Using This Documentation

- **Overview** – Describes how to use the Oracle Solaris Fault Management Architecture (FMA) feature to manage hardware faults and some software defects. FMA is one of the components of the wider Oracle Solaris Predictive Self Healing capability.
- **Audience** – System administrators who monitor and handle system faults and defects
- **Required knowledge** – Experience administering Oracle Solaris systems

Product Documentation Library

Late-breaking information and known issues for this product are included in the documentation library at [http://www.oracle.com/pls/topic/lookup?ctx=E36784](http://www.oracle.com/pls/topic/lookup?ctx=E36784).

Introduction to the Fault Manager

The Oracle Solaris OS includes an architecture for building and deploying systems and services that are capable of predictive self healing. The service that is the core of the Fault Management Architecture (FMA) receives data related to hardware and software errors, automatically diagnoses the underlying problem, and responds by attempting to take faulty components offline.

This chapter discusses the following topics:

- Description of the Oracle Solaris Fault Management feature
- Configuring when and how you will be notified of error events
- Features of messages from the Fault Manager

When specific hardware faults occur, Oracle Auto Service Request (ASR) can automatically open an Oracle service request. See http://www.oracle.com/asr for more information about ASR.

Fault Management Overview

The Oracle Solaris Fault Management feature includes the following components:

- An architecture for building resilient error handlers
- Structured error telemetry
- Automated diagnostic software
- Response agents
- Structured messaging

Many parts of the software stack participate in fault management, including the CPU, memory and I/O subsystems, Oracle Solaris ZFS, and many device drivers.

FMA can help with both faults and defects:
Faults – A faulted component is a component that used to work but no longer works.  
Defects – A defective component is a component that never worked correctly.

Hardware can experience both faults and defects. Most software problems are defects or are caused by configuration issues. Fault management and system services often interact. For example, a hardware problem might cause services to be stopped or restarted. An SMF service error might cause FMA to report a defect.

The fault management stack includes error detectors, a diagnosis engine, and response agents.

**Error detectors**  
Error detectors detect errors in the system and perform any immediate, required handling. Error detectors issue well-defined error reports, or ereports, to a diagnosis engine.

**Diagnosis engine**  
The diagnosis engine interprets ereports and determines whether a fault or defect is present in the system. When such a determination is made, the diagnosis engine issues a suspect list that describes the resource or set of resources that might be the cause of the problem. The resource might have an associated Field Replaceable Unit (FRU), a label, or an Automatic System Reconfiguration Unit (ASRU). An ASRU might be immediately removed from service to mitigate the problem until the FRU is replaced.

When the suspect list includes multiple suspects (for example, if the diagnosis engine cannot isolate a single suspect), each suspect is assigned a probability of being the key suspect. The probabilities in this list sum to 100 percent. Suspect lists are interpreted by response agents.

**Response agents**  
Response agents attempt to take action based on the suspect list. Responses include logging messages, taking CPU strands offline, retiring memory pages, and retiring I/O devices.

Error detectors, diagnosis engines, and response agents are connected by the Fault Manager daemon, fmd, which acts as a multiplexor between the various components, as shown in the following figure.
The lifecycle of a problem managed by the Fault Manager can include the following stages:

**Diagnose**  
A new problem has been diagnosed by the Fault Manager. The diagnosis includes a list of one or more suspects. A suspect might have been automatically isolated to prevent further errors from occurring. The problem is identified by a UUID in the event payload, and further events describing the resolution lifecycle of this problem quote a matching UUID.

**Update**  
One or more of the suspect resources in a problem diagnosis has been repaired, replaced, or acquitted, or the resource has faulted again. The suspect list still contains at least one faulted resource. A repair might have been made by executing an `fmadm` command, or the system might have detected a repair such as a changed serial number for a part. The `fmadm` command is described in Chapter 3, “Repairing Faults”.

**Repair**  
All of the suspect resources in a problem diagnosis have been repaired, resolved, or acquitted. Some or all of the resources might still be isolated.

**Resolve**  
All of the suspect resources in a problem diagnosis have been repaired, resolved, or acquitted and are no longer isolated. For example, a CPU that was a suspect and was offline is now back online again. Offlineing and onlining resources is usually automatic.
The Fault Manager daemon is a Service Management Facility (SMF) service. The svc:/system/fmd service is enabled by default. See “Managing System Services in Oracle Solaris 11.2” for more information about SMF services. See the fmd(1M) man page for more information about the Fault Manager daemon.

