Part I Concepts

1 Product Overview
  1.1 Key Features and Benefits................................................................................................. 1-1
  1.1.1 Ease of Deployment...................................................................................................... 1-2
  1.1.2 Simplified UI Customization ..................................................................................... 1-2
  1.1.3 Simplified Configuration ........................................................................................... 1-2
  1.1.4 Flexibility and Resilience ......................................................................................... 1-2
  1.1.5 Maximum Reuse of Existing Infrastructure ............................................................... 1-3
  1.1.6 Extensive User Management .................................................................................... 1-3
  1.1.7 Web-Based User Self-Service .................................................................................... 1-3
  1.1.8 Modular and Scalable Architecture ........................................................................ 1-3
  1.1.9 Based on Leading Software Development Standards ............................................. 1-3
  1.1.10 Powerful and Flexible Process Engine .................................................................. 1-4
  1.1.11 Built-In Change Management ............................................................................... 1-5
  1.1.12 Workflow and Policy ............................................................................................. 1-5
  1.1.13 Audit and Compliance Management ...................................................................... 1-6
  1.1.14 Integration Solutions ............................................................................................. 1-8
  1.1.15 User Provisioning ................................................................................................... 1-8
  1.2 System Requirements and Certification ...................................................................... 1-9

2 Product Architecture
  2.1 How Oracle Identity Manager Works: The Tiers of Oracle Identity Manager ............ 2-1
  2.1.1 Presentation Tier ...................................................................................................... 2-2
  2.1.2 Business Services Tier ........................................................................................... 2-2
  2.1.2.1 The API Services .............................................................................................. 2-3
  2.1.2.2 Integration Services .......................................................................................... 2-4
  2.1.2.2.1 Connector Framework .................................................................................. 2-4
3 Security Architecture

3.1 Security Model ................................................................. 3-2
3.1.1 Admin Role Assignment .............................................. 3-2
3.1.2 Attribute-Level Security for the User Attributes .......... 3-17
3.1.2.1 Using Plug-ins to Pass Attributes for Policy Evaluation 3-20
3.1.3 Policy Obligations ....................................................... 3-21
3.2 Functional and Data Security Mapping ............................. 3-22
3.3 Publishing Entities to Organizations ................................. 3-48
3.4 Managing OES Policies .................................................. 3-49
3.4.1 Customizing the Authorization Policies ....................... 3-49
3.4.1.1 Controlling Who can View Which Users .................. 3-50
3.4.1.2 Controlling Who can Modify Which Users ................ 3-51
3.4.1.3 Controlling Who can View Which Links .................. 3-51
3.4.1.4 Controlling Who can Request an Account in an Application Instance 3-53
3.4.1.5 Controlling Who can Modify an Account .................. 3-53
3.4.1.6 Controlling Who can Manage an Application Instance 3-54
3.4.1.7 Controlling Who can Change User Password ............. 3-54
3.4.1.8 Controlling Who can Change Account Password .......... 3-54
3.4.1.9 Controlling Which Operations Are Direct or Request-Based 3-54
3.4.1.10 Controlling the Denied Attributes for Self ................ 3-58
Part II  Application Provisioning

4  Developing Application Instances

4.1  Creating IT Resources ................................................................. 4-1
4.2  Managing IT Resources................................................................. 4-3
4.2.1 Viewing IT Resources ................................................................. 4-4
4.2.2 Modifying IT Resources .............................................................. 4-4
4.2.3 Deleting IT Resources ................................................................. 4-5
4.3  Managing Resources By Using the Design Console ....................... 4-5
4.3.1 Overview of Resource Management ........................................ 4-5
4.3.2 IT Resources Type Definition Form ........................................... 4-6
4.3.2.1 Defining a Template (a Resource Type) for IT Resources .......... 4-7
4.3.2.2 Tabs on the IT Resource Type Definition Form ......................... 4-7
4.3.2.2.1 IT Resource Type Parameter Tab ..................................... 4-7
4.3.2.2.2 IT Resource Tab ............................................................. 4-8
4.3.2.3 IT Resource Type Definition Table ......................................... 4-8
4.3.3 Rule Designer Form ................................................................. 4-8
4.3.3.1 Creating a Rule ................................................................. 4-10
4.3.3.2 Tabs on the Rule Designer Form ............................................ 4-11
4.3.3.2.1 Rule Elements Tab .................................................... 4-11
4.3.3.2.2 Usage Tab ................................................................. 4-14
4.3.3.3 Rule Designer Table .......................................................... 4-14
4.3.4 Resource Objects Form .......................................................... 4-15
4.3.4.1 Creating a Resource Object .................................................. 4-17
4.3.4.2 Tabs on the Resource Objects Form ....................................... 4-17
4.3.4.2.1 Depends On Tab ......................................................... 4-18
4.3.4.2.2 Object Authorizers Tab ............................................... 4-18
4.3.4.2.3 Process Determination Rules Tab .................................... 4-19
4.3.4.2.4 Event Handlers/Adapters Tab ....................................... 4-20
4.3.4.2.5 Resource Audit Objectives ............................................ 4-20
4.3.4.2.6 Status Definition Tab ................................................... 4-21
4.3.4.2.7 Administrators Tab ....................................................... 4-22
4.3.4.2.8 Password Policies Rule Tab ........................................... 4-23
4.3.4.2.9 User-Defined Fields Tab ............................................... 4-24
4.3.4.2.10 Process Tab ............................................................... 4-24
4.3.4.2.11 Object Reconciliation Tab ............................................. 4-24
4.3.4.3 Multiple Trusted Source Reconciliation ................................. 4-28
4.3.4.3.1 Multiple Trusted Source Reconciliation Using MTS-Compatible Connectors.... 4-29
4.3.4.3.2 Multiple Trusted Source Reconciliation Using Connectors That Are Not MTS-Compatible 4-31
4.3.5 Service Account Management ........................................................................................ 4-36
4.4 Converting a Disconnected Application Instance to Connected Application Instance. 4-36
4.4.1 Creating a Disconnected Application Instance in the Production Environment ... 4-37
4.4.2 Exporting Disconnected Application Instance From Production Environment .... 4-38
4.4.3 Importing the Disconnected Application Instance in Test Environment............. 4-39
4.4.4 Modifying the Application Instance from Disconnected to Connected .......... 4-40
4.4.5 Testing the Connected Application Instance............................................................ 4-42

5 Developing Provisioning Processes
5.1 Overview of Process Management.................................................................................. 5-1
5.2 Email Definition Form .................................................................................................... 5-1
5.2.1 Specifying the E-Mail Server ..................................................................................... 5-2
5.2.2 Email Definition Form ............................................................................................... 5-3
5.2.3 Creating an E-Mail Definition .................................................................................... 5-4
5.3 Process Definition Form.................................................................................................. 5-5
5.3.1 Creating a Process Definition .................................................................................... 5-7
5.3.2 Tabs on the Process Definition Form ........................................................................... 5-8
5.3.2.1 Tasks Tab .............................................................................................................. 5-9
5.3.2.1.1 Adding a Process Task .................................................................................. 5-9
5.3.2.1.2 Editing a Process Task ............................................................................... 5-10
5.3.2.1.3 Deleting a Process Task ............................................................................. 5-10
5.3.2.2 Reconciliation Field Mappings Tab ........................................................................ 5-10
5.3.2.2.1 User Account Status Reconciliation ......................................................... 5-11
5.3.2.2.2 Mapping a Target Resource Field to Oracle Identity Manager ............... 5-12
5.3.2.2.3 Deleting a Mapping .................................................................................... 5-14
5.3.2.3 Administrators Tab ............................................................................................... 5-14
5.3.2.3.1 Assigning a Role to a Process Definition .................................................... 5-14
5.3.2.3.2 Removing a Role From a Process Definition ............................................. 5-14
5.3.3 Modifying Process Tasks ............................................................................................ 5-15
5.3.3.1 General Tab .......................................................................................................... 5-15
5.3.3.1.1 Modifying a Process Task’s General Information ..................................... 5-17
5.3.3.1.2 Triggering Process Tasks for Events Defined in Lookup.USR_PROCESS_TRIGGERS Fields 5-19
5.3.3.2 Integration Tab ...................................................................................................... 5-20
5.3.3.2.1 Assigning an Adapter or Event Handler to a Process Task ....................... 5-21
5.3.3.2.2 Mapping Adapter Variables ....................................................................... 5-22
5.3.3.2.3 Removing an Adapter or Event Handler from a Process Task ............... 5-23
5.3.3.3 Task Dependency Tab .......................................................................................... 5-23
5.3.3.3.1 Assigning a Preceding Task to a Process Task ....................................... 5-23
5.3.3.3.2 Removing a Preceding Task from a Process Task ................................. 5-24
5.3.3.3.3 Assigning a Dependent Task to a Process Task ...................................... 5-24
5.3.3.3.4 Removing a Dependent Task from a Process Task .............................. 5-24
5.3.3.4 Responses Tab ................................................................................................. 5-24
6 Developing Process Forms

6.1 Creating a Form .......................................................................................................................... 6-3
6.2 Tabs of the Form Designer Form .................................................................................................. 6-4
  6.2.1 Additional Columns Tab ........................................................................................................ 6-4
  6.2.1.1 Adding a Data Field to a Form ....................................................................................... 6-7
  6.2.1.2 Removing a Data Field From a Form ............................................................................. 6-8
  6.2.1.3 Setting the Value of the AccountPassword Property .................................................. 6-9
  6.2.2 Child Table(s) Tab .................................................................................................................. 6-9
  6.2.2.1 Assigning a Child Table to a Form ................................................................................. 6-10
  6.2.2.2 Removing a Child Table from a Form ............................................................................. 6-10
  6.2.3 Object Permissions Tab ......................................................................................................... 6-10
  6.2.3.1 Assigning a User Group to a User-Created Form .......................................................... 6-11
  6.2.3.2 Removing a User Group From a User-Created Form ................................................... 6-11
  6.2.4 Properties Tab ........................................................................................................................ 6-11
    6.2.4.1 Adding a Property and Property Value to a Data Field ............................................. 6-12
    6.2.4.2 Adding a Property and Property Value for Customized Look up Query .................. 6-13
    6.2.4.3 Removing a Property and Property Value From a Data Field .................................. 6-15
  6.2.5 Administrators Tab .................................................................................................................. 6-15
    6.2.5.1 Assigning Privileges to a User Group for a Record of a User-Created Form ............ 6-15
    6.2.5.2 Removing User Group Privileges for a Record of a User-Created Form .................. 6-16
  6.2.6 Usage Tab .................................................................................................................................. 6-16
  6.2.7 Pre-Populate Tab ..................................................................................................................... 6-16
  6.2.8 Default Columns Tab .............................................................................................................. 6-17
  6.2.9 User Defined Fields Tab ......................................................................................................... 6-17
  6.3 Creating an Additional Version of a Form ................................................................................. 6-17
## 7 Managing Lookup Definitions

- **7.1 Overview** .................................................................................................................. 7-1
- **7.2 Lookup Definition Form** .......................................................................................... 7-1
- **7.2.1 Creating a Lookup Definition** ................................................................................ 7-2
- **7.2.2 Lookup Code Information Tab** ............................................................................. 7-3
- **7.2.2.1 Creating and Modifying a Lookup Value** ........................................................... 7-3
- **7.2.2.2 Deleting a Lookup Value** ................................................................................... 7-4
- **7.2.3 Configuring a Lookup Value** ................................................................................ 7-4

## 8 Using the Adapter Factory

- **8.1 Introduction to Adapters** .......................................................................................... 8-1
- **8.2 Types of Adapters** .................................................................................................... 8-3
- **8.3 Adapter Environment and Tools** .............................................................................. 8-7
- **8.3.1 Configuring the Adapter Environment** ................................................................. 8-7
- **8.3.2 Remote Manager** .................................................................................................. 8-7
- **8.3.3 The Adapter Factory** ........................................................................................... 8-8
- **8.3.4 Compiling Adapters** ............................................................................................ 8-8
- **8.3.4.1 Automatic Compilation of Adapters** ................................................................. 8-8
- **8.3.4.2 Compiling Adapters Manually** ......................................................................... 8-9
- **8.4 Defining Adapters** .................................................................................................... 8-10
- **8.5 Tabs of the Adapter Factory Form** ............................................................................ 8-11
- **8.5.1 Adapter Tasks** ...................................................................................................... 8-11
- **8.5.2 Execution Schedule** .............................................................................................. 8-11
- **8.5.3 Resources** ........................................................................................................... 8-12
- **8.5.4 Variable List** ........................................................................................................ 8-12
- **8.5.5 Usage Lookup** ..................................................................................................... 8-12
- **8.5.6 Responses** .......................................................................................................... 8-12
- **8.6 Disabling and Re-enabling Adapters** ...................................................................... 8-13
- **8.7 About Adapter Variables** ........................................................................................ 8-13
- **8.7.1 Creating an Adapter Variable** .............................................................................. 8-13
- **8.7.2 Modifying an Adapter Variable** .......................................................................... 8-15
- **8.7.3 Deleting an Adapter Variable** ............................................................................ 8-15
- **8.8 Creating Adapter Tasks** .......................................................................................... 8-15
- **8.8.1 Types of Adapter Tasks** ...................................................................................... 8-16
- **8.8.2 Creating a Java Task** .......................................................................................... 8-17
- **8.8.3 Creating a Remote Task** ..................................................................................... 8-21
- **8.8.4 Creating a Stored Procedure Task** ..................................................................... 8-22
- **8.8.5 Creating a Utility Task** ....................................................................................... 8-25
- **8.8.6 To Create an Oracle Identity Manager API Task** ................................................ 8-26
- **8.8.7 Reassigning the Value of an Adapter Variable** .................................................... 8-28
- **8.8.8 Adding an Error Handler Task** ......................................................................... 8-29
- **8.8.9 Creating a Logic Task** ......................................................................................... 8-30
- **8.9 Modifying Adapter Tasks** ....................................................................................... 8-33
- **8.10 Changing the Order and Nesting of Tasks** ............................................................ 8-33

10 Developing Identity Connectors Using Java

10.1 Developing a Flat File Connector                  | 10-1 |
10.1.1 Supporting Classes for File Input and Output Handling | 10-9 |
10.2 Uploading the Identity Connector Bundle to Oracle Identity Manager Database | 10-27 |
10.2.1 Registering the Connector Bundle with Oracle Identity Manager ................. 10-27
10.2.2 Creating Basic Identity Connector Metadata .................................................. 10-28
10.2.2.1 Creating the IT Resource Type Definition .................................................. 10-28
10.2.2.2 Creating the Resource Object ................................................................. 10-29
10.2.2.3 Creating Lookups ..................................................................................... 10-30
10.2.2.3.1 Creating the Main Configuration Lookup ............................................. 10-30
10.2.2.3.2 Creating Object Type Configuration Lookup ....................................... 10-31
10.2.3 Creating Provisioning Metadata ................................................................ 10-32
10.2.3.1 Creating a Process Form ........................................................................ 10-32
10.2.3.2 Creating Adapters ................................................................................ 10-34
10.2.3.3 Creating A Process Definition ............................................................... 10-36
10.2.3.4 Creating a Provisioning Attribute Mapping Lookup ................................... 10-39
10.2.3.4.1 Field Flags Used in the Provisioning Attributes Map .............................. 10-40
10.2.4 Creating Reconciliation Metadata .................................................................. 10-41
10.2.4.1 Creating a Reconciliation Schedule Task .................................................. 10-41
10.2.4.1.1 Defining the Schedule Task .................................................................. 10-41
10.2.4.1.2 Creating a Scheduled Task .................................................................. 10-42
10.2.4.2 Creating a Reconciliation Profile ................................................................ 10-43
10.2.4.3 Setting a Reconciliation Action Rule ......................................................... 10-44
10.2.4.4 Creating Reconciliation Mapping ............................................................ 10-45
10.2.4.4.1 Field Flags Used in the Reconciliation Attributes Map .......................... 10-46
10.2.4.5 Defining a Reconciliation Matching Rule ................................................. 10-46
10.3 Provisioning a Flat File Account ..................................................................... 10-47
10.4 Configuring SSL for Java Connector Server .................................................... 10-47

11 Developing Identity Connectors Using .NET

11.1 Developing a Flat File .NET Connector .......................................................... 11-1
11.2 Deploying the Identity Connector Bundle on .NET Connector Server............... 11-11
11.2.1 Registering the Connector Bundle with .NET Connector Server .................. 11-11
11.2.2 Creating Basic Identity Connector Metadata .................................................. 11-12
11.2.2.1 Creating the IT Resource Type Definition .................................................. 11-12
11.2.2.2 Creating the Resource Object ................................................................. 11-13
11.2.2.3 Creating Lookups ..................................................................................... 11-14
11.2.2.3.1 Creating the Main Configuration Lookup ............................................. 11-14
11.2.2.3.2 Creating Object Type Configuration Lookup ....................................... 11-15
11.2.3 Creating Provisioning Metadata .................................................................. 11-16
11.2.3.1 Creating a Process Form ........................................................................ 11-16
11.2.3.2 Creating Adapters ................................................................................ 11-18
11.2.3.3 Creating A Process Definition ............................................................... 11-20
11.2.3.4 Creating a Provisioning Attribute Mapping Lookup ................................... 11-25
11.2.3.4.1 Field Flags Used in the Provisioning Attributes Map .............................. 11-26
11.2.4 Creating Reconciliation Metadata .................................................................. 11-27
11.2.4.1 Creating a Reconciliation Schedule Task .................................................. 11-27
11.2.4.1.1 Defining the Schedule Task .................................................................. 11-28
11.2.4.1.2 Creating a Scheduled Job .................................................................. 11-28
11.2.4.2 Creating a Reconciliation Profile ............................................................. 11-29
11.2.4.3 Setting a Reconciliation Action Rule ......................................................... 11-30
12 Integrating ICF with Oracle Identity Manager

12.1 ICF Common ................................................................. 12-1
12.2 Integration Architecture.................................................. 12-1
12.3 Global Oracle Identity Manager Lookups ......................... 12-2
12.3.1 Main Lookup Configuration ........................................ 12-3
12.3.2 User Management Configuration ................................ 12-4
12.3.3 Recon Transformation Lookup (Lookup.CONNECTOR_ NAME.UM.ReconTransformation) 12-7
12.3.4 Recon Validation Lookup (Lookup.CONNECTOR_NAME.UM.ReconValidation) ........... 12-7
12.3.5 Optional Defaults Lookup .......................................... 12-8
12.4 IT Resource .................................................................. 12-9
12.5 Provisioning ................................................................. 12-9
12.5.1 ICF Provisioning Manager .......................................... 12-9
12.5.1.1 APIs for Provisioning ........................................ 12-9
12.5.1.2 Account Related Operations .............................. 12-10
12.5.1.3 Multivalued Operations .................................... 12-10
12.5.1.4 Other operations ............................................ 12-11
12.5.2 Provisioning Lookup ................................................ 12-11
12.5.3 Non-User Object Types ............................................ 12-12
12.5.4 Optional Lookups for Provisioning ............................ 12-12
12.5.4.1 Provisioning Validation Lookup ....................... 12-13
12.5.5 Optional Flags in Lookups for Provisioning Attribute Map ........................................... 12-13
12.5.6 Compound attributes in Provisioning Attribute Map .... 12-13
12.6 Concepts of Reconciliation in ICF Common ...................... 12-14
12.6.1 Types of Reconciliation .............................................. 12-14
12.6.1.1 Target and Trusted Reconciliation ....................... 12-14
12.6.1.2 Full, Incremental Reconciliation ........................ 12-15
12.6.1.3 Advanced Incremental Reconciliation ............... 12-15
12.6.1.4 Delete Reconciliation ..................................... 12-15
12.6.1.5 Group Lookup Reconciliation ............................ 12-15
12.6.2 List of Reconciliation Artifacts in Oracle Identity Manager .......................................... 12-15
12.6.2.1 Lookups for Reconciliation ................................ 12-16
12.7 Predefined Scheduled Tasks .......................................... 12-16
12.7.1 LookupReconTask ................................................. 12-17
12.7.2 SearchReconTask .................................................. 12-18
12.7.3 SearchReconDeleteTask ....................................... 12-18
12.7.4 SyncReconTask .................................................... 12-18
12.8 ICF Filter Syntax .......................................................... 12-19
# Using Java APIs for ICF Integration

## Configuring ICF Connectors

17  Predefined Providers for Generic Technology Connectors
17.1 Shared Drive Reconciliation Transport Provider ......................................................... 17-1
17.2 CSV Reconciliation Format Provider ........................................................................... 17-7
17.3 SPML Provisioning Format Provider ............................................................................ 17-7
17.3.1 Run-Time Parameters ............................................................................................. 17-9
17.3.2 Design Parameters .................................................................................................. 17-9
17.3.3 Nonmandatory Parameters ..................................................................................... 17-11
17.3.4 Parameters with Predetermined Values ..................................................................... 17-11
17.4 Web Services Provisioning Transport Provider ......................................................... 17-11
17.4.1 Configuring SSL Communication Between Oracle Identity Manager and the Target System Web Service 17-12
17.5 Transformation Providers ............................................................................................ 17-14
17.5.1 Concatenation Transformation Provider ................................................................. 17-15
17.5.2 Translation Transformation Provider ....................................................................... 17-16
17.5.2.1 Configuring Account Status Reconciliation ....................................................... 17-17
17.6 Validation Providers ..................................................................................................... 17-21

18  Creating Custom Providers for Generic Technology Connectors
18.1 Role of Providers ........................................................................................................... 18-1
18.1.1 Role of Providers During Generic Technology Connector Creation ......................... 18-1
18.1.2 Role of Providers During Reconciliation .................................................................. 18-3
18.1.3 Role of Providers During Provisioning ...................................................................... 18-5
18.2 Creating Custom Providers .......................................................................................... 18-7
18.2.1 Determining Provider Requirements ....................................................................... 18-8
18.2.1.1 Determining the Reconciliation Provider Requirements ....................................... 18-8
18.2.1.2 Determining the Provisioning Provider Requirements .......................................... 18-8
18.2.2 Identifying the Provider Parameters ........................................................................ 18-9
18.2.3 Developing Java Code Implementations of the Value Objects ................................ 18-9
18.2.4 Developing Java Code Implementations of the Provider SPI Methods .................... 18-10
18.2.5 Developing Java Code for Logging and Exception Handling .................................. 18-10
18.2.6 Creating the Provider XML File ............................................................................. 18-10
18.2.7 Creating Resource Bundle Entries for the Provider ............................................... 18-13
18.2.8 Deploying the Provider .......................................................................................... 18-14
18.3 Reusing Providers ....................................................................................................... 18-15
18.3.1 Reusing Reconciliation Providers ........................................................................... 18-15
18.3.2 Reusing Provisioning Providers ............................................................................. 18-16
18.4 Deploying the Custom Providers ................................................................................ 18-17

19  Creating and Managing Generic Technology Connectors
19.1 Overview ....................................................................................................................... 19-1
19.2 Creating Generic Technology Connectors ..................................................................... 19-1
19.2.1 Determining Provider Requirements ....................................................................... 19-2
19.2.2 Selecting the Providers to Include ........................................................................... 19-2
19.2.3 Addressing the Prerequisites .................................................................................. 19-2
19.2.4 Using Identity System Administration to Create the Connector ............................... 19-3
19.2.4.1 Step 1: Provide Basic Information Page ................................................................. 19-4
20 Troubleshooting Generic Technology Connectors

20.1 General Issues for Generic Technology Connectors .............................................. 20-1
20.1.1 Creation Issues ................................................................................................. 20-1
20.1.2 Multi-language Support .................................................................................. 20-3
20.1.3 Other General Issues ....................................................................................... 20-6
20.2 Configuration Issues for Generic Technology Connectors................................. 20-7
20.2.1 Names of Generic Technology Connectors and Connector Objects ............... 20-7
20.2.2 Step 3: Modify Connector Configuration Page ............................................... 20-8
20.2.3 Errors During Connector Creation .................................................................... 20-11
20.2.4 Errors During Reconciliation .......................................................................... 20-11
20.2.5 Errors During Provisioning ............................................................................. 20-13
21.8.1 Running Custom Code Based on Request Status Change ........................................ 21-51
21.8.2 Validating Request Data .......................................................................................... 21-51
21.8.2.1 Scenario I: Provisioning Users to a Target System ........................................ 21-53
21.8.2.2 Scenario II: Provisioning or Modifying Entitlement Request ............................ 21-53
21.8.3 Prepopulation of an Attribute Value During Request Creation ............................ 21-53
21.9 Enabling Auto-Approval for Self Registration Requests ........................................ 21-54

22 Using Segregation of Duties (SoD)

22.1 Understanding the SoD Validation Process ................................................................. 22-1
22.2 Introducing the SoD Invocation Library .................................................................... 22-2
22.3 Installing the SoD-enabled Connectors ................................................................. 22-4
22.4 Deploying the SIL and SIL Providers ...................................................................... 22-5
22.5 Configuring the SoD Engine ...................................................................................... 22-5
22.5.1 Configuring Oracle Application Access Controls Governor ............................. 22-5
22.5.2 Configuring SAP GRC ......................................................................................... 22-6
22.5.3 Configuring Oracle Identity Analytics ............................................................... 22-8
22.6 Enabling and Disabling SoD ..................................................................................... 22-8
22.6.1 Enabling SoD ......................................................................................................... 22-9
22.6.2 Disabling SoD ......................................................................................................... 22-10
22.7 Enabling SSL Communication ................................................................................. 22-10
22.7.1 Enabling SSL Between Oracle Application Access Controls Governor and Oracle Identity Manager ............................ 22-11
22.7.2 Enabling SSL Between SAP GRC and Oracle Identity Manager ....................... 22-12
22.7.3 Calling SoD Check Web Service Over SSL ....................................................... 22-12
22.8 Configuring Workflows on Non SoD-enabled Connectors .................................... 22-13
22.8.1 Modifying the Approval Workflow for SoD ....................................................... 22-13
22.8.2 Modifying the Provisioning Workflow for SoD .................................................. 22-25
22.9 Marking Child Process Form Tables That Hold Entitlement Data ............................ 22-29
22.10 Custom Combination of Target Systems and SoD Engines ................................. 22-29
22.10.1 Using a Custom Target System ........................................................................... 22-29
22.10.1.1 Addressing Prerequisites ............................................................................... 22-30
22.10.1.2 Creating the Transformation Layer ............................................................... 22-30
22.10.1.3 Deploying the Transformation Layer ............................................................. 22-30
22.10.1.4 Modifying the Registration XML File ............................................................ 22-31
22.10.1.5 Registering the New Target System ......................................................... 22-32
22.10.1.5.1 Running the Registration Script and Providing Registration Information ........ 22-32
22.10.1.5.2 Recording the Names of the System Types .............................................. 22-36
22.10.2 Adding Custom SoD Engine ............................................................................. 22-37
22.10.2.1 Addressing Prerequisites ............................................................................... 22-37
22.10.2.2 Creating an IT Resource to Hold Information about the SoD Engine .......... 22-37
22.10.2.3 Implementing the Service Components for the Provider .............................. 22-38
22.10.2.4 Deploying the Service Components .............................................................. 22-39
22.10.2.5 Modifying the Registration XML File for the New SoD Engine ................. 22-39
22.10.2.6 Registering the New SIL Provider ............................................................... 22-41
22.11 Performing Role SoD Check with Oracle Identity Analytics .................................. 22-41
22.11.1 Enabling Role SoD Check ..................................................................................... 22-41
Using Role SoD Check .......................................................... 22-42
SoD Check When A User Requests a Role ................................. 22-42
SoD Check When A User Revokes a Role .................................. 22-43
SoD Check When an Administrator Requests To Assign Roles .... 22-44
SoD Check When an Administrator Requests To Revoke Roles .... 22-45
Using SoD in Provisioning Workflow ........................................ 22-46
Provisioning Application Instance With Child Data ..................... 22-47
Modifying Application Instance to Add or Delete Child Data .......... 22-48
Provisioning Entitlements to a User ........................................... 22-49
Revoking Entitlements From a User ............................................ 22-49
Requesting for Roles and Entitlements ........................................ 22-49
Requesting for Roles and Application Instances With Child Data ... 22-49
Request Provisioning With the DefaultSODApproval Workflow .... 22-49
Requesting for Role With an Access Policy Attached .................... 22-50
Provisioning Based on Access Policies Without Approval .......... 22-50
Provisioning Based on Access Policies With Approval ................ 22-50
Requesting for Entitlements From Two Application Instances ....... 22-51
Enabling Logging for SoD-Related Events .................................. 22-51
Troubleshooting SoD Check..................................................... 22-51

Part V Data Synchronization

23 Customizing Reconciliation

23.1 Reconciliation Features ................................................... 23-1
Performance Enhancement Features ........................................... 23-1
New Metadata Model - Profiles ................................................ 23-2
Parameters to Control Flow and Processing of Events .................. 23-2
Grouping of Events by Reconciliation Runs ............................... 23-2
Grouping of Events by Batches ................................................. 23-3
Implementing Reconciliation Engine Logic in the Database .......... 23-3
Improved Java Engine .............................................................. 23-3
Improved Database Schema ..................................................... 23-3
Web-Based Event Management Interface ................................... 23-4
Other Features ........................................................................ 23-4
Staging Tables ........................................................................ 23-4
Handling of Race Conditions ................................................... 23-5
Ad Hoc Linking ....................................................................... 23-6
Reconciliation Architecture ...................................................... 23-6
Reconciliation Profile .............................................................. 23-8
Reconciliation Metadata .......................................................... 23-11
Reconciliation Target ............................................................... 23-12
Reconciliation Run .................................................................. 23-12
Reconciliation APIs ................................................................. 23-12
Reconciliation Schema ............................................................. 23-12
Reconciliation Engine ............................................................... 23-13
Matching Module .................................................................... 23-13
Action Module ........................................................................ 23-15
23.2.8 Connector for Reconciliation ................................................................. 23-16
23.2.9 Archival ............................................................................................... 23-17
23.2.10 Backward Compatibility ................................................................. 23-17
23.2.11 Reconciliation Event Management .................................................... 23-17
23.3 Defining Reconciliation Rules ............................................................... 23-18
  23.3.1 Defining a Reconciliation Rule .......................................................... 23-19
  23.3.2 Adding a Rule Element ................................................................. 23-20
  23.3.3 Nesting a Rule Within a Rule .......................................................... 23-22
  23.3.4 Deleting a Rule Element or Rule .................................................... 23-22
23.4 Developing Reconciliation Scheduled Tasks ........................................... 23-22
23.5 Updating Reconciliation Profiles Manually ............................................ 23-23
  23.5.1 Creating and Updating Reconciliation Profiles .................................. 23-24
  23.5.2 Changing the Profile Mode ............................................................ 23-24
  23.6 Understanding Reconciliation APIs ..................................................... 23-25
    23.6.1 The ReconOperationsService API .............................................. 23-26
    23.6.2 Invoking Non-scheduled Task-Based Reconciliation in a Multithreaded Environment .. 23-28
  23.7 Postprocessing for Trusted Reconciliation ............................................ 23-30
  23.8 Troubleshooting Reconciliation ............................................................ 23-30
    23.8.1 Troubleshooting General Reconciliation Issues ............................. 23-31
    23.8.2 Troubleshooting Database-Related Reconciliation Issues ............... 23-33
    23.8.3 Troubleshooting Reconciliation Profile Configuration Failures ........ 23-34
    23.8.4 Troubleshooting LDAP Reconciliation Issues ................................ 23-35
  23.9 Populating Data in the RECON_EXCEPTIONS Table ................................ 23-36
  23.10 Reconciliation Best Practices ............................................................. 23-37
    23.10.1 Additional Indexes Requirement for Matching Module .................. 23-37
    23.10.2 Collecting Database Schema Statistics for Reconciliation Performance ........................................ 23-39
    23.11 Monitoring Reconciliation Performance Using DMS ......................... 23-40

24 Using the Bulk Load Utility

  24.1 Features of the Bulk Load Utility .......................................................... 24-1
  24.2 Prerequisites for Running the Bulk Load Utility ..................................... 24-2
    24.2.1 Installing the Bulk Load Utility .................................................... 24-2
      24.2.1.1 Scripts That Constitute the Utility ........................................... 24-3
      24.2.1.2 Temporary Tables Used During a Bulk Load Operation .................. 24-3
      24.2.1.3 Options Offered by the Utility .............................................. 24-4
    24.2.2 Preparing Your Database for a Bulk Load Operation ......................... 24-5
      24.2.2.1 Creating a Tablespace for Temporary Tables .............................. 24-5
      24.2.2.2 Creating a Datafile in the Oracle Identity Manager Tablespace ........ 24-5
    24.3 Running the Utility .............................................................................. 24-6
    24.4 Performance Best Practices for Bulk Load .......................................... 24-7
    24.5 Loading OIM User Data ........................................................................ 24-7
      24.5.1 Setting a Default Password for OIM Users Added by the Utility .... 24-8
      24.5.2 Creating the Input Source for the Bulk Load Operation .................. 24-9
      24.5.2.1 Using CSV Files As the Input Source ...................................... 24-9
      24.5.2.2 Creating Database Tables As the Input Source .......................... 24-11
      24.5.3 Determining Values for the Input Parameters of the Utility ............ 24-12
Monitoring the Progress of the Operation ................................................................. 24-13
Handling Exceptions Recorded During the Operation .............................................. 24-13
Fixing Exceptions and Reloading Data Records ....................................................... 24-15
Verifying the Outcome of the Bulk Load Operation ................................................ 24-16
Generating an Audit Snapshot .................................................................................. 24-17
Creating Database Tables As the Input Source ....................................................... 24-20
Determining Values for the Input Parameters of the Utility .................................... 24-20
Monitoring the Progress of the Operation ............................................................... 24-22
Handling Exceptions Recorded During the Operation ............................................. 24-23
Fixing Exceptions and Reloading Data Records ...................................................... 24-24
Verifying the Outcome of the Bulk Load Operation ................................................ 24-25
Creating the Input Source for the Bulk Load Operation .......................................... 24-19
Using CSV Files As the Input Source ..................................................................... 24-19
Creating Database Tables As the Input Source ....................................................... 24-20
Determining Values for the Input Parameters of the Utility .................................... 24-20
Monitoring the Progress of the Operation ............................................................... 24-22
Handling Exceptions Recorded During the Operation ............................................. 24-23
Fixing Exceptions and Reloading Data Records ...................................................... 24-24
Verifying the Outcome of the Bulk Load Operation ................................................ 24-25
Loading Role, Role Hierarchy, Role Membership, and Role Category Data ............ 24-25
Using CSV Files As the Input Source ..................................................................... 24-26
Creating Database Tables As the Input Source ....................................................... 24-28
Determining the UGP_NAME Generated After Role Load ..................................... 24-28
Determining Values for the Input Parameters of the Utility .................................... 24-29
Monitoring the Progress of the Operation ............................................................... 24-30
Handling Exceptions Recorded During the Operation ............................................. 24-30
Fixing Exceptions and Reloading Data Records ...................................................... 24-31
Verifying the Outcome of the Bulk Load Operation ................................................ 24-32
Data Recorded During the Operation ..................................................................... 24-32
Gathering Diagnostic Data from the Bulk Load Operation .................................... 24-34
Cleaning Up After a Bulk Load Operation .............................................................. 24-35
Bulk Load High Volume Strategy and Case Studies ................................................ 24-35

25 Configuring LDAP Container Rules

26 Developing Scheduled Tasks

Overview of Task Creation ....................................................................................... 26-1
Steps in Task Creation ............................................................................................. 26-1
Example of Scheduled Task .................................................................................. 26-2
Defining the Metadata for the Scheduled Task ....................................................... 26-2
Configuring the Scheduled Task XML File ............................................................ 26-3
Developing the Scheduled Task Class ................................................................. 26-4
Configuring the Plug-in XML File .......................................................................... 26-4
Creating the Directory Structure for the Scheduled Task ...................................... 26-5
Scheduled Task Configuration File ......................................................................... 26-6
Structure of the Scheduler XML File ..................................................................... 26-6
The scheduledTasks Element .............................................................................. 26-7
The task Element ................................................................................................. 26-7
The name Element ............................................................................................... 26-8
The class Element ............................................................................................... 26-8
The description Element ...................................................................................... 26-9
Part VIII Interfaces to Integrate With Other Applications

31 Using APIs

31.1 Accessing Oracle Identity Manager Services ......................................................... 31-1
31.1.1 Using OIMClient ............................................................................................... 31-1
31.1.2 Using the tcUtilityFactory ............................................................................... 31-2
31.1.3 Using OIMClient and tcUtilityFactory in Integrated Deployments ............... 31-2
32 Using SPML Services

32.1 Introduction ........................................................................................................... 32-2
32.1.1 About SPML Interactions .................................................................................. 32-2
32.1.2 Integration Interface ......................................................................................... 32-2
32.2 General Considerations ......................................................................................... 32-3
32.2.1 Assigning SPML Admin Role to the User .......................................................... 32-3
32.2.2 Creating Autoapproval Policies ........................................................................ 32-4
32.3 Create Identity (SPML Core Service: addRequest) .............................................. 32-5
32.4 Modify Users, Roles, Change Attributes and Role Memberships (SPML Core Service: modifyRequest) 32-6
32.5 Delete an Identity or Role (SPML Core Service: deleteRequest) ......................... 32-7
32.6 Check Request Status (SPML Core Service: statusRequest) ............................. 32-7
32.7 List Available Targets (SPML Core Service: listTargets) .................................... 32-8
32.8 Disable a User (SPML Suspend Service: suspendRequest) ............................... 32-8
32.9 Enable a User (SPML Suspend Service: resumeRequest) ..................................... 32-9
32.10 Check if User is Active (SPML Suspend Service: activeRequest) ...................... 32-9
32.11 Validate a Username (SPML Username Service: validateUsername) ............... 32-10
32.12 Obtain a Username (SPML Username: suggestUsername) ............................... 32-10
32.13 Lookup an Identity or Role (SPML Core Service: lookupRequest) .................... 32-10
32.14 Reset Password (SPML Core Service: resetPasswordRequest) ......................... 32-12
32.15 Lookup Username Policy (SPML Username Service: lookupUsernamePolicy) ... 32-13
32.16 Cancel/Withdraw Request (SPML Async Service: cancelRequest) ..................... 32-13
32.17 Batch Request (SPML Batch Request Service: batchRequest) ......................... 32-14
32.18 Securing SPML Web Services ............................................................................. 32-14
32.18.1 About Web Services Security ......................................................................... 32-14
32.18.2 A Request Example ...................................................................................... 32-15
32.18.3 Applying Policies ......................................................................................... 32-15
32.19 Operations Not Supported .................................................................................. 32-15
32.20 SPML Attributes and LDAP Mappings, and Oracle Identity Manage Attributes ...... 32-16
32.20.1 Identity PSO Attributes....................................................................................... 32-16
32.20.1.1 Custom Identity Attributes .............................................................................. 32-19
32.20.2 Role PSO Attributes............................................................................................ 32-19
32.20.2.1 Custom Role Attributes .................................................................................. 32-20
32.20.3 Preference Attributes.......................................................................................... 32-20
32.20.4 Special Character Restrictions in Oracle Identity Manage Attributes .............. 32-25
32.20.4.1 Characters Available in All Attributes............................................................. 32-25
32.20.4.2 Special Characters in the Password Field ......................................................... 32-25
32.20.4.3 Usage of Single Quotation Mark ..................................................................... 32-25
32.20.4.4 Usage of Semicolon ....................................................................................... 32-26
32.20.4.5 Unsupported Special Characters ..................................................................... 32-26
32.20.5 Operation Data.................................................................................................... 32-26
32.20.5.1 Passing Operation Data .................................................................................. 32-26
32.20.5.2 Passing Reference Data .................................................................................. 32-27
32.21 SPML Examples .................................................................................................... 32-27
32.21.1 SPML Example - Add User ................................................................................ 32-28
32.21.2 SPML Example - Delete User .......................................................................... 32-32
32.21.3 SPML Example - Modify User .......................................................................... 32-32
32.21.4 SPML Example - Resume User ......................................................................... 32-33
32.21.5 SPML Example - Suggest User Name ............................................................... 32-34
32.21.6 SPML Example - Suspend User ........................................................................ 32-34
32.21.7 SPML Example - Validate User Name ............................................................... 32-35
32.21.8 SPML Example - Check If User is Active ........................................................... 32-35
32.21.9 SPML Example - Lookup Username Policy ...................................................... 32-35
32.21.10 SPML Example - Add User with Role Assignment ........................................... 32-36
32.21.11 SPML Example - Assign Role Membership ...................................................... 32-38
32.21.12 SPML Example - Revoke Role Membership ..................................................... 32-38
32.21.13 SPML Example - Add Role .............................................................................. 32-39
32.21.14 SPML Example - Add Role with Parent ........................................................... 32-40
32.21.15 SPML Example - Modify Role .......................................................................... 32-41
32.21.16 SPML Example - Add Parent to a Role ............................................................ 32-41
32.21.17 SPML Example - Role Grant ........................................................................... 32-42
32.21.18 SPML Example - Delete Role ......................................................................... 32-43
32.21.19 SPML Example - Status Request ..................................................................... 32-43
32.21.20 SPML Example - Identity/Role Lookup ............................................................ 32-46
32.21.21 SPML Example - Reset Password .................................................................... 32-49
32.21.22 SPML Example - Reset Password with Notification ....................................... 32-50
32.21.23 SPML Example - Lookup User Name Policy ..................................................... 32-51
32.21.24 SPML Example - Cancel Request ..................................................................... 32-51
32.21.25 SPML Example - Batch Request ...................................................................... 32-52

33 Using URLs

Part IX Notification Service
34 Developing Notification Events
34.1 Notification Concepts................................................................. 34-1
34.2 Developing Custom Notification.............................................. 34-2
34.2.1 Building the Notification Logic ........................................ 34-2
34.2.1.1 Defining Event Metadata.................................................. 34-2
34.2.1.2 Creating the Resolver Class ............................................ 34-4
34.2.1.3 Creating the plugin.xml File .......................................... 34-6
34.2.2 Creating Plug-in Pack Containing the Resolver Class .......... 34-6
34.2.3 Building the Invocation Logic............................................ 34-6
34.2.4 Configuring the Notification Service .............................. 34-7

35 Using the Callback Service
35.1 Introducing the Callback Service............................................ 35-1
35.1.1 Using Callbacks............................................................... 35-2
35.1.2 Understanding Event Processing..................................... 35-3
35.1.3 Retrying Callbacks......................................................... 35-4
35.2 Mapping Oracle Identity Manager Attributes....................... 35-4
35.3 Sending Event Callbacks..................................................... 35-6
35.4 Configuring the Callback Service....................................... 35-8
35.4.1 Understanding CallbackConfiguration.xml..................... 35-8
35.4.2 Importing CallbackConfiguration.xml............................ 35-12
35.4.3 Adding the OIM.DefaultTenantGUID System Property........ 35-13
35.5 Troubleshooting the Callback Service.............................. 35-13

Part X Customization Lifecycle

36 Understanding Customization Types

37 Deploying and Undeploying Customizations
37.1 Migrating User Modifiable Metadata Files......................... 37-1
37.1.1 Exporting Metadata Files to MDS................................. 37-1
37.1.2 Importing Metadata Files from MDS............................ 37-2
37.1.3 Deleting Metadata Files from MDS............................. 37-2
37.1.4 User Modifiable Metadata Files.................................. 37-2
37.1.5 Creating MDS Backup.................................................. 37-3
37.1.6 Exporting All MDS Data for Oracle Identity Manager........ 37-4
37.2 Migrating JARs and Resource Bundle............................... 37-5
37.2.1 Upload JAR Utility........................................................ 37-7
37.2.2 Download JAR Utility.................................................... 37-7
37.2.3 Delete JAR Utility........................................................ 37-8
37.2.4 Upload Resource Bundle Utility................................. 37-8
37.2.5 Download Resource Bundle Utility............................ 37-8
37.2.6 Delete Resource Bundle Utility................................. 37-9

The *Oracle Fusion Middleware Developer’s Guide for Oracle Identity Manager* describes how to develop and customize various components and features of Oracle Identity Manager.

**Audience**

This guide is intended for developers who use Oracle Identity Manager development tools to customize the product according to the requirements of an organization. The customization involves using APIs, configuring requests and approval workflows, developing connectors by using Identity Connector Framework, Generic Technology Connector, or Adapter Factory, and customizing the user interface.

**Documentation Accessibility**

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

**Access to Oracle Support**

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

This part provides concepts related to Oracle Identity Manager architecture and security.

It contains the following chapters:

- Chapter 1, "Product Overview"
- Chapter 2, "Product Architecture"
- Chapter 3, "Security Architecture"
Oracle Identity Manager is an enterprise identity management system that manages user’s access privileges in enterprise IT resources by controlling users, roles, accounts, and entitlements. It provides the functionalities for provisioning, identity and role administration, approval and request management, policy-based entitlement management, technology integration, and audit and compliance automation. Oracle Identity Manager is designed to administer intranet as well as extranet users, roles, and organizational access privileges across a company’s resources throughout the entire identity management life cycle.

Oracle Identity Manager platform automates access rights management, security, and provisioning of IT resources. It connects users to resources, and revokes and restricts unauthorized access to protect sensitive corporate information.

This chapter contains the following sections:

- Key Features and Benefits
- System Requirements and Certification

### 1.1 Key Features and Benefits

Oracle Identity Manager architecture is flexible and scalable, and provides the following features:

- Ease of Deployment
- Simplified UI Customization
- Simplified Configuration
- Flexibility and Resilience
- Maximum Reuse of Existing Infrastructure
- Extensive User Management
- Web-Based User Self-Service
- Modular and Scalable Architecture
- Based on Leading Software Development Standards
- Powerful and Flexible Process Engine
- Built-In Change Management
- Workflow and Policy
Key Features and Benefits

- Audit and Compliance Management
- Integration Solutions
- User Provisioning

1.1.1 Ease of Deployment

Oracle Identity Manager provides a flexible Deployment Manager utility to assist in the migration of integration and configuration information between environments. The utility exports integration and configuration information as XML files. These files are then imported into the destination environment, which can be staging or production. You can use the XML files to archive configurations and maintain versions, as well as replicate integrations.

The Deployment Manager provides you with the flexibility to select what to import and export. It also helps you to identify data object dependencies during both import and export steps. This flexibility enables you to merge integration work done by multiple people and to ensure the integrity of any migration.

1.1.2 Simplified UI Customization

Oracle Identity Manager provides a browser-based customization framework that does not require writing codes or relying on developers. The interface is based on Application Development Framework (ADF), which ensures that all customizations are consistent and safe from upgrades and patches. The browser-based customization can be performed by using the Oracle Web Composer.

Oracle Identity Manager also provides business-friendly user personalization by enabling users to save and reuse frequently-searched items, configure columns in the search results table, and sort and filter data.

1.1.3 Simplified Configuration

Oracle Identity Manager abstracts and simplifies the configuration complexities through a business user-friendly extension framework for all entities. This allows users to extend the user, role, organization, catalog, and resource schemas by using the Form Designer. In addition, Web browser-based management of disconnected applications is allowed instead of cumbersome configuration in the Design Console. The SOA Tasklist embedded in Oracle Identity Manager simplifies disconnected application fulfillment, in which the provisioning of a disconnected resource is performed manually. To do so, SOA Tasklist leverages additional features of the SOA Tasklist, such as reassign or suspend manual application fulfillment.

1.1.4 Flexibility and Resilience

You can deploy Oracle Identity Manager in single or multiple server instances. Multiple server instances provide optimal configuration options, supporting geographically dispersed users and resources for increased flexibility, performance, and control. The Java 2 Enterprise Edition (J2EE) application server model of Oracle Identity Manager also provides scalability, fault tolerance, redundancy, failover, and system load balancing. As deployments grow, moving from a single server to a multiserver implementation is a seamless operation.
1.1.5 Maximum Reuse of Existing Infrastructure

To lower cost, minimize complexity, and leverage existing investments, Oracle Identity Manager is built on an open architecture. This allows Oracle Identity Manager to integrate with and leverage existing software and middleware already implemented within the IT infrastructure of an organization. For example, if an implementation requires integrating with an existing customer portal, then the advanced APIs of Oracle Identity Manager offer programmatic access to a comprehensive set of system functions. This allows IT staff to customize any part of its Oracle Identity Manager provisioning implementation to meet the specific needs of the organization.

1.1.6 Extensive User Management

Oracle Identity Manager enables you to define unlimited user organizational hierarchies and roles. It supports inheritance, customizable user ID policy management, password policy management, and user access policies that reflect customers’ changing business needs. It also helps you to manage application parameters and entitlements, and to view a history of resource allocations. In addition, it provides delegated administration with comprehensive permission settings for user management.

Oracle Identity Manager contains a Web-based customizable Oracle Identity Manager Self Service that helps you extensively in user management.

1.1.7 Web-Based User Self-Service

Oracle Identity Manager contains a customizable Web-based, user self-service portal. This portal enables management of user information, self registration, changing passwords, resetting forgotten passwords, retrieving forgotten user login, requesting available applications, reviewing and editing available entitlements, and initiating or reacting to workflow tasks.

1.1.8 Modular and Scalable Architecture

Oracle Identity Manager is built on Java EE architecture. The J2EE application server model of Oracle Identity Manager provides scalability, fail over, load-balancing, and Web deployment. It is based on an open, standards-based technology and has a three-tier architecture (the client application, an Oracle Identity Manager supported J2EE-compliant Application Server, and an ANSI SQL-compliant database). Oracle Identity Manager can provision LDAP-enabled and non-LDAP-enabled applications. Java EE is a standard, robust, scalable, and secure platform that forms the basis for many enterprise applications. Oracle Identity Manager runs on leading Java EE compliant application server platforms, including Oracle WebLogic, to take advantage of the performance and scalability features inherent in these servers. Java EE defines a set of standardized, modular components, provides a complete set of services to those components, and handles many details of the application behavior.

The application server, on which Oracle Identity Manager runs, provides the life-cycle management, security, deployment, and run-time services to the logical components that constitute the Oracle Identity Manager application. These services include:

- **Scalable management of resources through clustering and failover:** A cluster in Java EE architecture is defined as a group of two or more Java EE compliant Web or application servers that cooperate with each other through transparent object replication mechanisms to ensure that each server in the group presents the same content. Each server or node in the cluster is identical in configuration and acts as a single virtual server. Any Java EE server in the cluster can handle client requests
directed to this virtual server independently, which gives the impression of a single entity hosting the Java EE application in the cluster.

High availability refers to the capability to ensure that applications hosted in the middle tier remain consistently accessible and operational to the clients. This is achieved through the redundancy of multiple Web and application servers within the cluster, and is implemented by the failover mechanisms of the cluster. If an application component fails to process its task, then the cluster’s failover mechanism reroutes the task and any supporting information to a copy of the object on another server to continue the task. Oracle Identity Manager supports a clustered environment. This includes ensuring that the EJBs and the Value Objects used to store data support serialization for the object replication to work.

- **Transaction management through load balancing:** Load balancing refers to the capability to optimally partition inbound client processing requests across all the Java EE servers that constitute a cluster based on certain factors, such as capacity, availability, response time, current load, historical performance, and administrative priorities placed on the clustered servers. A load balancer, which can be based on software or hardware, sits between the Internet and the physical server cluster, acting as a virtual server. When each client request arrives, the load balancer decides how the Java EE server satisfies that request.

- **Security management:** Oracle Identity Manager architecture relies on the application server for certain security services as part of its overall security infrastructure. In addition, Oracle Identity Manager leverages the Java EE security framework to provide a secure application environment. It also has a flexible permission model to provide control over the various functions within the application.

- **Messaging:** The basic concept behind messaging is that distributed applications can communicate by using a self-contained package of business data and routing headers. These packages are called messages. While RMI and HTTP rely on a two-way active communication between a client and a server, messaging relies on two or more interested parties communicating asynchronously through a messaging server without waiting for a response. Java Messaging Service (JMS) is a wrapper API incorporated in the J2EE standard as a way to standardize messaging functionality. All standard application servers provide their own JMS server implementations as a part of their service offerings.

### 1.1.9 Based on Leading Software Development Standards

Oracle Identity Manager incorporates leading industry standards. For example, Oracle Identity Manager components are fully based on a J2EE architecture, so customers can run them from within their standard application server environments. Complete J2EE support results in performance and scalability benefits while aligning with existing customer environments to leverage in-house expertise.

Oracle develops its identity management products on a foundation of current and emerging standards. For example, Oracle is a Management Board member of Liberty Alliance, and incorporates Liberty Alliance developments in its solutions. Oracle participates in the Provisioning Services Technical Committee (PSTC), which operates under the auspices of the Organization for the Advancement of Structured Information Standards (OASIS).

### 1.1.10 Powerful and Flexible Process Engine

With Oracle Identity Manager, you can create business and provisioning process models in easy-to-use applications. Process models include support for approval
workflows and escalations. You can track the progress of each provisioning event, including the current status of the event and error code support. Oracle Identity Manager supports complex, branching, and nested processes with data interchange and dependencies. The process flow is fully customizable and does not require programming.

1.1.11 Built-In Change Management

Oracle Identity Manager enables you to package new processes, import and export existing ones, and move packages from one system to another.

1.1.12 Workflow and Policy

The use of workflow and policy to automate business and IT processes can lead to improved operational efficiency, enhanced security, and more cost-effective compliance tracking. Oracle Identity Manager provides the following features in this category.

Policy Management

Oracle Identity Manager enables policy-based automated provisioning of resources with fine-grained entitlements. For any set of users, administrators can specify access levels for each resource to be provisioned, granting each user only the exact level of access required to complete the job. These policies can be driven by user roles or attributes, enabling implementation of role-based access control as well as attribute-based access control. Effective blending of role-based and attribute-based policies is key to a scalable and manageable organization provisioning solution.

A request goes through multiple approvals before it is executed. When the request is submitted, it must acquire approvals at different levels. An approval in the system can be configured by using an approval policy. An approval policy defines the approval process to be invoked and the approval rules associated with the policy. These approval rules help the request engine to select the approval process. Business analysts can define approval policies and approval rules.

Workflow Management

Oracle Identity Manager supports the separation of approval and provisioning workflows. An approval workflow enables an organization to model its preferred approval processes for managing resource access requests. A provisioning workflow enables an organization to automate IT tasks for provisioning resources with the most complex of provisioning procedures.

The separation of these two workflows empowers business and IT process owners to manage work efficiently with minimum cross-process interferences. It also enables an organization to leverage existing workflows already deployed in systems such as a help desk and HRMS. Oracle Identity Manager provides the Workflow Visualizer that allows business users, administrators, and auditors to visualize task sequences and dependencies to understand process flow and the Workflow Designer to edit and manage the process flow.

Dynamic Error Handling

The error-handling capability of Oracle Identity Manager enables you to handle exceptions that occur during provisioning. Frequent problems, for example, absence of resources, do not stop the entire provisioning transaction or cause it to fail. Business logic defined within the provisioning workflow offers customized fail-safe capabilities within an Oracle Identity Manager implementation.
**Transaction Integrity**
Based on embedded state management capabilities, Oracle Identity Manager provides the high level of transaction integrity required by other mission-critical organization systems. Oracle Identity Manager features a state engine with rollback and recovery capabilities. When a provisioning transaction fails or is stopped, the system is able to recover and roll back to the last successful state or reroute to a different path, in accordance with predefined rules.

**Real-Time Request Tracking**
To maintain better control and provide improved visibility into all provisioning processes, Oracle Identity Manager enables users and administrators to track request status in real time, at any point during a provisioning transaction.

### 1.1.13 Audit and Compliance Management
Identity management forms a key component in any audit compliance solution of an organization. Oracle Identity Manager helps an organization to minimize risk and reduces the cost of meeting internal and external governance and security audits. This section discusses the features of Oracle Identity Manager that are listed in the audit and compliance management category.

**Identity Reconciliation**
Reconciliation is one of the significant capabilities of Oracle Identity Manager that enables it to monitor and track the creation, updation, and deletion of account across all managed resources. The process of reconciliation is performed by the reconciliation engine. If Oracle Identity Manager detects any accounts or changes to user access privileges are affected beyond its control, then the reconciliation engine can immediately take corrective action, such as undo the change or notify you. Oracle Identity Manager also helps you to detect and map existing accounts in target resources. This helps in the creation of an organization-wide identity and access profile for each employee, partner, or customer user.

**Rogue and Orphan Account Management**
A *rogue account* is an account created "out of process" or beyond the control of the provisioning system. An *orphan account* is an operational account without a valid owner. These accounts represent serious security risks to an organization. Oracle Identity Manager can monitor rogue and orphan accounts continuously. By combining denial access policies, workflows, and reconciliation, an organization can perform the required corrective actions when such accounts are discovered, in accordance with security and governance policies.

**Service Accounts**
Oracle Identity Manager can also manage the life cycle of special *service accounts*, also known as administrator accounts. These accounts have special life cycle requirements that extend beyond the life cycle of an assigned user and across the life cycles of multiple assigned users. Proper management of service accounts can help to eliminate another source of potential orphan accounts.

**Comprehensive Reporting and Auditing**
Oracle Identity Manager reports on both the history and the current state of the provisioning environment. Some of the identity data captured by Oracle Identity Manager includes user identity profile history, role membership history, user resource access, and fine-grained entitlement history. Oracle Identity Manager also captures
data generated by its workflow, policy, and reconciliation engines. By combining this data along with identity data, an organization has all the required data to address any identity and access-related audit inquiry.

Attestation

Attestation, also referred to as recertification, is a key part of Sarbanes-Oxley compliance and a highly recommended security best practice. Organizations meet these attestation requirements mostly through manual processes based on spreadsheet reports and e-mails. These manual processes tend to be fragmented, are difficult and expensive to manage, and have little data integrity and auditability.

Oracle Identity Manager offers an attestation feature that can be deployed quickly to enable an organization-wide attestation process that provides automated report generation, delivery, and notification. Attestation reviewers can review fine-grained access reports within an interactive user interface that supports fine-grained certify, reject, decline, and delegate actions. All report data and reviewer actions are captured for future auditing needs. Reviewer actions can optionally trigger corrective action by configuring the workflow engine of Oracle Identity Manager.

Note: The attestation feature has been deprecated in Oracle Identity Manager 11g Release 2 (11.1.2.2.0). Attestation has been replaced by identity certification. See the following sections for information about identity certification:

- "Managing Tasks" and "Using Identity Certification" in the Oracle Fusion Middleware User’s Guide for Oracle Identity Manager
- "Managing Identity Certification" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager

However, the attestation feature is available if you upgrade from Oracle Identity Manager Release 9.x or 11g Release 1 (11.1.1) or 11g Release 2 (11.1.2).

Identity Certification

Identity certification enables Oracle Identity Manager to offer the following features in a single product:

- Access-request: Request privileges from a catalog, obtain approvals
- Fulfillment: Automated or manual provisioning
- Access-review: Certification of entities in Oracle Identity Manager

Identity certification also provides the following:

- Delegation of individual line-items within a certification allows a reviewer to spread the work among several people (who can work in parallel). This allows users who are responsible for reviewing access within an enterprise to spread the workload, and complete the work quickly.

- Two-phased review allows a single certification to combine the two key perspectives that inform access-review, which are:
  - The business reviewer, typically a Line-of-Business (LOB) manager
  - A technical reviewer, typically an IT expert or an application owner
1.1.14 Integration Solutions

A scalable and flexible integration architecture is critical for the successful deployment of organization provisioning solutions. Oracle Identity Manager offers a proven integration architecture and predefined connectors for fast and low-cost deployments.

**Adapter Factory**

Integrating most provisioning systems with managed resources is not easy. Connecting to proprietary systems might be difficult. The Adapter Factory eliminates the complexity associated with creating and maintaining these connections. The Adapter Factory provided by Oracle Identity Manager is a code-generation tool that enables you to create Java classes.

The Adapter Factory provides rapid integration with commercial or custom systems. Users can create or modify integrations by using the graphical user interface of the Adapter Factory, without programming or scripting. When connectors are created, Oracle Identity Manager repository maintains their definitions, creating self-documenting views. You use these views to extend, maintain, and upgrade connectors.

**Predefined Connectors**

Oracle Identity Manager offers an extensive library of predefined connectors for commercial applications and other identity-aware systems that are used widely. By using these connectors, an organization can get a head start on application integration. Each connector supports a wide range of identity management functions. These connectors use the most appropriate integration technology recommended for the target resource, whether it is proprietary or based on open standards. These connectors enable out-of-the-box integration between a set of heterogeneous target systems and Oracle Identity Manager. Because the connectors provide a set of components that were originally developed by using the Adapter Factory, you can further modify them with the Adapter Factory to enable the unique integration requirements of each organization.

**Generic Technology Connectors**

If you do not need the customization features of the Adapter Factory to create your custom connector, you can use the Generic Technology Connector (GTC) feature of Oracle Identity Manager to create the connector.

**Identity Connectors**

The Identity Connector Framework (ICF) decouples the connectors from Oracle Identity Manager. As a result, connectors can be used with any product. Identity connectors are designed to separate the implementation of an application from the dependencies of the system that the application is attempting to connect to.

1.1.15 User Provisioning

Provisioning provides outward flow of user information from Oracle Identity Manager to a target system. Provisioning is the process by which an action to create, modify, or delete user information in a resource is started from Oracle Identity Manager and passed into the resource. The provisioning system communicates with the resource and specifies changes to be made to the account.

Provisioning includes the following:

- Automated user identity and account provisioning: This manages user identities and accounts in multiple systems and applications. For example, when an
employee working in the payroll department is created in the human resources system, accounts are also automatically created for this user in the e-mail, telephone, accounting, and payroll reports systems.

- Workflow and policy management: This enables identity provisioning. Administrators can use interfaces provided by provisioning tools to create provisioning processes based on security policies.

- Reporting and auditing: This enables creating documentation of provisioning processes and their enforcement. This documentation is essential for audit, regulatory, and compliance purposes.

- Attestation: This enables administrators to confirm users’ access rights on a periodic basis.

- Access deprovisioning: When the access for a user is no longer required or valid in an organization, Oracle Identity Manager revokes access on demand or automatically, as dictated by role or attribute-based access policies. This ensures that a user's access is promptly terminated where it is no longer required. This is done to minimize security risks and prevent paying for access to costly resources, such as data services.

### 1.2 System Requirements and Certification

Before deploying and using Oracle Identity Manager, you must ensure that your environment meets the minimum installation requirements.

The following URL contains information about supported installation types, platforms, operating systems, databases, JDKs, and third-party products for Oracle Fusion Middleware:

The architecture of Oracle Identity Manager provides a number of compelling technical benefits for deploying a provisioning solution as part of identity and access management. Oracle Identity Manager has a flexible architecture that can handle IT and business requirements without requiring changes to existing infrastructure, policies, or procedures.

Oracle Identity Manager architecture is described in the following sections:

- How Oracle Identity Manager Works: The Tiers of Oracle Identity Manager
- System Components

### 2.1 How Oracle Identity Manager Works: The Tiers of Oracle Identity Manager

Oracle Identity Manager is based on the n-tier J2EE application architecture. Oracle Identity Manager architecture contains the following tiers:

- **Presentation Tier**
- **Business Services Tier**
- **Middleware Tier**
- **The Data Tier**

*Figure 2–1 illustrates Oracle Identity Manager architecture.*
2.1.1 Presentation Tier

The Presentation tier consists of three clients: Oracle Identity Self Service, Oracle Identity System Administration, and Oracle Identity Manager Design Console.

Oracle Identity Self Service is a Web-based thin client that can be accessed from any Web browser. This Web client provides user self-service and delegated administration features in a single interface that serve most of the users of Oracle Identity Manager.

Oracle Identity System Administration is a Web-based thin client that provides administrative and system management functions.

Oracle Identity Manager Design Console provides system configuration and development capabilities, including form, workflow design, and adapter creation and management. The Design Console is implemented as a Java Swing client that communicates directly with the Business Services layer in the application. You can access Oracle Identity Manager Design Console by using a desktop Java client.

Oracle Identity Manager interfaces support a highly sophisticated delegated administration model, guaranteeing that users can only work on those parts of the application configuration for which they are authorized.

In many enterprises, there is a requirement for the provisioning system to support a custom developed client. Some of the requirements that drive this are:

- Integration of the client into an existing enterprise portal and adherence to enterprise portal standards
- Creation of custom flows for user interaction
- Creation of custom pages built around unique requirements from the provisioning system

To support customization, Oracle Identity Manager exposes the bulk of the necessary functionality via its published public APIs. The client environment for Oracle Identity Manager is customizable via Java APIs.

2.1.2 Business Services Tier

The Business Services Tier is implemented as an Enterprise JavaBeans (EJB) application. The core functionality for Oracle Identity Manager platform is
implemented in Java using a highly modular, object-oriented methodology. This makes Oracle Identity Manager flexible and extensible. The Business Services Tier for Oracle Identity Manager includes the following services and capabilities:

- The Core Services that comprise the core of the business features offered by Oracle Identity Manager, such as the User Management Service, the Policy Management Services, and the Provisioning and Reconciliation Services.

