About This Document

Scope

The scope of this document includes all the information required to install, configure and administer the UCAI application.

Audience

This guide was written primarily for system administrators and persons installing, configuring and administering the UCAI application. However, sections of the document may be useful to anyone requiring an introduction to the application.

Prerequisites

This manual describes system tasks that should only be carried out by suitably trained operators.

A solid understanding of Unix and a familiarity with IN concepts are an essential prerequisite for safely using the information contained in this technical guide. A good of switch configuration is required to correctly configure the UCAI. A detailed understanding of M3UA is essential for configuring the M3UA interface.

Attempting to install, remove, configure or otherwise alter the described system without the appropriate background skills, could cause damage to the system; including temporary or permanent incorrect operation, loss of service, and may render your system beyond recovery.

Although there are no prerequisites for using this guide, familiarity with the target platform would be an advantage.

Related documents

The following documents are related to this document:

Specialized terms and acronyms are defined in the **Glossary** at the end of this guide.
Overview

Introduction
This chapter provides a high-level overview of the application. It explains the basic functionality of the system and lists the main components.

It is not intended to advise on any specific Oracle Communications Network Charging and Control (NCC) network or service implications of the product.

In this chapter

This chapter contains the following topics.

UCAI Introduction

Description
The Universal Call Agent for ISUP (UCAI) is a signaling element which provides Intelligent Network functionality, without having to upgrade or replace non-SS7 capable switches.

It does this by using fixed connections between incoming and outgoing calls.

UCAI controls call signaling, while internally looping the speech circuits of the call. Without the heavy load that speech traffic creates, UCAI is able to handle more calls than a service node solution.

Features
Using only the Call Set-Up Protocol ISUP, it can offer:

- Advanced number translation Services such as Free phone and Number portability
- Call monitoring services such as Prepaid

Features include:

- Support for standard protocols (INAP, ISUP)
- Support for all ISUP messages, including maintenance messages (for example: Blocking, unblocking, reset, and Circuit group messages).
- Provides basic (CS1) IN functionality
- Leg control can be used for more advanced solutions
- Can originate both legs of a Call (for example, a call can be originated from a web page)
- Each Transient switch can have its own UCAI for increased network performance and resilience
- Failover and load balancing can be easily supported by configuring the network routing to send messages between mated UCAIs
**Network architecture**

This diagram shows how UCAI is installed within a network. There may be one or more UCAI, each connected to one or more exchanges. The UCAI communicates with the SCF over SS7, using either ETSI/ITU-T INAP or AIN0.x. An operator may manage its configuration and alarms by SMS, or via a Q.3 agent using Q.751.

**Call processing**

UCAI achieves SSP functionality by:

- Effectively splitting a single physical switch into 2 logical switches.
- Using the routing plan of the network, the UCAI appears as another Transient switch to the original switch for signaling routing purposes.
- Voice circuits are looped back to provide the speech path.
- UCAI uses ISUP to control calls made to looped-back ISUP speech trunks.
- Each speech circuit going out of the switch has a permanently mapped circuit going into the switch.
Consequently, the UCAI can make a call on the egress circuit that is effectively a continuation of the original call (even if mapped to a destination determined by an SLC via an INAP protocol. UCAI controls processing of the whole call, or control of an individual leg.

- It can be used to implement most IN services.
- The type of processing is specified on a per service basis.

**Components**

This diagram shows the main components of the UCAI hosted on a SLC.

**UCAI Operation - Loop Back Mode**

**Basic processing**

Here is an example of how UCAI works in its simplest configuration. A single incoming circuit and a single outgoing circuit.

As shown in the example, the only actual connection to UCAI is the signaling link. No speech paths are routed. All signaling, for both the incoming and outgoing circuits on the loop, are carried on the signaling link. The speech path is looped with very low visibility to the switch. This may be achieved by using a static configuration of the switch matrix, or by an external piece of hardware. In either case, the switch's call process is unaware of the loop.

Calls to UCAI must only be routed down an incoming leg. Calls routed down a UCAI incoming leg that are not intended for UCAI, are still sent to the SCF for processing. This almost always results in that call being rejected.

Calls routed to a UCAI outgoing leg are rejected.

A full understanding of this is essential to correct configuration of a UCAI into a Telco’s network.
**Call processing**

The following steps describe what happens when a call arrives on the incoming leg to the UCAI.

**Note:** This process description assumes the network is configured as described above.

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The call is routed to UCAI.</td>
</tr>
</tbody>
</table>

**Notes:**
- Before this can happen, the external network must have been correctly configured to route the call into UCAI.
- The last part of the host network on which the call appears is the switch which is directly connected to UCAI. This is the switch which sends the ISUP IAM message to UCAI, indicating the call is being made.
- The specific circuit (that is, timeslot) which the call arrives on must be specified as "incoming". If a call arrives on a leg designated as "outgoing", it will be rejected.

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>UCAI queries an SCF to determine how the call is to be processed. This example assumes a simple number translation (for example, translating a free or premium rate phone number into its final destination).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>UCAI sends an outgoing ISUP IAM message on the outgoing leg that corresponds to the incoming leg on which the call arrived. The IAM contains the translated number. It may also have other parameters modified by the SCF. UCAI automatically selects a circuit on to route the outgoing call on. Because it contains no switch matrix, the only circuit the call's speech can be present is the one to which the incoming leg is looped.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Call processing continues as it would with any other SSP. The ISUP messages are acted on by the SSP under SCF control, exactly as would happen with a conventional SSP. The SCF is unaware UCAI is different from any other sort of SSP.</td>
</tr>
</tbody>
</table>

**Important installation planning**

In order to correctly plan, install and configure a working installation you must be aware of the following issues:
- Signaling
- Loop Back
- UCAI configuration

These issues are discussed further below.

**Signaling**

Signaling configuration is very important to the correct functioning of UCAI. The example network configuration above only has a single signaling link. That link is the only connection between UCAI and the attached network.

Signaling for both the incoming and outgoing legs is carried on the same link. This can cause some complex issues for the configuration of the attached switch, and these must be carefully addressed.

The signaling link is set up in a completely standard manner, with point codes allocated to both ends and an agreement on the allocation of cics to specific timeslots. However, the two circuits involved are looped without the switch’s knowledge. This has a major effect on the routing policy that must be configured on the attached switch.
In the example, two circuits are used. However, the switch may only make calls to the UCAI down the incoming leg. This requires the switch to be configured so routing is allocated not only on a point code basis (which permits the switch to route calls down any circuit), but also on a per circuit basis (so that calls are only routed down those circuits designated as "incoming" to the UCAI). The details of this are highly switch-specific, but must be provided to ensure correct operation.

**Configuration example**

This example extends the previous example.

**Assumptions:**
- UCAI has point code 1
- switch has point code 2
- single incoming circuit is assigned cic 1
- single outgoing circuit has cic 2
- calls should be processed with the prefix 0800.

**Required Configuration:**

The switch must be configured so it will route calls with the 0800 prefix to point code 1, but only on cic 1. A switch-specific example is an mml command of the form:

```
ROUTE:PREFIX=0800,DPC=1,CICS=1;
```

This command indicates calls prefixed with 0800 should be sent to point code 1, and the only available cic is 1.

If the switch does not offer this degree of routing control, there are several options discussed in *Routing Options* (on page 22).

**Loop back**

Ideally, the loop back is performed by the switch. However, it must be possible to do this without interfering with the switch's call processing. If this is impossible, some external form of loop back device must be employed. This may be possible with whatever device is used to extract the signaling information and pass it onto the UCAI.

**UCAI configuration**

UCAI must also be configured. Given the point codes and cics detailed in *Configuration* (on page 15), the configuration file need only contain:

```
connect 1/2/1 to 1/2/2.
```

**Note:** The full stop at the end of every configuration statement is essential.

**Throttling**

UCAI uses a sliding window of one second to measure load. If an IAM arrives less than one second after the one <CAPS limit> IAMs before it, it is rejected.

**Example:**

UCAI is set with a limit of 20 CAPS. This means in any single second window UCAI will allow 20 call attempts and the 21st will be rejected.

- If the IAMs arrive exactly at 1/20th of a second intervals, there will be 20 CAPS.
- If an IAM arrives even one microsecond 'early' it causes a peek of 21 CAPS and is rejected.

So, even if traffic is sent at 20 CAPS and a 20 CAPS limit is set, the occasional call will still be rejected.
Supported Messages Overview

Introduction

This table describes UCAI's main message groups:

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Call Processing</td>
<td>The basic call processing package is composed of a group of simple messages to progress the call.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Call processing messages (on page 6) below.</td>
</tr>
<tr>
<td>Additional Call Set-up</td>
<td>Call setup may be made more complex by the use of extra, more complex messages to progress the call.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Additional call setup messages (on page 7) below.</td>
</tr>
<tr>
<td>Continuity Testing</td>
<td>Some networks support use of ISUP's continuity testing procedures. UCAI is able to handle all such situations correctly.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Continuity testing messages (on page 8) below.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>The UCAI supports single circuit maintenance messages, or group messages, to allow for blocking, unblocking, or resetting of circuits.</td>
</tr>
<tr>
<td></td>
<td>For more information, see Maintenance messages (on page 9) below.</td>
</tr>
</tbody>
</table>

Call processing messages

This table lists the basic call processing messages which are supported by the UCAI.