The fmadm config command shows the name, description, and status of each module in the Fault Manager. These modules diagnose and repair problems on the system. The fmstat command displays additional information about these modules, as shown in “Fault Statistics” on page 20.

**Receiving Notification of Faults and Defects**

The Fault Manager daemon notifies you that a fault or defect has been detected and diagnosed.

**Configuring When and How You Will Be Notified**

Use the svcs -n and svccfg listnotify commands to show event notification parameters, as shown in “Showing Event Notification Parameters” in “Managing System Services in Oracle Solaris 11.2”.

Use the svccfg setnotify command to configure FMA error event notification, as shown in “Configuring Notification of State Transition and FMA Events” in “Managing System Services in Oracle Solaris 11.2”. For example, the following command creates a notification that sends an SMTP message when an FMA-managed problem is repaired:

```
$ svccfg setnotify problem-repaired smtp:
```

You can configure notification of fault management error events to use the Simple Mail Transfer Protocol (SMTP) or the Simple Network Management Protocol (SNMP).

FMA event tags include problem-diagnosed, problem-updated, problem-repaired, and problem-resolved. These tags correspond to the problem lifecycle stages described in “Fault Management Overview” on page 7.

Event notification and FMA event tags are also described in the “Notification Parameters” section in the smf(5) man page. For more information about the notification daemons, see the snmp-notify(1M) and smtp-notify(1M) man pages.

Settings for notification parameters for FMA events are stored in fmnotify properties in svc:/system/fm/notify-params:default. Events generated by SMF state transitions are stored in
the service or in the transitioning instance. System-wide notification parameters for SMF state transition events are stored in svc:/system/svc/global:default.

**Understanding Messages From the Fault Manager Daemon**

The Fault Manager daemon sends messages to both the console and the /var/adm/messages file. Messages from the Fault Manager daemon use the format shown in the following example:

```
1    SUNW-MSG-ID: SUN4V-8001-BH, TYPE: Fault, VER: 1, SEVERITY: Minor
3    PLATFORM: SUNW,T5440, CSN: -, HOSTNAME: bur419-61
4    SOURCE: cpumem-diagnosis, REV: 1.7
5    EVENT-ID: 7b83c87c-78f6-6a8e-fa2b-d0cf16834049
6    DESC: The number of integer register errors associated with this thread has exceeded acceptable levels.
7    AUTO-RESPONSE: The fault manager will attempt to remove the affected thread from service.
8    IMPACT: System performance may be affected.
9    REC-ACTION: Use ‘fmadm faulty’ to provide a more detailed view of this event. Please refer to the associated reference document at http://support.oracle.com/msg/SUN4V-8001-BH for the latest service procedures and polices regarding this diagnosis.
```

When you are notified of a diagnosed problem, consult the recommended knowledge article for additional details. Line 13 shows the recommended knowledge article in this example. The knowledge article might contain actions that you or a service provider should take in addition to other actions listed in the “REC-ACTION” section.
Displaying Fault Information

This chapter shows how to display detailed information about problems detected by the fault management system.

Displaying Information About Faults or Defects

Use the `fmadm faulty` command to display fault or defect information and determine which FRUs are involved. The `fmadm faulty` command displays active problems. The `fmdump` command displays the contents of log files associated with the Fault Manager daemon and is more useful as a historical log of problems on the system.

**Tip** - Base your administrative action on output from the `fmadm faulty` command. Log files output by the `fmdump` command can contain error statements that are not faults or defects.

The `fmadm faulty` command displays status information for resources that the Fault Manager identifies as faulty. The `fmadm faulty` command has many options for displaying different information or displaying information in different formats. See the `fmadm(1M)` man page for information about all the `fmadm faulty` options.

**EXAMPLE 2-1**  
fmadm faulty Output Showing One Faulty CPU

```bash
e # fmadm faulty
  1 TIME  EVENT-ID  MSG-ID  SEVERITY
  2 Aug 24 17:56:03 7b83c87c-78f6-6a8e-fa2b-d0cf16834049  SUN4V-8001-BH  Minor
  3 Host   : bur419-61
  4 Platform : SUNW,T5440 Chassis_id  : BEL07524BN
  5 Product_sn : BEL07524BN
  6 Fault class : fault.cpu.ultraSPARC-T2plus.ireg
  7 Affects  : cpu:///cpuid=0/serial=1F95806CD1421929
```
Displaying Information About Faults or Defects