- The API Services that describe the APIs supported by Oracle Identity Manager that allow custom clients to integrate with Oracle Identity Manager. This includes a rich set of APIs that expose the business functionality of Oracle Identity Manager for use by custom clients, in product customization, and in plug-in and adapter development.

- The Integration Services based on the Adapter Factory and Connector Framework, which dynamically generates integration code based on the metadata definition of the adapters.

- The Platform Services that are crucial to the business features offered by Oracle Identity Manager, such as the Request Management Service, the Entity Manager Service, and the Scheduler Service.

The Business Services Tier is described in the following sections:

- The API Services
- Integration Services
- Platform Services

2.1.2.1 The API Services

The API Services describe the APIs supported by Oracle Identity Manager that allow custom clients to integrate with Oracle Identity Manager. This includes a rich set of APIs that expose the business functionality of Oracle Identity Manager for use by custom clients, in product customization, and in plug-in and adapter development.

The API Services consist of:

- **SPML APIs**: Service Provisioning Markup Language (SPML) is a standard for managing the provisioning and allocation of identity information and system resources within and between organizations. Oracle Identity Manager supports a set of SPML-based Web services that expose identity administration functionality to the clients. The APIs provide support for:
  - Adding, modifying, and deleting identities
  - Adding, modifying, and deleting roles
  - Adding and deleting role memberships

These APIs support requests coming into Oracle Identity Manager for administration purposes, which is distinct and separate from SPML as the protocol used to integrate with provisioning targets.

- **EJB APIs**: Highly granular access to the functionality of the platform is via a set of EJB. These session beans are the basis for functionality implemented in Oracle Identity Manager Web application clients. It is also the interface that custom clients can use to access Oracle Identity Manager capabilities.
2.1.2.2 Integration Services

A scalable and flexible integration architecture is critical for the successful deployment of provisioning solutions. Oracle Identity Manager offers an integration architecture for fast and low-cost deployments.

Oracle Identity Manager integration services provide all the components required to support the development, deployment, and maintenance of connectors. The integration services includes:

- Connector Framework
- Identity Connectors
- Adapter Factory
- Generic Technology Connector
- Remote Manager

2.1.2.2.1 Connector Framework

Oracle Identity Manager connectors are packaged solutions that are used to integrate with target applications for the purposes of managing identities in those applications. Examples of such target applications are Microsoft Active Directory or Oracle E-Business Suite. A connector can be predefined by Oracle for particular target systems or can be custom developed.

Because a predefined connector is designed specifically for the target application, it offers the quickest integration method. These connectors support popular business applications such as Oracle eBusiness Suite, PeopleSoft, Siebel, JD Edward and SAP, as well as technology applications such as Active Directory, Java Directory Server, UNIX, databases, and RSA ClearTrust. Predefined connectors offer the quickest integration alternative because they are designed specifically for the target application. They use integration technologies recommended by target and are preconfigured with application specific attributes.

If predefined connectors does not use integration technologies recommended by target, then a custom connector can be developed. The Adapter Factory tool in Oracle Identity Manager Design Console provides a definitional user interface that facilitates such custom development efforts without coding or scripting.

A connector contains:

- Multiple connector-specific Oracle Identity Manager entities such as resource objects, data forms, provisioning workflows, and adapters
- Target-specific Java libraries that provide the underlying functions such as connectivity, authentication and user account management
- Event triggers that wire provisioning operations to both identity profile changes and policy operations

The connector framework combines all of these components together into a functional connector that is run at appropriate times, either manually based on user interaction or based on system triggering. It defines the various operational triggers, policy triggers, and hooks that allow the connector operation to be tailored to specific requirements.

2.1.2.2 Identity Connectors

Connectors are deployed with Oracle Identity Manager, which affects the portability of the connectors across various Oracle Identity Manager releases. The Identity Connector Framework (ICF) decouples the connectors from Oracle Identity Manager.
As a result, connectors can be used with any product. Identity connectors are designed to separate the implementation of an application from the dependencies of the system that the application is attempting to connect to.

Identity connectors have the following components:

- **The identity connector framework**: Provides a container that separates the connector bundle from the application. The framework provides many common features that developers would otherwise need to implement on their own. For example, the framework can provide connection pooling, buffering, timeouts, and filtering. The identity connector framework is separated into two parts:
  - The API: Applications use the API to call connectors
  - The SPI: Developers can create connectors by implementing the SPI

- **Identity connector bundle**: The specific implementation for a given resource target

- **The connector server (optional)**: Allows an application to remotely run one or more connector bundles that are deployed on another system. Connector servers are available in both Java™ and .NET. The .NET connector server is needed only if you are using .NET connector bundles, whereas the Java connector server is available for connector bundles written in Java.

Figure 2–2 shows the ICF architecture.

**Figure 2–2  ICF Architecture**

Connector SPI

Connector SPI interfaces represent operations supported on a connector. A connector developer can choose to implement one or more operation interfaces for framing target system calls. Extension on existing interfaces or creating new interfaces is not supported. The SPI is broken up into required interfaces, feature-based interfaces, and operation interfaces such as create, update, delete, and search.
The required interfaces include the org.identityconnectors.framework.spi.Connector interface and the org.identityconnectors.framework.spi.Configuration interface. These interfaces must be implemented in order for the API to understand which class contains the implementation of the configuration and which contains the implementation of the operations.

The feature-based interfaces are the org.identityconnectors.framework.spi.AttributeNormalizer and org.identityconnectors.framework.spi.PoolableConnector interfaces.

The operation interfaces determine the features that the connector supports such as create, delete, or search. See Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for details.

**Connector API**

The connector API is responsible for presenting a consistent view of a connector regardless of the operations it has implemented. For the convenience of the SPI developer, there are several common features that are provided by default. For most of these features there is no need for the application developer to handle the APIs, only configure them. Following is a list of API features:

- Provide connection pooling to those connectors that require it and avoid the need for the API to see it, because not all connectors have connections. In addition, if the connector uses connection pooling, it is not the responsibility of the API developer to handle the connections, nor dispose of them during error conditions.

- Provide timeouts to all operations. The API consumer should only configure the appropriate timeout if the default is unacceptable. Each SPI developer should not have to implement such a common service and, for this reason, it is implemented in the framework.

- Provide search filtering by way of a simple interface that accepts a large variety of filters. The connector developer only needs to implement whichever filters the resource natively supports. The rest is handled by the framework.

- Provide search/sync buffering, allowing queries and updates to be handled in chunks if need be. The application need not worry about this, as it is handled within the framework.

- Provide scripting via Groovy and Boo .NET for connectors. This allows for great flexibility within a connector, because the framework can run scripts both on the connector and on the target resource (if supported).

- The SPI developer has the ability to choose different implementations of an operation. For instance there are two types of updates. This is hidden from the API consumer because there is no need for the application developer to call two different operations that essentially do the same thing. Instead the framework will figure out which operation the connector supports and make the appropriate calls.

**2.1.2.2.3 Adapter Factory**

The Adapter Factory is a code-generation tool provided by Oracle Identity Manager. It enables an Oracle Identity Manager application developer to create Java classes, known as adapters.

A resource has an associated provisioning process, which in turn has various tasks associated with it. Each task in turn has an adapter associated to it, which in turn can connect to the target resource to carry out the required operations.
An adapter provides the following benefits:

- It extends the internal logic and functionality of Oracle Identity Manager.
- It interfaces with any software resource by connecting to that resource with the help of the API of the resource.
- It enables the integration between Oracle Identity Manager and an external system.
- It can be generated without manually writing code.
- It can be maintained easily because all the definitions for the adapter are stored in a repository. This repository can be edited through a GUI.
- A user in Oracle Identity Manager can retain the domain knowledge about the integration, while another user can maintain the adapter.
- It can be modified and upgraded.

The Adapter Factory provides rapid integration with commercial or custom systems. Users can create or modify integrations by using the graphical user interface of the Adapter Factory, without programming or scripting. When connectors are created, Oracle Identity Manager repository maintains the definitions and creates self-documenting views. You use these views to extend, maintain, and upgrade connectors.

2.1.2.2.4 **Generic Technology Connector**

Predefined Oracle Identity Manager connectors are designed for commonly used target systems such as Microsoft Active Directory and PeopleSoft Enterprise Applications. The architecture of a predefined connector is based on either the APIs that the target system supports or the data repository type and schema in which the target system stores user data.

The use of a predefined connector is the recommended integration method when such a connector is available for the target system. However, in some instances you might want to integrate Oracle Identity Manager with a target system that has no corresponding predefined connector. For example, XYZ Travels Inc. owns a custom Web-based application that its customers use to request airline fare quotes. Agents, who are also employees of XYZ Travels, respond to these requests by using the same application. Customers register themselves to create accounts in this application. However, XYZ Travels employees need to have accounts auto-provisioned based on their HR job title. Account management functions, such as create, update, and delete, of the application are available through Java APIs. There is no predefined connector available to integrate the custom application with Oracle Identity Manager. Therefore, you must create the custom connectors that call the Java APIs exposed by the target application.

To integrate Oracle Identity Manager with a target system that has no corresponding predefined connector, you can create a custom connector to link the target system and Oracle Identity Manager. If you do not need the customization features of the Adapter Factory, then you can create the connector by using the Generic Technology Connector (GTC) feature of Oracle Identity Manager.

You can quickly and easily build a basic connector without advanced features and customized behavior by using generic connectivity technologies such as SPML and JDBC. GTC is a wizard that provides an alternative environment for connector development to rapidly create all the necessary functional components that make up a target system connector in Oracle Identity Manager.
The GTC framework provides basic components that are used to rapidly assemble a custom connector. The reconciliation and provisioning modules of a generic technology connector are composed of these reusable components that you select. Each component performs a specific function during provisioning or reconciliation. The components are:

**Reconciliation:**
- Reconciliation Transport Provider: This provider is responsible for moving the reconciled data from the target system to Oracle Identity Manager.
- Reconciliation Format Provider: This provider parses the message received from the target system, which contains the reconciled data, into a data structure that can be interpreted by the reconciliation engine in Oracle identity Manager.
- Validation Provider: This provider validates any data received before passing it on to the reconciliation engine.

**Provisioning:**
- Provisioning Format Provider: This provider converts Oracle identity Manager provisioning data into a format that is supported by the target system.
- Provisioning Transport Provider: This provider carries the provisioning message received from the Provisioning Format Provider to the target system.

Figure 2–3 shows the functional architecture of a generic technology connector.

**Figure 2–3 Functional Architecture of a Generic Technology Connector**

Generic technology connectors have the following features:

**Features specific to the reconciliation module are:**
- **Generic technology connector in trusted source reconciliation:** A generic technology connector can be used for trusted source reconciliation. During reconciliation in trusted mode, if the reconciliation engine detects new target system accounts, then it creates corresponding OIM Users. If the reconciliation engine detects changes to existing target system accounts, then the same changes are made in the corresponding OIM Users.
– **Generic technology connector in account status reconciliation**: User account status information is used to track whether or not the owner of a target system account is to be allowed to access and use the account. If the target system does not store account status information in the format in which it is stored in Oracle Identity Manager, then you can use the predefined Translation Transformation Provider to implement account status reconciliation.

– **Generic technology connector in full or incremental reconciliation**: While creating a generic technology connector, you can specify that you want to use the connector for full or incremental reconciliation. In incremental reconciliation, only target system records that have changed after the last reconciliation run are reconciled (stored) into Oracle Identity Manager. In full reconciliation, all the reconciliation records are extracted from the target system.

– **Generic technology connector for batched reconciliation**: To exercise more control over the reconciliation process, you can use the generic technology connector to specify a batch size for reconciliation. By doing this, you can break into batches the total number of records that the reconciliation engine fetches from the target system during each reconciliation run.

– **Generic technology connector in reconciliation of multivalued attribute data (child data) deletion**: You can specify whether or not you want to reconcile into Oracle Identity Manager the deletion of multivalued attribute data on the target system.

– **Generic technology connector in failure threshold for stopping reconciliation**: During reconciliation, Validation Providers can be used to run checks on target system data before it is stored in Oracle Identity Manager. You can set a failure threshold to automatically stop a reconciliation run if the percentage of records that fail the validation checks to the total number of records processed exceeds the specified threshold percentage.

**Other features of generic technology connectors are:**

– **Custom Providers**: If the predefined providers shipped with Oracle Identity Manager do not address the transport, format change, validation, or transformation requirements of your operating environment, then you can create custom providers.

– **Multilanguage Support**: Generic technology connectors can handle both ASCII and non-ASCII user data.

– **Custom Date Formats**: While creating a generic technology connector, you can specify the format of date values in target system records that are extracted during reconciliation and the format in which date values must be sent to the target system during provisioning.

– **Propagation of Changes in OIM User Attributes to Target Systems**: While creating a generic technology connector, you can enable the automatic propagation of changes in OIM User attributes to the target system.

### 2.1.2.2.5 Remote Manager

When your adapter uses Java tasks, you must configure Oracle Identity Manager to find the appropriate Java APIs. The Java APIs are located in JAR files in the Meta Data Store (MDS). Sometimes, instead of directly communicating with the third-party system, Oracle Identity Manager must use an Oracle Identity Manager component that acts like a proxy. This component is known as Remote Manager. The Remote Manager is used for:
Invoking nonremotable APIs through Oracle Identity Manager

Invoking APIs that do not support Secure Sockets Layer (SSL) over secure connections

The Remote Manager is an Oracle Identity Manager server component that runs on a target system computer. It provides the network and security layer required to integrate with applications that do not have network-aware APIs or do not provide security. It is built as a lightweight Remote Method Invocation (RMI) server. The communication protocol is RMI tunneled through Hypertext Transfer Protocol/Secure (HTTP/S).

The J2EE RMI framework enables the creation of virtually transparent, distributed services and applications. RMI-based applications consist of Java objects making method calls to one another, regardless of their location. This enables one Java object to call methods on another Java object residing on another virtual computer in the same manner in which methods are called on a Java object residing on the same virtual computer.

Figure 2–4 shows an overview of the Remote Manager architecture.

See Also: “Installing and Configuring a Remote Manager” for information about the Remote Manager and its configuration in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager

2.1.2.3 Platform Services

The Platform Services include:

- **Plug-In Framework**
- **SoD Engine Framework**
2.1.2.3.1 Plug-In Framework

The Plug-in Framework allows customers to easily extend and customize the capabilities of the out-of-the-box Oracle Identity Manager features. The features expose specific plug-in points in the business logic where extensibility can be provided. An interface definition accompanies each such point and is called the plug-in interface. Customers can create code that extends these plug-in interfaces and defines customizations based on their business needs. These plug-ins are deployed and registered with Oracle Identity Manager by using the Plug-in Manager. Oracle Identity Manager then incorporates the plug-ins into the feature processing from that point onward.

Feature developers do not have to keep a track of where the custom implementations are stored and how they are loaded. The plug-in framework supports loading plug-ins from the classpath, from the file system, and from the database.

2.1.2.3.2 SoD Engine Framework

An attempt to enforce good compliance practices is through the definition of Segregation of Duties (SoD) policies. SoD is broadly defined as a way of preventing a user from acquiring a conflicting set of entitlements. This conflicting set is also referred to as a toxic combination. An example of a toxic combination is that a person should not have the ability to create and approve the same purchase order. Enterprises often have business application-specific SoD engines that define and enforce SoD policies on the entitlements users have within those business applications. Examples of such SoD engines are OAACG and SAP GRC.

The SoD Engine Framework allows customers to integrate Oracle Identity Manager with their choice of SoD Engine to enable SoD checks at appropriate points in the request and provisioning process. Oracle Identity Manager can send a request for an SoD check to the SoD Engine through the SoD Invocation Library (SIL). SIL provides a common service interface to all supported SoD engines. The common service interface provides an abstraction on the business components within Oracle Identity Manager. As a result, SoD checks do not have to take care of the correct data formats required by the SoD Engine and also the interpretation of the results returned.

SoD checks can be run at various times in the provisioning lifecycle, such as during an access request, during the approval workflow execution, or during the provisioning execution. If a violation is detected, then the request or resource is marked as being in violation, and the approver or administrator is responsible for deciding whether to proceed or not. If violations are detected during request processing, then various approval workflows can be invoked that allow for higher levels of approval.

Figure 2-5 shows the flow of data during the SoD validation process.
2.1.3 Middleware Tier

The Middleware Tier in Oracle Identity Manager architecture consists of the following:

- Request Service and Approval Workflow
- Authorization Service
- UI Customization Framework
- Scheduler Service
- Reporting

2.1.3.1 Request Service and Approval Workflow

Oracle Identity Manager architecture includes a request service that allows you to configure approval workflows. To deliver this functionality, Oracle Identity Manager uses Oracle Service Oriented Architecture (SOA) Suite.

Oracle SOA Suite enables you to build service-oriented applications and deploy them to your choice of middleware platform. It consists of a number of components, but for the purposes of delivering comprehensive workflow capabilities, Oracle Identity Manager relies on the following components:

- **BPEL Process Manager:** Oracle BPEL Process Manager provides a comprehensive solution for creating, deploying, and managing cross-application business processes with both automated and human workflow steps. It also provides audit trails for both completed and running processes, and process history that enables process improvement.

- **Human Request Service:** Although the BPEL standard does not cover manual tasks, it supports asynchronous services. Therefore, the Oracle SOA Suite supports the Human Request Service, which is a manual task service, so that manual steps can be included in standard BPEL processes. Oracle Identity Self Service includes a task list that allows users to view and interact with assigned tasks being managed within the Human Request Service.
Oracle Identity Manager embeds SOA task list in the UI. This optimizes and simplifies the interaction of users with the SOA suite. The approvers can approve requests originating in Oracle Identity Manager by using the embedded SOA task list. Embedded SOA task lists in Oracle Identity Manager enable making relevant data about the Oracle Identity Manager entities available to the SOA instance as Oracle Business Rules (OBR) facts on top of the default Web services. Therefore, writing complex Java code to resolve approver and approval routing in SOA workflows can be avoided. The following data is available in the SOA composites as OBR facts:

- User attribute for requestor and beneficiary
- All metadata associated with the base entity of requested item
- All metadata associated with the catalog entry of the requested item

Figure 2–6 shows the integration between the request service and SOA.

**Figure 2–6 Request Service and SOA Integration**

The request service also provides the services used to raise and track requests in Oracle Identity Manager. A request allows a user to ask that an action be taken after obtaining the necessary approvals, and that a tracking record of the entire process and its status be maintained. The request can be for various types of actions that are defined as request types. The request types can be:

- Creating, modifying, or deleting an entity
- Enabling or disabling an entity
- Adding or removing an identity as a member of a role
- Granting and revoking entitlements
- Provisioning, deprovisioning, enabling, disabling, and modifying application instances

**Note:** Application instance is a new entity introduced in Oracle Identity Manager 11g Release 2 (11.1.2.2.0). For information about application instances, see “Managing Application Instances” in Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.
The request service supports various types of requests and has the ability to accommodate multiple request types. Oracle Identity Manager provides a number of predefined request types that cover the most common use cases.

The request service also provides support for heterogeneous requests that enable requesting for multiple types of entities in the same request. For example, assigning roles, provisioning application instances, and granting entitlements are supported in a single request.

The request service defines the flow models by which data provided in a request flows through the various services in Oracle Identity Manager. This includes invoking approval workflows at the correct time, monitoring the status of the workflows, and running the request if approval is received.

Both transaction data and history data for requests is maintained, which supports audit and compliance requirements.

2.1.3.2 Authorization Service

Oracle Identity Manager requires a strong level of access control over what users can view and change in the application. To meet this requirement, Oracle Identity Manager lets you define authorization policies that determine at run time whether or not a particular action is allowed. This is controlled by the authorization service that uses Oracle Entitlements Server (OES) embedded within Oracle Identity Manager. OES is an authorization product and enables centralized management of entitlements and authorization policies to granularly determine access to both application components and application business objects.

The OES architecture is made up of two major components. The administration application acts as the policy administration point (PAP) and is used to manage policy, configuration, roles, and entitlements. The second major component is the use of one or more Security Modules (SMs) that are stored in the application container. The SMs evaluate fine-grain access control polices at the policy decision point (PDP) and enforce it at the policy enforcement point (PEP).

Figure 2–7 shows the architecture of OES-based authorization service:

Each time a privilege check is requested, the following takes place:
Oracle Identity Manager connects to the authorization service to prepare access decision for the operations performed on protected entities.

The service then finds and evaluates the policy or policies that apply to the resource.

All information required to evaluate a policy is collected by the Security Modules at run time.

If the policy references subject by role, all roles are evaluated and the access decision is made.

Oracle Identity Manager provides an abstraction service on top of OES that optimizes and simplifies the definition of policies in Oracle Identity Manager. This service includes a policy definition UI that allows the definition of authorization policies that are feature specific and support fine-grained controls for attributes and functions on entities such as users and roles.

2.1.3.3 UI Customization Framework

Oracle Identity Manager leverages Application Development Framework (ADF) to provide simple and business-friendly UI customization without the need to write code. The components used for customization are:

- **Oracle Web Composer**: Oracle Identity Manager supports Web browser-based UI customization and not IDE or JDeveloper-based customizations. JDeveloper is used to create pages, page fragments, regions, tabs and other UI artifacts. After these artifacts are deployed in Oracle Identity Manager, additional customizations can be done on this new content by using Oracle Web Composer.

  **Note:** If you want to use JDeveloper, then you can use APIs and build pages from scratch rather than customize predefined pages. There will be no interoperability between IDE and Web browser-based UI customizations.

Oracle Web Composer enables you perform browser-based run-time customization or personalization of pages, Changing page layouts, adding items to pages, and performing branding. Customizations can be temporarily saved, reviewed, and then finalized as deployment specific, tenant specific, or user specific. This provides durable customizations across patches and upgrade because UI customizations are preserved separately from the code and UI metadata.

- **ADF Business Editor**: Using the ADF Business Editor, you can extend or add custom attributes to user, role, organization, catalog, and application instance entities. In addition, you can configure request datasets for users, resource objects, and application instances.

- **Meta Data Store (MDS)**: Customizations and personalizations are stored in file system or database by using Oracle MDS.

Figure 2–8 illustrates the components of the UI customization framework.
2.1.3.4 Scheduler Service

Business systems frequently make use of scheduling systems, which are configured to run other programs at specified times. Scheduling systems run applications that generate reports, reformat data, or perform audits at regular intervals of time. Scheduling systems often run batch jobs or scheduled jobs that perform routine work automatically at a prescribed time.

Scheduling systems are an integral part of any enterprise provisioning solution. Provisioning often involves tasks to be performed in a time-based manner. Some examples are:

- Running a nightly job to reconcile all changes made directly on a managed application
- Do escalations of assigned tasks that have not been handled within a specified time period
- Execute requests at a specific time

Oracle Identity Manager platform includes the Scheduler to provide the scheduling capabilities necessary for enterprise provisioning requirements. This Service is managed as part of Oracle Identity Manager platform and not as an independent product. **Figure 2–9** provides an overview of Oracle Identity Manager Scheduler architecture.
Key capabilities provided by the Scheduler service are:

- The ability to create simple or complex schedules for running thousands of jobs
- The ability to run the scheduling service as a clustered service to provide the necessary high availability capabilities including fail-over and load balancing
- The ability to persist the job definitions for management and fail-over support
- The ability to create, modify, enable, disable, and delete jobs and manage individual job runs by using an administrative UI
- The ability to run a job in an ad-hoc fashion outside of regularly scheduled runs
- The ability to manage errors and failures
- The ability to maintain history of job runs, including statistics and results of these runs
- The ability to manage the Scheduler service itself

2.1.3.5 Reporting

The rich set of data stored in Oracle Identity Manager repository can be viewed through detailed reports that support management and compliance requirements. Oracle Identity Manager provides support for data reporting through the use of Oracle BI Publisher, which is an enterprise reporting solution and provides a single reporting environment to author, manage, and deliver all of your reports and business documents. Utilizing a set of familiar desktop tools, such as Microsoft Word, Microsoft Excel, or Adobe Acrobat, you can create and maintain report layouts based on data from diverse sources, including Oracle Identity Management products.

Oracle Identity Manager provides a set of standard Oracle BI Publisher report templates. However, you can customize each template to change its look and feel. in addition, you can create your own custom reports by leveraging Oracle Identity Manager database schema.

2.1.4 The Data Tier

Oracle Identity Manager is driven by data and metadata, which provides flexibility and adaptability to Oracle Identity Manager functionalities. Oracle Identity Manager data tier consists of Oracle Identity Manager repository or database, which manages and stores Oracle Identity Manager data and metadata in an ANSI SQL 92-compliant relational database, and an optional LDAP Identity Store.
This section describes the data tier in the following topics:

- Oracle Identity Manager Database
- The Metadata Store
- The Identity Store
- Integration Between LDAP Identity Store and Oracle Identity Manager

### 2.1.4.1 Oracle Identity Manager Database
Oracle Identity Manager repository is the authoritative store for the *Who Has What, When, How, and Why* data that is the core value of the identity administration and provisioning system. The data stored in Oracle Identity Manager database falls into the following broad categories:

- **Entity Data:** Users, organizations, roles, role memberships, resources, provisioned resources
- **Transactional Data:** Requests, approval and provisioning workflow instances, human tasks
- **Audit Data:** Request history, user profile history

#### High Availability
The database provides a scalable and redundant data layer to avoid downtime and performance issues. Reliability, recoverability, timely error detection, and continuous operations are primary characteristics of a highly available solution.

Oracle Identity Manager architecture relies on the corresponding capabilities provided by the Database Management System that is used with the product. These capabilities must:

- Encompass redundancy across all components
- Provide protection and tolerance from computer failures, storage failures, human errors, data corruption, lost writes, system hangs or slowdown, and site disasters
- Recover from outages as quickly and transparently as possible
- Provide solutions to eliminate or reduce planned downtime
- Provide consistent high performance
- Be easy to deploy, manage, and scale
- Achieve Service Level Agreements (SLAs) at the lowest possible total cost of ownership

A broad range of high availability and business continuity solutions are available. You can find out more about maximizing database availability by using technologies such as Oracle Real Application Clusters (Oracle RAC) and Oracle Data Guard at the following Web site:

### 2.1.4.2 The Metadata Store
The logic underlying Oracle Identity Manager is metadata driven. The structural and behavioral aspects are described by using metadata. Oracle Identity Manager architecture relies on Oracle Metadata Services (MDS) to provide a unified store for metadata. This ensures consistent and reliable access to the metadata for Oracle...
Identity Manager and for the other Fusion Middleware components that it is built on. The same metadata that is used during the design phase of an application is used at application runtime through the metadata services layer. This ensures consistency through the lifecycle of Oracle Identity Manager. MDS also provides common administrative tooling for the metadata that can be used across various types of metadata stored in the common repository.

Key features and architectural principles of the MDS include:

- Simplified resource management through a single, unified repository for all artifacts used by various Fusion Middleware components
- Management of the metadata lifecycle for each artifact as it moves through the various stages of development, testing, staging, and production
- Sharing and reuse of metadata across components
- Categorization and reuse of artifacts, encouraging reuse, and promoting consistency
- Visioning capabilities, which form the basis for various features
- An upgrade-safe and layered customization mechanism through which metadata and application logic can be tailored per usage of the metadata
- Advanced caching and assembling techniques coupled with configurable tuning options to optimize performance

Metadata accessed and managed via MDS can be in a file-based repository or a database-based repository. In Oracle Identity Manager architecture, the metadata is in Oracle Identity Manager database to take advantage of some of the advanced performance and availability features that this mode provides.

MDS provides features using which you can create applications to meet customization requirements, such as modifying applications to suit the requirements of a specific business group, customizing applications to suit the individual preferences of a user, and creating applications that are customizable at run time. For more information about customizing Oracle Identity Manager by using MDS features, see "Customizing the Interface" on page 30-1.

2.1.4.3 The Identity Store

Oracle Identity Manager provides the ability to integrate an LDAP-based identity store into Oracle Identity Manager architecture. You can connect and manage an LDAP-based identity store directly from Oracle Identity Manager. Using this feature, you can use advanced user management capabilities of Oracle Identity Manager, including request-based creation and management of identities, to manage the identities within the corporate identity store.

In this deployment architecture, user identity information is stored in Oracle Identity Manager database to support the relational functionality necessary for Oracle Identity Manager to function, as well as in the LDAP store. All data is kept in sync transparently without the need for provisioning actions and setting up policies and rules. Identity operations started within Oracle Identity Manager, such as user creation or modification, are run on both the stores in a manner that maintains transactional integrity. In addition, any changes in the LDAP store made outside of Oracle Identity Manager is pulled into Oracle Identity Manager and made available as a part of the identity context.
2.1.4.4 Integration Between LDAP Identity Store and Oracle Identity Manager

Oracle Identity Manager users and roles are stored in Oracle Identity Manager database. However, when a user, role, or role membership change takes place in Oracle Identity Manager, this information is propagated to LDAP identity store. If user, role, or role membership change takes place in LDAP directly, then these changes are synchronized into Oracle Identity Manager. The synchronization involves:

- User creation, modification, deletion, change in enable or disable states, and password change are made in LDAP in addition to the internal Oracle Identity Manager tables.
- Role creation, modification, and deletion actions update the LDAP groups, including membership changes.
- Initial load of users, roles, and role memberships are synchronized.
- Direct changes to user profile in LDAP are reconciled to Oracle Identity Manager. This does not include password changes.
- Direct changes to roles and role memberships in LDAP are reconciled to Oracle Identity Manager.

When changes are made in the user and role data, the actual operation is performed with the help of the kernel handlers. These handlers go through an orchestration lifecycle of various stages, such as validation, preprocessing, action, and postprocessing. For more information about the various stages of kernel orchestration, see "Developing Event Handlers" on page 28-1.

Oracle Identity Manager kernel orchestration connects to the Entity Manager, which in turn connects to the LDAP provider. The LDAP provider connects to Oracle Virtual Directory (OVD). The OVD is an interface to various directory systems, such as Oracle Internet Directory, iPlanet, and Active Directory. The LDAP provider reaches the LDAP data by using OVD. Figure 2–10 shows the communication between Oracle Identity Manager and LDAP.

**Figure 2–10 Oracle Identity Manager and LDAP**

The integration configuration and synchronization of data between Oracle Identity Manager and the LDAP identity store are described in the following sections:

- Configuring the Integration with LDAP
- Provisioning Data From Oracle Identity Manager to LDAP Identity Store
- Reconciliation From LDAP Identity Store to Oracle Identity Manager

2.1.4.4.1 Configuring the Integration with LDAP

Configuring the integration between Oracle Identity Manager and LDAP is performed while installing Oracle Identity Manager. You can choose to install Oracle Identity Manager with or without LDAP. If you install Oracle Identity Manager with LDAP, then you must install OVD and
Oracle Internet Directory, create a container to store reserved users, create a new user in Oracle Identity Manager to perform Oracle Identity Manager operations, and configure OVD and Oracle Internet Directory for Oracle Identity Manager. For information about how to perform these configuration steps, see "Setting Up LDAP Synchronization" in the Oracle Fusion Middleware Installation Guide for Oracle Identity and Access Management.

After installing Oracle Identity Manager with LDAP enabled, you must open the following scheduled jobs and update their Last Change Number parameter with the last changelog number value of Oracle Internet Directory:

- LDAP User Create and Update Reconciliation
- LDAP User Delete Reconciliation
- LDAP Role Membership Reconciliation
- LDAP Role Hierarchy Reconciliation
- LDAP Role Create and Update Reconciliation
- LDAP Role Delete Reconciliation

In addition, you must enable these scheduled jobs after updating the Last Change Number parameter. To do so, see "Disabling and Enabling Jobs" in the Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager.

See Also: "Managing Scheduled Tasks" for detailed information about scheduled jobs in the Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager.

2.1.4.4.2 Provisioning Data From Oracle Identity Manager to LDAP Identity Store

Oracle Identity Manager database stores the user and role information. When the user and role information is updated in Oracle Identity Manager, then the external repositories, such as the LDAP directory, must also be updated.

The LDAP changes are performed before Oracle Identity Manager changes. If Oracle Identity Manager changes fail, then the LDAP changes must be reverted to the original state. This is achieved by correcting an enable operation with a disable operation, a create operation with a delete operation, and a modification operation with another modification operation with the original values.

For instance, when a user is created, the validation processes are performed in the validation stage, such as password or any other policy validation. In the preprocessing stage, the user is created in LDAP first. Then, in the action stage, the user is to be created in Oracle Identity Manager. If there is an error in creating the user in Oracle Identity Manager, then the user must be deleted from LDAP because the corresponding user could not be created in Oracle Identity Manager. The operation to revert the change made is provided by the kernel handlers through the compensation method, which is predefined in Oracle Identity Manager.

Note: Each handler has predefined execute and compensate methods. The execute method runs any operation, such as creating a user. The compensate method is called when an error occurs to revert the operation performed by the execute method.

To synchronize data from Oracle Identity Manager to LDAP, the location of the LDAP must be known to Oracle Identity Manager. The information about the LDAP location is stored in Oracle Identity Manager as the Directory Server IT resource. This is a
default IT resource provided by Oracle Identity Manager. The various parameters of this IT resource, which you can specify while installing Oracle Identity Manager, allows the connection between Oracle Identity Manager and LDAP.

In order to identify the same entry in Oracle Identity Manager and LDAP, the Distinguished Name (DN) and GUID attributes are used. Each entry has the DN attribute in LDAP, which indicates the unique location of an entry in LDAP. The GUID attribute is an unique ID to identify the entry. The DN and GUID for users and roles are stored in columns in the users and role tables in Oracle Identity Manager database. For information about how to synchronize user-defined fields between Oracle Identity Manager and LDAP, refer "Synchronizing User-Defined Fields Between Oracle Identity Manager and LDAP" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

This section describes the following topics:

- Managing Users
- Managing Roles

### 2.1.4.4.3 Managing Users

The following user operations can be performed to synchronize data from Oracle Identity Manager to LDAP:

- Create user
- Update user
- Delete user
- Enable user
- Disable user
- Lock user
- Unlock user
- Add role member
- Delete role member
- Change password

### 2.1.4.4.4 Managing Roles

The following role operations can be performed to synchronize data from Oracle Identity Manager to LDAP:

- Create role
- Update role
- Delete role
- Add role to a member
- Add and Update role
- Remove role from a member
- Add role hierarchy
- Remove role hierarchy

### 2.1.4.4.5 Reconciliation From LDAP Identity Store to Oracle Identity Manager

When changes in the identities are made directly in the LDAP identity store, the changes must be replicated to Oracle Identity Manager through authoritative source reconciliation. The identities include users and roles.
Reconciling users from LDAP to Oracle Identity Manager works with the general configuration of reconciliation, which includes the scheduled tasks for reconciliation.

**See Also:** "Managing Scheduled Tasks" for information about scheduler and scheduled tasks in the *Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager*.

**Note:** Instead of using LDAP synchronization reconciliation jobs to reconcile users from LDAP to Oracle Identity Manager, if the Bulk Load utility is used, then subsequent operation on these users might fail if LDAP synchronization is enabled. To avoid this, all the users that are loaded in Oracle Identity Manager must be updated with correct GUID and DN values, and all these users in LDAP must be updated with an object class called orclIDXPerson.

For detailed information about the Bulk Load utility, see "Using the Bulk Load Utility" on page 24-1.

The role reconciliation works only with the LDAP groups. Role reconciliation supports creation, updation, and deletion of roles. Role membership reconciliation supports creation and deletion of role memberships being driven from changes in an external LDAP directory.

Without roles and users being present in Oracle Identity Manager, role membership reconciliation will fail. Therefore, configure the LDAP synchronization scheduled jobs to run in the following order:

1. Fusion Applications Role Category Seeding

**Note:** Fusion Applications Role Category Seeding is a predefined scheduled task that is generated only when LDAP synchronization is enabled, along with other LDAP synchronization scheduled jobs. This job gets all distinct business categories in LDAP and creates them as OIM role categories.

For a list of the predefined scheduled jobs, see "Predefined Scheduled Tasks" in the *Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager*.

2. LDAP Role Create and Update Reconciliation
3. LDAP Role Hierarchy Reconciliation
4. LDAP User Create and Update Reconciliation
5. LDAP Role Membership Reconciliation

For each of these jobs, except Fusion Applications Role Category Seeding, there is a parallel job to do the full reconciliation. All these jobs, except Fusion Applications Role Category Seeding, perform the reconciliation based on change logs, whereas full reconciliation jobs use the search base to do the reconciliation.

**2.1.4.4.6 Consolidated LDAP Sync Full Reconciliation** The LDAP Consolidated Full Reconciliation scheduled job runs the following jobs in order:

1. LDAP User Create and Update Full Reconciliation
How Oracle Identity Manager Works: The Tiers of Oracle Identity Manager

2. LDAP Role Create and Update Full Reconciliation
3. LDAP Role Membership Full Reconciliation
4. LDAP Role Hierarchy Full Reconciliation

See Also: "LDAP Scheduled Tasks" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about the LDAP Consolidated Full Reconciliation scheduled job

When you run the LDAP Consolidated Full Reconciliation scheduled job, the job status of the previous job and all event status for that particular job are checked because the next job must be run in a particular order. If any job fails to run, then the automatic run of the jobs stop, and error messages are logged in the diagnostic log.

Note: The LDAP User Delete Full Reconciliation and LDAP Role Delete Full Reconciliation jobs are not part of LDAP Consolidated Full Reconciliation. These scheduled jobs are disabled by default. They can be enabled by selecting the radio buttons and can be run individually.

You can also run the individual jobs by selecting the radio buttons on the LDAP Sync Consolidated Full Reconciliation job details page. The job details contain all the common parameters for the four full reconciliation jobs. In addition, you can specify the values for the following parameters of the LDAP Sync Consolidated Full Reconciliation scheduled job:

- **Reconciliation Search Base**: Search base for the full reconciliation of users or roles. This defines the location in the LDAP directory from which the LDAP search begins.

- **Reconciliation Role Search Filter**: Search filter for full reconciliation of roles. This filter allows certain role/group entries in the subtree of the LDAP directory and excludes others.

- **Reconciliation User Search Filter**: Search filter for full reconciliation of users. This filter allows certain user entries in the subtree of the LDAP directory and excludes others.

Based on the values entered for the Reconciliation Search Base and/or Reconciliation User Search Filter and Reconciliation Role Search Filter parameters, the user and role accounts are pulled into Oracle Identity Manager from LDAP when the LDAP Sync Consolidated Full Reconciliation job is run. As a result of this full reconciliation, the delete happens in the Oracle Identity Manager database for the deleted entries in LDAP from that particular node.

The Reconciliation Search Base and Reconciliation Search Filter parameters support the following:

- **Reconciling the user or role account from LDAP to Oracle Identity Manager database**: This provides the option to perform fine-grained reconciliation of a particular user or role. The value of the Reconciliation Search Base parameter is:

  "cn=cokeuser1,cn=users,cn=subrealm1,dc=us,dc=oracle,dc=com"

- **All users and roles or groups under the node is reconciled**: The value of Reconciliation Search Base is:
Here, the user full reconciliation and role full reconciliation are triggered. Therefore, all the users and roles or groups under the tenant1 node are reconciled.

- **All users under the node is reconciled:**
  
The value of Reconciliation Search Base is:
  
  "cn=users,cn=tenant1,dc=us,dc=oracle,dc=com"

  Here, all the users under the tenant1 node are reconciled.

- **All roles or groups under the node is reconciled:**
  
The value of the Reconciliation Search Base parameter is:
  
  "cn=groups,cn=tenant1,dc=us,dc=oracle,dc=com"

  Here, all roles or groups under the tenant1 node are reconciled.

The Reconciliation Search Base and Reconciliation Search Filter parameters are not bound together for LDAPSync Full reconciliation. Reconciliation Search Filter can be empty. Search Base can be used for provisioning or pushing entries from Oracle Identity Manager to LDAP, while Reconciliation Search Base can be used to perform full reconciliation from LDAP to Oracle Identity Manager database. If a value is not provided for Reconciliation Search Base, then the value for Search Base from the 'Directory Server' IT resource configuration is used for both provisioning and full reconciliation.

Sample values for the Reconciliation Search Base parameter:

  "cn=tenant1,dc=us,dc=oracle,dc=com"

Sample values for the Search Base parameter:

  "dc=us,dc=oracle,dc=com"

Sample values for the Reconciliation User Search Filter and Reconciliation Role Search Filter parameters:

  (objectclass=orclAPPIDPerson)
  (title=foobar)

**Messages Logged For the LDAP Sync Consolidated Full Reconciliation Scheduled Job**

The following is a list of messages for the LDAP Sync Consolidated Full Reconciliation scheduled job that are logged in the Oracle Identity Manager diagnostic log files:

  LDAP Sync Full Reconciliation Scheduler job {0} is currently Running.
  LDAP Sync Full Reconciliation Scheduler job {0} is not currently Running. It has Stopped.
  LDAP Sync Full Reconciliation Scheduler job {0} is currently being Interrupted while running.
  LDAP Sync Full Reconciliation Scheduler job {0} is not currently Running. It has Failed.
  Error occurred while running the LDAP Sync User Full Reconciliation scheduler job. Please refer to the OIM Server logs for more details.
  LDAP Sync Full Reconciliation Scheduler job {0} is not currently Running. It has been Shutdown.
  LDAP Sync Full Reconciliation Scheduler job {0} is not currently Running. SQLException has occurred.
All LDAPSync Full Reconciliation jobs ran successfully and Stopped.

2.2 System Components

Oracle Identity Manager is built on an enterprise-class, modular architecture that is both open and scalable. Each module plays a critical role in the overall functionality of the system. Figure 2–11 illustrates the system components of Oracle Identity Manager.

Figure 2–11 System Components of Oracle Identity Manager

Oracle Identity Manager user interfaces define and administer the provisioning environment. Oracle Identity Manager offers two user interfaces to satisfy both administrator and user requirements:

- Powerful Java-based Oracle Identity Manager Design Console for developers and system administrators
- Web-based Administration and Oracle Identity Manager Self Service interfaces for identity administrators and users respectively

This section describes the following Oracle Identity Manager components:

- Identity Administration
- Provisioning
- Audit and Reports
- Reconciliation and Bulk Load

---

**Note:** Only the users belonging to the SYSTEM ADMINISTRATORS group of Oracle Identity Manager can log in to Design Console.
- Common Services
- Workflow and Request Management
- Infrastructure and Middleware Integration
- Connector Framework

Identity Administration
Identity administration includes creation and management of identities in Oracle Identity Manager. Identities include users, organizations, and roles. Identity administration also enables password management and user Oracle Identity Manager Self Service operations. Identity administration is performed by using Oracle Identity Manager Administration and Oracle Identity Manager Self Service Web clients, and the SPML Web service.

Provisioning
The provisioning transactions are assembled and modified in the provisioning module. This module maintains the "who" and "what" of provisioning. User profiles, access policies, and resources are defined in the provisioning module, as are business process workflows and business rules.

The Provisioning Server is the run-time engine for Oracle Identity Manager. It runs the provisioning process transactions as defined through Oracle Identity Manager Administration and Oracle Identity Manager Design Console and maintained within the provisioning module.

Audit and Reports
The audit and compliance functions include evaluating a person, organization, system, process, project, or product. This occurs by capturing data generated by the suite’s workflow, policy, and reconciliation engines. By combining this data with identity data, an enterprise has all the information it requires to address any identity and to access a related audit inquiry. Audits are performed to ascertain the validity and reliability of information, and also provide an assessment of a system’s internal control.

Reporting is the process of generating a formal document, which is created as a result of an audit. The report is subsequently provided to a user, such as an individual, a group of persons, a company, a government, or even the general public, as an assurance service so that the user can make decisions, based on the results of the audit. An enterprise can create reports on both the history and the current state of its provisioning environment. Some captured identity data includes user identity profile history, role membership history, user resource access, and fine-grained entitlement history.

Reconciliation and Bulk Load
The reconciliation engine ensures consistency between the provisioning environment of Oracle Identity Manager and Oracle Identity Manager managed resources within the organization. The reconciliation engine discovers illegal accounts created outside Oracle Identity Manager. The reconciliation engine also synchronizes business roles located inside and outside the provisioning system to ensure consistency.

If you want to load a large amount of data from other repositories in your organization into Oracle Identity Manager, then you can use the Bulk Load utility. The Bulk Load utility reduces the downtime in loading the data. In addition, Bulk Load utility import Oracle Identity Manager users, roles, role memberships, and accounts provisioned to users.
Common Services
Various services are grouped together that are shared and used by other Oracle Identity Manager components. These services are:

- **Form Designer**: A form that allows you to create process and resource object forms that do not come packaged with Oracle Identity Manager.

- **Scheduler**: A service that provides the capability to run specific jobs at specific schedules. This service can be used by users, application developers, connector developer, and administrators to create and configure a job to be run at specified intervals. In addition, this service provides administrative capabilities to manage the functionality of jobs and their schedules.

- **Notification Templates**: A common notification service is used by other functional components to send notifications to interested parties about events occurring in Oracle Identity Manager. In addition, this service provides the administrative capabilities for notification template management. A notification template is used for sending the outgoing notifications. These templates typically contain the variables that refer to the available data to provide more contextual content.

- **System Properties**: A system property is an entity that controls the configuration aspect of an application. In addition, to the default system properties, you can create and manage system properties in Oracle Identity Manager.

- **Deployment Manager**: The Deployment Manager is a tool for exporting and importing Oracle Identity Manager configurations. The Deployment Manager enables you to export the objects that make up your Oracle Identity Manager configuration.

Workflow and Request Management
Various operations in Oracle Identity Manager cannot be performed directly. Instead, the operations must be requested. The request management service provides a mechanism to create, approve, and manage requests. A request is an entity created by the users or administrators who want to perform a specific action, which requires a discretionary permission to be obtained from someone or some process before the action can be performed. For example, a user can create a request to gain access to a laptop computer, a manager can approve the request and create an open requisition, and an IT resource administrator can approve the request.

The primary goal of a provisioning solution is to manage requests and provision resources. Request service provides an abstraction layer on the Business Process Execution Language (BPEL) 11g workflow engine. Functional components such as request, provisioning, and certification interacts with the workflow engine for human approvals. Request service caters to the various functional components in Oracle Identity Manager by managing workflow instances and categories, and provides an abstraction layer on BPEL.

Infrastructure and Middleware Integration
The Adapter Factory, Kernel Orchestration mechanism, Context Manager, and Plug-in Framework are designed to eliminate the need for hard-coding integrations with these systems.

Connector Framework
The integration solution strategy of Oracle Identity Manager provides connectors to various heterogeneous identity-aware IT systems. This strategy is designed to minimize custom development, maximize the reuse of code, and reduce deployment time. The tiers of the integration solution are:
■ Out-of-the box integration using predefined connectors and predefined generic technology connector providers

■ Identity connectors that are designed to separate the implementation of an application from the dependencies of the system that the application is attempting to connect to

■ Connectors based on custom generic technology connector providers

■ Custom connectors using the Adapter Factory
Oracle Identity Manager controls access to the application by the users to allow or prevent the users to perform various operations in the application. This is controlled by the authorization engine embedded in Oracle Identity Manager with the help of authorization policies. The purpose of authorization policies is to control user’s access to Oracle Identity Manager application, which includes data, UI, and API. The authorization policies determine at runtime whether or not a particular action is allowed. Authorization policies can be defined that satisfy the authorization requirements within Oracle Identity Manager.

In Oracle Identity Manager, authorization policy management is centralized as an administrative feature. Oracle Identity Manager’s authorization policy management and enforcement engine is based on an embedded version of Oracle Entitlements Server (OES), which is Oracle’s entitlements administration product. These authorization policies secure access control to the Oracle Identity Manager application, thereby defining ‘who can do what on what data’ inside the application.

Oracle Identity Manager supports the following:

- Use standard ADF security model for functional security and use OES best practices for data security.
- Use a consistent architecture that supports delegated administration of various entities in Oracle Identity Manager, such as roles, organizations, entitlements, application instances, and LDAP groups.
- Use a consistent architecture that lets backend make various security decisions, for example, who can request what, who can have what, and who needs to go through approval. This architecture facilitates the security of catalog-based request module and of converged UI and backend of self service and delegated-administration.
- Support for a scoping mechanism for delegated administration and data security of various entities. All entities are scoped by the organization structure defined as Oracle Identity Manager metadata.

Figure 3–1 shows the architecture of OES-based authorization service.
The authorization and security model is described in the following sections:

- **Security Model**
- **Functional and Data Security Mapping**
- **Publishing Entities to Organizations**
- **Managing OES Policies**
- **Enforcing Functional Security**

### 3.1 Security Model

The security model is described in the following sections:

- **Admin Role Assignment**
- **Attribute-Level Security for the User Attributes**
- **Policy Obligations**

#### 3.1.1 Admin Role Assignment

The new authorization model works on the basis of the admin role assignment to a user. There are two types of admin roles, global and scoped. Global admin roles, such as System Administrator, System Configuration Administrator, Catalog System Administrator, SPML Admin, Certification Administrator, and Certification Viewer, can only be assigned in the context of the Top organization only. Scoped admin roles can be assigned in the context of both Top as well as other organizations.

The Top organization is at the root of the organization hierarchy in Oracle Identity Manager. Authorization policies are created according to the admin roles. Admin roles are predefined in Oracle Identity Manager, and new admin roles cannot be added. Admin roles cannot be created, updated, deleted, searched, or requested.

Admin roles are predefined for each entity type. The entity type admin roles are scoped because entity management is performed by delegated administrators. Each entity has the following admin roles defined for it:

- **Entity Administrator**: Can manage the entire lifecycle of the entity and perform any operation on the entity.
- **Entity Viewer**: Can view the entity in the catalog or request profile and request for the entity.
- **Entity Authorizer:** Can view the entity in the catalog or request profiles and request for it, but does not require approval. There is no authorizer on the organization entity because organization membership cannot be requested. Similarly, there is no authorizer for the user. The user admin and user authorizer are the same.

**Note:**
- Entity refers to role, user, organization, entitlement, and application instance.
- See "Admin Roles" in the *Oracle Fusion Middleware User’s Guide for Oracle Identity Manager* for a description of each admin role.

Admin roles have no hierarchy. However, admin role membership organization scoping is hierarchy-aware, and can be cascaded downwards to the child organizations. Admin role membership is always given in an organization scope, and can only be assigned by the System Administrator or the Organization Administrator. The Organization Administrator can assign the admin role for that organization for which it is the Organization Administrator. System Configuration Administrators cannot assign admin roles. Admin roles do not have autogroup membership or role membership rules.

**Note:**
- Admin roles are stored only in Oracle Identity Manager database and are not stored or synchronized in LDAP data store.
- The admin roles cannot be requested and are never exposed to the users.

The System Administrator and System Configuration Administrator admin roles are available only to the Top organization. Therefore, only System Administrators can assign System Administrator and System Configuration Administrator roles because they have access to the Top organization.

The permissions a user has on a entity can be of the following types:

- **Inherent permissions:** The organization to which a user is a member is referred as the Home organization for that user. A user has certain implicit permissions on the entities available to the Home organization. These permissions are automatically assigned to a user. For example, a Role Administrator does not need explicit Role Viewer privileges to view and request for roles available to the Home organization. However, to view and request for roles in another organization, Role Viewer privileges must be explicitly assigned to the same Role Administrator.

- **Management hierarchy:** If User A is the manager of User B and User C, then User A has implicit permissions on User B and User C. If User B and User C are in a different organization, then User A has implicit permissions on User B and User C. User A does not need explicit privileges on the direct reports, irrespective of which organization the direct reports belong. Privileges through management hierarchy is applicable globally, and every manager is able to perform user administration operations on their reports.

Each admin role in Oracle Identity Manager has one-to-one mapping to the application roles in the OES. The application roles have associated policies that govern what permissions are allowed for users who belong to this role. If you want to change
the functional and data constraints on these policies, then you must open the respective policy in Authorization Policy Management (APM) UI in OES, and modify the policy.

Table 3–1 lists the organization-scoped admin roles in Oracle Identity Manager and the corresponding permissions provided by the admin roles.

Note: In Table 3–1 and Table 3–2, you will come across implicit permissions called org basic info, role basic info, entitlement basic info, and appinstance basic info. The basic-info permission gives the permission only to view-search the given entity. Consider the following examples:

- View Org permission provides all the permissions defined for the Organization Viewer admin role, but org basic info provides the permissions only to search and view the organization attributes.
- The User Viewer admin role provides the basic info permission on roles, organizations, application instances, and entitlements in that scoped organization.

3.1.2 Attribute-Level Security for the User Attributes

Oracle Identity Manager supports attribute-level security only for user attributes. The security for all other entities is supported at the entity-instance level.

Oracle Identity Manager contains the default User Viewer, User Administrator, and User HelpDesk admin roles along with the corresponding default authorization policies in OES. The default policies allow the User Viewer and User Administrator to view and modify all the user attributes including the attributes that are added as user-defined fields (UDFs), without requiring any changes to the default policies.

The User Viewer policy has the default constraint set as the deniedattributes obligation in the policy, and by default, it contains NULL list for the attributes.

Note: The following permissions in Oracle Identity Manager are not governed by OES policies:

- Create / Update / Delete Access Policies
- Add / Modify / Remove Lookup
- Import / Export using the Deployment Manager
- Attestation Administration

<table>
<thead>
<tr>
<th>Admin Role in Oracle Identity Manager</th>
<th>Implicit Permissions</th>
<th>Explicit Permissions</th>
<th>Request or Direct Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Modify Trigger</td>

<td></td>
</tr>
<tr>
<td></td>
<td>Stop Jobs</td>
<td>NA</td>
<td></td>
</tr>
<tr>
<td>Certification Viewer</td>
<td>View Certification</td>
<td>NA</td>
<td></td>
</tr>
</tbody>
</table>

Note: The only permission explicitly granted to the Certification Viewer admin role is View Certification. Permissions to view other entities are dynamically granted and scoped to those entities referenced in a certification.
Therefore, all users belonging to the User Viewer role are allowed to view all user attributes by default.

The User Administrator policy has the default constraint set as the deniedattributes obligation in the policy with a NULL list of attributes, and all users belonging to the User Administrator role are allowed to view and modify all user attributes by default. The User HelpDesk policy also has the default constraint set as the deniedattributes obligation in the policy with a NULL list of attributes.

When you add a new UDF, there is no need to change the User Viewer policy. This is because, this policy has default constraint set as deniedattributes, and by default a NULL list for the attributes. This automatically enables the users belonging to the User Viewer role to view the UDFs. There is no need to change the User Administrator policy because the constraint to view and modify all attributes automatically enables the users belonging to the User Administrator role to view and modify these UDFs.

Only if you want to restrict certain attributes to be viewed or modified, then you can change the policies in OES to include such attributes in the deny list. When you want to restrict the list of attributes to be viewed by the User Viewer role or restrict the list of attributes to be viewed and modified by the User Administrator role, you must open the respective policy in the APM UI in OES, and include the list of attributes to be restricted in the deny attribute list of the policy. For example, if you want to restrict the Salary user attribute to be available only for the User Administrator role and not for the User Viewer role, then use the APM UI and modify the User Viewer role to include the Salary attribute in the deny list. When Oracle Identity Manager queries OES to provide a list of attributes for the User Viewer role, OES provides all user attributes but excludes the attributes specified in the Deny List, which is the Salary attribute in this example. Here, there are no changes required for User Admin policy because the ‘View and Modify All Attributes’ returns the Salary information to be viewed and modified by the users belonging to the User Administrator role.

To change the denied attributes:

1. Open the required OES policy in APM UI. In this example, an OES policy by name OrclOIMUserViewerDirectWithAttributesPolicy has been opened that gives the permission to view-search user for the User Viewer admin role, as shown in Figure 3–2:
You can click the `OrcIOIMDeniedAttributesDirect` attribute in edit mode, and then provide the denied attributes, separated by commas, as shown in Figure 3–3:

**Figure 3–3  The Edit Obligation Attribute Dialog Box**

3. Click Update.
4. In the authorization policy details page, click **Apply** at the top-right corner.
3.1.2.1 Using Plug-ins to Pass Attributes for Policy Evaluation

You can use the `oracle.iam.platform.authopss.plugin.AttributeResolver` plug-in point to pass the attributes to OES for policy evaluation. To add a new attribute to be used in policies (condition), you must add the attributes in a Map by using the following methods:

To resolve the attributes of the target entity on which the logged-in user is working:

```java
public Map<String, Object> resolveResourceAttributes(String subjectId,
PolicyConstants.Resources resourceType, String resourceId) throws Exception;
```

To resolve the attributes related to logged-in user:

```java
public Map<String, Object> resolveSubjectAttributes(String subjectId, Policy
Constants.Resources resourceType) throws Exception;
```

### Note:
See Chapter 27, "Developing Plug-ins" for information about developing and using plug-ins.

The following is an example plug-in class:

```java
import java.util.HashMap;
import java.util.HashSet;
import java.util.Map;
import java.util.Set;
import oracle.iam.identity.usermgmt.api.UserManager;
import oracle.iam.identity.usermgmt.vo.User;
import oracle.iam.platform.Platform;
import oracle.iam.platform.authopss.api.PolicyConstants;
import oracle.iam.platform.authopss.plugin.AttributeResolver;

public class ResolveResourceUserTypeAttribute implements AttributeResolver {
    public Map<String, Object> resolveResourceAttributes(String subjectId,
PolicyConstants.Resources resourceType, String resourceId) {
        Map<String, Object> env = new HashMap<String, Object>();
        try {
            Set<String> searchAttributes = new HashSet<String>();
            if(resourceType!=PolicyConstants.Resources.USER) return null;
            return env;
        }
    }
    public Map<String, Object> resolveSubjectAttributes(String subjectId,
PolicyConstants.Resources resourceType) throws Exception {
        return env;
    }
}
```

### Note:
The following deviations are required in APM to deny the listed attributes:

- To deny the User Manager, the attribute must be `usr_manager_key` instead of User Manager.
- To deny the User Type, the attribute must be `Role` instead of User Type.
- Organization cannot be denied.
searchAttributes.add(oracle.iam.identity.utils.Constants.EMPTYPE);
searchAttributes.add(oracle.iam.identity.utils.Constants.USERID);
searchAttributes.add(oracle.iam.identity.utils.Constants.USERKEY);

String empType;

UserManager userManager = Platform.getService(UserManager.class);
User user;
user = userManager.getDetails(resourceId, searchAttributes, false);
empType = (String)user.getAttribute(oracle.iam.identity.utils.Constants.EMPTYPE);
if(empType.equalsIgnoreCase("Full-Time"))
    env.put("OrclOIMResourceUserAttributeType", "EMPLOYEE");
else env.put("OrclOIMResourceUserAttributeType", "NON-EMPLOYEE");
}

public Map<String, Object> resolveSubjectAttributes(String subjectId,
PolicyConstants.Resources
resourceType) {
    return null;
}

Added the plugin.xml as:
<plugins pluginpoint="oracle.iam.platform.authopss.plugin.AttributeResolver">
    <plugin
        pluginclass="oracle.iam.platform.authopss.plugin.impl.ResolveResourceUserTypeAttribute"
        version="1.0.0" name="ResolveResourceUserTypeAttribute">
    </plugin>
</plugins>

3.1.3 Policy Obligations

If a user has multiple roles that have different authorization policies applicable in the same context, then the user’s access rights are the cumulative rights across those policies. For example, the authorization check for the permission to search for users returns a list of obligations. This is a list of obligations from each applicable authorization policy. These obligations from multiple policies are combined to get a unified search result.

The following types of obligations are returned as a result of multiple authorization policies:

- **OrclOIMOrgScopingDirect**: This is used to search the given entity for the intent-based search. This is supported only for view-search.
- **OrclOIMOrgScopingWithHierarchy**: This considers the hierarchy of the Admin Role organization scoping, and it can search entities in down hierarchy. This
allows users to view and modify user profiles without approval as applicable for
the organization in which the user has the appropriate admin role, and its
suborganizations. This is controlled by the Hierarchy Aware data constraint.

- **OrclOIMNeedApproval**: This obligation defines if the authorization policies are
  applicable, then the operation requires approval or not. If the value of this flag is
  true, then a request is created. If the value is false, then it is a direct operation.

- **OrclOIMUserManagementScoping**: This is used for making the search criteria to
  search in the management chain of the user.

- **OrclOIMDeniedAttributesWithoutApproval**: This defines the obligation for the
  user attributes that are denied for modification without a request approval.

- **OrclOIMDeniedAttributesDirect**: This defined the obligation for the user
  attributes that are denied for the view user operation as a direct operation.

- **OrclOIMDeniedAttributesWithApproval**: This defines the obligation for the user
  attributes that are denied for modification with a request approval.

The following are examples of policy obligations returned as a result of multiple
authorization policies:

- The user with role viewer admin role for an organization need approval to grant a
  role to the user. The role viewer can view all users in the organization with
  hierarchy as a result of OrgScopingWithHierarchy policy obligation. For the same
  organization, granting a role to a user is a direct operation for a user with the role
  authorizer admin role.

- Suppose there are two admin roles assigned to a user in the same organization
  scoping, User Viewer and User Administrator. When both the users try to modify
  a user, the first admin role policy returns approval-required, and other policy
  returns that approval is not required. As a result, no request would be raised, and
  the cumulative effect of two approval-required obligations is NO-approval
  required.

- As a result of the OrgScopingDirect policy obligation, a user with the role
  authorizer admin role can view all users in an organization. The same user with
  role authorizer admin role can be denied modifying a few attributes by the
  DeniedAttributesWithApproval policy obligation, and as a result, the attributes
  are not displayed to the user.

- Suppose a user is a Role Viewer in Org1 and Role Authorizer in Org2. Then if the
  user searches for the roles, then the obligation returned from policy1 is
  OrgScopingDirect = org1 and OrgScopingDirect = org2. Therefore, roles will be
  returned from both the organizations.

### 3.2 Functional and Data Security Mapping

Table 3–3 lists the admin roles and the corresponding application roles, default
authorization policies, and policy obligations.

</table>
There are some application roles in OES that cannot be granted to users in Oracle Identity Manager, and therefore, do not have corresponding admin roles in Oracle Identity Manager. The policies associated with these application roles are used for request-related operations. For example, the policies associated with the OIM Request Approver application role are used to control the operations of the approver of a request. \textit{Table 3–4} lists the application roles that do not have corresponding admin roles in Oracle Identity Manager, and the associated policies.

\textit{Table 3–4}  \textit{OES Application Roles and Policies}

</tbody>
</table>
Application-role hierarchies for application roles are defined in OES. This means that a user that has been granted an application role on a given organization can perform all actions of application roles present in that given organization hierarchy. For example, if a user has the OrclOIMUserViewer application role (in other words, the User Viewer Admin role) on a given organization, then the user can perform all the actions of the OrclOIMApplicationInstanceViewerRole, OrclOIMEntitlementViewer, OrclOIMOrgViewer, and OrclOIMRoleViewer application roles present in that given organization.

Table 3–5 lists the mapping between an application role and the corresponding application roles in a given organization. Note that a user that has been granted an application role listed in the second column can perform all the actions by the corresponding application role in the first column.

### 3.3 Publishing Entities to Organizations

Publishing an entity to an organization is making the entity available to that organization. The enterprise roles, entitlements, or application instances can be published by respective administrators to a list of organizations to enable these to be

---

The policies listed in Table 3–7 provide the createUser permission to logged-in users having the admin-roles as given in the table.
Managing OES Policies

As listed in Table 3–3, each admin role in Oracle Identity Manager has a one-to-one mapping with a policy role in OES, which has a corresponding OES policy. To customize the default authorization policies, you can modify the OES policies by using the Authorization Policy Management (APM) UI. For example, to restrict the list of attributes to be viewed by a specific admin role, you can update the OrclOIMDeniedAttributes policy obligation in APM in the corresponding OES policies. Similarly, to restrict the list of attributes to be edited by a specific admin role, you can update the OrclOIMDeniedAttributesWithApproval obligation.

3.4.1 Customizing the Authorization Policies

The default functionality of authorization security in Oracle Identity Manager can be customized in one or more of the following ways:

- Changing the existing policy’s allowed actions.
- Changing the obligations. This includes:
  - Changing the denied-attributes list
  - Changing the approval-required Boolean flag from true/false
  - Changing the scoping attributes
- Changing the policy conditions. This includes:
  - Adding a FALSE condition to disable the policy
- Changing the default condition in the policy
- Adding a resource/dynamic attribute, and then using those attributes in the existing policies

- Deleting the default policies

The following sections provide the mapping between admin roles and authorization policies that can be modified to customize the default authorization:

- Controlling Who can View Which Users
- Controlling Who can Modify Which Users
- Controlling Who can View Which Links
- Controlling Who can Request an Account in an Application Instance
- Controlling Who can Modify an Account
- Controlling Who can Manage an Application Instance
- Controlling Who can Change User Password
- Controlling Who can Change Account Password
- Controlling Which Operations Are Direct or Request-Based
- Controlling the Denied Attributes for Self
- Controlling Modify User Operation for Self

3.4.1.1 Controlling Who can View Which Users

Controlling who can view which users can be controlled by using the admin roles listed in Table 3–8. These admin roles provide permissions to users to view or search users in scoped organizations.