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial Address Message (IAM)</td>
<td>The Initial Address Message has five mandatory parameters and 42 optional parameters (for more information, see Table 32 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes).</td>
</tr>
<tr>
<td></td>
<td>The mandatory parameters are:</td>
</tr>
<tr>
<td></td>
<td>• nature of connection indicators</td>
</tr>
<tr>
<td></td>
<td>• forward call indicators</td>
</tr>
<tr>
<td></td>
<td>• calling party’s category</td>
</tr>
<tr>
<td></td>
<td>• transmission medium requirement</td>
</tr>
<tr>
<td></td>
<td>• called party number</td>
</tr>
<tr>
<td></td>
<td>The UCAI handles all the mandatory and optional parameters. However, some filtering may take place, in order to ensure correct operation of the UCAI. In addition, certain pathological values for some parameters may cause rejection of the call in some cases.</td>
</tr>
<tr>
<td></td>
<td>Note: If a hop counter occurs on the incoming leg and its value is zero, the call is rejected. If its value is greater than zero, the value is decremented and used on the outgoing leg. If no hop counter was provided, one is inserted with a default value.</td>
</tr>
<tr>
<td></td>
<td>Use of the hop counter is very important. It avoids the possibility of a routing error in the network resulting in a 'circular call' that 'bounces' between the UCAI and its attached switches. Such an occurrence is a very dangerous network event, as it consumes very large amounts of processing power and signaling bandwidth.</td>
</tr>
<tr>
<td>Address Complete Message (ACM)</td>
<td>The Address Complete Message has one mandatory parameter and 19 optional parameters (for more information, see Table 21 of ITU-T. Q.763,</td>
</tr>
</tbody>
</table>
Signalling System No. 7 — ISDN User Part formats and codes).
The mandatory parameter is backward call indicators.
As with the Initial Address Message, some filtering of the message
parameters may take place.

Answer (ANM)
The Answer message has no mandatory parameters and 21 optional
parameters (for more information, see Table 22 of ITU-T. Q.763, Signalling
System No. 7 — ISDN User Part formats and codes).
As with the Initial Address message, some filtering of the message
parameters may take place.

Release (REL)
The Release message has one mandatory parameter, and up to seven
optional ones (for more information, see Table 33 of ITU-T. Q.763, Signalling
System No. 7 — ISDN User Part formats and codes).
The mandatory parameter is cause indicators.
As with the Initial Address message, some filtering of the message
parameters may take place.

Release Complete
The Release complete message has one optional parameter (for more
information, see Table 34 of ITU-T. Q.763, Signalling System No. 7 — ISDN
User Part formats and codes).
The optional parameter is cause indicators.
As with the Initial Address message, some filtering of the message
parameters may take place.

Additional call setup messages
Call setup may be made more complex by the use of some of the more complex messages to progress
the call. This table describes these message types supported by the UCAI.

<table>
<thead>
<tr>
<th>Message type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subsequent Address Message (SAM)</td>
<td>The Subsequent Address Message has one mandatory parameter (for more information, see Table 35 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes). The mandatory parameter is subsequent number. The UCAI will handle use of SAM messages (also known as ‘overlap’ sending). However, the service itself should be made aware that this form of signalling may be in use, as it can confuse some services, if they assume all the digits are to be presented at once. This can usually be avoided by careful use of network, UCAI and service configuration, but care should be taken to avoid it. In addition, use of SAM or overlap signalling results in increased network traffic and processing overhead. It should therefore be avoided, wherever possible.</td>
</tr>
<tr>
<td>Call Progress</td>
<td>The Call Progress has one mandatory parameter and 25 optional ones (for more information, see Table 23 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes). The single mandatory parameter is event information.</td>
</tr>
<tr>
<td>Connect</td>
<td>The Connect message has one mandatory parameter and 19 optional ones (for more information, see Table 27 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes). The mandatory parameter is backward call indicators. The UCAI treats the Connect message in a very similar manner to an Address Complete</td>
</tr>
</tbody>
</table>
Identification Request
The Identification Request message has no mandatory parameters and three optional ones (for more information, see Table 47 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes).

Identification Response
The Identification Response message has no mandatory parameters and seven optional ones (for more information, see Table 48 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes.).

Information Request
The Information Request message has one mandatory parameter and three optional ones (for more information, see Table 31 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes).

The single mandatory parameter is information request indicators.

Information
The Information message has one mandatory parameter and six optional ones (for more information, see Table 30 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes).

The single mandatory parameter is information indicators.

Suspend and Resume
The Suspend and Resume messages have one mandatory parameter and one optional (for more information, see Table 38 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes).

The single mandatory parameter is suspend/resume indicators.

The UCAI processes Suspend and Resume requests as required by §9.1.3 of ETR 164, Integrated Services Digital Network (ISDN); Intelligent Network (IN); Interaction between IN Application Protocol (INAP) and ISDN User Part (ISUP) version 2.

Continuity testing messages
Some networks support use of ISUP’s continuity testing procedures. UCAI handles the following cases correctly:

- Testing after an Initial Address message (this may occur after every IAM, or some form of statistical sampling may be employed).
- Testing an idle circuit.
- A call can be placed that is waiting for the results of a continuity test on a previous circuit.

Note: In theory, there should be no need for continuity checks in a modern network. The lower-level signalling should detect the failure of a speech or signalling link, and block use of those circuits. However, it can be useful for testing for correct configuration of the UCAI.

A major feature of the UCAI is speech circuits do not pass through it. Consequently, the UCAI (though able to detect failures in the signalling links) is unable to detect problems with the associated speech circuits. Instead it relies upon the attached switches to detect problems.

If the UCAI’s speech circuits are mis-configured, the usual result is for the call to be made and appear to work (including billing) but no speech is heard.

Continuity testing can help guard against these problems. Periodic and/or statistical testing is recommended, unless the operator has taken great care in the configuration of the UCAI and its attached switches.

The UCAI handling of continuity testing is in accordance with §2.1.8 of ITU-T. Q.764, Signalling System No. 7 — ISDN User Part signalling procedures.

Continuity check request
The Continuity Check Request message has no parameters (for more information, see Table 39 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes).
Use of CCR is only valid on idle incoming circuits, and the CCR message is passed onto the corresponding outgoing circuit.

**Continuity**  
The Continuity message has one mandatory parameter and no optional ones (for more information, see Table 28 of ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes).  
The mandatory parameter is continuity indicators.

**Maintenance messages**  
This table describes the single circuit and group circuit maintenance messages supported by UCAI.

<table>
<thead>
<tr>
<th>Message Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Single circuit maintenance messages | Several single circuit maintenance messages are defined in ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes. Those supported by the UCAI are:  
  - Blocking  
  - Blocking Acknowledgment  
  - Reset Circuit  
  - Unblocking  
  - Unblocking Acknowledgment.  
  None of these have any parameters.  
The functionality the same as is described in ITU-T. Q.764, Signalling System No. 7 — ISDN User Part signalling procedures, but with one addition imposed by the UCAI. As the UCAI ties incoming and outgoing circuit together, any blocking or unblocking coming into the UCAI on an outgoing circuit causes a similar message to be reflected on the corresponding incoming circuit. Similarly, if any problem occurs with an outgoing leg, the UCAI blocks the corresponding incoming leg, to avoid being given calls it cannot process. |
| Circuit group maintenance messages | It is often more efficient to use one of the group messages defined in ITU-T. Q.763, Signalling System No. 7 — ISDN User Part formats and codes, than to use a number of the corresponding single circuit maintenance message.  
The UCAI currently supports the following group messages:  
  - Circuit Group Blocking  
  - Circuit Group Blocking Acknowledgment  
  - Circuit Group Unblocking  
  - Circuit Group Unblocking Acknowledgment  
  - Circuit Group Reset  
  - Circuit Group Reset Acknowledgment.  
The functionality is the same as is described in ITU-T. Q.764, Signalling System No. 7 — ISDN User Part signalling procedures, but with one addition imposed by the UCAI. As the UCAI ties incoming and outgoing circuit together, any blocking or unblocking coming into the UCAI on an outgoing circuit causes a similar message to be reflected on the corresponding incoming circuit. Handling of some circuit group messages can be problematical in some networks. In addition, due to the potentially arbitrary nature in which incoming and outgoing circuits can be tied together for the UCAI, a circuit group block on an outgoing leg is repeated through to the incoming side,
as a series of single circuit blocks. A similar technique is used in handling circuit group resets and unblocking. Therefore, the UCAI only sends circuit group messages in response to circuit group messages received. If the network does not support circuit group messages, none will arrive at the UCAI and so the UCAI will not use them in response.

**Overlap Sending**

**Introduction**

Overlap Sending or Signalling can be used in a fixed line environment where a call set up can begin even before the caller has dialed all digits of the intended destination number. This is achieved when the caller has dialed enough digits for an originating exchange using the Overlap Sending method, to determine the target exchange. The originating exchange packs the digits collected from the calling party so far, into an Initial Address Message (IAM) and sends it to the next exchange.

Subsequent digits dialed by the caller are contained within the Subsequent Address Message (SAM). Each new SAM contains additional digits dialed by the caller. UCAI invokes appropriate IN services within the call setup path based on predefined triggering rules.

**Note:** Overlap sending is not possible in a mobile environment since the calling party must dial all the digits of the intended destination before initiating a call setup attempt.

**How Overlap Sending works**

Here is an example of how UCAI supports the Overlap Sending method of setting up a call.
The originating exchange will attempt to set up a call once it has collected sufficient digits from the calling party to identify the next target exchange (tandem or ultimate destination exchange) in the call flow. It will generate an IAM (Initial Address Message) with all the digits the calling party has dialed until then, and route it along the network.

Subsequent digits dialed by the caller will be contained within the Subsequent Address Message (SAM). Depending on the caller’s dialing speed, one or more SAMs may be generated. Each SAM will contain any new digits dialed since the last SAM (or the initial IAM) was sent.

IN services within the signalling path are activated based on the triggering rules used by UCAI. Currently, these triggering rules are defined in the tdp.conf file.

**Triggering Rules**

In the Overlap Sending method, the call setup begins even before the caller dials all the digits of the intended destination. However, in such a scenario, IN systems involved in the call signalling path cannot determine when to trigger the IN services. Currently, UCAI uses the triggering rules defined in the tdp.conf. This file is processed by the IN call model component of the UCAI.