17   faulted and taken out of service
18   FRU       : "MB/CPU0" (hc://:product-id=SUNW,T5440:server-id=bur419-61:"
19         serial=3529:part=541255304/motherboard=0/cpuboard=0)
20   faulty
21   Serial ID.  : 3529
22         7F95806CD1421929
23   Description : The number of integer register errors associated with this thread
24         has exceeded acceptable levels.
25   Response    : The fault manager will attempt to remove the affected thread from
26         service.
27   Impact      : System performance may be affected.
28   Action      : Use ‘fmadm faulty’ to provide a more detailed view of this event.
29         Please refer to the associated reference document at
30         http://support.oracle.com/msg/SUN4V-8001-8H for the latest service
31         procedures and policies regarding this diagnosis.

Line 14 identifies the impacted FRU. The string shown in quotation marks, “MB/CPU0,” should match the label on the physical hardware. The string shown in parentheses is the Fault Management Resource Identifier (FMRI) for the FRU. The FMRI includes descriptive properties about the system that contains the fault, such as its host name and chassis serial number. On some platforms, the part number and serial number of the FRU are also included in the FMRI of the FRU.

The Affects lines (lines 12 and 13) indicate the components that are affected by the fault and their relative state. In this example, a single CPU strand is affected. That CPU strand is faulted and has been taken out of service by the Fault Manager.

Following the FRU description in the `fmadm faulty` command output, line 16 shows the state as faulty. The Action section might include specific actions in addition to references to documents on the support site.

EXAMPLE 2-2  `fmadm faulty` Output Showing Multiple Faults

```bash
# fmadm faulty
```

```
lo         --------------- ------------------------------------  -------------
          TIME            EVENT-ID                              MSG-ID         SEVERITY
              --------------- ------------------------------------  -------------
          Sep 21 10:01:36 d482f935-5c8f-e9ab-9f25-d0aaafec1edc  PCIEX-0000-5Y  Major

    Fault class  : fault.io.pci.device-invreq

    FRU          : "SLOT 2" (hc://.../pciexrc=3/pciexbus=4/pciexdev=0)
    repair attempted
    "SLOT 3" (hc://.../pciexrc=3/pciexbus=4/pciexdev=1)
```
17 acquitted
18 "SLOT 4" (hc://.../pciexrc=3/pciexbus=4/pciexdev=2)
19 not present
20 "SLOT 5" (hc://.../pciexrc=3/pciexbus=4/pciexdev=3)
21 faulty
22
23 Description : The transmitting device sent an invalid request.
24
25 Response     : One or more device instances may be disabled
26
27 Impact       : Possible loss of services provided by the device instances
28 associated with this fault
29
30 Action       : Use ‘fmadm faulty’ to provide a more detailed view of this event.
31 Please refer to the associated reference document at
32 http://support.oracle.com/msg/PCIEX-8000-5Y for the latest service
33 procedures and policies regarding this diagnosis.

In this output, device 1 in slot 3 is described as “ok and in service” on line 10, and line 17 shows its state as “acquitted.” Device 3 in slot 5 is described as “faulty and taken out of service,” and its state is “faulty.” States shown for two other devices are “repair attempted” and “not present.”

EXAMPLE 2-3 Showing Faults With the fmdump Command

Some console messages and knowledge articles might instruct you to use the fmdump -v -u UUID command to display fault information, as shown in the following example:

```
# fmdump -v -u 7b83c87c-78f6-6a8e-fa2b-d0cf16834049
```

```
TIME     UUID                          SUNW-MSG-ID EVENT
Aug 24 17:56:03.4596 7b83c87c-78f6-6a8e-fa2b-d0cf16834049 SUN4V-8001-8H Diagnosed

100% fault.cpu.ultraSPARC-T2plus.ireg

Problem in: -
Affects: cpu:///cpuid=0/serial=1F95806CD14219290
FRU: hc:///product-id=SUNW,T5440:server-id=bur419-61:serial=9999:part=541255304/motherboard=0/cpuboard=0
Location: MB/CP0
```

The information about the affected FRUs is on lines 8 through 10. The Location string on line 10 presents the human-readable FRU string. Line 8 shows the FMRI of the FRU. To see the severity, descriptive text, and action in the fmdump output, use the -m option. See the fmdump(1M) man page for more information.

