This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

Using This Documentation

- **Overview** – Includes basic topics and tasks to assist you in planning for deploying IPv4 and IPv6 networks.
- **Audience** – System administrators.
- **Required knowledge** – Basic understanding of network administration concepts and practices.

Product Documentation Library

Documentation and resources for this product and related products are available at <http://www.oracle.com/pls/topic/lookup?ctx=E37838-01>.

Feedback

Provide feedback about this documentation at <http://www.oracle.com/goto/docfeedback>.

Planning For Network Deployment

This chapter describes the different considerations when planning for the deployment of a TCP/IP network. The planning tasks that are described can assist you in deploying your network in an organized and cost-effective manner. Note that the details of planning the network are outside the scope of this guide. Only general directions are provided. This guide also assumes that you are familiar with basic networking concepts and terminology.

This chapter contains the following topics:

- [“Determining the Network Hardware”](#)
- [“Network Topology Description”](#)
- [“Using Subnets on Your Network”](#)
- [“IPv4 Autonomous System Topology”](#)
- [“Planning for Routers on Your Network”](#)
- [“Obtaining IP Addresses for Your Network”](#)
- [“Using Naming Entities on Your Network”](#)

For an overview of network administration, see [Chapter 1, “About Network Administration in Oracle Solaris”](#) in *Configuring and Managing Network Components in Oracle Solaris 11.4*.

For information about administering an existing TCP/IP network, see [Chapter 1, “Administering TCP/IP Networks”](#) in *Administering TCP/IP Networks, IPMP, and IP Tunnels in Oracle Solaris 11.4*.

For a high-level overview of the networking strategies that you can implement in the Oracle Solaris release, see [Chapter 1, “Summary of Oracle Solaris Network Administration”](#) in *Strategies for Network Administration in Oracle Solaris 11.4*.

Determining the Network Hardware

Some of the planning decisions that you must make about hardware include the following:

- Network topology, the layout, and connections of the network hardware

- Type and number of systems your network can support, including the virtual systems that might be required on your server
- Network devices to be installed in these systems
- Type of network media to use, such as Ethernet, and so on
- Use of bridges, routers, and firewalls to extend the network media or connect the local network to external networks

Network Topology Description

Network topology describes how networks fit together. Networks are connected to each other by routers. For example, the following figure shows 3 networks connected by 2 routers.

FIGURE 1 Basic Network Topology

The following figure shows a more complex configuration:

FIGURE 2 A Network Topology That Provides an Additional Path Between Networks

The topology includes a third router that directly connects Networks 1 and 3. The resulting redundancy improves reliability by maintaining connectivity even if Network 2 fails. However, the networks must use the same network protocols.

Using Subnets on Your Network

The use of subnets is connected with the need for administrative subdivisions to address issues of size and control. The more hosts and servers that you have on a network, the more complex your management task. By creating administrative divisions and using subnets, managing complex networks becomes easier.

The decision about setting up administrative subdivisions for your network is determined by the following factors:

- **Size of the network**

Subnets are also useful even in a relatively small network whose subdivisions are located across an extensive geographical area.

- **Common needs shared by groups of users**

For example, you might have a network that is confined to a single building and supports a relatively small number of systems. These machines are divided among a number of subnetworks. Each subnetwork supports groups of users with different needs. In this example, you might use an administrative subdivision for each subnet.

- **Security**

You might want to segregate your mission critical servers, desktop systems, and Internet facing web servers into separate subnets where you can establish firewalls between them.

IPv4 Autonomous System Topology

Sites with multiple routers and networks typically administer their network topology as a single routing domain or an *autonomous system* (AS). [Figure 3, “Autonomous System With Multiple IPv4 Routers,” on page 13](#) shows an AS that is divided into three local networks: 203.0.113.0, 198.51.100.0, and 192.0.2.0.

The network is comprised of the following types of systems:

- **Routers**

Routers use routing protocols to manage how network packets are directed or routed from their source to their destinations within the local network or to external networks. For information about the routing protocols that are supported in Oracle Solaris and instructions on configuring a system as a router, see [“Routing Protocols” in *Configuring an Oracle Solaris 11.4 System as a Router or a Load Balancer*](#).

