predictor charts:

- 1 In the **Predictor Results** window, select **Preferences**, and then **Chart Preferences**.
- 2 In the **Chart Preferences** dialog, review the **Show Series** settings:
  - Clear the check box for any series that you do not want to include.
  - Make desired line color or line type changes.
- 3 **Optional:** Review the **Options** settings:
  - Change the **Gridlines** setting to display horizontal or vertical gridlines.
  - Change the **Legend** setting to display or hide the legend and change its position in the chart.
- 4 **Optional:** Review the **Effects** settings:
  - Select the **3D chart** setting to add three-dimensional perspective.
  - Select the **Transparency** setting to make the chart lines transparent, according to the number in the percent box.

- 5 Click **OK** to return to the **Predictor Results** window.

## Copying and Printing Charts

► To copy and print charts:

- 1 In the **Predictor Results** window, select **Edit**.
- 2 Perform an action:
  - Select **Copy Chart** to copy the chart to the Windows clipboard.
  - Select **Page Setup**, **Print Preview**, or **Print** to perform those printing tasks with Windows-standard dialogs.

## Creating Reports

► To create a report of Predictor data for each series:

- 1 Run a Predictor forecast and display the **Predictor Results** window.

If it is not visible, click Predictor Results in the Windows task bar. (It may be located in the Microsoft Office Excel group.)

- 2 Confirm that the following settings are complete and correct:
  - **Periods to forecast**—Determines the number of forecasted values that are displayed
  - **Confidence interval**—Indicates which confidence interval to calculate and plot
  - **Series**—Selects the data series to display
  - **Method**—Selects the forecasting method used to calculate forecasted values

See “[Viewing Charts](#)” on page 47.

- 3 In the **Predictor Results** menu bar, select **Analyze**, and then **Create Report**.
- 4 In the **Create Report Preferences** dialog, select a report type:
  - **Predictor** includes only Predictor data.
  - **Full** and **Custom** can include all other available data as well as Predictor data. For information about Full and Custom reports, click **Help**.

**Note:** If **Include events** is selected in the Data Attributes panel of the Predictor wizard, and at least one event is defined, the Events table is part of the Statistics section of the Series report. For custom reports, events data display is controlled by the Statistics check box in the Predictor Series settings of the Custom Report dialog.

- 5 **Optional:** Click **Options** to specify a location and formatting for the report. For an explanation of each setting, click **Help**.
- 6 Click **OK**.

By default, the report is created in a separate workbook. See [Figure 17 on page 65](#).

## Extracting Results Data

You can extract results and methods data from the current Predictor forecasting run.

► To extract Predictor results:

**1 Run a Predictor forecast and display the **Predictor Results** window.**

If it is not visible, click Predictor Results in the Windows task bar. (It may be located in the Microsoft Office Excel group.)

**2 Confirm that the following settings are complete and correct:**

- **Periods to forecast**—Determines the number of forecasted values that are displayed
- **Confidence interval**—Indicates which confidence interval to calculate and plot
- **Series**—Selects the data series to display
- **Method**—Selects the forecasting method used to calculate forecasted values

See [“Viewing Charts” on page 47](#).

**3 In the **Predictor Results** menu bar, select **Analyze**, and then **Extract Data**.**

**4 In the **Extract Data Preferences** dialog, select the **Predictor Data** tab, if it is not already visible, and select **Results Table**, **Methods Table**, or both:**

- **Results Table** shows fit and residual values for historical data, forecast and confidence interval values for the forecasted values (where residuals are the difference between the fit value and the historical data value), and events data (if selected).

**Note:** If **Include events** is selected in the Data Attributes panel of the Predictor wizard, and at least one event is defined, an additional Event column in the table of extracted data shows the event numbers defined for each series. Rows with events are also color coded. If the data has seasonality, seasonal differences are indicated with lighter colored rows. Screened data rows can also be highlighted. To change highlighting of these special types of data, select the **Results Window** and then select **Preferences** and any of the **Highlight** commands.

- **Methods Table** shows error measures, parameters, ranking, and statistics for each selected fit method.

**5 In the **Results Table Details** group, select the data types to include.**

Leave the defaults selected to extract all available data.

**6 Click **Options** and confirm that the desired location and formatting settings are selected.**

For details, select Help.

**7 Click **OK**.**

Depending on the Options settings, two tabs are displayed in the existing workbook or a new workbook. The tabs are Results Table and Methods Table. Each tab contains an interactive Microsoft Excel PivotTable with the selected data. See “Analyzing and Using Extracted Results” on page 39.

## Analyzing and Using Extracted Results

You can use extracted data as input for spreadsheet analysis or you can copy it into other applications. For an example of how to use the Results and Methods tables, see “[Working with Data in Interactive Tables](#)” on page 66. These are Microsoft Excel PivotTables, described in Microsoft documentation and help.

### Results Table

Even though Predictor tried all the methods you selected in the Method Gallery, it generates the Results table using the best method, unless you overrode the best method, in which case, the program generates the result values using the overriding method.

### Methods Table

The Methods table reports all the parameters and statistics for the methods you selected in the Methods panel. The method used to generate the forecasted values, either the best method or the overriding method, is highlighted in bold text. The method is likely to be different for each forecasted series.

To compare the quality of the results of different time-series forecasting methods, check the errors: RMSE, MAD, and MAPE. For all of these, the smaller the better. If you compare the RMSE of one method to the RMSE of another method, the smaller one should be ranked better. However, you cannot compare the RMSE of one method to the MAD or MAPE of another method. See “[Time-series Forecasting Accuracy Measures](#)” on page 88.

To compare the quality of a regression, look for the following values:

**Table 2** Evaluating Regression Quality

| Statistic               | Range          | Ideal Value    | Ideal Value Interpretation   |
|-------------------------|----------------|----------------|--|
| $R^2$ or Adjusted $R^2$ | 0 to 1         | Close to 1     | The linear regression accounts for almost all the variability in the dependent data.                               |
| $F$ probability         | 0 to 1         | Less than 0.05 | The quality of the overall regression (dependency of the dependent variable on the independent variables) is good. |
| $t$ probability         | 0 to 1         | Less than 0.05 | The quality of the coefficient of the regression equation is good.   |
| Durbin-Watson           | 0 to 4         | 2              | No autocorrelation (at lag 1) exists.  |
| Theil's $U$             | Greater than 0 | Less than 1    | The quality of the results is better than guessing.  |

See [Appendix C, “Important Predictor Concepts,”](#) and the *Oracle Crystal Ball Statistical Guide*.

# Predictor Tutorials

---

## In This Appendix

|                                 |    |
|---------------------------------|----|
| About Predictor Tutorials ..... | 53 |
| Tutorial 1—Shampoo Sales .....  | 53 |
| Tutorial 2—Toledo Gas .....     | 57 |

## About Predictor Tutorials

This chapter contains:

- “Tutorial 1—Shampoo Sales” on page 53, a basic tutorial that shows how Predictor works
- “Tutorial 2—Toledo Gas” on page 57, an advanced tutorial that uses multiple linear regression for forecasting

For less detailed examples, see [Appendix B, “Predictor Examples.”](#)

## Tutorial 1—Shampoo Sales

The easiest way to understand what Predictor does is to apply it to a simple example. In this example, you are sales manager for Tropical Cosmetics Co. The company’s latest product, shampoo with tropical ingredients, has been in the marketplace for almost a year. The vice president of marketing wants you to forecast the rest of the year’s shampoo sales and decide whether to recommend investing in advertising or enhancements for this product.

You have the weekly sales numbers for the last nine months.

► To begin the tutorial:

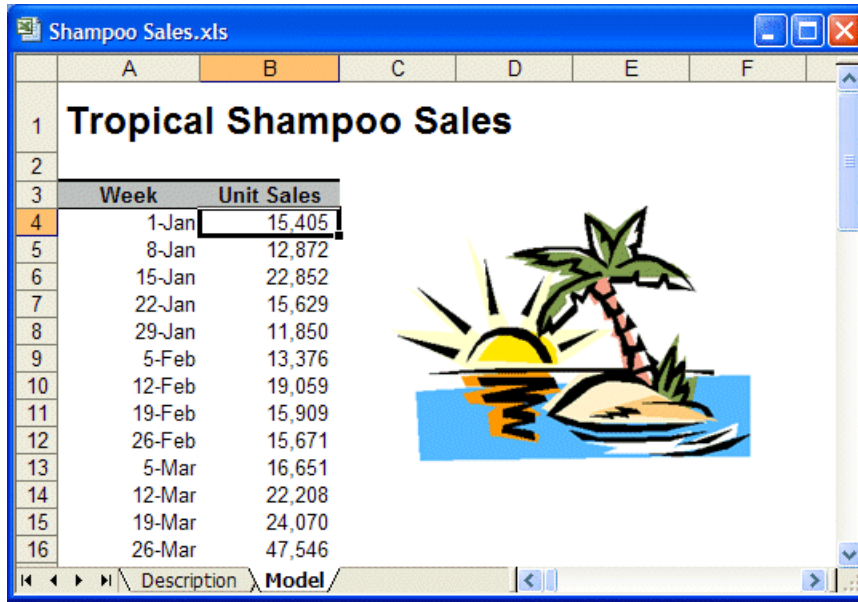

- 1 Start **Crystal Ball**, which automatically starts Microsoft Excel.
- 2 Select **Help**, then **Crystal Ball**, and then **Examples Guide**.

**Note:** In Microsoft Excel 2007 or later, select **Resources** in the **Help** group, and then select **Examples Guide**.

- 3 In the **Model Name** list, click **Shampoo Sales**.

The Shampoo Sales spreadsheet opens ([Figure 8](#)).

Figure 8 Shampoo Sales Spreadsheet

|    | A                             | B                 | C | D | E | F |
|----|-------------------------------|-------------------|---|---|---|---|
| 1  | <b>Tropical Shampoo Sales</b> |                   |   |   |   |   |
| 2  |                               |                   |   |   |   |   |
| 3  | <b>Week</b>                   | <b>Unit Sales</b> |   |   |   |   |
| 4  | 1-Jan                         | 15,405            |   |   |   |   |
| 5  | 8-Jan                         | 12,872            |   |   |   |   |
| 6  | 15-Jan                        | 22,852            |   |   |   |   |
| 7  | 22-Jan                        | 15,629            |   |   |   |   |
| 8  | 29-Jan                        | 11,850            |   |   |   |   |
| 9  | 5-Feb                         | 13,376            |   |   |   |   |
| 10 | 12-Feb                        | 19,059            |   |   |   |   |
| 11 | 19-Feb                        | 15,909            |   |   |   |   |
| 12 | 26-Feb                        | 15,671            |   |   |   |   |
| 13 | 5-Mar                         | 16,651            |   |   |   |   |
| 14 | 12-Mar                        | 22,208            |   |   |   |   |
| 15 | 19-Mar                        | 24,070            |   |   |   |   |
| 16 | 26-Mar                        | 47,546            |   |   |   |   |

In this spreadsheet, column A contains dates from January 1, 2010 until September 24, 2010 and column B contains Tropical shampoo sales data. You need to forecast sales through the end of the year, December 31, 2010.

**4 Select cell B4, if it is not already selected.**

Select any one cell in the data range, headers, or date range, and Predictor selects all the filled adjacent cells.

**5 Select Run, and then Predictor.**

This command is available only if no simulation is running and the last run was reset. If necessary, wait for a simulation to stop or reset the last simulation.

The Predictor wizard opens. If this is the first time you started Predictor, the Welcome panel is displayed. Otherwise, Input Data is displayed.

**6 If Welcome opens, click Next to display Input Data.**

When you select any one cell in the data range before you start the wizard, Predictor determines:

- The data series (in this case, A3:B42)
- Whether the data values are in columns or rows
- Whether headers display at the beginning of the data
- Whether the first column or row contains dates or time periods

**7 Confirm that cell range \$A\$3:\$B\$42 is selected and click Next.**

The Data Attributes panel opens.

**8 Confirm these settings and correct them if necessary:**

- Data is in **weeks**.

- **AutoDetect** is selected to determine whether data has seasonality.
- In the **Events** group, **Include events** is selected.
- In the **Data Screening** group, **Fill-in missing values** is selected.

9 Click **Next** to open the **Methods** panel.

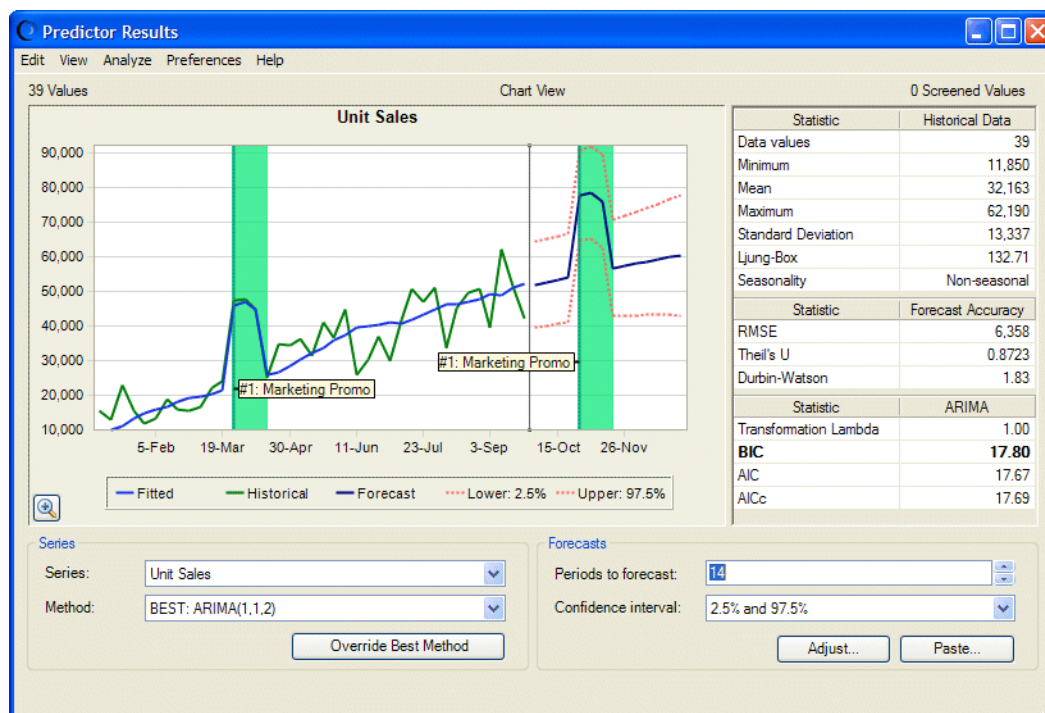

10 Leave the defaults selected and click **Next** to open the **Options** panel.

11 In **Options**, confirm that the defaults (**RMSE** and **Standard forecasting**) are selected, and then click **Run**.