EXAMPLE 2-4 Identifying Which CPUs Are Offline

Use the psrinfo command to display information about the CPUs:

```
$ psrinfo
0     faulted since 05/13/2013 12:55:26
```
Displaying Information About Defective Services

The `fmadm faulty` command can also display information about problems in SMF services, as shown in the following example:

```
# fmadm faulty
-------------- ------------------------------------  -------------- ---------
TIME            EVENT-ID                              MSG-ID         SEVERITY
-------------- ------------------------------------  -------------- ---------
May 12 22:52:47 915cb64b-e16b-4f49-efe6-de81ff96fce7  SMF-8000-YX    major

Host        : parity
Platform    : Sun-Fire-V40z     Chassis_id  : XG051535088
Product_sn  : XG051535088

Fault class : defect.sunos.smf.svc.maintenance
Affects     : svc:///system/intrd:default
              faulted and taken out of service
Problem in  : svc:///system/intrd:default
              faulted and taken out of service

Description : A service failed - it is restarting too quickly.
Response    : The service has been placed into the maintenance state.
Impact      : svc:/system/intrd:default is unavailable.
Action      : Run `svcs -xv svc:/system/intrd:default` to determine the
generic reason why the service failed, the location of any
logfiles, and a list of other services impacted. Please refer to
the associated reference document at
http://support.oracle.com/msg/SMF-8000-YX for the latest service procedures
and policies regarding this diagnosis.

Follow the instructions given in the Action section in the `fmadm` output to display information about the defective service.

```
# svcs -xv svc:/system/intrd:default
svc:/system/intrd:default (interrupt balancer)
State: maintenance since Wed May 12 22:52:47 2010
Reason: Restarting too quickly.
See: http://support.oracle.com/msg/SMF-8000-YX
See: man -M /usr/share/man -s 1M intrd
See: /var/svc/log/system-intrd:default.log
Impact: This service is not running.
```

The references in the “See” lines provide more information about this problem.
Repairing Faults

This chapter discusses the following topics:

- How to repair faults or defects
- What information the various fault management log files contain and how to view those log files
- How to view information about Fault Manager modules

Repairing Faults or Defects

You can configure Oracle Auto Service Request (ASR) to automatically request Oracle service when specific hardware problems occur. See http://www.oracle.com/asr for more information about ASR.

When a component in your system has faulted, the Fault Manager can repair the component implicitly or you can repair the component explicitly.

Implicit repair

An *implicit repair* can occur when the faulty component is replaced or removed if the component has serial number information that the Fault Manager daemon (fmd) can track. On many SPARC based systems, serial number information is included in the FMRI so that fmd can determine when components have been removed from operation, either through replacement or through other means such as blacklisting. When fmd determines that a component has been removed from operation, the Fault Manager no longer displays that component in fmadm faulty output. The component is maintained in the Fault Manager internal resource cache until the fault event is 30 days old.

When fmd detects faulty CPU or memory resources, those resources are placed on a blacklist. A faulty resource that is on the blacklist cannot be reassigned until fmd marks the resource as being repaired.

Explicit repair

Sometimes no FRU serial number information is available even though the FMRI includes a chassis identifier. In this case, fmd cannot detect an FRU replacement, and you must
perform an *explicit repair* by using the `fmadm` command with the `replaced`, `repaired`, or `acquit` subcommand as shown in the following sections. You should perform explicit repairs only at the direction of a specific documented repair procedure.

These `fmadm` commands take the following operands:

- The UUID, also shown as the EVENT-ID in Fault Manager output, identifies the fault event. The UUID can only be used with the `fmadm` `acquit` command. You can specify that the entire event can be safely ignored, or you can specify that a particular resource is not a suspect in this event.
- The FMRI and the label identify the suspect faulted resource. Examples of the FMRI and label of a resource are shown in Example 2-1. Typically, the label is easier to use than the FMRI.

A case is considered repaired when the fault event UUID is acquitted or when all suspect resources have been repaired, replaced, removed, or acquitted. A case that is repaired moves into the FMD_CASE_REPAIRED state, and the Fault Manager generates a `list.repaired` event.

### `fmadm replaced` Command

Use the `fmadm replaced` command to indicate that the suspect FRU has been replaced or removed. If multiple faults are currently reported against one FRU, the FRU shows as replaced in all cases.