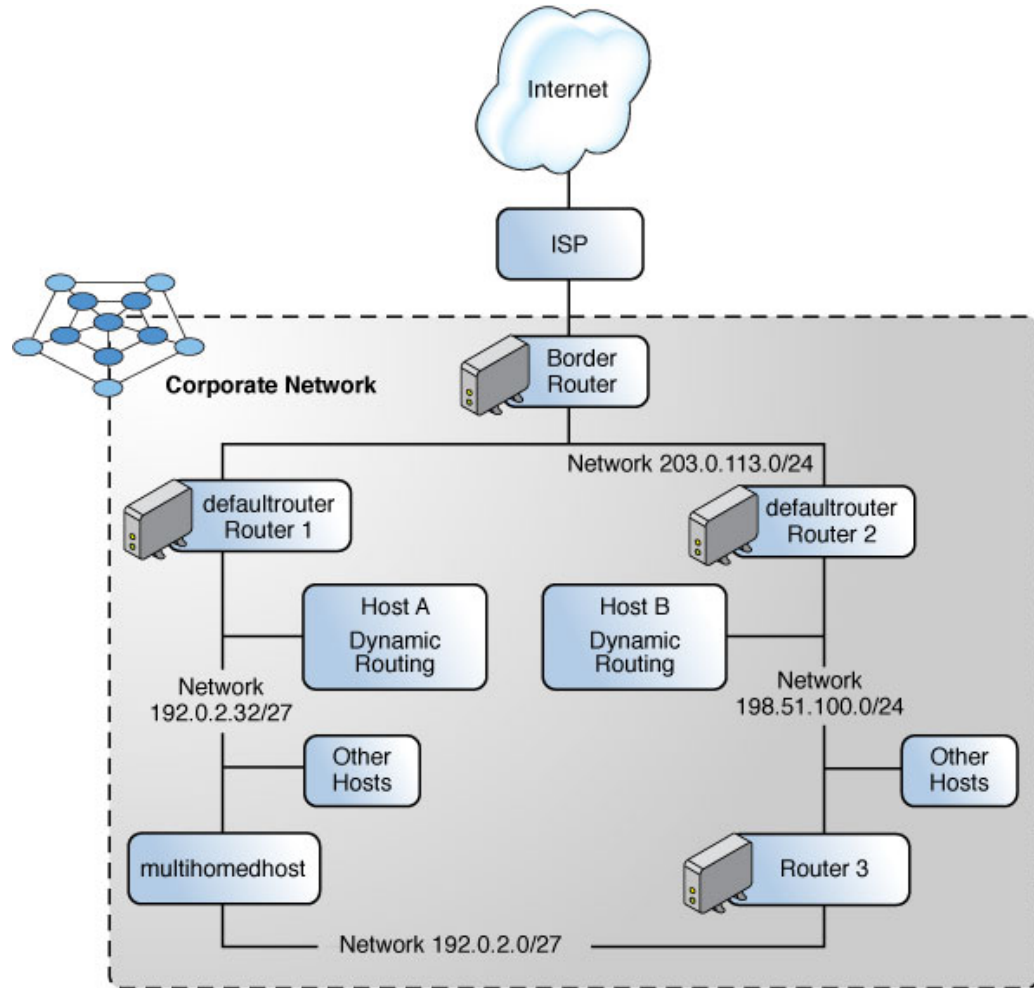

The different types of routers are:

- Border routers – Connect the local network, such as `203.0.113.0`, externally to a service provider.
- Default routers – Manage packet routing in the local network, which itself can include several local networks. For example, in [Figure 3, “Autonomous System With Multiple IPv4 Routers,” on page 13](#), Router 1 serves as the default router for `192.0.2.0`. Contemporaneously, Router 1 is also connected to the `203.0.113.0` internal network. Router 2’s interfaces connect to the `203.0.113.0` and `198.51.100.0` internal networks.
- Packet-forwarding routers – Forward packets between internal networks but do not run routing protocols. In [Figure 3, “Autonomous System With Multiple IPv4 Routers,” on page 13](#), Router 3 is a packet-forwarding router with connections to the `198.51.100.0` and `192.0.2.0` networks.
- Client systems
 - Multihomed systems or systems that have multiple NICs. In Oracle Solaris, these systems by default, can forward packets to other systems in the same network segment.
 - Single-interfaced systems rely on the local routers for both packet forwarding and receiving configuration information.