The Predictor Results window opens.

12 Set **Periods to forecast** to 14 and review window contents (Figure 9).

Figure 9 Predictor Results Window for the Shampoo Sales Spreadsheet Model

The Predictor Results window contains the following:

- A chart of historical and forecasted values; forecasted values appear as a dark blue line extending to the right of the historical data (green) and the fitted values (blue). Above and below the forecasted values is the confidence interval (a red dotted line), showing the 2.5th and 97.5th percentiles of the forecasted values. This is called a 95% confidence interval.
- A marketing event was defined for this model, indicated by vertical bars and labels. Because the historical data showed an increase during the event, the predicted data also shows an increase when the event is scheduled to repeat.

**Note:** You can select **Preferences**, and then **Highlight Events** to hide the event labels and bars.

- A Series list of all data series selected for forecasting; onscreen information pertains to the selected series
- A Method list of all the methods Predictor tried, in order from the best-fitting method to the worst-fitting method. Predictor calculates the forecasted values from the method that best fits the historical data. In this case, the BEST method is ARIMA(1,1,2).
- Historical data statistics for the selected series
- Error statistics for forecasted data
- Parameters for the current BEST method

See “[Selecting How to Display and Analyze Results](#)” on page 44 for more information about data, buttons, and menus in this window.

**13 Optional:** Select **View**, and then **Table** to display a table of historical data in place of the chart. Notice that an Event column contains the number and name of defined events. Select **View**, and then **Chart** to display the chart again.

**14** Click **Paste** to paste forecasted data into the spreadsheet as Crystal Ball assumptions.

**15** Select these settings in the **Paste Forecasts to Spreadsheet** dialog:

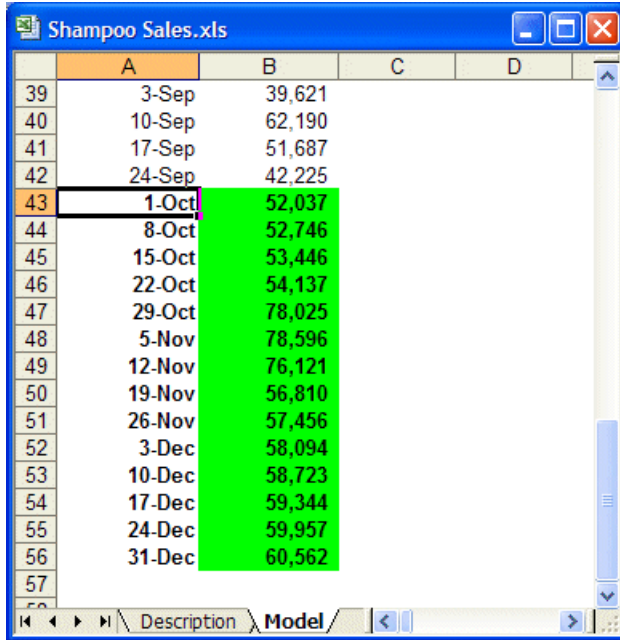

- At end of historical data
- Include date series
- Paste forecasts as Crystal Ball assumptions
- AutoFormat

**16** Click **OK**.

The results paste at the bottom of the table in cells B43 to B56 as Crystal Ball assumptions ([Figure 10](#)). The forecasted values were forecasted using the BEST method shown in the Predictor Results window.

Figure 10 Pasted Shampoo Sales Values

|    | A      | B      | C | D |
|----|--------|--------|---|---|
| 39 | 3-Sep  | 39,621 |   |   |
| 40 | 10-Sep | 62,190 |   |   |
| 41 | 17-Sep | 51,687 |   |   |
| 42 | 24-Sep | 42,225 |   |   |
| 43 | 1-Oct  | 52,037 |   |   |
| 44 | 8-Oct  | 52,746 |   |   |
| 45 | 15-Oct | 53,446 |   |   |
| 46 | 22-Oct | 54,137 |   |   |
| 47 | 29-Oct | 78,025 |   |   |
| 48 | 5-Nov  | 78,596 |   |   |
| 49 | 12-Nov | 76,121 |   |   |
| 50 | 19-Nov | 56,810 |   |   |
| 51 | 26-Nov | 57,456 |   |   |
| 52 | 3-Dec  | 58,094 |   |   |
| 53 | 10-Dec | 58,723 |   |   |
| 54 | 17-Dec | 59,344 |   |   |
| 55 | 24-Dec | 59,957 |   |   |
| 56 | 31-Dec | 60,562 |   |   |
| 57 |        |        |   |   |

Based on the results, you complete your memo to upper management. Current strategies seem to be working, so you recommend funding another project instead.

## Tutorial 2—Toledo Gas

Suppose you work for Toledo Gas Company in the Residential Division. The Public Utilities Commission requires that you predict gas usage for the coming year to make sure that the company can meet the demand.

► To start the tutorial:

- 1 Start Crystal Ball, which automatically starts Microsoft Excel.
- 2 Select **Help**, then **Crystal Ball**, then **Examples Guide**, and then **Toledo Gas** in the **Model Name** list. (In Microsoft Excel 2007 or later, select **Resources** in the **Help** group and then select **Examples Guide**).

The Toledo Gas spreadsheet opens (Figure 11).

Figure 11 Toledo Gas Spreadsheet

**Toledo Residential Gas Usage**

| Date   | Usage (ft <sup>3</sup> ) | Occupancy Permits | Average Temperature (Degrees F) | Cost of Natural Gas per ccf (Dollars) |
|--------|--------------------------|-------------------|---------------------------------|---------------------------------------|
| Jan-06 | 92.00                    | 151               | 31.97                           | \$6.40                                |
| Feb-06 | 53.00                    | 128               | 30.89                           | \$6.16                                |
| Mar-06 | 84.00                    | 85                | 41.17                           | \$5.95                                |
| Apr-06 | 54.00                    | 52                | 44.96                           | \$6.28                                |
| May-06 | 5.00                     | 5                 | 66.34                           | \$5.45                                |
| Jun-06 | 63.00                    | 134               | 70.40                           | \$5.23                                |
| Jul-06 | 46.00                    | 92                | 71.76                           | \$6.20                                |

| Feb-07 | 57.00                    | 124               | 36.30                           | \$8.30                                |
| Mar-07 | 49.00                    | 97                | 39.01                           | \$7.05                                |

3 Select cell C5.

4 Select **Run**, and then **Predictor**.

The Input Data panel appears. Predictor selected all the data from cell B4 to cell F64.

5 Click **Next** to display **Data Attributes**.

6 Confirm that the default settings are selected: **months**, **AutoDetect**, and **Fill-in missing values**. Then, click **Next** to open **Methods**.

The Methods panel offers four methods, including **Multiple Linear Regression**. Through research, you know that residential gas usage is primarily affected by three variables: new home starts, the temperature, and the price of natural gas. However, you are not certain how much effect each has on gas usage. Because you have independent variables affecting a dependent variable (the variable that you are interested in), regression is recommended for this forecast.

In the Toledo Gas spreadsheet, the dependent variable is the historical residential gas usage. Independent variables:

- Number of occupancy permits issued (new housing completions)
- Average temperature per month
- Unit cost of natural gas

7 In **Methods**, confirm that all four methods are selected, and then click **Multiple Linear Regression** to display the Multiple Linear Regression Details pane.

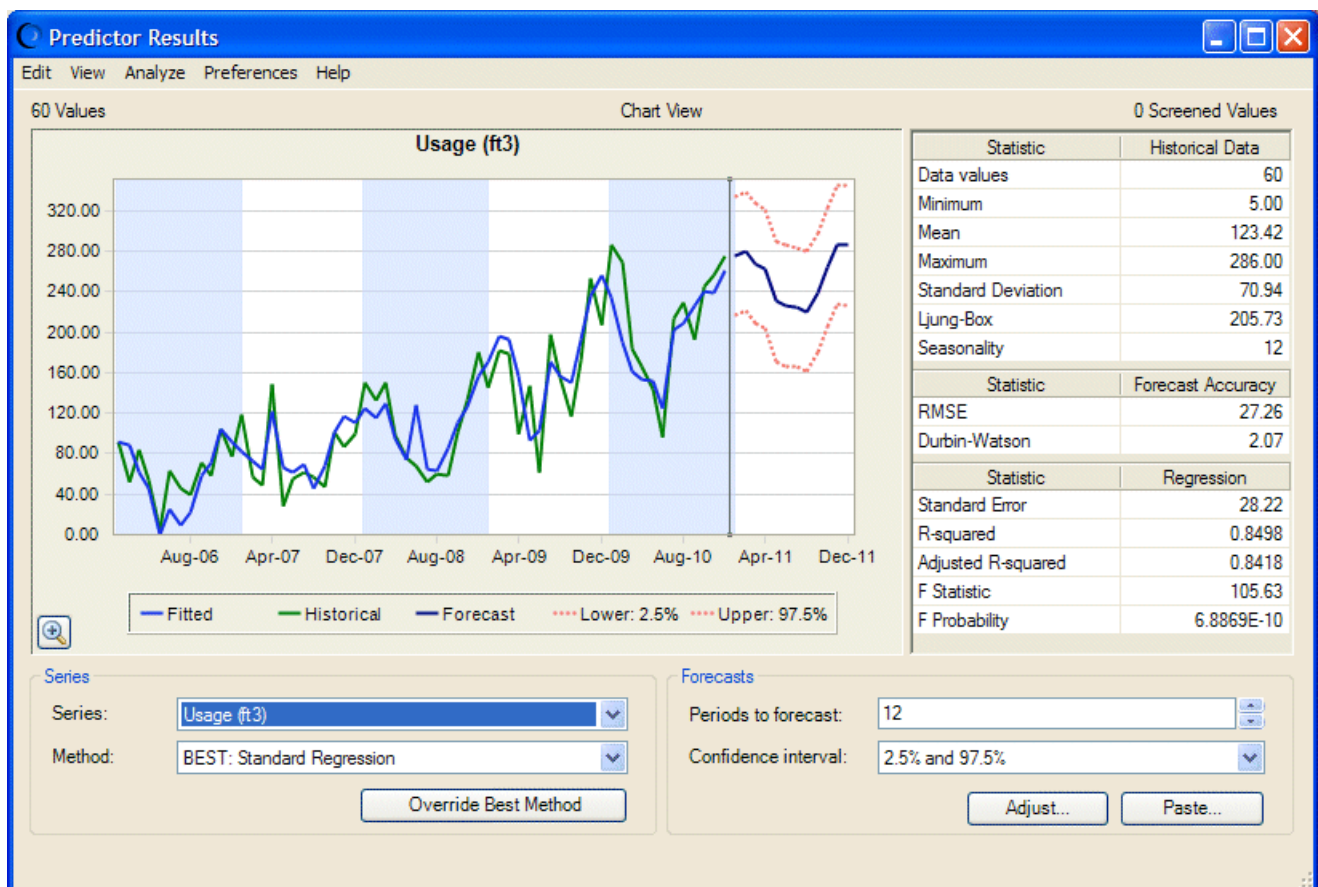

**Note:** Ensure that the Multiple Linear Regression check box stays selected.

8 Click **Select Variables** to open the **Regression Variables** dialog.

- 9 If necessary, in **Regression Variables**, select **Usage (ft3)** and use  to move it into **Dependent variables (Y's)**. Be sure the check box is selected, and confirm that the other three variables are listed under **Independent variables (X's)**.
- 10 Click **OK** to close **Regression Variables**.  
**Methods** is displayed again.
- 11 In the **Multiple Linear Regression Details** pane, confirm that **Method** is set to **Standard** and **Include constant in regression equation** is selected.
- 12 Click **Next**.  
The Options panel opens with these defaults: RMSE — Root Mean Squared Error and Standard forecasting.
- 13 Click **Run** to run the forecast and display the **Predictor Results** window (Figure 12).