```
fmadm replaced FMRI | label
```

When an FRU is replaced, the serial number of the FRU changes. If `fmd` automatically detects that the serial number of an FRU has changed, the Fault Manager behaves in the same way as if you had entered the `fmadm replaced` command. If `fmd` cannot detect whether the serial number of the FRU has changed, then you must enter the `fmadm replaced` command if you have replaced or removed the FRU. If `fmd` detects that the serial number of the FRU has not changed, then the `fmadm replaced` command exits with an error.

If you remove the FRU but do not replace the FRU, the Fault Manager displays the suspect as not present. The suspect is not considered to be permanently removed until the fault event is 30 days old.

### `fmadm repaired` Command

Use the `fmadm repaired` command when you have performed a physical repair other than replacement of the FRU to resolve the problem. Examples of such repairs include reseating a card or straightening a bent pin. If multiple faults are currently reported against one FRU, the FRU shows as repaired in all cases.
fmadm repaired FMRI | label

**fmadm acquit Command**

Use the acquit subcommand if you determine that the indicated resource is not the cause of the fault. Usually the Fault Manager automatically acquits some suspects in a multi-element suspect list. Acquittal can occur implicitly as the Fault Manager refines the diagnosis, for example if additional error events occur. Sometimes Support Services gives you instructions to perform a manual acquittal.

Replacement takes precedence over repair, and both replacement and repair take precedence over acquittal. Thus, you can acquit a component and then subsequently repair the component, but you cannot acquit a component that has already been repaired.

If you do not specify any *FMRI* or *label* with the *UUID*, then the entire event is identified as able to be ignored. A case is considered repaired when the fault event UUID is acquitted.

**fmadm acquit UUID**

Acquit by FMRI or label with no UUID only if you determine that the resource is not a factor in any current cases in which that resource is a suspect. If multiple faults are currently reported against one FRU, the FRU shows as acquitted in all cases.

**fmadm acquit FMRI**  
**fmadm acquit label**

To acquit a resource in one case and keep that resource as a suspect in other cases, specify both the fault event UUID and the resource FMRI or both the UUID and the resource label, as shown in the following examples:

**fmadm acquit FMRI UUID**  
**fmadm acquit label UUID**

**Fault Management Log Files**

The Fault Manager daemon records information in several log files. The log files are stored in `/var/fm/fmd`. To view these log files, use the `fmdump` command. See the `fmdump(1M)` man page for more information.

- The `errlog` log file records inbound telemetry information which consists of ereports.
- Informational events are recorded in two log files. The `infolog_hival` log file is for high-value events, and the `infolog` log file collects all other informational events.
- The `fltlog` log file records fault diagnosis and repair events.
Fault Statistics

Tip - Base your administrative action on output from the `fmadm faulty` command. Log files output by the `fmdump` command can contain error statements that are not faults or defects.

See “Displaying Information About Faults or Defects” on page 13 for information about using the `fmadm faulty` command.

The log files are automatically rotated. See the `logadm(1M)` man page for more information.

Fault Statistics

The Fault Manager daemon and many of its modules gather statistics. The `fmadm config` command shows the status of Fault Manager modules. The `fmstat` command reports statistics gathered by these modules.

```
# fmadm config
MODULE                   VERSION STATUS  DESCRIPTION
cpumem-retire            1.1     active  CPU/Memory Retire Agent

</tbody>
</table>

**ev_recv**
The number of telemetry events received by the module.

**ev_acpt**
The number of telemetry events accepted by the module as relevant to a diagnosis.

**wait**
The average number of telemetry events waiting to be examined by the module.

**svc_t**
The average service time for telemetry events received by the module, in milliseconds.

**%w**
The percentage of time that telemetry events were waiting to be examined by the module.

**%b**
The percentage of time that the module was busy processing telemetry events.

**open**
The number of active cases (open problem investigations) owned by the module. The open column applies only to fault management cases, which are created and solved only by diagnosis engines. This column does not apply to other modules, such as response agents.

**solve**
The total number of cases solved by this module since it was loaded. The solve column applies only to fault management cases, which are created and solved only by diagnosis engines. This column does not apply to other modules, such as response agents.

**memsz**
The amount of dynamic memory currently allocated by this module.

**bufsz**
The amount of persistent buffer space currently allocated by this module.

Different statistics and columns are displayed when you specify different options.

To display statistics on an individual module, use the `-m module` option. The `-z` option suppresses zero-valued statistics. The following example shows that the cpumem-retire response agent successfully processed a request to take a CPU offline.

```
# fmstat -z -m cpumem-retire
```
<table>