For task-related information, see [Chapter 3, “Configuring and Administering IP Interfaces and Addresses in Oracle Solaris” in *Configuring and Managing Network Components in Oracle Solaris 11.4*](#).

Use the following figure as a reference when configuring additional network components.

FIGURE 3 Autonomous System With Multiple IPv4 Routers

Planning for Routers on Your Network

In TCP/IP, two types of entities exist on a network: hosts and routers. All networks must have hosts, while not all networks require routers. The physical topology of the network determines if you need routers.

In most networks, commercial routers are typically used to manage network traffic. However, if necessary, you can also configure an Oracle Solaris system to function as a router. See [Chapter 2, “Configuring a System as a Router”](#) in *Configuring an Oracle Solaris 11.4 System as a Router or a Load Balancer*.

The following figure shows a network topology with three networks that are connected by two routers.

FIGURE 4 A Network Topology With Three Interconnected Networks

Router R1 connects networks 192.0.2.0/27 and 192.0.2.32/27. Router R2 connects networks 192.0.2.32/27 and 192.0.2.64/27.

If Host A on network 192.0.2.0/27 sends a message to Host B on network 192.0.2.32/27, the following events occur:

1. Host A examines its routing tables for the path to 192.0.2.70/27. The local network address range does not cover this address, but there is a previously learned default route through router R1 that covers the address. Therefore, Host A sends the packet to Router R1.
2. Router R1 examines its routing tables. No local network's address range covers the destination address, but there is a known route to network 192.0.2.64/27 through Router R2 that covers the address, Router R1 sends the packet to Router R2.
3. Router R2 is connected directly to network 192.0.2.64/27. The routing table lookup reveals that 192.0.2.70/27 is on the attached network. Router R2 sends the packet directly to Host B.

Obtaining IP Addresses for Your Network

When you plan your network addressing scheme, consider the following factors:

- Type of IP address that you want to use: IPv4 or IPv6
- Number of potential systems on your network
- Number of systems that are multihomed, or routers, which require multiple network interface cards (NICs), each with individual IP addresses
- Use of private addresses on your network
- Use of a DHCP server to manages pools of IP addresses

For an introduction to IP addresses, refer to available articles about the topic online such as the following resources:

- https://en.wikipedia.org/wiki/IP_address
- <http://tools.ietf.org/html/rfc791>
- <http://tools.ietf.org/html/rfc4632>
- <http://tools.ietf.org/html/rfc4291>

To obtain IP addresses, register with any Internet Service Provider, or through IANA's Internet Registries. See [IANA's IP Address Service page \(http://www.iana.org/ipaddress/ip-addresses.htm\)](http://www.iana.org/ipaddress/ip-addresses.htm).

Note - IP addresses that are used in Oracle Solaris 11 documentation conform to [RFC 5737, IPv4 Address Blocks Reserved for Documentation](https://tools.ietf.org/html/rfc5737) (<https://tools.ietf.org/html/rfc5737>) and [RFC 3849, IPv6 Address Prefix Reserved for Documentation](https://tools.ietf.org/html/rfc3849) (<https://tools.ietf.org/html/rfc3849>). IPv4 addresses used in this documentation are blocks 192.0.2.0/24, 198.51.100.0/24, and 203.0.113.0/24. IPv6 addresses have prefix 2001:DB8::/32.

To show a subnet, the block is divided into multiple subnets by borrowing enough bits from the host to create the required subnet. For example, host address 192.0.2.0 might have subnets 192.0.2.32/27 and 192.0.2.64/27.

Using Naming Entities on Your Network

The TCP/IP protocols locate a system on a network by using its IP address. However, a host name enables you to identify systems more easily than IP addresses.