UCAI triggers IN services when the incoming digits dialled so far trigger a matching rule in the tdp.conf. The decisive digits invoking the rule may be contained in:

- The IAM received from the originating exchange, or
- The IAM + one or more SAM messages received from the originating exchange.

**tdp.conf**

Here is an example of the tdp.conf file.

```plaintext
KEEP SD
ETC RULES=6 3
3 1 3 request all 3:01473222
```

**Stop digit**

Typically, when the caller dials a local/national number, the originating exchange will lookup the configured numbering plan information to determine if sufficient digits have been dialed to identify the target exchange. If it recognizes the numbering pattern of the dialed digits, the originating exchange will insert a stop digit into the called number signaling sequence.

UCAI triggers the IN service when a stop digit is detected and an appropriate rule in tdp.conf is found. The stop digit may be contained in either of the following:

- The IAM received from the originating exchange, that is at the end of the IAM
- The IAM + one or more SAM messages received from the originating exchange, that is, at the end of the last SAM

**SAM timer**

Sometimes, due to a lack of numbering plans available, a local or transit exchange within a country may not correctly decipher the numbering pattern of the dialed digits (typically an international number). Consequently, the originating exchange fails to insert the stop digit. This results in the UCAI waiting an indefinite period of time for the overlap sequence to end, not knowing when to trigger the IN service. To safeguard against this situation, the UCAI is equipped with a timer, known as SAM timer. The SAM timer is used for initiating IN services when Overlap Sending is invoked for a number with an unrecognizable numbering scheme.

The UCAI waits for a fixed period of time to receive the first or next SAM in an overlap sequence before activating the IN services. When this timer has expired the UCAI assumes that the caller has completed the dialing sequence for the intended destination number and ignores any additional dialed digits. This means no new digits will be accepted from the caller/network after the timer expires.
The UCAI starts the SAM timer for a call when it receives an IAM not containing the stop digit. The SAM timer is restarted each time a new SAM is received for the call.

**Note:** The SAM timer will not be started if the digits contained within the IAM or the SAM are sufficient for the UCAI to trigger an IN service.

**Forced trigger scenario**

If the SAM timer expires and an IN Service has not been triggered, then the UCAI adds a stop digit to the dialed overlap sequence. This is known as a “forced trigger” scenario.

One of the following results may occur in a forced trigger scenario:

- A matching rule in the `tdp.conf` file is found which triggers an IN service, or
- A matching rule is not found and the UCAI releases the call by sending a REL message on the A-leg.

**IN Service Processing**

After an IN service is triggered, it returns any one of the following results:

- Continue
- Connect ("cut and paste" option not set)
- Connect ("cut and paste" option set)
- ETC (treated as 'Connect' by UCAI)
- Release
- Error

After the UCAI has sent an IAM on the B-leg of the call and BEFORE an ACM message is received from the B-leg, it is possible that additional SAM messages may be received on the A-leg.

**Before an IAM is sent on the B-leg**

This table describes how the UCAI treats different message scenarios before an IAM is sent on the B-leg.

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional digits are received in SAM messages while IN service is treating the request.</td>
<td>UCAI will store the digits.</td>
</tr>
<tr>
<td>In a forced trigger scenario, additional digits are received in SAM messages while IN service is treating the request.</td>
<td>UCAI will ignore the digits.</td>
</tr>
<tr>
<td>‘Continue’ message is received from IN service.</td>
<td>All digits received by UCAI (including digits received/stored when the IN service was processing the call) will be used in the <code>calledPartyAddress</code> field of the IAM sent on the B-leg.</td>
</tr>
<tr>
<td>‘Connect’ message is received from IN service with the “cut and paste” field NOT set.</td>
<td>The number specified in the <code>destinationRoutingAddress</code> field of the ‘Connect’ message shall be used in the <code>calledPartyAddress</code> field of the IAM sent on the B-leg. Any additional digits received in the period when the IN service was processing the call will be ignored.</td>
</tr>
<tr>
<td>Scenario</td>
<td>Result</td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| 'Connect' message is received from IN service with the "cut and paste" field set. | All digits received by UCAI (including digits received/stored when the IN service was processing the call) will be used.  
Based on the options set in the "cut and paste" field, the required number of digits will be cut from the beginning of the calledPartyAddress received in the IAM and all the SAM messages.  
The cut number is then pasted to the number received in the destinationRoutingAddress.  
The resultant number from the cut and paste operation will be used in the calledPartyAddress field of the IAM which is sent on the B-leg.  
**Note:** In a forced trigger scenario any additional digits received during the IN service processing will be ignored and not be included in the resultant number when the “cut and paste” field is set. |
| An 'ETC' operation is received from IN service.                        | The number specified in that operation will be used in the calledPartyAddress field of the IAM sent on the B-leg.  
Any additional digits received in the period when the IN service was processing the call will NOT be used in the calledPartyAddress and will be ignored. |

**After an IAM is sent on the B-leg**

After the UCAI has sent an IAM on the B-leg of the call and BEFORE an ACM message is received from the B-leg, it is possible that additional SAM messages may be received on the A-leg. Any SAM messages received on the A-leg of the call after the IAM has been sent on the B-leg of the call shall be transparently sent onto the B-leg of the call.

The following cases are some exceptions to this transparent sending:

- ACM is received on the B-leg.
- IN services issues a 'Connect' message with the "cut and paste" option not set.
- IN services issues an ‘ETC’ message.
- IN service was triggered in a forced trigger scenario.

In case 2 and 3, the UCAI will add a stop digit to the number if one is not already present. The UCAI then ignores all subsequent messages if:

- A stop digit is encountered on either the IAM or SAM message sent on the B-leg
- The IN service was triggered in a forced trigger scenario

If the UCAI has been instructed by the IN service to route the call to a totally different number/address than as intended by the caller, the SAM being relayed onto the B-leg may have an undesirable affect on the destination (or transit exchange).

*For example:* The IN service routes the call to an IVR number where the caller was expecting to be connected to an international party.
Chapter 1

Transparent Passing of ISUP Messages

During call setup, the UCAI allows certain messages to be transparently passed between the A and B legs, even after the call has been established.

Here, the following ISUP messages are notable as examples:

- The call progress message (CPG) can be passed transparently between the A and B leg of a call after it has been established, that is, after the ANM message is received from B-leg.
- Facility (FAC) messages received on either A or B leg can be transparently passed onto the other leg without triggering the IN service.

Handling Called Party Suspends

In this situation, the called party suspends a call by replacing the receiver back on the hook, in order to change the physical phone that is currently connected to the call. The called party then physically attends the call from another phone on the same line. The UCAI handles this functionality by providing an appropriate safeguard that allows the B-leg to stay connected, even if the call has been suspended for a specific period of time.

On receiving a SUS (suspend) message on the B-leg, the UCAI starts a 'suspend' timer for the call. Currently, the T6 timer is implemented as the suspend timer. The UCAI will stop the suspend timer on receiving a RES (resume) message on the suspended B leg.

When the suspend timer expires, the UCAI sends a REL message on the B-leg of the call and waits for a RLC message. On receiving the RLC message, the IN call model is notified that the B-leg has been disconnected. If the IN service has armed an event for B-leg disconnect, it will be informed by the IN call model that the called party has disconnected. It is possible to configure the length of time used by the suspend timer in seconds.
Overview

Introduction

This chapter explains how to configure the Oracle Communications Network Charging and Control (NCC) application.

In this chapter

This chapter contains the following topics.
Configuration Overview 15
Configuring the Environment 16
UCAI Configuration File 16
M3UA Configuration 19
M3UA configuration file syntax 21
Routing Options 22
Configuring UCAI 25
Configuring IN Call Model Triggers 27

Configuration Overview

Configuration components

UCAI is configured by the following components:

<table>
<thead>
<tr>
<th>Component</th>
<th>Locations</th>
<th>Description</th>
<th>Further Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>vssp.config</td>
<td>all SLC</td>
<td>Required to configure the UCAI process.</td>
<td>UCAI Configuration Files</td>

</tbody>
</table>
Rereading configuration

UCAI will reread its configuration when it is restarted.

**Note:** To restart UCAI, you must restart the SLEE. For more information about restarting the SLEE, see *SLEE Technical Guide*.

Configuring the Environment

Introduction

The UCAI environmental variables are set in the *vssp.sh* file.

The file *vssp.sh* is used to set environment variables and command line parameters before the UCAI executable is started. There are potential stack-specific environment variables as well as UCAI-generic command line options.

Editing the vssp.sh file

There are three possible command line parameters in the format:

```
vssp [-c] dir/filename [-k] dir/filename [-m] dir/filename
```

The only mandatory option is the name of the vssp configuration file. This can either be specified by the `-c` flag or it is the first non-flagged parameter. For more information about setting up this file, see *UCAI Configuration Files* (see "UCAI Configuration Files" on page 16).

In UCAI builds which require a license key file, the name of the file may be specified on the command line. This may be specified either using the `-k` flag or it is the second non-flagged parameter. If it is not given, UCAI will default to using the file called keyfile in the same directory as the *vssp.config* file.

In UCAI builds which use the M3UA protocol, the M3UA configuration file name can be given. This can either be set using the `-m` flag or it is the third non-flagged parameter. If no file name is given, UCAI will default to using a file called *m3ua.config* in the same directory as the vssp.config file.