<table>
<thead>
<tr>
<th>Admin Role</th>
<th>Associated Authorization Policy Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApplicationInstanceAdministraRole</td>
<td>ApplicationInstanceAdministratorBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>ApplicationInstanceAuthorieRole</td>
<td>ApplicationInstanceAuthorizerBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>ApplicationInstanceViewerRole</td>
<td>ApplicationInstanceViewerBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>EntitlementAdministrator</td>
<td>EntitlementAdministratorBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>EntitlementAuthorizer</td>
<td>EntitlementAuthorizerBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>EntitlementViewer</td>
<td>EntitlementViewerBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>OrgAdministrator</td>
<td>OrgAdministratorBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>OrgViewer</td>
<td>OrgViewerBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>RoleAdministrator</td>
<td>RoleAdministratorBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>RoleAuthorizer</td>
<td>RoleAuthorizerBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>RoleViewer</td>
<td>RoleViewerBasicInfoUserDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>UserAdmin</td>
<td>UserAdminDirectWithAttributesPolicy</td>
</tr>
<tr>
<td>UserHelpDesk</td>
<td>UserHelpDeskDirectWithAttributesPolicy</td>
</tr>
</tbody>
</table>
To control the users that any user can view, update the admin roles assigned, as listed in Table 3–8. If you want to limit the users from home organizations, then you must change the authorization policies.

### 3.4.1.2 Controlling Who can Modify Which Users

Table 3–9 lists the admin roles and associated authorization policies that control who can modify which users.

<table>
<thead>
<tr>
<th>Admin Role</th>
<th>Associated Authorization Policy Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserAdmin</td>
<td>UserAdminApprovalWithAttributesPolicy</td>
</tr>
<tr>
<td>No Admin role, but home organization</td>
<td>UserHomeOrgApprovalWithAttributesPolicy</td>
</tr>
<tr>
<td>No Admin role, but for management hierarchy</td>
<td>UserManagementChainApprovalWithAttributesPolicy</td>
</tr>
<tr>
<td>SPMLAdmin</td>
<td>UserSPMLAdminApprovalWithAttributesPolicy</td>
</tr>
<tr>
<td>No Admin role, but for self</td>
<td>UserSelfServiceApprovalWithAttributesPolicy</td>
</tr>
<tr>
<td>UserViewer</td>
<td>UserViewerApprovalWithAttributesPolicy</td>
</tr>
</tbody>
</table>

To control the users that any user can modify, update the admin roles assigned, as listed in Table 3–9. If you want to limit the users from home organizations, then you must change the associated authorization policies.

### 3.4.1.3 Controlling Who can View Which Links

Table 3–10 lists the admin roles, associated authorization policies, and the corresponding links that are enabled because of the policies.
<table>
<thead>
<tr>
<th>Admin Role</th>
<th>Associated Authorization Policy Name</th>
<th>Links Enabled Because of the Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserHelpDesk</td>
<td>UserHelpDeskApprovalPolicy</td>
<td>enableUserStatus, disableUserStatus</td>
</tr>
<tr>
<td>UserHelpDesk</td>
<td>UserHelpDeskUserAccountsPolicy</td>
<td>modifyUserAccounts</td>
</tr>
<tr>
<td>No Admin role, but for self</td>
<td>UserSelfServiceApprovalPolicy</td>
<td>addUserRoles, deleteUserRoles, deleteUserEntitlements, deleteUserAccounts, addUserEntitlements, deleteUsaerAccounts</td>
</tr>
<tr>
<td>SPMLAdmin</td>
<td>UserSPMLAdminApprovalPolicy</td>
<td>enableUserStatus, disableUserStatus, createUsers, addUserRoles, deleteUserRole, deleteUser</td>
</tr>
</tbody>
</table>

Table 3–10  Admin Roles to Control the View of Links
As listed in Table 3–10, the admin roles and associated policies provide the permissions to enable the links according to the allowed actions. You can update the authorization policies and change the enabled links with the policies, or assign the admin roles accordingly.

### 3.4.1.4 Controlling Who can Request an Account in an Application Instance

Table 3–11 lists the admin roles and associated authorization policies that control which user can request an account in an application instance.

<table>
<thead>
<tr>
<th>Admin Role</th>
<th>Associated Authorization Policy Name</th>
<th>Links Enabled Because of the Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>No Admin role, but app-instance published in user's home organization</td>
<td>ApplicationInstanceHomeOrgApprovalPolicy</td>

</tbody>
</table>
To disable the users to search/raise-request for the user's peers except direct reportees, perform the following steps:

1. Disable/deactivate/delete the home-org policies for the user to disallow peer permissioning. These policies are as follows:
   - User Home Org Approval Policy
   - User Home Org Direct Policy
   - User Home Org Direct With Attributes Policy
2. To disallow users to search, view, and raise requests for indirect reportees:
   a. By default, Oracle Identity Manager allows searching, viewing, and raising requests for direct and indirect reportees. To remove the permissioning from indirect reportees, create an authorization plug-in, pass an attribute as isDirectReportee, and return its value as TRUE/FALSE.
   b. Update the following user policies to use the attribute in policy condition:
      - User Management Chain Approval Policy
      - User Management Chain Approval With Attributes Policy
      - User Management Chain Direct With Attributes Policy

3.4.1.10 Controlling the Denied Attributes for Self
To control the denied attributes for self profile, modify policy obligations for the following authorization policies by using APM:

- OrclOIMUserHomeOrgDirectWithAttributesPolicy
- OrclOIMUserSelfServiceDirectWithAttributesPolicy

3.4.1.11 Controlling Modify User Operation for Self
To control the modify user operation for self for the System Administrator:

1. customize the following self service authorization policies:
   - OrclOIMUserViewerApprovalWithAttributesPolicy
   - OrclOIMUserManagementChainApprovalWithAttributesPolicy
   - OrclOIMUserHomeOrgApprovalWithAttributesPolicy
2. Add the following condition in the AND condition along with other checks:
if OrclOIMUserId == OrclOIMTargetEntity is TRUE

3.4.2 Authorization Policy Customization Use Cases
Authorization policy customization is described with the help of the following use cases:

- Controlling the Attributes an Help-desk Administrator Can View/Modify
- Controlling the Permissions Based on Default Home Organization

3.4.2.1 Controlling the Attributes an Help-desk Administrator Can View/Modify
To control the user attributes that an Help-Desk Administrator can view or modify for an user of type Employee or Non-employee:

1. Using APM, edit the attribute definition to add the following attribute:

   ```xml
   <attribute>
     <name>OrclOIMResourceUserAttributeType</name>
     <display-name>OIM resource user type.</display-name>
     <description>OIM resource user type.</description>
     <attribute-category>DYNAMIC</attribute-category>
     <attribute-type>oracle.security.jps.service.policystore.info.OpssString</attribute-type>
     <is-single-valued>true</is-single-valued>
   </attribute>
   ``

   The possible values for this attribute is EMPLOYEE and NON-EMPLOYEE.

2. Change the authorization policy required for the View User permission:
   a. In the OrclOIMUserHelpDeskDirectWithAttributesPolicy policy, change the condition as follows:

   ```xml
   <Condition>
     <F nm="OR" exp="bool" params="***">
       <F nm="BOOLEAN_EQUAL" exp="bool" params="***">
         <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
           <Par tp="str" val="OrclOIMTargetEntity"/>
         </F>
         <Par tp="bool" val="false"/>
       </F>
       <F nm="OR" exp="bool" params="***">
         <F nm="AND" exp="bool" params="***">
           <F nm="BOOLEAN_EQUAL" exp="bool" params="***">
             <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
               <Par tp="str" val="OrclOIMUserOrganizations"/>
             </F>
             <Par tp="bool" val="true"/>
           </F>
           <F nm="BOOLEAN_EQUAL" exp="bool" params="***">
             <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
               <Par tp="str" val="OrclOIMUserHelpDeskOrgsDirect"/>
             </F>
             <Par tp="bool" val="true"/>
           </F>
         </F>
         <F nm="BOOLEAN_EQUAL" exp="bool" params="***">
           <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
             <Par tp="str" val="OrclOIMUserHelpDeskOrgsDirect"/>
           </F>
           <Par tp="bool" val="true"/>
         </F>
       </F>
     </F>
   </Condition>
   ```
Change the denied-attribute obligation and add the attributes denied for the EMPLOYEE user.
b. Duplicate the OrcIOMUserHelpDeskDirectWithAttributesPolicy policy changed in step 1a, and change the condition as follows:

```xml
<Condition>
  <F nm="OR" exp="bool" params="">
    <F nm="BOOLEAN_EQUAL" exp="bool" params="">
      <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
        <Par tp="str" val="OrclOIMTargetEntity"/>
      </F>
      <Par tp="bool" val="false"/>
    </F>
    <F nm="OR" exp="bool" params="">
      <F nm="AND" exp="bool" params="">
        <F nm="BOOLEAN_EQUAL" exp="bool" params="">
          <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
            <Par tp="str" val="OrclOIMUserOrganizations"/>
          </F>
          <Par tp="bool" val="true"/>
        </F>
        <F nm="BOOLEAN_EQUAL" exp="bool" params="">
          <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
            <Par tp="str" val="OrclOIMUserHelpDeskOrgsDirect"/>
          </F>
          <Par tp="bool" val="true"/>
        </F>
        <F nm="AND" exp="bool" params="">
          <F nm="BOOLEAN_EQUAL" exp="bool" params="">
            <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
              <Par tp="str" val="OrclOIMResourceUserAttributeType"/>
            </F>
            <Par tp="bool" val="true"/>
          </F>
          <F nm="STRING_EQUAL" exp="str" params="">
            <Par nm="OrclOIMResourceUserAttributeType"/>
            <Par tp="str" val="NON-EMPLOYEE"/>
          </F>
        </F>
      </F>
      <F nm="AND" exp="bool" params="">
        <F nm="BOOLEAN_EQUAL" exp="bool" params="">
          <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
            <Par tp="str" val="OrclOIMUserOrganizationsWithParents"/>
          </F>
          <Par tp="bool" val="true"/>
        </F>
        <F nm="BOOLEAN_EQUAL" exp="bool" params="">
          <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
            <Par tp="str" val="OrclOIMUserHelpDeskOrgsWithHierarchy"/>
          </F>
          <Par tp="bool" val="true"/>
        </F>
      </F>
    </F>
  </F>
</Condition>
```
Change the denied-attribute obligation and add the attributes denied for the NON-EMPLOYEE user.

3. Change the authorization policy required for the Modify User permission:
   a. Duplicate the OrclOIMUserHelpDeskApprovalPolicy policy, name it as OrclOIMUserHelpDeskApprovalWithAttributesPolicy, and put the permission as modifyUser. Change the condition as follows:

   ```xml
   <Condition>
     <F nm="OR" exp="bool" params=""/>
     <F nm="BOOLEAN_EQUAL" exp="bool" params="">
       <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
         <Par tp="str" val="OrclOIMTargetEntity"/>
       </F>
       <Par tp="bool" val="false"/>
     </F>
     <F nm="OR" exp="bool" params=""/>
     <F nm="AND" exp="bool" params="">
       <F nm="BOOLEAN_EQUAL" exp="bool" params="">
         <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
           <Par tp="str" val="OrclOIMUserOrganizations"/>
         </F>
         <Par tp="bool" val="true"/>
       </F>
       <F nm="BOOLEAN_EQUAL" exp="bool" params="">
         <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
           <Par tp="str" val="OrclOIMUserHelpDeskOrgsDirect"/>
         </F>
         <Par tp="bool" val="true"/>
       </F>
       <F nm="BOOLEAN_EQUAL" exp="bool" params="">
         <F nm="STRING_AT_LEAST_ONE_MEMBER_OF" exp="bool" params="">
           <Par nm="OrclOIMUserHelpDeskOrgsDirect"/>
           <Par nm="OrclOIMUserOrganizations"/>
         </F>
         <Par tp="bool" val="true"/>
       </F>
     </F>
   </Condition>
   ```
Add the denied attribute obligation as OrclOIMDeniedAttributesWithApproval and add the attributes denied for the EMPLOYEE user.

b. Duplicate the OrclOIMUserHelpDeskApprovalWithAttributesPolicy created in step 2a, and change the condition as follows:

```xml
<Condition>
  <F nm="OR" exp="bool" params=""/>
  <F nm="BOOLEAN_EQUAL" exp="bool" params=""/>
  <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params=""/>
  <Par tp="str" val="OrclOIMUserOrganizationsWithParents"/>
  <Par tp="bool" val="true"/>
</F>
</Condition>
```
Managing OES Policies

<Par tp="str" val="OrclOIMTargetEntity"/>
</F>
<Par tp="bool" val="false"/>
</F>
<F nm="OR" exp="bool" params="***">
    <F nm="AND" exp="bool" params="***">
        <F nm="BOOLEAN_EQUAL" exp="bool" params="***">
            <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
                <Par tp="str" val="OrclOIMUserOrganizations"/>
            </F>
        </F>
    </F>
</F>

<F nm="BOOLEAN_EQUAL" exp="bool" params="***">
    <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
        <Par tp="str" val="OrclOIMUserHelpDeskOrgsDirect"/>
    </F>
</F>

<F nm="BOOLEAN_EQUAL" exp="bool" params="***">
    <F nm="STRING_AT_LEAST_ONE_MEMBER_OF" exp="bool" params="*">
        <Par nm="OrclOIMUserHelpDeskOrgsDirect"/>
        <Par nm="OrclOIMUserOrganizations"/>
    </F>
</F>

<F nm="AND" exp="bool" params="***">
    <F nm="BOOLEAN_EQUAL" exp="bool" params="***">
        <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
            <Par tp="str" val="OrclOIMResourceUserAttributeType"/>
        </F>
    </F>
</F>

<F nm="STRING_EQUAL" exp="str" params="2">
    <Par nm="OrclOIMResourceUserAttributeType"/>
    <Par tp="str" val="NON-EMPLOYEE"/>
</F>

<F nm="AND" exp="bool" params="***">
    <F nm="BOOLEAN_EQUAL" exp="bool" params="***">
        <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
            <Par tp="str" val="OrclOIMUserOrganizationsWithParents"/>
        </F>
    </F>
</F>

<F nm="BOOLEAN_EQUAL" exp="bool" params="***">
    <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
        <Par tp="str" val="OrclOIMUserHelpDeskOrgsWithHierarchy"/>
    </F>
</F>

<F nm="BOOLEAN_EQUAL" exp="bool" params="***">
    <F nm="STRING_AT_LEAST_ONE_MEMBER_OF" exp="bool" params="*">
        <Par nm="OrclOIMUserHelpDeskOrgsWithHierarchy"/>
        <Par nm="OrclOIMUserOrganizationsWithParents"/>
    </F>
</F>

<F nm="AND" exp="bool" params="***">
    <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="***">
        <Par tp="str" val="OrclOIMUserHelpDeskOrgsWithHierarchy"/>
    </F>
</F>

<F nm="BOOLEAN_EQUAL" exp="bool" params="***">
    <F nm="STRING_AT_LEAST_ONE_MEMBER_OF" exp="bool" params="*">
        <Par nm="OrclOIMUserHelpDeskOrgsWithHierarchy"/>
        <Par nm="OrclOIMUserOrganizationsWithParents"/>
    </F>
</F>

<F nm="AND" exp="bool" params="***"/>
Change the denied-attribute obligation and add the attributes denied for the NON-EMPLOYEE user.

c. Add the plug-in class as follows:

```java
public class ResolveResourceUserTypeAttribute implements AttributeResolver {
    public Map<String, Object> resolveResourceAttributes(String subjectId,
        PolicyConstants.Resources resourceType,
        String resourceId)
    {
        if(resourceType!=PolicyConstants.Resources.USER) return null;

        Map<String, Object> env = new HashMap<String, Object>();
        try {
            Set<String> searchAttributes = new HashSet<String>();
            searchAttributes.add(oracle.iam.identity.utils.Constants.EMPTYPE);
            searchAttributes.add(oracle.iam.identity.utils.Constants.USERID);
            searchAttributes.add(oracle.iam.identity.utils.Constants.USERKEY);
            String empType;

            UserManager userManager = Platform.getService(UserManager.class);
            User user;
            user = userManager.getDetails(resourceId, searchAttributes, false);
            empType = (String)user.getAttribute(oracle.iam.identity.utils.Constants.EMPTYPE);
            if(empType.equalsIgnoreCase("Full-Time"))
                env.put("OrclOIMResourceUserAttributeType","EMPLOYEE");
            else env.put("OrclOIMResourceUserAttributeType","NON-EMPLOYEE");
        } catch (Exception e) {
            e.printStackTrace();
        }
        return env;
    }
```
Managing OES Policies

```java
public Map<String, Object> resolveSubjectAttributes(String subjectId,
  PolicyConstants.Resources resourceType) {
    return null;
}
```

Added the plugin.xml as:
```
<?xml version="1.0" encoding="UTF-8"?>
<oimplugins xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.oracle.com/schema/oim/plugin
  plugin.xsd">
  <plugins
    pluginpoint="oracle.iam.platform.authopss.plugin.AttributeResolver">
    <plugin
      pluginclass="oracle.iam.platform.authopss.plugin.impl.ResolveResourceUserTy
      peAttribute"
      version="1.0" name="ResolveResourceUserTypeAttribute">
      </plugin>
  </plugins>
</oimplugins>
```

A logged-in Help Desk Administrator user can view some attributes of the
EMPLOYEE users and some attributes for the NON-EMPLOYEE users. In addition,
the Help Desk Administrator user can modify different attributes for EMPLOYEE
users and different attributes for NON-EMPLOYEE users.

### 3.4.2.2 Controlling the Permissions Based on Default Home Organization

To control the permissions based on the default Home organization and use a flag to
enable/disable these policies:

1. Using APM, edit the attribute definition of the user to add the following attribute:

   ```
   <attribute>
     <name>OrclOIMHomeOrganizationPoliciesEffective</name>
     <display-name>OIM flag for putting the OES policies for home-org in
effect.</display-name>
     <description>OIM flag for putting the OES policies for home-org in
effect.</description>
     <attribute-category>DYNAMIC</attribute-category>
     <attribute-type>oracle.security.jps.service.policystore.info.OpssBoolean</attribute-type>
     <is-single-valued>true</is-single-valued>
   </attribute>
   ```

2. Change the policy condition as follows:

   ```
   <Condition>
     <F nm="AND" exp="bool" params=""/>
     <F nm="OR" exp="bool" params=""/>
     <F nm="BOOLEAN_EQUAL" exp="bool" params="">
       <F nm="ATTRIBUTE_HAS_VALUE" exp="bool" params="">
         <Par tp="str" val="OrclOIMHomeOrganizationPoliciesEffective"/>
       </F>
       <Par tp="bool" val="true"/>
     </F>
     <F nm="AND" exp="bool" params=""/>
     <F nm="BOOLEAN_EQUAL" exp="bool" params=""/>
   </Condition>
   ```
3. Add the plug-in class as follows:

```java
import java.util.Map;
import oracle.iam.platform.authpss.api.PolicyConstants;
import oracle.iam.platform.authpss.plugin.AttributeResolver;

public class RemoveHomeOrgUserPolicies implements AttributeResolver {
    public Map<String, Object> resolveResourceAttributes(String subjectId,
        PolicyConstants.Resources resourceType,
        String resourceId) {
        return null;
    }
}
```
Enforcing Functional Security

```java
PolicyConstants.Resources resourceType) {
    Map<String, Object> env = new HashMap<String, Object>();
    env.put("OrclOIMHomeOrganizationPoliciesEffective", false);
    return env;
}
```

Added the plugin.xml as:
```xml
<?xml version="1.0" encoding="UTF-8"?>
<oimplugins xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.oracle.com/schema/oim/plugin
    plugin.xsd">

    <plugins
        pluginpoint="oracle.iam.platform.authopss.plugin.AttributeResolver">
        <plugin
            pluginclass="oracle.iam.platform.authopss.plugin.impl.RemoveHomeOrgUserPolicies"
            version="1.0" name="RemoveHomeOrgUserPolicies">
        </plugin>
    </plugins>
</oimplugins>
```

The authorization policies related to Home organization will not work for the user entity. Therefore, the end-user cannot perform any operation on peers.

### 3.5 Enforcing Functional Security

You can enforce security by the following ways:

- **UI-level security**: This is used for UI-level validations to enforce security. For example, you can implement field-level security to ensure that only users with permissions to view and edit fields are able to access the fields. The fields are disabled or not displayed for users who do not have permissions on the fields. This type of security enforcement is at the UI level, and can be overridden if you use APIs to perform the validation.

  **Note**: To enforce functional security at the UI level, you must be aware of the following:

  - UI components and how to customize the components. See "Customizing the Interface" on page 30-1 for details.
  - Expression Language (EL) syntax and usage. See "Using Expression Language in UI Customization" on page 30-21 for details.

- **Backend security**: To enforce security at the backend, you can modify the OES policies by using the APM UI.

  For implementing functional security, first a JAVA authorization file is created in PlatformUI. This file contains the UIPermission variables for all the permissions defined in PolicyConstants (OES policies) for each functionality or page or module. All the authorization files have an entry in the adfc-config.xml file in the MainUI project in JDeveloper.

  Implementing functional security involves the following:

  - Implementing Task Flow or Region
3.5.1 Implementing Task Flow or Region

This level of implementation determines if the taskflow region is to be hidden or disabled to the user based on the permissions of the user. For securing a region, consider the following example:

On the my-access-accounts.jsff page, the taskflow details-information-tf is rendered selectively to the end users by using an expression that follows the Expression Language (EL) syntax, as shown:

```
rendered='#{oimappinstanceAuth.view[bindings.appInstanceKey].allowed}*
```

Here:

- `oimappinstanceAuth` is the mapped name of the ApplicationInstanceAuthz.java authorization bean in the adfc-config.xml file.
- `view` is the name of the UIPermission that is to be checked, where the permission defined in ApplicationInstanceAuthz.java, which is the actual bean file for reference of oimappinstanceAuth, is the following:

```java
private UIPermission view = new UIPermission(PolicyConstants.Resources.APPLICATION_INSTANCE.getId(), PolicyConstants.ApplicationInstanceActions.VIEW_SEARCH.getId());
```

- `appInstanceKey` is the ID of the application instance that the user is trying to view passed as a parameter.

3.5.2 Defining Actions

If actions, such as create, modify, disable, enable, revoke, delete, and withdraw request, are to be hidden or disabled for the user based on the user's permissions. For example, the **Create** button is displayed only to users with permission to create users.

Permissions defined in UserAuthz.java based on PolicyConstants is:

```java
private UIPermission create = new UIPermission(PolicyConstants.Resources.USER.getId(), PolicyConstants.UserActions.CREATE.getId());
```

Mapping entry for UserAuthz.java in adfc-config.xml in the MainUI project is as follows:

```xml
<managed-bean id="__30">
  <managed-bean-name id="__36">oimuserAuth</managed-bean-name>
  <managed-bean-class id="__29">oracle.iam.ui.platform.view.authz.UserAuthz</managed-bean-class>
  <managed-bean-scope id="__31">session</managed-bean-scope>
</managed-bean>
```

Now, you can define EL expression for permission that is defined in the JSFF page. In search-users.jsff, use the following EL expression in the rendered attribute, which is the Create button in this example:

```
<af:commandToolbarButton rendered='#{oimuserAuth.create.allowed}*
```
The EL expression defined in the rendered attribute hides or shows the button based on the Boolean value returned. Otherwise, the button can be made to read-only by defining the EL expression as disabled attribute instead of rendered. The Create button is now only shown to users whose role have permission defined in policies.

Similarly, you can define EL expressions for other actions, such as modify, enable, and disable. Another example of using EL expressions is to specify that reset password will be available to HelpDesk Admin only, and it will be hidden or read-only for other users.

### 3.5.3 Implementing Field-Level Security

Fields are displayed based on whether the user has permission to view those fields. For securing display fields, consider the following example:

On the userdetails.jsff page, under the Attributes tab, the user attributes, such as First Name, Last Name, and so on, have been secured by using the following EL expression:

```
rendered="#{oimuserAuth.viewSearch.attributes[bindings.firstName.hints.OIM_ATTRIBUTE]}"
```

Here:

- `oimuserAuth` is the mapped name of UserAuthz.java in the adfc-config.xml.
- `viewsearch` is the UIPermission name, and the Oracle Identity Manager attribute name for the field to be secured is passed as a parameter.
This part describes how to configure application-specific connectors.

It contains the following chapters:

- Chapter 4, "Developing Application Instances"
- Chapter 5, "Developing Provisioning Processes"
- Chapter 6, "Developing Process Forms"
- Chapter 7, "Managing Lookup Definitions"
Developing Application Instances

Application instance is a provisionable entity. It is a combination of IT resource instance (target connectivity and connector configuration) and resource object (provisioning mechanism). Application instances have business-friendly names that are easier to remember. Creating and managing application instances are performed by using the Oracle Identity System Administration.

Application instances can be connected or disconnected. A connected application instance has a connector defined for the provisioning of entities. A disconnected application instance is used for the provisioning of a disconnected resource, for which a connector is not defined, and therefore, the provisioning is performed manually by the administrator.

For information about application instance concepts and how to create and manage application instances, see “Managing Application Instances” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

This chapter describes how application developers can manage resource objects and IT resources manually. In addition, it describes the procedure to convert a disconnected application instance to a connected application instance.

This chapter includes the following topics related to managing resources, IT resources, and application instances:

- Creating IT Resources
- Managing IT Resources
- Managing Resources By Using the Design Console
- Converting a Disconnected Application Instance to Connected Application Instance

4.1 Creating IT Resources

To create an IT resource:

1. Login to Oracle Identity System Administration.

Note: The IT resource type is created before the IT resource can be created. The IT resource type can be created either by using the Design Console, or by importing the IT resource type using the Deployment Manager.
2. Under Configuration, click **IT Resource**. The Manage IT Resource page is displayed.

3. Click **Create IT Resource**. The Create IT Resource wizard is displayed.

4. On the Step 1: Provide IT Resource Information page, enter the following information:
   - **IT Resource Name**: Enter a name for the IT resource.
   - **IT Resource Type**: Select an IT resource type for the IT resource.
     - If you want to create an IT resource of the Remote Manager type, then select **Remote Manager** from the **IT Resource Type** list.
   - **Remote Manager**: If you want to associate the IT resource with a particular remote manager, then select the remote manager from this list. If you do not want to associate the IT resource with a remote manager, then leave this field blank.

   **Note**: If you select **Remote Manager** from the **IT Resource Type** list, then you must not select a remote manager from the **Remote Manager** list.

5. Click **Continue**.

6. On the Step 2: Specify IT Resource Parameter Values page, specify values for the parameters of the IT resource, and then click **Continue**.

7. On the Step 3: Set Access Permission to IT Resource page, if you want to assign roles to the IT resource and set access permissions for the roles, then:
   a. Click **Assign Role**.
   b. For the roles that you want to assign to the IT resource, select **Assign** and the access permissions that you want to set. For example, if you want to assign the **ALL USERS** role and set the Read and Write permissions to this role, then you must select the respective check boxes in the row, as well as the Assign check box, for this role.
   c. Click **Assign**.

8. On the Step 3: Set Access Permission to IT Resource page, if you want to modify the access permissions of roles assigned to the IT resource, then:
   a. Click **Update Permissions**.
   b. Depending on whether you want to set or remove specific access permissions for roles displayed on this page, select or deselect the corresponding check boxes.
   c. Click **Update**.

9. On the Step 3: Set Access Permission to IT Resource page, if you want to unassign a role from the IT resource, then:
a. Select the **Unassign** check box for the role that you want to unassign.

b. Click **Unassign**.

10. Click **Continue**.

11. On the Step 4: Verify IT Resource Details page, review the information that you provided on the first, second, and third pages. If you want to make changes in the data entered on any page, click **Back** to revisit the page and then make the required changes.

12. To proceed with the creation of the IT resource, click **Continue**.

13. The Step 5: IT Resource Connection Result page displays the results of a connectivity test that is run using the IT resource information. If the test is successful, then click **Create**. If the test fails, then you can perform one of the following steps:
   - Click **Back** to revisit the previous pages and then make corrections in the IT resource creation information.
   - Click **Cancel** to stop the procedure, and then begin from the first step onward.
   - Proceed with the creation process by clicking **Continue**. You can fix the problem later, and then rerun the connectivity test by using the Diagnostic Dashboard.

14. Click **Finish**.

### 4.2 Managing IT Resources

To locate an IT resource:

1. In Oracle Identity System Administration, under Configuration, click IT Resource. The Manage IT Resource page is displayed.

2. On the Manage IT Resource page, you can use one of the following search options to locate the IT resource that you want to view:
   - IT Resource Name: Enter the name of the IT resource, and then click **Search**.
   - IT Resource Type: Select the IT resource type of the IT resource, and then click **Search**.
   - Click **Search**.

On the Manage IT Resource page, the list of IT resources that meet the search criteria is displayed.

From this point onward, you can perform one of the following procedures on the IT resource:

- **Viewing IT Resources**
- **Modifying IT Resources**
4.2.1 Viewing IT Resources

To view an IT resource:

1. From the list of IT resources displayed in the search results, click the IT resource name.

2. If you want to view the IT resource parameters and their values, then select Details and Parameters from the list at the top of the page. Similarly, if you want to view the administrative roles assigned to the IT resource, then select Administrative Roles from the list.

4.2.2 Modifying IT Resources

To modify an IT resource:

1. From the list of IT resources displayed in the search results, click the edit icon for the IT resource that you want to modify.

2. If you want to modify values of the IT resource parameters, then:
   a. Select Details and Parameters from the list at the top of the page.
   b. Make the required changes in the parameter values.
   c. To save the changes, click Update.

3. If you want to modify the administrative roles assigned to the IT resource, first select Administrative Roles from the list at the top of the page and then perform the required modification.

4. If you want to unassign an administrative role, select the Unassign check box in the row in which the role name is displayed and then click Unassign.

Note:

- When you click Unassign, the administrative roles that you select are immediately unassigned from the IT resource. You are not prompted to confirm that you want to unassign the selected administrative roles.
- You cannot unassign the SYSTEM ADMINISTRATORS role.

5. If you want to assign new administrative roles to the IT resource, then:
   a. Click Assign Role.
   b. For the administrative roles that you want to assign to the IT resource, select the access permission check boxes and the Assign check box.
   c. Click Assign.

6. If you want to modify the access permissions of the administrative roles that are currently assigned to the IT resource, then:
   a. Click Update Permissions.
   b. Depending on the changes that you want to make, select or deselect the check boxes in the table.
c. To save the changes, click Update.

4.2.3 Deleting IT Resources

To delete an IT resource:

1. From the list of IT resources displayed in the search results, click the Delete icon for the IT resource that you want to delete.

2. To confirm that you want to delete the IT resource, click Confirm Delete.

Note: Deleting IT resource instances soft-deletes the corresponding application instances.

4.3 Managing Resources By Using the Design Console

This chapter describes resource management in the Design Console. It contains the following sections:

Note: Only the users belonging to the SYSTEM ADMINISTRATORS group of Oracle Identity Manager can log in to Design Console.

- Overview of Resource Management
- IT Resources Type Definition Form
- Rule Designer Form
- Resource Objects Form
- Service Account Management

4.3.1 Overview of Resource Management

The Resource Management folder provides you with tools to manage Oracle Identity Manager resources. This folder contains the following forms:

- **IT Resources Type Definition**: Use this form to create resource types that are displayed as lookup values on the IT Resources form.

- **Rule Designer**: Use this form to create rules that can be applied to password policy selection, automatic role membership, provisioning process selection, task assignment, and prepopulating adapters.

- **Resource Objects**: Use this form to create and manage resource objects. These objects represent resources that you want to make available to users and organizations.

See Also: See Chapter 8, "Using the Adapter Factory" for more information about adapters and adapter tasks.
4.3.2 IT Resources Type Definition Form

The IT Resources Type Definition form is in the Resource Management folder. You use the IT Resources Type Definition form to classify IT resource types, for example, AD, Microsoft Exchange, and Solaris. Oracle Identity Manager associates resource types with resource objects that it provisions to users and organizations.

After you define an IT resource type on this form, it is available for selection when you define an IT resource. The type is displayed in the Create IT Resource and Manage IT Resource pages of Advanced Administration.

IT resource types are templates for the IT resource definitions that reference them. If an IT resource definition references an IT resource type, the resource inherits all of the parameters and values in the IT resource type. The IT resource type is the general IT classification, for example, Solaris. The resource is an instance of the type, for example, Solaris for Statewide Investments.

You must associate every IT resource definition with an IT resource type.

Figure 4–1 shows the IT Resources Type Definition form.

Figure 4–1  The IT Resources Type Definition Form

Table 4–1 describes the fields of the IT Resources Type Definition form.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server Type</td>
<td>The name of the IT resource type</td>
</tr>
<tr>
<td>Insert Multiple</td>
<td>Specifies whether or not this IT resource type can be referenced by more than one IT resource</td>
</tr>
</tbody>
</table>

Note: If an IT resource must access an external resource but is not able to do so by using the network, you must associate it with a remote manager. For more information, see "Installing and Configuring a Remote Manager" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.
4.3.2.1 Defining a Template (a Resource Type) for IT Resources
To define an IT resource type:

1. Enter the name of the IT resource type in the Server Type field, for example, Solaris.
2. To make the IT resource type available for multiple IT resources, select Insert Multiple.
3. Click Save.

The IT resource type is defined. You can select it when defining IT resources in the Create IT Resource page of Advanced Administration.

4.3.2.2 Tabs on the IT Resource Type Definition Form
After you save the basic information for a new IT resource type, and when an IT resource type is returned on a query, the fields on the tabs of the IT Resources Type Definition form’s lower region are enabled.

The IT Resources Type Definition form contains the following tabs:

- IT Resource Type Parameter tab
- IT Resource tab

4.3.2.2.1 IT Resource Type Parameter Tab You use the IT Resource Type Parameter tab to specify default values and encryption settings for all connection parameters for the IT resource type, as shown in Figure 4–1. Oracle recommends that you do not specify default values for passwords and encrypted fields. Parameters and values on this tab are inherited by all IT resources that reference this IT resource type.

When you define a new parameter, the parameter and its values and encryption settings are added to the current IT resource type and to any new or existing IT resource definitions that reference this IT resource type. For an applicable resource definition, the new parameter is displayed in the Details and Parameters section of the Create IT Resource and Manage IT Resource pages of Advanced Administration.

---

**Note:** You can customize the values and encryption settings for these parameters within each IT resource.

---

Adding a Parameter to an IT Resource Type
To add a parameter to an IT Resource Type:

1. Click Add.

A new row is displayed in the IT Resource Type Parameter tab.

2. In the Field Name field, enter the name of the parameter.

3. In the Default Field Value field, enter a default value.

This value is inherited by all IT resources that reference this IT resource type

4. Select or clear the Encrypted option.

This check box determines if this parameter’s value is masked, that is, represented with asterisk (*) in a form field.

If you want the parameter’s value to be masked, select this check box.

5. Click Save.
Removing a Parameter from an IT Resource Type

To remove a parameter from an IT Resource Type:

1. Select the parameter you want to remove.
2. Click Delete.

   The parameter and its associated value are removed from the IT resource type and from IT resource definitions that reference this type.

4.3.2.2  IT Resource Tab

This tab displays IT resources that reference a selected IT resource type. All IT resources on this tab share the same parameters, but the values can be unique for each IT resource.

4.3.2.3  IT Resource Type Definition Table

The IT Resource Type Definition Table displays the following information:

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server Type</td>
<td>The name of the resource asset type, as defined in the IT Resource Type Definition form</td>
</tr>
<tr>
<td>Insert Multiple</td>
<td>Indicates whether or not multiple instances of this IT Resource Definition can be created</td>
</tr>
</tbody>
</table>

4.3.3  Rule Designer Form

Rules are criteria that enable Oracle Identity Manager to match conditions and take action based on them. A rule can be assigned to a specific resource object or process, or a rule can apply to all resource objects or processes.

The following are examples of rule usage:

- Determining a password policy to apply to a resource object of type Application.
- Enabling users to be added to roles automatically.
- Specifying the provisioning process that apply to a resource object after that resource object is assigned to a request.
- Determining how a process task is assigned to a user.
- Specifying which prepopulate adapter is executed for a given form field.

See Also: Oracle Identity Manager Tools Reference for more information about prepopulate adapters

The Rule Designer form shown in Figure 4–2 is in the Resource Management folder. You use this form to create and manage rules that are used with resources.
There are four types of rules:

**General:** Enables Oracle Identity Manager to add a user to a role automatically and to determine the password policy that is assigned to a resource object.

**Process Determination:** Determines the provisioning processes for a resource object.

**Task Assignment:** Specifies the user or role that is assigned to a process task.

**Prepopulate:** Determines which prepopulate adapter is executed for a form field.

A rule contains the following items:

- **A rule element:** Consists of an attribute, an operator, and a value. In Figure 4–2, the attribute is `User Login`, the operator is `==`, and the value is `XELSYSADM`.

- **A nested rule:** If one rule must be placed inside another rule for logic purposes, the internal rule is known as a nested rule. In Figure 4–2, a **Rule to Prevent Solaris Access** is nested in a **Rule for Solaris**.

- **An operation:** When a rule contains multiple rule elements or nested rules, an operation shows the relationship among the components. In Figure 4–2, if the **AND** operation is selected, the `User Login==XELSYSADM` rule element and the **Rule to Prevent Solaris Access** nested rule must both be true for the rule to be successful.

Table 4–2 describes the fields of the Rule Designer form.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The rule's name.</td>
</tr>
</tbody>
</table>
Managing Resources By Using the Design Console

4.3.3.1 Creating a Rule

To create a rule:

Note: In the following procedure, note that the options do not apply to rule elements within nested rules. For example, in Figure 4–2 the AND operation applies to the User Login == XELSYSADM rule element and the Rule to Prevent Solaris Access nested rule. But this operation has no effect on the Object Name != Solaris rule element in the Rule to Prevent Solaris Access rule.
1. Open the Rule Designer form.

2. In the Name field, enter the name of the rule.

3. To stipulate that a rule is successful only when all of its rule elements or nested rules are true, select the AND option.

   To indicate that a rule is successful if any of its rule elements or nested rules are true, select the OR option.

4. Click the Type box, and in the custom menu select the classification status (General, Process Determination, Task Assignment, or Prepopulate) to associate with the rule.

   For Process Determination, click Sub-Type and select the classification status (Organizational Provisioning or User Provisioning) to associate with the rule.

   For Task Assignment or Prepopulate, click Sub-Type and select the classification status (Organization Provisioning or User Provisioning) to associate with the rule.

   If you select General from the Type box, go to Step 7.

5. To associate the rule with a single resource object, double-click the Object lookup field, and in the Lookup dialog box select a resource object.

   If you want the rule to be available to all resource objects, select the All Objects option.

6. To assign a rule to one process, double-click the Process lookup field, and from the Lookup dialog box, select the process to associate with the rule.

   **Note:** The only processes that are displayed in this Lookup window are the ones that are associated with the resource object you selected in Step 5.

   If you want the rule to be available to all processes, select the All Processes option.

   **Note:** If you select a resource object in Step 5 by selecting the All Processes option, this rule is available to every process that is associated with the selected resource object.

7. In the Description field, enter explanatory information about the rule.

8. Click Save.

### 4.3.3.2 Tabs on the Rule Designer Form

The Rule Designer form contains the following tabs:

- Rule Elements tab
- Usage tab

Each of these tabs is discussed in the following sections.

#### 4.3.3.2.1 Rule Elements Tab

From this tab, you can create and manage elements and nested rules for a rule. For example, in Figure 4–3, the Rule for Solaris contains the User Login==XELSYSADM rule element. It also has a nested Rule to Prevent Solaris Access. Figure 4–3 displays the Rule Elements tab of the Rule Designer form.
Figure 4–3  Rule Elements Tab of the Rule Designer Form

The rule in Figure 4–3 can be applied to a provisioning process for the Solaris resource object. After this resource object is assigned to a request, the rule is triggered. If the target user's login is XELSYSADM, and the name of the resource object is Solaris, the Solaris resource object is provisioned to the user. Otherwise, the user cannot access Solaris.

When a rule element or nested rule is no longer valid, remove it from the rule.

The following procedures describe how to:

- Add a rule element to a rule
- Add a nested rule to a rule
- Remove a rule element or nested rule from a rule

Adding a Rule Element to a Rule

To add a rule element to a rule:

1. Click Add Element.

   The Edit Rule Element dialog box is displayed.

   The custom menus in the boxes on the Edit Rule Element dialog box reflect the items in the Type and Sub-Type boxes of the Rule Designer form.

   Table 4–3 describes the data fields in the Edit Rule Element dialog box.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attribute Source</td>
<td>From this box, select the source of the attribute. For example, if the attribute you wish to select is Object Name, the attribute source to select would be Object Information.</td>
</tr>
<tr>
<td>User-Defined Form</td>
<td>This field displays the user-created form that is associated with the attribute source that is displayed in the adjacent box. Note: If Process Data are not displayed in the Attribute Source box, the User-Defined Form field will be empty.</td>
</tr>
<tr>
<td>Attribute</td>
<td>From this box, select the attribute for the rule.</td>
</tr>
</tbody>
</table>
2. Set the parameters for the rule you are creating, as shown in Figure 4–4.

**Figure 4–4  Edit Rule Element Window**

![Edit Rule Element Window](image)

In this example, if the Login ID of the target user is XELSYSADM, the rule element is true. Otherwise, it is false.

**See Also:** For more information about the parameters, see "Rule Elements Tab" on page 4-11

3. From the Toolbar of the Edit Rule Element dialog box, click **Save**, and click **Close**.
   
The rule element is displayed in the **Rule Elements** tab of the Rule Designer form.

4. From the main screen’s toolbar, click **Save**.
   
The rule element is added to the rule.

**Adding a Nested Rule to a Rule**

To nest a rule within a rule:

**Note:** In the following procedure, only rules of the same type and subtype as the parent rule are displayed in the Select Rule window.

1. Click **Add Rule**.
   
The Select Rule dialog box is displayed.

2. Select a nested rule and click **Save**.

3. Click **Close**.
   
The nested rule is displayed in the **Rule Elements** tab of the Rule Designer form.

4. From the main screen’s Toolbar, click **Save**.
   
The nested rule is added to the rule.
Removing a Rule Element or Nested Rule from a Rule
To remove a rule element or a nested rule:

1. Select the rule element or nested rule that you want to remove.
2. Click Delete.

The rule element or nested rule is removed from the rule.

4.3.3.2 Usage Tab
This tab is displayed on the Rule Designer form. The information in the Usage tab reflects the rule’s classification type. For example, if a rule type is prepopulate, the user-created field that this rule is applied to is displayed in this tab.

Figure 4–5 shows the Usage tab.

Figure 4–5 Usage Tab of the Rule Designer Form

This tab displays the following items:

- The password policy, resource object, process, process task, auto-role membership criteria, role, Oracle Identity Manager form field, and prepopulate adapter associated with a rule.
- A one-letter code, signifying the rule’s classification type: P=Provisioning.
  - This code is displayed for process determination rules only.
- The rule’s priority number.

4.3.3.3 Rule Designer Table
The Rule Designer Table, as shown in Figure 4–6, displays all available rules defined in the Rule Designer form.
Table 4–4 shows the information displayed in the Rule Designer Table.

Table 4–4 Information in the Rule Designer Table

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Name</td>
<td>The name of the rule.</td>
</tr>
<tr>
<td>Rule Type</td>
<td>A rule can belong to one of four types:</td>
</tr>
<tr>
<td></td>
<td>- <strong>General</strong>: Enables Oracle Identity Manager to add a user to a role automatically and determines the password policy that is assigned to a resource object.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Process Determination</strong>: Determines the provisioning processes that are selected for a resource object.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Task Assignment</strong>: Determines which user, role, or both are assigned to a process task.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Pre-Populate</strong>: Determines which prepopulate adapter is executed for a given form field.</td>
</tr>
<tr>
<td>Rule Sub-Type</td>
<td>A rule of type Process Determination, Task Assignment, or Pre-Populate can be categorized into one of four sub-types:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Organization Provisioning</strong>: Classifies the rule as a provisioning rule. You use this subtype to determine the organization for which a process is provisioned, a task is assigned, or the prepopulate adapter is applied.</td>
</tr>
<tr>
<td></td>
<td>- <strong>User Provisioning</strong>: Classifies the rule as a provisioning rule. You use this subtype to determine the user for which a process is provisioned, a task is assigned, or a pre-populate adapter is applied.</td>
</tr>
<tr>
<td>Rule Operator</td>
<td>The relationship between the attribute and the attribute value represented by the <code>==</code> or <code>!=</code> operators.</td>
</tr>
<tr>
<td>Description</td>
<td>Explanatory information about the rule.</td>
</tr>
<tr>
<td>Last Updated</td>
<td>The date when the rule was last updated.</td>
</tr>
</tbody>
</table>

4.3.4 Resource Objects Form

The Resource Objects form is in the Resource Management folder. You use this form to create and manage the resource objects for the Oracle Identity Manager resources that you want to provision for organizations or users. Resource object definitions are templates for provisioning the resource. However, the provisioning of the resource depends on the design of the provisioning processes that you link to the resource object.
Figure 4–7 shows the Resource Objects form.

**Figure 4–7  The Resource Objects Form**

![Resource Objects Form Diagram]

Table 4–5 describes the data fields of the Resource Objects form.

**Table 4–5  Fields of the Resource Objects Form**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the resource object form that is associated with this resource. (This is actually the name of the table that represents the form.)</td>
</tr>
<tr>
<td>Order For User/Order For Organization</td>
<td>Options that determine whether or not the resource object can be requested for users or organizations. To request the resource object for a user, select <strong>Order For User</strong>. To request the resource object for an organization, select <strong>Order For Organization</strong>.</td>
</tr>
<tr>
<td>Type</td>
<td>The resource object's classification status. A resource object can belong to one of the following types:</td>
</tr>
<tr>
<td></td>
<td>■ <strong>Application</strong>: Classifies this resource object as an application.</td>
</tr>
<tr>
<td></td>
<td>■ <strong>Generic</strong>: Contains business-related processes.</td>
</tr>
<tr>
<td></td>
<td>■ <strong>System</strong>: Oracle Identity Manager uses this type of resource object internally. Do not modify system resource objects without first consulting Oracle.</td>
</tr>
<tr>
<td></td>
<td>■ <strong>Disconnected</strong>: Classifies the resource object as a disconnected resource.</td>
</tr>
</tbody>
</table>
4.3.4.1 Creating a Resource Object

To create a resource object:

1. Open the Resource Objects form.
2. In the Name field, enter the name of the resource object.
3. To request the resource object for a user, select Order For User.
   To request the resource object for an organization, select Order For Organization.

4. Double-click the Type lookup field.
   From the Lookup dialog box that is displayed, select the classification status (Application, Generic, System, or Disconnected) to associate with the resource object.
5. If you want to use the resource object for trusted source user reconciliation, you must select the Trusted Source option. Otherwise, go to Step 6.
6. Click Save.
   The resource object is created.

4.3.4.2 Tabs on the Resource Objects Form

When you start the Resource Objects form and create a resource object, the tabs of this form become functional.

The Resource Objects form contains the following tabs:

- Depends On Tab
- Object Authorizers Tab
- Process Determination Rules Tab
- Event Handlers/Adapters Tab
- Resource Audit Objectives
- Status Definition Tab
- Administrators Tab
- Password Policies Rule Tab
- User-Defined Fields Tab
- Process Tab
- Object Reconciliation Tab

---

**Table 4–5 (Cont.) Fields of the Resource Objects Form**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trusted Source</td>
<td>You can select this check box if you want to use the resource object for trusted user reconciliation. By default, this check box is not selected. It is selected by default only for the Xellerate User resource object.</td>
</tr>
</tbody>
</table>
4.3.4.2.1 Depends On Tab  From this tab, you can select resource objects that Oracle Identity Manager must provision before provisioning the current resource object. If Oracle Identity Manager can provision the current resource object without first provisioning a resource object that is displayed on the Depends On tab, you must remove that resource object from the tab.

In addition, you must setup a parent-child relationship between the application instances as well. This is done by opening the application instance for the dependent resource and selecting the independent application instance as the parent from the drop-down for parent application instance. See “Managing Application Instances” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about the application instance UI.

The following topics are related to the Depends On tab:

- Selecting a resource object on which the current resource object is dependent
- Removing the dependent resource object

Selecting a Dependent Resource Object
To select a dependent resource object:
1. Click Assign.
   The Assignment dialog box is displayed.
2. Select the resource object.
3. Click OK.
   The dependent resource object is selected.

Removing a Dependent Resource Object
To remove a dependent resource object:
1. Select the dependent resource object that you want to remove.
2. Click Delete.
   The resource object is removed from the Depends On tab.

4.3.4.2.2 Object Authorizers Tab  Use this tab to specify roles that are the object authorizers for this resource. You can select users who are members of the Object Authorizers roles as targets for task assignments.

Each role on the Object Authorizers tab has a priority number. The priority number can also be referenced when a task assigned to a role is escalated due to lack of action. You can increase or decrease the priority number for any role on this tab.

For example, suppose that you configure members of the SYSTEM ADMINISTRATORS roles to be object authorizers. Also suppose that a process task associated with this resource object has a task assignment rule attached to it. The first user authorized to complete this process task is the user with the priority number 1. If the user does not complete the process task in a user-specified time, Oracle Identity Manager reassigns the task to the user with the next priority in the SYSTEM ADMINISTRATORS role.

See Also:  "Rule Designer Form” on page 4-8 and "Assignment Tab of the Editing Task Window” on page 5-30 for more information about task assignment rules and process tasks
Assigning a Role to a Resource Object
To assign a role to a resource object:

1. Click Assign.
   The Assignment dialog box is displayed.
2. Select a role.
3. Click OK.
   The role is selected.

Removing a Role from a Resource Object
To remove a role from a resource object:

1. Select the desired role.
2. Click Delete.
   The role is removed from the Object Authorizers tab.

4.3.4.2.3 Process Determination Rules Tab
A resource object is a template for the resource that is provisioned to users or organizations. This template can be linked to multiple provisioning processes. Oracle Identity Manager uses process determination rules to select a provisioning process when a resource is requested or directly provisioned.

Process determination rules provide the following criteria:
- Which provisioning process to select when a resource is requested
- Which provisioning process to select when a resource is provisioned directly

Each provisioning process has a process determination rule. Each rule and process combination has a priority number that indicates the order in which Oracle Identity Manager will evaluate it.

If the condition of a rule is false, Oracle Identity Manager evaluates the rule with the next highest priority. If a rule is true, Oracle Identity Manager executes the process associated with it.

Adding a Process Determination Rule to a Resource Object
To add a process determination rule to a resource object:

1. Click Add in the Provisioning Processes region, depending on the rule or process combination you intend to create.
2. From the row that is displayed, double-click the Rules lookup field.
3. From the Lookup dialog box, select a rule, and assign it to the resource object (only rules of Process Determination type are available for selection).
4. Click OK.
5. In the adjacent column, double-click the Processes lookup field.
6. From the Lookup dialog box, select a process, and assign it to the rule.
7. Click OK.
8. Enter a numeric value in the Priority field.
   This determines the order in which Oracle Identity Manager evaluates the rule and process combination.
9. Click Save.
The rule and process combination is added to the resource object.

**Remove a Process Determination Rule From a Resource Object**

To remove a process determination rule from a resource object:

1. Select a rule and process combination.
2. Click *Delete*.

The rule and process combination is removed from the resource object.

**4.3.4.2.4 Event Handlers/Adapters Tab**

A resource object’s provisioning process contains tasks that must be completed automatically. When this occurs, you must assign an event handler or an adapter to the resource object. An event handler is a software routine that provides the processing of this specialized information. An adapter is a specialized type of event handler that generates Java code, which enables Oracle Identity Manager to communicate and interact with external resources.

When an event handler or adapter that is assigned to a resource object that is no longer valid, you must remove it from the resource object.

For this example, the `adpAUTOMATEPROVISIONINGPROCESS` adapter was assigned to the `Solaris` resource object. Once this resource object is assigned to a request, Oracle Identity Manager triggers the adapter, and the associated provisioning process is executed automatically.

**Assigning an Event Handler or Adapter to a Resource Object**

To assign an event handler to an adapter or a resource object:

1. Click *Assign*.
   
The Assignment dialog box is displayed.
2. Select an event handler, and assign it to the resource object.
3. Click *OK*.
   
The event handler is assigned to the resource object.

**Remove an Event Handler or Adapter from a Resource Object**

To remove an event handler or adapter from a resource object, perform the following steps:

1. Select an event handler.
2. Click *Delete*.

   The event handler is removed from the resource object.

**4.3.4.2.5 Resource Audit Objectives**

The Resource Objects form in the Design Console includes a resource attribute named Resource Audit Objectives. This resource attribute helps you link resources to regulatory mandates.

A lookup is defined for the values of the Resource Audit Objectives resource attribute. The predefined values in the Resource Audit Objectives list are:

- SOX (Hosts Financially Significant Information)
- HIPAA (Hosts Private Healthcare Information)
- GLB (Hosts Non-Public Information)
- Quarterly Review
• Annual Review

You can extend this list by editing the Lookups.Resource Audit Objective.Type lookup by using the Lookup Definition Form in the Design Console.

4.3.4.2.6 Status Definition Tab You use this tab to set provisioning status for a resource object. A provisioning status indicates the status of a resource object throughout its lifecycle, until it is provisioned to the target user or organization.

Every provisioning status of a resource object is associated with a task status for the relevant provisioning process. Oracle Identity Manager selects the provisioning process when the resource object is assigned to a request. For example, if the Provision for Developers process is selected, and a task in this process achieves Completed status, the corresponding status of the resource object can be set to Provisioned. This way, you can see how the resource object relates to the provisioning process, quickly and easily.

A resource object has the following predefined statuses:

• Waiting: This resource object depends on other resource objects that have not yet been provisioned.

• Revoked: The resources represented by the resource object are provisioned to target users or organizations that have been permanently deprovisioned from using the resources.

• Ready: This resource object either does not depend on any other resource objects, or all resource objects upon which this resource object depends are provisioned.

After a resource is assigned to a request and the resource object’s status is Ready, Oracle Identity Manager evaluates the process determination rules to determine the provisioning process. When this happens, the status of the resource object changes to Provisioning.

• Provisioning: The resource object is assigned to a request and a provisioning process has been selected.

• Provisioned: The resources represented by the resource object are provisioned to the target users or organizations.

• Provide Information: Additional information is required before the resources represented by the resource object can be provisioned to the target users or organizations.

• None: This status does not represent the provisioning status of the resource object. Rather, it signifies that a task that belongs to the provisioning process that Oracle Identity Manager selects has no effect on the status of the resource object.

• Enabled: The resources represented by the resource object are provisioned to the target users or organizations, and these users or organizations have access to the resources.

• Disabled: The resources represented by the resource object are provisioned to the target users or organizations, but these users or organizations have temporarily lost access to the resources.

Each provisioning status has a corresponding Launch Dependent check box. If the check box is selected and if the parent resource object achieves that provisioning status, then Oracle Identity Manager will continue the provisioning of the dependent resource object.

For example, suppose that the Exchange resource object depends on Active Directory and has the Launch Dependent check box selected for the Provisioned and Enabled status.
provisioning statuses. When the provisioning status of Active Directory changes to Provisioned or Enabled, and if Exchange provisioning is waiting on it, then Oracle Identity Manager will continue the provisioning process of Exchange.

You might want to add additional provisioning statuses to a resource object to reflect the various task statuses of a provisioning process. For example, when the status of a task that belongs to a provisioning process is Rejected, you might want to set the corresponding provisioning status of the resource object to Revoked.

Similarly, when an existing provisioning status is no longer valid, you must remove it from the resource object.

The following sections discuss how to add a provisioning status to a resource object and remove a provisioning status from a resource object.

**Adding a Provisioning Status to a Resource Object**

To add a provisioning status to a resource object:

1. Click Add.
2. Add a provisioning status in the Status field.
3. When you want other, dependent resource objects to launch their own provisioning process once the resource object achieves the provisioning status you are adding, select the Launch Dependent check box. Otherwise, go to Step 4.
4. Click Save.

   The provisioning status is added to the resource object.

**Removing a Provisioning Status from a Resource Object**

The following procedure describes removing a provisioning status from a resource object:

1. Select a provisioning status.
2. Click Delete.

   The provisioning status is removed from the resource object.

**4.3.4.2.7  Administrators Tab**  This tab is used to select roles that can view, modify, and delete the current resource object.

When the Write check box is selected, the corresponding role can modify the current resource object. When the Delete check box is selected, the associated role can delete the current resource object.

The following sections describe how to assign a role to a resource object, and remove a role from a resource object.

**Assigning a Role to a Resource Object**

To assign a role to a resource object:

1. Click Assign.

   The Assignment dialog box is displayed.
2. Select the role, and assign it to the resource object.
3. Click OK.

   The role is displayed in the Administrators tab. By default, all members of this role can view the active record.
4. If you want this role to be able to modify the current resource object, select the corresponding **Write** check box.
   Otherwise, go to Step 5.

5. If you want this role to be able to delete the current resource object, select the associated **Delete** check box.
   Otherwise, go to Step 6.

6. Click **Save**.
   The role is assigned to the resource object.

**Removing a Role from a Resource Object**
To remove a role from a resource object:
1. Highlight the role that you want to remove.
2. Click **Delete**.
   The role is removed from the resource object.

**4.3.4.2.8 Password Policies Rule Tab**
If a resource object is of type Application, and you want to provision the resource object to a user or organization, you might want that user or organization to meet password criteria before accessing the resource object. This password criteria is created and managed in the form of password policies. These policies are created by using the Password Policies form.

Because the resource object definition is only a template for governing how a resource is to be provisioned, Oracle Identity Manager must be able to make determinations about how to provision the resource based on actual conditions and rules. These conditions might not be known until the resource is actually requested. Therefore, rules must be linked to the various processes and password policies associated with a resource. This enables Oracle Identity Manager to decide which ones to invoke in any given context.

Oracle Identity Manager determines which password policy to apply to the resource when creating or updating a particular user’s account. This is done by evaluating the password policy rules of the resource and applying the criteria of the policy associated with the first rule that is satisfied. Each rule has a priority number, which indicates the order in which Oracle Identity Manager will evaluate it.

The following sections discuss how to add and remove a password policy rule from a resource object.

**Adding a Password Policy Rule to a Resource Object**
To add a password policy rule to a resource object:
1. Click **Add**.
2. From the row that is displayed, double-click the **Rule** lookup field.
3. From the Lookup dialog box, select a rule, and assign it to the resource object.
4. Click **OK**.
5. In the adjacent column, double-click the **Policy** lookup field.
6. From the Lookup dialog box, select an associated password policy, and assign it to the resource object.
7. Click **OK**.
8. Add a numeric value in the **Priority** field.
   This field contains the rule's priority number.

9. Click **Save**.
   The password policy rule is added to the resource object.

---

**Note:**
- If the resource type is Order for Organization, you cannot attach a password policy to the resource object. The exception to this rule is the Xellerate User resource object. Although this resource object is of Order for Organization type, password policies can be attached to it.
- If two or more rules evaluate to True, the password policy attached to the rule with the highest priority is applied.
- A Default rule is predefined in Oracle Identity Manager. This rule always evaluates to True. If no rules have been created through the Rule Designer, a password policy can be attached to the Default rule.

---

**Removing a Password Policy Rule from a Resource Object**
To remove a password policy from a resource object:

1. Select a password policy rule.
2. Click **Delete**.
   The password policy rule is removed from the resource object.

---

**4.3.4.2.9 User-Defined Fields Tab** You use this tab to view and access user-defined fields that were created for the Resource Objects form. After a user-defined field is created, it is displayed on this tab and can accept and supply data.

**4.3.4.2.10 Process Tab** The **Process** tab displays all provisioning processes that are associated with the current resource object. The **Default** check boxes on this tab indicate what provisioning processes are the defaults for the resource.

---

**Note:** You create provisioning processes and associate them with a resource by using the Process Definition form. Each process can be linked to a process determination rule by using the **Process Determination Rules** tab of the Resource Object form.

---

For example, suppose that the Solaris resource object has one provisioning processes (Provision Solaris for Devel.) associated with it. The Provision Solaris for Devel. has been designated as the default provisioning process for this resource object.

**4.3.4.2.11 Object Reconciliation Tab** The Object Initial Reconciliation Date field on the Object Reconciliation Tab displays the date when initial reconciliation was performed for the resource.

---

**Note:** The purpose of initial reconciliation is to bring all the user accounts from the target system into Oracle Identity Manager.
The date value stored in the Object Initial Reconciliation Date field is used to distinguish between initial reconciliation and subsequent reconciliations events. This date value is used by the two exception reports. These exception reports display differences in the entitlements a user must have as compared to what the user actually has in the target system. The differences in entitlements are determined by using reconciliation data, along with other data items. The exception reports return data associated with only those reconciliation events that are created after the date stored in the Object Initial Reconciliation Date field. In addition, exception data is generated only if the Initial Object Reconciliation Date field displays a date value that is in the past. If required, you can enter a date value in this field so that the exception reports are generated.

The Object Reconciliation tab contains two subtabs, Reconciliation Fields and Reconciliation Action Rules.

- The **Reconciliation Fields** tab is used to define the fields on the target resources or trusted sources that are to be reconciled with (for example, mapped to) information in Oracle Identity Manager

- The **Reconciliation Action Rules** tab is used to specify the actions Oracle Identity Manager is to take when particular matching conditions are met.

Click the **Create Reconciliation Profile** button in the Object Reconciliation tab to generate reconciliation profile whenever any changes are made to the resource object or associated process forms.

**Reconciliation Fields Tab**

This tab is used to define the fields on the target resources or trusted sources that are to be reconciled with (for example, mapped to) information in Oracle Identity Manager. For each field on the target system or trusted source, the following information will be listed:

- Name of the field on the target resource or trusted source that is to be reconciled with data in Oracle Identity Manager (for example, targetfield1)

- Data type associated with the field (for example, String). Possible values are multi-valued, string, number, date, IT resource

- Indicator that designates whether or not this field is required in a reconciliation event

**Note:** Oracle Identity Manager will not begin to match provisioning processes, users or organizations to the reconciliation event until all fields are processed on the Reconciliation section of the Event Management tab in the Advanced Administration.

The following is an example of a reconciliation field definition:

```
TargetField1 [String], Required
```

In the Reconciliation Fields tab, you can perform the following:

- Add a reconciliation field

  The following procedure adds fields from the target system or trusted source to the list of fields that are to be reconciled with information in Oracle Identity Manager.
To add a reconciliation field:

1. Click **Add Field**.
   
   The Add Reconciliation Field dialog box is displayed.

2. Enter the name of the field on the target resource or trusted source in the **Field Name** field.
   
   This is the name that will reference the target resource or trusted source field in Oracle Identity Manager.

3. Select one of the following values from the menu in the **Field Type** field:
   
   - **Multi-Valued**
     
     This is meant for use with fields that contain one or more component fields.
   
   - **String**
   
   - **Number**
   
   - **Date**
   
   - **IT resource**
     
     During reconciliation event creation, the value this field receives must be the same as the name of an IT resource defined in Oracle Identity Manager.

4. Select the **Required** check box.
   
   If selected, the reconciliation field must be processed on the Reconciliation section of the Event Management tab in the Advanced Administration before Oracle Identity Manager will begin matching a provisioning process, user, or organization to the reconciliation event. If this check box is not selected, the inability to process this field in a reconciliation event will not prevent matching from occurring.

5. Click **Save**.
   
   The field will be available for mapping in the resource’s default provisioning process.

- **Delete a reconciliation field**

  Use the following procedure to remove a target system field from the list of fields that are to be reconciled with information in Oracle Identity Manager. For a trusted source, this must be the user resource definition.

To delete a reconciliation field:

1. Select the field you wish to remove.

2. Click **Delete Field**.
The selected field will be removed from the list of fields with which Oracle Identity Manager reconciles data on the target system (this will have no effect on the data in the target system itself).

**Reconciliation Action Rules Tab**

By using this tab, you can specify the actions that Oracle Identity Manager will perform when some matches within reconciliation event records are encountered. Each record in this tab is a combination of:

- The matching condition criteria
- The action to be performed

The conditions and actions from which you can select are predefined. Depending on the matching conditions, certain actions might not be applicable. A complete list of the available options is provided in Table 4-6.

**Table 4-6  Rule Conditions and Possible Rule Actions**

<table>
<thead>
<tr>
<th>Rule Condition</th>
<th>Possible Rule Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>No matches found</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>Create User (only available with the trusted source)</td>
</tr>
<tr>
<td>One Process Match Found</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>Establish Link</td>
</tr>
<tr>
<td>Multiple Process Matches Found</td>
<td>None</td>
</tr>
<tr>
<td>One Entity Match Found</td>
<td>None</td>
</tr>
<tr>
<td></td>
<td>Establish Link</td>
</tr>
<tr>
<td>Multiple Entity Matches Found</td>
<td>None</td>
</tr>
</tbody>
</table>

**See Also:** "Assignment Tab of the Editing Task Window" on page 5-30 for a description of the classification types for the users and roles listed in the preceding table

**Adding a Reconciliation Action Rule**

To add a reconciliation action rule:

1. **Click Add Field.**
   
   The **Add a new Action Rule** dialog box is displayed.

2. **Select the desired value from the Rule Condition menu.**
   
   This is the matching condition that will cause the associated action to be executed. Each match condition can only be assigned to a single rule action.

3. **Select a value from the Rule Action menu.**
   
   This is the action that will be executed if the matching condition is met.

4. **Click Save,** and close the Add a new Action Rule dialog box.

**Deleting a Reconciliation Action Rule**

To delete a reconciliation action rule:

1. Select the matching action combination to delete.
2. Click Delete.

The reconciliation action rule will be removed and the action associated with its condition will not be executed automatically.

### 4.3.4.3 Multiple Trusted Source Reconciliation

You can create the reconciliation fields, reconciliation action rules, field mappings, and matching roles for the Xellerate User resource object and the process definition.

If there are two trusted sources from which you want to reconcile identities to create OIM Users, you are not able to configure a single resource object (Xellerate User) for both the trusted sources. Even if you create reconciliation fields for both the trusted sources in the Xellerate User resource object, you cannot create the corresponding reconciliation field mappings in the Xellerate User process definition.

You can configure resource objects other than Xellerate User as trusted sources for identity reconciliation. You can do this by selecting the Trusted Source check box in the Resource Objects form while creating a resource object.

For a resource object to which the Trusted Source flag is attached, you can create multiple reconciliation fields to denote the target system fields. You can also configure the reconciliation action rule in which if there are no process matches found, either a user is created or the data is sent to the administrator or authorizer for identity creation. If a process match is found, the link is established.

When defining provisioning process for trusted source resources, do not attach user-defined process forms. For these provisioning processes, reconciliation field mappings can be created between reconciliation fields defined on the resource and OIM User attributes.

---

**Note:** If the resource object is for target resource reconciliation, then the mapping is between the reconciliation fields and process data fields.

Do not use any resource objects that are defined as a trusted source for provisioning activities. These resources are meant to be used only for OIM Users’ reconciliation.

---

The attribute authoritative sources feature means that the sources are trusted for only attributes of the identities and not the identities themselves. You can configure attribute authoritative source reconciliation by creating appropriate reconciliation action rules. If no process match is found, it is assigned to the administrator. This ensures that a user is not created by mistake even if there are no matches found. If a process match is found, the reconciliation action rule will establish a link.

The following sections discuss two use cases in which you can implement multiple trusted source reconciliation:

---

**Note:** At some places in this document:

- Multiple trusted source reconciliation has been referred to as MTS.
- The terms fields and attributes have been used interchangeably.

---

- Multiple Trusted Source Reconciliation Using MTS-Compatible Connectors
Multiple Trusted Source Reconciliation Using Connectors That Are Not MTS-Compatible

Note: For both use cases, create reconciliation profiles by referring to "Reconciliation Profile" on page 23-8 and "Updating Reconciliation Profiles Manually" on page 23-23.

4.3.4.3.1 Multiple Trusted Source Reconciliation Using MTS-Compatible Connectors

Note: To determine whether or not your connector is MTS-compatible, see connector-specific documentation.

The following sections discuss scenarios in which you can implement multiple trusted source reconciliation by using MTS-compatible connectors:

- Configuring MTS-Compatible Connectors for Trusted Source Reconciliation by User Type
- Configuring MTS-Compatible Connectors for Trusted Source Reconciliation of Specific OIM User Attributes

Configuring MTS-Compatible Connectors for Trusted Source Reconciliation by User Type

In this context, user type refers to the type of users whose records you want to reconcile. Examples of user types are Employee and Customer.

To implement trusted source reconciliation by user type, perform the procedure to implement trusted source reconciliation while deploying the connectors of each target system that you want to configure as a trusted source.

During reconciliation, all the target system records of the specified user types are reconciled. If the target systems contain multiple user types, you can use the Limited Reconciliation feature to specify the user type for which records must be reconciled from each target system.

Configuring MTS-Compatible Connectors for Trusted Source Reconciliation of Specific OIM User Attributes

You might want to configure trusted source reconciliation for specific OIM User attributes from multiple target systems. The procedure to implement this is described with the help of the following sample scenario:

You want to reconcile identities from one target system, for example TS1, and specific attributes of these identities (for example attr1, attr2, and attr3) from another target system, for example TS2. This means that TS1 is the trusted source for the identities, and TS2 is the trusted source for specific attributes of those identities and not the identities themselves. TS1 must provide all the mandatory OIM User attributes for the successful creation of an OIM User. TS2 will provide only those OIM User attributes (either a mandatory OIM User attribute or a non-mandatory one) for which TS2 is the trusted source. If you reconcile a mandatory OIM User attribute from TS2, the value of this attribute overwrites the value contained in this attribute after the OIM User is created from TS1. If you want to reconcile only non-mandatory OIM User attributes from TS2, you can choose not to reconcile these attributes from TS1 during OIM User creation.
For the TS1 connector:

1. Perform all the steps required to deploy the TS1 connector and configure it for trusted source reconciliation.

   **See Also:** The documentation for the connector you are deploying for information about the procedure to configure trusted source reconciliation.

2. In the Reconciliation Fields tab on the Object Reconciliation page, delete all the TS1 attributes that you want to reconcile from TS2 (in this case attr1, attr2, and attr3).

3. In the Reconciliation Field Mappings tab on the Process Definition page, delete all the mappings other than the ones you want to retain.

   Instead of deleting reconciliation fields, you can remove the reconciliation field mappings of those fields for which you do not want to reconcile the values into the OIM User created through reconciliation.

4. In the Reconciliation Action Rules tab on the Object Reconciliation page, ensure that the following rule condition and action mappings exist:

   **Rule Condition:** No Matches Found

   **Action:** Create User

For the TS2 connector:

1. Perform all the steps required to deploy the TS2 connector and configure it for trusted source reconciliation.

   **See Also:** The documentation for the connector you are deploying for information about the procedure to configure trusted source reconciliation.

2. In the Reconciliation Field Mappings tab on the Process Definition page, delete all the mappings other than the ones you want to retain.

   Instead of deleting reconciliation fields, you can also choose to just remove the reconciliation field mappings of those fields for which you do not want to reconcile the values into the OIM User created through reconciliation.

3. In the Reconciliation Fields tab on the Object Reconciliation page, delete all the TS2 attributes other than attr1, attr2, and attr3. In addition, retain the attributes that you want to use to match OIM Users with existing TS2 accounts. This means that you retain only those attributes that will be used for reconciliation rule evaluation. For example, you might want to use the *username* attribute in Oracle Identity Manager to match the value of the *first name* attribute in TS1.

4. In the Reconciliation Action Rules tab on the Object Reconciliation page, create rule conditions and action mappings. One of these rule condition-action mappings must be the following:

   **Rule Condition:** No Matches Found

---

**Note:** When there are multiple trusted sources, the logic to reconcile the entity attributes from the trusted sources is provided by the connector.
4.3.4.3.2  Multiple Trusted Source Reconciliation Using Connectors That Are Not MTS-Compatible

**Note:** To determine whether or not your connector is MTS-compatible, see connector-specific documentation.

For a connector that is not MTS-compatible, the following prerequisites must be addressed before you can use the connector in a multiple trusted source reconciliation setup:

i. Only one of the trusted source resource objects can be Xellerate User. In your operating environment, if the Xellerate User resource object is already in use by a connector for trusted source reconciliation, for the trusted source connector that you want to configure, you must create a new resource object and process definition.

ii. The scheduled task of the connector must have an attribute that accepts the name of the resource object used for trusted source user reconciliation as its value.

The following sections discuss scenarios in which you can implement multiple trusted source reconciliation by using non-MTS-compatible connectors:

- Configuring Non-MTS-Compatible Connectors for Trusted Source Reconciliation by User Type
- Configuring Non-MTS-Connectors for Trusted Source Reconciliation of Specific OIM User Attributes

**Configuring Non-MTS-Compatible Connectors for Trusted Source Reconciliation by User Type**

In this context, user type refers to the type of users whose records you want to reconcile. Examples of user types are Contractor, Employee, and Customer.

You use Microsoft Active Directory and Oracle e-Business Suite as trusted sources in your operating environment. Active Directory is used to store information about identities that belong to the Contractor user type. Oracle e-Business Suite is used to store information about identities that belong to the Customer and Employee user type. You want to reconcile Contractor records from Active Directory and Employee records from Oracle e-Business Suite. To do this, perform the following:

For Active Directory:

1. Perform all the steps required to deploy the Active Directory connector and configure it for trusted source reconciliation.

   **See Also:** The documentation for the connector you are deploying for information about the procedure to configure trusted source reconciliation

   When you import the connector XML file for trusted source reconciliation, information specific to Active Directory is added in the Xellerate User resource object and process definition.

2. On the Resource Object tab, create the ActDir resource object for trusted source reconciliation with Active Directory.
Managing Resources By Using the Design Console

**Note:** You can assign any name to the resource object. This procedure is based on the use of ActDir as the name assigned to the resource object.

For detailed information about the procedure to create a resource object, see "Resource Objects Form" on page 4-15.

While creating the resource object:

a. Select the Trusted Source check box on the Resource Object tab.

b. On the Object Reconciliation>>Reconciliation Fields tab, see Xellerate User resource object and add the Active Directory-specific fields that you want to reconcile in ActDir. All the mandatory OIM User fields must be covered by the fields that you add on this tab.

3. On the Object Reconciliation>>Reconciliation Action Rules tab, create rule conditions and action mappings. One of these rule condition-action mappings must be the following:

   Rule Condition: No Matches Found
   Action: Create User

4. Delete the fields specific to Active Directory and the corresponding rules from the Xellerate User resource object.

5. Create the ActDir process definition in the Process Definition form.

   For detailed information about the procedure to create a process definition, see "Process Definition Form" on page 5-5. Based on the reconciliation field mappings in the Xellerate User process definition, on the Reconciliation Field Mappings tab, add the reconciliation field mappings for the ActDir process definition.

6. Delete the Active Directory-specific field mappings in the Xellerate User resource object.

7. In the Reconciliation Rule Builder form on the Reconciliation Rules page, query and open the reconciliation rule for this connector and change the value of the Object field to map to the resource object that you have created. By default, the value of this field is mapped to that of the Xellerate User resource object.

For Oracle e-Business Suite, repeat all the steps you performed for Active Directory. Perform the following steps of that procedure differently for the Oracle e-Business Employee Reconciliation connector:

   **Note:** You can assign a name to the resource object. This procedure is based on the use of EmpRecon as the name assigned to the resource object.

2. On the Object Reconciliation>>Reconciliation Action Rules tab, create rule conditions and action mappings. One of these rule condition-action mappings must be the following:

   Rule Condition: No Matches Found
   Action: Create User
Use the Limited Reconciliation feature to specify that only identities that belong to the Employee user type must be reconciled.

3. After you add the fields and the reconciliation rules, delete the Oracle e-Business Suite-specific fields and the corresponding rules created in the Xellerate User resource object.

4. Create the EmpRecon process definition in the Process Definition form. For detailed information about the procedure to create a process definition, see "Process Definition Form" on page 5-5. Based on the Xellerate User reconciliation field mappings, on the Reconciliation Field Mappings tab, add the field mappings for the EmpRecon process definition.

5. Delete the Oracle e-Business Suite-specific field mappings in the Xellerate User resource object.

6. On the Reconciliation Rules>>Reconciliation Rule Builder form, query and open the reconciliation rule for this connector and change the value of the Object field to map to the resource object that you have created. By default, the value of this field is mapped to that of the Xellerate User resource object.

For both Active Directory and Oracle e-Business Suite, perform the rest of the steps required to configure trusted source reconciliation. For example, while configuring the reconciliation scheduled task for each connector, specify the name of the trusted source resource object that must be used during trusted source user reconciliation.

The current value of the scheduled task attribute would be Xellerate User and it must be updated with the name of the new resource object configured for trusted source user reconciliation for this connector.

Figure 4–8 shows the design time implementation of trusted source reconciliation based on the user type.

Figure 4–8  Trusted Source Reconciliation by User Type
Configuring Non-MTS-Connectors for Trusted Source Reconciliation of Specific OIM User Attributes

You might want to configure trusted source reconciliation for specific OIM User attributes from multiple target systems. The procedure to implement this is described with the help of the following sample scenario:

You use Microsoft Active Directory and IBM Lotus Notes as your target systems. You want to reconcile identities from Active Directory and only the value of the e-mail address attribute of each identity (reconciled into Oracle Identity Manager from Active Directory) from Lotus Notes. To achieve this:

For the Active Directory connector:

1. Perform all the steps required to deploy the Active Directory connector and configure it for trusted source reconciliation.

   See Also: The documentation for the connector you are deploying for information about the procedure to configure trusted source reconciliation.

   When you import the connector XML file for trusted source reconciliation, Active Directory-specific information is added in the Xellerate User resource object and process definition.

2. On the Resource Object tab, create the ActDir resource object for trusted source reconciliation with Active Directory.

   Note:

   You can assign any name to the resource object. This procedure is based on the use of ActDir as the name assigned to the resource object.

   For detailed information about the procedure to create a resource object, see "Resource Objects Form" on page 4-15.

While creating the resource object:

   i. Select the Trusted Source check box on the Resource Object tab.

   ii. On the Object Reconciliation>>Reconciliation Fields tab, see Xellerate User resource object and add the Active Directory-specific fields that you want to reconcile in ActDir. All the mandatory OIM User fields must be covered by the fields that you add on this tab.

3. On the Object Reconciliation>>Reconciliation Action Rules tab, create rule conditions and action mappings. One of these rule condition-action mapping must be the following:

   Rule Condition: No Matches Found

   Action: Create User

4. Delete the Active Directory-specific fields and the corresponding rules from the Xellerate User resource object.

5. Create the ActDir process definition in the Process Definition form. For detailed information about the procedure to create a process definition, see "Process Definition Form" on page 5-5. Based on the reconciliation field mappings in the
Xellerate User process definition, on the Reconciliation Field Mappings tab, create the field mappings for the ActDir process definition.

6. Delete the Active Directory-specific field mappings in the Xellerate User resource object.

7. On the Reconciliation Rules>>Reconciliation Rule Builder form, query and open the reconciliation rule for this connector and change the value of the Object field to map to the resource object that you have created. By default, the value of this field is mapped to that of the Xellerate User resource object.

For IBM Lotus Notes, repeat all the steps you performed for Active Directory. Perform the following steps of that procedure differently for the Lotus Notes connector:

1. On the Resource Object tab, create the LotNotes resource object for trusted source reconciliation with Lotus Notes.

**Note:** You can assign a name to the resource object. This procedure is based on the use of LotNotes as the name assigned to the resource object.

2. When you create the resource object, add only the e-mail address attribute.

3. On the Object Reconciliation>>Reconciliation Action Rules tab, create rule conditions and action mappings. Create any rule condition other than user creation if no matches are found. If a match is found, the link is established.

4. After you have added the fields and the reconciliation rules, delete the Lotus Notes-specific fields and the corresponding rules created in the Xellerate User resource object.

5. Create the LotNotes process definition in the Process Definition form. For detailed information about the procedure to create a process definition, see "Process Definition Form" on page 5-5. Based on the Xellerate User reconciliation field mappings, on the Reconciliation Field Mappings tab, add the field mappings for the LotNotes process definition.

6. Delete the Lotus Notes-specific field mappings in the Xellerate User resource object.

For both Active Directory and Lotus Notes, perform the rest of the steps required to configure trusted source reconciliation. For example, while configuring the reconciliation scheduled task for each connector, specify the name of the trusted source resource object that must be used during reconciliation.

The current value of the scheduled task attribute would be Xellerate User and it must be updated with the name of the new resource object configured for trusted source user reconciliation for this connector.

**Figure 4–9** shows the design time implementation of trusted source reconciliation of specific OIM User attributes.
4.3.5 Service Account Management

Oracle Identity Manager supports service accounts. Service accounts are general administrator accounts (for example, admin1, admin2, admin3, and so on) that are used for maintenance purposes, and are typically shared by a set of users. The model for managing and provisioning service accounts is slightly different from normal provisioning.

Service accounts are requested, provisioned, and managed in the same manner as regular accounts. They use the same resource objects, provisioning processes, and process forms as regular accounts. A service account is distinguished from a regular account by an internal flag.

When a user is provisioned with a service account, Oracle Identity Manager manages a mapping from the user’s identity to the service account. When the resource is revoked, or the user gets deleted, the provisioning process for the service account does not get canceled (which would cause the undo tasks to start). Instead, a task is inserted into the provisioning process (the same way Oracle Identity Manager handles Disable and Enable actions). This task removes the mapping from the user to the service account, and returns the service account to the pool of available accounts.

This management capability is available through APIs.

4.4 Converting a Disconnected Application Instance to Connected Application Instance

To describe the procedure to convert a disconnected application instance to a connected application instance, the following assumptions have been made:

- A disconnected application instance exists in Oracle Identity Manager deployment, for example, the production environment. This disconnected application instance will be exported to another deployment of Oracle Identity Manager, for example, a test environment, and converted to a connected...
Converting a Disconnected Application Instance to Connected Application Instance

application instance. After testing the connected application instance in the test environment, it will be imported in the production environment again.

Note: Optionally, the disconnected resource can be converted to a connected resource in the same environment. See "Modifying the Application Instance from Disconnected to Connected" on page 4-40 for further details.

- The application instance, process definition, forms, IT resource type definition, and IT resource retain the same name while converting a disconnected application instance to connected application instance.

The following are the broad-level steps to convert a disconnected application instance to a connected application instance:

- Import the existing disconnected resource from the existing environment to the test environment.
- Modify the implementation of the application instance, such as resource object definition and process definition.
- Test the application instance by provisioning it to users and validating the behavior for enable, disable, revoke, and update tasks.
- Export the new connected resource from the test environment and import it to the production environment.

Note:

- Only the resource is exported between environments and not the application instance.
- This section outlines the steps to import/export the resource of the application instance by using the Deployment Manager. Alternatively, the connector upgrade utility can also be used for import/export of the resource. See "Managing Connector Lifecycle" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about using the connector upgrade utility.

4.4.1 Creating a Disconnected Application Instance in the Production Environment

To create a disconnected application instance in the production environment:

1. Login to Oracle Identity System Administration.
2. Click Sandboxes to access sandbox management, create a sandbox, and activate it. See "Managing Sandboxes" on page 30-4 for information about sandboxes and how to create, activate, and publish sandboxes.
3. Under Configuration, click Application Instances. Click Create on the toolbar to open the Create Application Instance page.
4. Enter values in the Name and Display Name fields, such as LaptopAppInstance.
5. Select the Disconnected option to specify a disconnected application instance. Selecting the Disconnected option disables the Resource Object and IT Resource Instance fields in the page.
6. Click **Save**, and then click **OK** to confirm creation of the FinApp application instance. The artifacts for a disconnected application instance are created.

7. Go to the Manage Sandboxes page, and publish the sandbox.

Upon successful creation of the application instance, organization and entitlements can be configured if necessary. For testing purpose, create four or five users and provision the newly created disconnected application instance to the users. Ensure that the users have the application instance in one of the following status: Provisioned, Enabled, Disabled, and Revoke. Try modifying one of the users to ensure that the account can be successfully updated.

### 4.4.2 Exporting Disconnected Application Instance From Production Environment

To export the disconnected application instance from the production environment:

1. Login to Oracle Identity System Administration. In the left pane, under System Management, click **Export**. The Deployment Manager wizard is displayed in a new window.

2. Search for the disconnected application instance. To do so, in the search section, select Resource from the list, enter the name of the disconnected application instance, for example LaptopApplication*, and click **Search**. The disconnected application instance is displayed in the Search Results section.

3. Select **LaptopApplicationInstance** in the Search Results section, and then click **Select Children**. The Select Children page is displayed.

4. Select the required child attributes, as shown in **Figure 4–10**:

**Figure 4–10  Child Attributes**

5. Click **Select Dependencies**. The Select Dependencies page is displayed.

6. Click **Confirmation**. In the Confirmation page, click **Add For Export**.

7. After verifying that all the required dependencies are displayed in the export summary, as shown in **Figure 4–11**, click **Export**.
Figure 4–11  Export Summary

8. Provide a name to the XML file, such as DisconnectedLaptopExp.xml. Upon successful export, a message is displayed.

4.4.3 Importing the Disconnected Application Instance in Test Environment

To import the disconnected application instance in test environment:

1. In the left pane of the Oracle Identity System Administration, under System Management, click **Import**.

2. Provide the path to the exported XML file, and then click **OK**. A confirmation page is displayed. Click **Add File**.

3. In the Substitutions page, you can provide substitutions for users or groups. If there are no substitutions, then click **Cancel Substitution**.

4. In the import summary, as shown in , check for any unresolved dependency, and then click **Import**.

Figure 4–12  Import Summary
5. Verify that the process definition, resource object, and forms have been successfully imported.

4.4.4 Modifying the Application Instance from Disconnected to Connected

In the environment where the application instance has been imported, make the following changes to convert the disconnected application instance to a connected application instance:

1. Login to the Design Console.
3. Change the type of the resource object from Disconnected to Application.
4. Define new IT resource parameters in conjunction with the connected resource as required in the IT Resource Type Definition form.
5. Modify the existing IT resource (assuming that the ITResource is the same) with the new parameters added in step 4.
7. Search the process definition of the disconnected application instance. The following tasks are displayed:
   - ManualProvisioningStart
   - ManualProvisioningEnd
   - ManualEnableStart
   - ManualEnableEnd
   - ManualDisableStart
   - ManualDisableEnd
   - ManualRevokeStart
   - ManualRevokeEnd
8. For each task, perform the following:
   a. Double-click the Task row to open the task details. See "Modifying Process Tasks" on page 5-15 for more information about modifying process tasks.
   b. Rename the task. For example, change the task name from ManualProvisioningStart to XXManualProvisioningStart.
   c. Make sure the Conditional option is selected. In addition, ensure that the Required for Completion option is not selected.
   d. If the task is an enable/disable/revoke task, then change the task effect to No effect.
   e. In the Integration tab, disassociate the adapters attached to the task by clicking on Remove.
   f. Remove task dependency, if any.
   g. Remove undo/recovery/generated tasks, if any.
   h. Change the object status mapping, if any, to none.
Note: Step 6a through 6g are to ensure that the existing tasks for disconnected application instance do not start when the application instance is exported as a connected application instance.

9. There is a task by the name PARENT_FORM_NAME Updated. This task triggers whenever the parent form is updated. Make sure to disassociate the existing adapters attached to the task and customize the task as required.

10. If there are any tasks related to the child form, then make sure to remove the triggers for create/update/delete by clicking Clear. If these tasks are not going to be reused, then disassociate the adapters attached to these tasks and rename the tasks to ensure that they do not run. Oracle recommends creating new tasks for each create, update, and delete trigger.

Note:
- Optionally, the same tasks for the child data can be retained but custom adapters must be defined for the create/update/delete trigger.
- For a disconnected application instance with child data, the task with the delete trigger will be associated with the tcCompleteTask adapter. Make sure to define and attach a custom adapter to this task to enable proper deletion of entitlement or child data.

11. Define custom adapters for the create, disable, enable, revoke, and update account tasks. If there are child tables, then make sure to define custom adapters for the same.

12. Create the following tasks in the process definition, and associate the corresponding adapters to each of those tasks. Map the required undo/recovery tasks and set the object status mapping.

- **Create User**: Ensure that in the task properties, the Required for Completion option is selected and the Conditional option is not selected.
- **Disable User**: Ensure that the task effect is Disable Processes or Access to Application.
- **Enable User**: Ensure that the task effect is Enable Processes or Access to Application.
- **Delete User**: Ensure that the task effect is Revoke Processes or Access to Application.
- **ATTRIBUTE_NAME Updated**: For each attribute defined in the process form, corresponding update tasks have to be created. These tasks are triggered on updates to the process form, for example, Account Name Update, Account ID Updated, and so on.

13. If there is a child table, then define tasks for each trigger type, such as create, update, and delete.

Test the connected application instance by provisioning it to a few users in the test environment. You must define a new application instance with the modified resource object and IT resource to provision the application instance to users.
4.4.5 Testing the Connected Application Instance

After converting the disconnected application instance to a connected application instance:

- Export the modified resource from the test environment.
- Import the modified resource to the production environment.
This chapter describes process management with the Design Console. It contains the following topics:

- Overview of Process Management
- Email Definition Form
- Process Definition Form

5.1 Overview of Process Management

The Process Management folder provides you with tools for creating and managing Oracle Identity Manager processes and e-mail templates.

This folder contains the following forms:

- **Email Definition**: This form enables you to create templates for e-mail notifications.
- **Process Definition**: This form lets you create and manage provisioning processes. It also lets you start the Workflow Definition Renderer that displays your workflow definition graphically.

5.2 Email Definition Form

The Email Definition form, as shown in Figure 5–1, is located in the Process Management folder. You use this form to create templates for e-mail notifications. These notifications can be set for sending to the user when:

- A task is assigned to the user.
- The task achieves a particular status.
You apply e-mail definitions through the Assignment tab of the Process Definition form.

5.2.1 Specifying the E-Mail Server

Before using the Email Definition form, you must specify the address of the e-mail server that Oracle Identity Manager will use to send e-mail notifications to users.

The e-mail server is specified by using Oracle Identity System Administration. To specify the e-mail server:

1. Login to Oracle Identity System Administration.
2. Under System Management, click System Configuration.
3. Search for the Email Server system property, and click the property to open the details of the property.
4. Ensure that the property name is set to the name of the resource asset instance that represents your e-mail server, and click Save.

Note: The value of the Email Server system property must be the e-mail server IT resource and not the hostname of the e-mail server.

When you click Save, a message box is displayed that states the following:

System Property has been modified. Please restart the server for changes to take effect. Also make sure that IT Resource Definition for Mail Server is also updated to reflect the changed value.
5. Click OK.

5.2.2 Email Definition Form

Table 5–1 describes the fields of the Email Definition form.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the e-mail definition.</td>
</tr>
<tr>
<td>Type</td>
<td>This region contains three options for the following:</td>

<td>The ID of the user in the From region of the e-mail notification.</td>
</tr>
<tr>
<td></td>
<td>Note: If the User item is not displayed in the From box, the User Login</td>
</tr>
<tr>
<td></td>
<td>field is grayed out.</td>
</tr>
<tr>
<td>Subject</td>
<td>The title of the e-mail definition.</td>
</tr>
</tbody>
</table>
Creating an E-Mail Definition

To create an e-mail definition:

1. Open the Email Definition form.
2. In the Name field, enter the name of the e-mail definition.
3. If the e-mail definition is to be used with a provisioning process, select the Provisioning Related option.
4. Double-click the Language lookup field, and select a language to associate with this e-mail definition.
5. Double-click the Region lookup field, and select a region to associate with the e-mail definition language.
6. Click Save.

The remaining data fields of the Email Definition form are now operational.

7. To associate this e-mail definition with a particular resource object, double-click the Object Name lookup field in the Lookup dialog box. Then, select the resource object that is associated with the provisioning process to which this e-mail definition is related.

Leave this lookup field empty to make the e-mail definition available for use with all resource objects.

8. Double-click the Process Name lookup field.

From the Lookup dialog box, select a provisioning process that is assigned to the resource object you selected in Step 7. This is the provisioning process to which this e-mail definition is to be related.

Note: If the Provisioning Related option is not selected, both the Object Name and Process Name lookup fields are grayed out. The Process Name field is grayed out until a value is selected in the Object Name field.

9. Click the From box.

From the custom menu that is displayed, select the type of the user (Requester, User, or Manager of Provisioned User) that is displayed in the From region of the e-mail notification.

Note: If the Provisioning Related option is not selected in Step 3, the Manager of Provisioned User item will not be displayed in the From box.

### Table 5–1 (Cont.) Fields of the Email Definition Form

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Body</td>
<td>The content of the e-mail definition.</td>
</tr>
</tbody>
</table>
10. Optional. If you have selected the User option in the From box, double-click the User Login lookup field.

From the Lookup dialog box, select the user ID that is displayed in the From region of the e-mail notification.

If you did not select the User item in the From box, the User Login field is grayed out.

11. Add information in the Subject field.

This field contains the title of the e-mail definition.

12. Add information in the Body text area.

This text area contains the contents of the e-mail definition.

13. When necessary, populate the Subject field and Body text area with e-mail variables.

The following table describes the e-mail variables that you can customize for the e-mail definition.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>These options specify if a variable for the e-mail definition will be related to a provisioning process. To associate the e-mail variable with a provisioning process, select the Provisioning Related option.</td>
</tr>
<tr>
<td>Targets</td>
<td>From this box, select the source of the variable for the e-mail definition. For example, if you want to use the User Login variable, the source to select will be User Profile Information.</td>
</tr>
<tr>
<td>Variables</td>
<td>From this box, select the variable for the e-mail definition, for example, User Login.</td>
</tr>
</tbody>
</table>

**Note:** The items that are displayed in the custom menu of the Targets box reflect the selection of either the Provisioning Related or the General radio button. Similarly, the items that are displayed in the custom menu of the Variables box correspond to the items that are displayed in the Targets box.

14. Create an e-mail variable for the Subject field or Body text area.

15. Click Save.

The e-mail definition is created.

### 5.3 Process Definition Form

A process is the mechanism for representing a logical workflow for provisioning in Oracle Identity Manager. Process definitions consist of tasks. Process tasks represent the steps that you must complete to fulfill the purpose of a process. For example, in a provisioning process, tasks are used to enable a user or organization to access the target resource.

The Process Definition form shown in Figure 5–2 is in the Process Management folder. You use this form to create and manage the provisioning processes that you associate with your resource objects.
In Figure 5–2, the Xellerate Organization provisioning process is created and assigned to the resource object of the same name.

Table 5–2 describes the fields of the Process Definition form.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the process.</td>
</tr>
<tr>
<td>Type</td>
<td>The classification type of the process definition.</td>
</tr>
<tr>
<td>Object Name</td>
<td>The name of the resource object to which the process will be assigned.</td>
</tr>
<tr>
<td>Map Descriptive Field</td>
<td>Click this button to select a field that will be used as an identifier of the process definition after an instance is assigned to a resource object.</td>
</tr>
<tr>
<td>Render Workflow</td>
<td>Click this button to start a Web browser and display the current workflow definition by using the Workflow Renderer tool.</td>
</tr>
<tr>
<td>Default Process</td>
<td>This check box determines if the current process is the default provisioning process for the resource object with which it is associated. Select the check box to set the process as the default provisioning process for the resource object to which it is assigned. If you deselect the check box, the process will not be the default. It will only be invoked if a process selection rule causes it to be chosen.</td>
</tr>
</tbody>
</table>
5.3.1 Creating a Process Definition

To create a process definition:

1. Open the Process Definition form.
2. In the Name field, type the name of the process definition.
3. Double-click the Type lookup field.
   - From the Lookup dialog box that is displayed, select the classification type (Approval) of the process definition.
4. Double-click the Object Name lookup field.
   - From the Lookup dialog box that is displayed, select the resource object that will be associated with the process definition.
5. Optional. Select the Default Process check box to make this the default provisioning process for the resource object to which it is assigned.

If you do not want the current process definition to be the default, go to Step 6.

Table 5–2 (Cont.) Fields of the Process Definition Form

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Save Form</td>
<td>This check box designates whether Oracle Identity Manager suppresses the display of the custom form associated with this provisioning process or display it and allow a user to supply it with data each time the process is instantiated. Select this check box to automatically save the data in the custom process form without displaying the form. If you select this check box, you must supply either system-defined data or ensure that an adapter is configured to populate the form with the required data because the user will not be able to access the form. Deselect this check box to display the custom process form and allow users to enter data into its fields.</td>
</tr>
<tr>
<td>Auto Pre-Populate</td>
<td>This check box designates whether the fields of a custom form are populated by Oracle Identity Manager or a user. Two types of forms are affected: Forms that are associated with the process Forms that contain fields with prepopulated adapters attached to them. If the Auto Pre-Populate check box is selected, when the associated custom form is displayed, the fields that have prepopulate adapters attached to them will be populated by Oracle Identity Manager. When this check box is deselected, a user must populate these fields by clicking the Pre-Populate button on the toolbar or by manually entering the data. Note: This setting does not control the triggering of the prepopulate adapter. It only determines if the contents resulting from the execution of the adapter are displayed in the associated form field(s) because of Oracle Identity Manager or a user. For more information about prepopulate adapters, see &quot;Working with Prepopulate Adapters&quot; on page 8-47. Note: This check box is only relevant if you have created a process form that is to be associated with the process and prepopulate adapters are used with that form.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table that represents the form that is associated with the process definition.</td>
</tr>
</tbody>
</table>
6. Optional. Select the **Auto Save Form** check box to suppress the display of the provisioning process' custom form and automatically save the data in it. This setting is only applicable to provisioning processes.

To display provisioning process' custom form and solicit users for information, deselect this check box.

---

**Note:** If you select the **Auto Save Form** check box, ensure that all fields of the associated "custom" process form have adapters associated with them. However, a process form can have default data or object to the process data flow mapping or organization defaults.

For more information about adapters and their relationship with fields of custom forms, see Chapter 8, "Using the Adapter Factory".

---

7. If a custom form is to be associated with the process definition, this form contains fields that have prepopulate adapters attached to them, and you want these fields to be populated automatically by Oracle Identity Manager, select the **Auto Pre-Populate** check box.

If the fields of this form are to be populated manually (by an user clicking the **Pre-Populate** button on the Toolbar), deselect the **Auto Pre-Populate** check box.

---

**Note:** If the process definition has no custom form associated with it, or this form's fields have no pre-popsulate adapters attached to them, deselect the **Auto Pre-Populate** check box. For more information about prepopulate adapters, see "Working with Prepopulate Adapters" on page 8-47.

---

8. Double-click the **Table Name** lookup field.

From the Lookup window that is displayed, select the table that represents the form associated with the process definition.

9. Click **Save**.

The process definition is created and the **Map Descriptive Field** button is enabled. If you click this button, the Map Descriptive Field dialog box is displayed.

From this window, you can select the field (for example, the Organization Name field) that will be used as an identifier of the process definition when an instance of the process is assigned to a resource object. This field and its value will be displayed in the reconciliation Manager form.

---

**Note:** If a process has a custom process form attached to it, the fields on that form will also be displayed in this window and be available for selection.

---

### 5.3.2 Tabs on the Process Definition Form

After you start the Process Definition form and create a process definition, the tabs of this form become functional.

The Process Definition form contains the following tabs:

- **Tasks Tab**
Reconciliation Field Mappings Tab

Administrators Tab

Each of these tabs is described in the following sections.

5.3.2.1 Tasks Tab

You use this tab to:

- Create and modify the process tasks that comprise the current process definition
- Remove a process task from the process definition (when it is no longer valid)

Figure 5–3 displays the Tasks tab of the Process Definition form.

Figure 5–3 Tasks Tab of the Process Definition Form

5.3.2.1.1 Adding a Process Task

Process tasks represent the steps that you must complete in a process.

To add a process task:

1. Click Add.

   The Creating New Task dialog box is displayed.

2. In the Task Name field, enter the name of the process task.

3. From the Toolbar of the Creating New Task window, click Save. Then, click Close.

   The process task is added to the process definition.

See Also: See "Modifying Process Tasks" on page 5-15 for information about editing process tasks

5.3.2.1.1 Adding a Process Task

Process tasks represent the steps that you must complete in a process.

To add a process task:

1. Click Add.

   The Creating New Task dialog box is displayed.

2. In the Task Name field, enter the name of the process task.

3. From the Toolbar of the Creating New Task window, click Save. Then, click Close.

   The process task is added to the process definition.
5.3.2.1.2 Editing a Process Task

For instructions about how to edit and set process tasks, see "Modifying Process Tasks" on page 5-15.

5.3.2.1.3 Deleting a Process Task

To delete a process task:

1. Select the process task that you want to delete.
2. Click Delete.

   The process task is removed from the process definition.

5.3.2.2 Reconciliation Field Mappings Tab

You use the Reconciliation Field Mappings tab shown in Figure 5–4 to define a relationship between data elements in a target system or trusted source and fields in Oracle Identity Manager.

**Figure 5–4  Reconciliation Field Mappings Tab of the Process Definition Form**

Only fields that you define in the Reconciliation Fields tab of the associated resource are available for mapping. Using a reconciliation event, these mappings determine which fields in Oracle Identity Manager to populate with information from the target system. For target resources (not trusted sources), you can use this tab to indicate which fields are key fields. Key fields determine the values that must be same on the process form and the reconciliation event to generate a match on the Processes Matched Tree tab of the Reconciliation Manager form.

For each mapping, the following information is displayed:

- Name of the field, as defined on the Reconciliation Fields tab of the associated resource, on the target system or trusted source that is to be reconciled with data in Oracle Identity Manager.

- Data type associated with the field, as defined on the Reconciliation Fields tab of the associated resource.

  Possible values are **Multi-Valued, String, Number, Date, and IT resource**.

**Note:** The IT Resource must be marked as a key field.
■ **For trusted sources:** For user discovery, mapping of the data in the trusted source field to the name of a field on the users form, or for organization discovery, mapping of the data in the trusted source field to the name of a field on the Oracle Identity Manager Organizations form.

If you are performing user and organization discovery with a trusted source, organization discovery must be conducted first.

---

**See Also:** "Multiple Trusted Source Reconciliation" on page 4-28 for information about how fields are mapped for multiple trusted source reconciliation

---

■ **For target resources:** The name of the field on the resource's custom (provisioning) process form to which the data in the target resources field is to be mapped.

■ **For target resources:** Indicator designating if the field is a key field in the reconciliation for this target resource.

For provisioning processes to match a reconciliation event data, the key field values in their process forms must be the same as those in the reconciliation event.

---

**Note:** Oracle recommends configuring both the entitlement attribute and the key attribute for the child data in reconciliation field mappings to enable effective duplicate entitlement or child data validation. See "Duplicate Validation for Entitlements or Child Data" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for information about duplicate validation for entitlements or child data.

---

### 5.3.2.2.1 User Account Status Reconciliation

To configure user account status reconciliation, you must do the following:

■ **For trusted sources:** You must create a reconciliation field, for example, `Status`, in the corresponding trusted resource object, which denotes the status of the user in the target. The value of this field must be either `Active` or `Disabled`. This reconciliation field must be mapped to the user attribute `status` in the corresponding process definition.

■ **For target resources:** You must create a reconciliation field, for example, `Status`, in the corresponding resource object, which denotes the status of the resource in the target. This reconciliation field must be mapped to the process attribute `OIM_OBJECT_STATUS` in the corresponding process definition. The following statuses are supported for target resource reconciliation:
  - Revoked
  - Provisioned
  - Ready
  - Provide Information
  - Enabled
  - None
  - Waiting
  - Provisioning

---

*Developing Provisioning Processes 5-11*
5.3.2.2 Mapping a Target Resource Field to Oracle Identity Manager

You can map the fields on a target resource or trusted source, as defined on the Reconciliation Fields tab of the associated resource definition, to applicable fields in Oracle Identity Manager. These mappings determine the fields that must be updated in Oracle Identity Manager in a reconciliation event. These mappings occur when you click one of the following on the Reconciliation Manager form:

- The Create User or Create Organization button
- The Link button on the Matched Users or Matched Organizations tab
- The Establish Link button on the Processes Matched Tree tab

For user discovery on a trusted source, you define the fields to be mapped from the User resource to fields in the User provisioning process. The fields (that is, the user attributes) to which you will map your trusted source fields are derived from the Users form.

For organization discovery on a trusted source, you define fields to be mapped from the Oracle Identity Manager Organization resource to fields in the Oracle Identity Manager Organization provisioning process. The fields (that is, the organization attributes) to which you will map your trusted source fields are derived from the Organizations form.

After you have accessed the provisioning process definition for the associated resource and selected the Reconciliation Field Mappings tab, use one of the two procedures described in the following sections.

Mapping a Single Value Field

To map a single value field:

1. Click Add Field Map.

   The Add Reconciliation Field Mappings dialog box is displayed.

2. Select the field on the target system that you want to map from the menu in the Field Name field.

   Oracle Identity Manager will automatically supply the field type based on what was entered for this field on the associated Resource Object form.

3. For trusted sources:

   Select a value from the User Attribute menu and click OK. Go to Step 4.

   For target resources:

   Double-click Process Data Field. Select the correct mapping from the Lookup dialog box and click OK.

4. If you are defining mapping for a trusted source, go to step 5.

   Set the Key Field for Reconciliation Matching check box for target resources only.

   If this check box is selected, Oracle Identity Manager evaluates if the value of this field on the provisioning process form matches the value of the field in the reconciliation event. All matched processes are displayed on the Processes Matched Tree tab of the Reconciliation Manager form. If this check box is deselected, Oracle Identity Manager does not require the value of this field to match the process form and reconciliation event for process matching.
5. Click Save.

The mapping for the selected fields is applied the next time a reconciliation event is received from the target resource or trusted source.

**Mapping a Multi-Value Field (For Target Resources Only)**

To map a multi-value field:

1. Click **Add Table Map**.

   The Add Reconciliation Table Mappings dialog box is displayed.

2. Select the multi-value field on the target system that you want to map from the menu in the **Field Name** field.

   Oracle Identity Manager will automatically supply the field type based on what was entered for this field on the associated Resource Object form.

3. Select the child table you defined on the target resource's process form from the **Table Name** menu.

4. Double-click **Process Data Field**, and select the correct mapping from the Lookup dialog box, and click **OK**.

5. Save and close the Add Reconciliation Table Mappings dialog box.

6. Right-click the multi-value field you just mapped, and select Define a property field map from the menu that is displayed.

7. Select the component (child) field you want to map.

   Oracle Identity Manager will automatically supply the field type based on what was entered for this field on the associated Resource Object form.

8. Double-click the **Process Data Field** field.

   Select the correct mapping from the Lookup dialog box and click **OK**.

9. Set the **Key Field for Reconciliation Matching** check box.

   If this check box is selected, Oracle Identity Manager compares the field value on the provisioning process child form with the field value in the reconciliation event. All matching processes are displayed on the **Processes Matched Tree** tab of the Reconciliation Manager form. If you deselect this check box, the value of this field does not have to match on the process form and reconciliation event for process matching. Ensure that at least one component (child) field of each multi-valued field is set as a key field. This improves the quality of the matches generated on the **Process Matched Tree** tab.

10. Repeat Steps 6 through 9 for each component (child) field defined on the multi-value field.

11. Click **Save**.
The mapping for the selected fields will be applied the next time a reconciliation event is received from the target resource.

5.3.2.2.3 Deleting a Mapping

This procedure is used to delete a mapping that has been established between a field in Oracle Identity Manager and a field on the target system or trusted source as defined on the Reconciliation Fields tab of the associated resource definition.

To delete a mapping:
1. Go to the provisioning process definition for the associated resource.
2. Select the Reconciliation Field Mappings tab.
3. Select the field mapping you want to delete.
4. Click Delete Map.

The mapping for the selected field is deleted.

5.3.2.3 Administrators Tab

You use this tab to select the roles that can view, modify, and delete the current process definition.

On this tab, when the Write check box is selected, the corresponding role can read and modify the current process definition. When the Delete check box is selected, the associated role can delete the current process definition.

5.3.2.3.1 Assigning a Role to a Process Definition

To assign a role:
1. Click Assign.
   The Groups window is displayed.
2. Select the unassigned role, and assign it to the process definition.
3. Click OK.
   The role is displayed in the Administrators tab.
4. To enable this role to view or modify, or view and modify the current process definition, double-click the corresponding Write check box. Otherwise, go to Step 5.
5. To enable this role to delete the current process definition, double-click the associated Delete check box. Otherwise, go to Step 6.
6. Click Save.
   The role is assigned to the process definition.

5.3.2.3.2 Removing a Role From a Process Definition

To remove a role:
1. Highlight the role that you want to remove.
2. Click Delete.
   The role is removed from the process definition.
5.3.3 Modifying Process Tasks

To modify a process task for a process definition, double-click its row heading. The Editing Task window is displayed, containing additional information about the process task.

The Editing Task window contains the following tabs:

- General Tab
- Integration Tab
- Task Dependency Tab
- Responses Tab
- Undo/Recovery Tab
- Notification Tab
- Task to Object Status Mapping Tab
- Assignment Tab of the Editing Task Window

---

**Note:** You must not modify the Xellerate Users process definition.

5.3.3.1 General Tab

You use this tab to set high-level information for the task that you want to modify. For this example, the Create User task is used to create a user in the Solaris environment.

Table 5–3 describes the fields of the General tab.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task Name</td>
<td>The name of the process task.</td>
</tr>
<tr>
<td>Task Description</td>
<td>Explanatory information about the process task.</td>
</tr>
<tr>
<td>Duration</td>
<td>The expected completion time of the current process task in days, hours, and minutes.</td>
</tr>
<tr>
<td>Conditional</td>
<td>This check box determines if a condition is met to add the current process task to the process.</td>
</tr>
<tr>
<td></td>
<td>Select this check box to prevent the process task from being added to the process unless a condition has been met.</td>
</tr>
<tr>
<td></td>
<td>Clear this check box to not require the condition to be met for the process task to be added to the process.</td>
</tr>
<tr>
<td>Required for Completion</td>
<td>This check box determines if the current process task must be completed for the process to be completed.</td>
</tr>
<tr>
<td></td>
<td>Select this check box to require the process task to have a status of Completed before the process can be completed.</td>
</tr>
<tr>
<td></td>
<td>Deselect this check box to ensure that the status of the process task does not affect the completion status of the process.</td>
</tr>
<tr>
<td>Constant Duration</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>
Table 5–3 (Cont.) Fields of the General Tab of the Editing Task Dialog Box

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task Effect</td>
<td>From this box, select the process action you want to associate with the task, for example, disable or enable. A process can enable or disable a user's access to a resource. When the disable action is chosen, all tasks associated with the disable action are inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If you do not want the process task to be associated with a particular process action, select <strong>No Effect</strong> from the box.</td>
</tr>
<tr>
<td>Disable Manual Insert</td>
<td>This check box determines if a user can manually add the current process task to the process.</td>
</tr>
<tr>
<td></td>
<td>Select this check box to prevent the process task from being added to the process manually.</td>
</tr>
<tr>
<td></td>
<td>Deselect this check box to enable a user to add the process task to the process.</td>
</tr>
<tr>
<td>Allow Cancellation while Pending</td>
<td>This check box determines if the process task can be canceled if its status is Pending.</td>
</tr>
<tr>
<td></td>
<td>Select this check box to allow the process task to be canceled if it has a Pending status.</td>
</tr>
<tr>
<td></td>
<td>Deselecting this check box to prevent the process task from being canceled if its status is Pending.</td>
</tr>
<tr>
<td>Allow Multiple Instances</td>
<td>This check box determines if the process task can be inserted into the current process more than once.</td>
</tr>
<tr>
<td></td>
<td>Select this check box to enable multiple instances of the process task to be added to the process.</td>
</tr>
<tr>
<td></td>
<td>Deselect this check box to enable the process task to be added to the current process only once.</td>
</tr>
<tr>
<td>Retry Period in Minutes</td>
<td>If a process task is rejected, this field determines the interval before Oracle Identity Manager inserts a new instance of that task with the status of Pending.</td>
</tr>
<tr>
<td></td>
<td>When the value of the Retry Period in Minutes field is 30, it means that if the Create User process task is rejected, then in 30 minutes Oracle Identity Manager adds a new instance of this task and assigns it a status of Pending;</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If you specify a value for this field, then you must ensure the following:</td>
</tr>
<tr>
<td></td>
<td>- The Task Timed Retry scheduled job is not disabled. See the &quot;Predefined Scheduled Tasks&quot; section in Oracle Fusion Middleware Administrator's Guide for more information.</td>
</tr>
<tr>
<td></td>
<td>- Frequency of the Task Timed Retry scheduled job is less than or equal to value of this field.</td>
</tr>
<tr>
<td></td>
<td>- The <strong>Allow Multiple Instances</strong> checkbox of the process task that is being retried must be selected.</td>
</tr>
<tr>
<td>Retry Count</td>
<td>Determines how many times Oracle Identity Manager retries a rejected task. When the value of the Retry Count field is 5, it means that if the Create User process task is rejected, then Oracle Identity Manager adds a new instance of this task, and assigns it a status of Pending. When this process task is rejected for the fifth time, Oracle Identity Manager no longer inserts a new instance of it.</td>
</tr>
</tbody>
</table>
To modify the general information for a process task:

1. Double-click the row heading of the task you want to modify.
   The Editing Task dialog box is displayed.

2. Click the General tab.

3. In the Description field, enter explanatory information about the process task.

4. Optional. In the Duration area, enter the expected completion time of the process task (in days, hours, and minutes).

5. If you want a condition to be met for the process task to be added to the Process Instance, select the Conditional check box. Otherwise, go to Step 6.

   **Note:** If you select the Conditional check box, you must specify the condition to be met for the task to be added to the process.

6. When you want the completion status of the process to depend on the completion status of the process task, select the Required for Completion check box.
   By doing so, the process cannot be completed if the process task does not have a status of Completed.
   If you do not want the status of the process task to affect the completion status of the process, go to Step 7.

7. To prevent a user from manually adding the process task into a currently running instance of the process, select the Disable Manual Insert check box. Otherwise, go to Step 8.
8. To enable a user to cancel the process task if its status is Pending, select the **Allow Cancellation while Pending** check box. Otherwise, go to Step 9.

9. To allow this task to be inserted multiple times in a single process instance, select the **Allow Multiple Instances** check box. Otherwise, go to Step 10.

10. Click the **Task Effect** box.

    From the custom menu that is displayed, select one of the following:

    - **Enable Process or Access to Application.** If a resource is reactivated by using the enable function, all tasks with this effect are inserted into the process. If you select this option, you must also select the **Allow Multiple Instances** check box.
    
    - **Disable Process or Access to Application.** If a resource is deactivated by using the disable function, all tasks with this effect are inserted into the process. If you select this option, you must also select the **Allow Multiple Instances** check box.
    
    - **Revoke Process or Access to Application.** When the resource is revoked, the revoke workflow is executed without canceling the existing tasks in the provisioning process.
    
    - **No Effect.** This is the default process action associated with all tasks. If this option is selected, the task is only inserted during normal provisioning unless it is conditional.

11. Optional. If the process task is **Rejected**, you might want Oracle Identity Manager to insert a new instance of this process task (with a status of **Pending**).

    For this to occur, enter a value in the **Retry Period in Minutes** field. This designates the time in minutes that Oracle Identity Manager waits before adding this process task instance.

    In the **Retry Count** field, enter the number of times Oracle Identity Manager will retry a rejected task. For example, suppose 3 is displayed in the **Retry Count** field. If the task is rejected, Oracle Identity Manager adds a new instance of this task, and assigns it a status of Pending. After this process task is rejected for the fourth time, Oracle Identity Manager no longer inserts a new instance of the process task.

    **Note:** If either **Retry Period** or **Retry Count** is selected, you must specify parameters for the other option because they are both related.

12. From the **Child Table** box, select the child table of the custom form where Oracle Identity Manager will perform an action.

    From the **Trigger Type** box, specify the action that Oracle Identity Manager will perform in the child table. These actions include the following:

    - **Insert:** Adds a new value to the designated column of the child table
    
    - **Update:** Modifies an existing value from the corresponding column of the child table
    
    - **Delete:** Removes a value from the designated column of the child table

    **Note:** If the custom process form does not have any child tables associated with it, the **Child Table** box will be empty. In addition, the **Trigger Type** box will be grayed out.
13. Click **Save**.

The modifications to the process task’s top-level information reflects the changes you made in the **General** tab.

### 5.3.3.1.2 Triggering Process Tasks for Events Defined in Lookup.USR_PROCESS_TRIGGERS Fields

When a user attribute is defined in Lookup.USR_PROCESS_TRIGGERS, for each modification of the attribute, the corresponding process task is triggered for each provisioned resource. This is same for the First Name, Last Name, Display Name (USR_DISPLAY_NAME) user attributes and custom user attributes. However, for the Lookup.USR_PROCESS_TRIGGERS fields USR_STATUS, USR_LOCKED, USR_LOCKED_ON, and USR_MANUALLY_LOCKED, the attached process task is not triggered.

The following sections describe how to trigger the process tasks for the Lookup.USR_PROCESS_TRIGGERS fields:

#### For the USR_STATUS Attribute

It is not possible to run a task via Lookup.USR_PROCESS_TRIGGERS for the USR_STATUS attribute because this attribute is processed separately by Oracle Identity Manager. This attribute is changed by enabling, disabling, or deleting a user. These operations have a special effect on the provisioned resources because the corresponding process tasks are started via the Task Effect setting, as described in **Table 5–3, "Fields of the General Tab of the Editing Task Dialog Box"**. For these three operations, the Lookup.USR_PROCESS_TRIGGERS is not used. Therefore, when the status changes, perform the following to run the process task:

**For transition from Disabled to Enabled status:**

1. In the Process Definition form, create a process task named **Enable User**.
2. Open the Editing Task window, and click the **General** tab.
3. From the Task Effect list, select **Enables Process or Access to Application**.
4. Select **Conditional** and specify the condition to be met for the task to be added to the process.

**For transition from Enabled to Disabled status:**

1. In the Process Definition form, create a process task named **Disable User**.
2. Open the Editing Task window, and click the **General** tab.
3. From the Task Effect list, select **Enables Process or Access to Application**.
4. Select **Conditional** and specify the condition to be met for the task to be added to the process.

**For transition from Enabled/Disabled/Provisioned to Revoked status:**

1. In the Process Definition form, create a process task named **Delete User**.
2. Then set this task as an Undo task for the Create User task, which is the task that creates the user and is typically unconditional.
3. Select **Conditional** and specify the condition to be met for the task to be added to the process.
For the **USR_LOCKED, USR_LOCKED_ON, USR_MANUALLY_LOCKED** Attributes

The lock and unlock operations, are handled in Oracle Identity Manager as separate orchestrations. The orchestration is on:

```plaintext
entity-type="User" operation="LOCK"
```

Or:

```plaintext
entity-type="User" operation="UNLOCK"
```

The event handler that does the evaluation for Lookup.USR_PROCESS_TRIGGERS is:

```plaintext
oracle.iam.transUI.impl.handlers.TriggerUserProcesses
```

This is triggered only in the following user orchestrations:

- **MODIFY**: For generic fields
- **CHANGE_PASSWORD, RESET_PASSWORD**: For USR_PASSWORD propagation
- **ENABLE, DISABLE, DELETE**: For handling the execution of process tasks

For lock/unlock operations, the TriggerUserProcesses event handler is not triggered. Therefore, for the attributes modified through lock/unlock operations, the Lookup.USR_PROCESS_TRIGGERS is not checked.

If you want to run custom code for these operations when these fields are changed, then you can create event handlers and register them on the orchestrations mentioned in this section.

### 5.3.3.2 Integration Tab

By using the **Integration** tab, you can:

- Automate a process task by attaching an event handler or task adapter to it.
- Map the variables of the task adapter, so Oracle Identity Manager can pass the appropriate information when the adapter is triggered. This occurs when the process task's status is Pending.
- Break the link between the adapter handler and the process task, once the adapter or event handler is no longer applicable with the process task.

For example, suppose that the adpSOLARISCREATEUSER adapter is attached to the Create User process task. This adapter has nine adapter variables, all of which are mapped correctly as indicated by the Y that precedes each variable name.

**Note:** when the OIM user is deleted, for each completed task in each resource, Oracle Identity Manager tries to run the Undo tasks.
5.3.3.2.1 Assigning an Adapter or Event Handler to a Process Task

The following procedure describes how to assign an adapter or event handler to a process task.

1. Double-click the row heading of the process task to which you want to assign an event handler or adapter.
   
   The Editing Task window is displayed.

2. Click the Integration tab.

3. Click Add.

   The Handler Selection dialog box is displayed, as shown in Figure 5–5.

4. To assign an event handler to the process task, select the System option.

   To add an adapter to the process task, select the Adapter option. A list of event handlers or adapters, which you can assign to the process task, is displayed in the Handler Name region.

---

Note:

- Event handlers are preceded with tc (Thor class), such as tcCheckAppInstalled. These are event handlers that Oracle provides. Customer-created event handlers cannot have a tc prefix in their name. Adapters are preceded with adp, for example, adpSOLARISCREATEUSER.

- From the Design Console, you cannot create or modify DOB event handlers. You can only view the existing event handlers.

See Also: Chapter 8, “Using the Adapter Factory” and Chapter 28, “Developing Event Handlers” for more information about adapters and event handlers.

---

Important: If you assign an adapter to the process task, the adapter will not work until you map the adapter variables correctly. See “Mapping Adapter Variables” on page 5-22 for details.
5. Select the event handler or adapter that you want to assign to the process task.

6. From the Handler Selection window’s Toolbar, click **Save**.
   A confirmation dialog box is displayed.

7. Click **OK**.
   The event handler or adapter is assigned to the process task.

### 5.3.3.2.2 Mapping Adapter Variables

**See Also:** "Adapter Mapping Information" on page 8-56 for more information about the items to select in this procedure

**Note:** To trigger a task associated with a change to a parent form field, the name of the task must be `fieldUpdated`, where `field` is the name of the parent form field. If the task is not named according to this convention, it is not triggered during a field update.

To map an adapter variable:

1. Select the adapter variable that you want to map.

2. Click **Map**.
   The Data Mapping for Variable window is displayed.

3. Complete the **Map To**, **Qualifier**, **IT Asset Type**, **IT Asset Property**, **Literal Value**, and **Old Value** fields.
4. From the Data Mapping for Variable window’s Toolbar, click **Save**.

5. Click **Close**.

   The mapping status for the adapter variable changes from \( N \) to \( Y \). This indicates that the adapter variable has been mapped.

### 5.3.3.2.3 Removing an Adapter or Event Handler from a Process Task

To remove an adapter or event handler from a process task:

1. Click **Remove**.

   A confirmation dialog box is displayed.

2. Click **OK**.

   The event handler or adapter is removed from the process task.

### 5.3.3.3 Task Dependency Tab

You use the **Task Dependency** tab to determine the logical flow of process tasks in a process. Through this tab, you can:

- Assign **preceding** tasks to a process task.
  
  These tasks must have a status of Completed before Oracle Identity Manager or a user can trigger the current process task.

- Assign **dependent** tasks to a process task.

  Oracle Identity Manager or a user can trigger these tasks only after the current process task has a status of Completed.

- Break the link between a preceding task and the current task so that the preceding task’s completion status no longer has any effect on the current task being triggered.

- Break the link between the current task and a dependent task so that the current task’s completion status no longer has any bearing on triggering the dependent tasks.

For example, the **Create User** process task does not have any preceding tasks. Oracle Identity Manager triggers this task whenever the task is inserted into a process (for example, when an associated resource is requested). The **Create User** process task has seven dependent tasks. Before completion of this process task, each dependent task will have a status of **Waiting**. Once this task achieves a status of Completed, each of these process tasks are assigned a status of **Pending**, and Oracle Identity Manager can trigger them.

#### 5.3.3.3.1 Assigning a Preceding Task to a Process Task

To assign a preceding task to a process task:

1. Double-click the row heading of the process task to which you want to assign a preceding task.

---

**Note:** IT Asset Type and IT Asset Property are displayed only when It Resources is selected from the Map To operations. The Literal Value field is displayed only when Literal is selected from Map To. Old Value check box is enabled only when Organization Definition or User Definition is selected from Map To.
The **Editing Task** window is displayed.

2. Click the **Task Dependency** tab.

3. From the Preceding Tasks region, click **Assign**.
   
   The **Assignment** window is displayed.

4. From this window, select the preceding task, and assign it to the process task.

5. Click **OK**.

   The preceding task is assigned to the process task.

### 5.3.3.3.2 Removing a Preceding Task from a Process Task

To remove a preceding task from a process task:

1. Select the preceding task that you want to delete.

2. From the Preceding Tasks region, click **Delete**.

   The preceding task is removed from the process task.

### 5.3.3.3 Assigning a Dependent Task to a Process Task

To assign a dependent task to a process task:

1. Double-click the row heading of the process task to which you want to assign a dependent task.

   The Editing Task window is displayed.

2. Click the **Task Dependency** tab.

3. From the **Dependent Tasks** region, click **Assign**.

   The Assignment window is displayed.

4. From this window, select the dependent task, and assign it to the process task.

5. Click **OK**.

   The dependent task is assigned to the process task.

### 5.3.3.4 Removing a Dependent Task from a Process Task

To remove a dependent task from a process task:

1. Select the dependent task that you want to delete.

2. From the **Dependent Tasks** region, click **Delete**.

   The dependent task is removed from the process task.

### 5.3.4 Responses Tab

You use the Responses tab to do the following:

■ Define the response codes that can be received in conjunction with the execution of a particular process tasks. You can use response codes to represent specific conditions on the target system.

■ Define the conditional tasks that are started if a response code is received during execution of this process task. These tasks are called generated tasks.

■ Remove a response from a process task.

■ Remove a generated task from a process task.
For example, when a Create User process task is completed, the **SUCCESS** response is activated. This response displays a dialog box with the message "The user was created successfully." In addition, Oracle Identity Manager triggers the Enable User process task.

---

**Note:** By default, the **UNKNOWN** response is defined for each process task that is rejected. This way, even when the system administrator does not add any responses to a process task, if this task is rejected, the user will be notified in the form of an error message in a dialog box.

---

### 5.3.3.4.1 Adding a Response to a Process Task

To add a response to a process task:

1. Double-click the row heading of the process task to which you want to add a response.
   
The Editing Task window is displayed.
2. Click the **Responses** tab.
3. In the **Responses** region, click **Add**.
   
   A blank row is displayed in the Responses region.
4. Enter information in the **Response** field.
   
   This field contains the response code value. This field is case-sensitive.
5. Enter information in the **Description** field. This field contains explanatory information about the response.
   
   If the process task triggers the response, this information is displayed in the task information dialog box.
6. Double-click the **Status** lookup field.
   
   From the Lookup window that is displayed, select a task status level. If the response code is received, it will cause the task to be set to this status.
7. Click **Save**.
   
   The response you added would now reflect the settings you have entered.

### 5.3.3.4.2 Removing a Response from a Process Task

To remove a response from a process task:

1. Select the response that you want to delete.
2. From the **Responses** region, click **Delete**.
   
   The response is removed from the process task.

---

**Note:** You will not be able to delete a response from a process task that is invoked for any provisioning instance, even if the response is existing or is newly added. However, if the process task is not invoked for any provisioning instance, you will be able to delete the response.

---

### 5.3.3.4.3 Assigning a Generated Task to a Process Task
To assign a generated task to a process task:

1. Double-click the row heading of the process task to which you want to assign a generated task.
   The Editing Task window is displayed.

2. Click the **Responses** tab.

3. Select the response code for which you want to assign generated tasks.

4. From the **Tasks to Generate** region, click **Assign**.
   The Assignment window is displayed.

5. From this window, select the generated task, and assign it to the process task response.

6. Click **OK**.
   The generated task is assigned to the process task.

### 5.3.3.4.4 Removing a Generated Task From a Process Task

To remove a generated task from a process task:

1. Select a response code.

2. Select the generated task that you want to delete.

3. From the Tasks to Generate region, click **Delete**.
   The generated task is removed from the process task.

### 5.3.3.5 Undo/Recovery Tab

You use the Undo/Recovery tab for the following:

- To define process tasks that are triggered when the current process task is canceled. These process tasks are known as undo tasks.
- To remove an undo task from a process task, when it is no longer valid.
- To define process tasks that are triggered when the current process task is rejected. These tasks are called recovery tasks.
- To remove a recovery task from a process task.

For example, if the Create User process task has a **Cancelled** status, the Delete User undo task is triggered. Similarly, if the Create User task is **Rejected**, Oracle Identity Manager triggers the Enable User recovery task.

**Note:** When the current process task is rejected, Oracle Identity Manager triggers recovery tasks that are assigned to the process task. If you select the Complete on Recovery check box, Oracle Identity Manager changes the status of the current process task from **Rejected** to **Unsuccessfully Completed** upon completion of all recovery tasks that are generated. This enables Oracle Identity Manager to trigger other dependent process tasks.

The following sections describe how to assign an undo and recovery task to the current process task, and how to remove an undo and recovery task from the current process task.
5.3.3.5.1 Assigning an Undo Task to a Process Task

To assign an undo task to a process task:

1. Double-click the row heading of the process task to which you want to assign an undo task.
   The Editing Task window is displayed.
2. Click the Undo/Recovery tab.
3. In the Undo Tasks region, click Assign.
   The Assignment window is displayed.
4. From this window, select the undo task, and assign it to the process task.
5. Click OK.
   The undo task is assigned to the process task.

5.3.3.5.2 Removing an Undo Task From a Process Task

To remove an undo task from a process task:

1. Select the undo task that you want to delete.
2. From the Undo Tasks region, click Delete.
   The undo task is removed from the process task.

5.3.3.5.3 Assigning a Recovery Task to a Process Task

To assign a recovery task to a process task:

1. Double-click the row heading of the process task to which you want to assign a recovery task.
   The Editing Task window is displayed.
2. Click the Undo/Recovery tab.
3. From the Recovery Tasks region, click Assign.
   The Assignment window is displayed.
4. From this window, select the recovery task, and assign it to the process task.
5. Click OK.
   The recovery task is assigned to the process task.

6. Optional. If you want the status of the current process task to change from Rejected to Unsuccessfully Completed upon completion of all recovery tasks that are generated (so Oracle Identity Manager can trigger other, dependent process tasks) select the Complete on Recovery check box. Otherwise, do not select this check box.

5.3.3.5.4 Removing a Recovery Task from a Process Task

To remove a recovery task from a process task:

1. Select the recovery task that you want to delete.
2. From the Recovery Tasks region, click Delete.
   The recovery task is removed from the process task.
5.3.3.6 Notification Tab

You use this tab to designate the e-mail notification to be generated when the current process task achieves a particular status. A separate e-mail notification can be generated for each status a task can achieve. If an e-mail notification is no longer valid, you can remove it from the Notification tab.

For example, when the Create User process task achieves a status of Completed, Oracle Identity Manager sends the Process Task Completed e-mail notification to the user who is to be provisioned with the resource. If the Create User process task is rejected, the Process Task Completed e-mail notification is sent to the user and the user’s manager.

---

**Note:** Oracle Identity Manager can only send an e-mail notification to a user if you first create a template for the e-mail message by using the Email Definition form.

See “Email Definition Form” on page 5-1 for details.

---

The following sections describe how to assign e-mail notifications to a process task, and remove e-mail notifications from a process task.

5.3.3.6.1 Assigning an E-Mail Notification to a Process Task

To assign an e-mail notification to a process task:

1. Double-click the row heading of the process task to which you want to assign an e-mail notification.
   
The Editing Task dialog box is displayed.

2. Click the Notification tab.

3. Click Assign.
   
The Assignment dialog box is displayed.

4. From this window, select the e-mail template definition to use, and assign it to the process task.

5. Click OK.
   
The name of the e-mail notification is displayed in the Notification tab.

6. Double-click the Status lookup field.
   
From the Lookup window that is displayed, select a completion status level. When the process task achieves this status level, Oracle Identity Manager will send the associated e-mail notification.

7. Select the check boxes that represent the users who will receive the e-mail notification.

Currently, an e-mail notification can be sent to the following users:

- **Assignee.** This user is responsible for completing the associated process task.
- **Requester.** This user requested the process that contains the corresponding process task.
- **User.** This user will be provisioned with the resource once the associated process task is Completed.
- **User's Manager.** This user is the supervisor of the user, who will be provisioned with the resource once the corresponding process task is Completed.

8. Click **Save**.
   
   The e-mail notification is assigned to the process task.

5.3.3.6.2 **Removing an E-mail Notification from a Process Task**

The following procedure describes how to remove an e-mail notification from a process task.

To remove an e-mail notification from a process task:

1. Select the e-mail notification that you want to delete.
2. Click **Delete**.
   
   The e-mail notification is removed from the process task.

5.3.3.7 **Task to Object Status Mapping Tab**

A resource object contains data that is used to provision resources to users and applications.

In addition, a resource object is provided with predefined provisioning statuses, which represent the various statuses of the resource object throughout its life cycle as it is being provisioned to the target user or organization.

---

**Note:** Provisioning statuses are defined in the **Status Definition** tab of the **Resource Objects** form.

---

The provisioning status of a resource object is determined by the status of its associated provisioning processes, and the tasks that comprise these processes. For this reason, you must provide a link between the status of a process task and the provisioning status of the resource object to which it is assigned.

The **Task to Object Status Mapping** tab is used to create this link. Also, when this connection is no longer required, or you want to associate a process task status with a different provisioning status for the resource object, you must break the link that currently exists.

For this example, there are five mappings among process task statuses and provisioning statuses of a resource object. When the Create User process task achieves a status of **Completed**, the associated resource object will be assigned a provisioning status of **Provisioned**. However, if this task is canceled, the provisioning status for the resource object will be **Revoked**. **None** indicates that this status has no effect on the provisioning status of the resource object.

The following sections describe how to map a process task status to a provisioning status and unmap a process task status from a provisioning status.

5.3.3.7.1 **Mapping a Process Task Status to a Provisioning Status**

To map a process task status to a provisioning status:

1. Double-click the row heading of the process task, which has a status that you want to map to the provisioning status of a resource object.

   The Editing Task window is displayed.
2. Click the **Task to Object Status Mapping** tab.

3. Select the desired process task status.

4. Double-click the **Object Status** lookup field.
   From the Lookup window that is displayed, select the provisioning status of the resource object to which you want to map the process task status.

5. Click **OK**.
   The provisioning status you selected is displayed in the Task to Object Status Mapping tab.

6. Click **Save**.
   The process task status is mapped to the provisioning status.

5.3.3.7.2 Unmapping a Process Task Status From a Provisioning Status

To unmapped a process task status from a provisioning status:

1. Select the desired process task status.

2. Double-click the **Object Status** lookup field.
   From the Lookup window that is displayed, select None. None indicates that this status has no effect on the provisioning status of the resource object.

3. Click **OK**.
   The provisioning status of None is displayed in the **Task to Object Status Mapping** tab.

4. Click **Save**.
   The process task status is no longer mapped to the provisioning status of the resource object.

5.3.3.8 Assignment Tab of the Editing Task Window

This tab is used to specify assignment rules for the current process task. These rules will determine how the process task will be assigned.

---

**Note:** Task assignment rules are useful when associated with tasks that are to be completed manually. Most provisioning process tasks are automated, and as a result, they might not require task assignment rules.

---

If the criteria of the Solaris Process Tasks - User rule are not satisfied, Oracle Identity Manager evaluates the criteria of the Solaris Process Tasks - Group rule. If that rule’s criteria are met, the task is assigned to the SYSTEM ADMINISTRATORS role, and the task is marked to escalate in 10 minutes.

---

**Note:** Only rules with a classification type of Task Assignment can be assigned to a process task. For more information about specifying the classification type of a rule, see “Rule Designer Form” on page 4-8. In addition, a Default rule is predefined in Oracle Identity Manager. This rule always evaluates to True. Therefore, it can be used as a safeguard mechanism to ensure that at least one predefined task assignment occurs if all the other rules fail.
Table 5–4 describes the fields of the Assignment tab.

**Table 5–4  Fields of the Assignment Tab of the Editing Task Window**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule</td>
<td>The name of the Task Assignment rule to evaluate.</td>
</tr>
<tr>
<td>Target Type</td>
<td>The classification type of the user or role that is responsible for completing the current process task. Currently, the process task can be assigned to:</td>
</tr>
<tr>
<td></td>
<td>- User. An Oracle Identity Manager user.</td>
</tr>
<tr>
<td></td>
<td>- Role. A role.</td>
</tr>
<tr>
<td></td>
<td>- Group User with Least Load. The member of the specified role with the fewest process tasks assigned.</td>
</tr>
<tr>
<td></td>
<td>- Request Target User's Manager. The supervisor of the user who is being provisioned with the resource.</td>
</tr>
<tr>
<td></td>
<td>- Object Authorizer User with Least Load. The member of the role (designated as an Object Authorizer role for the resource) with the fewest process tasks assigned.</td>
</tr>
<tr>
<td></td>
<td>- Object Administrator. A role that is defined as an administrator of the associated resource object.</td>
</tr>
<tr>
<td></td>
<td>- Object Administrator User with Least Load. The member of the role (designated as an Object Administrator role) with the fewest process tasks assigned.</td>
</tr>
<tr>
<td></td>
<td>- Requestor's Manager: The manager of the user who created the request.</td>
</tr>
<tr>
<td>Note:</td>
<td>Object Authorizer and Object Administrator roles are defined in the Object Authorizers and Administrators tabs, respectively, of the Resource Objects form.</td>
</tr>
<tr>
<td>Adapter</td>
<td>This is the name of the adapter. Double-click this field to get a lookup form for all existing adapters.</td>
</tr>
<tr>
<td>Adapter Status</td>
<td>This is the status of the adapter.</td>
</tr>
<tr>
<td>Group</td>
<td>The role to which the current process task is assigned.</td>
</tr>
<tr>
<td>User</td>
<td>The user to which the current process task is assigned.</td>
</tr>
<tr>
<td>Email Name &amp; Send Email</td>
<td>By selecting an e-mail notification from the Email Name lookup field, and selecting the Send Email check box, Oracle Identity Manager will send the e-mail notification to a user or role once the current process task is assigned.</td>
</tr>
<tr>
<td>Escalation Time</td>
<td>The amount of time (in milliseconds) that the user or role, which is associated with the rule that Oracle Identity Manager triggers, has to complete the process task. If this process task is not completed in the allotted time, Oracle Identity Manager will re-assign it to another user or role. The escalation rule adheres to the order defined by the target type parameter.</td>
</tr>
<tr>
<td>Priority</td>
<td>The priority number of the rule that is associated with the current process task. This number indicates the order in which Oracle Identity Manager will evaluate the rule.</td>
</tr>
</tbody>
</table>

The following sections describe adding a task assignment rule to a process task and how to remove it from the process task.

**5.3.3.8.1  Adding a Rule to a Process Task**

To add a rule to a process task:
1. Double-click the row heading of the task to which you want to add a rule. The Editing Task window is displayed.

2. Click the **Assignment** tab.

3. Click **Add**.
   
   A blank row is displayed in the Assignment tab.

4. Double-click the **Rule** lookup field.
   
   From the Lookup window that is displayed, select the rule that you want to add to the process task. Then, click **OK**.

5. Double-click the **Target Type** lookup field.
   
   From the Lookup window that is displayed, select the classification type of the user or role (User, Role, Group User with Least Load, Request Target User’s Manager, Object Authorizer User with Least Load, Object Administrator, Object Administrator User with Least Load), and Requestor’s Manager that is responsible for completing the process task. Then, click **OK**.

6. Double-click the **Group** lookup field.
   
   From the Lookup window that is displayed, select the role that is responsible for completing the process task. This setting is only necessary if you selected Group or Group User with Least Load in the **Target Type** field. Then, click **OK**.

   OR

   Double-click the **User lookup** field. From the Lookup window that is displayed, select the user who is responsible for completing the process task. This setting is only necessary if you selected User in the **Target Type** field. Then, click **OK**.

7. Double-click the **Email Name** field.
   
   From the Lookup window that is displayed, select the e-mail notification that will be sent to the corresponding user or role once the task is assigned. Click **OK**. Then, select the **Send Email** check box.

   If you do not want Oracle Identity Manager to send an e-mail notification when the task is assigned, go to Step 8.

8. In the **Escalation Time** field, enter the time (in milliseconds) that the selected user or role has to complete the process task.

   When you do not want to associate a time limit with the rule you are adding to the process task, leave the **Escalation Time** field empty, and proceed to Step 10.

9. In the **Priority** field, enter the priority number of the rule that you are adding to the process task.

10. Click **Save**.

    The rule is added to the process task.

### 5.3.3.8.2 Removing a Rule from a Process Task

To remove a rule from a process task:

1. Select the rule that you want to delete.

2. Click **Delete**.

The rule is removed from the process task.
Developing Process Forms

The information required to provision resources to a target user or organization cannot always be retrieved from an existing Oracle Identity Manager form. You can use the Form Designer form in the Development Tools folder of the Design Console to create a form with fields that contain the relevant information. After creating the form, you assign it to the process or resource object that is associated with provisioning resources to the user or organization. Figure 6–1 shows the Form Designer Form.

Oracle Identity Manager displays a resource object or process form that a user creates by using the Form Designer form for the following reason:

When the process form is attached to the appropriate provisioning process, and the Launch Form menu command is selected by right-clicking the process from the Object Process Console tab of the Organizations or Users forms.

For example, when Oracle Identity Manager or one of its users attempts to complete the resource object or process, the assigned form is triggered. When this occurs, either Oracle Identity Manager or a user populates the fields of this form. After the data is saved, the corresponding process or resource object can achieve a status of Completed, and Oracle Identity Manager can provision the appropriate resources to the target organizations or users.
For example, the Solaris form (represented by the UD_SOLARIS name in the Table Name field) has been created and assigned to both the Solaris resource object and provisioning process.

**Note:** The table name contains a UD_prefix, followed by the form name. For this example, because the name of the form is SOLARIS, its table name is UD_SOLARIS.

Table 6–1 describes the data fields of the Form Designer form.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Name</td>
<td>The name of the database table that is associated with the form.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The table name contains the UD_prefix, followed by the form name. If the name of the form is SOLARIS, its table name is UD_SOLARIS.</td>
</tr>
<tr>
<td>Description</td>
<td>Explanatory information about the form.</td>
</tr>
<tr>
<td></td>
<td><strong>Important:</strong> The text that is displayed in the Description field is the name of the form.</td>
</tr>
<tr>
<td>Preview Form</td>
<td>When you click this button, the form is displayed. This way, you can see how it looks and functions before you make it active.</td>
</tr>
</tbody>
</table>
The following sections describes how to work with forms:

- **Creating a Form**
- **Tabs of the Form Designer Form**
- **Creating an Additional Version of a Form**

## 6.1 Creating a Form

To create a form:

1. Open the Form Designer form.
2. In the **Table Name** field, enter the name of the database table that is associated with the form.

   **Note:** The table name contains the UD_ prefix followed by the form name. If the name of the form is SOLARIS, its table name is UD_SOLARIS.

3. In the **Description** field, enter explanatory information about the form.
4. Verify that the **Process** option is selected. This option is selected because the form is assigned to a provisioning process.
5. Click **Save**.
The form is created. The words Initial Version are displayed in the Latest Version field. This signifies that you can populate the tabs of the Form Designer form with information, so the form is functional with its assigned process or resource.

---

**Note:** When you create an application instance, associate a process form with it and publish the sandbox, and then make some changes to the process form in the Design Console, such as add new fields or prepopulate adapters, then the changes are not reflected in the application instance. To reflect the changes in the application instance, create a new process form and associate it with the application instance. The recommended method to do so is by using the Form Designer in Oracle Identity System Administration, and not the Form Designer form in the Design Console. See “Managing Forms” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for details.

---

### 6.2 Tabs of the Form Designer Form

After you open the Form Designer form, and create a form, the tabs of this form become functional. The Form Designer form contains the following tabs:

- Additional Columns Tab
- Child Table(s) Tab
- Object Permissions Tab
- Properties Tab
- Administrators Tab
- Usage Tab
- Pre-Populate Tab
- Default Columns Tab
- User Defined Fields Tab

#### 6.2.1 Additional Columns Tab

You use the Additional Columns tab to create and manage data fields. These data fields are displayed on the associated form that is created by using the Form Designer form.

*Table 6-2* describes the data fields of the Additional Columns tab.

**Table 6-2  Fields of the Additional Columns Tab**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Name | The name of the data field that is displayed in the database and is recognized by Oracle Identity Manager.  
  Note: This name consists of the `<TABLENAME_>` prefix followed by the name of the data field.  
  For example, if the name in the Table Name field of the Form Designer form is UD_PASSWORD and the name for the data field is `USERNAME`, the data field name that is displayed in the database and that Oracle Identity Manager recognizes, would be `UD_PASSWORD_USERNAME`. |
Tabs of the Form Designer Form

**Table 6–2 (Cont.) Fields of the Additional Columns Tab**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variant Type</td>
<td>From this lookup field, select the variant type for the data field. The variant type denotes the type of data that the field accepts. This data field must be one of nine variant types: <strong>Byte, Double, Date, Byte Array, Boolean, Long, String, Short, and Integer.</strong></td>
</tr>
<tr>
<td>Length</td>
<td>The length in characters of the data field.</td>
</tr>
<tr>
<td>Field Label</td>
<td>The label that is associated with the data field. This label is displayed next to the data field on the form that is generated by Oracle Identity Manager.</td>
</tr>
</tbody>
</table>
You can select one of the following data types:

- **TextField**: This data field is displayed on the generated form as a text field. The field type for TextField is displayed as `com.thortech.xl.gui.base.tcTextField` in lookup selection.

  If the text field is display-only (the text in the field is displayed in red font), a user can use the field only to run a query. Otherwise, the user can also populate the field with information, and save it to the database.

- **LookupField**: This data field is displayed on the generated form as a lookup field.

  If this lookup field is display-only, a user can use the field only to run a query. Otherwise, the user can also populate the field with a value from the associated Lookup window, and save this value to the database.

- **TextArea**: This data field is displayed on the generated form as a text area.

  If this text area is display-only, a user can only read the information that is displayed in it. Otherwise, the user can also populate the text area with data, and save this information to the database.

- **ITResourceLookupField**: This data field is displayed on the generated form as a lookup field. From this lookup field, a user can select a lookup value that represents an IT resource, and save this value to the database.

  **Note**: If you select this data field, you must specify the type of server for the IT resource from the Property Value field.

  For more information about adding a property value to a data field, see “Adding a Property and Property Value to a Data Field” on page 6-12.

- **DateFieldWithDialog**: This data field is displayed on the generated form as a text field.

  If this text field is display-only, a user can use the field only to run a query. Otherwise, the user can also populate the field with a date and time (by double-clicking the field and selecting a date and time from the Date & Time window). Then, this date and time can be saved to the database.

- **CheckBox**: This data field is displayed on the generated form as a check box.

  If this check box is display-only, a user can only see whether the check box is selected or deselected. Otherwise, the user can also select or deselect the check box, and save this setting to the database.

- **PasswordField**: The text entered in this field is displayed as a series of asterisk (*) characters.

  Oracle Identity Manager checks if a field with field type as Password Field has the `AccountPassword` property set to true. If so, then password policies apply. If such a field does not exist, then Oracle Identity Manager checks if a field of Password Field type having name in the `FORM_NAME_PASSWORD` format exists. If so, then password policies apply.

  Oracle Identity Manager automatically sets AccountPassword=true to a field with field type as Password Field and name in the `FORM_NAME_PASSWORD` format when such a field is being created.

  For information about setting the AccountPassword property to true, see “Setting the Value of the AccountPassword Property” on page 6-9.

  For information about adding a property value to a data field, see “Adding a Property and Property Value to a Data Field” on page 6-12.

- **RadioButton**: This data field is displayed on the generated form as an option.

  A user can select or deselect the radio button, and save this setting to the database.

- **DataCombobox**: This data field is displayed on the generated form as a list.

  A user can select an item from the list and save this selection to the database.

- **DisplayOnlyField**: This data field is not enabled for the user to enter a value. This type of fields can only display data based on values in other fields.
6.2.1.1 Adding a Data Field to a Form

To add a data field to a form:

1. In the Additional Columns tab, click Add.

A blank row is displayed in the Additional Columns tab.

2. In the Name field, enter the name of the data field, which is displayed in the database, and is recognized by Oracle Identity Manager.

3. Double-click the Variant Type lookup field.

From the Lookup window that is displayed, select the variant type for the data field.

---

**Table 6–2 (Cont.) Fields of the Additional Columns Tab**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>This value is displayed in the associated data field after the form is generated and if no other default value was specified from the following scenarios:</td>
</tr>
<tr>
<td></td>
<td>■ A prepopulate adapter, which is attached to the form field, is run.</td>
</tr>
<tr>
<td></td>
<td>■ A data flow exists between a field of a custom form assigned to one process and a field of a custom form associated with another process.</td>
</tr>
<tr>
<td></td>
<td>■ A resource object, which has been requested for an organization, has a custom form attached to it. In addition, one of the fields of this custom form has a default value associated with it. It is strongly recommended that you do not specify default values for passwords and encrypted fields.</td>
</tr>
<tr>
<td>Order</td>
<td>The Order field is not used in Oracle Identity Manager 11g Release 2 (11.1.2.2.0).</td>
</tr>
<tr>
<td>Application Profile</td>
<td>This check box designates if the most recent value of this field should be displayed on the Object Profile tab of the Users form after the resource associated with this form has been provisioned to the user and achieved the Enabled status.</td>
</tr>
<tr>
<td></td>
<td>If this check box is selected, the label and value of this field is displayed on the Object Profile tab of the Users form for users provisioned with the resource.</td>
</tr>
<tr>
<td>Encrypted</td>
<td>This check box determines if the information, which is displayed in the associated data field, is to be encrypted when it is transmitted between the server and the client.</td>
</tr>
<tr>
<td></td>
<td>If this check box is selected, the information that is displayed in the data field is encrypted when it is transmitted between the client and the server.</td>
</tr>
</tbody>
</table>

---

**Note:** Password fields are encrypted by default. When a data field of password field type is created, the value is displayed as asterisk (*) characters, and the data is encrypted in the database.

Do not use ParentAccountId as a form field name. ParentAccountId is used to store system information.

For example, if the name that is displayed in the Table Name field is **UD_PASSWORD**, and the name for the data field is **USERNAME**, the data field name that is displayed in the database and Oracle Identity Manager recognizes, would be **UD_PASSWORD_USERNAME**.
Currently, a data field can have one of nine variant types: Byte, Double, Date, Byte Array, Boolean, Long, String, Short, and Integer.

4. In the **Length** field, enter the length (in characters) of the data field.

5. In the **Field Label** field, enter the label that will be associated with the data field. This label is displayed next to the data field on the form that is generated by Oracle Identity Manager.

6. Double-click the **Field Type** lookup field. From the Lookup dialog box that is displayed, select the data type for the data field. Presently, a data field can have one of nine data types: Text Field, Lookup Field, Text Area, IT Resource Lookup Field, Date Field, Check Box, Password Field, Radio Button, and box.

   **See Also:** Table 6–2 for more information about data types

7. In the **Default Value** field, enter the value that is displayed in the associated data field once the form is generated, and if no other default value has been specified.

   **See Also:** Table 6–2 for more information about the scenarios where a default value could be set

8. In the **Order** field, enter the sequence number, which will represent where the data field will be positioned on the generated form.

   For example, a data field with an order number of 2 is displayed below a data field with an order number of 1.

9. If you want a specific organization or user’s values to supersede the value that is displayed in the **Default Value** field, select the **Application Profile** check box. Otherwise, go to Step 10.

10. If you want the information that is displayed in the data field to be encrypted when it is transmitted between the client and the server, select the **Encrypted** check box. Otherwise, go to Step 11.

11. Click **Save**.

### 6.2.1.2 Removing a Data Field From a Form

To remove a data field from a form:

**Note:** While adding a new field, if you assign it the same name as a field that was removed, the variant type (data type) of the new field remains the same as that of the field that was removed. For example, suppose you remove the Addr1 field to which the String variant type was applied. You create a field with the same name and apply the Boolean variant type to it. Now, when you view or use the form on which the new Addr1 field is added, the variant type of the field is String and not Boolean.

1. Delete all properties that are associated with the data field you want to remove by following the instructions in Section 6.2.4.3, "Removing a Property and Property Value From a Data Field”.

2. Select the data field that you want to remove.
3. Click **Delete**.

   The data field is removed from the form.

While adding a new field, if you assign it the same name as a field that was removed, the variant type (data type) of the new field remains the same as that of the field that was removed. For example, suppose you remove the Addr1 field to which the String variant type was applied. You create a field with the same name and apply the Boolean variant type to it. Now, when you view or use the form on which the new Addr1 field is added, the variant type of the field is String and not Boolean.

### 6.2.1.3 Setting the Value of the AccountPassword Property

To set the value of the AccountPassword property to true:

1. Create a password field in Form Designer form.
2. Click the **Properties** tab.
3. Select the password field, and click **Add Property**.
4. From the Property Name list, select **AccountPassword**.
5. In the Property Value field, enter **true**.
6. Click **Save**.

### 6.2.2 Child Table(s) Tab

Sometime you might have to add the same data fields to multiple forms that are created by using the Form Designer form. There are two ways to do this:

- You can add the data fields to each form manually, through the form’s **Additional Columns** tab.
- You can group the data fields together and save them under one form name. Then, you can assign this form to each form that requires these data fields.

If this form contains the data fields that are required by another form, it is known as a child table.

Assigning child tables to a form increases your efficiency as a user. Without child tables, for every form that needs data fields, you would have to set the parameters for each field. For example, if five forms require the identical data field, you would have to set the parameters for this field five, separate times (one for each form).

If you use a child table for one form, and decide that you want to apply it to another form, the Design Console enables you to do so. Remove the child table from the first form, and assign it to the target form. This way, the child table that you assign to one form can be reused for all forms created with the Form Designer form.

You can configure Oracle Identity Manager to perform one of the following actions in a column of a child table:

- **Insert**: Adds a new value to the designated column of the child table
- **Update**: Modifies an existing value from the corresponding column of the child table
- **Delete**: Removes a value from the designated column of the child table
For example, suppose that the UD_SOUTH child table is assigned to the Results of 1Q 2004 Sales form (represented by the UD_SALES2 table name). After this form is started, the data fields in the UD_SOUTH child table are displayed in the form.

The following sections describe how to assign a child table to a form and how to remove a child table from a form.

**Note:** If the form, which is represented by the child table, has not been made active, you cannot assign it to the parent form.

### 6.2.2.1 Assigning a Child Table to a Form

To assign a child table to a form:

**Note:** If the form that is represented by the child table is active, it will not be displayed in the Assignment window, and you will not be able to assign it to the parent form.

1. Click **Assign**.
   - The Assignment window is displayed.
2. From this window, select the child table, and assign it to the form.
3. Click **OK**.
   - The selected child table is assigned to the form.

### 6.2.2.2 Removing a Child Table from a Form

To remove a child table from a form:

1. Select the child table that you want to remove.
2. Click **Delete**.
   - The child table is removed from the form.

### 6.2.3 Object Permissions Tab

You use this tab to select the user groups that can add, modify, and remove information from a custom form when it is instantiated.

- When the **Allow Insert** check box is selected, the corresponding user group can add information into the fields of the user-created form. If this check box is not selected, the user group cannot populate the fields of this form.

- When the **Allow Update** check box is selected, the associated user group can modify existing information in the fields of the user-created form. If this check box is not selected, the user group cannot edit the fields of this form.

- When the **Allow Delete** check box is selected, the corresponding user group can delete data from instantiations of the user-created form. If this check box is not selected, the user group cannot delete data from fields of this form (when it is instantiated).
Suppose the SYSTEM ADMINISTRATORS user group can create, modify, and delete information that is displayed in the Results of 1Q 2004 Sales form (represented by the UD_SALES2 name in the Table Name field). The IT DEPARTMENT user group can only delete records of this form (its Allow Insert and Allow Update check boxes are not selected). The HR DEPARTMENT user group can create and modify information from within the Results of 1Q 2004 Sales form. However, because the Allow Delete check box is not selected, this user group is not able to delete this information.

The following section describes how to assign a user group to a user-created form, and remove a user group from a user-created form.

6.2.3.1 Assigning a User Group to a User-Created Form

To assign a user group to a user-created form:
1. Click Assign.
   The Assignment dialog box is displayed.
2. Select the user group, and assign it to the form that was created by a user.
3. Click OK.
   The user group is displayed in the Object Permissions tab.
4. If you do not want this user group to be able to add information into a record of the user-created form, double-click the corresponding Allow Insert check box. Otherwise, go to Step 5.
5. If you do not want this user group to be able to modify information from within a record of the user-created form, double-click the associated Allow Update check box. Otherwise, go to Step 6.
6. If you do not want this user group to be able to delete a record of the user-created form, double-click the corresponding Allow Delete check box. Otherwise, go to Step 7.
7. Click Save.
   The user group is assigned to the user-created form.

6.2.3.2 Removing a User Group From a User-Created Form

To remove a user group from a user-created form:
1. Select the user group that you want to remove.
2. Click Delete.
   The user group is removed from the user-created form.

6.2.4 Properties Tab

You use the Properties Tab of the Form Designer Form to assign properties and property values to the data fields that are displayed on the form that is created through the Form Designer form.

For example, suppose that the Results of 1Q 2004 Sales form has two data fields: User Name and Password. Each data field contains the following properties:
Tabs of the Form Designer Form

- **Required**, which determines whether or not the data field must be populated for the generated form to be saved. The default value for the `Required` property is `false`.

- **Visible Field**, which establishes whether the data field is displayed on the form, once Oracle Identity Manager generates the form. The default value for the `Visible Field` property is `true`.

Because the property values for the `Required` and `Visible Field` properties are `true` for both data fields, once the Results of 1Q 2004 Sales form is generated, both of these data fields are displayed. In addition, each field must be populated for the form to be saved.

The following sections describe how to add a property and property value to a data field, and how to remove them from the data field.

---

**Note:** The Properties tab is grayed out until you create a data field for the form by using the Additional Columns tab.

For more information about the properties and property values you can select, see “Rule Elements, Variables, Data Types, and System Properties” on page A-1.

---

### 6.2.4.1 Adding a Property and Property Value to a Data Field

To add a property and property value to a data field:

1. Select the data field to which you want to add a property and property value.
2. Click **Add Property**. The Add Property dialog box is displayed.

**Note:** The text that is displayed in the Column Name and Column Type fields are the names and types of data fields you selected.

In this example, the User Name data field was selected (as indicated by User Name displayed in the **Column Name** field). In addition, the data type of this field is a text field.

**Table 6–3** lists the fields of the Add Property dialog box.

<table>
<thead>
<tr>
<th><strong>Table 6–3</strong> Fields of the Add Property Dialog Box</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>Column Name</td>
</tr>
<tr>
<td>Column Type</td>
</tr>
<tr>
<td>Property Name</td>
</tr>
<tr>
<td>Property Value</td>
</tr>
</tbody>
</table>

**Note:** The menu items displayed in the Property Name box reflect the data type of the selected data field.

3. Set the parameters for the property and property value that you are adding to the data field.
For this example, because the value of the Required property for the User Name data field was set to true, once the associated form is generated, this field must be populated. Otherwise, the form cannot be saved.

See Also: See "Rule Elements, Variables, Data Types, and System Properties" on page A-1 for more information about the parameters and property values to select.

4. From the Add Property window's Toolbar, click Save.
5. Click Close.

The property and property value are added to the data field.

6.2.4.2 Adding a Property and Property Value for Customized Look up Query

To add a property and a property value for a customized lookup query:

1. Select the data field to which you want to add a property and a property value.
2. Click Add Property.

The Add Property dialog box is displayed, as shown in Figure 6–2.

Figure 6–2 Add Property Dialog Box

Note: The text that is displayed in the Column Name and Column Type fields shows the name and type of the data field you selected (from the Properties tab of the Form Designer).

In this example, the Name data field was selected (as indicated by Name displayed in the Column Name field). In addition, the data type of this field is a lookup field.
The boxes of the Add Property dialog box are used to help build the WHERE clause in the custom lookup query. As you select the values for each box (from the menu), the WHERE clause is appended to the custom lookup query.

Table 6–4 describes the regions of the Add Property dialog box. Initially, all the fields are grayed out. After you have defined the lookup query and clicked **Save**, the fields become active.

**Table 6–4  Fields of the Add Property Dialog Box**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column Name</td>
<td>The name of the data field.</td>
</tr>
<tr>
<td>Column Type</td>
<td>The data type of the data field.</td>
</tr>
<tr>
<td>Property Name</td>
<td>From this list, select the property for the data field.</td>
</tr>
<tr>
<td>Property Value</td>
<td>In this field, enter the property value, which is associated with the property that is displayed in the <strong>Property Name</strong> box. In the case of a lookup query, you must specify both the Oracle Identity Manager form and field, which will be referenced for the query and will be recognized by the database. For example, if Oracle Identity Manager is referring to the user's login, you enter <code>select usr_key from usr</code> in the <strong>Property Value</strong> field. After clicking <strong>Save</strong>, the <strong>Filter Column</strong> is active with all the columns of tables.</td>
</tr>
<tr>
<td>Filter Column</td>
<td>This is the Oracle Identity Manager form field that is referenced for the lookup query, and which is recognized by the database. This field is populated with all columns of table specified in the <strong>Property Value</strong> field. If multiple tables are used in the query, all tables are shown. For example, <code>usr.USR_LOGIN</code> signifies that Oracle Identity Manager will see the <strong>User Login</strong> field from the Users form for the lookup query.</td>
</tr>
<tr>
<td>Source</td>
<td>After the <strong>Filter Column</strong> variable is selected, the <strong>Source</strong> field is populated with all possible sources of value. The list of values in this field is dependent upon the type of form, for which the lookup field is being defined. For instance, the list displayed is different if the lookup query is for an Object form or a Process form. The <strong>Source</strong> field is a user-friendly name for the value that is displayed in the <strong>Filter Column</strong> box. For example, <strong>Requester Information</strong> refers to the <code>usr.USR</code> portion of the <strong>Filter Column</strong> value.</td>
</tr>
<tr>
<td>Field</td>
<td>This field is populated based on what value is selected in the <strong>Source</strong> field. Use this field to create the SELECT statement, which is needed for the column name. For example, the User Login corresponds to the <code>_LOGIN</code> part in the <strong>Filter Column</strong> value.</td>
</tr>
</tbody>
</table>

**Note:** The menu items displayed in the **Property Name** box show the data type of the selected data field.

The **Source** and **Field** boxes of the Add Property dialog box are applicable only when **Lookup Query** is displayed in **Property Name**.

3. Set the parameters for the property and the property value that you are adding to the data field. **Figure 6–3** shows the Edit Property dialog box.
6.2.4.3 Removing a Property and Property Value From a Data Field

To remove a property and property value from a data field:

1. Select the property and the property value that you want to remove.
2. Click Delete Property.

The property and its associated value are removed from the data field.

6.2.5 Administrators Tab

This tab is used to select the user groups that can view, modify, and delete the current record of the form that was created by a user by using the Form Designer form.

When the Write check box is selected, the corresponding user group can view and modify information for the current record of the form. If this check box is not selected, the user group cannot view or edit information for this record.

When the Delete check box is selected, the associated user group can remove information from the current record of the form. If this check box is not selected, the user group cannot delete information from this record.

The following sections describe how to assign administrative privileges to a user group for a record of a user-created form and remove administrative privileges from a user group for a record of a user-created form.

6.2.5.1 Assigning Privileges to a User Group for a Record of a User-Created Form

To assign administrative privileges to a user group for a record of a user-created form:

1. Click Assign.

   The Assignment dialog box is displayed.

2. Select the user group, and assign it to the record of the user-created form.

3. Click OK.

   The user group is displayed in the Administrators tab.
4. If you want this user group to be able to create and modify information for the current record of the user-created form, double-click the corresponding **Write** check box. Otherwise, go to Step 5.

5. If you want this user group to be able to remove information from the current record of the user-created form, double-click the associated **Delete** check box. Otherwise, go to Step 6.

6. **Click Save.**

   The user group now has administrative privileges for this record of the user-created form.

### 6.2.5.2 Removing User Group Privileges for a Record of a User-Created Form

To remove administrative privileges from a user group for a record of a user-created form:

1. Select the user group that you want to remove.

2. **Click Delete.**

   The user group no longer has administrative privileges for this record of the user-created form.

### 6.2.6 Usage Tab

In this tab, you can see the resource objects and processes to which the current form has been assigned.

For example, the **Solaris** form (represented by the **UD_SOLARIS** name in the **Table Name** field) was created and assigned to both the Solaris resource object and provisioning process.

---

**Note:** The table name contains the **UD_** prefix, followed by the form name. For this example, because the name of the form is Solaris, its table name is **UD_SOLARIS**.

This tab will be populated with information only after you click **Make Version Active**.

---

### 6.2.7 Pre-Populate Tab

You use this tab to do the following:

- Attach a pre-populate adapter to a data field of the user-created form.
- Select the rule that will determine if this adapter will be executed to populate the designated data field with information.
- Set the priority number for the selected rule.
- Map the adapter variables of the prepopulate adapter to their correct locations.

---

**See Also:** Chapter 8, "Using the Adapter Factory" for more information about prepopulate adapters, attaching pre-populate adapters to fields of user-created forms, or mapping the variables of a pre-populate adapter.
6.2.8 Default Columns Tab

A form that is created by using the Form Designer form is composed of two types of data fields:

- Data fields that are created by a user (by using the Additional Columns tab)
- Data fields that are created by Oracle Identity Manager, and added to the form, once the form is created

Through the Default Columns tab, you can see the names, variant types, and lengths of the data fields, which are added, by default, to a user-created form. As a result, by viewing these data fields, you can see all data fields for this type of form, without starting SQL*Plus, or a similar database application.

6.2.9 User Defined Fields Tab

This tab is used to view and access any user-defined fields that were created for the Form Designer form. Once a user-defined field has been created, it is displayed on this tab and is able to accept and supply data.

6.3 Creating an Additional Version of a Form

Sometimes, when you create a form and populate the tabs of the Form Designer form with information, so the form will work with the process or resource object to which it will be assigned, you might want to create a different version of the form. This way, you can modify this version, without changing the original version of the form.

To create an additional version of a form:

1. Open the Form Designer form.
2. Search for the specific form of which you want to create a different version.
3. Click the Current Version box.
   
   From the drop-down menu that is displayed, select the version of the form of which you are creating an additional version.
4. Click the Create New Version button.
   
   The Create a New Version window is displayed.
5. In the Label field, enter the name of the additional version of the form.
6. From the Create a New Version window’s toolbar, click Save.
7. From this toolbar, click Close.

The additional version of the form is created. When you click the Current Version box, the version’s name, which you entered into the Label field in Step 5, is displayed. By selecting this version, you can populate the tabs of the Form Designer form with information, without changing the original version of the form.

If you use the new form version to manage all users, then run the Form Version Control (FVC) utility after the new form version is made active. See “Using the Form Version Control Utility” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about the FVC utility.
This section describes how to use the Design Console to administer Oracle Identity Manager. It contains the following topics:

- Overview
- Lookup Definition Form

### 7.1 Overview

The Design Console Administration folder provides system administrators with tools for managing Oracle Identity Manager administrative features. This folder contains the following form:

**Lookup Definition**: You use this form to create and manage lookup definitions. A lookup definition represents a lookup field and the values you can access from that lookup field.

**Note**: Oracle Identity Manager recommends that you create and manage lookups by using the Oracle Identity System Administration. See "Managing Lookups" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for details.

### 7.2 Lookup Definition Form

A lookup definition represents one of the following:

- The name and description of a text field
- A lookup field and the values that are accessible from that lookup field by double-clicking it
- A box, and the commands that can be selected from that box

These items, which contain information pertaining to the text field, lookup field, or box, are known as lookup values. Users can access lookup definitions from one of two locations:

- A form or tab that comes packaged with Oracle Identity Manager
- A user-created form or tab built by using the Form Designer form

The Lookup Definition form shown in Figure 7–1 is in the Design Console Administration folder. You use this form to create and manage lookup definitions.
Figure 7–1  Lookup Definition Form

Table 7–1 describes the data fields of the Lookup Definition form.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code</td>
<td>The name of the lookup definition.</td>
</tr>
<tr>
<td>Field</td>
<td>The name of the table column of the form or tab from which the text field, lookup field, or box field will be accessible.</td>
</tr>
<tr>
<td>Lookup Type/Field Type</td>
<td>These options designate if the lookup definition is to represent a text field, a lookup field, or a box.</td>
</tr>
<tr>
<td>Required</td>
<td>By selecting this check box, the lookup definition is designated as required. As a result, Oracle Identity Manager will not allow the contents of the corresponding form or tab to be saved to the database until the field or box, represented by the lookup definition, is supplied with data.</td>
</tr>
<tr>
<td>Group</td>
<td>The name of the Oracle Identity Manager or user-defined form on which the lookup definition is to be displayed.</td>
</tr>
</tbody>
</table>

The following sections describe how to create a lookup definition.

7.2.1 Creating a Lookup Definition

To create a lookup definition:

1. Login to Oracle Identity Manager Design Console.
2. Navigate to Administration, Lookup Definition.

3. In the Code field, enter the name of the lookup definition.

4. In the Field field, enter the name of the table column of the Oracle Identity Manager or user-created form or tab, from which the text field, lookup field, or box field will be accessible.

5. If the lookup definition is to represent a lookup field or box, select the Lookup Type option.
   If the lookup definition is to represent a text field, select the Field Type option.

6. Optional. To save the contents of this form or tab only when the field or box represented by the lookup definition is supplied with data, select the Required check box. Otherwise, go to Step 7.

7. In the Group field, enter the name of the Oracle Identity Manager or user-defined form on which the lookup definition is displayed.
   You must follow naming conventions for the text you enter into the Code, Field, and Group fields.
   
   See Also: See "Lookup Definition Form" on page 7-1 for more information about naming conventions

8. Click Save.

   The lookup definition is created. The associated text field, lookup field, or box will be displayed in the Oracle Identity Manager or user-defined form or tab you specified.

7.2.2 Lookup Code Information Tab

The Lookup Code Information tab is in the lower half of the Lookup Definition form. You use this tab to create and manage detailed information about the selected lookup definition. This information includes the names, descriptions, language codes, and country codes of a value pertaining to the lookup definition. These items are known as lookup values.

The following procedures show how to create, modify, and delete a lookup value.

7.2.2.1 Creating and Modifying a Lookup Value

To create or modify a lookup value:

Note: For internationalization purpose, you must provide both a language and country code for a lookup value.

When creating a new lookup definition, you must save it before adding lookup values to it.

1. Open the Lookup Definition form.

2. Access a lookup definition.

3. If you are creating a lookup value, click Add.

   A blank row is displayed in the Lookup Code Information tab.

   If you are modifying a lookup value, select the lookup value that you want to edit.

   When creating a new lookup definition, you must save it before adding lookup values to it.
4. Add or edit the information in the Code Key field.
This field contains the name of the lookup value.
In addition, if the Lookup Type option is selected, this field also represents what is displayed in the lookup field or box once the user makes a selection.

5. Add or edit the information in the Decode field.
This field contains a description of the lookup value.

---

**Note:** The decode value is a humanly readable description of the field. The encode value is the actual code value that is used for provisioning. For example, decode value can be an LDAP group name, and encode value is the LDAP group GUID.

---

If the Lookup Type option is selected, this field also represents one of the following:
- The items that is displayed in a lookup window after the user double-clicks the corresponding lookup field
- The commands that are to be displayed in the associated box

6. Click Save.
The lookup value you created or modified now reflects the settings you have entered.

### 7.2.2.2 Deleting a Lookup Value

To delete a lookup value:

---

**Caution:** Deleting a lookup value might cause problems depending on what the lookup represents. For example, if a lookup value represents an entitlement and it is deleted, then it must be removed from various locations, such as any access policy with that entitlement or any user account having that entitlement granted. Therefore, Oracle recommends that you check all the possible effects before deleting a lookup value.

---

1. Open the Lookup Definition form.
2. Search for a lookup definition.
3. Select the lookup value that you want to remove.
4. Click Delete, and then click OK in the message box. The selected lookup value is deleted.

### 7.2.3 Configuring Challenge Questions for the User

You can configure challenge questions for the users by using the Lookup Definition Form. These challenge questions are prompted if the user forgets the password and tries to retrieve it. The user must enter the same answers provided while creating a password.

To configure challenge questions for the user:
1. Login to Oracle Identity Manager Design Console.
2. Navigate to **Administration, Lookup Definition**.

4. Click **Add**.

5. In the Lookup Code Information tab, add questions by entering the appropriate values in the Code Key and Decode fields.

6. Add this key to the custom model bundle. For example the challenge question you want to add is "What is your dream destination?" Enter this in both Code Key and Decode fields, and save the Lookup Definition, as shown:
   a. Extracts the contents of the oracle.iam.ui.model.ear file, which is in the `OIM_ORACLE_HOME/server/apps/` directory.
   b. Open the adflibCommonModel.jar file, which is in the `/APP-INF/lib/` directory of the extracted EAR file.
   c. Navigate to the `/oracle/iam/ui/common/model/` directory.
   d. Add new Key in the CommonModelBundle.properties and CommonModelBundle_en.properties files in the following format:
      
      ```
      KEY_WHAT_IS_YOUR_DREAM_DESTINATION?= What is your dream destination?
      ```
   e. Update the JAR file with the two new files, and update the EAR file with the updated JAR file.
   f. Redeploy the updated EAR file.
   g. Restart the Admin Server, SOA server, and Oracle Identity Manager server.
This part familiarizes you with tools and features for Oracle Identity Manager developers, and provides some simple examples to illustrate the concepts.

It contains the following chapters:

- Chapter 8, "Using the Adapter Factory"
- Chapter 9, "Understanding the Identity Connector Framework"
- Chapter 10, "Developing Identity Connectors Using Java"
- Chapter 11, "Developing Identity Connectors Using .NET"
- Chapter 12, "Integrating ICF with Oracle Identity Manager"
- Chapter 13, "Using Java APIs for ICF Integration"
- Chapter 14, "Configuring ICF Connectors"
- Chapter 15, "Understanding ICF Best Practices and FAQs"
- Chapter 16, "Understanding Generic Technology Connectors"
- Chapter 17, "Predefined Providers for Generic Technology Connectors"
- Chapter 18, "Creating Custom Providers for Generic Technology Connectors"
- Chapter 19, "Creating and Managing Generic Technology Connectors"
- Chapter 20, "Troubleshooting Generic Technology Connectors"
Adapters are Java programs that enable you to integrate Oracle Identity Manager with other software solutions. This chapter describes how to create adapters using the Adapter Factory form. It contains these sections:

- Introduction to Adapters
- Types of Adapters
- Adapter Environment and Tools
- Defining Adapters
- Tabs of the Adapter Factory Form
- Disabling and Re-enabling Adapters
- About Adapter Variables
- Creating Adapter Tasks
- Modifying Adapter Tasks
- Changing the Order and Nesting of Tasks
- Deleting Adapter Tasks
- Working with Responses
- Scheduling Rule Generators and Entity Adapters
- Working with Rule Generator Adapters
- Working with Entity Adapters
- Working with Task Assignment Adapters
- Working with Prepopulate Adapters
- Working with Process Task Adapters
- Adapter Mapping Information
- Defining Error Messages

## 8.1 Introduction to Adapters

To be effective, it must be possible to integrate an access rights management application, such as Oracle Identity Manager, with other software solutions. This is necessary not only because there are many resources, but also because there is no single integration standard for connecting to these resources.
The traditional way to tackle this challenge is by using the common functionality that is supported by all the integrations. To do this, you need developers who can write this code. In addition, every time an existing software resource is modified, or a new one is added, you must write more code.

The Adapter Factory is a code-generation tool provided by Oracle Identity Manager. It helps you create Java classes, known as adapters, that simplify the integration challenge.

---

**Note:** Oracle Identity Manager can connect to external systems such as databases and directory servers by using Java APIs for JDBC and LDAP. In addition, for all other APIs, such as C, C++, VB, and COM/DCOM, you can create a Java wrapper so that Oracle Identity Manager can communicate with the API directly.

---

A resource has an associated provisioning process, which in turn has various tasks associated with it. Each task in turn has an adapter associated to it, which in turn can connect to the target resource to carry out the required operations.

An adapter provides the following benefits:

- It extends the internal logic and functionality of Oracle Identity Manager.
- It interfaces with any software resource, by connecting to that resource by using the API of the resource.
- It enables the integration between Oracle Identity Manager and an external system.
- It can be generated without manually writing code. However, Oracle Identity Manager does not restrict you from writing your own code for creating adapters.
- It is lightweight and specific to your needs.
- It can be maintained easily because all of the definitions for the adapter are stored in a repository. This repository can be edited through a GUI.
- One Oracle Identity Manager user can retain the domain knowledge about the integration, while another user can maintain the adapter.
- It can be modified and upgraded efficiently.

Adapters can be developed for a range of tasks:

- A process task adapter, which allows Oracle Identity Manager to automate the completion of a process task.
- A task assignment adapter, which enables Oracle Identity Manager to automate the assignment of a process task to a user or group.
- A rule generator, which incorporates business rules to the fields of either an Oracle Identity Manager form or a user-defined form (created by using the Form Designer form), so these fields can be populated automatically and saved to the Oracle Identity Manager database.

---

**Note:** For more information about the Form Designer form, see "Developing Process Forms" on page 6-1.

---

- A pre-populate adapter, which is a specific type of rule generator adapter that can be attached to a user-created form field. The data generated by this type of adapter
can appear either automatically or manually. In addition, it uses criteria that enable Oracle Identity Manager to determine which pre-populate adapter will be applied to the designated form field. It populates the designated form field without saving this information to the Oracle Identity Manager database.

- An entity adapter, which is attached to an Oracle Identity Manager or user-created form field. Oracle Identity Manager triggers an entity adapter on preinsert, preupdate, predelete, postinsert, postupdate, or postdelete. After this occurs, the field to which the adapter is attached is populated automatically and saved to the Oracle Identity Manager database.

---

**Note:** Oracle Identity Manager also allows you to create postprocessing handlers on entities, such as user, role, and organization.

---

### 8.2 Types of Adapters

This section provides additional details about the five adapter types.

**Rule Generator Adapters**

Certain business rules must be applied to perform field validations and enter default values into the forms which either come packaged with Oracle Identity Manager or are created by Oracle Identity Manager users. For example, for the Users form, you might want Oracle Identity Manager to generate the User ID automatically by concatenating the user's first name and last name.

To do this, you must create a specific type of adapter, which is designed to modify the field value in a form. This type of adapter, which can generate, modify, or verify the value of a form field automatically, is called a rule generator. Oracle Identity Manager triggers a rule generator on preinsert and preupdate.

After you create this adapter and attach it to a form, Oracle Identity Manager automatically updates the field value for all records of that form, and saves this information to the Oracle Identity Manager database.

If you create a rule generator that contains adapter variables, you must map these adapter variables to their proper locations. Otherwise, the adapter will not be functional.

You can also attach this type of adapter to a provisioning process. Once the process is provisioned to a target user or organization, Oracle Identity Manager will trigger the associated rule generator.

On occasion, a rule generator which has been assigned to a provisioning process might no longer be needed to complete the process. If this happens, you can remove the rule generator from the provisioning process. Similarly, after you attach one rule generator to a form field, you can connect a different rule generator to that form field. When this occurs, you must first remove the rule generator currently attached to the form field.

**Entity Adapters**

Similar to rule generator adapters, entity adapters are also responsible for generating, modifying, or verifying the value of a form field automatically, and saving this information to the Oracle Identity Manager database.
Some differences between rule generators and entity adapters are:

- **Execution schedule.** Entity adapters can be triggered by Oracle Identity Manager on preinsert, preupdate, predelete, postinsert, postupdate, and postdelete. A rule generator adapter can be executed only on preinsert and preupdate.

- **Manual field value modification.** The adapter populates the form field to which an entity adapter is attached. An Oracle Identity Manager user should not edit this value because the entity adapter will overwrite this modification. As a result, the modification will not be saved to the database.

  Similarly, the adapter also populates the form field to which a rule generator adapter is attached. However, an Oracle Identity Manager user can edit this value because this modification will take precedence over the value that the rule generator adapter generates. Because of this, the modification will be saved to the database.

- **Background color of form field.** If a rule generator is attached to a form field, the field will appear in a particular background color such as pink. This is a visual indicator that the field has a rule generator attached to it. On the other hand, when an entity adapter is attached to a form field, the field will not have a distinct background color.

### Task Assignment Adapters

For a process task that must be completed manually, you can configure Oracle Identity Manager to automate the assignment of the task to either a specific user or a user who belongs to a particular role. This is achieved through the use of a task assignment adapter. Task assignment adapters are used only for assigning a task to a particular user or role.

When a task that is associated with specific provisioning process is created using the Tasks tab in the Process Definition form of the Design Console, you can choose the rule that decides if adapter will be picked up for execution. Note that this rule is defined in the Rule Definition form of the Design Console. An example of a rule is "Target User’s Org name is XYZ. If this rule is satisfied, then the corresponding task assignment is picked up. However, you can have multiple rules defined and used while deciding task assignment. For multiple rules, Oracle Identity Manager associates priority with the task assignment functionality to decide the order in which the rule determination must occur. When the rule is determined, corresponding task assignment is run.

**Note:** In other words, the task assignment rule allows Oracle Identity Manager to decide whether to assign a process task to a user or role. The task assignment adapter enables Oracle Identity Manager to determine which user or role will be the recipient of the process task.

For this example, Oracle Identity Manager will trigger the Associate Adapter with User rule first (because it has the highest priority). If the condition of this rule is TRUE, it is successful. As a result, Oracle Identity Manager will associate the related task assignment adapter (the Assign Task to User adapter) with the process task.
On the other hand, when the condition of a rule is FALSE, the rule has failed. Oracle Identity Manager triggers the rule with the next highest priority. If this rule is successful, then Oracle Identity Manager assigns the designated adapter to the target process task.

So, in this example, if the Associate Adapter with User rule fails, then Oracle Identity Manager triggers the Associate Adapter with Role rule. If this rule is successful, then Oracle Identity Manager associates the related task assignment adapter (the Assign Task to Role adapter) to the process task.

After assigning a rule to a task assignment adapter, if this type of adapter contains adapter variables, you must map these variables to their proper locations. Otherwise, the adapter will not be functional.

Finally, when a task assignment adapter becomes invalid, or is no longer necessary for Oracle Identity Manager to allocate the process task to a user or group, you must remove the adapter from the task.

Prepopulate Adapters

Sometimes a user-created form contains both fields that can be populated by Oracle Identity Manager and fields into which an Oracle Identity Manager user must enter data. When the information that the user types into a field is contingent upon the data that appears in a system-generated field, Oracle Identity Manager must first populate this field. When the form is displayed, the user can view the system-generated data to enter information into the appropriate fields.

This is achieved by creating a type of rule generator known as a prepopulate adapter. By attaching it to a field designated to be system-generated, you enable Oracle Identity Manager to automatically populate this field with the appropriate information, without saving this information to the Oracle Identity Manager database.

The data generated by a prepopulate adapter can appear automatically or it can be manually entered. Oracle Identity Manager displays this information automatically when the Auto-prepopulate check box is selected for a provisioning process. When this check box is cleared, an Oracle Identity Manager user must manually generate the displaying of the data that is generated by the prepopulate adapter. To do this, click the prepopulate button on the form section of the Direct Provisioning wizard in the Web client, while provisioning the form to a user.

You can use the same prepopulate adapter for different form fields. In addition, you can designate multiple prepopulate adapters to be associated with a particular field. As a result, Oracle Identity Manager must know which prepopulate adapter it must select for the form field. This requires the use of prepopulate rules. These rules enable Oracle Identity Manager to select one prepopulate adapter, which is associated with a form field, when this prepopulate adapter is assigned to the field.

Each prepopulate adapter has a prepopulate rule associated with it. In addition every rule has a priority number which indicates the order in which Oracle Identity Manager triggers it.

For example, Oracle Identity Manager can trigger the Rule for Uppercase User ID rule first because it has the highest priority. If the condition of this rule is TRUE, it is successful. As a result, Oracle Identity Manager will attach the related prepopulate adapter (the Display Uppercase Letters for User ID adapter) to the User ID field.

On the other hand, when the condition of a rule is FALSE, the rule has failed. Oracle Identity Manager will trigger the rule with the next highest priority. If this rule is successful, Oracle Identity Manager will attach the associated adapter to the designated field.
So, in this example, if the Rule for Uppercase User ID rule fails, Oracle Identity Manager will trigger the Rule for Lowercase User ID rule. If this rule is successful, Oracle Identity Manager will attach the related prepopulate adapter (the Display Lowercase Letters for User ID adapter) to the User ID field.

After assigning a rule to a prepopulate adapter, if this type of adapter contains adapter variables, you must map these adapter variables to their proper locations. Otherwise, the adapter will not be functional.

Finally, when a prepopulate adapter associated with a field is no longer valid, you must remove the adapter from the field.

**Process Task Adapters**

A process task adapter enables Oracle Identity Manager to automatically execute process tasks in provisioning processes.

Each process and process task has a status, which indicates the stage of its completion. The statuses for a process or process task are listed in the following table in order of importance.

<table>
<thead>
<tr>
<th>Task Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Completed: This process/process task has been completed successfully.</td>
</tr>
<tr>
<td>MC</td>
<td>Manually Completed: This process task has been completed successfully by an Oracle Identity Manager user (that is, manually).</td>
</tr>
<tr>
<td>P</td>
<td>Pending: This process/process task is in the process of being completed. All preceding tasks and processes, respectively, have been completed.</td>
</tr>
<tr>
<td>PX</td>
<td>Pending Cancellation: This process task will be canceled, but this task has to be completed first before it can be canceled.</td>
</tr>
<tr>
<td>R</td>
<td>Rejected: This process/process task has not been completed successfully or has not been approved. The status of rejected process tasks can only be changed to Cancelled or Unsuccessfully Completed.</td>
</tr>
<tr>
<td>S</td>
<td>Suspended: This process/process task has been put on hold temporarily.</td>
</tr>
<tr>
<td>UC</td>
<td>Unsuccessfully Completed: This process task has been set to Completed. However, it had been rejected before.</td>
</tr>
<tr>
<td>W</td>
<td>Waiting: This process/process task cannot be completed until all preceding process tasks or processes are completed.</td>
</tr>
<tr>
<td>X</td>
<td>This process/process task has been stopped. Its status cannot change anymore</td>
</tr>
</tbody>
</table>

The status level of a process represents the most important status level of its process tasks, which must be completed for the process to be completed. Suppose a process has three process tasks, each process task has a different status level (Completed, Waiting, and Rejected), and all three process tasks must be completed for the process to complete. Because the highest task status level is Rejected, the status level of the process is also Rejected.

A process task can be managed in these ways:

- It can be handled manually by using the Object Process Console tab of the Organizations or Users forms, or the Oracle Identity Manager Web Application.
An Oracle Identity Manager process can be configured so that one (or more) of its tasks is triggered automatically once it achieves a status of *Pending*.

8.3 Adapter Environment and Tools

This section contains these topics:

- Configuring the Adapter Environment
- Remote Manager
- The Adapter Factory
- Compiling Adapters

8.3.1 Configuring the Adapter Environment

To construct adapter tasks, ensure that Oracle Identity Manager has access to the target API JAR files and third-party applications to which you want to connect.

When your adapter uses Java tasks, you must configure Oracle Identity Manager to find the appropriate Java APIs. To do this, you must place the .jar files that contain these APIs into the Meta Data Store (MDS).

**See Also:** Chapter 36, "Understanding Customization Types" for information about utilities to modify Oracle Identity Manager metadata

Then, you can access the Java classes associated with these Java APIs and use them in the Java task you are creating.

To configure Oracle Identity Manager to reference JAR and class files:

1. Open the JavaTasks subdirectory, which can be found within the OIM_HOME directory path. For example, C:\oracle\Xellerate\JavaTasks.
2. Place the JAR file or files into this subdirectory. You can use these files to create Java tasks within an adapter without restarting the server.

**Note:**

When the Java code is in two different JAR files in the Adapter Factory, and in the adapter tasks if an object from the first JAR file (which has the common or shared code) is passed into the constructor of the next adapter task that is located in the second JAR file, then a compilation error is thrown.

As a workaround for this issue, ensure that the entire Java code is in a single JAR file only.

8.3.2 Remote Manager

Sometimes, instead of directly communicating with the third-party system, Oracle Identity Manager must use an Oracle Identity Manager component that acts like a proxy. This component is known as Remote Manager.

The Remote Manager is used for:

- Invoking nonremovable APIs through Oracle Identity Manager
Invoking APIs that do not support Secure Sockets Layer (SSL) over secure connections

To configure the Remote Manager, follow the instructions described in Oracle Fusion Middleware Installation Guide for Oracle Identity and Access Management.

The Connector Server also has the ability to run Action Scripts. See “Understanding the Identity Connector Framework” on page 9-1 for information about the Identity Connector Server.

8.3.3 The Adapter Factory

As stated earlier, an adapter is a Java class created by an Oracle Identity Manager user through the Adapter Factory, which is accessed through the Design Console.

Adapters extend the internal logic and functionality of Oracle Identity Manager. In addition, they interact with any IT resource by connecting to that resource's API.

The Adapter Factory is a code-generation tool provided by Oracle Identity Manager that enables a user to create Java classes, known as adapters. Figure 8–1 shows the Adapter Factory Form in the Design Console.

Figure 8–1 Adapter Factory Form

8.3.4 Compiling Adapters

Oracle Identity Manager provides various options for compilation, including:

- compile individual adapters one at a time
- compile a set of adapters at once
- compile all adapters that exist in the Oracle Identity Manager database with a single click

8.3.4.1 Automatic Compilation of Adapters

Adapters are compiled automatically when you import connector files by using the Deployment Manager. The compiled adapter class files are stored in the Oracle Identity Manager database, as opposed to the file system, from where they are loaded at run time. The following two APIs are available to compile adapters programmatically:

- public void compileAdapter (String adapterName): This API compiles a single adapter and stores the compiled classfile in the database. It takes the name of the
adapter as a parameter. If the adapter is not found or if there are any errors, the API throws an appropriate exception.

- **public void compileAll**: This API compiles all adapters in a system. If it encounters any errors during compilation, it throws an exception of the type tcBulkException. This exception comprises all the individual errors that the API encounters during compilation.

You can modify the adapters manually if you make any changes.

---

**Note:** You must set the path of the JDK directory in the XL.CompilerPath system property. Otherwise, an error is encountered during the adapter compilation stage when you import an XML file using the Deployment Manager.

Refer to the "System Properties in Oracle Identity Manager" in the Oracle Fusion Middleware System Administrator's Guide for Oracle Identity Manager for information about setting values of system properties.

---

### 8.3.4.2 Compiling Adapters Manually

The Adapter Manager form is located in the Development Tools folder. You use it to compile multiple adapters simultaneously.

To manually compile multiple adapters, perform these steps:

1. Open the Adapter Manager form.

   The Adapter Manager form is in the Development Tools folder. It is used to compile multiple adapters simultaneously, as shown in Figure 8–2.

**Figure 8–2 Adapter Manager Form**

2. To compile every adapter that resides within the Oracle Identity Manager database, select the **Compile All** option.

   To compile multiple adapters, select the adapters you want to compile. Then, select the **Compile Selected** option.

   To compile all adapters that do not have an OK status, select the **Compile Previously Failed** option.

3. Click the **Start** button.

   Oracle Identity Manager will compile the adapters that match the criteria you specified in Step 2.
8.4 Defining Adapters

To define an adapter:

1. Log in to Oracle Identity Manager Design Console.

2. Open the Adapter Factory form. This form is in the Development Tools folder in the Design Console.

3. In the Adapter Name field, enter the name of the adapter, for example, Create Solaris User.

4. Double-click the Adapter Type lookup field. The Lookup window is displayed, displaying the five types of Oracle Identity Manager adapters. These are:
   - Process Task
   - Rule Generator
   - Pre-populate Rule Generator
   - Entity
   - Task Assignment

5. To enable the adapter to automate a process task, select Process Task (T).
   To incorporate business rules into an Oracle Identity Manager or user-defined form field, select Rule Generator (R). For example, for the User ID field of a form, you can configure Oracle Identity Manager to concatenate the initial letter of the user's first name with the user's last name.
   You can attach a type of rule generator adapter to a user-created form field, so that it can:
   - Display the data, which is generated by the adapter, automatically or manually.
   - Use criteria that enable Oracle Identity Manager to determine which adapter is applied to the designated form field.
   To attach the adapter to an Oracle Identity Manager or user-defined form field, and have Oracle Identity Manager trigger the adapter on preinsert, preupdate, predelete, postinsert, postupdate, or postdelete, select Entity (E).
   To allow the adapter to automate the allocation of a process task to a user or group, select Task Assignment (A).
Tip: If you create an entity adapter, then an error might be generated while compiling the adapter on computers with less file limits. To avoid this problem, change the file limits in the `/etc/security/limits.conf` file to the following:

```
soft nofile 4096
hard nofile 4096
```

Then, restart Oracle Identity Manager.

6. Select the type of adapter you want, for example, Process Task (T). Then, click **OK**.

**See Also:** "Developing Process Forms" on page 6-1 for more information about the Form Designer form.

7. In the Description field, type a description for the adapter, for example, **This adapter is used to create a new user for the Solaris environment.**

8. From the toolbar, click **Save**.

The adapter is now stored in the Oracle Identity Manager database.

### 8.5 Tabs of the Adapter Factory Form

The Adapter Factory form in the Design Console contains the following tabs:

- **Adapter Tasks**
- **Execution Schedule**
- **Resources**
- **Variable List**
- **Usage Lookup**
- **Responses**

#### 8.5.1 Adapter Tasks

In the Adapter Tasks tab, you can create and manage the atomic function calls of an adapter. These function calls are known as adapter tasks.

The sequence of calls is vital because these calls in turn get converted into Java statements. In other words, if you put an Else call before an If call, then the adapter is not compiled. In addition, you must understand the logical flow of the java program while creating adapter. Analogically, this is like writing an algorithm instead of a program with Java syntax.

#### 8.5.2 Execution Schedule

The Execution Schedule tab lets you specify when you want Oracle Identity Manager to trigger a rule generator or an entity adapter. You can schedule Oracle Identity Manager to run a rule generator (Adapter Type R) on preinsert and/or preupdate. You can also configure Oracle Identity Manager to execute an entity adapter (Adapter Type E) on preinsert, preupdate, predelete, postinsert, postupdate, or postdelete.
8.5.3 Resources
From the Resources tab, you can:

- Click the Java APIs subtab to see the Java APIs that are being used by the adapter.
- Click the Other subtab to document a non-Java API file to the adapter, if necessary.

### Note:
This Resources tab does not represent resource objects.

8.5.4 Variable List
For prepopulation adapters, the data is passed to adapter input variables and are processed by using adapter logic. The adapter returns output variable, which is then assigned to process form field.

From the Variable List tab, you can:

- Create, modify, and delete adapter variables.
- Set the data type and provide a description for each variable.
- Map an adapter variable to a literal or an adapter reference. You can also postpone the mapping until it is attached to a process task or a form field.

You also can resolve the value of the adapter variable at run time, when it is attached to a process task and the process task is run. As a result, process-specific data is available to map to this variable.

8.5.5 Usage Lookup
For a process task or task assignment adapter, the Usage Lookup tab displays the process task to which the adapter is attached, as well as the process of which this process task is a member.

For a rule generator or entity adapter, this tab shows the Oracle Identity Manager form and associated data object to which the adapter is attached. In addition, it displays the execution schedule of the adapter, along with a sequence number that represents the order in which Oracle Identity Manager will trigger the adapter.

For a pre-populate adapter, this tab displays the user-defined form and form field to which the adapter is attached. Also, it shows the pre-populate rule that is associated with the adapter.

8.5.6 Responses
The Responses tab is used for defining meaningful responses to the process task. These responses depend on the execution result of the adapter. The various error messages
returned by the external system can be mapped to these responses in a way that they make sense in the context of the process task. On attaching the adapter to a process task, the status bucket, which consists of Pending, Completed, and Rejected, of the process task (and subsequently the Object status) can be set, based on the adapter response code.

**Tip:** Oracle Identity Manager enables the Responses tab only for process task adapters. If an adapter is a task assignment, rule generator, pre-populate, or entity adapter, Oracle Identity Manager disables this tab.

### 8.6 Disabling and Re-enabling Adapters

To disable an adapter so that it cannot be used with a process task or form field, select the **Disable Adapter** option, and save the adapter.

To re-enable it, clear the **Disable Adapter** option, and save the adapter.

### 8.7 About Adapter Variables

For a newly-created adapter to work, you can map data to the parameters of the adapter tasks. For this reason, you create placeholders, also known as adapter variables, to map the data at run time.

**Note:** An adapter variable can be reused for all adapter tasks.

Once an adapter variable is not needed for the adapter to run, you can remove it from the adapter. After you have deleted the adapter variable, ensure to recompile the adapter.

#### 8.7.1 Creating an Adapter Variable

To create an adapter variable:

1. Select the adapter to which you wish to add an adapter variable, for example, the Create Solaris User adapter.
2. Select the Variable List tab.
3. Click **Add**.
   
   The Add a Variable window is displayed.
4. When you do not want Oracle Identity Manager to be able to change the adapter variable value after it is activated, select **Final**.
5. In the Variable Name field, enter the name of the adapter variable, for example, SolarisUserID.

**Caution:** The adapter variable name cannot contain spaces.

6. From the Type menu, select the classification type of the adapter variable, such as String. The available items are:
   - Object
   - IT Resource
About Adapter Variables

- String
- Boolean
- Character
- Byte
- Date
- Integer
- Float
- Long
- Short
- Double

7. Within the Description text area, you can enter explanatory information about the adapter variable.

8. From the Map To menu, you can map your adapter variable to one of the items listed in Table 8–1.

Table 8–1  Items on the Map To Menu

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Literal</td>
<td>This adapter variable is mapped to a constant (or literal).</td>
</tr>
<tr>
<td>Resolve at Run time</td>
<td>This adapter variable’s mapping occurs later, at run time. Selecting this option increases the reusability of the adapter.</td>
</tr>
<tr>
<td>Adapter References</td>
<td>This adapter variable gives access to an Oracle Identity Manager database reference or an Oracle Identity Manager data object reference.</td>
</tr>
<tr>
<td>System Date</td>
<td>When this adapter variable is triggered by Oracle Identity Manager, it is mapped to the current date and time of the Server. Note: This option appears only when you select the Date type.</td>
</tr>
</tbody>
</table>

Note: When you select the object type, a Qualifier menu is displayed within the Add a Variable window. From this menu, you can select either of the following:

- Database Reference. If you select this item, the adapter variable is mapped to the reference of the database that the Oracle Identity Manager is currently running against.
- Data Object Reference. If you select this item, the adapter variable is mapped to an Oracle Identity Manager data object.

Note: If you select the IT Resource type, a Resource Type menu is displayed within the Add a Variable window. From this menu, you can select one of the IT resource types that have been created by using the IT Resource Type Definition form. By doing so, you can map the adapter variable to a parameter of this IT resource type.

9. On the toolbar in the Add a Variable window, click Save. The information for your adapter variable is stored in the Oracle Identity Manager database.
Close the Add a Variable window to activate the main screen. The name, classification type, mapping selection, and description of the adapter variable you created appear in the child table of the Variable List tab.

This adapter variable now belongs to the adapter in the Adapter Factory form. It is saved to the Oracle Identity Manager database, and the adapter variable is ready to use.

### 8.7.2 Modifying an Adapter Variable

To modify an adapter variable:

1. Select the adapter that contains the adapter variable you want to edit, for example, the `Create Solaris User` adapter.
2. Click the Variable List tab and double-click the row header of the adapter variable you want to modify. The Edit a Variable window is displayed, showing information about the adapter variable.
3. Make the necessary edits, for example, changing the adapter variable’s data type from String to Character.
4. On the Edit a Variable toolbar, click **Save**. The modified information about the adapter variable is stored in the Oracle Identity Manager database.
5. Close the Edit a Variable window to activate the main screen. The adapter variable you modified appears within the child table of the Adapter Factory form.

---

**Note:** Ensure that you check your data mappings and recompile the adapter, especially if you change the adapter variable’s data type.

### 8.7.3 Deleting an Adapter Variable

When an adapter variable is no longer necessary for the adapter to run, you can remove it from the adapter. To do this:

1. Select the adapter that contains an adapter variable you want to remove, for example, the `Create Solaris User` adapter.
2. Select the Variable List tab.
3. From the list of this tab, select the adapter variable you want to delete.
4. Click **Delete**.
5. Recompile the adapter after deleting any variable.

The adapter variable disappears from the child table. The adapter variable has been deleted.

### 8.8 Creating Adapter Tasks

After you construct the adapter and create its variables, you can create the atomic function calls of an adapter. These function calls are known as adapter tasks.

This section explains adapter tasks and how to create tasks:

- **Types of Adapter Tasks**
- **Creating a Java Task**
- **Creating a Remote Task**
Creating Adapter Tasks

8.8.1 Types of Adapter Tasks

Oracle Identity Manager allows you to create the following adapter tasks:

- A Java task, which allows an adapter to communicate with an external source by invoking Java API.
- A remote task, which enables an adapter to call a method on an API. This API resides on a computer that is external to Oracle Identity Manager.
  
  This type of task is used mostly with integrations of third-party APIs that are not network-enabled. A remote manager executes the remote API method, which is located on a remote computer. In addition, if the third-party API does not use SSL, you can use the remote manager to invoke third-party APIs over SSL-protected communication. Remote tasks can also be used with integrations of third-party APIs, which are network-enabled, but are not located on the Oracle Identity Manager server for scalability purposes. The remote API method is still executed by a remote manager. However, because the third-party API is network-enabled, the remote manager does not have to reside on the target system.
- A stored procedure task, which allows Oracle Identity Manager to map to and execute SQL programs located within a particular database schema. These programs are known as stored procedures. They contain information, such as SQL statements, which are pre-compiled for greater efficiency.
  
  By incorporating a stored procedure task into an adapter, and attaching this adapter to a process task, Oracle Identity Manager can incorporate stored procedures on any Oracle Database or Microsoft SQL Server database that is accessible on its network. This includes retrieving primitive values from stored procedures.
- A utility task, which enables you to populate an adapter with methods and APIs that come packaged with Oracle Identity Manager. In addition, this type of task provides you with access to the Java Standard Library APIs.
- An Oracle Identity Manager API task, which enables access to Oracle Identity Manager published APIs from adapter tasks. This allows for enhanced portability of adapter code.
- A set variable task, which allows you to set a variable within an adapter.
- An error handler task, which lets you display any errors associated with an adapter that occur at run time. In addition, you can see the reasons for the errors, along with possible solutions.
- A logic task, which lets you build a conditional statement within an adapter.

You can create the following types of logic tasks:

- FOR loops
- WHILE loops
Creating Adapter Tasks

- IF statements
- ELSE statements
- ELSE IF statements
- BREAK statements
- RETURN statements
- CONTINUE statements
- SET VARIABLE statements
- Handle Error statements

**See Also:** Section 8.8.9, "Creating a Logic Task" for more information about the types of logic tasks you can build

For classification purposes, Oracle Identity Manager represents each type of adapter task by an icon. The icon, which precedes the task name, is a visual indicator of the type of task it is. For example, "J" represents a Java task, and "LT" represents a logic task.

To see a list of these icons, select the Adapter Tasks tab, and click **Legend**. The Legend window appears, displaying the following list of icons:

- Functional Task
  - Java
  - Remote
  - Stored Procedure
- Utility Task
  - Utility
  - Oracle Identity Manager API
- Logical Task

### 8.8.2 Creating a Java Task

Oracle Identity Manager can handshake with an external source through a Java API. To make this happen, you must add a task to an adapter which, when triggered by Oracle Identity Manager, initiates communications with the external source. This type of task is called a Java task.

To create a Java task:

1. Select the adapter to which you want to add a Java task, for example, the Update Solaris Password adapter.
2. Select the Adapter Tasks tab.
3. Click **Add**.

   After the Adapter Task Selection window is displayed, select the **Functional Task** option.
4. From the display area to the right of this option, select the Java item, and click **Continue**.

The Object Instance Selection window is displayed.
Table 8–2 explains the options in the Object Instance Selection window.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Object Instance</td>
<td>When you click this option, you are creating a new Java object instance.</td>
</tr>
<tr>
<td>Persistent Instance</td>
<td>You can call the method on a persistent object by clicking this option, clicking the adjacent combo box, and selecting an object instance from the drop-down menu.</td>
</tr>
<tr>
<td>Task Return Value Instance</td>
<td>You can call this method on an object returned by an adapter task defined earlier by clicking this option, clicking the combo box, and selecting an adapter task from the drop-down list.</td>
</tr>
</tbody>
</table>

**Note:** When the Persistent Instance option is grayed out, it indicates that you have not defined any persistent objects for your adapter. Similarly, if the Task Return Value Instance option is grayed out, none of the tasks have Java Object return values associated with them.

5. Click an option—for example, New Object Instance—and click **Continue**. The Add an Adapter Factory Task window is displayed.

Table 8–3 lists and describes the various regions of the Add an Adapter Factory Task window:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task Name</td>
<td>This field displays the name of the Java task.</td>
</tr>
<tr>
<td>Persistent Instance</td>
<td>If this Java object is to be used again, the check box is selected, and the name of the task instance is entered in the adjacent field.</td>
</tr>
<tr>
<td>API Source</td>
<td>This combo box contains a list of all JAR and class files to which you have access.</td>
</tr>
<tr>
<td>Application API</td>
<td>This combo box contains a list of all class files to which you have access, and which belong to the JAR file that has been selected from the API Source list.</td>
</tr>
<tr>
<td>Constructors</td>
<td>This text area displays all the constructors, which are available for the Java object.</td>
</tr>
<tr>
<td>Methods</td>
<td>This text area shows a list of all the methods, which are available for the Java object.</td>
</tr>
<tr>
<td>Application Method Parameters</td>
<td>This area contains the parameters of the selected constructor and method. These parameters are mapped to the adapter variables and Oracle Identity Manager components.</td>
</tr>
</tbody>
</table>

6. In the Task Name field, enter the name of the task you are creating, for example, **Update Password**.

7. (Optional.) To make your Java object reusable, select **Persistent Instance**, type the name of the instance of this task in the text field located to the right of the check box.

**Caution:** Ensure that name of the instance contains no spaces.
8. Select the API Source. The JAR files appear, which Oracle Identity Manager references from the JavaTasks subdirectory of the OIM_HOME/ directory path—for example, C:\oracle\Xellerate\JavaTasks.

9. Select the Application API. The class files, which belong to the JAR file you selected in the API Source, appear.

10. From the Constructors area, select the method to be used to initialize the Java class you selected.

11. From the Methods area, select the method that will be used with your Java task.

12. From the toolbar, click Save.

The information pertaining to the Java task is stored in the Oracle Identity Manager database. You can now access the parameters of your Java task’s constructors and methods. These parameters appear in the Application Method Parameters region of the Add an Adapter Factory Task window.

13. To display the Java class constructors and methods for which you must set mappings, click the plus icons displayed to the left of the Constructor and Method icons.

14. Select the parameter of the constructor or method for which you must set a mapping.

15. In the Description text area, you can enter a description for this mapping.

16. Click the Map to combo box, and select an item that you can map to the parameter of the constructor or method, for example, Adapter Variables.

17. Set the appropriate mappings.

See Also: "Adapter Mapping Information" on page 8-56 for more information about which mappings to set.

18. Click Set.

The parameter of the selected constructor or method now appears in blue. This signifies that it has been mapped.

Tip: To remove a parameter mapping, right-click the appropriate parameter, and select Un-Map Parameter from the popup menu that appears.
19. Repeat steps 15 through 18 for all parameters of the constructors and methods that appear in the Application Method Parameters region.

20. On the Add an Adapter Factory Task window toolbar, click **Save**. The information pertaining to the Java task is stored in the Oracle Identity Manager database.

21. On the toolbar, click **Close**. The Add an Adapter Factory Task window disappears, and the main screen is active once again. The Java task that you created—for example, Update Password—appears within the Adapter Factory form.

22. (Optional.) To create additional Java tasks for the adapter, repeat steps 3-21.

   **Tip:** You can create different types of adapter tasks, and add them to the adapter.

   If the adapter is logically complete, and all variables on the adapter tasks are mapped, you can compile it to use with a process task or form field.

23. To compile the adapter, click **Build**.
   
   The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and found no errors. You can now attach the adapter to a process task or form field.

24. (Optional.) To see the code that Oracle Identity Manager generates, from the toolbar, click **Notes**.

   The Notes window is displayed, containing the code that Oracle Identity Manager generated.

---

**Note:** If, after clicking Build, CODE GEN ERROR appears in the Compile Status field, it means that Oracle Identity Manager encountered one of two types of errors while validating and compiling the adapter:

- **Validation Error**
  
  While Oracle Identity Manager is checking the adapter to verify that it is valid, an error is found. This error can result from a parameter of an adapter task not being mapped, a parameter being mapped improperly, or an adapter task being placed out of order.

  Because Oracle Identity Manager generates code for an adapter only after it is validated, if Oracle Identity Manager encounters a validation error, it does not create any code.

- **Java Compilation Error**
  
  Oracle Identity Manager has verified that the adapter is valid. However, while Oracle Identity Manager is compiling the adapter, an error is found. This error can result from assigning an incorrect data type to an adapter task parameter.

  Because Oracle Identity Manager has validated the adapter, it generates code. However, Oracle Identity Manager stops building code at the point of the compilation where it encounters the error.
Tip: Once you create a Java task, and add it to an adapter, you can see the following information by accessing the Resources tab of the Adapter Factory form:

- The JAR and class files used to create the Java task.
- The name, which represents the directory path that contains these JAR and class files.

8.8.3 Creating a Remote Task

A remote task enables an adapter to invoke an API method by using the Remote Manager. This API resides on a computer that is external to Oracle Identity Manager. This section explains how to create a remote task.

1. Select the adapter to which you wish to add a remote task.
2. Click the Adapter Tasks tab.
3. Click Add.
   The Adapter Task Selection window is displayed.
4. Select the Functional Task option.
5. From the display area to the right of the button, select the Remote item to create a remote task. Then, click Continue.
   The Object Instance Selection window is displayed.
6. Click Continue.
   The Add an Adapter Factory Task window is displayed.
7. In the Task Name field, enter the name of the remote task you are creating.
8. (Optional.) If you want your remote task to be reusable, select the Persistent Instance option. Then, type the name of the instance of this task in the text field, located to the right of the check box.

Caution: Ensure that the name of the instance contains no spaces.

See Also:

Section 8.8.2, “Creating a Java Task” for more information about the regions of the Add an Adapter Factory Task window

Section 8.3.1, “Configuring the Adapter Environment” for information about how to enable Oracle Identity Manager to use third-party JAR files with a Java task
9. From the Add an Adapter Factory Task window, select a JAR file, class file, constructor, and method. Then, set the mappings for the parameters of the constructor and method.

**Note:** One of the input parameters will have a classification type of IT Resource. You must associate this parameter with an adapter variable of type IT Resource.

**See Also:** "Adapter Mapping Information" on page 8-56 for more information about which mappings to select.

10. From the Add an Adapter Factory Task window toolbar, click **Save**.
    The information pertaining to the remote task is stored in the Oracle Identity Manager database.

11. From this window toolbar, click **Close**.
    The Add an Adapter Factory Task window disappears, and the main screen is active once again. The remote task that you created appears within the Adapter Factory form.

12. (Optional.) To create additional remote tasks for the adapter, repeat Steps 3 through 11.
    You are now ready to compile the adapter, so it can be used with a process task or form field.

13. To compile the adapter, click **Build**.
    The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and did not find any errors.
    You can now attach the adapter to a process task or form field, so Oracle Identity Manager can communicate with the external API.

### 8.8.4 Creating a Stored Procedure Task

Through Oracle Identity Manager, you can map to and execute SQL programs that are located within a particular database schema. These SQL programs are known as stored procedures. Stored procedures contain information, such as SQL statements, which are precompiled for greater efficiency.

For this to occur, you must add a stored procedure task to an adapter. When triggered by Oracle Identity Manager, this task incorporates stored procedures on any Oracle Database or Microsoft SQL Server database that is accessible on its network. This includes retrieving primitive values from stored procedures.

Take these steps to create a stored procedure task:
Creating Adapter Tasks

Using the Adapter Factory

1. For Oracle Identity Manager Installations that use Oracle Database, copy the ojdbc14.jar file from the OIM_HOME/ext/ directory to the OIM_DC_HOME/xlclient/ext directory.

For Oracle Identity Manager Installations that use Microsoft SQL Server, you must obtain the following files from Microsoft and copy them to the OIM_DC_HOME/xlclient/ext directory:

- msbase.jar
- mssqlserver.jar
- msutil.jar

2. Select the adapter to which you wish to add a stored procedure task, for example, the Update User ID adapter.

3. Click the Adapter Tasks tab.

4. Click Add.

The Adapter Task Selection window is displayed.

5. Select the Functional Task option.

6. From the display area to the right of the option, select Stored Procedure, and click Continue. The Add an Adapter Factory Task window is displayed.

The following table lists and describes the regions of the Add an Adapter Factory Task window.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task Name</td>
<td>Displays the name of the stored procedure task.</td>
</tr>
<tr>
<td>Description</td>
<td>Displays explanatory information about the stored procedure task.</td>
</tr>
<tr>
<td>Database</td>
<td>Lists the databases defined in the IT Resources form.</td>
</tr>
<tr>
<td>Important: Only those IT resources with a server type of Database appear in the Database list.</td>
<td></td>
</tr>
<tr>
<td>Schema</td>
<td>Lists the schemas, which are associated with the database that appears in the Database list.</td>
</tr>
<tr>
<td>Procedure</td>
<td>Lists the stored procedures, which reside within the database schema that is displayed in the Schema list.</td>
</tr>
</tbody>
</table>
In the Task Name field, enter the name of the stored procedure task you are creating (for example, Update ID).

8. In the Description text area, you can enter a description for this stored procedure task.

9. Click the Database list. The databases, which are defined in the IT Resources form, appear.

10. Click the Schema list. The schemas appear, which are associated with the database you selected.

11. Click the Procedure list. The stored procedures, which reside within the database schema that you selected from the Schema combo box, appear.

12. From the Add an Adapter Factory Task window’s toolbar, click Save. The information pertaining to the stored procedure task is saved into the Oracle Identity Manager database.

---

**Table 8–4 (Cont.) Regions of the Add an Adapter Factory Task Window**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Connection Status | Displays the status of the connection between Oracle Identity Manager and the database that contains the target stored procedure. When Oracle Identity Manager can connect to the database, Connection Established is displayed in the Connection Status region. **Note:** If Oracle Identity Manager cannot connect, Connection Failed appears in the display area. In addition, the Notes button of the Add an Adapter Factory Task window is enabled. Clicking this button shows you why a connection could not be established, for example:  
  - Exception Type: java.lang.ClassNotFoundException  
  - Message: java.lang.ClassNotFoundException: oracle.jdbc.driver.OracleDriver  
  In this example, Oracle Identity Manager could not connect to the designated database because it could not find a particular Java class. |
| Parameters   | Contains parameters that can be mapped to the stored procedure. These parameters appear after you select a database, schema, and stored procedure and save this information to the Oracle Identity Manager database. |

---

**Tip:** Schemas and stored procedures appear only after you select a database to which Oracle Identity Manager can connect. Based on this selection, related schemas and stored procedures appear in the corresponding combo boxes.

---

**Note:** If Oracle Identity Manager cannot connect to the database you selected, Connection Failed appears in the display area. In addition, the Notes button of the Add an Adapter Factory Task window is enabled. Clicking this button shows you why a connection could not be established.
You can now set the mappings for the parameter(s) of the stored procedure. These parameters appear in the Parameters region of the Add an Adapter Factory Task window.

**Note:** Oracle Identity Manager automatically maps the database and schema of the selected stored procedure. However, Oracle Identity Manager enables you to override these mappings.

**See Also:** "Adapter Mapping Information" on page 8-56 for more information about which mappings to select

13. From the Add an Adapter Factory Task window’s toolbar, click **Save**. The mappings that you have set for the parameter(s) of the stored procedure task are stored in the Oracle Identity Manager database.

14. From this window’s toolbar, click **Close**.

   The Add an Adapter Factory Task window disappears, and the main screen is active once again. The stored procedure task you created (for example, Update ID) appears within the Adapter Factory form.

15. (Optional.) Repeat steps 3 through 13 to create additional stored procedure tasks for the adapter.

16. To compile the adapter, click **Build**.

   The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and did not find any errors. You can now attach the adapter to a process task or form field, so Oracle Identity Manager can map to and execute the stored procedure you selected.

### 8.8.5 Creating a Utility Task

The Adapter Factory is shipped with a library of utility classes and methods, which increase the efficiency of developing adapters.

These utility classes and methods are contained within the **xlUtils.jar**, **xlIntegration.jar**, and **rt.jar** files. A Java task you create by using a class or method from one of these JAR files is called a **utility task**.

**See Also:** Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for more information about the class files that contains the xlUtils.jar, x1API.jar, xlIntegration.jar, and rt.jar files

1. Select the adapter to which you wish to add a utility task, for example, the Update Solaris User Group adapter.

2. Click the Adapter Tasks tab.

3. Click **Add**.

   The Adapter Task Selection window is displayed.

4. Select the **Utility Task** option.

5. From the display area to the right of the option, select **Utility**, and click **Continue**.

   The Object Instance Selection window is displayed.
See Also: "Creating a Java Task" on page 8-17 to learn more about the choices of this window

6. Click **Continue**. The Add an Adapter Factory Task window is displayed

7. In the **Task Name** field, enter the name of the utility task you are creating, for example, Update User Group.

8. (Optional.) If you want your utility task to be reusable, select **Persistent Instance**, type the name of the instance of this task in the text field to the right of the check box.

   **Caution:** Ensure that name of the instance does not contain any spaces.

   **See Also:**
   - "Creating a Java Task" on page 8-17 for more information about the regions of the Add an Adapter Factory Task window
   - "Configuring the Adapter Environment" on page 8-7

9. Click the Application API list. The class files appear, which belong to the `xlUtils.jar`, `xlIntegration.jar`, and `rt.jar` files.

   **Note:** The `xlUtils.jar`, `xlIntegration.jar`, and `rt.jar` files contain all of the class files that you can use for a utility task. Therefore, you do not have to access the API Source list.

10. From the Add an Adapter Factory Task window, select a constructor and method. Then, set the mappings for the parameters of the constructor and method.

11. From the Add an Adapter Factory Task window’s toolbar, click **Save**. The information pertaining to the utility task is stored in the Oracle Identity Manager database.

12. From this window’s toolbar, click **Close**.

    The Add an Adapter Factory Task window disappears, and the main screen is active once again. The utility task that you created (for example, Update User Group) appears within the Adapter Factory form.

13. (Optional.) Repeat steps 3 through 12 to create additional utility tasks for the adapter.

    You are now ready to compile the adapter, so it can be used with a process task or form field.

14. To compile the adapter, click **Build**.

    The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and did not find any errors. You can now attach the adapter to a process task or form field.

### 8.8.6 To Create an Oracle Identity Manager API Task

For greater portability of the adapter code, an Oracle Identity Manager API task enables Adapter tasks to call APIs published by Oracle Identity Manager. This is better
than accessing Oracle Identity Manager data directly through hardcoded SQL statements.

The Adapter Factory is shipped with a library of utility classes and methods, which increase the efficiency of developing adapters that contain Oracle Identity Manager API tasks. These utility classes and methods are contained within the xlAPI.jar file.

**See Also:** *Oracle Fusion Middleware Java API Reference for Oracle Identity Manager* for more information about the class files that contain the xlUtils.jar, xlAPI.jar, xlIntegration.jar, and rt.jar files.

To create this type of adapter task:

1. Select the adapter to which you wish to add an Oracle Identity Manager API task, for example, the Get User's Password adapter.
2. Click the Adapter Tasks tab.
3. Click Add.
4. The Adapter Task Selection window is displayed.
5. Select the Utility Task option.
6. From the display area to the right of the option, select Xellerate API, and click Continue. The Object Instance Selection window is displayed.

**See Also:** "Creating a Java Task" on page 8-17 to learn more about this window

6. Click Continue. The Add an Adapter Factory Task window is displayed.
7. In the Task Name field, enter the name of the Oracle Identity Manager API task you are creating, for example, Retrieve Password.
8. (Optional.) If you want your Oracle Identity Manager API task to be reusable, select Persistent Instance. Then, type the name of the instance of this task in the text field to the right of the check box.

**Tip:** Ensure that name of the instance contains no spaces.

**See Also:**

"Creating a Java Task" on page 8-17 for more information about the regions of the Add an Adapter Factory Task window

"Configuring the Adapter Environment" on page 8-7 to learn how to enable Oracle Identity Manager to use third-party JAR files with a Java task

9. Click the Application API list. The class files appear, which belong to the xlAPI.jar file.

**Note:** The xlAPI.jar file contains all of the class files that you can use for an Oracle Identity Manager API task. Therefore, you do not have to access the API Source list.

10. From the Add an Adapter Factory Task window, select a class file, constructor, and method. Then, set the mappings for the parameters of the constructor and method.
8.8.7 Reassigning the Value of an Adapter Variable

Sometimes, for an adapter to accomplish its required objective, you must reassign the value of one adapter variable to another adapter variable, a different type of adapter task, or a constant (or literal). The task that enables you to reallocate an adapter variable value is known as a set variable task.

For example, you can create a set variable task to set the adapter variable return value to equal the output of an adapter task (UserName) if the User ID length is fewer than 11 characters.

To create a set variable task:

1. Select the adapter to which you wish to add a set variable task (for example, the Check the Solaris User ID adapter).
2. Click the Adapter Tasks tab.
3. Click Add. The Adapter Task Selection window is displayed.
4. Select the Logic Task option.
5. From the display area, select SET VARIABLE, and click Continue. The Add Set Variable Task Parameters window is displayed.
6. From the Variable Name list, select the adapter variable that has a value you want to reassign—for example, Adapter return value.
7. From theOperand Type list, select the type of operand that will provide the value for the variable.

Tip: You can reassign an adapter variable's value to another adapter variable, a different type of adapter task, or a literal.
Creating Adapter Tasks

Use Table 8–5 to understand the various types of operands.

<table>
<thead>
<tr>
<th>Operand Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Variable     | If you select this operand type, adapter variables appear in the Operand Qualifier list. From this list, select the specific adapter variable that will provide the reassigned value.  
  Note: The only adapter variables that will appear in the Operand Qualifier combo box will be those variables that have the same data type as the adapter variable that is displayed within the Variable Name combo box. |
| Adapter Task | By selecting this operand type, adapter tasks are displayed in the Operand Qualifier combo box. From this combo box, select the particular adapter task that will provide the reallocated value.  
  Note: The only adapter tasks that will appear in the Operand Qualifier combo box will be those tasks that have the same data type as the adapter variable that is displayed within the Variable Name combo box. |
| Literal      | When you select this operand type, types of literals appear in the Operand Qualifier combo box. From this combo box, select the type of literal that will provide the reallocated value. Then, type the specific literal into the field that appears underneath the combo box. |

The following task sets the adapter variable's return value to be equal to the UserName adapter variable.

1. On the toolbar in the Add Set Variable Task Parameters window, click **Save**. The set variable task you created is stored in the Oracle Identity Manager database.

2. On the Add Set Variable Task Parameters window toolbar, click **Close**. The Add Set Variable Task Parameters window disappears, and the main screen is active once again. The set variable task that you created, for example, `Set Adapter return value = UserName`, appears in the Adapter Factory form.

3. (Optional.) Repeat Steps 3-9 to create additional set variable tasks for the adapter.

You are now ready to compile the adapter, so it can be used with a process task or form field.

4. To compile the adapter, click **Build**. The text in the Compile Status field changes from Recompile to OK. Oracle Identity Manager compiled the adapter and found no errors. You can attach the adapter to a process task or form field.

### 8.8.8 Adding an Error Handler Task

To add an error handler task:

1. An adapter task can return errors. When this occurs, the process task or form field to which the adapter is attached gets rejected.

   You can attach your own customizable error messages, which will be displayed to the user. These messages are known as error handler tasks.

   For example, you can attach an error handler task to an adapter that will display an error message when the length of a User ID is greater than 10 characters.

2. Select the adapter to which you wish to add an error handler task (for example, the Check the Solaris User ID adapter).
3. Click the Adapter Tasks tab.

4. Click Add.
   
The Adapter Task Selection window is displayed.

5. Select the Logic Task option.

6. From the display area, select Handle Error, and click Continue. The Add an Adapter Factory Task window is displayed.

7. Double-click this window’s lookup field. The Lookup window is displayed, displaying the error handler tasks you can add to the adapter.

   **Note:** The only error handler tasks that appear in this Lookup window are the ones that begin with ADAPTER—such as ADAPTER.USERIDLENERR).

   If you do not see the error handler task that you want to incorporate into the adapter, you can create one by accessing the Error Message Definition form. Refer to "Defining Error Messages" on page 8-67.

8. Select the error handler task you want, for example, ADAPTER.USERIDLENERR.

9. Click OK. The Lookup window disappears, and the Add an Adapter Factory Task window is active. In addition, the error handler task you selected appears in the field of this window.

10. From the Add an Adapter Factory Task window toolbar, click Save. The error handler task you incorporated into the adapter is stored in the Oracle Identity Manager database.

11. From this window's toolbar, click Close.

    The Add an Adapter Factory Task window disappears, and the main screen is active once again. The error handler task you added, for example, Handle Error.ADAPTER.USERIDLENERR, appears within the child table of the Adapter Factory form.

12. (Optional.) Repeat Steps 3-10 to create additional error handler tasks for the adapter.

    If the adapter is logically complete and all variables on the adapter tasks are mapped, you can compile it to use with a process task or form field.

13. To compile the adapter, click Build.

    The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and did not find any errors. You can now attach the adapter to a process task or form field.

    **See Also:** "Defining Error Messages" on page 8-67 for information about creating error messages by using the Error Message Definition form.

### 8.8.9 Creating a Logic Task

While defining the adapter, you can add conditional statements to the adapter to control its logic flow. These conditional statements are known as logic tasks. For example, you can create a logic task that will trigger an action if the length of a User ID is greater than 10 characters.
To create a logic task:

1. Select the adapter to which you wish to add a logic task (for example, the Check the Solaris User ID adapter).
2. Click the Adapter Tasks tab.
3. Click Add. The Adapter Task Selection window is displayed.
4. Select the Logic Task option.
5. From the display area, select the type of logic task you want to create. Then, click Continue.

**Note:** If you select a conditional expression, and click Continue, one of the following actions occurs:

- Oracle Identity Manager adds the conditional statement to the adapter directly; or
- A secondary window is displayed, containing fields about the conditional expression that you can configure.

To see what happens when you select a particular conditional statement, refer to Table 8–6.

### Table 8–6  Actions Resulting from Particular Conditional Statements

<table>
<thead>
<tr>
<th>Conditional Statement</th>
<th>Statement Is Added to the Adapter Directly</th>
<th>Secondary Window Appears</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>WHILE</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>IF</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>ELSE</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>ELSE IF</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>BREAK</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>RETURN</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>CONTINUE</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

Table 8–7 explains the various regions of the Add Adapter Factory Logic Task Parameters window:

### Table 8–7  Regions of the Add Adapter Factory Logic Task Window

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand Type</td>
<td>These combo boxes contain types of operands, such as adapter tasks and adapter variables.</td>
</tr>
<tr>
<td>Comparator Combo Box</td>
<td>From this combo box, you can set the relationship between two operands (for example, $&lt;$, $=$, $&gt;$).</td>
</tr>
<tr>
<td>Operand Qualifier</td>
<td>These combo boxes contain the qualifiers for the operands.</td>
</tr>
<tr>
<td>Literal Text Box</td>
<td>When you select the Literal operand type, enter the specific literal into this field.</td>
</tr>
</tbody>
</table>
Creating Adapter Tasks

By selecting the FOR conditional statement, an Add Adapter Factory Logic Task Parameters window is displayed. However, it contains different text and combo boxes.

For the FOR conditional expression, use Table 8–8 to understand the various regions of this Add Adapter Factory Logic Task Parameters window.

Table 8–8  Add Adapter Factory Logic Task Parameters for FOR Conditional Statement

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand Type</td>
<td>These combo boxes contain types of operands, such as adapter tasks and adapter variables.</td>
</tr>
<tr>
<td>Comparator Combo Box</td>
<td>From this combo box, you can set the relationship between two operands (for example, &lt;, =, &gt;).</td>
</tr>
<tr>
<td>Operand Qualifier</td>
<td>These combo boxes contain the qualifiers for the operands.</td>
</tr>
<tr>
<td>Increment Combo Box</td>
<td>Within this area, you can set whether the initial value will increase or decrease, and by how much.</td>
</tr>
</tbody>
</table>

If you select the ELSE, BREAK, RETURN, or CONTINUE conditional expressions, proceed to Step 8.

6. Set the parameters for your conditional expression.
   This logic task will check to see if the length of the User ID is greater than 10 characters.

7. From the Add Adapter Factory Logic Task Parameters window toolbar, click Save.
   The logic task you created is stored in the Oracle Identity Manager database.

8. From this window toolbar, click Close. The Add Adapter Factory Logic Task Parameters window disappears, and the main screen is active once again. The logic task that you created—for example, If (Check ID Length > 10)—appears within the Adapter Factory form.

9. (Optional.) Repeat Steps 3-8 to create additional logic tasks for the adapter.

   All adapter tasks that can be executed for a condition of a logic task should be nested properly under that logic task.

   For more information about nesting tasks, see Section 8.10, "Changing the Order and Nesting of Tasks".

10. To compile the adapter, click Build.
    The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and did not find any errors. You can now attach the adapter to a process task or form field.
8.9 Modifying Adapter Tasks

The following procedure will show you how to edit an adapter task, in case you must make changes to it. To modify an adapter task:

1. Select the adapter that contains the adapter task you wish to edit (for example, the Update Solaris User Group adapter).
2. Click the Adapter Tasks tab.
3. Double-click the adapter task that you want to modify.
   The Edit Adapter Factory Task Parameters window is displayed, displaying information that relates to the adapter task you selected. Within this window, make the necessary modifications.
4. On the Edit Adapter Factory Task Parameters window toolbar, click Save.
   The information you modified is stored in the Oracle Identity Manager database.
5. On the toolbar, click Close.
   The Edit Adapter Factory Task Parameters window disappears. The main screen is active again. The modified task appears within the child table of the Adapter Factory form. You must re-compile the adapter, so it can be used with a process task or form field.
6. To recompile the adapter, click Build.
   The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and did not find any errors. You can now attach the adapter to a process task or form field.

---

Caution: You cannot modify the API call inside a Java, Xellerate API, or Utility task. The adapter task has to be deleted and re-created.

In addition, if CODE GEN ERROR appears in the Compile Status field, Oracle Identity Manager encountered errors while compiling the adapter. Rectify the errors, if necessary re-do the adapter task modifications, and compile the adapter again.

---

8.10 Changing the Order and Nesting of Tasks

If you add multiple tasks to an adapter, you can either change the order in which the tasks are executed, or place one task inside of another task for the adapter to work.

The following procedure will show you how to change the order and nesting of tasks.

---

Caution: You should not change the order and nesting of adapter tasks unless you understand the mapping dependencies of the adapter tasks.

---

To change the order and nesting of tasks:

1. Select the adapter that contains tasks of which you want to change the order and/or nest (for example, the Check the Solaris User ID adapter).
2. Click the Adapter Tasks tab.
   The tasks appear, which belong to the current adapter.
In this example, the following changes must occur:

- The error handler task must be nested inside of the IF (Check ID Length > 10) logic task.
- The set variable task has to be nested inside of the ELSE logic task.
- The IF logic task precedes the ELSE logic task.

Therefore, you must first reorganize the logic tasks. Then, you must nest the error handler task and set variable task inside of the IF and ELSE logic tasks, respectively. To reorganize tasks:

3. Select the task that must run before another task, and click the Up arrow button. The selected task will switch places with the task that precedes it.

or

Select the task that must be executed after another task, and click the Down arrow button. The highlighted task is displayed below the task that previously followed it.

To nest tasks/remove task nestings:

4. Select the task that must be placed inside of another task, and click the Right arrow button. The selected task will be nested inside of the task that appears above it.

or

Select the task that no longer be nested inside of another task, and click the Left arrow button. The highlighted task will not be nested inside of the task that is displayed above it.

5. On the toolbar, click Save.

The order and nesting of the adapter’s tasks is stored in the Oracle Identity Manager database. If the adapter is logically complete and all variables on the adapter tasks are mapped, you can compile it to use with a process task or form field.

6. To compile the adapter, click Build.

The text in the Compile Status field changes from Recompile to OK. This indicates that Oracle Identity Manager compiled the adapter and did not find any errors. You can now attach the adapter to a process task or form field.

---

**Caution:** If you see CODE GEN ERROR in the Compile Status field, Oracle Identity Manager found errors while compiling the adapter. Rectify the errors, if necessary re-do the adapter task modifications, and compile the adapter again.

---

### 8.11 Deleting Adapter Tasks

When an adapter task is no longer necessary for the adapter to run, you must remove it from the adapter. To delete an adapter task:

1. Select the adapter that contains the task you wish to remove (for example, the Update Solaris User Group adapter).

2. Click the Adapter Tasks tab.

3. Select the task that you want to remove (for example, the CONTINUE logic task).
4. Click **Delete**.
   The selected task is deleted and disappears from the child table.

5. On the toolbar, click **Save**.

6. Recompile the adapter.

---

**Caution:** While deleting adapter tasks, ensure that the logic of the adapter is consistent and maintained.

---

## 8.12 Working with Responses

Adapters can have different outcomes, called **responses**. Based on these responses, adapters can trigger other process tasks.

For example, if the adapter returns a *True* response, the process task’s status can be set automatically to **Completed**. However, if the adapter returns a *False* response, the process task’s status can be set automatically to **Rejected**, and another process task can be triggered.

These responses can be added, modified, or removed on the Responses tab of the Adapter Factory form.

The following procedures will show you how to create, modify, and delete responses.

---

**Note:** Responses are used only with process task adapters, because these adapters are attached to process tasks. Rule generators, pre-populate adapters, and entity adapters are not connected to processes. In addition, task assignment adapters are not associated with responses. Therefore, if the active adapter is a task assignment adapter, rule generator, pre-populate adapter, or entity adapter, Oracle Identity Manager disables the Responses tab.

---

### 8.12.1 To Create a Response

1. Select the adapter to which you want to add responses (for example, the *Create Solaris User* adapter).

2. Click the **Responses** tab.

3. Click **Add**.
   An empty row is inserted into the **Responses** tab.

4. Click the field that appears within the **Code Name** column.

5. Enter a code, which represents a response type that can be generated (for example, *True*).

6. Click the field that appears within the **Description** column.

7. Enter a description for this response (for example, *The user was created successfully*).

8. Double-click the field that appears within the **Status** column.
   The Lookup popup window is displayed, containing the different status levels that you can associate with the response.
9. Click the desired status level (for example, Completed (C)). Then, click OK.

The Lookup window disappears, and the Responses tab is active once again.

10. Create another response, by clicking the Add button, and entering False and The user was not created successfully into the Code Name and Description fields, respectively. Then, access the Lookup window, and assign the Rejected (R) status level to this response.

11. On the toolbar, click Save.

The responses that you created for this adapter have been stored in the Oracle Identity Manager database. After you attach this adapter to a process task, these responses will appear in the Responses tab of the Editing Task window of the Process Definition form.

8.12.2 To Modify a Response

The following procedure demonstrates how to edit a response.

1. Select the adapter that contains the response you want to edit (for example, the Create Solaris User adapter).

2. Click the Responses tab.

3. Double-click the field of the response, which contains information that you want to modify.

   a. If the field is a text field, Oracle Identity Manager enables it. You can now edit the contents within this field.

   b. When the field is a lookup field, the Lookup popup window is displayed, containing the different status levels that you can associate with the response. Click the desired status level, click OK.

For example, double-click the Status column of the False response, select the Suspended (S) status level, and click OK.

4. On the toolbar, click Save.

The information that you modified for the response is stored in the Oracle Identity Manager database.

8.12.3 To Delete a Response

When a response is no longer necessary, you can delete it from the adapter.

1. Select the adapter, which contains a response that you want to remove.

2. Click the Responses tab.

3. Select the response that you want to delete.

4. Click Delete.

The response disappears. This indicates that Oracle Identity Manager has deleted the response.

Note: For more information about Oracle Identity Manager's status levels, refer to Chapter 4, "About Process Task Adapters" on page 4-1.
8.13 Scheduling Rule Generators and Entity Adapters

Oracle Identity Manager triggers a process task adapter or a task assignment adapter automatically if it is attached to a process task, and the process task’s status is Pending. In addition, Oracle Identity Manager always triggers pre-populate adapters on pre-insert. Therefore, you do not schedule when process task adapters, task assignment adapters, or pre-populate adapters will be executed.

On the other hand, a rule generator and an entity adapter are attached to a form field. The only way that Oracle Identity Manager will be able to execute the rule generator or entity adapter is for you to specify when it will be triggered. You do this through the Execution Schedule tab.

Note: If an entity adapter is attached to a process form or an object form for validation of field values, these adapters will trigger if we edit data in these forms after completing direct or request provisioning.

Using this tab, you can determine that Oracle Identity Manager will trigger the rule generator or entity adapter on pre-insert or pre-update. In addition, you can also schedule an entity adapter to be executed on pre-delete, post-insert, post-update, and post-delete.

This procedure demonstrates how to configure Oracle Identity Manager to trigger a rule generator or entity adapter.

8.13.1 Scheduling Rule Generators and Entity Adapters

To schedule rule generator and entity adapters:

1. Select the rule generator or entity adapter that you want Oracle Identity Manager to trigger (for example, Solaris User ID Generator).

   Note: When you work with process task adapters or pre-populate adapters, you do not use the Execution Schedule tab. As a result, this tab, as well as its contents, are grayed out.

2. Click the Execution Schedule tab.

   The contents of the Execution Schedule tab appear.

   The following table will help you understand the various check boxes of the Execution Schedule tab:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-Insert</td>
<td>By clicking this check box, Oracle Identity Manager can trigger the rule generator or entity adapter before the record is inserted into the database.</td>
</tr>
<tr>
<td>Pre-Update</td>
<td>When you click this check box, Oracle Identity Manager can trigger the rule generator or entity adapter before the record is updated in the database.</td>
</tr>
<tr>
<td>Pre-Delete</td>
<td>By clicking this check box, Oracle Identity Manager can trigger the entity adapter before the record is deleted from the database.</td>
</tr>
</tbody>
</table>
Working with Rule Generator Adapters

3. Enable the desired check boxes. Then, from the toolbar, click **Save**.

The criteria you set for Oracle Identity Manager to execute the rule generator or entity adapter is stored in the Oracle Identity Manager database.

### 8.14 Working with Rule Generator Adapters

This section explains how to work with rule generator adapters, and contains these topics:

- Mapping Rule Generator Adapter Variables
- Associating Rule Generators with Processes
- Removing Rule Generators from Form Fields

#### 8.14.1 Mapping Rule Generator Adapter Variables

After creating a rule generator, you must map the adapter variables of the rule generator to their proper locations to ensure that the adapter will function as intended.

To map these adapter variables, access the Data Object Manager form from the Development Tools/Business Rule Definition folder of the Design Console.

To map the adapter variables of a rule generator to their proper locations:

1. Open the Data Object Manager form. In the Design Console workshops, the Data Object Manager form is displayed.

   The following table lists and describes the various regions of the Data Object Manager form:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Form Description</td>
<td>From this lookup field, select the form that contains the field to which you are attaching the rule generator.</td>
</tr>
</tbody>
</table>
2. Double-click the **Form Description** field. A Lookup dialog box appears with the forms to which you can attach rule generators.

3. Select the form you want (for example, *Solaris*). Then, click **OK**.

4. On the toolbar, click **Save**.

   The selected form, the form’s data object, and the rule generator adapters associated with the form appear. In addition, Oracle Identity Manager enables the Map Adapters tab.

   For this example, the Solaris form has been selected. Its data object Thor.CarrierBase.tcUD_SOLARIS appears, along with the four rule generator adapters associated with it (adpCONVERTTOLOWERCASE, adpSOLARISHMDSTRINGGEN, adpSETSOLARISASSET, and adpSETPASSWORDFROMMAIN). Oracle Identity Manager will trigger these four rule generators on preinsert.

   Based on the sequence numbers of these adapters, Oracle Identity Manager will trigger the adpCONVERTTOLOWERCASE adapter first, followed by the adpSOLARISHMDSTRINGGEN, adpSETSOLARISASSET, and adpSETPASSWORDFROMMAIN adapters respectively.

   **Tip:** To change the sequence of triggering a rule generator:

   1. Click **Assign**. The Event Handlers dialog box is displayed.
   2. Select the rule generator from.
   3. Click the up arrow and down arrow buttons to modify the order of the rule generator.

   For these rule generators to work properly, you must map the adapter variables to their proper locations.

5. Click the **Map Adapters** tab.

6. From the Name combo box, select the rule generator, which has adapter variables that can be mapped (for example, the adpCONVERTTOLOWERCASE rule generator).
The Map Adapters tab now displays the following:

- The name of the rule generator that is to be attached to the form.
- The status of the rule generator.
- The names, descriptions, and mapping statuses of the rule generator’s adapter variables.

See Also: "Attaching Process Task Adapters to Process Tasks" on page 8-51 for information about various mapping statuses for an adapter.

7. Set the mappings for each variable that appears in the Adapter Variables region of the Map Adapters tab. To do so, double-click the row header of the variable you want to map (for example, Data). The Data Mapping for Variable dialog box is displayed.

Table 8–9 describes the various fields of the Data Mapping for Variable dialog box.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Name</td>
<td>This field displays the name of the adapter variable for which you are setting a mapping (for example, Data).</td>
</tr>
<tr>
<td>Data Type</td>
<td>This field shows the data type of the adapter variable (for example, String is the data type for the Data adapter variable).</td>
</tr>
<tr>
<td>Map To</td>
<td>This field contains the source and target locations of the mappings you can set for the adapter variable (for example, User Definition).</td>
</tr>
<tr>
<td></td>
<td>When you map the adapter variable to a location or a contact, Oracle Identity Manager enables the adjacent combo box. From this combo box, select the specific type of location or contact to which you are mapping the adapter variable.</td>
</tr>
<tr>
<td></td>
<td>If you are not mapping the adapter variable to a location or contact, this combo box is grayed out.</td>
</tr>
<tr>
<td>Qualifier</td>
<td>This field contains the qualifiers for the mapping you selected in the Map To combo box (for example, User Login).</td>
</tr>
<tr>
<td>IT Asset Type</td>
<td>This field enables you to select a specific IT Resource (for example, Solaris) when you map an adapter variable to an IT Resource, and this variable's data type is String.</td>
</tr>
<tr>
<td></td>
<td>If you are not mapping the adapter variable to an IT Resource, or the variable's data type is not String, this field does not appear.</td>
</tr>
<tr>
<td>IT Asset Property</td>
<td>This field enables you to select a specific field that will receive the results of the mapping (for example, User Name), when you map an adapter variable to an IT Resource, and this variable's data type is String.</td>
</tr>
<tr>
<td></td>
<td>If you are not mapping the adapter variable to an IT Resource, or the variable's data type is not String, this field does not appear.</td>
</tr>
<tr>
<td></td>
<td>Important: The IT Asset Type and IT Asset Property fields are included within this window for backward compatibility. The preferred way is to create an adapter variable with a data type of IT Resource, in which case these fields will not appear.</td>
</tr>
</tbody>
</table>
Complete the Map To, Qualifier, IT Asset Type, IT Asset Property, and Literal Value fields.

See Also: "Adapter Mapping Information" on page 8-56 for more information about the mappings to select.

8. Click Save. Then, click Close

The Data Mapping for Variable window disappears. The Map Adapters tab is active again.

9. On the main screen toolbar, click Save.

Repeat Steps 7 and 8 for all adapter variables that can be mapped.

The contents in the Status field change from Mapping Incomplete to Ready. In addition, the mapping statuses for the adapter variables change from No (N) to Yes (Y).

This signifies that all the adapter variables for the rule generator adapter have been mapped correctly. You are now ready to attach this rule generator to a provisioning process, so it can be triggered after the process is provisioned to a target user or organization.

Tip: When you map all the adapter variables for a rule generator that is associated with a form, a quick way to see the form to which it is attached as well as the execution schedule of the rule generator, is by accessing the Usage Lookup tab of the Adapter Factory form.

After the rule generator is assigned to a process, and the process is provisioned, the rule generator will be executed by Oracle Identity Manager.

8.14.2 Associating Rule Generators with Processes

After you map the adapter variables of a rule generator to their proper locations, you must attach it to a provisioning process. Then, once the process is provisioned to a target user or organization, Oracle Identity Manager will trigger the associated rule generator.

Similarly, when a rule generator, which has been assigned to a provisioning process, is no longer needed for the process to be completed, you must remove the rule generator from the provisioning process.

To assign a rule generator to a provisioning process or remove a rule generator from a provisioning process, access the Event Handlers/Adapters tab in the Process Definition form. This form can be found in the Process Management folder.
8.14.3 Removing Rule Generators from Form Fields

Sometimes, after you attach a rule generator to a form field, you can connect a different rule generator to that form field. When this occurs, you must first remove the rule generator that is currently attached to the form field.

---

**Caution:** If you remove a rule generator from a form and if the class name of the form's data object matches the table name of a provisioning process, you will not be able to assign the rule generator to that provisioning process.

For example, suppose the adpCONVERTTOLOWERCASE rule generator is removed from the Solaris form. If the class name of the form's associated data object is UD_SOLARIS, the rule generator cannot be assigned to any provisioning process with a table name of UD_SOLARIS.

---

To remove a rule generator from a form field, perform the following steps:

1. Open the Data Object Manager form.
2. Select the form that contains a rule generator you want to remove.
3. The selected form, along with its rule generators, appear in the Data Object Manager form.
4. Click the rule generator that you want to remove from the form field.
5. Click Delete.

The selected rule generator no longer appears in the Data Object Manager form. This indicates that you have removed the rule generator from the form field.

---

**Caution:** If you attempt to remove a rule generator from a form field, and if an error box appears, the adapter has already been associated with a provisioning process. First, detach the rule generator from the process. Then, you can remove it from the form field.

---

8.15 Working with Entity Adapters

For information about working with entity adapters, see:

---

**Note:** In Oracle Identity Manager 11g Release 2 (11.1.2.2.0), creating new entity adapters and modifying existing entity adapters are not supported.

---

- Entity Adapters in "Types of Adapters" on page 8-3.
- The procedures in "Working with Rule Generator Adapters" on page 8-38 for details about mapping the variables of an entity adapter with Oracle Identity Manager forms and/or provisioning processes.

8.16 Working with Task Assignment Adapters

This section contains these topics:
Working with Task Assignment Adapters

- Attaching Task Assignment Adapters to Process Tasks
- Removing Task Assignment Adapters from Process Tasks

8.16.1 Attaching Task Assignment Adapters to Process Tasks

After creating a task assignment adapter, you must attach it to a process task so that Oracle Identity Manager can automate the assignment of the task to a user or role.

To connect a task assignment adapter to a process task, access the Assignment tab (from the Process Definition form). From this tab, you can also map any adapter variables to their proper locations.

The following procedure shows you how to attach a task assignment adapter to a process task.

1. Open the Process Definition form, which is located in the Process Management folder.
   Within the Oracle Identity Manager workspace, the Process Definition form appears.

2. Select the process, which contains a task to which you want to attach an adapter.
   The selected process, along with its tasks, appears in the Process Definition form.

3. Double-click the row header of the task to which you want to attach a task assignment adapter.
   The Editing Task window appears, containing information about the task (for example, the Get Solaris UUID process task).

4. Click the Assignment tab. The Assignment dialog box is displayed.

5. From this tab, click Add.
   A blank row appears within the Assignment tab.
   The following table lists the relevant fields of the Assignment tab:

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority</td>
<td>From this field, set the priority number for the associated task assignment rule.</td>
</tr>
<tr>
<td>Rule</td>
<td>From this lookup field, select the rule that will determine if the associated adapter will be used to automate the assignment of the process task to a user or role.</td>
</tr>
<tr>
<td>Target Type</td>
<td>From this lookup field, specify whether the task is to be assigned to an Oracle Identity Manager user or role.</td>
</tr>
<tr>
<td>Adapter</td>
<td>From this lookup field, select the adapter that is to be associated with the designated task assignment rule.</td>
</tr>
<tr>
<td>Adapter Status</td>
<td>This field displays the mapping status of the adapter's variables. See &quot;Attaching Process Task Adapters to Process Tasks&quot; on page 8-51 for information about the various mapping statuses for an adapter.</td>
</tr>
</tbody>
</table>

6. Double-click the Priority field. From this field, set the priority number for the associated task assignment rule.
7. Double-click the Rule lookup field. From the Lookup dialog box that is displayed, select the rule that will determine if the associated adapter will be used to automate the assignment of the process task to a user or role.

8. Double-click the Target Type lookup field. From the Lookup dialog box that is displayed, specify whether the task is to be assigned to an Oracle Identity Manager user or role.

9. Double-click the Adapter lookup field. From the Lookup dialog box that is displayed, specify the task assignment adapter that is to be associated with the rule you selected in Step 7 of this procedure.

10. On the toolbar that is displayed within the Assignment tab, click Save.

    The mapping status of the task assignment adapter variables is displayed within the Adapter Status field. Use the following table to decide which action to perform, based on the adapter's mapping status.

<table>
<thead>
<tr>
<th>Mapping Status</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ready</td>
<td>The adapter does not have any variables that can be mapped. In other words, none of the adapter variables are return variables or have been designated as Resolve at Run time. So, proceed to Step 14 of this procedure.</td>
</tr>
<tr>
<td>Mapping Incomplete</td>
<td>At least one of the adapter's variable must be mapped. So, proceed to Step 11 of this procedure.</td>
</tr>
<tr>
<td>Adapter Unavailable</td>
<td>After the adapter had been compiled successfully, it was modified. As a result, you must recompile the adapter.</td>
</tr>
</tbody>
</table>

**Note:** To learn more about the various mapping statuses for an adapter, see “Attaching Process Task Adapters to Process Tasks” on page 8-51.

11. Click Map.

    The Adapter Variables window appears. It displays the following information:
    ■ The name of the task assignment adapter that is attached to the process task;
    ■ The status of the adapter; and
    ■ The mapping statuses, names, and descriptions of the adapter’s variables.

12. Set the mappings for each variable that appears in the Adapter Variables region of this window. To do so, double-click the row header of the variable you want to map (for example, UUID).

    The Edit Data Mapping for Variable dialog box is displayed.

    Table 8–10 lists the fields of the Edit Data Mapping for Variable dialog box.

**Table 8–10** Fields of the Edit Data Mapping for Variable Dialog Box

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Name</td>
<td>This field displays the name of the adapter variable for which you are setting a mapping (for example, UUID).</td>
</tr>
<tr>
<td>Data Type</td>
<td>This field shows the data type of the adapter variable (for example, String is the data type for the UUID variable).</td>
</tr>
</tbody>
</table>
13. Complete the Map To, Qualifier, IT Asset Type, IT Asset Property, Literal Value, and Old Value fields.

**See Also:** "Adapter Mapping Information" on page 8-56 for more information about the mappings to select.

14. On the toolbar, click Save. Then, click Close.
The Edit Data Mapping for Variable window disappears. The Adapter Variables dialog box is active again.

The contents in the Status field change from Mapping Incomplete to Ready. In addition, the mapping statuses for the adapter’s variables change from No (N) to Yes (Y).

15. Click **Save**. Then, click **Close**.

The Adapter Variable dialog box disappears, and the Assignment tab is active once again.

The adapter that you assigned to the process task (for example, *Assign Solaris Task*) now has a status of Ready.

16. From the toolbar that appears within the Assignment tab, click **Save** and **Close**

The Assignment tab disappears, and the main screen is active once again. This signifies that the task assignment adapter is attached to the process task.

---

**Note:** Once you attach a task assignment adapter to a process task, a quick way to see the process and the task to which it is connected is by accessing the Usage Lookup tab of the Adapter Factory form.

---

### 8.16.2 Removing Task Assignment Adapters from Process Tasks

When a task assignment adapter either becomes invalid, or is no longer necessary for Oracle Identity Manager to allocate the process task to a user or role, you must remove the adapter from the task.

#### 8.16.2.1 To Remove a Task Assignment Adapter from a Process Task

To detach a task assignment adapter from a process task, perform the following tasks:

1. Open the Process Definition form.

   The Process Definition form appears in the Design Console workspace.

2. Select the process, which contains a task from which you want to remove an adapter (for example, the Solaris 8 process).

   The selected process, along with its tasks, appears in the Process Definition form.

3. Double-click the row header of the process task from which you want to remove the adapter (for example, the Get Solaris UUID task).

   The Editing Task dialog box is displayed, containing information about the process task.

4. Click the **Assignment** tab.

   The Assignment tab appears, displaying information about the adapter that is attached to the process task.

5. Highlight the row, containing the adapter that you want to remove from the process task.

6. Click **Delete**. The adapter no longer appears within the Assignment tab.

7. Click **Save**. Then, click **Close**.

   The Assignment tab disappears, and the Main Screen is active once again. This signifies that the task assignment adapter is removed from the process task.
8.17 Working with Prepopulate Adapters

This section contains these topics:

- Attaching Prepopulate Adapters to Form Fields
- Removing Prepopulate Adapters from Form Fields

8.17.1 Attaching Prepopulate Adapters to Form Fields

To attach a prepopulate adapter to a form field, perform the following steps:

1. Select the field to which a prepopulate adapter will be attached.
2. Select the rule that will determine if the adapter will be used to populate the designated field with information.
3. Select the adapter that will be associated with the designated field.
4. Set the priority number of the selected rule.
5. Map the adapter variables of the prepopulate adapter to their proper locations.

**Note:** To attach a prepopulate adapter to a form field, you must ensure the following:

- The form is not in an active state. Otherwise, create a new form version.
- After attaching the adapter, you must activate the form to be able to use it.

6. Open the Form Designer form.
7. Query for the form to which you want to attach a prepopulate adapter (for example, Solaris).
8. Click the prepopulate tab.

The prepopulate adapters, which have already been attached to the form you queried, appear within this tab.

**Note:** If no adapters have been attached to a form field, the prepopulate tab will be empty.

If a process form has two IT resource fields, then the second IT resource must be populated using programmatic mechanism and prepopulate adapters. Two IT resources cannot be populated because the UI Form Designer does not support an IT resource type widget.

9. Click Add.

The prepopulate Adapters dialog box is displayed.

Table 8–11 lists and describes the fields of the prepopulate Adapters dialog box.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Name</td>
<td>This combo box contains a list of all of the form fields to which a prepopulate adapter can be attached.</td>
</tr>
</tbody>
</table>
Working with Prepopulate Adapters

10. From the Field Name combo box, select the form field, such as User ID, to which the prepopulate adapter will be attached.

11. Double-click the Rule lookup field. From the Lookup dialog box that is displayed, select the rule that will determine if the associated adapter will be used to populate the designated form field with information (for example, Rule for Lowercase User ID).

12. Double-click the Adapter lookup field. From the Lookup dialog box that is displayed, choose the adapter that will be associated with the field you selected in Step 10, for example, Display Lowercase Letters for User ID.

13. In the Order field, enter the priority number of the rule you selected in Step 11, for example, 2.

14. On the prepopulate Adapters window toolbar, click Save.

15. Mapping Incomplete appears within the Adapter Status field. This signifies that the adapter you selected contains variables that have not been mapped correctly. These variables can be mapped to their proper locations. Otherwise, the adapter will not work.

16. Set the mappings for each variable that appears in the Adapter Variables region of the prepopulate Adapters window. To do so, double-click the row header of the variable you want to map, for example, UserID.

The Map Adapter Variables window is displayed.

Table 8–12 describes the fields of the Map Adapter Variables window.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Name</td>
<td>This field displays the name of the adapter variable for which you are setting a mapping (for example, UserID).</td>
</tr>
</tbody>
</table>
### Table 8–12 (Cont.) Fields of the Map Adapter Variables Window

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Type</td>
<td>This field shows the data type of the adapter variable (for example, String is the data type for the UserID adapter variable).</td>
</tr>
<tr>
<td>Map To</td>
<td>This field contains the types of mappings that you can set for the adapter variable (for example, Organization Definition and User Definition).</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: Process Data is not a valid source for mapping prepopulate adapter variables.</td>
</tr>
<tr>
<td></td>
<td>When you map the adapter variable to a location or a contact, Oracle Identity Manager enables the adjacent combo box. From this combo box, select the specific type of location or contact to which you are mapping the adapter variable.</td>
</tr>
<tr>
<td></td>
<td>If you are not mapping the adapter variable to a location or contact, this combo box is grayed out.</td>
</tr>
<tr>
<td>Qualifier</td>
<td>This field contains the qualifiers for the mapping you selected in the Map to combo box (for example, User ID).</td>
</tr>
<tr>
<td>IT Asset Type</td>
<td>This field enables you to select a specific IT Resource (for example, Solaris) when you map an adapter variable to an IT Resource, and this variable's data type is String.</td>
</tr>
<tr>
<td></td>
<td>If you are not mapping the adapter variable to an IT Resource, or the variable's data type is not String, this field does not appear.</td>
</tr>
<tr>
<td>IT Asset Property</td>
<td>This field enables you to select a specific field that will receive the results of the mapping (for example, User Name), when you map an adapter variable to an IT Resource, and this variable's data type is String.</td>
</tr>
<tr>
<td></td>
<td>If you are not mapping the adapter variable to an IT Resource, or the variable's data type is not String, this field does not appear.</td>
</tr>
<tr>
<td></td>
<td><strong>Important</strong>: The IT Asset Type and IT Asset Property fields are included within this window for backward compatibility. The preferred way is to create an adapter variable with a data type of IT Resource, in which case these fields will not appear.</td>
</tr>
<tr>
<td>Literal Value</td>
<td>When you map the adapter variable to a literal, use this field to specify the specific literal value.</td>
</tr>
<tr>
<td></td>
<td>If you are not mapping the adapter variable to a literal, this field does not appear.</td>
</tr>
</tbody>
</table>

17. Complete the Map To, Qualifier, IT Asset Type, IT Asset Property, and Literal Value fields.

**See Also:** "Adapter Mapping Information" on page 8-56 for more information about the mappings to select

18. On the Map Adapter Variable window toolbar, click **Save**. Then, click **Close**. The Map Adapter Variables window disappears. The prepopulate Adapters window is active again.

   The text in the Adapter Status field changes from Mapping Incomplete to Ready. In addition, the mapping statuses for the adapter's variables change from No (N) to Yes (Y).

19. On the prepopulate Adapters window toolbar, click **Close**. The prepopulate Adapters window disappears, and the Form Designer form is active again. The prepopulate adapter, which you attached to the User ID form field (Display
Lowercase Letters for User ID), appears in the prepopulate tab of the Results of 1Q Sales 2003 form.

After a process, which references this form, is provisioned to a target user or organization, the form will appear. Oracle Identity Manager will check to see if the prepopulate rule, which has the highest priority, is valid. If so, Oracle Identity Manager will assign the associated prepopulate adapter to the designated field (User ID), and execute it. At this point, one of the following actions occur:

- If the Auto-prepopulate check box is selected for the provisioning process, Oracle Identity Manager will display the data that is generated by the prepopulate adapter automatically.
- If the Auto-prepopulate check box is cleared, an Oracle Identity Manager user must manually trigger the displaying of the data that is generated by the prepopulate adapter. To do this, the administrator must click the prepopulate button on the form section of the direct provisioning wizard in the Web client, while provisioning the form to a user.

**Tip:** Once you allocate a prepopulate adapter to a form field, and assign a prepopulate rule to the adapter, a quick way to see the association among the adapter, the form field, and the rule is by accessing the Usage Lookup tab of the Adapter Factory form.

### 8.17.2 Removing Prepopulate Adapters from Form Fields

If a prepopulate adapter, which has been associated with a form field, is no longer valid, you must remove the adapter from the field.

**Note:** Before removing the prepopulate adapter from a form field, you must create a new version of the form.

To remove a prepopulate adapter from a form field:

1. Select the prepopulate adapter that you want to remove.
2. Click **Delete**. The prepopulate adapter is removed from the form field. It cannot be triggered when the form is launched.
3. After removing the adapter, you must activate the form.

### 8.18 Working with Process Task Adapters

This section contains these topics:

- Guidelines for Working with a Process Task Adapter
- Attaching Process Task Adapters to Process Tasks
- Removing Process Task Adapters from Process Tasks

#### 8.18.1 Guidelines for Working with a Process Task Adapter

After you create a process task adapter, you attach it to the appropriate process task by using the Integration tab of the Process Definition form. From this tab, you can also map any variables of the adapter to their proper locations, which were designated as either *Resolve at Run time* or as an adapter return variable.
For example, the adapter named adpSOLARISPASSWORDUPDATED is connected to the Password Updated task of the Solaris process.

After you attach an adapter to a process task, for the adapter to be functional, it might need data from fields of other forms. For this example, the adpSOLARISPASSWORDUPDATED adapter cannot work unless it obtains the following information:

- The user’s Oracle Identity Manager ID and password.
- The user’s Solaris ID and password.
- The IP address where Solaris is located.

Therefore, it must get this information from the UserID, Passwd, SolarisUserID, SolarisUserPasswd, and ServerAddress adapter variables respectively. These five variables are created by using the Adapter Factory form. The "Y" that precedes each adapter variable signifies that it has been mapped correctly.

The form that enables you to create process-specific fields, which will be used by a process to obtain the information it needs, is called the Form Designer. When you create these fields, Oracle Identity Manager stores them into a table. Then, by associating this table with a process (through the Table Name lookup field of the Process Definition form), the adapter, which you attach to a task of this process, will use the table to retrieve the appropriate data.

If you want to modify this table, you can do so through the Form Designer form.

The UD_SOLARIS table contains two fields: UD_SOLARIS_USERID and UD_SOLARIS_PASSWD. By accessing this record of the Form Designer form, you can edit the fields of the table.

Once you attach the process task adapter to a dependent process task, and the status of this process task is Pending (the status of the previous process task is Completed), Oracle Identity Manager will trigger the adapter automatically. When the process task is an independent task, Oracle Identity Manager will execute the adapter as soon as the process is requested.

The result of the adapter being executed represents the state of the process task. When the adapter is finished successfully, the process task to which this adapter is attached will have a status of Completed.

On the other hand, if the adapter cannot perform its designated function, the process task to which this adapter is attached will have a status of Rejected. By discovering the cause of the error, you can modify the process task and/or adapter so it can run successfully.

---

**Note:** To determine why a process task might have failed:

Find the process task. When the process task has not yet been provisioned to the target user or organization, it is located in the To Do List or Pending Approvals. To find the task:

1. Log in as the user.
2. Select the To Do List link or the Pending Approvals links in the left side of the window.

---

### 8.18.2 Attaching Process Task Adapters to Process Tasks

In the previous chapter, you learned how to create a process task adapter. You must attach it to a process task to execute that process task automatically.
To connect an adapter to a process task, access the Integration tab (from the Process Definition form). From this tab, you can also map any adapter variables to their proper locations.

The following procedure shows you how to attach a process task adapter to a process task:

1. Open the Process Definition form, which is located in the Process Management folder.
   
   In the Oracle Identity Manager Workspace, the Process Definition form appears.

2. Select the process, which contains a task to which you want to attach an adapter. The selected process, along with its tasks, appears in the Process Definition form. For this example, the Solaris process has been selected.

3. Double-click the row header of the task to which you want to attach an adapter. The Editing Task window appears, containing information about the task (for example, the Password Updated process task).

4. Click the Integration tab.

5. Click Add.
   
   The Handler Selection window appears.

6. To access Oracle Identity Manager adapters, click the Adapter option. The adapters appear, which you can attach to the process task.

7. From this region, select the adapter that you want to attach to the process task, for example, the adpSOLARISPASSWORDUPDATED adapter.
   
   **Tip:** For classification purposes, the first three letters of each adapter's name are adp. For classification purposes, the first three letters of each adapter's name are *adp*.

8. From the Handler Selection window's toolbar, click Save.
   
   A dialog box appears, stating that the adapter was successfully added to the process task.

9. Click OK.
   
   The dialog box disappears, and the Integration tab is now active. This tab now displays the following:

   - The name of the adapter that is attached to the process task;
   - The status of the adapter, and
   - The names, descriptions, and mapping statuses of the adapter's variables.

**Note:** An adapter can have one of three mapping statuses:

*Ready.* This adapter has been successfully compiled, and all of its variables have been mapped correctly.

*Mapping Incomplete.* This adapter has been successfully compiled, but at least one of its variables have not been mapped correctly.

*Adapter Unavailable.* After this adapter had been compiled successfully, it was modified, and recompiled.
10. Set the mappings for each variable that appears in the Adapter Variables region of the Integration tab. To do so, double-click the row header of the variable you want to map (for example, SolarisUserID).

The Data Mapping for Variable window is displayed.

Table 8–13 describes the fields of the Data Mapping for Variable window.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Name</td>
<td>This field displays the name of the adapter variable for which you are setting a mapping (for example, SolarisUserID).</td>
</tr>
<tr>
<td>Data Type</td>
<td>This field shows the data type of the adapter variable (for example, String is the data type for the SolarisUserID variable).</td>
</tr>
<tr>
<td>Map To</td>
<td>This field contains the types of mappings that you can set for the adapter variable (for example, IT Resources). When you map the adapter variable to a location or a contact, Oracle Identity Manager enables the adjacent combo box. From this combo box, select the specific type of location or contact to which you are mapping the adapter variable. In addition, if you map the adapter variable to a custom process form, and this form contains child table(s), Oracle Identity Manager enables the adjacent combo box. From this combo box, select the child table to which you are mapping the adapter variable. If you are not mapping the adapter variable to a location, contact, or child table of a custom process form, this combo box is grayed out.</td>
</tr>
<tr>
<td>Qualifier</td>
<td>This field contains the qualifiers for the mapping you selected in the Map to combo box (for example, IT Asset).</td>
</tr>
<tr>
<td>IT Asset Type</td>
<td>This field enables you to select a specific IT Resource (for example, Solaris) when you map an adapter variable to an IT Resource, and this variable’s data type is String. If you are not mapping the adapter variable to an IT Resource, or the variable’s data type is not String, this field does not appear.</td>
</tr>
</tbody>
</table>
11. Complete the Map To, Qualifier, IT Asset Type, IT Asset Property, Literal Value, and Old Value fields.

   **See Also:** "Adapter Mapping Information" on page 8-56 for more information about the mappings to select.

12. On the toolbar, click **Save**. Then, click **Close**.

    The Data Mapping for Variable window disappears. The **Integration** tab is active again.

13. On the Editing Task window toolbar, click **Save**.

    The contents in the **Status** field change from **Mapping Incomplete** to **Ready**. In addition, the mapping statuses for the adapter’s variables change from **No (N)** to **Yes (Y)**.

14. On the toolbar, click **Close**.

    The Editing Task window disappears, and the main screen is active once again. The adapter you added to the **Password Updated** task (**adpSOLARISPASSWORDUPDATED**) appears in the **Process Definition** form.

    This signifies that the **adpSOLARISPASSWORDUPDATED** process task adapter was attached to the **Password Updated** process task.

### Table 8–13 (Cont.) Fields of the Data Mapping for Variable Window

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| IT Asset Property| This field enables you to select a specific field that will receive the results of the mapping (for example, *User Name*), when you map an adapter variable to an IT Resource, and this variable's data type is *String*.  

   If you are not mapping the adapter variable to an IT Resource, or the variable's data type is not *String*, this field does not appear.  

   **Important**: The **IT Asset Type** and **IT Asset Property** fields are included within this window for backward compatibility. The preferred way is to create an adapter variable with a data type of *IT Resource*, in which case these fields will not appear. |
| Literal Value     | When you map the adapter variable to a literal, use this field to specify the specific literal value.  

   If you are not mapping the adapter variable to a literal, this field does not appear. |
| Old Value         | By selecting this check box, you map the adapter variable to the value that was originally in the selected Qualifier field before modification.  

   Process task adapters associated with process tasks are conditionally triggered when some field on the process form gets changed. If you click the Old Value option, and the process task is marked Conditional, the value that is passed to the adapter is the previous value of the field, before it got modified. This is useful in cases of fields that accept passwords. For example, if you want to disallow setting the password to the same value, you can use the old value for comparison.  

   If you are not mapping the adapter variable to a field that belongs to a child table of a custom process form, this check box is grayed out. |
Tip: Once you attach a process task adapter to a process task, a quick way to see the process and task to which it is connected is by accessing the Usage Lookup tab of the Adapter Factory form.

8.18.3 Removing Process Task Adapters from Process Tasks

If a process task adapter is no longer necessary for Oracle Identity Manager to complete the process task automatically, or when you wish to attach a different adapter to a process task, you must first remove the adapter that is attached to the process task.

This procedure will show you how to remove a process task adapter from a process task.

8.18.3.1 To Remove a Process Task Adapter from a Process Task

1. Open the Process Definition form.
   In the Design Console workspace, the Process Definition form appears.

2. Select the process, which contains a task from which you want to remove an adapter (for example, the Solaris process).
   The selected process, along with its tasks, appears in the Process Definition form.

3. Double-click the row header of the process task from which you want to remove the adapter (for example, the Password Updated task).
   The Editing Task window appears, containing information about the process task. Click the Integration tab.

4. Click the Integration tab.
   The Integration tab displays information about the adapter that is attached to the process task.

5. Click Remove.
   A dialog box appears, asking if you want to remove the adapter from the process task.

6. Click OK.
   A dialog box appears, signifying that the adapter has been removed from the process task.

7. Click OK.
   The contents of the adapter no longer appear in the Integration tab.

8. On the toolbar, click Close.
   The Editing Task window disappears, and the main screen is active once again. The adapter that was once linked to the Password Updated task (adpSOLARISPASSWORDUPDATED) no longer appears in the child table of the Process Definition form.

   This signifies that you have removed the adapter from the process task.
8.19 Adapter Mapping Information

An adapter is a Java class, generated by the Adapter Factory, which enables Oracle Identity Manager to interact with an external JAR file, a target IT resource (for example, a resource asset), or a user-defined form. The Adapter Factory is a code-generation tool provided by Oracle Identity Manager, which enables a User Administrator to create Java classes.

An adapter extends the internal logic and functionality of Oracle Identity Manager. It automates process tasks, and defines the rules for the auto-generation and validation of data in fields within Oracle Identity Manager. There are five types of adapters: task assignment adapters, task adapters, rule generator adapters, pre-populate adapters, and entity adapters.

The following topics are discussed in this section:
- Adapter Task Mapping Information
- Adapter Variable Mapping Information

8.19.1 Adapter Task Mapping Information

An adapter task is one of the several possible components within an adapter. And this is a logical step within an adapter, equivalent to calling a programming language method. The following types of adapter tasks are available: Functional Tasks (Java Task, Remote Task, and Stored Procedure Task), Utility Tasks (Utility Task and Oracle Identity Manager API Task), and Logic Tasks (Set Variable Task and Error Handler Task).

This section lists the mappings that you can set for the parameters of an adapter task, in the following topics:
- Adapter Variables
- Adapter Task
- Literal
- Adapter References
- Organization Definition
- Process Definition
- User Definition

8.19.1.1 Adapter Variables

The following table lists and describes the items of the Map To list box of the Data Mapping for Variable window and the Name list box to which you can map the parameters of an adapter variable for an adapter task.
8.19.1.2 Adapter Task
The following table lists and describes the items of the Map To, Name, and Output combo boxes of the Adapter Factory form to which you can map the parameters of an adapter task.

<table>
<thead>
<tr>
<th>Map To Combo Box</th>
<th>Name Combo Box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adapter Task</td>
<td>A list of adapter tasks are displayed</td>
<td>You can map the parameter to the adapter tasks that you created for this adapter.</td>
</tr>
</tbody>
</table>

**Note:** When the adapter variable's classification type is Object, it cannot be used with process task adapters.

**Note:** If the adapter variable's classification type is IT Resource, then an Attribute combo box is displayed. From this combo box, select the attribute of the IT resource to which you wish to map the parameter.

8.19.1.3 Literal
The following table lists and describes the items of the Map To and Type combo boxes, as well as the Value field of the Adapter Factory form, to which you can map the parameters of a constant (or literal) for an adapter task.

<table>
<thead>
<tr>
<th>Map To Combo Box</th>
<th>Type Combo Box</th>
<th>Value Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Literal</td>
<td>String, Boolean, Character, Byte, Date, Integer, Float, Long, Short, Double</td>
<td>Enter the value of the literal into this field.</td>
<td>You can map the parameter to a String, Boolean, Character, Byte, Date, Integer, Float, Long, Short, or Double data type, respectively.</td>
</tr>
</tbody>
</table>

8.19.1.4 Adapter References
The following table lists and describes the items of the Map To and Type combo boxes of the Adapter Factory form to which you can map the parameters of an adapter reference for an adapter task.

<table>
<thead>
<tr>
<th>Map To Combo Box</th>
<th>Type Combo Box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adapter References</td>
<td>Event Handler Name or Database Reference</td>
<td>You can map the parameter to the active adapter.</td>
</tr>
</tbody>
</table>
8.19.1.5 Organization Definition

The following table lists and describes the items of the Map To and Field combo boxes of the Adapter Factory form to which you can map the parameters of an organization definition for an adapter task.

<table>
<thead>
<tr>
<th>Map To combo box</th>
<th>Field Combo Box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Organization Definition</td>
<td>Organization Name</td>
<td>You can map the parameter to the Organization Name field of the Organizations form.</td>
</tr>
<tr>
<td></td>
<td>Organization Type</td>
<td>You can map the parameter to the Type field of the Organizations form.</td>
</tr>
<tr>
<td></td>
<td>Organization ID</td>
<td>You can map the parameter to the Organization # field of the Organizations form.</td>
</tr>
<tr>
<td></td>
<td>Organization Parent</td>
<td>You can map the parameter to the Parent Organization field of the Organizations form.</td>
</tr>
<tr>
<td></td>
<td>Organization Status</td>
<td>You can map the parameter to the Status field of the Organizations form.</td>
</tr>
<tr>
<td></td>
<td>Organization Parent ID</td>
<td>You can map the parameter to the parent_key field in the ACT database table.</td>
</tr>
<tr>
<td></td>
<td>Any fields that are displayed in the User Defined Fields tab of the Organizations form</td>
<td>You can map the parameter to the selected user-defined field.</td>
</tr>
</tbody>
</table>

8.19.1.6 Process Definition

The following table lists and describes the items of the Map To and Field combo boxes of the Adapter Factory form to which you can map the parameters of a process definition for an adapter task.

<table>
<thead>
<tr>
<th>Map To Combo Box</th>
<th>Field Combo Box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process Definition</td>
<td>Name</td>
<td>You can map the parameter to the Name field of the Process Definition form.</td>
</tr>
<tr>
<td></td>
<td>Type</td>
<td>You can map the parameter to the Type field of the Process Definition form.</td>
</tr>
</tbody>
</table>

8.19.1.7 User Definition

The following table lists and describes the items of the Map To and Field combo boxes of the Adapter Factory form to which you can map the parameters of a user definition for an adapter task.

<table>
<thead>
<tr>
<th>Map To Combo Box</th>
<th>Field Combo Box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Definition</td>
<td>User Key</td>
<td>You can map the parameter to a key, representing a unique record of the Users form.</td>
</tr>
<tr>
<td></td>
<td>First Name</td>
<td>You can map the parameter to the First Name field of the Users form.</td>
</tr>
</tbody>
</table>
### 8.19.2 Adapter Variable Mapping Information

For a newly created adapter to work, you can map data to the parameters of the adapter's tasks. For this reason, you create placeholders, also known as adapter variables, to map the data at run time. Once an adapter variable is not needed for the adapter to run, you can remove it from the adapter. After you have deleted the adapter variable, recompile the adapter.

<table>
<thead>
<tr>
<th>Map To Combo Box</th>
<th>Field Combo Box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Middle Initial</td>
<td>You can map the parameter to the Middle Name field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Last Name</td>
<td>You can map the parameter to the Last Name field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>User Login</td>
<td>You can map the parameter to the User ID field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Password</td>
<td>You can map the parameter to user password of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>You can map the parameter to the Xellerate Type field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>User Status</td>
<td>You can map the parameter to the Status field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Role</td>
<td>You can map the parameter to the Role field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Identity</td>
<td>You can map the parameter to the Identity field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Disabled</td>
<td>You can map the parameter to the Disable User check box of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Organization</td>
<td>You can map the parameter to the Organization field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Manager</td>
<td>You can map the parameter to the Manager field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Start Date</td>
<td>You can map the parameter to the Start Date field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>End Date</td>
<td>You can map the parameter to the End Date field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Email</td>
<td>You can map the parameter to the Email field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Provisioning Date</td>
<td>You can map the parameter to the Provisioning Date field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Provisioned Date</td>
<td>You can map the parameter to the Provisioned Date field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Deprovisioning Date</td>
<td>You can map the parameter to the Deprovisioning Date field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Deprovisioned Date</td>
<td>You can map the parameter to the Deprovisioned Date field of the Users form.</td>
<td></td>
</tr>
<tr>
<td>Any fields that are displayed in the User Defined Fields tab of the Users form.</td>
<td>You can map the parameter to the selected user-defined field.</td>
<td></td>
</tr>
</tbody>
</table>
When an adapter variable is not the adapter return variable, or it is not designated as Resolve at Run time, it should be mapped within the Variable List tab of the Adapter Factory form. On the other hand, if the adapter variable is classified as an adapter return variable, or the adapter variable is set to Resolve at Run time, it can be mapped at another location within Oracle Identity Manager. This location is contingent upon the adapter's type. For example, the variables of a process task adapter will be mapped at a different place than the variables of a pre-populate adapter. The following table lists the variables of a particular type of adapter that can be mapped.

### Adapter Type

<table>
<thead>
<tr>
<th>Adapter Type</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process Task</td>
<td>The Integration tab of the Editing Task window</td>
</tr>
<tr>
<td>Task Assignment</td>
<td>The Assignment tab of the Editing Task window</td>
</tr>
<tr>
<td>Rule Generator</td>
<td>The Map Adapters tab of the Data Object Manager form</td>
</tr>
<tr>
<td>Pre-Populate</td>
<td>The Pre-Populate tab of the Form Designer form</td>
</tr>
<tr>
<td>Entity</td>
<td>The Map Adapters tab of the Data Object Manager form</td>
</tr>
</tbody>
</table>

The following topics are discussed in this section:

- **From the Variable List Tab**
- **Process Task Adapter Variable Mappings**
- **Task Assignment Adapter Variable Mappings**
- **Rule Generator and Entity Adapter Variable Mappings**
- **Prepopulate Adapter Variable Mappings**

### 8.19.2.1 From the Variable List Tab

The following table lists the mappings that you can set from the Variable List tab.

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Map To</th>
<th>Qualifier/Resource Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Adapter References</td>
<td>Database References</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Data Object References</td>
</tr>
<tr>
<td></td>
<td>Set at run time</td>
<td>Database References</td>
</tr>
<tr>
<td></td>
<td>(for Task Assignment</td>
<td>Data Object References</td>
</tr>
<tr>
<td></td>
<td>adapters only)</td>
<td></td>
</tr>
<tr>
<td>IT Resource</td>
<td>Resolve at Run time</td>
<td>The IT Resource types that are displayed in the Table view of</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the IT Resources Type Definition form</td>
</tr>
<tr>
<td>String, Character, Byte, Integer, Float, Long, Short, Double</td>
<td>Literal</td>
<td>If you are mapping the adapter variable to a literal, a Literal Value field is displayed below the Resource Type combo box. Within this field, enter the value of this literal.</td>
</tr>
<tr>
<td></td>
<td>Resolve at Run time</td>
<td>NA</td>
</tr>
<tr>
<td></td>
<td>Event Handler Name</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** If the data type of the adapter variable is not String, Adapter References cannot be selected from the Map To combo box.
Using the Adapter Factory

8.19.2.2 Process Task Adapter Variable Mappings

The following table lists the process task adapter variable mappings.

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Map To</th>
<th>Qualifier/Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object (Adapter Return Variable)</td>
<td>Process Data</td>
<td>You can map the parameter to a field of either the associated custom process form, or a child table that belongs to this form.</td>
</tr>
<tr>
<td>Response Code</td>
<td>NA</td>
<td></td>
</tr>
<tr>
<td>Task Information</td>
<td>Note: You can map the parameter to the Note tab of the Task List form.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Reason: You can map the parameter to the Error Details window. To access this window, double-click a task that is displayed within the Task List form.</td>
<td></td>
</tr>
<tr>
<td>Process Definition</td>
<td>Name. You can map the parameter to the Name field of the Process Definition form.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Type. You can map the parameter to the Type lookup field of the Process Definition form.</td>
<td></td>
</tr>
<tr>
<td>Object (Adapter Return Variable)</td>
<td>Organization Definition</td>
<td>The fields of the Organizations form to which you can map the adapter variable.</td>
</tr>
<tr>
<td></td>
<td>Note: Because the data type of the adapter variable is Object, you cannot select Organization ID from the Qualifier combo box.</td>
<td></td>
</tr>
<tr>
<td>User Definition</td>
<td>The fields of the Users form to which you can map the adapter variable.</td>
<td></td>
</tr>
</tbody>
</table>
### Adapter Mapping Information

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Map To</th>
<th>Qualifier/Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resource</td>
<td>IT Resource</td>
<td>You can map the parameter to an IT resource. This IT resource is a member of the IT resource type that is displayed in parenthesis from within the Data Type field.</td>
</tr>
<tr>
<td>Process Data</td>
<td>IT Resource</td>
<td>You can map the parameter to a field of the associated process-specific form. Note: The only field names that are displayed in this combo box are ones with a data type of IT Resource Lookup Field.</td>
</tr>
<tr>
<td>String, Boolean,</td>
<td>Process Data</td>
<td>You can map the parameter to a field of either the associated custom process form, or a child table that belongs to this form.</td>
</tr>
<tr>
<td>Character, Byte,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Date, Integer,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Float, Long, Short, Double</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task Information</td>
<td>Note</td>
<td>You can map the parameter to the Note tab of the Task List form.</td>
</tr>
<tr>
<td>Reason</td>
<td></td>
<td>You can map the parameter to the Error Details window. To access this window, double-click a task that is displayed within the Task List form.</td>
</tr>
<tr>
<td>Process Definition</td>
<td>Name</td>
<td>You can map the parameter to the Name field of the Process Definition form.</td>
</tr>
<tr>
<td></td>
<td>Type</td>
<td>You can map the parameter to the Type lookup field of the Process Definition form.</td>
</tr>
<tr>
<td>Organization</td>
<td></td>
<td>The fields of the Organizations form to which you can map the adapter variable.</td>
</tr>
<tr>
<td>Definition</td>
<td></td>
<td></td>
</tr>
<tr>
<td>User Definition</td>
<td></td>
<td>The fields of the Users form to which you can map the adapter variable.</td>
</tr>
<tr>
<td>String, Boolean,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Character, Byte,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Date, Integer,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Float, Long, Short, Double</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Variable Type | Map To | Qualifier/Description
--- | --- | ---
Literal | IT Resources | If you are mapping the adapter variable to an IT Resource, three combo boxes are displayed below the Map To combo box: Qualifier, IT Asset Type, and IT Asset Property. From these combo boxes, select the qualifier for the mapping, the specific name of the IT resource, and the field of the IT resource that will receive the results of the mapping.

Note: If the data type of the adapter variable is not String, IT Resources cannot be selected from the Map To combo box.

### 8.19.2.3 Task Assignment Adapter Variable Mappings
The following table lists the task assignment adapter variable mappings.

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Map To</th>
<th>Qualifier/Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resource</td>
<td>Object Data</td>
<td>You can map the parameter to an IT resource's instance key. This IT resource is a member of the IT resource type that is displayed in parenthesis from within the Data Type field.</td>
</tr>
<tr>
<td>IT Resource</td>
<td>Object Data</td>
<td>You can map the parameter to an IT resource.</td>
</tr>
<tr>
<td>Object (Adapter Return Value)</td>
<td>Object Data</td>

### Adapter Mapping Information

**Using the Adapter Factory**

**8.19.2.4 Rule Generator and Entity Adapter Variable Mappings**

The following table lists the rule generator and entity adapter variable mappings.

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Map To</th>
<th>Qualifier/Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Literal</strong></td>
<td></td>
<td>If you are mapping the adapter variable to a literal, a Literal Value field is displayed below the Qualifier combo box. Within the field, enter the value of this literal.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> If the data type of the adapter variable is Boolean, two options are displayed in place of the field: True and False. Select the option that reflects the value of the adapter variable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> If the data type of the adapter variable is Object, Literal cannot be selected from the Map To combo box.</td>
</tr>
<tr>
<td><strong>String</strong></td>
<td>IT Resources</td>
<td>Resource Instance. You can map the parameter to an IT resource's instance key. This IT resource is a member of the IT resource type that is displayed in parenthesis from within the Data Type field.</td>
</tr>
<tr>

<td>The fields of the Organizations form to which you can map the adapter variable.</td>
</tr>
<tr>
<td>User Definition</td>
<td></td>
<td>The fields of the Users form to which you can map the adapter variable.</td>
</tr>
<tr>
<td>String, Boolean, Character, Byte, Date, Integer, Float, Long, Short, Double</td>
<td>Literal</td>
<td>If you are mapping the adapter variable to a literal, and the variable's data type is String, Character, Byte, Integer, Float, Long, Short, or Double, a Literal Value field is displayed below the Qualifier combo box. Within the field, enter the value of this literal. When you are mapping the adapter variable to a literal, and the variable's data type is Boolean, two Literal Value options are displayed below the Qualifier combo box: True and False. Select the option that corresponds to the value of the adapter variable. If you are mapping the adapter variable to a literal, and the variable's data type is Date, a Literal Value lookup field is displayed below the Qualifier combo box. Double-click this lookup field. From the Date &amp; Time window that is displayed, select the date and time that will be the value of this literal.</td>
</tr>
</tbody>
</table>
Defining Error Messages

8.20 Defining Error Messages

The Error Message Definition form, as shown in Figure 8–3, is in the Development Tools folder of the Design Console. It is used to:

- Create the error messages that are displayed in dialog boxes when certain problems occur.
- Define the error messages that users can access when they create error handler tasks by using the Adapter Factory form.

The error messages you create are displayed on the Identity Self Service or Identity System Administration if they are added to an adapter definition while creating a new adapter by using an error handler logic task based on a failure condition.

Table 8–14 describes the data fields of the Error Message Definition form.
Defining Error Messages

When you create an error message, Oracle Identity Manager populates the **Key** field with a unique, system-generated identification number. When a condition occurs that causes the error message to be displayed, the text in the **Description** field is displayed in a dialog box.

<p>| <strong>Table 8–14 Fields of the Error Message Definition Form</strong> |</p>
<table>
<thead>
<tr>
<th><strong>Field Name</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>The error message definition’s unique, system-generated identification number.</td>
</tr>
<tr>
<td>Code</td>
<td>The code that represents the error message definition.</td>
</tr>
<tr>
<td>Reset Count</td>
<td>When you click this button, Oracle Identity Manager resets the counter to zero. This counter is the number of times the error message is displayed.</td>
</tr>
<tr>
<td>Description</td>
<td>A description of the error message.</td>
</tr>
<tr>
<td>Remedy</td>
<td>A description of how to correct the condition that caused the error message to be displayed.</td>
</tr>
<tr>
<td>Help URL</td>
<td>The link to the URL that contains an online Help topic for this error message.</td>
</tr>
<tr>
<td>Action</td>
<td>A one-letter code, representing the seriousness of the condition that causes the error message to be displayed. An error message has three levels of seriousness: Error (E), Rejection (R), and Fatal Rejection (F).</td>
</tr>
<tr>
<td>Severity</td>
<td>For classification purposes, you can categorize the seriousness of the condition that results in the error message being displayed, even further. An error message has five sub-levels of severity: None (N), Low (L), Medium (M), High (H), and Crash (C).</td>
</tr>
<tr>
<td>Note</td>
<td>Explanatory information about the error message.</td>
</tr>
</tbody>
</table>

When you create an error message, Oracle Identity Manager populates the **Key** field with a unique identification number. When a condition occurs that causes the error message to be displayed, the text in the **Description** field is displayed in a dialog box.

**Note:** After you create an error message definition, to reset the count of how many times the error message is displayed, click the **Reset Count** button. This resets the count to zero.

To create an error message:

1. Open the Error Messaging Definition form.
2. In the **Code** field, enter the code that represents the error message definition.
3. In the **Description** field, enter a description for the error message.
4. In the **Remedy** field, you can enter a description for how to correct the condition that causes the error message to be displayed.
5. In the **Help URL** field, you can enter the link to the URL that contains an online Help topic for this error message.
6. (Optional) Double-click the **Action Lookup** field.

   From the Lookup dialog box that is displayed, you can select a code that represents the seriousness of the condition that causes the error message to be displayed. These codes, listed by degree of seriousness (from lowest to highest), are:
- Error (E). Oracle Identity Manager stores the error message, and stops any related operations from being triggered. Instead, the operation rolls back to the previous operation.

- Reject (R). Oracle Identity Manager stores the rejection message, but it does not prevent subsequent operations from being executed.

- Fatal Reject (F). Oracle Identity Manager stores the rejection message, and it stops any subsequent operations from being triggered. However, it stores all operations that were executed up to the fatal rejection.

7. (Optional) Double-click the **Severity Lookup** field. From the Lookup dialog box that is displayed, you can select a code (None (N), Low (L), Medium (M), High (H), or Crash (C)). This code presents a detailed classification of the code that is displayed in the **Action** lookup field.

8. In the **Note** field, enter explanatory information about the error message.

9. Click **Save**.

The error message is created.

After creating error messages by using the Error Message Definition form, you must add new error codes and advice messages in the Oracle Identity Manager customResources.properties resource bundle. These localized error codes and advice messages will be displayed in Identity Self Service or Identity System Administration.
Identity connectors are components developed to link Oracle Identity Manager with external stores of applications, directories, and databases. Oracle Identity Manager provides support for developing and building identity connectors by using the Identity Connector Framework (ICF). ICF decouples Oracle Identity Manager from other applications to which it connects. Therefore, you can build and test an identity connector before integrating it with Oracle Identity Manager. This chapter contains conceptual information and sample code in the following sections:

- Advantages of ICF
- Introducing the ICF Architecture
- Using the ICF API
- Introducing the ICF SPI
- Extending an Identity Connector Bundle
- Using an Identity Connector Server

**Note:** Earlier releases of Oracle Identity Manager have other options for building identity connectors. These options are still supported, but it is recommended that you build new identity connectors by using the ICF.

## 9.1 Advantages of ICF

ICF provides the following benefits:

- Single platform: Identity Connectors are shared between Oracle Identity Manager and Oracle Waveset (OW), which means they are built on top of the same platform so that a single connector can be used for both OIM and OW to communicate with external identity-aware applications.

- Simple installation: ICF offers simple installation as most of the manual configuration during installation, such as copying the connector files and the external code files are automatically taken care by ICF.

- Stateless by design: Identity connectors are stateless by design. An identity connector stores nothing. The calling application supplies to the connector the values for its configuration, including the information required to connect to the target application. This is because, identity connectors are stateless, each bundle
implementation are kept as simple as possible, and coupling the implementation with that of the calling application is also prevented.

- ICF Common: ICF provides common connector integration layer for all ICF based connectors in OIM and no development effort is required to develop ICF Common.
- Remote Execution: ICF supports remote execution of connector server using Java or .NET implementation.
- JVM Isolation: Remote ICF provides JVM isolation, which means running a Java connector on a different host avoids JVM conflicts.
- Reuse: In future, other products can reuse Identity Connectors.

9.2 Introducing the ICF Architecture

Identity connectors allow Oracle Identity Manager to carry out user provisioning and reconciliation operations on target systems in the enterprise. ICF decouples any calling application, such as Oracle Identity Manager, from the implementation of the connector. ICF also decouples the implementation of the connector from the calling application. The same connector implementation can work with several different calling applications. Figure 9–1 illustrates how this is accomplished by situating the ICF API and SPI between Oracle Identity Manager and the target system.

The API implementation always post-processes the results returned by the SPI Search operation. This double-checks the SPI implementation if the connector bundle does not implement all Filter types, or does not implement them properly for all attributes. If the implementation of Search in the SPI returns every object of the specified type, then the API implementation discards every object that does not match the specified Filter. Post-processing in the API implementation is expensive in terms of processing-time and network-bandwidth, and therefore, it is more efficient if each connector-bundle supports every type of filter (search predicate or logical operator) that the target application can support natively. See the details for Filter Translator in "Common Classes" on page 9-21.

Figure 9–1 illustrates that the calling application sees only the ICF API. The ICF API dedicates a classloader to each connector bundle, so that the calling application is not exposed to the classes and libraries in the implementation of the connector-bundle (SPI). Bundle classloader also ensures isolation between the bundles as well as making any bundled library available to the connector bundle only, thereby avoiding conflicts between dependencies.
Figure 9–1  Identity Connector Framework Deployment

Figure 9–2 illustrates the backwards compatibility of the ICF. Newer bundles may be deployed without affecting existing ones. In addition, newer versions of the ICF are generally backward-compatible with existing bundles. Therefore, any connector should work with a new version of framework.

Figure 9–2  Compatibility Between the ICF and Connector Bundles

Figure 9–3 illustrates deployment methodology of the ICF. Framework supports LCM to clone connector to support multiple versions of the same target. In addition, Framework supports connection pooling.
**Figure 9–3  Deployment Methodology to Support Multiple Versions of Same Target**

*Figure 9–4* illustrates Framework installed on remote system. This enables remote execution of connector server using Java or .NET implementation with targets being local or remote to connector bundles. This is required when a connector bundle is not directly executed with in an application and ICF allows the application to communicate with externally deployed bundles. In addition, the connector artifacts can be same for local or remote system.
Figure 9–4 Connector Server Remote System Framework

Figure 9–5 illustrates ICF Framework, which enables the convergence of Oracle Identity Manager and Oracle Waveset (OW) connectors to a single connector, best of both.
9.3 Using the ICF API

The org.identityconnectors.framework.api package contains the ICF API. Oracle Identity Manager uses the API to call Connector implementations. The API provides a consistent view of any implemented Connector, regardless of the supported operations. The following sections explain these interfaces and classes.

- The ConnectorInfoManagerFactory Class
- The ConnectorInfoManager Interface
- The ConnectorKey Class
- The ConnectorInfo Interface
- The APIConfiguration Interface
- The ConfigurationProperties Interface
- The ConnectorFacadeFactory Class
- The ConnectorFacade Interface

9.3.1 The ConnectorInfoManagerFactory Class

The ConnectorInfoManagerFactory class allows Oracle Identity Manager to load Connector classes from a set of bundles. The static getInstance method returns an object of type ConnectorInfoManagerFactory. This object can then be used to get a reference to the ConnectorInfoManager. (See Section 9.3.2, "The ConnectorInfoManager Interface" for more information.) Example 9–1 illustrates the ConnectorInfoManagerFactory implementation.