Domain Names

Many networks organize their hosts and routers into a hierarchy of administrative domains. If you are using the domain name system (DNS) or the Network Information Service (NIS) naming system, you must select a domain name for your organization that is unique worldwide. To ensure that your domain name is unique, you should register the domain name with *InterNIC*. A unique domain name is required if you plan to allow other sites on the Internet locate your systems through DNS.

The domain name structure is hierarchical. A new domain typically is located under an existing, related domain. For example, the domain name for a subsidiary company can be located below the domain of the parent company. If the domain name has no other relationship, an organization can place its domain name directly under one of the existing top-level domains such as .com, .org, .edu, .gov, and so forth.

Selecting a Naming Service and Directory Service

In Oracle Solaris, you can select from three types of naming services: local files, NIS, and DNS. Naming services maintain critical information about the machines on a network, such as the host names, IP addresses, and so forth. You can also use the LDAP directory service

in addition to or instead of a naming service. LDAP is a secure network protocol that is used to access directory servers for distributed naming and other directory services. This standard based protocol supports a hierarchical database structure. The same protocol can be used to provide naming services in both UNIX and multi-platform environments. For an introduction to naming services in Oracle Solaris, refer to [Chapter 1, “About Naming and Directory Services” in *Working With Oracle Solaris 11.4 Directory and Naming Services: DNS and NIS*](#).

The configuration of the network databases is critical. Therefore, you need to decide which naming or directory service to use as part of the network planning process. Moreover, the decision to use naming services also affects whether you organize your network into an administrative domain.

For a naming or directory service, you can select from the following choices:

- DNS – The DNS naming service maintains network databases on several servers on the network. See [Working With Oracle Solaris 11.4 Directory and Naming Services: DNS and NIS](#) for a description of these naming services and information about how to configure the databases. In addition, the guide explains the *namespace* and *administrative domain* concepts in more detail.
- LDAP – You can also use the LDAP directory service in addition to or instead of a naming service. LDAP is a secure network protocol that is used to access directory servers for distributed naming and other directory services. For more information, see [Working With Oracle Solaris 11.4 Directory and Naming Services: LDAP](#).
- Local files – If you do not implement NIS, DNS, or LDAP, the network uses *local files* to provide the naming service. The term "local files" refers to the series of files in the `/etc` directory that the network databases use. The procedures in this book assume you are using local files for your naming service, unless otherwise indicated.

Note - If you decide to use local files as the naming service for your network, you can set up another naming service at a later date.

- NIS – The NIS naming service is supported in this release. See [Working With Oracle Solaris 11.4 Directory and Naming Services: DNS and NIS](#).

Administering Host Names

Plan a naming scheme for the systems that will comprise the network. Each machine on the network should have a TCP/IP host name that corresponds to the IP address on its primary network interface. The host name must be unique within the sub-domain of the system. Just like physical machines, virtual systems should also have a unique IP address and host name.

The following system configurations are possible:

- Multiple host names that map to the IP address of the system. For example, `systema.example.com` can also be known as `www.example.com`
- The same host name for both IPv4 and IPv6 addresses
- A new IP address and an old deprecated IP address that are configured with the same host name for a period of time to support network renumbering
- Multiple network interfaces on different subnets, each with a unique IP address and host name

When planning your network, make a list of IP addresses and their associated host names for easy access during the setup process. The list can help you verify that all of your host names are unique.

Note - The TCP/IP host name of the primary interface is a distinct entity from the *system host name* that you set with the `hostname` command. Although not required by Oracle Solaris, the same name is normally used for both. Some network applications depend on this convention. See the [hostname\(1\)](#) man page for more information.

Planning for Using IPv6 Addresses

This chapter supplements [Chapter 1, “Planning For Network Deployment”](#) by describing additional considerations when using IPv6 addresses on your network. If you do plan to use IPv6 addresses in addition to IPv4 addresses, ensure that your current ISP supports both address types.

This chapter contains the following topics:

- [“IPv6 Planning Tasks”](#)
- [“IPv6 Network Topology Overview”](#)
- [“Ensuring Hardware Support for IPv6”](#)
- [“Preparing an IPv6 Addressing Plan”](#)
- [“Configuring Network Services to Support IPv6”](#)
- [“Planning for Tunnel Use in the Network”](#)
- [“Security Considerations for an IPv6 Implementation”](#)

For an introduction to IPv6 concepts, refer to [Internet Protocol, Version 6 \(IPv6\) Specification](#) (<http://www.ietf.org/rfc/rfc2460.txt>).