Example vssp.sh file

Here is an example *vssp.sh* file.

```
LD_LIBRARY_PATH=/usr/lib/secure
export LD_LIBRARY_PATH
exec /IN/service_packages/VSSP/bin/vssp -c /IN/service_packages/VSSP/etc/vssp.config
 -m /IN/service_packages/VSSP/etc/m3ua.config >> /IN/service_packages/VSSP/tmp/logfile 2>&1
```

UCAI Configuration File

Introduction

The main UCAI configuration file is *vssp.config*. It configures the UCAI process and is located in:

```
/IN/service_packages/VSSP/etc
```

*vssp.config* has two sections:

1. **Global vssp options** (see "Parameters" on page 34)
2. **Point Code routing (Circuit Loops)**
Configuring circuit loops

Circuit loops are described using the connect statement. In their simplest form connects take the form of:

`connect circuit to circuit`

**Note:** Each command in `vssp.config` must end with one of the following:

- Period (.)
- Semi-colon (;)

The `circuit` in the above example is composed of three parts in the format:

`a/b/c`

Where:

- `a` = the point code of the UCAI end
- `b` = the point code of the remote end
- `c` = the circuit identification code

**Example 1**

A circuit loop has two circuits:

1. Incoming circuit to point code 1 from remote point code 2 on cic 1
2. Outgoing circuit from point code 1 to remote point code 2 on cic 2

This setup would be configured in `vssp.config` as:

```
connect 1/2/1 to 1/2/2.
```

**Example 2**

A single 2.048 Mbps 'E1' link has 32 timeslots (0-31), of which:

- timeslot 0 is used for link management
- timeslots 1-15 are where incoming calls have their speech arrive
- timeslot 16 for signalling
- timeslots 17-31 are used by outgoing calls

The point codes are the same as in Example 1, so vssp has point code 1 and the attached switch has point code 2.

The circuit loop section of the `vssp.config` for this scenario would appear as follows:

```plaintext
connect 1/2/1 to 1/2/17.
connect 1/2/2 to 1/2/18.
connect 1/2/3 to 1/2/19.
connect 1/2/4 to 1/2/20.
connect 1/2/5 to 1/2/21.
connect 1/2/6 to 1/2/22.
connect 1/2/7 to 1/2/23.
connect 1/2/8 to 1/2/24.
connect 1/2/9 to 1/2/25.
connect 1/2/10 to 1/2/26.
connect 1/2/11 to 1/2/27.
connect 1/2/12 to 1/2/28.
connect 1/2/13 to 1/2/29.
connect 1/2/14 to 1/2/30.
connect 1/2/15 to 1/2/31.
```

Signalling is in timeslot 16. This will need to be sent out to UCAI.
Speech sent out on timeslot 1 must return on timeslot 17, so that the called party can hear the calling party. Similarly, the speech sent out on timeslot 17 must return on timeslot 1, so the caller can hear the called party. This is repeated with timeslot 2 and 18 and so on, up to timeslot 15 and 31.

**Shorthand configuration**

This can also be written as:

```
connect 1/2/1 to 1/2/17 for 15.
```

The “for 15” on the end instructs the UCAI that the connect is to be repeated for a total of 15 times, including the one specified in the line. Each time, UCAI adds 1 to the cics for both the incoming and the outgoing circuits.

The number after the “for” indicates the total number of circuits generated and not the number of additional circuits. It includes the circuit number specified in the line it is set in.

Care must be taken, as it is very easy to get the count of the circuits wrong. The final number of cics used is the first one, plus the number of repetitions minus one. For example, if you are starting at cic 1 and specify “for 2”, the final cic will be 2 and not 3.

Mistakes in this configuration will result in mismatches of conversations, for example:

- A one-way call (where one party can hear the other, but not the other way round)
- Different calls connected together
- (Most commonly) total silence at both ends

**Diagram**

The diagram shows the logical structure of how a loop box should be set up to handle Example 2. The speech paths are looped but the signalling is extracted and passed onto UCAI. The exact method for doing this will be very site-specific (several methods may even be employed in the same site).

![Diagram](image)

**Note:** The connections for incoming timeslots 2 to 14 and 18 to 30 have been omitted, so the diagram is less cluttered.
Example configuration - vssp.config

This is an example of the vssp.config file (comments have been removed).

```plaintext
set option slee.
set option syslog.
set option stats.
set cdr file="cdr.log";
#set option debug.
#set option mtp debug.

set ica iam cpc 10;

connect 1/2/1 to 1/2/17 for 15;
```

Optimal configuration

Optimal configuration for the network depends on many variables, including:

- Types of service to be implemented
- Detailed estimates of the calling pattern to each service
- Trunking a call between switches
- Cost of trunk and signalling interfaces
- Network topology
- UCAI costs

It is beyond the scope of this document to detail the modeling required to produce an optimal solution.

The basic requirements for installation of the UCAI are the same regardless of the configuration chosen for a network. The requirements may be broken into the connection to the originating exchange, and the connection to the terminating exchange.

These may be subtly different from a signalling perspective, since each call arriving at the UCAI from the originating exchange may result in multiple sequential calls being made to the terminating exchange. For example, a call may be routed to an announcement prior to being routed to the eventual destination.

M3UA Configuration

Overview

This section introduces the configuration of the UCAI M3UA interface.

We will give a very simplified example of a M3UA network and its configuration to illustrate the fundamental concepts of UCAI's M3UA configuration.

In our example network we consider the last switch in a chain of SS7 switches. Everything further away from the UCAI will be pure SS7. For this example it will have a switch point code of 1.

Note: This chapter is not a substitution for a detailed knowledge of M3UA. A thorough understanding of the principles and techniques of M3UA is a vital prerequisite to successful configuration of the UCAI M3UA interface.

Switch configuration

As with standard configuration, UCAI needs loopbacks to be set up on the switch.

For this example, we will use two E1 links which are looped back to each other. (In other words, the transmit of the first link is connected to the receive of the second link and vice versa.) Signalling is not carried in the traditional timeslot 16, this timeslot is unused.
Elsewhere on the switch are signalling links that connect to the SS7-sigtran gateway (the signalling gateway (SG), commonly a Cisco ITP). It will have a point code of 2. These links have signaling on timeslot 16 but the other timeslots (1–15 and 17–31) are unused.

The switch has a link to the SG on local point code 1 and remote point code 2. It has 60 circuits. The first 30 are bi-directional, the second 30 are incoming only. These circuits are on the loopback that we built previously and not anything to do with the unused timeslots on the link to the SG. Although the linkset is between point codes 1 and 2, the point code of the remote end at the ISUP level is that of the UCAI (which we will define to be 3). This is the configuration normally used for ISUP if the traffic is being routed via some sort of SS7 router.

To summarize the configuration of the switch it has:

- Two E1 ports being used for the loopback (only carries speech, no signalling)
- A port being used signal to the SG (only carries signalling, no speech)
- Signaling is configured with a local point code of 1 and a remote point code of 2
- ISUP on the switch is configured to use the 60 speech circuits of the looped links
- ISUP DPC is set to be 3
- Point code of the UCAI and the switch is configured to route to DPC 3 via point code 2 (the SG)

**SG (ITP) Configuration**

The SG is assumed to be a Cisco ITP. To set it up, configure the baseline internet and the SS7 link. This provides the core SS7 and IP routing functions.

First set the port and IP address for the M3UA SCTP port, that is, the Signalling gateway Point (SGP) as follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>UCAI Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>cs7 m3ua 5000</td>
<td>Loop Back Mode:</td>
</tr>
<tr>
<td>local-ip 192.168.1.1</td>
<td>The M3UA is configured on the SG.</td>
</tr>
<tr>
<td></td>
<td>In this example:</td>
</tr>
<tr>
<td></td>
<td>• SCTP port 5000 is used for the sigtran M3UA</td>
</tr>
<tr>
<td></td>
<td>• ITP has an IP address of 192.168.1.1</td>
</tr>
<tr>
<td></td>
<td>• IP address of the UCAI machine is 192.168.1.2</td>
</tr>
<tr>
<td>cs7 m3ua 5000</td>
<td>Basic Inline Mode:</td>
</tr>
<tr>
<td>local-ip 192.168.1.1</td>
<td>In this mode, we define 2 local M3UA stacks.</td>
</tr>
<tr>
<td>cs7 m3ua 5001</td>
<td></td>
</tr>
<tr>
<td>local-ip 192.168.1.2</td>
<td></td>
</tr>
</tbody>
</table>

**VSSP configuration**

The vssp.config for this example is:

```
connect 3/1/1 to 3/1/33 for 15;
connect 3/1/17 to 3/1/49 for 15;
```

This configuration indicates that the circuit with local (to the UCAI) point code 3, remote (to the UCAI) point code 1 and cic 1 is looped to circuit local 3, remote 1 and cic 33. This is repeated for the other 29 circuits skipping the unused timeslot 16.

When using M3UA, a second configuration file is also needed. This details the M3UA-specific configuration. For this example, it could be:

```
asp port 5000 addrs {192.168.1.2};
sgp itpl port 5000 addrs {192.168.1.1};
gateway sgl
```
Chapter 2

sgp itp1 key 1234;
   pc {2, 1};
}

as pc 3 gateway {sg1};
This shows a local ASP on SCTP port 5000 with local address 192.168.1.2.

Note: There can only be a single port but it can be on multiple addresses. All the addresses given must belong to the local machine.

It also shows an ITP called itp1 with a port number of 5000 on the remote address of 192.168.1.1. Again, multiple addresses can be given and they must all belong to the remote SGP.

It also shows a signalling gateway called sg1. This contains the single SGP itp1 and identifies the routing key on the peer SGP. It also shows a list of point codes. The first is the point code of the SG itself (in this case 2) and any following point codes are those which can be reached via the SG. For this example, we specify that point code 1 may be reached via this SG.

It also shows our local AS. For this example, it has a point code of 3 and is peered with SG sg1.

M3UA configuration file syntax

Lexical considerations

The M3UA configuration file supports two sorts of comments:

- comment to end of line is indicated by a double forward slash (// with no space in between them).
  
  Example:
  
  Comment to end of line // This is the M3UA configuration file for the test network.