## Viewing and Analyzing Predictor Results

Figure 12 Predictor Results Window, Toledo Gas Example

The Predictor Results window shows a chart with historical and fitted data, statistics, the name of the selected series and fitting method, the number of forecasted time periods, and the selected confidence interval. Because the data is seasonal, vertical bands appear in the chart to separate

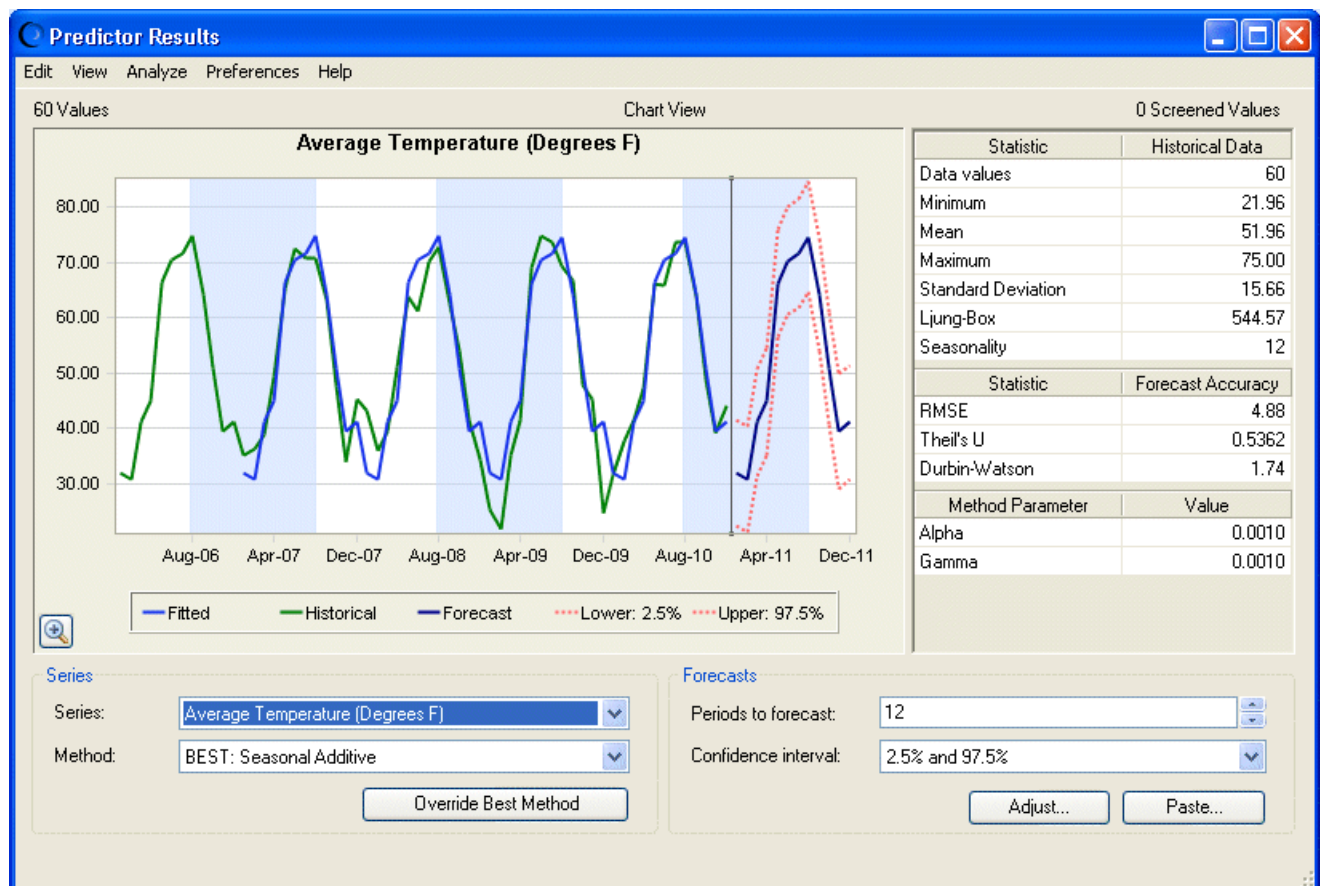

each season (or cycle). For more information about the Predictor Results window, see [“Understanding the Predictor Results Window”](#) on page 41.

► To continue with the tutorial:

- 1 Forecast the monthly usage for the next year by confirming that 12 is entered in **Periods to forecast**.
- 2 Notice that **Confidence interval** is set to 2.5% and 97.5%, the default.
- 3 Confirm that the selected **Series** is **Usage (ft3)**, the dependent variable.
- 4 Notice that **Method** indicates that **Standard Regression** was selected as the best forecasting method.
- 5 View another variable: in the **Series** list, select **Average Temperature (Degrees F)**.

Forecasted values appear for Average Temperature. Seasonal Additive is identified as the best-fitting method ([Figure 13](#)).

Figure 13 Average Temperature Before Method Override

- 6 In the **Method** list, select **Double Moving Average**.

The chart changes to show the forecast using Double Moving Average instead of Seasonal Additive. A warning indicates that the Thiel's U statistic exceeds preset limits.

- 7 To experiment, click **Override Best Method**.

This action changes the forecast to use Double Moving Average instead of Seasonal Additive (Figure 14). A note indicates a best-method override.

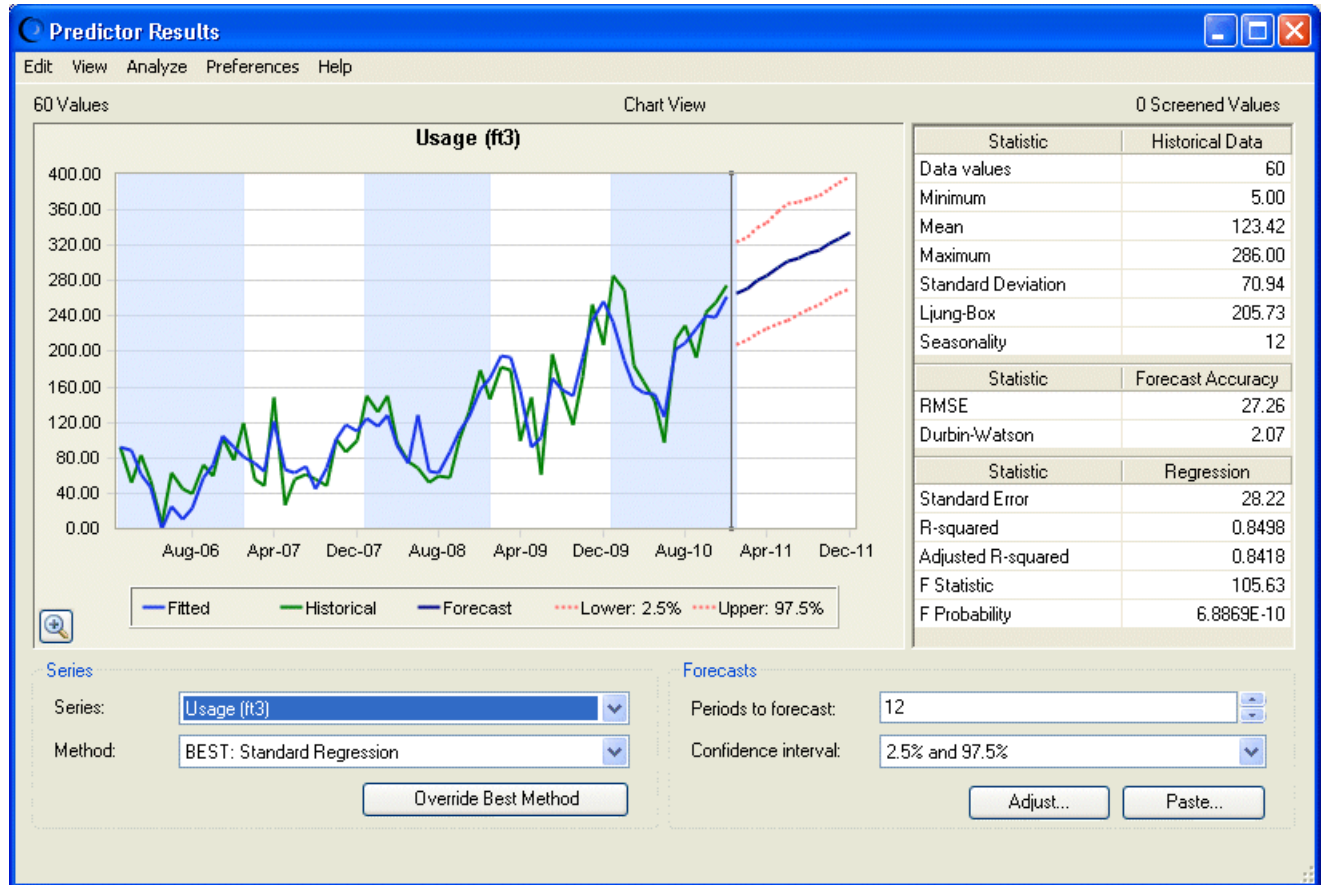

Figure 14 Average Temperature After Method Override

The primary work of Predictor is to create forecasts based on historical data. When you override the selected forecasting method, you should carefully analyze the results.

- 8 To determine the effect of this **Method** change on the Usage forecast, change **Series** back to **Usage (ft3)** (Figure 15).

Figure 15 Result Window for Usage after Average Temperature Method Override

Overriding the Average Temperature had a noticeable effect on the forecast (but not the fit) of the Usage variable. When Figure 15 is compared with Figure 12, you can see that the predicted results for Usage (ft3) are higher and more linear than those originally calculated.

**Tip:** Unless you have a compelling reason to do so, it is better not to override the selected forecast method.

## Pasting Results into the Spreadsheet

You can paste the forecasted results into the spreadsheet for further analysis using Crystal Ball or Microsoft Excel.

► To paste forecasted results:

- 1 In the **Predictor Results** window, click **Paste**.
- 2 In the **Paste Forecasts to Spreadsheet** dialog:
  - Select **At end of historical data** to indicate where to paste results.
  - Select **Include date series** to list dates in the first column.
  - Select **Paste forecasts as Crystal Ball assumptions**.

- Confirm that **AutoFormat** is selected.
- 3 Click **OK** to paste the results as assumptions.
  - 4 Look at the results pasted below the historical data (Figure 16).

The upper spreadsheet pane was frozen below the column headers so they would appear in this figure.

Figure 16 Gas Service Predictions for the Next Twelve Months

|    | A                                   | B            | C      | D      | E     | F       |
|----|-------------------------------------|--------------|--------|--------|-------|---------|
| 1  | <b>Toledo Residential Gas Usage</b> |              |        |        |       |         |
| 2  |                                     |              |        |        |       |         |
| 3  |                                     |              |        |        |       |         |
| 4  |                                     |              |        |        |       |         |

| 78 |                                     | Coefficients | 125.85 | 0.2409 | -1.71 | -2.43   |
| 79 |                                     |              |        |        |       |         |

- 5 In Figure 16, notice that:
  - Forecasted results for 12 months are pasted at the end of the historical data.
  - The independent variables have been defined as Crystal Ball assumptions. These assumptions are defined as normal distributions with a mean equal to the cell value.
  - The dependent variable (Usage) column contains the regression equation that references the independent variable forecast values.
  - The Coefficients row below the pasted forecasts contains the regression coefficients referenced in the dependent variable regression equations.

## Creating a Report of Predictor Results

➤ To create a report of Predictor data for each series:

**1 Display the Predictor Results window.**

If it is not visible, click Predictor Results in the Windows task bar. (It may be in the Microsoft Office Excel group.)