```java
//create ConnectorInfoManagerFactory
```
ConnectorInfoManagerFactory cInfoManagerFactory =
ConnectorInfoManagerFactory.getInstance();

9.3.2 The ConnectorInfoManager Interface

The ConnectorInfoManager interface maintains a list of ConnectorInfo instances. Each instance describes an identity connector. ConnectorInfoManager can be obtained by calling the getLocalManager method on the ConnectorInfoManagerFactory, and a list of bundle URLs is passed to it. ConnectorInfoManager can also be obtained by calling getRemoteManager method on the ConnectorInfoManagerFactory. The getRemoteManager method accepts an instance of RemoteFrameworkConnectionInfoand, which is used for getting information about connectors deployed on Connector Server.

In Example 9–2, cInfoManagerFactory is the instance of the ConnectorInfoManagerFactory and bundleURL is a list of bundle URLs that may point to directories consisting of JAR-ed or un-JAR-ed bundles.

Example 9–2  ConnectorInfoManager Implementation

//get the ConnectorInfoManager
ConnectorInfoManager cInfoManager =
cInfoManagerFactory.getLocalManager(bundleURL);

9.3.3 The ConnectorKey Class

A ConnectorKey uniquely identifies a Connector instance within an installation. The ConnectorKey class takes a bundleName (name of the Connector bundle), a bundleVersion (version of the Connector bundle) and a connectorName (name of the Connector bundle) as illustrated in Example 9–3.

Example 9–3  ConnectorKey Implementation

//get the ConnectorKey reference
ConnectorKey flatFileConnectorKey =
    new ConnectorKey(bundleName, bundleVersion, connectorName);

9.3.4 The ConnectorInfo Interface

The ConnectorInfo interface contains information about a specific identity connector. It contains the display name, key and message details regarding the particular identity connector. Example 9–4 illustrates how to implement the ConnectorInfo.

Example 9–4  ConnectorInfo Implementation

//get the ConnectorInfo
ConnectorInfo info =
cInfoManager.findConnectorInfo(flatFileConnectorKey);

In the example, cInfoManager is the ConnectorInfoManager and flatFileConnectorKey is the identity connector key.
9.3.5 The APIConfiguration Interface

The APIConfiguration interface shows the configuration properties from both the SPI and the API sides. The getConfigurationProperties method returns a ConfigurationProperties instance based on the connector Configuration implementation, initialized to the defaults. Caller can then modify the properties, as required. Example 9–5 illustrates this.

Example 9–5  APIConfiguration Definition

```
APIConfiguration apiConfig =
    info.createDefaultAPIConfiguration();
```

9.3.6 The ConfigurationProperties Interface

The ConfigurationProperties interface encapsulates the SPI Configuration and uses reflection to identify the individual properties that are available for an application to manipulate. Set all of the identity connector's configuration properties using the setPropertyValue method as defined in Example 9–6.

Example 9–6 setPropertyValue Method Signature

```
public void setPropertyValue
    (java.lang.String name, java.lang.Object value)
```

Example 9–7 illustrates an implementation of the ConfigurationProperties interface.

Example 9–7 ConfigurationProperties Implementation

```
//get the default APIConfiguration
ConfigurationProperties flatFileConfigProps =
    apiConfig/configurationProperties();
```

9.3.7 The ConnectorFacadeFactory Class

The ConnectorFacadeFactory class allows an application to get a Connector instance and to manage a pool of Connector instances. Example 9–8 illustrates the ConnectorFacadeFactory definition.

Example 9–8 ConnectorFacadeFactory Definition

```
//get a reference to ConnectorFacadeFactory
ConnectorFacadeFactory facadeFactory =
    ConnectorFacadeFactory.getInstance();
```

9.3.8 The ConnectorFacade Interface

The ConnectorFacade interface is used by the target system to invoke identity connector operations by representing a specific identity connector on the API side. Example 9–9 illustrates the ConnectorFacade implementation.

Example 9–9 ConnectorFacade Implementation

```
//create a ConnectorFacade (nothing but a reference to Connector on SPI side)
ConnectorFacade connectorFacade = facadeFactory.newInstance(apiConfig)
```
9.4 Introducing the ICF SPI

Developers implement the ICF SPI to create identity connectors. The ICF SPI is made up of many interfaces but the developer need only implement those supported by the target system. SPI can again be classified into required, operation, and feature-based interfaces. Required interfaces must be implemented irrespective of the operations supported and they help to create the connector and maintain the connection with the target system, while operation interfaces help the connector to support various operations. Feature-based interfaces support certain features supported by the ICF.

The following sections have more information.

- Implementing the Required Interfaces
- Implementing the Feature-based Interfaces
- Implementing the Operation Interfaces
- Common Classes

9.4.1 Implementing the Required Interfaces

All identity connectors are required to provide an implementation of two interfaces. These two interfaces declare and initialize the identity connector with the target system. The following sections have more information.

- org.identityconnectors.framework.spi.Connector
- org.identityconnectors.framework.spi.Configuration

9.4.1.1 org.identityconnectors.framework.spi.Connector

This is the main interface to declare an identity connector. Many connectors create the connection to the target system when the connection is required, removing the connection when finished with it, and disposing of any resources it has used. The interface provides the init and dispose life cycle methods for this purpose.

**Note:** Connector implementations must be annotated with type
org.identityconnectors.framework.spi.ConnectorClass by providing the configurationClass and displayNameKey information. The displayNameKey must be a key defined in the Messages.properties file.

Every connector implementation must be annotated with @ConnectorClass. This is required because the ICF would scan all top level .class files in the connector bundle looking for classes that have the @ConnectorClass annotation, therefore, autodiscovering connectors that are defined in the bundle. This annotation requires the following elements:

- configurationClass: This is the configuration class for this connector. This class has all the information about the target that can be used by the connector to connect and perform various provisioning and reconciliation operations. See section "org.identityconnectors.framework.spi.Configuration" on page 9-12 for more information on how to implement the configuration class.

- displayNameKey: Display name key that must be present in the message catalog. Example 9–10 is a sample connector implementation.
### Example 9–10  Flat File Connector Implementation

```java
/**
 * Flat file connector implementation. This connector supports create,
 * delete, search and update operations.
 */
@ConnectorClass
(configurationClass=FlatFileConfigurationImpl.class,
displayNameKey="FLAT_FILE_CONNECTOR")
public class FlatFileConnector implements Connector,
CreateOp, DeleteOp, SearchOp<Map<String, String>>, UpdateOp{

In Example 9–10:

- **CreateOp**: Helps the connector to create an entity on the target system
- **DeleteOp**: Helps the connector to delete an entity on the target system
- **SearchOp**: Helps the connector to search an entity on the target system
- **UpdateOp**: Helps the connector to update an existing entity on the target system

See "Implementing the Operation Interfaces" on page 9-15 for more information.

The following sections contain information and sample code that illustrates how you might implement the Connector methods. For complete code regarding a Connector implementation, see "Developing a Flat File Connector" on page 10-1.

- Implementing the init Method
- Implementing the dispose Method
- Implementing the getConfiguration Method

#### 9.4.1.1.1 Implementing the init Method

The init method initializes the connector. The connector initializes itself with the configuration instance as provided with the annotation @ConnectorClass. The init method takes a Configuration object as an argument. The Configuration object has all the information required by the Connector to connect to the target system.

Example 9–11 illustrates how to implement the init method of interfaces in JDK 1.6.

---

**Note:** In this document, all code samples use the methods implementing interfaces in JDK 1.6.

---

### Example 9–11  init Method Implementation

```java
@Override
public void init(Configuration config) {
    this.flatFileConfig = (FlatFileConfiguration) config;

    FlatFileIOFactory flatFileIOFactory =
        FlatFileIOFactory.getInstance(flatFileConfig);
    this.flatFileMetadata = flatFileIOFactory.getMetadataInstance();
    this.flatFileParser = flatFileIOFactory.getFileParserInstance();
    this.flatFileWriter = flatFileIOFactory.getFileWriterInstance();
    log.ok("Initialization done");
}
```
The init method implementation shown in Example 9–11 does the following:

- Stores the configuration information of the target system. This can be used later while performing an operation.
- Initializes all the supporting classes it uses while performing any provisioning and reconciliation operations.

### 9.4.1.1.2 Implementing the dispose Method

The dispose method disposes of any resources held by this Connector instance. Once the method is called, the Connector instance is discarded and cannot be used. Example 9–12 illustrates how to implement the `dispose` method.

#### Example 9–12 `dispose` Method Implementation

```java
/**
 * Disposes any resource used by the connector.
 */
@override
public void dispose() {
    // close any open FileReader or FileWriter instances.
    // close connection with the target
    // close connection if any with database
}
```

### 9.4.1.1.3 Implementing the getConfiguration Method

The `getConfiguration` method returns the `Configuration` instance passed to the Connector when the `init` method was used. Example 9–13 illustrates how to implement the `getConfiguration` method.

#### Example 9–13 `getConfiguration` Method Implementation

```java
/**
 * returns the Configuration of this connector
 */
@override
public Configuration getConfiguration() {
    return this.flatFileConfig;
}
```

**Note:** Sometimes, components must be able to access the `Configuration` instance after initialization. This is supported by the accessor method `getConfiguration()`.
9.4.1.2 org.identityconnectors.framework.spi.Configuration

The implementation of this interface encapsulates the configuration of a connector. Configuration implementation includes all the necessary information of the target system, which is used by the Connector implementation to connect to the target system and perform various reconciliation and provisioning operations. The implementation should have a default Constructor with setters and getters defined for its properties. Every property declared may not be required but if a property is required, then it should be marked required using the annotation org.identityconnectors.framework.spi.ConfigurationProperty. Configuration implementation is a Java bean and all the instance variables (mandatory or not) do have default values. For example, a string userName is used to connect to the target system and this is a mandatory attribute. This has a default value of null. When userName is a mandatory attribute, ICF expects a value to be provided by Oracle Identity Manager. In other words, Oracle Identity Manager cannot miss out this parameter. If missed, then the connector throws ConfigurationException.

The implementation should check that all required properties are available and validated before passing itself to the Connector. The interface provides a validate method for this purpose. For example, there are three mandatory configuration parameters, such as the IP address of the target, the username to connect to the target, and the password for the user. The validate method implementation can check for non-NULL values and valid IP address by using regex.

Note: ICF also provides a convenient base class org.identityconnectors.framework.spi.AbstractConfiguration for configuration objects to extend.

Example 9–14 Configuration Implementation

```java
/**
 * Configuration implementation for the flat file connector.
 */
public class FlatFileConfigurationImpl extends AbstractConfiguration{

The following sections contain information and sample code that illustrates how you might implement the Configuration methods.

The Configuration implementation must provide implementation for the following methods:

- The validate() Method
- The setConnectorMessages() Method
- The getConnectorMessages() Method

9.4.1.2.1 The validate() Method

The validate method checks that the values of all required properties are set. It also validates that all values of configuration properties are valid. In other words, it validates that all values of the configuration properties are in the expected range and have the expected format. If the configuration is not valid, then the implementations generate the most specific RuntimeException available. When no specific exception is available, the implementations can throw ConfigurationException. Example 9–15 illustrates how to implement the validate method.
Example 9–15  validate Method Implementation

```java
@override
public void validate() {
    // Validate if file exists and is usable
    boolean validFile = (this.storeFile.exists() &&
                           this.storeFile.canRead() &&
                           this.storeFile.canWrite() &&
                           this.storeFile.isFile());
    if (!validFile)
        throw new ConfigurationException("User store file not valid");
    FlatFileIOFactory.getInstance(this);
}
```

Here, if the target flat file provided is valid or not is checked, such as is a file, is writeable, is readable. If not valid, then an exception is generated.

Implementations of the validate method should NOT connect to the target system to validate the properties.

Note: This implementation depends on an instance variable (private File storeFile) and a supporting class (FlatFileIOFactory). A complete implementation is illustrated in “Developing a Flat File Connector” on page 10-1.

9.4.1.2.2  The setConnectorMessages() Method

The setConnectorMessages method sets the org.identityconnectors.framework.common.objects.ConnectorMessages message catalog instance, allowing the Connector to localize messages. Example 9–16 illustrates the setConnectorMessages method definition.

Example 9–16  setConnectorMessages Method Definition

```java
public final void setConnectorMessages(ConnectorMessages messages) {
    _connectorMessages = messages;
}
```

9.4.1.2.3  The getConnectorMessages() Method

The getConnectorMessages method returns the ConnectorMessages set by the setConnectorMessages method. Example 9–17 illustrates the getConnectorMessages method definition.

Example 9–17  getConnectorMessages Method Definition

```java
public final ConnectorMessages getConnectorMessages() {
    return _connectorMessages;
}
```

9.4.2  Implementing the Feature-based Interfaces

The following sections contain information on the interfaces used to enable identity connector pooling and attribute normalizing.

- org.identityconnectors.framework.spi.PoolableConnector
- org.identityconnectors.framework.spi.AttributeNormalizer
Connection pooling by ICF is a feature provided by the ICF in which the framework maintains a pool of connector instances and uses them while performing provisioning and reconciliation operations. Connectors can make use of pooling by implementing the PoolableConnector interface instead of plain Connector interface. To make use of this feature, implement the PoolableConnector interface. If you implement the Connector interface, then ICF creates a new connector instance for every operation, creates a new connection with the target, completes the provisioning/reconciliation operation, removes the connection with the target system, and finally disposes this connector instance. Therefore, the advantages of implementing PoolableConnector is that a pool of configurable connector instances are maintained and are reused for many operations.

Some of configurable options are:

- Maximum connector objects in the pool that are idle and active (_maxObjects)
- Maximum connector objects that are idle (_maxIdle)
- Max time to wait if the pool is waiting for a free object to become available before failing (_maxWait)
- Minimum time to wait before evicting an idle object (_minEvictableIdleTimeMillis)
- Minimum number of idle objects (_minIdle)

These values must be set by connector API developer, and if not provided, then the following default values are used:

- _maxObjects = 10
- _maxIdle = 10
- _maxWait = 150 * 1000 ms
- _minEvictableIdleTimeMillis = 120 * 1000 ms
- _minIdle = 1

The PoolableConnector interface extends the Connector interface. It is implemented to enable identity connector pooling that ICF provides. ICF must make sure that the Connector instance is alive before being used. For this purpose, the interface provides a checkAlive method. Example 9–18 is a sample flat file PoolableConnector implementation.

**Example 9–18  Flat File Poolable Connector Implementation**

```java
/**
 * Flat file connector implementation. This is a poolable connector
 * which supports create, delete, search and update operations.
 */

@ConnectorClass
@ConfigurationClass=FlatFileConfigurationImpl.class,
displayNameKey="FLAT_FILE_CONNECTOR")
public class FlatFileConnector implements PoolableConnector,
CreateOp, DeleteOp, SearchOp<Map<String, String>>, UpdateOp{

To implement the PoolableConnector interface, provide an implementation of the checkAlive method along with all the methods discussed in Section 9.4.1.1, "org.identityconnectors.framework.spi.Connector." The checkAlive method determines if the Connector instance is alive and can be used for operations on the target system. checkAlive can be called often thus the developer should make sure the implementation is fast. The method should throw a specific RuntimeException (if
available) when the Connector is no longer alive. Example 9–19 illustrates how to implement the checkAlive method.

**Example 9–19  checkAlive Method Implementation**

```java
/**
 * Checks if this connector is alive, if not throws a RuntimeException
 */
@Override
public void checkAlive() {
  //check if the connector is still connected to target
}
```

### 9.4.2.2 org.identityconnectors.framework.spi.AttributeNormalizer

This interface must be implemented by a Connector that needs to normalize any attributes passed to it. A normalizer converts values to a standard form for the purpose of display, consumption, or comparison. For example, a normalizer might convert text values to a specific case, trim whitespace, or order the elements of a DN in a specific way.

The interface defines a normalizeAttribute method for this purpose. This method takes an ObjectClass and an Attribute to be normalized as arguments and returns the normalized Attribute. Attribute normalization is applied during many operations including:

- Filters that are passed to SearchOp
- Results returned from SearchOp
- Results returned from SyncOp
- Attributes passed to UpdateAttributeValuesOp
- Uids returned from UpdateAttributeValuesOp
- Attributes passed to UpdateOp
- Uids returned from UpdateOp
- Attributes passed to CreateOp
- Uids returned from CreateOp
- Uids passed to DeleteOp

Example 9–20 illustrates the normalizeAttribute method definition.

**Example 9–20  normalizeAttribute Method Definition**

```java
public Attribute normalizeAttribute (ObjectClass oClass, Attribute attribute) {
  if (attribute instanceof Uid) {
    return new Uid(LdapUtil.createUniformUid((String)newValues.get(0),
    configuration.getSuffix()));
  }
}
```

### 9.4.3 Implementing the Operation Interfaces

Each operation interface defines an action that the Connector may perform on a target system, if supported by it. The operation interfaces belong to the org.identityconnectors.framework.spi.operations package. The names of these
operation interfaces are listed below, but subsequent sections elaborate on each interface:

- AuthenticateOp
- CreateOp
- DeleteOp
- ResolveUsernameOp
- SchemaOp
- ScriptOnConnectorOp
- ScriptOnResourceOp
- SearchOp<T>
- SyncOp
- TestOp
- UpdateAttributeValuesOp
- UpdateOp

The following sections contain more information on some of these operations.

- Implementing the SchemaOp Interface
- Implementing the CreateOp Interface
- Implementing the DeleteOp Interface
- Implementing the SearchOp Interface
- Implementing the UpdateOp Interface

### 9.4.3.1 Implementing the SchemaOp Interface

The SchemaOp interface is implemented to allow the connector to describe the objects it can handle on the target system. The schema that a connector returns describes the object-classes that it exposes for management. Each object-class has a name, a description, and a set of attribute definitions. Each attribute definition has a name, a syntax, and certain flags that describe its properties, such as multi-valued, single-valued, readable, or writeable.

The schema that a connector returns describes the attributes of each type of object that the connector exposes. Sometimes, this requires translation from an internal representation to this Schema format. In other instances, the Schema presents as an attribute; something that is natively available only via calls to the target API. Irrespective of how the SPI implementation accomplishes the mapping between the native representation and the corresponding ConnectorObject, the Schema provides the metadata that describes what a client can expect to find in a ConnectorObject of each type, which is objectClass.

To implement this interface, provide an implementation for the schema method as defined in Example 9–21.

**Example 9–21  schema Method Signature**

```java
public Schema schema
```

The implementation should return the schema containing the types of objects that this identity connector supports.
Example 9–22  schema Method Implementation

@Override
public Schema schema() {
    SchemaBuilder flatFileSchemaBldr = new SchemaBuilder(this.getClass());
    Set<AttributeInfo> attrInfos = new HashSet<AttributeInfo>();
    for (String fieldName : flatFileMetadata.getOrderedTextFieldNames()) {
        AttributeInfoBuilder attrBuilder = new AttributeInfoBuilder();
        attrBuilder.setName(fieldName);
        attrBuilder.setCreateable(true);
        attrBuilder.setUpdateable(true);
        attrInfos.add(attrBuilder.build());
    }
    // Supported class and attributes
    flatFileSchemaBldr.defineObjectClass
        (ObjectClass.ACCOUNT.getDisplayNameKey(), attrInfos);
    return flatFileSchemaBldr.build();
}

// Supported class and attributes
flatFileSchemaBldr.defineObjectClass
    (ObjectClass.ACCOUNT.getDisplayNameKey(), attrInfos);
return flatFileSchemaBldr.build();

Note: The Uid should not appear in the returned schema.

9.4.3.2 Implementing the CreateOp Interface

The CreateOp interface is implemented to enable creating objects on the target system. To implement this interface, provide an implementation of the create() method, as shown in Example 9–23.

Example 9–23  create Method Signature

public Uid create
    (ObjectClass objectClass, Set<Attribute> attributes,
     OperationOptions options)

This method takes an ObjectClass (for example, account or group), a set object attributes, and operation options. The implementation creates an object on the target system by using passed object attributes and object type defined by ObjectClass. The ObjectClass argument specifies the class of object to create. The class of object to be created is one of the inputs to the create operation. ObjectClass is the first argument to the create() method, as shown in Example 9–24.

Example 9–24  create Method Implementation

@Override
public Uid create(ObjectClass arg0, Set<Attribute> attrs,
    OperationOptions ops) {
    System.out.println("Creating user account " + attrs);
    assertUserObjectClass(arg0);
    try {
        FlatFileUserAccount accountRecord = new FlatFileUserAccount(attrs);
        // Assert uid is there
        assertUidPresence(accountRecord);

        // Create the user
        this.flatFileWriter.addAccount(accountRecord);

        // Return uid
    }
String uniqueAttrField = this.flatFileConfig
         .getUniqueAttributeName();
String uniqueAttrVal = accountRecord
         .getAttributeValue(uniqueAttrField);
System.out.println("User " + uniqueAttrVal + " created");

    return new Uid(uniqueAttrVal);
  } catch (Exception ex) {

    // If account exists
    if (ex.getMessage().contains("exists"))
      throw new AlreadyExistsException(ex);

    // For all other causes
    System.out.println("Error in create " + ex.getMessage());
    throw ConnectorException.wrap(ex);
  }
}

If the operation is successful, Uid instance representing object identifier on the target
system is supposed to be created and returned. The caller can then use the Uid to refer
to the created object.

9.4.3.3 Implementing the DeleteOp Interface

The DeleteOp interface is implemented to enable deleting objects from the target
system. To implement this interface, provide an implementation for the delete method
as defined in Example 9–25.

Example 9–25  delete Method Signature

public void delete
      (ObjectClass objectClass, Uid uid, OperationOptions options)

This method takes an ObjectClass (for example, account or group), the Uid of the
object being deleted from the target system, and operation options. The
implementation deletes the object identified by the provided Uid from the target
system. if the object does not exist on the target system, then an
org.identityconnectors.framework.common.exceptions.UnknownUidException is
generated. Example 9–26 illustrates how to implement the delete method.

Example 9–26  delete Method Implementation

@Override
public void delete(ObjectClass arg0, Uid arg1, OperationOptions arg2) {
  final String uidVal = arg1.getUidValue();
  this.flatFileWriter.deleteAccount(uidVal);
  log.ok("Account (0) deleted", uidVal);
}

Note:  If the delete operation fails, then ICF generates subclasses of
        RuntimeException. See Oracle Fusion Middleware Java API Reference for
        Identity Connector Framework for details.
9.4.3.4 Implementing the SearchOp Interface

The SearchOp interface is implemented to enable searching objects on the target system. Here, the search operation consists of:

- Creation of a native filter to implement search conditions that are specified generically.
- Executing the actual query.

Implementing these methods in the SPI allows the API to support search. The API performs (by post-processing the result) any filtering that the connector does not perform, for example, by translating any specified filter conditions into native search conditions.

To implement this interface, provide an implementation for the createFilterTranslator and executeQuery methods as documented in the following sections.

- Implementing the createFilterTranslator Method
- Implementing the executeQuery Method

9.4.3.4.1 Implementing the createFilterTranslator Method

The createFilterTranslator method returns an instance of implementation of FilterTranslator, which converts the ICF Filter object passed to it from the API side into a native query. Following the conversion, ICF passes the query to the executeQuery method. Example 9–27 illustrates the createFilterTranslator method definition.

**Example 9–27 createFilterTranslator Method Signature**

```java
public FilterTranslator createFilterTranslator
(ObjectClass oClass, OperationsOptions options)
```

**Note:** The return value should not be null.

Example 9–28 illustrates an implementation of the createFilterTranslator method.

**Example 9–28 createFilterTranslator Method Implementation**

```java
@Override
custom FilterTranslator<Map<String, String>> createFilterTranslator
(ObjectClass arg0, OperationOptions arg1) {
    return new ContainsAllValuesImpl();
}
```

This example supports only a single type of search predicate, which is ContainsAllValues. See "Implementation of AbstractFilterTranslator<T>" on page 10-8 for an example of an implementation of ContainsAllValuesImpl. The implementation of ContainsAllValues translates into native form a condition of the form: Attribute A contains all of the values V(1), V(2) ... V(N).

For information on the org.identityconnectors.framework.common.objects.filter.FilterTranslator, see "Common Classes" on page 9-21.

9.4.3.4.2 Implementing the executeQuery Method
The `executeQuery` method is called for every query produced by the `FilterTranslator` implementation (as documented in "Implementing the `createFilterTranslator` Method" on page 9-19). It takes an `ObjectClass` (for example, account or group), the query, an instance of `ResultsHandler` used as a callback to handle found objects, and operation options, as illustrated in Example 9–29.

**Example 9–29**  `executeQuery` Method Signature

```java
public void executeQuery
    (ObjectClass oClass, T query,
     ResultsHandler handler, OperationOptions options)
```

The implementation of the `executeQuery` method searches for the target objects by using the passed query, creates instances of `ConnectorObject` for each target object found, and uses `ResultsHandler` to handle `ConnectorObjects`. `ConnectorObject` is ICF representation of target resource object. It contains information such as `ObjectClass`, `Uid`, `Name`, and `Set of Attributes`. `ConnectorObject` is central to search. `executeQuery` streams `ConnectorObjects` into the `ResultsHandler`, and therefore, to the client. Example 9–30 illustrates how to implement the `executeQuery` method.

**Example 9–30**  `executeQuery` Method Implementation

```java
@Override
public void executeQuery(ObjectClass objectClass,
                          Map<String, String> matchSet, ResultsHandler resultHandler,
                          OperationOptions ops) {

    // searches the flat file for accounts which fulfil the condition 'matchSet'
    // created by `FilterTranslator`
    Iterator<FlatFileUserAccount> userAccountIterator = this.flatFileParser
                                .getAccountIterator(matchSet);

    boolean handleMore = true;
    while (userAccountIterator.hasNext() && handleMore) {
        FlatFileUserAccount userAcc = userAccountIterator.next();
        ConnectorObject userAccObject = convertToConnectorObject(userAcc);
        // Let the client handle the result by doing callback
        handleMore = resultHandler.handle(userAccObject);
    }

    while (userAccountIterator.hasNext()) {
        FlatFileUserAccount userAcc = userAccountIterator.next();
        ConnectorObject userAccObject = convertToConnectorObject(userAcc);
        if (!resultHandler.handle(userAccObject)) {
            System.out.println("Not able to handle " + userAcc);
            break;
        }
    }
}
```

**9.4.3.5 Implementing the UpdateOp Interface**

The `UpdateOp` interface is implemented to enable updating objects on the target system. To implement this interface, provide an implementation of the `update` method as defined in Example 9–31.

**Example 9–31**  `update` Method Signature

```java
public Uid update(ObjectClass oClass, Uid uid,
```
This method takes an ObjectClass (for example, account or group), Uid of the object being updated, a set of object attributes being updated, and operation options. The implementation updates the object on the target system identified by the Uid with the new values of attributes. If the object identified by the Uid does not exist on the target system, then an UnknowUidException is generated. **Example 9–32** illustrates how to implement the update method.