- comments that run over several lines are introduced by a /* and ended with a */.
  
  Example:
  
  /*
   * Now we set up the various SGPs in our network. There are three of them.
   * sgpl --- located in The Fort this deals with its local area.
   * sgpl2 --- located in The Hoist this is a hot standby for sgpl.
   * sgpl3 --- located in Heaven this handles all international traffic.
   */

Whitespace

Whitespace is only used to separate other lexical items. Otherwise it is ignored.

Example: The following methods of defining an asp are identical.

asp port 5000 addrs {192.168.1.2};

asp
   port 5000
   addrs { 192.168.1.2 }
;

Example M3UA configuration file

This text shows an example M3UA configuration:

#start file
asp port 6969 addrs {192.168.26.117};
Routing Options

Introduction

It is possible for attached switches to be configured so calls are only presented to the UCAI on circuits designated as "incoming" to the UCAI. There may be switches that do not allow routing on a per cic basis, and this section deals with several possible workarounds for this problem.

These options are necessarily, highly switch-specific, but one or more of them should be effective.

Per link fix

Some switches do not perform their routing based on point code. Instead they route based on sending calls down a specific link or linkset. In this case, the fix is fairly simple.

Routing should be configured so an entire link or linkset is designated as either all "incoming" to the UCAI or "outgoing" from the UCAI. Routing is then configured so calls are only routed down the links or link sets designated as "incoming" to the UCAI.

Example: A hypothetical mml command might be of the form:

```
ROUTE:PREFIX=0800,LINKS=LNK1,LNK3;
```
where the links LNK1 and LNK3 are designated as “incoming” to the UCAI and the unreferenced links (LNK2 and LNK4) are for the “outgoing” from the UCAI circuits. This would lead us to a loop-back structure looking something like this diagram.

![Diagram showing loop-back structure](image)

Quite how the signalling would work in this situation is somewhat unclear. However, it is possible to do it with just the one signalling link, provided care is taken to assign the cics correctly.

One possible method would be to have LNK1 using cics in the range 1 to 31 (based on the timeslots) and then to have the rest shifted up by 32, so LNK2 would be 33 to 63, LNK3 65 to 95 and LNK4 97 to 127.

This would lead to a vssp.config file which looks like:

```plaintext
connect 1/2/1 to 1/2/33 for 31 except 15.
connect 1/1/65 to 1/2/97 for 31.
```

This assumes:

- The UCAI has point code 1 and the attached switch point code 2
- timeslot 16 of LNK1 carries the signaling.

**Multiple point code fix**

Another possible option to work around routing problems in an attached switch, is to use multiple point codes on the attached switch. This means a switch may be able to support multiple links between itself and the UCAI.

These links may have different sets of point codes at the switch end. In this case, calls can be routed out from the switch to the UCAI from one point code, and be sent back into the switch from the UCAI on another point code.

**Example:**
If the UCAI has point code 1 and the switch has point codes 2 and 3, our network diagram would look something like this diagram.

![Network Diagram]

**Note:** The major difference between this and the ‘per link’ fix is there are now two signalling links involved. The signalling for the traffic from the switch to the UCAI uses one link, while the signalling for the traffic coming from the UCAI to the switch uses the other.

Routing should be configured so this is the case. All traffic to the UCAI should be routed out of the switch’s point code 2 link, to the UCAI’s point code 1. No traffic should be routed out of the switch’s point code 3.

A hypothetical mml command might be of the form:

```
ROUTE:PREFIX=0800,OPC=2,DPC=1;
```

Both signalling links must also be configured so they can send signalling information. This is usually a lower-level operation than setting up routing information. The configuration for UCAI only requires connecting the inputs to the outputs:

```
connect 1/2/0 to 1/3/0 for 32 except 0 and 16.
```

This assumes timeslot 16 carries the signalling on both the links.

**Two switch fix**

This method solves the problem of dealing with routing issues, by placing the UCAI between two switches (called ‘A’ and ‘B’ in this example).

![Two Switch Diagram]

In this case, UCAI is simply modifying the signalling on an otherwise ordinary link between two switches. The timeslots associated with link management and speech (usually, all except 16) are left intact. UCAI takes the signalling out to be processed.

To implement this method, configure all the nodes to have their signalling point codes allocated according to the signalling requirements.
In the example:

- switch ‘A’ talks with its point code of 2 to a remote point code of 1
- switch ‘B’ talks with its point code of 3 to a remote point code of 1, and
- UCAI talks with its point code of 1 to both 2 and 3).

Switch ‘B’ is configured to route no calls to point code 1 and switch ‘A’ is configured to route calls to UCAI to point code 1.

This configuration can be performed on either a point code or a link basis (as illustrated in the previous examples). There is no requirement for excluding any timeslots from use (apart from the management and signaling ones, usually 0 and 16).

Configure UCAI with just 30 incoming and outgoing circuits, as follows:

connect 1/2/0 to 1/3/0 for 32 except 0 and 16.

### Configuring UCAI

#### Case studies

The following two case studies illustrate the configuration modes of the UCAI.

**Loop back UCAI**

A GSM mobile operator has invested in a network that does not support CS-1 IN features. To allow it to provide a prepaid function, the operator deploys a service node solution that requires all prepaid calls to be trunked to the service node platform for service logic and then back to the eventual destination.

This solution has obvious cost and scalability issues, but allows entry to the emerging prepaid mobile market. The operator is caught out by the unforeseen rapid growth of prepaid mobiles combined with the drastic reduction in charges due to strong competition. He now finds that the solution is prohibitively expensive and the limit of the solution’s scalability is reached.

Two UCAIs are installed (co-resident on hardware with prepaid service logic SLC), connected to the operator’s SS7 network through STPs. Loop-back trunks are deployed on each of the operator’s mobile service switching centers (MSC), and signalling for these trunks is routed to UCAIs. The GSM HLR (Home Location Register) is configured with a service flag, to route calls from prepaid mobiles to UCAI trunks, allowing service logic to be invoked.

For mobile to mobile calls, the eventual destination of the call is not known, so routing between switches may be counter-productive, since the destination switch may need to route the call back or on to another switch. A possibility exists that, for calls to fixed phones or other mobile operators’ phones, the call could be triggered at the point of interconnect between the operators using an in-line UCAI. This would reduce the number of loop-backs required. However, the complexities of configuring switch routes that are based on calling party (being prepaid) and called party (whether fixed or other operator mobile), are considered too complex and costly in terms of man-power to be worth the saving in loop-back trunks.

**Loop back UCAI example**

This example shows a loop-back UCAI configuration. This configuration is optimal for triggering services:

- That often result in the call being terminated on the same switch from which it originated
- When the eventual destination for the call is unpredictable

**In line UCAI**

An application service provider (ASP), offering advanced services to other operators via their own switch, wishes to offer services beyond the capabilities of the AIN build of software currently available on the switch. The vast majority of the ASP's traffic originates from other networks, and traverses their switch to offer the service and route the call.

In this case, in-line UCAIs are very helpful, as most of the traffic is via points of interconnection. A UCAI placed on the signalling line of the other operator's switch and the ASP's network can control all incoming calls, avoiding loop-backs on the ASP switch entirely. Some loop-backs may be required for traffic originating on the ASP's network.

**In line UCAI example**

This example shows an in line or inter-switch UCAI configuration. This type of configuration is optimal for calls for which the vast majority of calls requiring UCAI processing originate from, or are eventually routed to, a network address that is not on the originating network switch, but which can be efficiently reached via the destination network switch.

**Example**: This diagram shows a network where:

- the originating switch is a local exchange (end office)
- the destination switch is a trunk level or international switch (central office), and
• the service to be triggered via the UCAI is a national or international freephone service.

**Configuring IN Call Model Triggers**

**Overview**

This introduces the generic configuration requirements of the NCC IN Call Model. The NCC IN Call Model is not a separate product, rather it is a set of libraries that is bound into a final usable interface (such as the UCA-ISUP).

**Environment variables**

This table describes the UNIX shell environment variables to be configured.

<table>
<thead>
<tr>
<th>Environment Variable Name</th>
<th>Description</th>
<th>Example Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TDP DEFINITIONS</td>
<td>Defines the full path name of the Trigger Detection Point definition file.</td>
<td>/IN/service_packages/SLEE/etc/tdp.conf</td>
</tr>
</tbody>
</table>

**Trigger detection point (TDP) definition file**

The tdp.conf file has two sections:

1. A number of configuration parameters.
2. The trigger tables used to determine when to trigger a call to the SCF.

**Example:** This text shows an example tdp.conf file:

```ini
# A comment
KEEP SD
ETC RULES=6 3
3 1 3 request all 123 6
4 2 4 notify all 222 keep
3 1 3 request 2:122 3:222 5 keep
```
Note: All lines starting with # are treated as comments. If no TDP definition file is defined, a default action is taken where:

- ALL calls are triggered to the SCF with a service key of 1 (one) and a trigger point of 3 (analyzedInformation.)
- None of the global configuration parameters are considered set.

### Global configuration parameters

The following configuration parameters may be set once on individual lines in the TDP definition file.