**2 In the Predictor Results window menu bar, select *Analyze*, and then *Create Report*.**

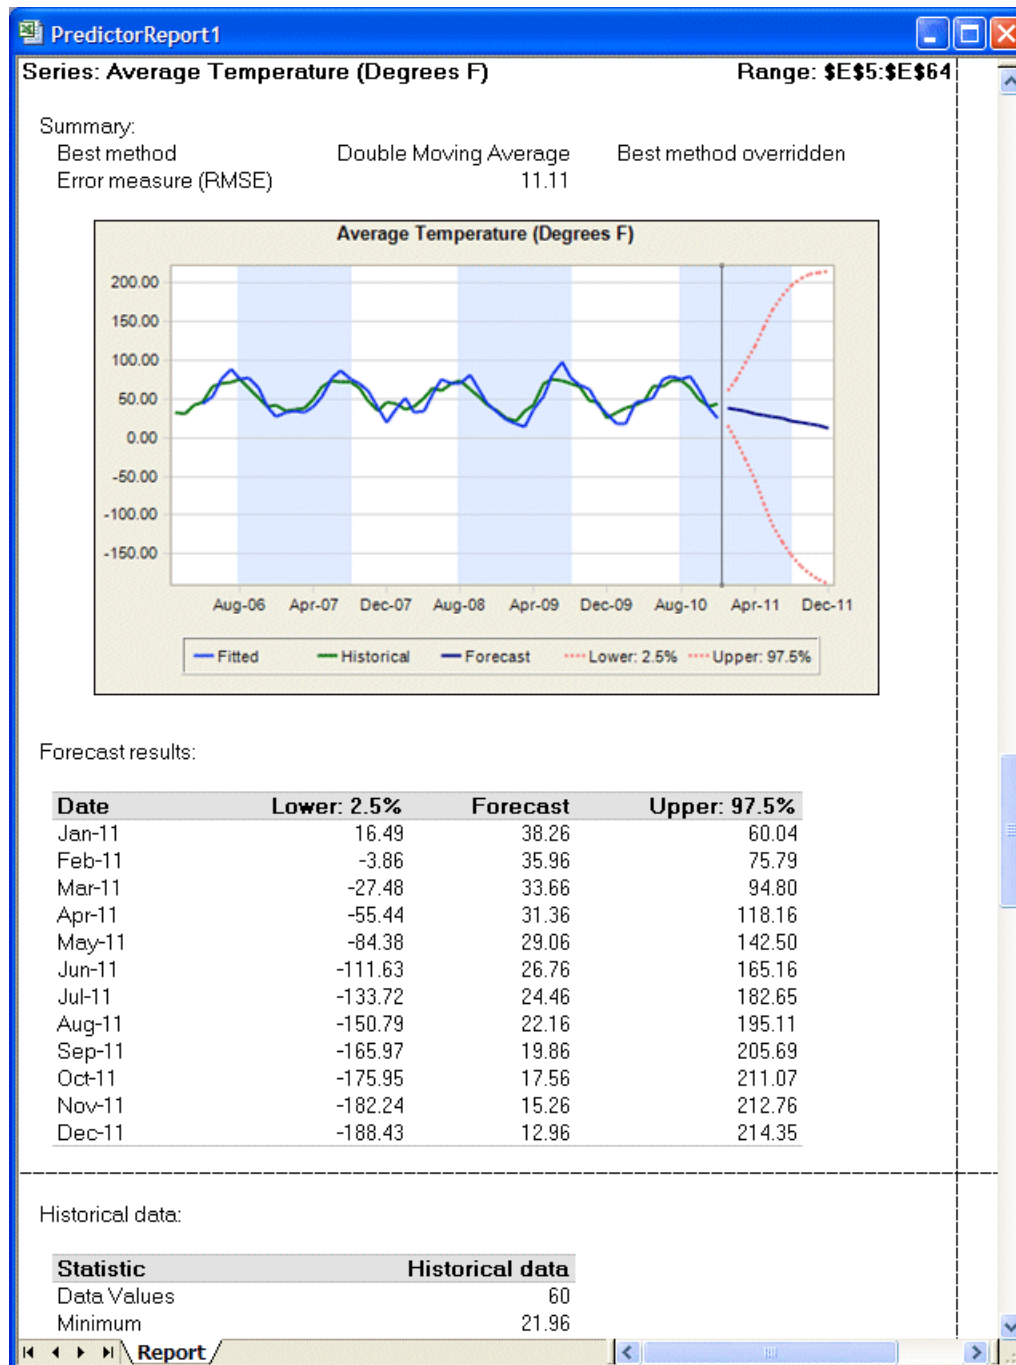

**3 In the *Create Report Preferences* dialog, confirm that *Predictor* is selected and then click *OK*.**

By default, the report is created in a separate workbook. The report contains summary data followed by information for each dependent and independent variable.

**4 Click the *Report* workbook and scroll to the *Average Temperature* section ([Figure 17](#)).**

Figure 17 Average Temperature Data Report for Toledo Gas

Notice the indication above the chart that the method used was an override of the best method.

## Extracting Results

You can extract results and methods data from the current Predictor forecasting run.

➤ To extract Predictor results:

- 1 Run a Predictor forecast and display the **Predictor Results** window.

If it is not visible, click Predictor Results in the Windows task bar. (It may be located in the Microsoft Office Excel group.)

- 2 In the **Predictor Results** window menu bar, select **Analyze**, and then **Extract Data**.
- 3 In the **Extract Data Preferences** dialog, select the **Predictor Data** tab, if it is not already visible, and select **Results Table** and **Methods Table**. Leave the defaults selected to extract all available data.
- 4 Select **Options** and confirm that the defaults are selected: **New workbook**, with sheet names **Results Table** and **Methods Table**, using **AutoFormat**.
- 5 Click **OK**.

A new Microsoft Excel workbook opens with two tabs, **Results Table** and **Methods Table**. Each tab contains an interactive Microsoft Excel PivotTable:

- **Results Table** shows fit values and residuals for historical data, plus forecast and confidence interval values for the forecasted values. (Residuals are the difference between the data value and the calculated best fit value). By default, data seasons (cycles) appear as alternating bands of white and a light color. To hide these bands, you can return to the **Results Window**, select **Preferences**, and then clear **Highlight Seasonality**.
- **Methods Table** shows error calculations and other statistics for each selected fit method.

See [“Extracting Results Data”](#) on page 50.

## Working with Data in Interactive Tables

➤ To work with Predictor data in interactive tables:

- 1 Select the **Methods Table** worksheet.

Figure 18 Toledo Gas Methods Table, Default View

|     | A                            | B           | C            | D            | E             | F         | G             |

| 284 |                              |             |              |              |               |           |               |

- Next to the **Series** button, select **Average Temperature** from the list and click **OK**.

The table changes to show the parameters and statistics for each method of the Average Temperature forecast.

- Click the **Series** button and drag it to the left of the **Methods** button.

The Methods table expands to include all the data series. When you drop the Series button next to the Methods button, the list of methods repeats for each series (Figure 19).

Figure 19 Methods Grouped by Series

| Series                                | Methods                      | Rank     | RMSE          | MAD           | MAPE          | T |

|                                       | Double Exponential Smoothing | 1        | 103           | 75            | 41.79%        |   |

- 4 Click the arrow to the right of the **Table Items** button.

A list of fields is displayed.

- 5 Clear all the items except for **Rank** and click **OK**.

The Methods table changes to show the Rank parameter. Look at the Average Temperature data. In the Methods column, Double Moving Average is labeled **Best method** and highlighted in bold text to show that it was used to generate the results. Seasonal Additive, originally the best, is still listed with a rank of 1 (Figure 20).

Figure 20 Methods Within each Series Identified by Rank

| Series                                | Methods                             | Rank     |

For more information about using interactive Microsoft Excel PivotTables, see the Microsoft Excel online help.

# Predictor Examples

---

## In This Appendix

|                            |    |
|----------------------------|----|
| About These Examples ..... | 71 |
| Inventory Control .....    | 72 |
| Company Finances .....     | 74 |
| Human Resources .....      | 77 |

## About These Examples

Monica's Bakery, a hypothetical company used in the Predictor examples, is a rapidly growing bakery in Albuquerque, New Mexico. Since the opening, Monica has kept careful records (in a Microsoft Excel workbook) of the sales of her three main products: French bread, Italian bread, and pizza. With these records, she can better predict her sales, control her inventory, market her products, and make strategic, long-term decisions.

- To open Monica's workbook, select **Help**, then **Crystal Ball**, then **Examples Guide**, and then select **Monica's Bakery**. (In Microsoft Excel 2007 or later, select **Resources** in the **Help** group and then select **Examples Guide**).

The workbook has worksheets for sales data, operations, and cash flow. The Sales Data worksheet contains all the historical sales data that is available for forecasting. The Operations worksheet calculates the amount of different ingredients required to make different quantities of three breads. The Cash Flow worksheet calculates how much money the bakery has to spend on various capital projects. The Labor Costs worksheet estimates the increase in hourly wages to decide whether to invest in labor-saving equipment.

The following examples track Monica's decision-making processes as she uses Predictor to work through both short-term and long-term decisions:

- "Inventory Control" on page 72
- "Company Finances" on page 74
- "Human Resources" on page 77

For more detailed product tutorials, see [Appendix A, "Predictor Tutorials."](#)

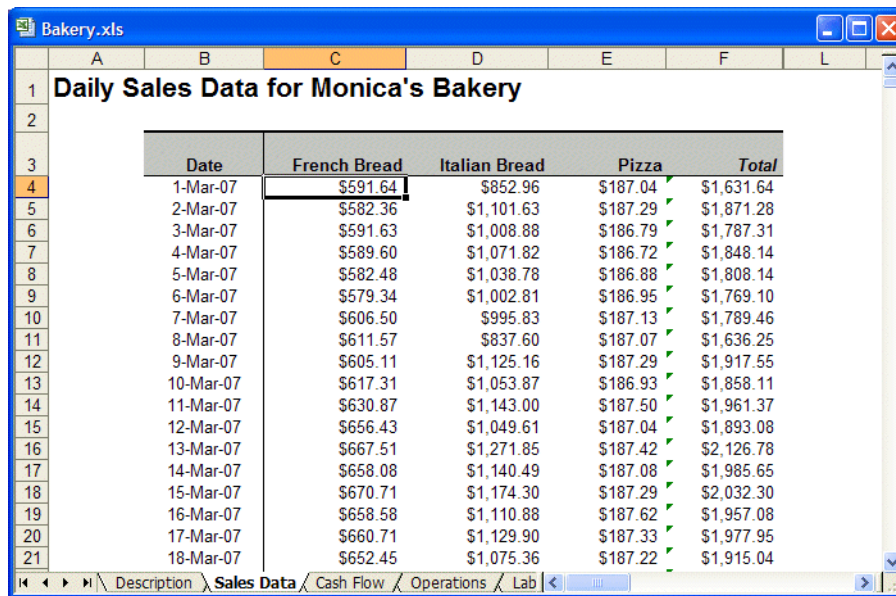

# Inventory Control

The initial reason that Monica needs to forecast is to maintain enough ingredients to keep up with production. Monica's distributors give her discounts for buying in bulk. However, she must balance this savings with maintaining product quality, which requires using the freshest ingredients possible. Monica wants improved forecasting to help her place orders that give her the best volume pricing while maintaining the quality of her products.

To follow along with this example, open Bakery.xls as described in [“About These Examples” on page 71](#).

The Sales Data worksheet ([Figure 22](#)) shows the daily sales data of each of these products from the opening until the end of June 2010.

Figure 22 Bakery Sales Data Worksheet

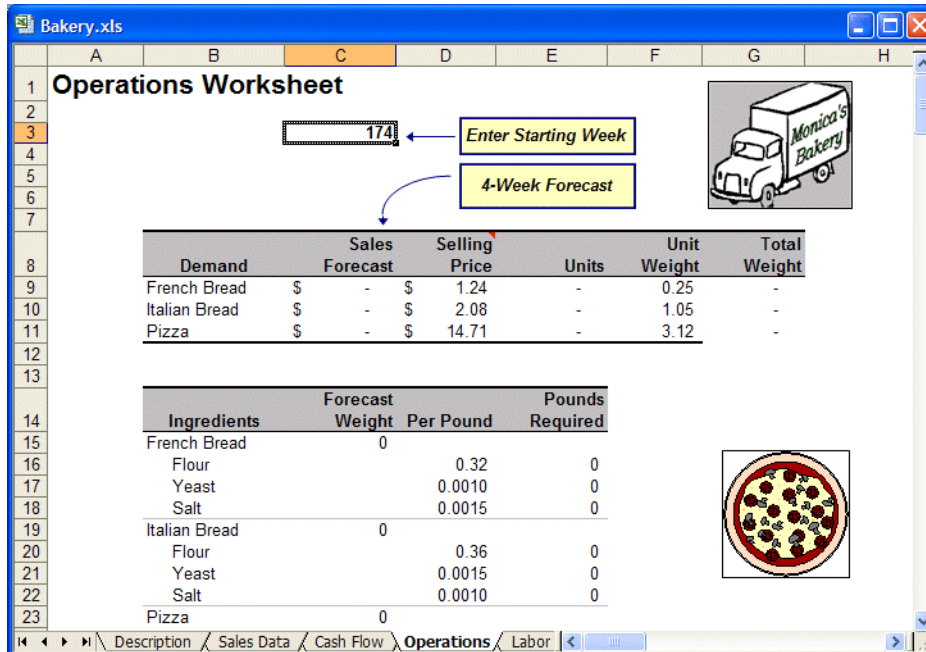

| Date      | French Bread | Italian Bread | Pizza    | Total      |
|-----------|--------------|---------------|----------|------------|
| 1-Mar-07  | \$591.64     | \$852.96      | \$187.04 | \$1,631.64 |
| 2-Mar-07  | \$582.36     | \$1,101.63    | \$187.29 | \$1,871.28 |
| 3-Mar-07  | \$591.63     | \$1,008.88    | \$186.79 | \$1,787.31 |
| 4-Mar-07  | \$589.60     | \$1,071.82    | \$186.72 | \$1,848.14 |
| 5-Mar-07  | \$582.48     | \$1,038.78    | \$186.88 | \$1,808.14 |
| 6-Mar-07  | \$579.34     | \$1,002.81    | \$186.95 | \$1,769.10 |
| 7-Mar-07  | \$606.50     | \$995.83      | \$187.13 | \$1,789.46 |
| 8-Mar-07  | \$611.57     | \$837.60      | \$187.07 | \$1,636.25 |
| 9-Mar-07  | \$605.11     | \$1,125.16    | \$187.29 | \$1,917.55 |
| 10-Mar-07 | \$617.31     | \$1,053.87    | \$186.93 | \$1,858.11 |
| 11-Mar-07 | \$630.87     | \$1,143.00    | \$187.50 | \$1,961.37 |
| 12-Mar-07 | \$656.43     | \$1,049.61    | \$187.04 | \$1,893.08 |
| 13-Mar-07 | \$667.51     | \$1,271.85    | \$187.42 | \$2,126.78 |
| 14-Mar-07 | \$658.08     | \$1,140.49    | \$187.08 | \$1,985.65 |
| 15-Mar-07 | \$670.71     | \$1,174.30    | \$187.29 | \$2,032.30 |
| 16-Mar-07 | \$658.58     | \$1,110.88    | \$187.62 | \$1,957.08 |
| 17-Mar-07 | \$660.71     | \$1,129.90    | \$187.33 | \$1,977.95 |
| 18-Mar-07 | \$652.45     | \$1,075.36    | \$187.22 | \$1,915.04 |

A summary of data for the three main products by week is displayed at the bottom of the Operations worksheet ([Figure 23](#)). Monica can change the table to summarize her results by product, by time period, and more.