For information about troubleshooting IPv6 networks, see [“Troubleshooting Issues With IPv6 Deployment”](#) in *Troubleshooting Network Administration Issues in Oracle Solaris 11.4*.

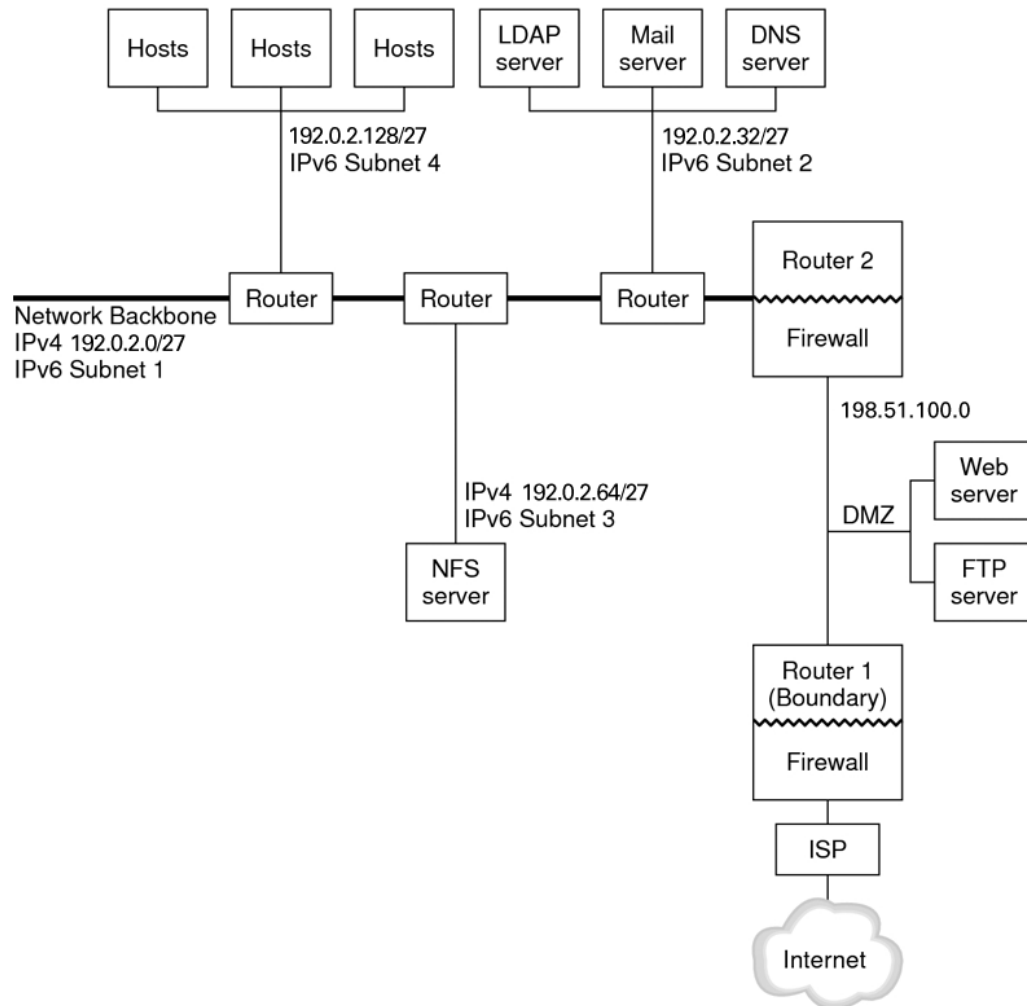

IPv6 Planning Tasks

The following table describes different considerations when planning to implement IPv6 on your network. If you are migrating from an existing IPv4 network to an IPv6 network, see [“Migrating From an IPv4 Network to an IPv6 Network”](#) in *Configuring and Managing Network Components in Oracle Solaris 11.4* for additional instructions.