<table>
<thead>
<tr>
<th>Global Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEEP SD</td>
<td>If defined ALL all stop digits (defined by the BCD digit 'F') on the end of called party numbers are kept in the called party number. By default the stop digit is stripped from ALL triggered numbers.</td>
</tr>
<tr>
<td>CAMEL</td>
<td>This parameter is intended for CAMEL testing purposes only and should not be defined under normal usage. If defined, the called party number is also copied into the initialDP's calledPartyBCDNumber CAMEL parameter. The NOA of the called party number becomes the BCD number type.</td>
</tr>
<tr>
<td>ADDITIONALNUMS</td>
<td>If defined, the IN Call Model will request all additional numbers available from the underlying protocol and insert them into the InitialDP message sent to the SLC. All these additional numbers are placed into a G8 extension in the InitialDP except any additional calling party number that is placed in the additionalCallingPartyNumber field.</td>
</tr>
<tr>
<td>ETC RULES= c or ETC RULES= c s</td>
<td>If defined then additional EstablishTemporaryConnection (ETC) rules are used. If the integer c is defined, the correlationID in all ETC messages from the SCF are appended on to the end of the assistingSSPIPRoutingAddress that is used, the digits are padded to a width of c digits. If s is also defined, then the scfID of the ETC is also appended on afterwards in the same way. <strong>For example:</strong> With &quot;ETC RULES=6 4&quot; and an ETC message with: assistingSSPIPRoutingAddress =1111, correlationID =55, scfID =0x42 Then the actual assistingSSPIPRoutingAddress used will be &quot;11110000550042&quot;</td>
</tr>
<tr>
<td>USER LIB = library</td>
<td>If defined the call model will use the user written shared object <em>library</em> specified by the full pathname library when dealing with ApplyCharging operations.</td>
</tr>
<tr>
<td>AC=a,b,c,...</td>
<td>Sets the TCAP application context used by the call model to the comma separated list of OIDs supplied.</td>
</tr>
<tr>
<td>ORIG_PC= pc</td>
<td>See note 1 If defined, all InitialDPs will be sent with an SCCP calling party (origination) address that includes a Point Code defined by the integer pc. <strong>Note:</strong> This value may be defined in hex using a prefix of 0x.</td>
</tr>
<tr>
<td>ORIG_SSN= ssn</td>
<td>If defined, all initialDPs will be sent with an SCCP calling party (origination) address that includes a subsystem number defined by</td>
</tr>
<tr>
<td>Global Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>See note 1</td>
<td>the integer sn.</td>
</tr>
<tr>
<td>ORIG_GT=1, n, addr or ORIG_GT=2, t, addr or ORIG_GT=3, t, p, addr or ORIG_GT=4, t, p, n, addr</td>
<td></td>
</tr>
</tbody>
</table>
| See note 1       | If defined, all InitialDPs will be sent with an SCCP calling party (origination) address that includes a Global Title defined by the integers n, t, p and the number string addr. The initial value (1 to 4) identifies the Global Title type:  
  - n is the NOA  
  - t is the translation type  
  - p is the numbering plan  
  - addr is the address digits (0 to 9, A to F) |
| DEST_PC= pc      | If defined, all InitialDPs will be sent with an SCCP called party (destination) address that includes a Point Code defined by the integer pc.  
  **Note:** This value may be defined in hex using a prefix of 0x. |
| See note 2       | DEST_SSN= ssn |
| See note 2       | If defined, all InitialDPs will be sent with an SCCP called party (destination) address that includes a subsystem number defined by the integer ssn. |
| DEST_GT=1, n, addr or DEST_GT=2, t, addr or DEST_GT=3, t, p, addr or DEST_GT=4, t, p, n, addr |
| See note 2       | If defined all InitialDPs will be sent with an SCCP called party (destination) address that includes a Global Title defined by the integers n, t, p and the number string addr. The initial value (1 to 4) identifies the Global Title type:  
  - n is the NOA  
  - t is the translation type  
  - p is the numbering plan  
  - addr is the address digits (0 to 9, A to F) |
| ACH WARN PERIOD= period | Sets the default ApplyCharging warning to occur *period* seconds before the end of the call. |
| ACH RESOURCE= ad  | Sets the default ApplyCharging warning announcement/tone to use the resource identified by the address digits *ad*.  
  **Note:** This is only applicable if the underlying controlled call supports the ability to play announcements/tones. |
| ACH ANNOUNCE= messageId | Causes the default ApplyCharging warning to use announcement with message identifier *messageId*.  
  **Note:** This is only applicable if the underlying controlled call supports the ability to play announcements/tones. |
| ACS TONE= id.dur  | Causes the default ApplyCharging warning to use tone with identifier *id* for a duration of *dur* seconds.  
  **Note:** This is only applicable if the underlying controlled call supports the ability to play announcements/tones. |

**Note 1**

If none of these entries is defined all InitialDPs will be sent without an SCCP calling party address.
Trigger detection point definitions

After any global parameters have been set, the configuration file may take one or more trigger detection point (TDP) definitions.

Each line defines a single trigger; its trigger parameter values that get sent and the conditions under which it gets sent.

Each line takes the following form:

```
tdp svcKey eventType msgType cgPn cdPn [wild] [keep]
```

The table below defines the meanings and forms of these parameters.

<table>
<thead>
<tr>
<th>Global Parameter Value</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tdp</td>
<td>integer</td>
<td>This integer value defines the point that the TDP is triggered at. Together with cgPn, cdPn and wild it defines the condition that the trigger will fire on. See the TDP event type table for a list of valid values and meanings.</td>
</tr>
<tr>
<td>svcKey</td>
<td>integer</td>
<td>This parameter defines the serviceKey value that will be inserted into the initialDP message when this trigger fires.</td>
</tr>
<tr>
<td>eventType</td>
<td>integer</td>
<td>This parameter defines the eventTypeBCSM value that will be inserted into the InitialDP message when this trigger fires. See the TDP event type table for a list of valid values and meanings. Generally this will be the same value as tdp.</td>
</tr>
<tr>
<td>msgType</td>
<td>request or notify</td>
<td>This parameter defines whether the TDP is sent as a TDP-R (request) or TDP-N(notify). Generally request is used here.</td>
</tr>
</tbody>
</table>
| cgPn                   | num or nat:num or all | This parameter defines the calling party numbers that will trigger the TDP. Together with tdp, cdPn and wild it defines the condition that the trigger will fire on.  
  - num defines the prefix of the calling party digits, numbers must begin with these digits for the trigger to fire.  
  - nat is optional and defines additionally a nature of address (NOA) of the calling party that must match for the trigger to fire. If not provided a nature of 2 (unknown) is assumed.  
  If all is defined then ALL calling party numbers will match. |
| cdPn                   | num or nat:num or all | This parameter defines the called party numbers that will trigger the TDP. Together with tdp, cgPn and wild it defines the condition that the trigger will fire on.  
  - num defines the prefix of the called party digits, numbers must begin with these digits for the trigger to fire.  
  - nat is optional and defines additionally a nature of address (NOA) of the called party that must match for the trigger to fire. If not provided a nature of 2 (unknown) is assumed. |

Overview

Introduction

This chapter explains the processes which run automatically as part of the application. These processes are started automatically by one of the following:

- inittab
- crontab
- Service Logic Execution Environment SLEE

Note: This chapter also includes some plug-ins to background processes which do not run independently.

In this chapter

This chapter contains the following topics.

vssp

vssp

Purpose

vssp is the binary which runs the UCAI application.

No other binaries are installed with UCAI.

Startup

This task is started by the SLEE, by the following lines in SLEE.cfg:

```
INTERFACE=VSSP vssp.sh /IN/service_packages/VSSP/bin EVENT
```

Notes:

- The actual startup script name may vary.
- If you have configured UCAI to run without the SLEE, you can also start UCAI from the command line.

Configuration

vssp accepts the following parameters from vssp.config.

```
unset option slee.
set option syslog.
set option stats.
set cdr file="filename";
set option debug.
set option mtp debug.
set option stats.
```
set startup time _seconds_.
set network _network_identifier_.

filter iam drop [{number,} number and] number.

connect circuit to circuit [for number_of_circuits].

**M3UA configuration**

vssp supports these parameters from m3ua.config.

```plaintext
asp
  port _port_
  addrs {ip_address}
;

sgp itpl
  port _port_
  addrs {ip_address}
;

gateway sgl
{  
  sgp itpl key int;
  pc {int, [int, ...]};
}

as
  pc int
  gateway {sg1}
;
```

**Parameters**

Here are the parameters for vssp.

**Command line parameters**

vssp supports the following command line parameters.

**Note:** These are usually specified in the startup script, vssp.sh.

- `-c <configuration file>`
  Specifies the filepath and name of the vssp configuration file.
  Default: none
  Notes: (Required.)

- `-k <keyfile>`
  Specifies the filepath and name of the keyfile file which sets the maximum number of circuits UCAI can use.
  Default: keyfile
  Notes: (Optional.)

- `-m <m3ua configuration file>`
  Specifies the filepath and name of the M3UA configuration file.
  Default: m3ua.config
  Note: (Optional.)
**Standard options**
These parameters are available for all types of UCAI installation.

**cdr file**
If set to a valid filepath, vssp will log CDRs to the specified file.
- Default: off
- Allowed: string
- Format: `set cdr file = "filename";`
- Note: The equals sign (=) is optional.

**connect**
Defines the circuit loops for vssp. For more information about configuring circuit loops, see *Configuring circuit loops* (on page 17).
- Default: none
- Allowed: `connect circuit to circuit[ for number of circuits][ except cic[ and cic]]`.  
- Note: The full stop or semi-colon on the end is essential if you are not specifying a number of circuits.

**debug**
Turns vssp debug output on or off. If enabled, an operator can debug SSP functionality, as well as lower-level ISUP functionality.
The SSP functionality details how calls are being progressed and the ISUP debugging prints out all the ISUP messages sent and received.
- Default: off
- Format: `set option debug`
- Notes: This output is sent out on the debugging output of the VSSP (stdout).

**filter**
Drops specified parameters within an IAM. Drops the parameters with the name value of any of the given numbers on an outgoing IAM message.
- Default: empty set
- Format: `filter iam drop [{number,} number and] number`
- Where:
  - Square brackets enclose optional entries
  - Curly brackets enclose zero or more entries
- Note: Mandatory parameters cannot be dropped.