Figure 23 Bakery Operations Worksheet

| Demand        | Sales Forecast | Selling Price | Units | Unit Weight | Total Weight |
|---------------|----------------|---------------|-------|-------------|--------------|
| French Bread  | \$ -           | \$ 1.24       | -     | 0.25        | -            |
| Italian Bread | \$ -           | \$ 2.08       | -     | 1.05        | -            |
| Pizza         | \$ -           | \$ 14.71      | -     | 3.12        | -            |

| Ingredients   | Forecast Weight | Per Pound | Pounds Required |
|---------------|-----------------|-----------|-----------------|
| French Bread  | 0               |           |                 |
| Flour         |                 | 0.32      | 0               |
| Yeast         |                 | 0.0010    | 0               |
| Salt          |                 | 0.0015    | 0               |
| Italian Bread | 0               |           |                 |
| Flour         |                 | 0.36      | 0               |
| Yeast         |                 | 0.0015    | 0               |
| Salt          |                 | 0.0010    | 0               |
| Pizza         | 0               |           |                 |

Monica wants to order monthly, one month in advance. The bakery has already received this month's delivery, which she placed last month. This month, she must place the order that will be delivered at the end of this month for the next month, so she must forecast sales for the next two months. Because she is in week 173 of her business, the forecast is for weeks 174 to 181.

➤ To forecast the sales for weeks 174 to 181:

1 In the **Bakery.xls** workbook, click the **Operations** tab.

The Operations worksheet is displayed.

2 Select one cell—for example, C41—in the Historical Demand By Week table at the bottom of the worksheet.

3 Start Predictor.

Predictor automatically selects all the data in that table.

4 Ensure that:

- The cell range \$B\$40:\$E\$213 is selected correctly on the **Input Data** panel, with headers, dates, and data in columns settings also selected
- The **Data Attributes** panel shows time periods are in weeks with **Seasonality** set to **AutoDetect**
- In the **Methods** panel, **Multiple Linear Regression** is cleared and all time-series methods are selected
- Options settings are the defaults, RMSE and Standard forecasting

5 Click **Run**.

6 In the **Predictor Results** window, set **Periods to forecast** to 8, and then click **Paste**.

7 In the **Paste Forecasts to Spreadsheet** dialog, use the following settings and click **OK**:

- Select **At end of historical data** to indicate where to paste results.
- Select **Include date series** to list dates in the first column.
- Select **Paste forecasts as Crystal Ball assumptions**.
- Confirm that **AutoFormat** is selected.

The results paste to the end of the Historical Demand table as shown in [Figure 24](#).

Figure 24 Forecasted Bakery Operations Results

|     | B   | C         | D         | E        | F | G | H |
|-----|-----|-----------|-----------|----------|---|---|---|
| 210 | 170 | 17,817.74 | 10,457.24 | 1,471.40 |   |   |   |
| 211 | 171 | 18,278.89 | 10,061.90 | 1,488.27 |   |   |   |
| 212 | 172 | 18,621.32 | 9,655.71  | 1,490.36 |   |   |   |
| 213 | 173 | 18,596.88 | 9,371.57  | 1,483.24 |   |   |   |
| 214 | 174 | 18,628.46 | 9,452.62  | 1,482.91 |   |   |   |
| 215 | 175 | 18,678.62 | 9,284.84  | 1,480.80 |   |   |   |
| 216 | 176 | 18,734.84 | 9,231.54  | 1,468.52 |   |   |   |
| 217 | 177 | 18,792.94 | 9,171.12  | 1,451.85 |   |   |   |
| 218 | 178 | 18,851.51 | 9,182.43  | 1,444.55 |   |   |   |
| 219 | 179 | 18,910.07 | 8,962.38  | 1,444.11 |   |   |   |
| 220 | 180 | 18,968.49 | 9,395.15  | 1,440.17 |   |   |   |
| 221 | 181 | 19,026.69 | 9,812.40  | 1,433.58 |   |   |   |
| 222 |     |           |           |          |   |   |   |
| 223 |     |           |           |          |   |   |   |

The last four weeks of forecast values for each data series are automatically summed and placed into the table at the top of the spreadsheet, in the Sales Forecast column (cells C9:C11). In this table, the monthly sales forecast is converted to the number of items sold and then into the weight of each product.

The second table (below this top table) takes the total weight of each product (in cells C15, C19, C23) and calculates how much of each ingredient is required to produce that much product. The ingredients for each are then summed in the third table (below the second table) into the total amounts to order for the month (cells D31 to D34).

Based on the forecast, Monica should order:

- 12,080 pounds of flour
- 55 pounds of yeast
- 42 pounds of salt
- 125 pounds of tomatoes

## Company Finances

Monica is always concerned about the bakery's month-to-month cash flow (on a percent of sales basis). Predictor can help her manage her inventory, and she can use it to predict her revenue

► To forecast the next three months of revenue:

1 In the **Bakery.xls** workbook, click the **Cash Flow** tab.

The Cash Flow worksheet is displayed.

2 Select one cell—C36, for example—in the **Historical Revenue By Month** table at the bottom of the worksheet.

3 Start Predictor.

Predictor automatically selects all the data in the Historical Revenue table.

4 Confirm the following settings:

- In the **Input Data** panel, the cell range \$C\$36:\$AP\$36 is selected correctly, with **Data in rows** selected and no date or header settings selected.
- In **Data Attributes**, the first setting is **Data is in periods** with **Seasonality** set to **AutoDetect**.
- In **Methods**, all time-series methods are selected and **Multiple Linear Regression** is cleared (if available).
- Options settings are the defaults: **RMSE** and **Standard** forecasting.

5 Click **Run**.

6 In the **Predictor Results** window, enter 3 for **Periods to forecast**.

7 Click **Paste**, and then, in the **Paste Forecasts to Spreadsheet** dialog, confirm that results are set to paste at the end of historical data as **Crystal Ball** assumptions and click **OK**.

The results paste into the table at the bottom of the worksheet, cells AQ36 to AS36, and also appear at the top of the worksheet (cells E4 to G4) as shown in [Figure 26](#).

| 33         |  | Total Sales                    | Year         | Month          |               |              |              |              |              |              |
| 34         |  |                                | 2007         |                |               |              |              |              |              |              |
| 35         |  |                                |              | 3              | 4             | 5            | 6            | 7            | 8            | 9            |
| 36         |  | Total                          | \$ 59,286.31 | \$ 59,195.68   | \$ 66,809.98  | \$ 67,010.83 | \$ 67,763.62 | \$ 69,704.65 | \$ 64,389.54 | \$ 70,967.36 |
| 37         |  |                                |              |                |               |              |              |              |              |              |

The revenue forecasts for the next three months are used to calculate the percentage expenses in the second table.

The second table calculates the total expenses, and the third table calculates the necessary expenditure for each extraordinary item. Below these tables is the cash flow summary for the next three months, based on the forecasts. The net cash at the end of each month is what Monica is looking for (row 27). Based on forecasted sales, the new net cash values are \$19,536.34 for July, \$11,833.04 for August, and \$35,452.31 for September. Based on the forecast, the bakery should wait until September to buy the van.

## Human Resources

Monica's Bakery is a labor-intensive operation that pays a competitive wage. However, to maintain her target profitability, Monica must control labor costs. She knows there are many things done around the bakery that could be done by expensive machinery, such as kneading, mixing, and forming. By accurately predicting her labor costs, she can decide when to invest in some of this equipment to keep her total expenses within budget.

From her interest in economics, Monica knows that a few key macro-economic figures drive labor costs, such as the Industrial Production Index, local CPI, and local unemployment. All of these figures are available on the Internet on a monthly basis from the Bureau of Labor Statistics and the Department of Commerce.

To follow along with this example, open Bakery.xls as described in “About These Examples” on page 71. If Bakery.xls is already open from the previous example, select Run, and then Reset to clear existing results.

Monica has created her Labor Costs worksheet with an interactive table at the bottom that lists the bakery's average hourly wage for each month and the monthly numbers for the three economic indicators.

Figure 27 Bakery Labor Costs worksheet

**Labor Cost Analysis for Monica's Bakery**

|                   | Jun-10       | Dec-10 |
|-------------------|--------------|--------|
| Wages             | \$ 14.27     | \$ -   |
| Overhead          | 33%          | 33%    |
| Total Employees   | 18           | 18     |
| Total Labor Costs | \$ 54,652.74 | \$ -   |
| Labor Cost Change |              | -100%  |

*Average labor costs from regression analysis*

**Economic Variables for Regression Analysis:**

| Date   | Monica's Average Wage | Industrial Prod. Index | Local CPI | Local Unemployment |
|--------|-----------------------|------------------------|-----------|--------------------|
| Jun-07 | \$13.22               | 121.9                  | 469.0     | 8.0                |
| Jul-07 | \$13.19               | 122.6                  | 469.3     | 8.4                |
| Aug-07 | \$13.24               | 121.9                  | 470.7     | 8.2                |
| Sep-07 | \$13.25               | 121.1                  | 471.7     | 8.1                |
| Oct-07 | \$13.19               | 120.9                  | 473.0     | 8.3                |
| Nov-07 | \$13.38               | 121.0                  | 473.6     | 8.1                |
| Dec-07 | \$13.23               | 121.3                  | 473.4     | 8.0                |
| Jan-08 | \$13.24               | 123.0                  | 476.5     | 8.8                |

The average hourly wage depends on or is affected by the other three variables. Because of the dependency, Monica decides to use regression instead of time-series forecasting. For regression, the dependent variable is Monica's Average Wage, and the other three are the independent variables.

► To forecast the hourly wage using regression:

1 In the Bakery.xls workbook, click the **Labor Costs** tab.

The Labor Costs worksheet opens.

2 Select one cell—for example, C14—in the **Economic Variables for Regression Analysis** table at the top of the worksheet.

3 Start Predictor.

4 Ensure that:

- In **Input Data**, the cell range \$B\$13:\$F\$50 is selected correctly, with data in columns, header, and date settings also selected

- In **Data Attributes**, the time periods are in **months** with a **Seasonality** of **AutoDetect**
- In **Methods**, **Non-seasonal Methods**, **ARIMA**, and **Multiple Linear Regression** are selected
- Regression variables are defined as follows: **Monica's Average Wage** is a dependent variable, all the others are independent variables
- In **Options**, **RMSE** and **Standard forecasting** are selected

5 Click **Run**.

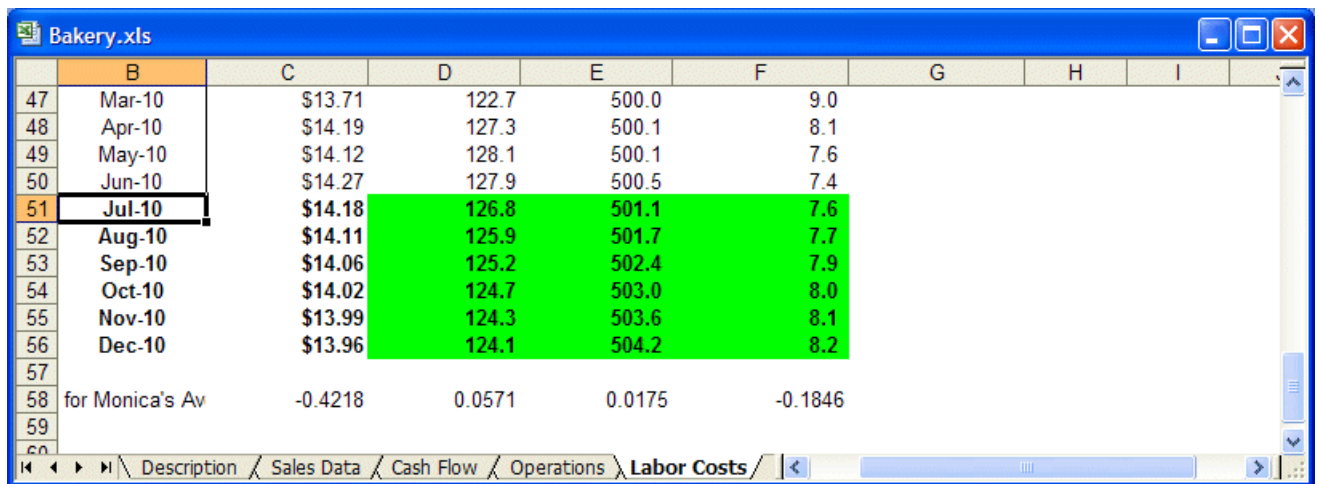

6 In the **Predictor Results** window, set **Periods to forecast** to **6** and click **Paste**.

7 In **Paste Forecasts to Spreadsheet**, set the controls to paste forecasts as assumptions at the end of historical data with **Include date series** and **AutoFormat** selected.

8 Click **OK**.

The results paste at the bottom of the table (cells B51 to F56) as shown in [Figure 28](#). Notice the results for independent variables are defined as assumptions.