Task	Description	For Instructions
Prepare your hardware to support IPv6	Ensure that your hardware can be upgraded to IPv6.	“Ensuring Hardware Support for IPv6” on page 22
Ensure that your applications are IPv6 ready	Verify that your applications can run in an IPv6 environment.	“Configuring Network Services to Support IPv6” on page 24
Design a plan for tunnel usage	Determine which routers should run tunnels to other subnets or external networks.	“Planning for Tunnel Use in the Network” on page 26
Plan how to secure your networks and develop an IPv6 security policy	For security purposes, you need an addressing plan for the Demilitarized Zone (DMZ) and its entities before you configure IPv6. Decide how you would implement security, such as using Packet Filter, IP security architecture (IPsec), Internet Key Exchange (IKE), and other security features.	“Security Considerations for an IPv6 Implementation” on page 27 <i>Securing the Network in Oracle Solaris 11.4</i>
Create an addressing plan for systems on the network	Your plan for addressing servers, routers, and hosts should be in place before IPv6 configuration. This step includes obtaining a site prefix for your network as well as planning IPv6 subnets, if needed.	“Preparing an IPv6 Addressing Plan” on page 23

IPv6 Network Topology Overview

Typically, IPv6 is used in a mixed network topology that also uses IPv4, such as shown in the following figure. The following figure is used as reference in the description of IPv6 configuration tasks that are described in this chapter.

FIGURE 5 IPv6 Network Topology Scenario

The enterprise network scenario depicted in the figure consists of five subnets with existing IPv4 addresses. The links of the network correspond directly to the administrative subnets. The four internal networks are shown with RFC 1918-style private IPv4 addresses, which is a common solution for the lack of IPv4 addresses.

These internal networks use the following address scheme:

- Subnet 1 is the internal network backbone 192.0.2.0/27
- Subnet 2 is the internal network 192.0.2.32/27, with LDAP, sendmail, and DNS servers
- Subnet 3 is the internal network 192.0.2.64/27, with the NFS servers of the enterprise
- Subnet 4 is the internal network 192.0.2.128/27, which contains hosts for the employees of the enterprise

The external, public network 198.51.100 functions as the corporation's DMZ. This network contains web servers, anonymous FTP servers, and other resources that the enterprise offers to the outside world. Router 2 runs a firewall and separates public network 198.51.100 from the internal backbone. On the other end of the DMZ, Router 1 runs a firewall and serves as the boundary server of the enterprise.

In [Figure 5, “IPv6 Network Topology Scenario,” on page 21](#), the public DMZ has the RFC 1918 private address 198.51.100. In the real world, the public DMZ must have a registered IPv4 address. Most IPv4 sites use a combination of public addresses and RFC 1918 private addresses. However, when you introduce IPv6, the concept of public addresses and private addresses changes. Because IPv6 has a much larger address space, you use public IPv6 addresses on both private networks and public networks.

The Oracle Solaris dual protocol stack supports concurrent IPv4 and IPv6 operations. You can successfully run IPv4-related operations during and after deploying IPv6 on your network. When you deploy IPv6 on an operating network that is already using IPv4, ensure that you do not disrupt ongoing operations.

Ensuring Hardware Support for IPv6

Check the documentation of the manufacturers for IPv6 readiness regarding the following classes of hardware:

- Routers
- Firewalls
- Servers
- Switches

Note - All of the procedures in this book assume that your equipment, particularly routers, can be upgraded to IPv6. However, some router models cannot be upgraded to IPv6. For more information and a workaround, refer to [“Cannot Upgrade IPv4 Router to IPv6” in *Troubleshooting Network Administration Issues in Oracle Solaris 11.4*](#).

Preparing an IPv6 Addressing Plan

A major part of transitioning from IPv4 to IPv6 includes developing an addressing plan, which involves the following preparations:

- [“Obtaining a Site Prefix” on page 23](#)
- [“Creating the IPv6 Numbering Scheme” on page 23](#)

For actual migration tasks, see [“Migrating From an IPv4 Network to an IPv6 Network” in *Configuring and Managing Network Components in Oracle Solaris 11.4*](#).

Obtaining a Site Prefix

Before you configure IPv6, you must obtain a site prefix. The site prefix is used to derive IPv6 addresses for all the nodes in your IPv6 implementation.