**limit**
Sets a CAPS limit on vssp. The first number is the CAPS limit and the second is the release cause to be used if the CAPS limit is exceeded.
- Default: Cause defaults to 42.
- Format: `set option limit to number caps cause [cause number]`
- Notes: The to can be replaced with an equals sign.  
  *cause_number* is optional.
mtp debug
Turns mtp traffic output from vssp on or off. If on, a hexadecimal representation of all the ISUP messages is written to the vssp's debugging output (stdout).
Default: off
Format: set option mtp debug

network
Sets the network identifier in the MTP3 header to be the specified value.
Default: 2
Note: This only applies to the M3UA and Data Kinetics stacks.
2 is national network.

set ica iam cpc
Sets the calling party category on the legs of ICA calls. The CPC can be set on just the A-leg or on both legs.
Default: none
Format: set ica iam cpc A-leg_number [B-leg_number]
Where:
  • number = the override value for the calling party category.
Notes: By default, the CPC set for the A-leg number will be used for the B-leg.
  There is an NCC extension to INAP that allows the CPC to be set on the A-leg of an ICA-created call.
  Service logic may override a set B-leg value.

slee
Enable or disable the interface between vssp and the SLEE. If the SLEE interface is disabled, vssp acts simply as a call router, in effect providing a null service.
Default: on
Format: unset option slee
Note: This option should only be used for debugging.

startup time
Seconds vssp takes to reset all its circuits at start up.
Default: 15
Allowed: number
Format: set startup time = seconds
Note: If there are a large number of circuits, the default may need to be increased to avoid temporary congestion of the network.
The equals sign (=) is optional.

stats
If set, vssp will log a basic calculation of the number of calls being processed by vssp per second.
Default: off
Format: set option stats

syslog
Send error messages to the syslog as well as UNIX stderr.
Any errors will now be logged to syslog. The syslog identifier is set to VSSP, the facility is set to LOG_USER and errors are logged at level LOG_ERR.

Default: off
Format: set option syslog

**M3UA parameters**
The M3UA configuration uses a cascading definition structure. The first parameter (file) is defined by four other parameters. Those four parameters are in turn defined by other parameters set later in the file.

For more information about how these parameters work together to configure vssp, see *M3UA Configuration* (on page 19).

vssp supports these parameters from the m3ua.config file.

**Note:** These parameters are only available if you have installed the M3UA version of UCAI.

**as**
Application Server definition. Assigns ASPs to ASs.

Default:
Syntax: as pc  number gateway { gateway_list};
Where:
- *number* is the Point Code number of the AS
- *gateway_list* is the list of SGs the AS is peered with.

**Note:**

**asp**
Defines the local ASP.

Default:
Syntax: asp port  port addr {ip};
Where:
- *port* is the port the AS process is running on
- *ip* is the IP address the AS process is running on

**gateway**
Gateway definitions.

Default:
Syntax: gateway  identifier
{ sgp itp1 key  key
  pc {pcs};
}
Where:
- *identifier* is a unique identifier
- *key* is a keyed_sgps parameter
- *pcs* is a list of comma separated point codes
sgp
Signalling Gateway Process definitions.

Default:

Syntax:  

\[
\text{sgp itp1 port port addrs \{ip\};}
\]

Where:
- **port** is the port the SG process is running on
- **ip** is the IP address the SG process is running on

**Example configuration - vssp.config**

This is an example of the vssp.config file (comments have been removed).

```plaintext
set option slee.
set option syslog.
set option stats.
set cdr file="cdr.log";
#set option debug.
#set option mtp debug.

set ica iam cpc 10;

connect 1/2/1 to 1/2/17 for 15;
```

**Example M3UA configuration file**

This text shows an example M3UA configuration:

```plaintext
#start file
asp port 6969 addrs \{192.168.26.117\};

sgp itp1 port 2905 addrs \{192.168.26.215\};

gateway sgl
{  
  sgp itp1 key 6969;
  \pc \{999, 4805, 4807\};
}

as pc 4701 gateway \{sgl\};
#end file
```

Using more whitespace, this file could also be displayed as follows:

```plaintext
#start file
asp
    port 6969
    addrs \{192.168.26.117\}
;

sgp itp1
    port 2905
    addrs \{192.168.26.215\}
;

gateway sgl
{  
  sgp itp1 key 6969;
  \pc \{999, 4805, 4807\};
}

as
    pc 4701
```
Output

vssp writes error messages to the system messages file, and also writes additional output to the following default:

/IN/service_packages/VSSP/output/outputFile.log

**Note:** May vary as per configuration in the startup script.
Overview

Introduction

This chapter explains the important processes on each of the server components in the NCC, and a number of example troubleshooting methods which will help aid the troubleshooting process before raising a support ticket.

In this chapter

This chapter contains the following topics.

Common Troubleshooting Procedures
Possible Problems

Common Troubleshooting Procedures

Introduction

Refer to *NCC System Administrator's Guide* for troubleshooting procedures common to all NCC components.

Turning on debug

The vssp process supports debug. To turn on debug for vssp, set the debug option in the *vssp.config* file and reload the configuration.

For information about turning on debug, see *debug* (on page 35).

Important: Turning on debug increases the load on the vssp process. It should only be used on a production platform when absolutely necessary.

Turning on M3UA vssp debug

The vssp process supports debug for its M3UA. To turn on M3UA debug for vssp, set the mtp debug option in the vssp.config file and reload the configuration.

For information about turning on debug, see *mtp debug* (on page 36).

Important: Turning on debug increases the load on the vssp process. It should only be used on a production platform when absolutely necessary.

Checking current processes

You can check which processes are running using the standard UNIX command: ps. To find processes being run by Oracle software, you can grep for the string 'oper', which will display all processes being run by the application operator accounts (for example, acs_oper, ccs_oper and smf_oper).

Note: Some processes which are required for proper functioning may be run by other users, including root or the user which runs the webserver.
Example command: `ps -ef | grep oper`

For more information about the `ps` command, see the system documentation for the `ps` command.

You can also check how much of the processor a process is using by running the standard UNIX tool: `top`. If you have some baseline measurements, you will be able to compare it with the current load.

Example command: `top`

Tip: Some processes should only have one instance. If there are two or more instances, this may indicate a problem. For example, there will usually only be one timerIF running on each SLC.

For more information about which processes should be running on each node, check the Process List for each node in *Installation*.

**Checking installed packages**

To check the details of an installed package, use the `pkginfo` command.

Example command: `pkginfo -l smsSms`

Example output: This is an example of the output of the example command above.

```
PKGINST: smsSms
   NAME: Oracle smsSms
CATEGORY: application
    ARCH: sun4u
  VERSION: 3.1.0
      VENDOR: Oracle
       P_stamp: smsNode20041020104925
   INSTDATE: Oct 20 2004 13:15
      EMAIL: support@oracle.com
     STATUS: completely installed
        FILES: 348 installed pathnames
               39 directories
               89 executables
              152448 blocks used (approx)
```

For more information about the `pkginfo` utility, see the system documentation.

**Checking network connectivity**

Network connectivity will affect any process which requires communication between two different network addresses.

Network connectivity should support ssh sessions between the two machines experiencing the problem.

If you can open an ssh session between the two machines, check the following before contacting Level 1 support with details:

- If the address of either of the machines specified in the Node Management screens is a hostname, check that the hostnames used in the ssh sessions are the hostnames specified in the Node Management screen.

If you cannot ssh, check the following before contacting Level 1 support with details:

- Check that the hostname is resolving correctly in the DNS.
- Check that the physical network connection is working correctly.
- Check that the inetd and sshd are running.
- Check that sshd is listening on the expected port.
- Check that the smf_oper and acs_oper accounts are not locked, and that the username and password combinations being used are correct.
Checking configuration files

One of the significant areas where faults can occur and be remedied is in the configuration of processes. Configuration files can be edited by any standard text editor. A backup of the existing configuration file should always be taken before editing a configuration file.

For more information about the configuration files used in this application, see Configuration.

For more information about the configuration file for a specific program or tool, see the section named after the binary in question.

Possible Problems

Introduction

This topic lists common problems and actions which can be taken to investigate or solve them. This list enables you to check for alarms based on the overall behavior you are experiencing.

Circuit mismatches

If any of the following are true, it may indicate that the circuit loop configuration is mismatched:

1. One party can hear the other, but not the other way round.
2. Different calls connected together.
3. Total silence at both ends.

Check the vssp.config file for possible mismatches. For more information about configuring circuit loops, see Configuring circuit loops (on page 17).
About Installation and Removal

Overview

Introduction
This chapter provides details of the installation and removal process for the application.

In this chapter

This chapter contains the following topics.

- UCAI Requirements...
- Installation and Removal Overview...
- Checking the Installation...

UCAI Requirements

Environment
The UCAI can reside on one of the following:
- A SLC Solaris host machine using internal INAP communication between the VSSP and SCF software
- Its own independent Solaris machine and communicate with the SLC(s) through SS7 TCAP or TCAP over IP

ISUP Signaling Link Set Dimensioning

Originating Exchange Signaling
The signaling capacity requirements for the SS7 links to the originating network switch are dependent on the following parameters:
- BHCA for service
- Required normal network link load
- Average number of octets send and received per call

The bit rate capacity can be estimated as:

\[ r = \frac{x \cdot b}{450} \]

Where:
- \( x \) = the BHCA number
- \( b \) = number of octets per call (sent or received)

Example:
Assuming 100 octets per call (both sent and received), a service with 300000 BHCA would require 66.7 Kbits per second.

If 64Kbit s\(^{-1}\) links are used, and a link load of 60% is required, a link would support 38.4 Kbit s\(^{-1}\).
Therefore, 2 links would be required to support the load. For redundancy, an additional link is normally installed unless the link load figure takes account of this.

**ISUP Signalling Link Set Dimensioning**

**Terminating Exchange Signaling**

Since the terminating trunk signaling may need to establish and clear more than one call per call to the service, the terminating exchange signaling requirements are a multiple of the originating signaling requirements.