Figure 28 Forecasted Labor Costs for Monica's Bakery

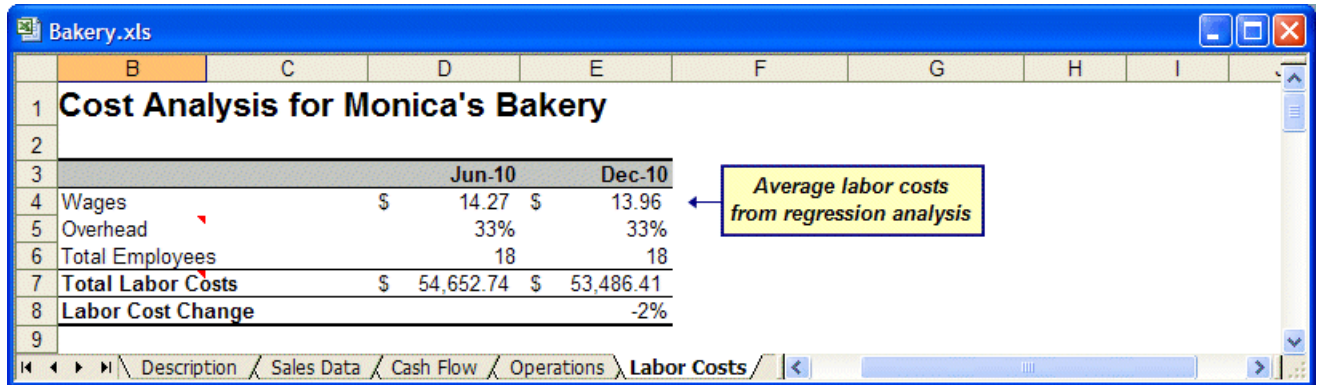

|    | B               | C       | D      | E      | F       | G | H | I |
|----|-----------------|---------|--------|--------|---------|---|---|---|
| 47 | Mar-10          | \$13.71 | 122.7  | 500.0  | 9.0     |   |   |   |
| 48 | Apr-10          | \$14.19 | 127.3  | 500.1  | 8.1     |   |   |   |
| 49 | May-10          | \$14.12 | 128.1  | 500.1  | 7.6     |   |   |   |
| 50 | Jun-10          | \$14.27 | 127.9  | 500.5  | 7.4     |   |   |   |
| 51 | Jul-10          | \$14.18 | 126.8  | 501.1  | 7.6     |   |   |   |
| 52 | Aug-10          | \$14.11 | 125.9  | 501.7  | 7.7     |   |   |   |
| 53 | Sep-10          | \$14.06 | 125.2  | 502.4  | 7.9     |   |   |   |
| 54 | Oct-10          | \$14.02 | 124.7  | 503.0  | 8.0     |   |   |   |
| 55 | Nov-10          | \$13.99 | 124.3  | 503.6  | 8.1     |   |   |   |
| 56 | Dec-10          | \$13.96 | 124.1  | 504.2  | 8.2     |   |   |   |
| 57 |                 |         |        |        |         |   |   |   |
| 58 | for Monica's Av | -0.4218 | 0.0571 | 0.0175 | -0.1846 |   |   |   |
| 59 |                 |         |        |        |         |   |   |   |

Predictor first generates a regression equation to define the relationship between the dependent and independent variables. Second, it uses the time-series forecasting methods to forecast the independent variables individually. Third, Predictor uses those forecasted values to calculate the dependent variable forecast values using the regression equation. See [Figure 29](#).

The forecast cells of the independent variables are simple value cells. The forecast cells of the dependent variable are formula cells containing the regression equation and using the forecast values from the independent variables.

The average wage in December is used to calculate the total increase in her payroll. Labor costs actually decrease –2%. With these results, Monica decides that labor costs over the next six months do not justify a major equipment capital purchase.

Figure 29 Predicted Labor Cost Increases

|                          |    | Jun-10    | Dec-10       |
|--------------------------|----|-----------|--------------|
| Wages                    | \$ | 14.27     | \$ 13.96     |
| Overhead                 |    | 33%       | 33%          |
| Total Employees          |    | 18        | 18           |
| <b>Total Labor Costs</b> | \$ | 54,652.74 | \$ 53,486.41 |
| <b>Labor Cost Change</b> |    |           | -2%          |

*Average labor costs from regression analysis*

9 Exit **Bakery.xls** without saving the changes.

If you save the changes, you will overwrite the example spreadsheet.

## About Forecasting Concepts

This appendix describes forecasting terminology. It defines the time-series forecasting methods that Predictor uses, as well as other forecasting-related terminology. This appendix also describes the statistics the program generates and the techniques that Predictor uses to do the calculations and select the best-fitting method.

Forecasting refers to the act of predicting the future, usually for planning and managing resources. There are many scientific approaches to forecasting. You can perform “what-if” forecasting by creating a model and simulating outcomes, as with Crystal Ball, or by collecting data over time and analyzing the trends and patterns. Predictor uses the latter concept, analyzing the patterns of a time series to forecast future data.

The scientific approaches to forecasting usually fall into one of several categories:

- Time-series — Performs time-series analysis on past patterns of data to forecast results. This works best for stable situations in which conditions are expected to remain the same.
- Regression — Forecasts results using past relationships between a variable of interest and several other variables that might influence it. This works best for situations in which you need to identify the different effects of different variables. This category includes multiple linear regression.
- Simulation — Randomly generates many scenarios for a model to forecast the possible outcomes. This method works best where you may not have historical data, but you can build the model of the situation to analyze its behavior.

- Qualitative — Uses subjective judgment and expert opinion to forecast results. These methods work best for situations for which no historical data or models are available.

Predictor uses time-series and multiple linear regression for forecasting. Oracle Crystal Ball, Fusion Edition uses simulation. Each technique and method has advantages and disadvantages for particular types of data, so often you might forecast the data using several methods and then select the method that yields the best results.

The following section, [“Classic Time-series Forecasting” on page 82](#), describes forecast methods available in Predictor and their uses.

These sections offer information about other data and forecast methodologies:

- [“Multiple Linear Regression” on page 92](#)
- [“Historical Data Statistics” on page 96](#)

## Classic Time-series Forecasting

### Subtopics

- [Classic Non-seasonal Forecasting Methods](#)
- [Classic Seasonal Forecasting Methods](#)

This section provides more information about classic time-series forecasting methods used in Predictor and described in [“Using Classic Time-series Forecasting Methods” on page 30](#). Information about ARIMA (also known as Box-Jenkins) time-series forecasting methods are found in [“Using ARIMA Time-series Forecasting Methods” on page 33](#).

Time-series forecasting assumes that historical data is a combination of a pattern and some random error. Its goal is to isolate the pattern from the error by understanding the pattern’s level, trend, and seasonality. You can then measure the error using a statistical measurement to describe both how well a pattern reproduces historical data and to estimate how accurately it projects the data into the future. See [“Time-series Forecasting Accuracy Measures” on page 88](#).

By default, Predictor tries all of the classic time-series methods in the Methods Gallery. It then ranks them according to which method has the lowest error, depending on the error measure selected in the Options pane. The method with the lowest error is the best method.

There are two primary techniques of classic time-series forecasting used in Predictor:

- [“Classic Non-seasonal Forecasting Method Parameters” on page 85](#) — Estimate a trend by removing extreme data and reducing data randomness
- [“Classic Seasonal Forecasting Methods” on page 85](#) — Combine forecasting data with an adjustment for seasonal behavior

For information about regression forecasting methods, see [“Multiple Linear Regression” on page 92](#). See the *Oracle Crystal Ball Statistical Guide* for more information about the formulas

Predictor uses for the non-seasonal and seasonal forecasting methods described in the following sections.

## Classic Non-seasonal Forecasting Methods

Non-seasonal methods attempt to forecast by removing extreme changes in past data where repeating cycles of data values are not present. The following classic non-seasonal forecasting methods are available:

- “Single Moving Average (SMA)” on page 83
- “Double Moving Average (DMA)” on page 83
- “Single Exponential Smoothing (SES)” on page 84
- “Double Exponential Smoothing (DES)” on page 84

For information about associated parameters, see “Classic Non-seasonal Forecasting Method Parameters” on page 85.

### Single Moving Average (SMA)

Smooths historical data by averaging the last several periods and projecting the last average value forward. Predictor can automatically calculate the optimal number of periods to average, or you can select the number of periods to average.

This method is best for volatile data with no trend or seasonality. It results in a straight, flat-line forecast.

Figure 30 Typical Single Moving Average Data, Fit, and Forecast Line

### Double Moving Average (DMA)

Applies the moving average technique twice, once to the original data and then to the resulting single moving average data. This method then uses both sets of smoothed data to project forward. Predictor can automatically calculate the optimal number of periods to average, or you can select the number of periods to average.

This method is best for historical data with a trend but no seasonality. It results in a straight, sloped-line forecast.

Figure 31 Typical Double Moving Average Data, Fit, and Forecast Line

### Single Exponential Smoothing (SES)

Weights all of the past data with exponentially decreasing weights going into the past. In other words, usually the more recent data has greater weight. Weighting in this way largely overcomes the limitations of moving averages or percentage change methods. Predictor can automatically calculate the optimal smoothing constant, or you can manually define the smoothing constant.

This method, which results in a straight, flat-line forecast is best for volatile data with no trend or seasonality.

Figure 32 Typical Single Exponential Smoothing Data, Fit, and Forecast Line

### Double Exponential Smoothing (DES)

Applies SES twice, once to the original data and then to the resulting SES data. Predictor uses Holt's method for double exponential smoothing, which can use a different parameter for the second application of the SES equation. Predictor can automatically calculate the optimal smoothing constants, or you can manually define the smoothing constants.

This method is best for data with a trend but no seasonality. It results in a straight, sloped-line forecast.

Figure 33 Typical Double Exponential Smoothing Data, Fit, and Forecast Line

## Classic Non-seasonal Forecasting Method Parameters

The classic non-seasonal methods use several forecasting parameters. For the moving average methods, the formulas use one parameter, period. When performing a moving average, Predictor averages over a number of periods. For single moving average, the number of periods can be any whole number between 1 and half the number of data points. For double moving average, the number of periods can be any whole number between 2 and one-third the number of data points.

For single exponential smoothing, there is one parameter: alpha. Alpha ( $\alpha$ ) is the smoothing constant. The value of alpha can be any number between 0 and 1, not inclusive.

For double exponential smoothing, there are two parameters: alpha and beta. Alpha is the same smoothing constant as described above for single exponential smoothing. Beta ( $\beta$ ) is also a smoothing constant exactly like alpha except that it is used during second smoothing. The value of beta can be any number between 0 and 1, not inclusive.

## Classic Seasonal Forecasting Methods

Seasonal forecasting methods extend the non-seasonal forecasting methods by adding an additional component to capture the seasonal behavior of the data. Predictor offers four classic seasonal forecasting methods:

- [“Seasonal Additive” on page 86](#)
- [“Seasonal Multiplicative” on page 86](#)
- [“Holt-Winters’ Additive” on page 86](#)
- [“Holt-Winters’ Multiplicative” on page 87](#)

For associated parameters, see [“Classic Seasonal Forecasting Method Parameters” on page 87](#).

See the *Oracle Crystal Ball Statistical Guide* for more information about the formulas Predictor uses.

## Seasonal Additive

Calculates a seasonal index for historical data that does not have a trend. The method produces exponentially smoothed values for the level of the forecast and the seasonal adjustment to the forecast. The seasonal adjustment is added to the forecasted level, producing the seasonal additive forecast.

This method is best for data without trend but with seasonality that does not increase over time. It results in a curved forecast that reproduces the seasonal changes in the data.

Figure 34 Typical Seasonal Additive Data, Fit, and Forecast Curve without Trend

## Seasonal Multiplicative

Calculates a seasonal index for historical data that does not have a trend. The method produces exponentially smoothed values for the level of the forecast and the seasonal adjustment to the forecast. The seasonal adjustment is multiplied by the forecasted level, producing the seasonal multiplicative forecast.

This method is best for data without trend but with seasonality that increases or decreases over time. It results in a curved forecast that reproduces the seasonal changes in the data.

Figure 35 Typical Seasonal Multiplicative Data, Fit, and Forecast Curve without Trend

## Holt-Winters' Additive

Is an extension of Holt's exponential smoothing that captures seasonality. This method is based upon three equations that can be found in the *Oracle Crystal Ball Statistical Guide*. The method produces exponentially smoothed values for the level of the forecast, the trend of the forecast,

and the seasonal adjustment to the forecast. This seasonal additive method adds the seasonality factor to the trended forecast, producing the Holt-Winters' additive forecast.

This method is best for data with trend and seasonality that does not increase over time. It results in a curved forecast that shows the seasonal changes in the data.

Figure 36 Typical Holt-Winters' Additive Data, Fit, and Forecast Curve

### Holt-Winters' Multiplicative

Is similar to the Holt-Winters' additive method. Holt-Winters' Multiplicative method also calculates exponentially smoothed values for level, trend, and seasonal adjustment to the forecast. This method's equations can also be found in the Oracle Crystal Ball Statistical Guide. This seasonal multiplicative method multiplies the trended forecast by the seasonality, producing the Holt-Winters' multiplicative forecast.

This method is best for data with trend and with seasonality that increases over time. It results in a curved forecast that reproduces the seasonal changes in the data.

Figure 37 Typical Holt-Winters' Multiplicative Data, Fit, and Forecast Curve

### Classic Seasonal Forecasting Method Parameters

The seasonal forecast methods use three smoothing parameters: alpha, beta, and gamma:

- alpha (  $\alpha$  ) — Smoothing parameter for the level component of the forecast. The value of alpha can be any number between 0 and 1, not inclusive.
- beta (  $\beta$  ) — Smoothing parameter for the trend component of the forecast. The value of beta can be any number between 0 and 1, not inclusive.

- $\gamma$  (gamma) — Smoothing parameter for the seasonality component of the forecast. The value of gamma can be any number between 0 and 1, not inclusive.

Each seasonal forecasting method uses some or all of these parameters, depending on the forecasting method. For example, the seasonal additive forecasting method does not account for trend, so it does not use the beta parameter.

## Time-series Forecasting Accuracy Measures

One component of every time-series forecast is the data's random error that is not explained by the forecast formula or by the trend and seasonal patterns. The error is measured by fitting points for the time periods with historical data and then comparing the fitted points to the historical data.

All the examples are based on the set of data illustrated in the following chart (Figure 38). Most of the formulas refer to the actual points ( $Y$ ) and the fitted points ( $\hat{Y}_t$ ). In the chart, the horizontal axis illustrates the time periods ( $t$ ) and the vertical axis illustrates the data point values.