Any ISP that supports IPv6 can provide your organization with a 48-bit IPv6 site prefix. If your current ISP only supports IPv4, you can use another ISP for IPv6 support while retaining your current ISP for IPv4 support. In such an instance, you can use one of several workarounds. For more information, see [“Current ISP Does Not Support IPv6” in *Troubleshooting Network Administration Issues in Oracle Solaris 11.4*](#).

If your organization is an ISP, then you can obtain site prefixes for your customers from the appropriate Internet registry. For more information, see the [Internet Assigned Numbers Authority \(IANA\) \(http://www.iana.org\)](http://www.iana.org).

Creating the IPv6 Numbering Scheme

Unless your proposed IPv6 network is entirely new, use your existing IPv4 topology as the basis for the IPv6 numbering scheme.

For most hosts, stateless auto-configuration of IPv6 addresses for their interfaces is an appropriate, time saving strategy. When the host receives the site prefix from the nearest router, the *Neighbor Discovery Protocol* automatically generates IPv6 addresses for each interface on the host.

Servers need to have stable IPv6 addresses. If you do not manually configure the IPv6 addresses of a server, a new IPv6 address is auto-configured whenever a NIC card is replaced on the server.

Keep the following tips in mind when you create addresses for servers:

- Give servers meaningful and stable interface IDs. One strategy is to use a sequential numbering scheme for interface IDs. For example, the internal interface of the LDAP server in [Figure 5, “IPv6 Network Topology Scenario,” on page 21](#) might become `2001:db8:3c4d:2::2`
- Alternatively, if you do not regularly renumber your IPv4 network, consider using the existing IPv4 addresses of the routers and servers as their interface IDs. In [Figure 5, “IPv6 Network Topology Scenario,” on page 21](#), suppose Router 1's interface to the DMZ has the IPv4 address `192.0.2.0/27`, then you can convert the IPv4 address to hexadecimal, and use the result as the interface ID. The new interface ID would be `::c000:0200`
Only use this approach if you own the registered IPv4 address, rather than having obtained the address from an ISP. If you use an IPv4 address that was provided to you by an ISP, you create a dependency that would create problems if you change ISPs.

Due to the limited number of IPv4 addresses that are available, in the past, a network designer had to consider where to use global, registered addresses and private, RFC 1918 addresses. However, the notion of global and private IPv4 addresses does not apply to IPv6 addresses. You can use *global unicast addresses*, which include the site prefix, on all links of the network, including the public DMZ.

For your IPv6 subnets, begin your numbering scheme by mapping your existing IPv4 subnets into equivalent IPv6 subnets. You can use various online tools to convert IPv4 subnets to their equivalent IPv6 designations.

Configuring Network Services to Support IPv6

The following typical IPv4 network services are also IPv6 ready:

- DNS
- HTTP (supported release of Apache or Orion)
- LDAP
- NFS
- sendmail

The IMAP mail service is for IPv4 only.

Nodes that are configured for IPv6 can run IPv4 services. When you turn on IPv6, not all services accept IPv6 connections. Services that have been ported to IPv6 will accept a

connection. Services that have not been ported to IPv6 continue to work with the IPv4 portion of the protocol stack.

Some issues can arise after you upgrade services to IPv6. For details, see [“Problems Encountered When Upgrading Services to Support IPv6”](#) in *Troubleshooting Network Administration Issues in Oracle Solaris 11.4*.

▼ How to Prepare Network Services for IPv6 Support

1. Update the following network services to support IPv6:

- Mail servers
- NIS servers
- NFS

Note - LDAP supports IPv6 without requiring IPv6-specific configuration tasks.

2. Verify that your firewall hardware is IPv6 ready.

Refer to the appropriate firewall-related documentation for instructions.

3. Verify that other services on your network have been ported to IPv6.

For more information, refer to marketing collateral and associated documentation for the software.