The average number of calls that must be established as a result of each incoming call determines the required multiple.

**Example:** If each service invocation requires a call to be established to an SRF and then routed to final destination, a multiplication factor of 2 would be applied to determine the terminating exchange signaling requirements.

**Trunk dimensioning**

The number of trunks that must be configured is totally dependent on the number of simultaneous calls UCAI must handle.

This is dependent on traffic forecasts and quality of service (QoS) data. If a service is expected to have x busy hour call attempts (BHCA), with each call lasting an average of y seconds, then the number of simultaneous calls C is:

\[ c = \frac{x \cdot y}{3600} \]

The number of VSSP trunks is the number of simultaneous calls divided by the number of speech channels in a trunk (E1=30, T1=24).

When QoS is taken into consideration, the number of trunks will be increased, to allow for the non-uniform profile of real service usage.

**Example:** A service requires 10000 BHCA and has an average call hold time of 2 minutes. The number of simultaneous calls is therefore 3334, which is 14 T1 trunks. To achieve the desired QoS requires a 30% over provisioning of capacity, which results in 19 T1 trunks.

**Installation and Removal Overview**

**Introduction**

For information about the following requirements and tasks, see *NCC Installation Guide*:

- NCC system requirements
- Pre-installation tasks
- Installing and removing NCC packages

**UCA-ISUP package**

An installation of UCA-ISUP includes the following package, on the SLC:

- VSSP

**Add vssp entry to SLEE.cfg**

Configure UCAI to use the SLEE by adding an entry for the vssp process in SLEE.cfg.

Unless the setup of this installation of UCAI is unusual, the line should be:

```bash
INTERFACE=VSSP vssp.sh /IN/service_packages/VSSP/bin EVENT
```
For more information about adding entries to SLEE.cfg, see SLEE Technical Guide.

Checking the Installation

Introduction

Refer to these checklists to ensure that UCAI has installed correctly.

Checklist

Follow the steps in this checklist to ensure UCAI has been installed on a SLC machine correctly.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Log in to SLC machine as root.</td>
</tr>
<tr>
<td>2</td>
<td>Check the following directory structure exists with subdirectories: /IN/service_packages/VSSP</td>
</tr>
<tr>
<td>3</td>
<td>Check the directory contains subdirectories and that all are owned by: acs_oper user (group oracle)</td>
</tr>
<tr>
<td>4</td>
<td>Check the entries of following file: /IN/service_packages/SLEE/etc/SLEE.cfg SLEE startup entries for VSSP on a SLC: INTERFACE=VSSP vssp.sh /IN/service_packages/VSSP/bin EVENT</td>
</tr>
<tr>
<td>5</td>
<td>Check that the processes listed in the process lists are running on the relevant machine. For a list of the processes which should be running, see Process list (on page 47).</td>
</tr>
</tbody>
</table>

Process list

If the application is running correctly, the following processes should be running on each SLC:

- Started during SLEE startup:
  - vssp
NCC Glossary of Terms

AAA

AC
Application Context. A parameter in a TCAP message which indicates what protocol is conveyed. May indicate, for example, MAP, CAMEL, or INAP. Also usually specifies the particular version of the conveyed protocol, for example, which CAMEL Phase.

ACS
Advanced Control Services configuration platform.

AIN
Advanced Intelligent Network

AS
Application Server. The logical entity serving a SUA routing key. An AS is equivalent to an SS7 end point (for example, HLR, MSC,…). An AS contains, at least, one ASP.

ASP
- Application Service Provider, or

C7
See SS7.

CAMEL
Customized Applications for Mobile network Enhanced Logic
This is a 3GPP (Third Generation Partnership Project) initiative to extend traditional IN services found in fixed networks into mobile networks. The architecture is similar to that of traditional IN, in that the control functions and switching functions are remote. Unlike the fixed IN environment, in mobile networks the subscriber may roam into another PLMN (Public Land Mobile Network), consequently the controlling function must interact with a switching function in a foreign network. CAMEL specifies the agreed information flows that may be passed between these networks.

CCR
Credit-Control-Request, used in Diameter by the credit-control client to request credit authorization from the credit-control server.

Connection
Transport level link between two peers, providing for multiple sessions.
cron
Unix utility for scheduling tasks.

crontab
File used by cron.

CS1
ETSI INAP Capability Set 1. An ITU standard.

Diameter
A feature rich AAA protocol. Utilises SCTP and TCP transports.

DTMF
Dual Tone Multi-Frequency - system used by touch tone telephones where one high and one low frequency, or tone, is assigned to each touch tone button on the phone.

ETSI
European Telecommunications Standards Institute

GPRS
General Packet Radio Service - employed to connect mobile cellular users to PDN (Public Data Network- for example the Internet).

GSM
Global System for Mobile communication.
It is a second generation cellular telecommunication system. Unlike first generation systems, GSM is digital and thus introduced greater enhancements such as security, capacity, quality and the ability to support integrated services.

GT
Global Title.
The GT may be defined in any of the following formats:
- Type 1: String in the form "1,<noa>,<BCD address digits>"
- Type 2: String in the form "2,<trans type><BCD address digits>"
- Type 3: String in the form "3,<trans type>,<num plan>,<BCD address digits>"
- Type 4: String in the form "4,<trans type>,<num plan>,<noa>,<BCD address digits>"
The contents of the Global Title are defined in the Q713 specification, please refer to section 3.4.2.3 for further details on defining Global Title.

HLR
The Home Location Register is a database within the HPLMN (Home Public Land Mobile Network). It provides routing information for MT calls and SMS. It is also responsible for the maintenance of user subscription information. This is distributed to the relevant VLR, or SGSN (Serving GPRS Support Node) through the attach process and mobility management procedures such as Location Area and Routing Area updates.
**HPLMN**

Home PLMN

**HTML**

HyperText Markup Language, a small application of SGML used on the World Wide Web.

It defines a very simple class of report-style documents, with section headings, paragraphs, lists, tables, and illustrations, with a few informational and presentational items, and some hypertext and multimedia.

**ICA**

InitiateCallAttempt. A CAMEL/INAP operation sent by the SLC to an SSP request that a voice call is started.

**IN**

Intelligent Network

**INAP**

Intelligent Network Application Part - a protocol offering real time communication between IN elements.

**IP**

1) Internet Protocol

2) Intelligent Peripheral - This is a node in an Intelligent Network containing a Specialized Resource Function (SRF).

**IP address**

Internet Protocol Address - network address of a card on a computer

**ISDN**

Integrated Services Digital Network - set of protocols for connecting ISDN stations.

**ISUP**

ISDN User Part - part of the SS7 protocol layer and used in the setting up, management, and release of trunks that carry voice and data between calling and called parties.

**ITU**

International Telecommunication Union

**IVR**

Interactive Voice Response - systems that provide information in the form of recorded messages over telephone lines in response to user input in the form of spoken words or, more commonly, DTMF signalling.

**M3UA**

MTP3 User Adaptation. The equivalent of MTP in the SIGTRAN suite.
MAP
Mobile Application Part - a protocol which enables real time communication between nodes in a mobile cellular network. A typical usage of the protocol would be for the transfer of location information from the VLR to the HLR.

MSC
Mobile Switching Centre. Also known as a switch.

MT
Mobile Terminated

MTP
Message Transfer Part (part of the SS7 protocol stack).

MTP3
Message Transfer Part - Level 3.

NOA
Nature Of Address - a classification to determine in what realm (Local, National or International) a given phone number resides, for the purposes of routing and billing.

Oracle
Oracle Corporation

PC
Point Code. The Point Code is the address of a switching point.

PLMN
Public Land Mobile Network

SCCP
Signalling Connection Control Part (part of the SS7 protocol stack).

SCF
Service Control Function - this is the application of service logic to control functional entities in providing Intelligent Network services.

SCTP
Stream Control Transmission Protocol. A transport-layer protocol analogous to the TCP or User Datagram Protocol (UDP). SCTP provides some similar services as TCP (reliable, in-sequence transport of messages with congestion control) but adds high availability.
SGML

SGP
Signalling Gateway Process.

SGSN
Serving GPRS Support Node

SLC
Service Logic Controller (formerly UAS).

SLEE
Service Logic Execution Environment

SMS
Depending on context, can be:
- Short Message Service
- Service Management System platform
- NCC Service Management System application

SRF
Specialized Resource Function - This is a node on an IN which can connect to both the SSP and the SLC and delivers additional special resources into the call, mostly related to voice data, for example play voice announcements or collect DTMF tones from the user. Can be present on an SSP or an Intelligent Peripheral (IP).

SS7
A Common Channel Signalling system used in many modern telecoms networks that provides a suite of protocols which enables circuit and non circuit related information to be routed about and between networks. The main protocols include MTP, SCCP and ISUP.

SSN
Subsystem Number. An integer identifying applications on the SCCP layer. For values, refer to 3GPP TS 23.003.

SSP
Service Switching Point

SUA
Signalling Connection Control Part User Adaptation Layer
Switching Point
Anything that can send and receive C7 messages.

System Administrator
The person(s) responsible for the overall set-up and maintenance of the IN.

TCAP
Transaction Capabilities Application Part – layer in protocol stack, message protocol.

TCP
Transmission Control Protocol. This is a reliable octet streaming protocol used by the majority of applications on the Internet. It provides a connection-oriented, full-duplex, point to point service between hosts.

TDP
Trigger Detection Point.

Telco
Telecommunications Provider. This is the company that provides the telephone service to customers.

Telecommunications Provider
See Telco.

UCAI
Universal Call Agent ISUP (formerly VSSP)

VLR
Visitor Location Register - contains all subscriber data required for call handling and mobility management for mobile subscribers currently located in the area controlled by the VLR.

VSSP
Virtual SSP - old name for UCAI