Figure 38 Sample Data

Predictor measures the error using one of the methods described in the following sections:

- “RMSE” on page 89, below
- “MAD” on page 89
- “MAPE” on page 89

Another statistic, “Theil’s U” on page 89, is used as a relative accuracy measure. Also see “Durbin-Watson” on page 89.

## RMSE

RMSE (root mean squared error) is an absolute error measure that squares the deviations to keep the positive and negative deviations from cancelling out one another. This measure also tends to exaggerate large errors, which can help eliminate methods with large errors.

## MAD

MAD (mean absolute deviation) is an absolute error measure that originally became very popular (in the days before hand-held calculators) because it didn't require the calculation of squares or square roots. While it is still fairly reliable and widely used, it is most accurate for normally distributed data.

## MAPE

MAPE (mean absolute percentage error) is a relative error measure that uses absolute values. There are two advantages of this measure. First, the absolute values keep the positive and negative errors from cancelling out each other. Second, because relative errors do not depend on the scale of the dependent variable, this measure lets you compare forecast accuracy between differently scaled time-series data.

## Theil's U

Theil's *U* statistic is a relative accuracy measure that compares the forecasted results with a naive forecast. It also squares the deviations to give more weight to large errors and to exaggerate errors, which can help eliminate methods with large errors ([Table 3](#)). For the formula, see the *Oracle Crystal Ball Statistical Guide*.

**Table 3** Interpreting Theil's U

| Theil's U Statistic | Interpretation  |
|---------------------|---|
| Less than 1         | The forecasting technique is better than guessing.      |
| 1                   | The forecasting technique is about as good as guessing. |
| More than 1         | The forecasting technique is worse than guessing.       |

## Durbin-Watson

Detects autocorrelation at lag 1. This means that each time-series value influences the next value. This is the most common type of autocorrelation. For the formula, see the *Oracle Crystal Ball Statistical Guide*.

This statistic can have any value between 0 and 4. Values indicate slow-moving, none, or fast-moving autocorrelation ([Table 4](#)).

**Table 4** Interpreting the Durbin Watson Statistic

| Durbin-Watson Statistic | Interpretation  |
|-------------------------|---|
| Less than 1             | The errors are positively correlated. An increase in one period follows an increase in the previous period. |
| 2                       | No autocorrelation.   |
| More than 3             | The errors are negatively correlated. An increase in one period follows a decrease in the previous period.  |

Avoid using independent variables that have errors with a strong positive or negative correlation, because this can lead to an incorrect forecast for the dependent variable.

## Time-series Forecasting Techniques

### Subtopics

- [Standard Forecasting](#)
- [Simple Lead Forecasting](#)
- [Weighted Lead Forecasting](#)
- [Holdout Forecasting](#)

Predictor uses one of four forecasting techniques to perform time-series forecasting:

- [“Standard Forecasting” on page 90](#)
- [“Simple Lead Forecasting” on page 91](#)
- [“Weighted Lead Forecasting” on page 91](#)
- [“Holdout Forecasting” on page 91](#)

Classic time-series forecasting methods can use any of these techniques, but ARIMA methods can use only Standard and Holdout forecasting.

## Standard Forecasting

Standard forecasting optimizes the forecasting parameters to minimize the error measure between the fit values and the historical data for the same period. For example, consider [Table 5](#) showing historical data and calculated fit values for periods 1 through 7.

**Table 5** Example of Historical Data and Fit with Standard Forecasting

| Period | Historical Data Value | Fit Value |
|--------|-----------------------|-----------|
| 1      | 472                   | 488       |
| 2      | 599                   | 609       |
| 3      | 714                   | 702       |
| 4      | 892                   | 888       |

| Period | Historical Data Value | Fit Value |
|--------|-----------------------|-----------|
| 5      | 874                   | 890       |
| 6      | 896                   | 909       |
| 7      | 890                   | 870       |

Predictor calculates the RMSE using the differences between the historical data and the fit data from the same periods. For example:

$$(472-488)^2 + (599-609)^2 + (714-702)^2 + (892-888)^2 + \dots$$

For standard forecasting, Predictor optimizes the forecasting parameters so that the RMSE calculated in this way is minimized.

## Simple Lead Forecasting

Simple lead forecasting optimizes the forecasting parameters to minimize the error measure between the historical data and the fit values, offset by a specified number of periods (lead). Use this forecasting technique when a forecast for some future time period has the greatest importance, more so than the forecasts for the previous or later periods. For example, single lead forecasting can be used if your company must order extremely expensive manufacturing components two months in advance, making any forecast for two months out the most important.

## Weighted Lead Forecasting

Weighted lead forecasting optimizes the forecasting parameters to minimize the average error measure between the historical data and the fit values, offset by 0, 1, 2, and so on, up to the specified number of periods (weighted lead). It uses the simple lead technique for several lead periods and then averages the forecast over the periods, optimizing this average value. Use this technique when the future forecast for several periods is most important. For example, weighted lead forecasting can be used if your company must order extremely expensive manufacturing components zero, one, and two months in advance, making any forecast for all the time periods up to two months out the most important.

## Holdout Forecasting

Holdout forecasting:

1. Removes the last few data points of the historical data.
2. Calculates the fit and forecast points using the remaining historical data.
3. Compares the error between the forecasted points and their corresponding, excluded, historical data points.
4. Changes the parameters to minimize the error between the forecasted points and the excluded points.

Predictor determines the optimal forecast parameters using only the non-holdout set of data.

Note that if you have a small amount of data and want to use seasonal forecasting methods, using the holdout technique might restrict you to non-seasonal methods.

For more information on the holdout technique and when to use it effectively, see the Makridakis, Wheelwright, and Hyndman reference in [Appendix D, “Bibliography.”](#)

## Multiple Linear Regression

Multiple linear regression is used for data where one data series (the dependent variable) is a function of, or depends on, other data series (the independent variables). For example, the yield of a lettuce crop depends on the amount of water provided, the hours of sunlight each day, and the amount of fertilizer used.

The goal of multiple linear regression is to find an equation that most closely matches the historical data. “Multiple” indicates that you can use more than one independent variable to define the dependent variable in the regression equation. “Linear” indicates that the regression equation is a linear equation.

The linear equation describes how the independent variables ( $x_1, x_2, x_3, \dots$ ) combine to define the single dependent variable ( $y$ ). Multiple linear regression finds the coefficients for the equation:

$$y = b_0 + b_1x_1 + b_2x_2 + b_3x_3 + \dots + e$$

where  $b_1, b_2$ , and  $b_3$ , are the coefficients of the independent variables,  $b_0$  is the y-intercept constant, and  $e$  is the error.

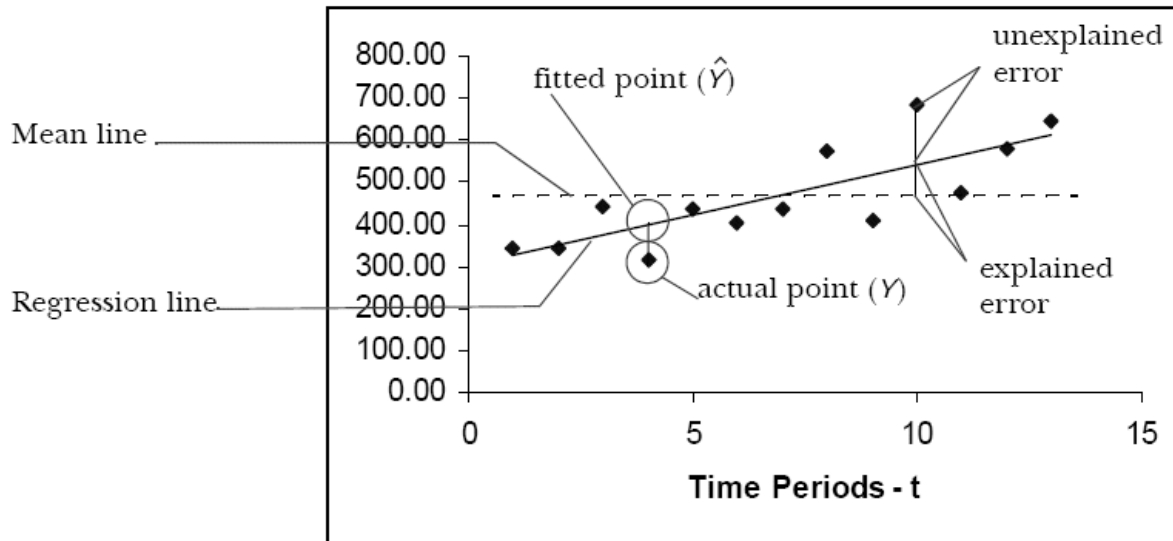

If there is only one independent variable, the equation defines a straight line. This uses a special case of multiple linear regression called simple linear regression, with the equation:

$$y = b_0 + b_1x + e$$

where  $b_0$  is where the regression line crosses the graph's y axis,  $x$  is the independent variable, and  $e$  is the error. When the regression equation has only two independent variables, it defines a plane. When the regression equation has more than two independent variables, it defines a hyperplane.

To find the coefficients of these equations, Predictor uses singular value decomposition. For more information on this technique, see the *Oracle Crystal Ball Statistical Guide*.

Figure 39 Parts of a Scatter Plot

For more information on multiple linear regressions, see:

- [“Regression Methods” on page 93](#)
- [“Regression Statistics” on page 95](#)

## Regression Methods

Predictor uses one of three methods for calculating multiple linear regression:

- [“Standard Regression” on page 93](#)
- [“Forward Stepwise Regression” on page 93](#)
- [“Iterative Stepwise Regression” on page 94](#)

## Standard Regression

Standard regression performs multiple linear regression, generating regression coefficients for each independent variable you specify, no matter how significant.

## Forward Stepwise Regression

Forward stepwise regression adds one independent variable at a time to the multiple linear regression equation, starting with the independent variable with the most significant probability of the correlation (partial  $F$  statistic). It then recalculates the partial  $F$  statistic for the remaining independent variables, taking the existing regression equation into consideration.

The resulting multiple linear regression equation will always have at least one independent variable.

Forward stepwise regression continues to add independent variables until either:

- It runs out of independent variables.
- It reaches one of the selected stopping criteria in the Stepwise Options dialog.
- The number of included independent variables reaches one-third the number of data points in the series.

There are two stopping criteria:

- *R*-squared ( $R^2$ ) — Stops the stepwise regression if the difference between a specified statistic (either  $R^2$  or adjusted  $R^2$ ) for the previous and new regression solutions is below a threshold value. When this happens, Predictor does not use the last independent variable. For example, the third step of a stepwise regression results in an  $R^2$  value of 0.81, and the fourth step adds another independent variable and results in an  $R^2$  value is 0.83. The difference between the  $R^2$  values is 0.02. If the threshold value is 0.03, Predictor returns to the regression equation for the third step and stops the stepwise regression.
- Partial *F*-test significance — Stops the stepwise regression if the probability of the partial *F* statistic for a new solution is above a maximum value. For example, if you set the maximum probability to 0.05 and the partial *F* statistic for the fourth step of a stepwise regression results in a probability of 0.08, Predictor returns to the regression equation for the third step and stops the stepwise regression.

## Iterative Stepwise Regression

Iterative stepwise regression adds or removes one independent variable at a time to or from the multiple linear regression equation.

To perform iterative stepwise regression, Predictor:

1. Calculates the partial *F* statistic for each independent variable.
2. Adds the independent variable with the most significant correlation (partial *F* statistic).
3. Checks the partial *F* statistic of the independent variables in the regression equation to see if any became insignificant (have a probability below the minimum) with the addition of the latest independent variable.
4. Removes the least significant of any insignificant independent variables one at a time.
5. Repeats step 3 until no insignificant variables remain in the regression equation.
6. Repeats steps 1 through 5 until one of the following occurs:
  - The model runs out of independent variables.
  - The regression reaches one of the stopping criteria (see the [“Forward Stepwise Regression” on page 93](#) for information on how the stopping criteria work).
  - The same independent variable is added and then removed.

The resulting equation always has at least one independent variable.

# Regression Statistics

After Predictor finds the regression equation, it calculates several statistics to help you evaluate the regression:

- “ $R^2$ ” on page 95
- “Adjusted  $R^2$ ” on page 95
- “Sum of Squared Errors (SSE)” on page 95
- “F statistic” on page 96
- “t statistic” on page 96
- “p” on page 96

See the *Oracle Crystal Ball Statistical Guide* for more information on the formulas Predictor uses to calculate these statistics.

## $R^2$

Coefficient of determination. This statistic indicates the percentage of the variability of the dependent variable that the regression equation explains.

For example, an  $R^2$  of 0.36 indicates that the regression equation accounts for 36% of the variability of the dependent variable.

## Adjusted $R^2$

Corrects  $R^2$  to account for the degrees of freedom in the data. In other words, the more data points you have, the more universal the regression equation is. However, if you have only the same number of data points as variables, the  $R^2$  might appear deceptively high. This statistic corrects for that.

For example, the  $R^2$  for one equation might be very high, indicating that the equation accounted for almost all the error in the data. However, this value might be inflated if the number of data points was insufficient to calculate a universal regression equation.

## Sum of Squared Errors (SSE)

The least squares technique for estimating regression coefficients minimizes this statistic, which measures the error not eliminated by the regression line.

For any line drawn through a scatter plot of data, there are several ways to determine which line fits the data best. One method used to compare the fit of lines is to calculate the SSE (sum of the squared errors, or deviations) for each line. The lower the SSE, the better the fit of the line to the data.