4. If your site deploys the following services, make sure that you have taken the appropriate measures for these services:

- **Firewalls** – Consider strengthening the policies that are in place for IPv4 to support IPv6. For more security considerations, see [“Security Considerations for an IPv6 Implementation”](#) on page 27
- **Mail**– In the mail exchanger record (MX record) for DNS, consider adding the IPv6 address of your mail server
- **DNS**– For DNS-specific considerations, see [“How to Prepare DNS for IPv6 Support”](#) on page 26
- **IPQoS** – Use the same *Diffserv* policies on a host that were used for IPv4

5. Audit any network services that are offered by a node prior to converting that node to IPv6.

▼ How to Prepare DNS for IPv6 Support

Oracle Solaris supports DNS resolution on both the client side and the server side. Use the following procedure to prepare DNS services for IPv6.

For more information that is related to DNS support for IPv6, refer to [Working With Oracle Solaris 11.4 Directory and Naming Services: DNS and NIS](#).

1. **Ensure that the DNS server that performs recursive name resolution is dual-stacked (IPv4 and IPv6) or for IPv4 only.**
2. **On the DNS server, populate the DNS database with relevant IPv6 database AAAA records in the forward zone.**

Note - Servers that run multiple critical services require special attention. Ensure that the network is working properly. Also ensure that all critical services are ported to IPv6. Then, add the IPv6 address of the server to the DNS database.

3. **Add the associated PTR records for the AAAA records into the reverse zone.**
4. **Add either IPv4 only data, or both IPv6 and IPv4 data into the NS record that describes zones.**

Planning for Tunnel Use in the Network

The IPv6 implementation supports a number of tunnel configurations to serve as transition mechanisms as your network migrates to a mix of IPv4 and IPv6. Tunnels enable isolated IPv6 networks to communicate. Because most of the Internet runs IPv4, IPv6 packets from your site need to travel across the Internet through tunnels to destination IPv6 networks.

The following are some major scenarios for using tunnels in the IPv6 network topology:

- The ISP from which you purchase IPv6 service allows you to create a tunnel from the boundary router of your site to the ISP network. [Figure 5, “IPv6 Network Topology Scenario,” on page 21](#) shows such a tunnel. In this case, you would run a manual IPv6 over IPv4 tunnel.
- You manage a large, distributed network with IPv4 connectivity. To connect the distributed sites that use IPv6, you can run an automatic 6to4 tunnel from the edge router of each subnet.

- Sometimes, a router in your infrastructure cannot be upgraded to IPv6. In this case, you can manually create a tunnel over the IPv4 router, with two IPv6 routers as endpoints.

For procedures for configuring tunnels, refer to [Chapter 5, “Administering IP Tunnels” in *Administering TCP/IP Networks, IPMP, and IP Tunnels in Oracle Solaris 11.4*](#). For more information about IP tunnel configuration, refer to [“IP Tunnel Feature Summary” in *Administering TCP/IP Networks, IPMP, and IP Tunnels in Oracle Solaris 11.4*](#).

Security Considerations for an IPv6 Implementation

When you introduce IPv6 into an existing network, you must take necessary precautions to ensure that you do not compromise the security of the site.

Be aware of the following security issues as you phase in your IPv6 implementation:

- The same amount of filtering is required for both IPv6 packets and IPv4 packets.
- IPv6 packets are often tunneled through a firewall.
Therefore, you should implement either of the following scenarios:
 - Have the firewall perform content inspection inside the tunnel.
 - Put an IPv6 firewall with similar rules at the opposite tunnel endpoint.
- Some transition mechanisms that use IPv6 over User Datagram Protocol (UDP) over IPv4 tunnels exist. These mechanisms might prove problematic by short-circuiting the firewall.
- IPv6 nodes are globally reachable from outside the enterprise network. If your security policy prohibits public access, you must establish stricter rules for the firewall. For example, consider configuring a *stateful firewall*.

Refer to the following documents for information about security features that you can use with an IPv6 implementation:

- IPsec enables you to provide cryptographic protection for IPv6 packets. For more information, refer to [Chapter 6, “About IP Security Architecture” in *Securing the Network in Oracle Solaris 11.4*](#).
- IKE and IKEv2 automates keys management for IPsec. For more information, refer to [Chapter 8, “About Internet Key Exchange” in *Securing the Network in Oracle Solaris 11.4*](#).