## F statistic

Tests the significance of the regression equation as measured by  $R^2$ . A significant value means that the regression equation accounts for some of the variability of the dependent variable.

## t statistic

Tests the significance of the relationship between the coefficients of the dependent variable and an individual independent variable, in the presence of the other independent variables. A significant value means that the independent variable contributes to the dependent variable.

## p

Indicates the probability of the calculated  $F$  or  $t$  statistic being as large as it is (or larger) by chance. A low  $p$  value is good and means that the  $F$  statistic is not coincidental and, therefore, is significant. A significant  $F$  statistic means that the relationship between the dependent variable and the combination of independent variables is significant.

Generally,  $p$  should be less than 0.05.

## Historical Data Statistics

Predictor automatically calculates the following statistics for historical data series:

- [“Mean” on page 96](#)
- [“Standard Deviation” on page 97](#)
- [“Minimum” on page 97](#)
- [“Maximum” on page 97](#)
- [“Ljung-Box Statistic” on page 97](#)

If an ARIMA model is displayed in the Method box, the transformation lambda and three selection criteria values are also included in the Statistics group. For more information about these values, see [“Using ARIMA Time-series Forecasting Methods” on page 33](#) and the Bibliography.

## Mean

The mean of a set of values is found by adding the values and dividing their sum by the number of values. “Average” usually refers to the mean. For example, 5.2 is the mean or average of 1, 3, 6, 7, and 9.

## Standard Deviation

The standard deviation is the square root of the variance for a distribution. Like the variance, it is a measure of dispersion about the mean and is useful for describing the “average” deviation.

For example, you can calculate the standard deviation of the values 1, 3, 6, 7, and 9 by finding the square root of the variance that is calculated in the variance example below.

The standard deviation, denoted as  $s$ , is calculated from the variance as follows:

$$s = \sqrt{10.2} = 3.19$$

where the variance is a measure of the dispersion, or spread, of a set of values about the mean. When values are close to the mean, the variance is small. When values are widely scattered about the mean, the variance is larger.

## Minimum

The minimum is the smallest value in the data range.

## Maximum

The maximum is the largest value in the data range.

## Ljung-Box Statistic

Measures whether a set of autocorrelations is significantly different from a set of autocorrelations that are all zero. See the *Oracle Crystal Ball Statistical Guide* for the formula.

## Data Screening and Adjustment Methods

Historical data can have missing values and outliers, which are data points that differ significantly from the rest of the data. Settings in the Data Attributes panel of the Predictor wizard enable you to select several ways of handling missing values and identifying and adjusting outliers. Because adjusted outliers are treated as missing values, both of these situations are discussed and handled together.

“[Setting Screening Options](#)” on page 28 describes how to display the Screening Options dialog. The groups in this dialog list:

- “[Outlier Detection Methods](#)” on page 97
- “[Outlier and Missing Value Adjustment Methods](#)” on page 99

## Outlier Detection Methods

Predictor offers three methods for detecting outliers, or significantly extreme values:

- [“Mean and Standard Deviation Method” on page 98](#)
- [“Median and Median Absolute Deviation Method \(MAD\)” on page 98](#)
- [“Median and Interquartile Deviation Method \(IQD\)” on page 98](#)

In each case, the difference is calculated between historical data points and values calculated by the various forecasting methods. These differences are called residuals. They can be positive or negative depending on whether the historical value is greater than or less than the smoothed value. Various statistics are then calculated on the residuals and these are used to identify and screen outliers.

A certain number of values must exist before the data fit can begin. If outliers appear at the beginning of the data, they are not detected.

**Note:** Time-series data is typically treated differently from other data because of its dynamic nature, such as the pattern in the data. A time-series outlier need not be extreme with respect to the total range of the data variation but it is extreme relative to the variation locally.

## Mean and Standard Deviation Method

For this outlier detection method, the mean and standard deviation of the residuals are calculated and compared. If a value is a certain number of standard deviations away from the mean, that data point is identified as an outlier. The specified number of standard deviations is called the threshold. The default value is 3.

This method can fail to detect outliers because the outliers increase the standard deviation. The more extreme the outlier, the more the standard deviation is affected.

## Median and Median Absolute Deviation Method (MAD)

For this outlier detection method, the median of the residuals is calculated. Then, the difference is calculated between each historical value and this median. These differences are expressed as their absolute values, and a new median is calculated and multiplied by an empirically derived constant to yield the median absolute deviation (MAD). If a value is a certain number of MAD away from the median of the residuals, that value is classified as an outlier. The default threshold is 3 MAD.

This method is generally more effective than the mean and standard deviation method for detecting outliers, but it can be too aggressive in classifying values that are not really extremely different. Also, if more than 50% of the data points have the same value, MAD is computed to be 0, so any value different from the residual median is classified as an outlier.

## Median and Interquartile Deviation Method (IQD)

For this outlier detection method, the median of the residuals is calculated, along with the 25th percentile and the 75th percentile. The difference between the 25th and 75th percentile is the interquartile deviation (IQD). Then, the difference is calculated between each historical value

and the residual median. If the historical value is a certain number of MAD away from the median of the residuals, that value is classified as an outlier. The default threshold is 2.22, which is equivalent to 3 standard deviations or MADs.

This method is somewhat susceptible to influence from extreme outliers, but less so than the mean and standard deviation method. Box plots are based on this approach. The median and interquartile deviation method can be used for both symmetric and asymmetric data.

## Outlier and Missing Value Adjustment Methods

Predictor provides two methods for filling in missing values and adjusting outliers:

- [“Cubic Spline Interpolation Method” on page 99](#)
- [“Neighbor Interpolation Method” on page 99](#)

Missing values at the beginning of a data series are ignored. Missing values at the end of a data series are allowed, but this condition is not ideal. The cubic spline interpolation method is especially sensitive to data missing at the end of the series. If one or two values are missing, cubic spline interpolation can be used. If multiple values are missing, neighbor interpolation provides a better estimate.

**Tip:** An obvious outlier, such as a large data spike, should be replaced by a blank cell in the original data set. Otherwise, neighbor interpolation is probably a better adjustment method, especially if the specified neighbors do not include the spike. Because cubic spline interpolation takes into account the whole data set, that adjustment method will be affected by the outlier.

### Cubic Spline Interpolation Method

Cubic spline interpolation is based on a drafting tool used to draw smooth curves through a number of points. The spline tool consists of weights attached to a flat surface at the points to be connected. A flexible strip is then bent across each of these weights, resulting in a smooth curve.

The cubic spline interpolation is a piecewise continuous curve that passes through each value in the data set. Each interval of the curve has a separate cubic polynomial, each with its own coefficients. These are equivalent to the spline tool's weights. The cubic spline interpolation method considers the entire data set when adjusting outliers and filling in missing values.

### Neighbor Interpolation Method

This method is also called the single imputation method. A certain number of neighbors on each side of the missing value are considered when estimating the missing value. This value is called  $n$ , and the total number of neighbors evaluated is  $2n$ . The missing data is replaced by the mean or median of the  $2n$  data points. The default value for  $n$  is 1, and the default statistic is Mean.

**Note:** To preserve the local nature of time series data, the number of neighbors on each side of the missing value or values should be small, ideally  $n = 1$  or  $n = 2$ .

# Glossary

---

**Adjusted  $R^2$**  Corrects  $R^2$  to account for the degrees of freedom in the data.

**ARIMA** Often called the Box-Jenkins forecasting methodology, ARIMA is a set of univariate time-series forecasting methods. ARIMA involves the identification, selection, and checking of models with estimated autoregressive (AR), integration or differencing (I), and moving average (MA) parameters.

**assumptions** Estimated values in a spreadsheet model that Crystal Ball defines with a probability distribution.

**autocorrelation** Describes a relationship or correlation between values of the same data series at different time periods.

**autoregression** Describes a relationship similar to autocorrelation, except instead of the variable being related to other independent variables, it is related to previous values of its own data series.

**causal methods** A relationship between two variables where changes in one independent variable not only correspond to a particular increase or decrease in the dependent variable, but actually cause the increase or decrease.

**Crystal Ball forecast** A statistical summary of the assumptions in a spreadsheet model, output graphically or numerically.

**degrees of freedom** The number of data points minus the number of estimated parameters (coefficients).

**dependent variable** In multiple linear regression, a data series or variable that depends on another data series. You should use multiple linear regression as the forecasting method for any dependent variable.

**DES** Double exponential smoothing.

**double exponential smoothing** Double exponential smoothing applies single exponential smoothing twice, once to the original data and then to the resulting single exponential smoothing data. It is useful where the historic data series is not stationary.

**double moving average** Smooths out past data by performing a moving average on a subset of data that represents a moving average of an original set of data.

**Durbin-Watson** Tests for autocorrelation of one time lag.

**error** The difference between the actual data values and the forecasted data values.

**F statistic** Tests the overall significance of the multiple linear regression equation.

**F-test statistic** See [F statistic](#).

**forecast** The prediction of values of a variables based on known past values of that variable or other related variables. Forecasts can also describe predicted values based on Crystal Ball spreadsheet models and expert judgements.

**forward stepwise** A regression method that adds one independent variable at a time to the multiple linear regression equation, starting with the independent variable with the greatest significance.

**holdout** Optimizes the forecasting parameters to minimize the error measure between a set of excluded data and the forecasting values. Predictor does not use the excluded data to calculate the forecasting parameters.

**Holt-Winters' additive forecasting method** Separates a series into its component parts: seasonality, trend and cycle, and error. This method determines the value of each, projects them forward, and reassembles them to create a forecast.

**Holt-Winters' multiplicative forecasting method** Considers the effects of seasonality to be multiplicative, that is, growing (or decreasing) over time. This method is similar to the Holt-Winters' additive method.

**hyperplane** A geometric plane that spans more than two dimensions.

**independent variable** In multiple linear regression, the data series or variables that influence the another data series or variable.

**iterative stepwise regression** A regression method that adds or subtracts one independent variable at a time to or from the multiple linear regression equation.

**lag** Defines the offset when comparing a data series with itself. For autocorrelation, this refers to the offset of data that you choose when correlating a data series with itself.

**lead** A type of forecasting that optimizes the forecasting parameters to minimize the error measure between the historical data and the fit values, offset by a specified number of periods (lead).

**least-squares approach** Measures how closely a line matches a set of data. This approach measures the distance of each actual data point from the line, squares each distance, and adds up the squares. The line with the smallest square deviation is the closest fit.

**level** A starting point for the forecast. For a set of data with no trend, this is equivalent to the  $y$ -intercept.

**linear equation** An equation with only linear terms. A linear equation has no terms containing variables with exponents or variables multiplied by each other.

**linear regression** A process that models a variable as a function of other first-order explanatory variables. In other words, it approximates the curve with a line, not a curve, which would require higher-order terms involving squares and cubes.

**MAD** Mean absolute deviation. This is an error statistic that average distance between each pair of actual and fitted data points.

**MAPE** Mean absolute percentage error. This is a relative error measure that uses absolute values to keep the positive and negative errors from cancelling out each other and uses relative errors to let you compare forecast accuracy between time-series methods.

**multiple linear regression** A case of linear regression where one dependent variable is described as a linear function of more than one independent variable.

**naive forecast** A forecast obtained with minimal effort based on only the most recent data; e.g., using the last data point to forecast the next period.

**$p$**  Indicates the probability of obtaining an  $F$  or  $t$  statistic as large as the one calculated for the data.

**partial  $F$  statistic** Tests the significance of a particular independent variable within the existing multiple linear regression equation.

**PivotTable** An interactive table in Microsoft Excel. You can move rows and columns and filter PivotTable data.

**$R^2$**  Coefficient of determination. This statistic indicates what proportion of the dependent variable error that the regression line explains.

**regression** A process that models a dependent variable as a function of other explanatory (independent) variables.

**residuals** The difference between the actual data and the predicted data for the dependent variable in multiple linear regression.

**RMSE** Root mean squared error. This is an absolute error measure that squares the deviations to keep the positive and negative deviations from cancelling out each other. This measure also tends to exaggerate large errors, which can help when comparing methods.

**seasonal additive forecasting method** Calculates a seasonal index for historical data that does not have a trend. The seasonal adjustment is added to the forecasted level, producing the seasonal additive forecast.

**seasonal multiplicative forecasting method** Calculates a seasonal index for historical data that does not have a trend. The seasonal adjustment is multiplied by the forecasted level, producing the seasonal multiplicative forecast.

**seasonality** The change that seasonal factors cause in a data series. For example, if sales increase during the Christmas season and during the summer, the data is seasonal with a six-month period.

**single exponential smoothing forecasting method (SES)** Weights past data with exponentially decreasing weights going into the past; that is, the more recent the data value, the greater its weight. This largely overcomes the limitations of moving averages or percentage change methods.

**single moving average forecasting method** Smooths out past data by averaging the last several periods and projecting that view forward. Predictor automatically calculates the optimal number of periods to be averaged.

**singular value decomposition** A method that solves a set of equations for the coefficients of a regression equation.

**smoothing** Estimates a smooth trend by removing extreme data and reducing data randomness.

**SSE** Sum of square deviations. The least squares technique for estimating regression coefficients uses this statistic, which measures the error not eliminated by the regression line.

**SVD** Singular value decomposition.

**t statistic** Tests the significance of the relationship between the dependent variable and any individual independent variable, in the presence of the other independent variables.

**time series** A set of values that are ordered in equally spaced intervals of time.

**trend** A long-term increase or decrease in time-series data.

**variables** In regression, data series are also called variables.

**weighted lead** A type of forecasting that optimizes the forecasting parameters to minimize the average error measure between the historical data and the fit values, offset by several different periods (leads).