**Example 9–32  update Method Implementation**

```java
@Override
public Uid update(ObjectClass arg0, Uid arg1,
        Set<Attribute> arg2, OperationOptions arg3) {
    String accountIdentifier = arg1.getUidValue();
    // Fetch the account
    FlatFileUserAccount accountToBeUpdated = this.flatFileParser
        .getAccount(accountIdentifier);

    // Update
    accountToBeUpdated.updateAttributes(arg2);
    this.flatFileWriter
        .modifyAccount(accountIdentifier, accountToBeUpdated);
    log.ok("Account {0} updated", accountIdentifier);

    // Return new uid
    String newAccountIdentifier = accountToBeUpdated
        .getAttributeValue(this.flatFileConfig.getUniqueAttributeName());
    return new Uid(newAccountIdentifier);
}
```

### 9.4.4 Common Classes

There are many ICF classes mentioned in the previous sections. The most important classes are:

- **org.identityconnectors.framework.common.objects.Attribute**

  An Attribute is a named collection of values within a target system object. A target system object may have many attributes and each may have many values. In its simplest form, an Attribute can be considered a name-value pair of a target system object. Empty and null values are supported. The developer should use org.identityconnectors.framework.common.objects.AttributeBuilder to construct Attribute instances.

  **Note:** All attributes are syntactically multivalued in this model. A particular attribute being singlevalued is only a semantic restriction.

- **org.identityconnectors.framework.common.objects.Uid**

  A single-valued Attribute (Uid is a subclass of Attribute) that represents the unique identifier of an object on the target resource. Ideally, it should be immutable.
Introducing the ICF SPI

- org.identityconnectors.framework.common.objects.ObjectClass
  
  An ObjectClass defines the type of the object on the target system. Account, group, or organization are examples of such types. ICF defines predefined ObjectClasses for account (ObjectClass.ACCOUNT) and group (ObjectClass.GROUP).

- org.identityconnectors.framework.common.objects.ConnectorObject
  
  A ConnectorObject represents an object (for example, an account or group) on the target system. The developer must use org.identityconnectors.framework.common.objects.ConnectorObjectBuilder to construct a ConnectorObject.

- org.identityconnectors.common.security.GuardedString
  
  A guarded string is a secure String implementation which solves the problem of storing passwords in memory in a plain String format. Passwords are stored as Bytes in an encrypted format. The encryption key will be randomly generated.

- org.identityconnectors.framework.common.objects.filter.FilterTranslator
  
  A FilterTranslator object is responsible for converting all the filters specified on the API side of the ICF into native queries during a search operation. ICF Filters support both search predicates and logical operators:
  - Search predicates match objects based on the values of a specified attribute. For example, an EqualsFilter returns true when at least one value of an attribute is equal to a specified value.
  - Logical operators AND and OR join search predicates to build complex expressions. For example, an expression of the form "A AND B" is true only if both A and B are true. An expression of the form "A OR B" is true if at least one of A or B is true.

  The ICF provides the AbstractFilterTranslator<T> base class to make search implementation easier. A FilterTranslator sub class should override the following whenever possible.
  - createAndExpression(T, T)
  - createOrExpression(T, T)
  - createContainsExpression(ContainsFilter, boolean)
  - createEndsWithExpression(EndsWithFilter, boolean)
  - createEqualsExpression(EqualsFilter, boolean)
  - createGreaterThanExpression(GreaterThanFilter, boolean)
  - createGreaterThanOrEqualExpression(GreaterThanOrEqualFilter, boolean)
  - createStartsWithExpression(StartsWithFilter, boolean)
  - createContainsAllValuesExpression(ContainsAllValuesFilter, boolean)

  For more information see Section 9.4.3.4, "Implementing the SearchOp Interface."

- org.identityconnectors.framework.common.objects.ResultsHandler
  
  This is a callback interface for operations returning one or more results. The sub class should provide an implementation to the handle method whereas the caller

---

**Note:** A singlevalued attribute is particularly relevant to UID being a unique identifier.
can decide what to do with the results. Currently, this is used only by the SearchOp interface. For more information, see Section 9.4.3.4, "Implementing the SearchOp Interface."

## 9.5 Extending an Identity Connector Bundle

An identity connector bundle is the specific implementation for a particular target system. The bundle is a Java archive (JAR) that contains all the files required by the identity connector to connect to the target system and perform operations. It also has special attributes (defined in the MANIFEST file) that are recognized by the ICF. These are:

- **ConnectorBundle-FrameworkVersion** is the minimum version of the ICF required for this identity connector bundle to work. Newer ICF versions will be backwards compatible.
- **ConnectorBundle-Name** is the unique name for this identity connector bundle; it is generally the package name.
- **ConnectorBundle-Version** is the version of this bundle. Within a given deployment of Oracle Identity Manager, the ConnectorBundle-Name and ConnectorBundle-Version combination should be unique.

You extend an identity connector bundle, for example, to reuse common code. The AbstractDatabaseConnector is a good example, because different types of connectors can reuse the same basic logic that accesses database tables using JDBC. A connector for database tables might share this common code with a connector for Oracle Database users, a connector for IBM DB2 database users, and a connector for MySQL users.

A given Connector can be extended by adding the extended bundle to the /lib directory of a new bundle and creating a new class that subclasses the target class. This can be illustrated with the AbstractDatabaseConnector bundle. The common logic would be in a common bundle as follows:

---

**Note:** You do not extend the original bundle. Instead, you extend the connector by embedding the original bundle in a new bundle that wraps the original bundle.

---

- META-INF/MANIFEST.MF
  - ConnectorBundle-FrameworkVersion: 1.0
  - ConnectorBundle-Name: org.identityconnectors.database.common
  - ConnectorBundle-Version: 1.0
- org.identityconnectors/database/common/AbstractDatabaseConnector.class

---

**Note:** This identity connector would not have a @ConnectorClass annotation.

---

- org/identityconnectors/database/common/* (other common source files)
- lib/

There would be as many database (resource) specific bundles as needed. For example:
9.6 Using an Identity Connector Server

An identity connector server is required when an identity connector bundle is not directly executed within your application. By using one or more identity connector servers, the ICF architecture permits your application to communicate with externally deployed identity connector bundles. Identity connector servers are available for Java™ and Microsoft .NET Framework applications.

A single connector server can support multiple ICF connectors, and these ICF connectors may be of different connector types. A single ICF connector can be used to communicate with multiple targets.

Figure 9–6 shows how Oracle Identity Manager connectors integrate with resources via ICF connectors:
In Figure 9–6:

- Oracle Identity Manager connectors do not directly interact with the target resource. Instead, the create, read, update, delete, and query (CRUDQ) operations are performed via the appropriate ICF connector.

- A single ICF Connector can be used to connect to multiple resources of the same resource type. In Figure 9–6, an ICF Connector for LDAP is used to connect to a local LDAP resource, as well as being used to connect to a remote LDAP resource.

- The .NET Connector Server is used to deploy .NET ICF Connectors on the target host. An Active Directory resource is connected in this manner.

- An ICF Connector for Google Apps provides a connection to Google Apps across the Internet.

- While not shown in the diagram, a Connector Server can support multiple ICF Connectors of different resource types.

The types of connector servers are described in the following sections:

- Using the Java Connector Server
- Using the Microsoft .NET Framework Connector Server
9.6.1 Using the Java Connector Server

A Java Connector Server is used when you do not want to execute a Java Connector Bundle in the same Java Virtual Machine (JVM) as the application. This deployment may be beneficial in terms of performance as the bundle works faster when deployed on the same host as the managed target system. In addition, use Java Connector Server to eliminate possibility of an application JVM crash because of faulty JNI-based connector.

Using the Java connector server is described in the following sections:

- Installing and Configuring a Java Connector Server
- Running the Java Connector Server on Microsoft Windows
- Running the Java Connector Server on Solaris and Linux
- Installing an Identity Connector in a Java Connector Server
- Using SSL to Communicate with a Connector Server

9.6.1.1 Installing and Configuring a Java Connector Server

To install and configure the Java Connector Server:

1. Create a new directory on the computer on which you want to install the Java Connector Server. In this section, CONNECTOR_SERVER_HOME represents this directory.

2. Unzip the Java Connector Server package in your new directory from Step 1. Java Connector Server is available for download in the Oracle Technology Network Web site at the following URL:

   http://www.oracle.com/technetwork/index.html

3. In the ConnectorServer.properties file in the conf/ directory, set the properties as required by your deployment. Table 9–1 lists the properties in the ConnectorServer.properties file:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectorserver.port</td>
<td>This is a common property for denoting both SSL and non-SSL connector server port. If the connectorserver.useSSL property is set to true, then the connector server listens on a secure channel using the same port. The default SSL and non-SSL port number is 8759. To change the default connector server port (SSL or non-SSL), update the connectorserver.bundleDir property with the new port number in the ConnectorServer.properties file.</td>
</tr>
<tr>
<td>connectorserver.bundleDir</td>
<td>Directory where the connector bundles are deployed. The default value is bundles.</td>
</tr>
</tbody>
</table>
4. Set the properties in the ConnectorServer.properties file, as follows:

- To set connectorserver.key, run the Java Connector Server with the /setKey option. See "Running the Java Connector Server on Microsoft Windows" on page 9-27 and "Running the Java Connector Server on Solaris and Linux" on page 9-28 for more information.
- For all other properties, edit the ConnectorServer.properties file manually.

5. The conf directory also contains the logging.properties file, which you can edit if required by your deployment.

9.6.1.2 Running the Java Connector Server on Microsoft Windows

To run the Java Connector Server on Microsoft Windows, use the ConnectorServer.bat script, as follows:

1. Make sure that you have set the properties required by your deployment in the ConnectorServer.properties file, as described in "Installing and Configuring a Java Connector Server" on page 9-26.

2. Change to the CONNECTOR_SERVER_HOME\bin directory and find the ConnectorServer.bat script.

Table 9–2 lists the options supported by the ConnectorServer.bat script:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/install [serviceName]</td>
<td>Installs the Java Connector Server as a Microsoft Windows service. Optionally, you can specify a service name and Java options. If you do not specify a service name, then the default name is ConnectorServerJava.</td>
</tr>
<tr>
<td>-J java-option</td>
<td>&quot;-J java-option&quot;</td>
</tr>
</tbody>
</table>

Table 9–1 (Cont.) Properties in the ConnectorServer.properties File

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectorserver.libDir</td>
<td>Directory in which to place dependent libraries. The default value is lib.</td>
</tr>
<tr>
<td>connectorserver.usessl</td>
<td>If set to true, the Java Connector Server uses SSL for secure communication. The default value is false.</td>
</tr>
<tr>
<td></td>
<td>If you specify true, then use the following options on the command line when you start the Java Connector Server:</td>
</tr>
<tr>
<td></td>
<td>-Djavax.net.ssl.keyStore</td>
</tr>
<tr>
<td></td>
<td>-Djavax.net.ssl.keyStoreType (optional)</td>
</tr>
<tr>
<td></td>
<td>-Djavax.net.ssl.keyStorePassword</td>
</tr>
<tr>
<td>connectorserver.ifaddress</td>
<td>Bind address. To set this property, uncomment it in the file, if required. The bind address can be useful if there are more NICs installed on the computer.</td>
</tr>
<tr>
<td>connectorserver.key</td>
<td>Java Connector Server key.</td>
</tr>
</tbody>
</table>
Using an Identity Connector Server

9.6.1.3 Running the Java Connector Server on Solaris and Linux

To run the Java Connector Server on Solaris and Linux, use the connectorserver.sh script, as follows:

1. Make sure that you have set the properties required by your deployment in the ConnectorServer.properties file, as described in "Installing and Configuring a Java Connector Server" on page 9-26.

2. Change to the CONNECTOR_SERVER_HOME/bin directory.

3. Use the 

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/run [&quot;-J java-option&quot;]</td>
<td>Runs the Java Connector Server from the console. Optionally, you can specify one or more Java options. For example, to run the Java Connector Server with SSL:</td>
</tr>
<tr>
<td></td>
<td>ConnectorServer.bat /run&lt;br&gt;-J-Djavax.net.ssl.keyStore=mykeystore.jks&lt;br&gt;-J-Djavax.net.ssl.keyStorePassword=password</td>
</tr>
<tr>
<td>/setKey [key]</td>
<td>Sets the Java Connector Server key. The ConnectorServer.bat script stores the hashed value of the key in the connectorserver.key property in the ConnectorServer.properties file.</td>
</tr>
<tr>
<td>/uninstall [serviceName]</td>
<td>Uninstall the Java Connector Server. If you do not specify a service name, then the script uninstall the ConnectorServerJava service.</td>
</tr>
</tbody>
</table>

3. If you need to stop the Java Connector Server, then stop the respective Microsoft Windows service.

Table 9–3 lists the options supported by the connectorserver.sh script:

9-28   Oracle Fusion Middleware Developer's Guide for Oracle Identity Manager
9.6.1.4 Installing an Identity Connector in a Java Connector Server

This section contains the procedures to deploy a Java Connector Bundle in a Java Connector Server.

1. Change to the bundles directory in your Java Connector Server directory.
2. Copy the Java Connector Bundle JAR to the bundles directory.
3. Add any applicable third party JAR files required by the identity connector to the lib directory.
4. Restart the Java Connector Server.

9.6.1.5 Using SSL to Communicate with a Connector Server

Follow these steps to communicate with a Connector Server using Secure Sockets Layer (SSL).

1. Deploy an SSL certificate to the Connector Server's system.
2. Configure your Connector Server to provide SSL sockets.
3. Configure your application to communicate with the Connector Server using SSL.

Refer to the target system's manual for specific notes on configuring connections to identity connector servers. You will indicate to your application that an SSL connection is required when establishing a connection for each SSL-enabled connector server. Additionally, if any of the SSL certificates used by your connector servers are issued by a non-standard certificate authority, your application must be configured to respect the additional authorities. Refer to your manual for notes regarding certificate authorities.

Table 9–3 (Cont.) Options Supported by the connectordriver.sh Script

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/stop n -force</td>
<td>Stops the Java Connector Server. Waits up to n seconds, and then uses the kill -KILL command if the process is still running.</td>
</tr>
<tr>
<td>/setKey key</td>
<td>Sets the Java Connector Server key. The connectordriver.sh script stores the hashed value of the key in the connectordriver.key property in the ConnectorServer.properties file.</td>
</tr>
</tbody>
</table>

Note: Java applications may solve the issue of non-standard certificate authorities by expecting the following Java system properties to be passed when launching the application:

- javax.net.ssl.trustStorePassword
  For example:
  -Djavax.net.ssl.trustStorePassword=changeit

- javax.net.ssl.trustStore
  For example:
  -Djavax.net.ssl.trustStore=/usr/myApp_cacerts

Alternately, the non-standard certificate authorities may be imported to the standard ${JAVA_HOME}/lib/security/cacerts directory.
9.6.2 Using the Microsoft .NET Framework Connector Server

The use of a Microsoft .NET Framework (.NET) Connector Server is useful when an application is written in Java but a Connector Bundle is written using C#. Because a Java Platform, Enterprise Edition (JEE™) application cannot load C# classes, you can deploy the C# bundles under a .NET Connector Server. The Java application can then communicate with the C# (.NET) Connector Server over the network. The C# (.NET) Connector Server serves as a proxy to provide any authenticated application access to the C# bundles. The following sections contain additional information.

- Installing the .NET Connector Server
- Configuring the .NET Connector Server
- Configuring Trace Settings
- Running the .NET Connector Server
- Installing Multiple Connectors on a .NET Connector Server

9.6.2.1 Installing the .NET Connector Server

The minimum requirements to run a .NET Connector Server are:

- Microsoft Windows Server 2003 or 2008
- Microsoft .NET Framework 3.5 or higher

Refer to the particular .NET identity connector documentation to determine if there are additional requirements.

To install the .NET Connector Server, execute the ServiceInstall.msi file and follow the instructions displayed in the Installation Wizard. Upon completion of the installation, the Connector Server will be installed as a Windows Service.

9.6.2.2 Configuring the .NET Connector Server

Follow this procedure to configure the .NET Connector Server. Common configurations include port, trace and SSL settings as well as the Connector Server key.

1. Start the Microsoft Services Console.
2. Check to see if the Connector Server is currently running. If yes, stop it.
3. Set the key for the Connector Server using the command prompt.
   - This key is required by any client that connects to this Connector Server.
   - Change to the directory in which the Connector Server was installed. By default: \Program Files\Identity Connectors\Connector Server
   - Execute the following command:
     ConnectorServer /setkey NEWKEY
     where NEWKEY is the value for the key.
4. Configure additional properties by inspecting the settings in connectorserver.exe.config.

The connectorsserver.exe.config file contains information about the Connector Server. The port, SSL configuration and trace settings are most commonly changed. Port and SSL settings are in a tag called AppSettings as follows:

```
<add key="connectorserver.port" value="8759" />
<add key="connectorsserver.usessl" value="false" />
```
The `connectorserver.port` property is a common key for denoting both SSL and non-SSL connector server port. If the `connectorserver.usessl` property is set to true, then the connector server listens on a secure channel using the same port. The default SSL and non-SSL port number is 8759. To change the default connector server port (SSL or non-SSL), update the `connectorserver.port` property with the new port number in the `connectorserver.exe.config` file.

To use SSL, set the value of `connectorserver.usessl` to true, and set the value of `connectorserver.certificatetestorename` to the name of your certificate store. The listening socket can be bound to a particular address, or can be left as 0.0.0.0. For more information about configuring the Connector Server with SSL, see Section 9.6.1.5, "Using SSL to Communicate with a Connector Server." For information on trace setting configurations, see Section 9.6.2.3, "Configuring Trace Settings."

### 9.6.2.3 Configuring Trace Settings

The Connector Server uses the standard .NET trace mechanism. Trace settings are defined in the `connectorserver.exe.config` configuration file. Example 9–33 illustrates how they are defined.

**Example 9–33 Defined Trace Settings**

```xml
<system.diagnostics>
  <trace autoflush="true" indentsize="4">
    <listeners>
      <remove name="Default" />
      <add name="myListener"
        type="System.Diagnostics.TextWriterTraceListener"
        initializeData="c:\connectorserver2.log"
        traceOutputOptions="DateTime">
        <filter type="System.Diagnostics.EventTypeFilter"
          initializeData="Information" />
      </add>
    </listeners>
  </trace>
</system.diagnostics>
```

The default settings are a good starting point but you may change these settings as follows.

- For less tracing, change the filter type's `initializeData` setting to `Warning` or `Error`.
- For more verbose logging, set the value to `Verbose` or `All`.

**Caution:** The amount of logging performed has a direct effect on the performance of the Connector Servers.

Any configuration changes require that the Connector Server be stopped and restarted.

**Note:** For more information about the tracing options, see Microsoft .NET documentation for System.Diagnostics.
9.6.2.4 Running the .NET Connector Server
The best way to run the .NET Connector Server is as a Windows Service. During installation, the Connector Server is installed as a Windows service. If this is not adequate for your environment, the Connector Server may be installed or uninstalled as a Windows Service by using the /install or /uninstall arguments at the command prompt.

To run the Connector Server interactively, issue the command ConnectorServer /run.

9.6.2.5 Installing Multiple Connectors on a .NET Connector Server
To install new identity connectors, change to the directory where the Connector Server was installed, extract the new identity connector ZIP into it, and restart the Connector Server.
This chapter is a tutorial that walks through the procedures necessary to develop an identity connector using the Identity Connector Framework (ICF) and the Oracle Identity Manager metadata. It includes information about important ICF classes and interfaces, the connector bundle, the connector server, and code samples for implementing a flat file identity connector and creating Oracle Identity Manager metadata for user provisioning and reconciliation processes. It contains the following sections:

- Developing a Flat File Connector
- Uploading the Identity Connector Bundle to Oracle Identity Manager Database
- Provisioning a Flat File Account
- Configuring SSL for Java Connector Server

### 10.1 Developing a Flat File Connector

The procedure for developing a flat file connector is to develop an implementation of the Configuration interface followed by the implementation of the Connector class. Before beginning, you must prepare IO representation modules for all flat file connector operations. This might include all or some of the following:

- Read the column names of the flat file and prepare metadata information.
- Add a record to the flat file with the corresponding column values separated by the specified delimiter.
- Delete a record to the flat file based on the UID value.
- Search operations on flat file.

This tutorial is focused on identity connector development, and therefore, these preparations are not discussed in detail.
To develop a flat file connector:

1. Implement the configuration class for the Flat File Connector by extending the org.identityconnectors.framework.spi.AbstractConfiguration base class.

   Example 10–1 is a sample of this. See Section 9.4.1.2, “org.identityconnectors.framework.spi.Configuration” for more information.

**Example 10–1  Implementation of AbstractConfiguration**

```java
package org.identityconnectors.flatfile;
import java.io.File;
import org.identityconnectors.flatfile.io.FlatFileIOFactory;
import org.identityconnectors.framework.common.exceptions.ConfigurationException;
import org.identityconnectors.framework.spi.AbstractConfiguration;
import org.identityconnectors.framework.spi.ConfigurationProperty;
/**
 * Class for storing the flat file configuration
 */
public class FlatFileConfiguration extends AbstractConfiguration {
    /*
     * Storage file name
     */
    private File storeFile;
    /*
     * Delimeter used
     */
    private String textFieldDelimeter;
    /*
     * Unique attribute field name
     */
    private String uniqueAttributeName = "";
    /*
     * Change attribute field name. Should be numeric
     */
    private String changeLogAttributeName = "";

    public File getStoreFile() {
        return storeFile;
    }

    public String getTextFieldDelimeter() {
        return textFieldDelimeter;
    }

    public String getUniqueAttributeName() {
        return uniqueAttributeName;
    }

    public String getChangeLogAttributeName() {
        return changeLogAttributeName;
    }
}
```

**Note:** The following supporting classes are used for file input and output handling during identity connector operations:

- org.identityconnectors.flatfile.io.FlatFileIOFactory
- org.identityconnectors.flatfile.io.FlatFileMetadata
- org.identityconnectors.flatfile.io.FlatFileParser
- org.identityconnectors.flatfile.io.FlatFileWriter

See “Supporting Classes for File Input and Output Handling” on page 10-9 for the implementations of the input and output handling supporting classes.
public String getChangeLogAttributeName() {
    return changeLogAttributeName;
}

/**
 * Set the store file
 * @param storeFile
 */
@ConfigurationProperty(order = 1, helpMessageKey = "USER_ACCOUNT_STORE_HELP",
    displayMessageKey = "USER_ACCOUNT_STORE_DISPLAY")
public void setStoreFile(File storeFile) {
    this.storeFile = storeFile;
}

/**
 * Set the text field delimeter
 * @param textFieldDelimeter
 */
@ConfigurationProperty(order = 2, helpMessageKey = "USER_STORE_TEXT_DELIM_HELP",
    displayMessageKey = "USER_STORE_TEXT_DELIM_DISPLAY")
public void setTextFieldDelimeter(String textFieldDelimeter) {
    this.textFieldDelimeter = textFieldDelimeter;
}

/**
 * Set the field whose values will be considered as unique attributes
 * @param uniqueAttributeName
 */
@ConfigurationProperty(order = 3, helpMessageKey = "UNIQUE_ATTR_HELP",
    displayMessageKey = "UNIQUE_ATTR_DISPLAY")
public void setUniqueAttributeName(String uniqueAttributeName) {
    this.uniqueAttributeName = uniqueAttributeName;
}

/**
 * Set the field name where change number should be stored
 * @param changeLogAttributeName
 */
@ConfigurationProperty(order = 3, helpMessageKey = "CHANGELOG_ATTR_HELP",
    displayMessageKey = "CHANGELOG_ATTR_DISPLAY")
public void setChangeLogAttributeName(String changeLogAttributeName) {
    this.changeLogAttributeName = changeLogAttributeName;
}

@Override
public void validate() {
    // Validate if file exists and is usable
    boolean validFile = (this.storeFile.exists() &&
        this.storeFile.canRead() &&
        this.storeFile.canWrite() &&
        this.storeFile.isFile());

    if (!validFile)
        throw new ConfigurationException("User store file not valid");

    // Validate if there is a field on name of unique attribute field name
2. Create connector class for the Flat File Connector by implementing the org.identityconnectors.framework.spi.Connector interface.

Example 10–2 implements the CreateOp, DeleteOp, SearchOp and UpdateOp interfaces and thus supports all four operations. The FlatFileMetadata, FlatFileParser and FlatFileWriter classes are supporting classes. Their implementation is not shown as they do not belong to the ICF.

Example 10–2  Implementation of PoolableConnector

```java
package org.identityconnectors.flatfile;

import java.util.HashSet;
import java.util.Iterator;
import java.util.List;
import java.util.Map;
import java.util.Set;
import org.identityconnectors.flatfile.io.FlatFileIOFactory;
import org.identityconnectors.flatfile.io.FlatFileMetadata;
import org.identityconnectors.flatfile.io.FlatFileParser;
import org.identityconnectors.flatfile.io.FlatFileWriter;
import org.identityconnectors.framework.api.operations.GetApiOp;
import org.identityconnectors.framework.common.exceptions.AlreadyExistsException;
import org.identityconnectors.framework.common.exceptions.ConnectorException;
import org.identityconnectors.framework.common.objects.Attribute;
import org.identityconnectors.framework.common.objects.AttributeInfo;
import org.identityconnectors.framework.common.objects.AttributeInfoBuilder;
import org.identityconnectors.framework.common.objects.ConnectorObject;
import org.identityconnectors.framework.common.objects.ConnectorObjectBuilder;
import org.identityconnectors.framework.common.objects.ObjectClass;
import org.identityconnectors.framework.common.objects.OperationOptions;
import org.identityconnectors.framework.common.objects.ResultsHandler;
import org.identityconnectors.framework.common.objects.Schema;
import org.identityconnectors.framework.common.objects.SchemaBuilder;
import org.identityconnectors.framework.common.objects.Uid;
import org.identityconnectors.framework.common.objects.filter.AbstractFilterTranslator;
import org.identityconnectors.framework.common.objects.filter.FilterTranslator;
import org.identityconnectors.framework.spi.Configuration;
import org.identityconnectors.framework.spi.ConnectorClass;
import org.identityconnectors.framework.spi.operations.CreateOp;
import org.identityconnectors.framework.spi.operations.DeleteOp;
import org.identityconnectors.framework.spi.operations.SchemaOp;
import org.identityconnectors.framework.spi.operations.SearchOp;
import org.identityconnectors.framework.spi.operations.UpdateOp;

/**
 * The main connector class
 */
@ConnectorClass(configurationClass = FlatFileConfiguration.class, displayNameKey =
```
public class FlatFileConnector implements SchemaOp, CreateOp, DeleteOp, UpdateOp, SearchOp<Map<String, String>>, GetApiOp, PoolableConnector {
    private FlatFileConfiguration flatFileConfig;
    private FlatFileMetadata flatFileMetadata;
    private FlatFileParser flatFileParser;
    private FlatFileWriter flatFileWriter;
    private boolean alive = false;

    @Override
    public Configuration getConfiguration() {
        return this.flatFileConfig;
    }

    @Override
    public void init(Configuration config) {
        this.flatFileConfig = (FlatFileConfiguration) config;
        FlatFileIOFactory flatFileIOFactory = FlatFileIOFactory.getInstance(flatFileConfig);
        this.flatFileMetadata = flatFileIOFactory.getMetadataInstance();
        this.flatFileParser = flatFileIOFactory.getFileParserInstance();
        this.flatFileWriter = flatFileIOFactory.getFileWriterInstance();
        this.alive = true;
        System.out.println("init called: Initialization done");
    }

    @Override
    public void dispose() {
        this.alive = false;
    }

    @Override
    public Schema schema() {
        SchemaBuilder flatFileSchemaBldr = new SchemaBuilder(this.getClass());
        Set<AttributeInfo> attrInfos = new HashSet<AttributeInfo>();
        for (String fieldName : flatFileMetadata.getOrderedTextFieldNames()) {
            AttributeInfoBuilder attrBuilder = new AttributeInfoBuilder();
            attrBuilder.setName(fieldName);
            attrBuilder.setCreateable(true);
            attrBuilder.setUpdateable(true);
            attrInfos.add(attrBuilder.build());
        }

        // Supported class and attributes
        flatFileSchemaBldr.defineObjectClass
            (ObjectClass.ACCOUNT.getDisplayNameKey(), attrInfos);
        System.out.println("schema called: Built the schema properly");
        return flatFileSchemaBldr.build();
    }

    @Override
    public Uid create(ObjectClass arg0, Set<Attribute> attrs, OperationOptions ops) {
        System.out.println("Creating user account " + attrs);
        assertUserObjectClass(arg0);
        try {
            FlatFileUserAccount accountRecord = new FlatFileUserAccount(attrs);
            return accountRecord;
        } finally {
            if (accountRecord != null) {
                accountRecord.dispose();
            }
        }
    }
}
// Assert uid is there
assertUidPresence(accountRecord);

// Create the user
this.flatFileWriter.addAccount(accountRecord);

// Return uid
String uniqueAttrField = this.flatFileConfig
    .getUniqueAttributeName();
String uniqueAttrVal = accountRecord
    .getAttributeValue(uniqueAttrField);
System.out.println("User "+ uniqueAttrVal + " created");

return new Uid(uniqueAttrVal);
} catch (Exception ex) {

    // If account exists
    if (ex.getMessage().contains("exists"))
        throw new AlreadyExistsException(ex);

    // For all other causes
    System.out.println("Error in create "+ ex.getMessage());
    throw ConnectorException.wrap(ex);
}

@Override
public void delete(ObjectClass arg0, Uid arg1, OperationOptions arg2) {
    final String uidVal = arg1.getUidValue();
    this.flatFileWriter.deleteAccount(uidVal);
    System.out.println("Account "+ uidVal + " deleted");
}

@Override
public Uid update(ObjectClass arg0, Uid arg1, Set<Attribute> arg2,
    OperationOptions arg3) {
    String accountIdentifier = arg1.getUidValue();
    // Fetch the account
    FlatFileUserAccount accountToBeUpdated = this.flatFileParser
        .getAccount(accountIdentifier);

    // Update
    accountToBeUpdated.updateAttributes(arg2);
    this.flatFileWriter
        .modifyAccount(accountIdentifier, accountToBeUpdated);
    System.out.println("Account "+ accountIdentifier + " updated");

    // Return new uid
    String newAccountIdentifier = accountToBeUpdated
        .getAttributeValue(this.flatFileConfig.getUniqueAttributeName());
    return new Uid(newAccountIdentifier);
}

@Override
public FilterTranslator<Map<String, String>> createFilterTranslator(
    ObjectClass arg0, OperationOptions arg1) {
    // TODO: Create a fine grained filter translator

    // Return a dummy object as its not applicable here.
    // All processing happens in the execute query
return new AbstractFilterTranslator<Map<String, String>>() {
    @Override
    public ConnectorObject getObject(ObjectClass arg0, Uid uid,
            OperationOptions arg2) {
        // Return matching record
        String accountIdentifier = uid.getUidValue();
        FlatFileUserAccount userAcc = this.flatFileParser
                .getAccount(accountIdentifier);
        ConnectorObject userAccConnObject = convertToConnectorObject(userAcc);
        return userAccConnObject;
    }

    @Override
    public void executeQuery(ObjectClass objectClass,
            Map<String, String> matchSet, ResultsHandler resultHandler,
            OperationOptions ops) {
        System.out.println("Inside executeQuery");
        // Iterate over the records and handle individually
        Iterator<FlatFileUserAccount> userAccountIterator = this.flatFileParser
                .getAccountIterator(matchSet);

        while (userAccountIterator.hasNext()) {
            FlatFileUserAccount userAcc = userAccountIterator.next();
            ConnectorObject userAccObject = convertToConnectorObject(userAcc);
            if (!resultHandler.handle(userAccObject)) {
                System.out.println("Not able to handle " + userAcc);
                break;
            }
        }
    }

    private void assertUserObjectClass(ObjectClass arg0) {
        if (!arg0.equals(ObjectClass.ACCOUNT))
            throw new UnsupportedOperationException("Only user account operations supported.");
    }

    private void assertUidPresence(FlatFileUserAccount accountRecord) {
    }
}
Developing a Flat File Connector

String uniqueAttrField = this.flatFileConfig.getUniqueAttributeName();
String uniqueAttrVal = accountRecord.getAttributeValue(uniqueAttrField);

if (uniqueAttrVal == null) {
    throw new IllegalArgumentException("Unique attribute not passed");
}

private ConnectorObject convertToConnectorObject(FlatFileUserAccount userAcc) {
    ConnectorObjectBuilder userObjBuilder = new ConnectorObjectBuilder();
    // Add attributes
    List<String> attributeNames = this.flatFileMetadata.getOrderedTextFieldNames();
    for (String attributeName : attributeNames) {
        String attributeVal = userAcc.getAttributeValue(attributeName);
        userObjBuilder.addAttribute(attributeName, attributeVal);

        if (attributeName.equals(this.flatFileConfig.getUniqueAttributeName())) {
            userObjBuilder.setUid(attributeVal);
            userObjBuilder.setName(attributeVal);
        }
    }
    return userObjBuilder.build();
}

@Override
public void checkAlive() {
    if (!alive)
        throw new RuntimeException("Connection not alive");
}

3. This connector supports only the ContainsAllValuesFilter operation. Implement the ContainsAllValuesFilter operation. Example 10–3 illustrates the sample implementation of org.identityconnectors.framework.common.objects.filter.AbstractFilterTranslator<T> that defines the filter operation.

Example 10–3 Implementation of AbstractFilterTranslator<T>

package org.identityconnectors.flatfile.filteroperations;

import java.util.HashMap;
import java.util.Map;
import org.identityconnectors.framework.common.objects.Attribute;
import org.identityconnectors.framework.common.objects.filter.AbstractFilterTranslator;
import org.identityconnectors.framework.common.objects.filter.ContainsAllValuesFilter;

public class ContainsAllValuesImpl extends AbstractFilterTranslator<Map<String, String>> {
    @Override
    protected Map<String, String> createContainsAllValuesExpression(
        ContainsAllValuesFilter filter, boolean not) {
        Map<String, String> containsAllMap = new HashMap<String, String>();
    }
}
Attribute attr = filter.getAttribute();
containsAllMap.put(attr.getName(), attr.getValue().get(0).toString());
return containsAllMap;
}

4. Create the connector bundle JAR. The MANIFEST.MF file must contain the following entries:
   - ConnectorBundle-FrameworkVersion
   - ConnectorBundle-Name
   - ConnectorBundle-Version

   Example 10–4 shows the contents of the MANIFEST.MF file:

   ```
   Example 10–4  The MANIFEST.MF File
   Manifest-Version: 1.0
   Ant-Version: Apache Ant 1.7.0
   Created-By: 14.1-b02 (Sun Microsystems Inc.)
   ConnectorBundle-FrameworkVersion: 1.0
   ConnectorBundle-Name: org.identityconnectors.flatfile
   ConnectorBundle-Version: 1.0
   Build-Number: 609
   Subversion-Revision: 4582
   ```

5. Update the connector bundle JAR as created in step 4. To do so:
   a. Extract the connector bundle JAR into any desired location.
   b. Create a lib directory in the directory in which you extracted the JAR.
   c. Add the dependent third-party JARs into the lib directory.
   d. JAR the entire directory.

   **Note:** The MANIFEST.MF file must contain the entries listed in step 4.

### 10.1.1 Supporting Classes for File Input and Output Handling

This section shows the implementation of the following supporting classes for file input and output handling:

- Example 10–5, "FlatFileIOFactory"
- Example 10–6, "FlatFileMetadata"
- Example 10–7, "FlatFileParser"
- Example 10–8, "FlatFileWriter"
- Example 10–9, "FlatfileLineIterator"
- Example 10–10, "FlatfileUserAccount"
- Example 10–11, "FlatfileAccountConversionHandler"
- Example 10–12, "Messages.Properties"

Example 10–5 shows the implementation of the FlatFileIOFactory supporting class:
Example 10–5  FlatFileIOFactory

```java
package org.identityconnectors.flatfile.io;

import org.identityconnectors.flatfile.FlatFileConfiguration;

public class FlatFileIOFactory {

    private FlatFileMetadata flatFileMetadata;
    private FlatFileConfiguration flatFileConfig;

    /**
     * Provides instance of the factory
     * @param fileConfig Configuration bean for the flat file
     */
    public static FlatFileIOFactory getInstance(FlatFileConfiguration fileConfig) {
        return new FlatFileIOFactory(fileConfig);
    }

    /**
     * Making it private to avoid public instantiation. Encouraging use of getInstance
     * @param fileConfig
     */
    private FlatFileIOFactory(FlatFileConfiguration fileConfig) {
        this.flatFileConfig = fileConfig;
        this.flatFileMetadata = new FlatFileMetadata(flatFileConfig);
        System.out.println("Metadata set");
    }

    /**
     * Returns the metadata instance
     * @return
     */
    public FlatFileMetadata getMetadataInstance() {
        return this.flatFileMetadata;
    }

    /**
     * Returns the FlatFileParser instance
     * @return
     */
    public FlatFileParser getFileParserInstance() {
        return new FlatFileParser(this.flatFileMetadata, this.flatFileConfig);
    }

    /**
     * Returns the FlatFileWriter instance
     * @return
     */
    public FlatFileWriter getFileWriterInstance() {
        return new FlatFileWriter(this.flatFileMetadata, this.flatFileConfig);
    }
}
```

Example 10–6 shows the implementation of the FlatFileMetaData supporting class:

Example 10–6  FlatFileMetadata

```java
package org.identityconnectors.flatfile.io;
```
import java.io.BufferedReader;
import java.io.File;
import java.io.FileReader;
import java.io.IOException;
import java.util.ArrayList;
import java.util.List;
import java.util.StringTokenizer;
import org.identityconnectors.flatfile.FlatFileConfiguration;

/**
 * This class contains all the metadata related information Example: Ordering of
 * columns, Number of columns etc.
 *
 * @author harsh
 */
public class FlatFileMetadata {

    private FlatFileConfiguration fileConfig;
    private List<String> orderedTextFieldNames;
    private String changeLogFieldName;
    private String uniqueAttributeFiledName;

    /**
     * Instantiates the class with the file configuration.
     * Making it package private to encourage instantiation from Factory class
     * @param fileConfig
     */
    FlatFileMetadata(FlatFileConfiguration fileConfig) {
        this.fileConfig = fileConfig;
        initializeMetadata();
        validateConfigProps();
    }

    /**
     * Returns the text field names in the order of their storage
     * @return
     */
    public List<String> getOrderedTextFieldNames() {
        return this.orderedTextFieldNames;
    }

    /**
     * Returns the number of columns
     */
    public int getNumberOfFields() {
        int numberOfTextFields = this.orderedTextFieldNames.size();
        return numberOfTextFields;
    }
}
/**
 * Specifies if number of tokens are matching with the standard length of metadata
 * @param countTokens
 * @return
 */
public boolean isDifferentFromNumberOfFields(int countTokens) {
    return (getNumberOfFields() != countTokens);
}

/**
 * Reads the header line and sets the metadata
 */
private void initializeMetadata() {
    // Read the file.
    File recordsStore = this.fileConfig.getStoreFile();
    try {
        BufferedReader storeFileReader = new BufferedReader(new FileReader(
            recordsStore.getAbsolutePath()));

        // Read the header line
        String headerString = storeFileReader.readLine();

        // Tokenize the headerString
        StringTokenizer tokenizer = new StringTokenizer(headerString,
            fileConfig.getTextFieldDelimeter());

        this.orderedTextFieldNames = new ArrayList<String>();
        while (tokenizer.hasMoreTokens()) {
            String header = tokenizer.nextToken();

10.2 Uploading the Identity Connector Bundle to Oracle Identity Manager Database

The identity connector bundle must be available to ICF in Oracle Identity Manager database. Follow the list of sections in order to integrate the ICF identity connector with Oracle Identity Manager. Some of the procedures include configuration by using the Oracle Identity Manager Design Console.

■ Registering the Connector Bundle with Oracle Identity Manager
■ Creating Basic Identity Connector Metadata
■ Creating Provisioning Metadata
■ Creating Reconciliation Metadata

10.2.1 Registering the Connector Bundle with Oracle Identity Manager

The connector bundle must be available for the Connector Server local to Oracle Identity Manager. Following is the procedure to accomplish this:

1. Copy the connector bundle JAR to the machine on which Oracle Identity Manager is installed.
2. Run the following command to upload the JAR.
$MW_HOME/server/bin/UploadJars.sh

3. Select ICFBundle as the JAR type.
4. Enter the location of the connector bundle JAR.
5. Press Enter.

10.2.2 Creating Basic Identity Connector Metadata

This metadata configuration is needed for both provisioning and reconciliation. The set of procedures in this section are completed by using the Oracle Identity Manager Design Console.

- Creating the IT Resource Type Definition
- Creating the Resource Object
- Creating the Main Configuration Lookup
- Creating Object Type Configuration Lookup

10.2.2.1 Creating the IT Resource Type Definition

An IT resource type definition is the representation of a resource’s connection information. The configuration parameters in the IT resource type definition should be matched with the configuration parameters of the connector bundle. The values of the parameters in the IT resource will be set in the bundle configuration.

Note: You may include parameters the bundle configuration is not using. They produce no negative effects on the bundle operations.

1. Log in to the Oracle Identity Manager Design Console.
2. Click IT Resource Type Definition under Resource Management.
3. Create a new IT Resource Type Definition with the Server Type defined as Flat File.
4. Add the following parameters as illustrated in Figure 10–1.
   - **Configuration Lookup** is the marker of the main configuration lookup for the resource. The name of the parameter must be Configuration Lookup. It is a good practice to add a value to Default Field Value.
   - **textFieldDelimeter** maps to the textFieldDelimeter parameter in the bundle configuration. The value of this parameter will be passed.
   - **storeFile** maps to the storeFile parameter in the bundle configuration. The value of this parameter will be passed.
10.2.2.2 Creating the Resource Object

The resource object is the Oracle Identity Manager representation of a resource. The connector bundle is tied to the resource object.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Resource Objects under Resource Management.
3. Create a new resource object with the name FLATFILERO.

As the resource object is a target resource don’t check the Trusted Source box as illustrated in Figure 10–2.
10.2.2.3 Creating Lookups

Separate lookups have to be defined for different objects supported by the connector bundle. This lookup can contain provisioning and reconciliation related information for those objects. The Main Configuration Lookup is the root for object specific lookups as it contains the pointers to those lookups. The following sections contain information on how to create lookups.

- Creating the Main Configuration Lookup
- Creating Object Type Configuration Lookup

10.2.2.3.1 Creating the Main Configuration Lookup The Configuration Lookup (as defined in Section 10.2.2.1, "Creating the IT Resource Type Definition") holds connector bundle configurations that are not counted as connection information. If a configuration parameter is not found in the IT Resource Type Definition, Oracle Identity Manager will look in the Configuration Lookup. The main Configuration Lookup contains bundle properties and bundle configurations. Bundle Property parameters are mandatory as they are needed for identifying the correct bundle. Bundle configurations that are not defined as part of the IT resource type definition (discussed in Section 10.2.2.1, "Creating the IT Resource Type Definition") can be declared here.

**Note:** The values for Code Key should match exactly as illustrated. The values for Decode are specific to the connector bundle.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Lookup Definition under Administration.
3. Create a new lookup and add Lookup.FF.Configuration as the value for Code.
4. Add the following Lookup Code Information as illustrated in Figure 10–3.
   - Add VERSION as the required Bundle Version.
   - Add org.identityconnectors.flatfile as the required Bundle Name.
   - Add org.identityconnectors.flatfile.FlatFileConnector as the required Connector Name.
   - Add AccountId as the value of uniqueAttributeName. AccountId is a unique string identifier that represents the account to be provisioned or reconciled. It is the name of the column in the flat file. AccountId is unique and is used to represent a user (account detail) uniquely.
   - Add ChangeNumber as the value of changeLogAttributeName. When an account is created, a number is attached to it indicating the total accounts created. This value is maintained in the variable called ChangeNumber.
   - OBJECT_TYPE_NAME Configuration Lookup is the configuration lookup for the particular object type. In this example, the object type is User as User Configuration Lookup is defined.
10.2.2.3.2 Creating Object Type Configuration Lookup  
Object type configuration lookup contains the parameters specific to the particular object type. Object type is an entity over which an identity connector operates. It is mapped to ICF ObjectClass. In Section 10.2.2.3.1, "Creating the Main Configuration Lookup," User Configuration Lookup has been referenced so that User is the object type, in this case mapped to ObjectClass.ACCOUNT. (Roles and UserJobData are two other object types.) The object type name has to match with ObjectClass name supported by the identity connector bundle. The User object type is mapped to predefined ObjectClass.ACCOUNT, the Group object type is mapped to predefined ObjectClass.GROUP. If the identity connector supports multiple objects, then this step must be repeated for each.

Note: Because these use cases cover only the basic functionality, the configuration is kept to the mandatory attribute.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Lookup Definition under Administration.
3. Create a new Lookup and add Lookup.FF.UM.Configuration as the Code.
4. Set the following attributes as illustrated in Figure 10–4.

Note: This tutorial focuses on the minimum configurations needed to run an identity connector.

- **Provisioning Attribute Map** takes a value of Lookup.FF.UM.ProvAttrMap. This lookup contains the mapping between Oracle Identity Manager fields and identity connector attributes. The mapping is used during provisioning.
- **Reconciliation Attribute Map** takes a value of Lookup.FF.UM.ReconAttributeMap. This lookup contains the mapping...
between Oracle Identity Manager reconciliation fields and identity connector attributes. The mapping is used during reconciliation.

**Figure 10–4 Second Lookup Definition in Design Console**

10.2.3 Creating Provisioning Metadata

The following sections should be followed in order to configure Oracle Identity Manager for flat file provisioning.

- Creating a Process Form
- Creating Adapters
- Creating A Process Definition
- Creating a Provisioning Attribute Mapping Lookup

10.2.3.1 Creating a Process Form

A process form is used as the representation of object attributes on Oracle Identity Manager. This facilitates user input to set object attributes before passed to the connector bundle for an operation.

Attributes defined in the process form are not conventions. The form is a way to challenge the attributes that need to be passed to the identity connector. In general, define an attribute for each supported attribute in the identity connector.

**Note:** It is good practice to have a one to one mapping on the identity connector attributes.
There should be a field for querying the IT resource that should be associated with the respective IT Resource Type Definition. Variable type of each field should map to the type of the object attribute.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Form Designer under Development Tools.
3. Create a new form with the Table Name UD_FLAT_FIL as illustrated in Figure 10–5.

Figure 10–5  Form Designer in Design Console

4. Add the attributes defined in the connector schema, as listed in Table 10–1.

<table>
<thead>
<tr>
<th>Name</th>
<th>Variant</th>
<th>Field Label</th>
<th>Field Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>UD_FLAT_FIL_FIRSTNAME</td>
<td>String</td>
<td>First Name</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLAT_FIL_UID</td>
<td>String</td>
<td>Universal ID</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLAT_FIL_CHANGENO</td>
<td>String</td>
<td>Change Number</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLAT_FIL_MAILID</td>
<td>String</td>
<td>Email ID</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLAT_FIL_SERVER</td>
<td>long</td>
<td>Server</td>
<td>ITResource</td>
</tr>
<tr>
<td>UD_FLAT_FIL_LASTNAME</td>
<td>String</td>
<td>Last Name</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLAT_FIL_ACCOUNTID</td>
<td>String</td>
<td>Account ID</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLAT_FIL_RETURN</td>
<td>String</td>
<td>Return ID</td>
<td>TextField</td>
</tr>
</tbody>
</table>
5. Click the Properties tab.
6. Add the following properties to Server(ITResourceLookupField) as illustrated in Figure 10–6.
   - Required = true
   - Type = Flat File

![Figure 10–6  Properties of Form Designer in Design Console](image)

7. Save the form.
8. Click Make Version Active.

### 10.2.3.2 Creating Adapters
An adapter has to be created for all operations supported by the connector bundle, including Create, Update, and Delete.

1. Log in to the Oracle Identity Manager Design Console.
2. Click **Adapter Factory** under Development Tools.
3. Create a new adapter and add FFCreateUser as the Adapter Name.
4. Add Process Task as the Adapter Type.
5. Save the adapter.
6. Click the **Variable List** tab and add the following variables, as shown in Figure 10–7.

---

**Note:** The flat file column names are FirstName, ChangeNo, EmailID, Server, LastName, and AccountID.
- objectType with Type String and Mapped as Resolve at runtime.
- processInstanceKey with Type long and Mapped as Resolve at runtime.
- itResourceFieldName with Type String and Mapped as Resolve at runtime.

Figure 10–7  Adapter Factory Variable List in Design Console

7. Add a Java functional task to the adapter by following this sub procedure, as shown in Figure 10–8.
   a. Click the Adapter Tasks tab.
   b. Select the adapter and click Add.
   c. Select Java from the task options.
   d. Select icf-oim-intg.jar from the API source.
   e. Select oracle.iam.connetors.icfcommon.prov.ICProvisioninManager as the API Source.
   f. Select createObject as the method for the task.
   g. Save the configurations.
   h. Map the variables (previously added to the Variables List) against the appropriate method inputs and outputs.
   i. Map the configuration parameters against the appropriate method inputs and outputs.

Database Reference maps to Database Reference (Adapter References) and Return Variable maps to Return Variable (Adapter Variables).
8. Save and build the adapter.

10.2.3.3 Creating A Process Definition

Process Definition defines the behavior of the connector bundle for a particular operation. Every operation has a corresponding task associated with it. This procedure will configure the process definition and integration of the process task for the Create operation.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Process Definition under the Process Management tab.
3. Create a new process definition and name it Flat File as illustrated in Figure 10–9.
4. Select Provisioning as the Type of process.

5. Provide the resource Object Name for the identity connector; in this example, FLATFILERO.

6. Provide the process form Table Name; in this example, UD_FLAT_FIL.

7. Add a process task and name it Create User.

8. Double click Create User to edit as illustrated in Figure 10–10.
9. Click the **Integration** tab.

10. Click Add and select the FFCreateUser adapter from the list as illustrated in Figure 10–11.

    The adapter will be available only after it is compiled.

*Figure 10–11  Integration Tab in Design Console*

11. Map the variables as follows to set the response code returned by the identity connector.

    - Adapter Return Variable – Response Code
    - Object Type – [Literal:String] User (Name of the object type)
    - IT Resource Field Name – [Literal:String] UD_FLAT_FIL_SERVER (Form field name that contains the IT resource information)

12. Click the Responses tab and configure the responses as illustrated in Figure 10–12.

    - **UNKNOWN** can be described as *Unknown response received* with a status of R (Rejected).
    - **SUCCESS** can be described as *Operation completed* with a status of C (Completed).
    - **ERROR** can be described as *Error occurred* with a status of R.
13. Click the Task to Object Status Mapping tab.

14. Update the Object Status to Provisioned for Status C, as shown in Figure 10–13:

15. Save the process task.

10.2.3.4 Creating a Provisioning Attribute Mapping Lookup

Provisioning Attribute Mapping Lookup contains mappings of Oracle Identity Manager fields to identity connector bundle attributes. In the Provisioning Attribute Mapping Lookup:

- Code keys are Field Labels of the process form.
- Decodes are identity connector bundle attributes.
- Child form attributes can be configured as embedded objects in inputs.
- The identity connector's provisioning operation returns the UID in response. This can be set in a form field by coding it against the identity connector bundle attribute.
Following is the procedure to create a Provisioning Attribute Mapping Lookup.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Lookup Definition under the Administration tab.
3. Create a new lookup and name it Lookup.FF.UM.ProvAttrMap.
   The name of this lookup is referred from the object type configuration lookup. See Section 10.2.2.3.2, "Creating Object Type Configuration Lookup.”
4. Add the form Field Labels as the code keys and identity connector bundle attributes as the decode.
   - Return ID : __UID__
   - Account ID: AccountId
   - Change Number: ChangeNumber
   - First Name: FirstName
   - Last Name: LastName
   - Email ID: MailId

10.2.3.4.1 Field Flags Used in the Provisioning Attributes Map

For provisioning attributes mapping, the following field flags can be appended to the code key:

- **LOOKUP**: This must be specified for all fields whose values are obtained by running a lookup reconciliation job. The values obtained from lookup reconciliation job have IT Resource Name/Key appended to it. Specifying this flag helps ICF integration to remove the appended value just before passing them onto the bundle. For example, the code key for a field with label Database whose value is obtained by running a lookup reconciliation job looks similar to Database[LOOKUP].

  **Note**: The LOOKUP flag can be specified for both Provisioning and Reconciliation Attribute Map. For provisioning, IT Resource Name/IT Resource Key prefix must be removed. For reconciliation, IT Resource Name/IT Resource Key prefix must be added.

- **IGNORE**: This must be specified for all fields whose values are to be ignored and not sent to bundle. For example, the code key for a field with label Database whose value need not be sent to bundle looks similar to Database[IGNORE].

- **WRITEBACK**: This must be specified for all fields whose values need to be written back into the process form right after the create or update operation. Adding this flag makes the ICF integration layer call ICF Get API to get values of attributes marked with the WRITEBACK flag. For example, the code key for a field with label Database whose value needs to be written back to the process form right after create/update looks similar to Database[WRITEBACK]. For this to work, the connector must implement the GetApiOp interface and provide an implementation for the ConnectorObject getObject(ObjectClass objClass,Uid uid,OperationOptions options) API. This API searches the target for the account whose Uid is equal to the passed in Uid, and builds a connector object containing all the attributes (and their values) that are to be written back to process form.
10.2.4 Creating Reconciliation Metadata

This section contains the procedures to configure the reconciliation of records from the flat file. We will use the target reconciliation as an example; trusted reconciliation can also be configured in a similar fashion. Do the procedures in the listed order.

1. Creating a Reconciliation Schedule Task
2. Creating a Reconciliation Profile
3. Setting a Reconciliation Action Rule
4. Creating Reconciliation Mapping
5. Defining a Reconciliation Matching Rule

10.2.4.1 Creating a Reconciliation Schedule Task

By default, reconciliation uses a Search operation on the connector bundle. This operation is invoked with a schedule task configured using Oracle Identity Manager. This procedure is comprised of the following sub procedures.

1. Defining the Schedule Task
2. Creating a Scheduled Task

10.2.4.1.1 Defining the Schedule Task  To define the scheduled task:

1. Create a Deployment Manager XML file containing the scheduled task details as shown in Example 10–13. Make sure to update database value to your database.

Example 10–13  Deployment Manager XML with Scheduled Task Details

```xml
<?xml version = '1.0' encoding = 'UTF-8'?>
<x1-ddm-data version="2.0.1.0" user="XELSYSADM"
database="jdbc:oracle:thin:@localhost:5524/estView.regress.rdbms.dev.mycompany.com"
exported-date='1307546406635' description="FF">
<scheduledTask repo-type="MDS" name="Flat File Connector User Reconciliation"
mds-path="/db" mds-file="Flat File Connector User Reconciliation.xml">
<completeXml>
    <scheduledTasks xmlns="http://xmlns.oracle.com/oim/scheduler">
        <task>
```

**Note:** If the connector does not implement the GetApiOp interface, then the WRITEBACK flag does not work and an error is generated.
Uploading the Identity Connector Bundle to Oracle Identity Manager Database

2. Save the file as Flat File Connector User Reconciliation.xml.

3. Login to Oracle Identity System Administration. Under System Management, click Import.

4. Select the Flat File Connector User Reconciliation.xml file, and click Import.

5. Complete the steps in the wizard.

10.2.4.1.2 Creating a Scheduled Task  This procedure explains how to create a scheduled task.

1. Log in to the Oracle Identity Manager Advanced Administration.

2. Click Scheduler under the System Management tab.

3. Add a schedule task and add Flat File Connector User Reconciliation as the type as illustrated in Figure 10–14.
4. Set the parameters as follows:
   - IT Resource Name takes a value of Flat File.
   - Resource Object Name takes a value of FLATFILERO.
   - Object Type takes a value of User.

5. Click Apply.

10.2.4.2 Creating a Reconciliation Profile
A reconciliation profile defines the structure of the object attributes while reconciliation. The reconciliation profile should contain all the attributes that have reconciliation support.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Resource Objects under Resource Management.
3. Open the FLATFILERO resource object.
4. Click the Object Reconciliation tab as illustrated in Figure 10–15.
5. Add following reconciliation fields:
   - First Name [String]
   - Universal ID [String]
   - Email ID [String]
   - IT Resource Name [String]
   - Last Name [String]
   - Account ID [String], Required

6. Save the configuration.

10.2.4.3 Setting a Reconciliation Action Rule

A Reconciliation Action Rule defines the behavior of reconciliation. In this procedure, define the expected action when a match is found. This procedure assumes you are logged into the Oracle Identity Manager Design Console.

1. Open the FLATFILERO resource object.

2. Click the Object Reconciliation tab.

3. Click the Reconciliation Action Rules tab in the right frame.
4. Add an action rule defined as One Process Match Found (Rule Condition) and Establish Link (Action).

5. Add an action rule defined as One Entity Match Found (Rule Condition) and Establish Link (Action).

6. Click Create Reconciliation Profile.

7. Click Save.

10.2.4.4 Creating Reconciliation Mapping

The reconciliation mapping has to be done in the process definition. This is to map the supported reconciliation fields (from resource object) to the process form fields. This mapping is needed only for configuring target reconciliation.

1. Log in to the Oracle Identity Manager Design Console.

2. Click Process Definition under Process Management.

3. Open the Flat File process definition.

4. Click the Reconciliation Field Mappings tab as illustrated in Figure 10–17.
5. Add mappings between the reconciliation profile fields and the process form fields.
   - **First Name[String] = UD_FLAT_FIL_FIRSTNAME**
   - **Email ID[String] = UD_FLAT_FIL_MAILID**
   - **IT Resource Name[String] = UD_FLAT_FIL_SERVER**
   - **Last Name[String] = UD_FLAT_FIL_LASTNAME**
   - **Account ID [String] = UD_FLAT_FIL_ACCOUNTID <KEY>**
     <KEY> sets Account ID as a key field.

6. Save the configuration.

### 10.2.4.4.1 Field Flags Used in the Reconciliation Attributes Map
For reconciliation attributes mapping, the following field flags can be appended to the code key:

- **TRUSTED**: This must be specified in the Recon Attribute Map for the field that represents the status of the account. This flag must be specified only for trusted reconciliation. If this is specified, then the status of the account is either Active or Disabled. Otherwise, the status is either Enabled or Disabled. For example, the code key for a field with label Status whose value needs to be either Active/Disabled must look similar to **Status[TRUSTED]**.

- **DATE**: In Recon Attribute Map, this must be specified for fields whose type need to be considered as Date. For example, the code key for a field with label Today whose value needs to be displayed in the date format must look similar to **Today[DATE]**.

### 10.2.4.5 Defining a Reconciliation Matching Rule
A reconciliation matching rule defines the equation for calculating the user match.

1. Log in to the Oracle Identity Manager Design Console.
2. Open the Reconciliation Rules form under Development Tools.

3. Click Add Rule.

**Figure 10–18 Adding Reconciliation Matching Rule**

4. Select resource object FLATFILERO.

5. Save and add the rule element.

   User Login from the user profile data equals the Account ID resource attribute.

6. Save the rule.

### 10.3 Provisioning a Flat File Account

The flat file connector is ready to work. Now, the user needs to log in to Oracle Identity Manager and create an IT resource (target) using the following procedure.

- Create IT resource of type "Flat File".
- Provide the IT resource parameters as appropriate.
- Provide the configuration parameters in Lookup.FF.Configuration as appropriate.

### 10.4 Configuring SSL for Java Connector Server

To enable SSL for Java connector server:

1. Edit `$CONNECTOR_SERVER_HOME/conf/ConnectorServer.properties` as the following:

   ```properties
   connectorserver.usessl=true
   connectorserver.keyStore=(full path to your keystore file)
   connectorserver.keyStoreType=JKS (optionally you can set key store type, if
   ```
Configuring SSL for Java Connector Server

2. Provide key store password:
   a. Set it in ConnectorServer.properties.
   b. Set connectorserver.promptKeyStorePassword=false in ConnectorServer.properties.
   c. Set the password:
      
      cd $CONNECTOR_SERVER/bin

      For UNIX
      
      connectorserver.sh /setKeyStorePassword thepassword

      For Windows
      
      ConnectorServer.bat /setKeyStorePassword thepassword

      This command will set the encrypted value to
      "connectorserver.keyStorePassword" in ConnectorServer.properties.

3. Ask for key store password every time by starting the connector server set connectorserver.promptKeyStorePassword=true in ConnectorServer.properties.

The following example snippet shows the ConnectorServer.properties shipped with Java Connector Server:

```properties
# The port we are to run on
connectorserver.port=8759
#
# The bundle directory in which to find the bundles
connectorserver.bundleDir=bundles
#
# The bundle directory in which to find any libraries needed by bundles at runtime
connectorserver.libDir=lib
#
# Set to true to use SSL.
# NOTE: Check also the following settings which are related to SSL:
#  connectorserver.promptKeyStorePassword
#  connectorserver.keyStore
#  connectorserver.keyStoreType
#  connectorserver.keyStorePassword
connectorserver.usessl=false
#
# If set to true the user is prompted for key store password at startup.
# If set to false the key store password needs to be set with
#  -setKeyStorePassword command first.
# connectorserver.promptKeyStorePassword=true
```
## Full path to key store.
##
#connectorserver.keyStore=/tmp/KeyStore.jks
#
## KeyStore type
##
#connectorserver.keyStoreType=JKS
#
## Encrypted password. Set this by using the -setKeyStorePassword flag.
## It is used only if connectorserver.promptKeyStorePassword is set to false.
##
#connectorserver.keyStorePassword=
#
## Optionally specify a specific address to bind to
##
#connectorserver.ifaddress=localhost
#
## Secure hash of the gateway key. Set this by using the 
## -setKey flag
##
#connectorserver.key=lmA6bMfENJGlIDbfrVtklXFK32s=
#
## Use standard JDR logging
##
#connectorserver.loggerClass=org.identityconnectors.common.logging.impl.JDKLogger
This chapter is a tutorial that walks through the procedures necessary to develop an identity connector in .NET using the Identity Connector Framework (ICF) and the Oracle Identity Manager metadata. It includes information about important ICF classes and interfaces, the connector bundle, the connector server, and code samples for implementing a flat file .NET identity connector and creating Oracle Identity Manager metadata for user provisioning and reconciliation processes. It contains the following sections:

- Section 11.1, "Developing a Flat File .NET Connector"
- Section 11.2, "Deploying the Identity Connector Bundle on .NET Connector Server"
- Section 11.3, "Provisioning a Flat File Account"

### 11.1 Developing a Flat File .NET Connector

The procedure for developing a flat file connector is to develop an implementation of the Configuration interface followed by the implementation of the Connector class. In the documentation we would discuss sample implementation of a flat file connector showing Create, Delete, Update and Search operations. To keep implementations and documentation simple, Configuration properties and Schema supported by connector have been kept to a minimum. This connector implementation should only be used as a sample which would help to create actual connectors.

To keep the connector implementation simple, lets assume that flat file has only Name, Gender, Qualification, Age attributes. We would have only two configurations File Location and Delimiter. Rest configurations would be hardcoded in the sample.

1. Setting up the project in Microsoft Visual Studio and using the connector:
   a. Create a new visual studio project of type library.
   b. Make sure to add the following dlls as references:
      - Common.dll
      - Framework.dll
      - FrameworkInternal.dll
      - System.dll
      - System.Core.dll

These dlls should be available with the .NET connector server.
Developing a Flat File .NET Connector

Example 11–1 Implementation of AbstractConfiguration

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.IO;

namespace Org.IdentityConnector.FlatFileConnector
{
    /// <summary>
    /// Configuration class for flat file connector representing target system information.
    /// </summary>
    public class FlatFileConfiguration : AbstractConfiguration
    {
        #region FileName
        /// <summary>
        /// Target file name
        /// </summary>
        /// <value>
        /// File name with complete path. As for executing the .NET Connector bundle we need .NET Connector Server, hence the file should reside on the machine where the connector server is present.
        /// </value>
        [ConfigurationProperty(Required = true, Order = 1)]
        public String FileName { get; set; }
        #endregion

        #region Delimiter
        /// <summary>
        /// Delimiter used within the target flat file
        /// </summary>
        /// <value>
        /// Delimiter
        /// </value>
        [ConfigurationProperty(Required = true, Order = 2)]
        public String Delimiter { get; set; }
        #endregion

        #region
        /// <summary>
        /// Validates if the configuration properties provided are as required, if not throw ConfigurationException
        /// </summary>
        public override void Validate()
        {
            if (this.FileName == null || this.FileName.Length == 0)
            {
                throw new ConfigurationException("Configuration property FileName cannot be null or empty");
            }
            if (!File.Exists(this.FileName))
            {
                throw new ConfigurationException("Target file " + this.FileName + " does not exist");
            }
        }
    }
}

**Example 11–2** implements the PoolableConnector, CreateOp, SchemaOp, TestOp, DeleteOp, UpdateOp, SearchOp<String> interfaces and thus supports all CRUD operations

**Example 11–2  Implementation of PoolableConnector**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.IO;
using Org.IdentityConnectors.Common;

namespace Org.IdentityConnector.FlatFileConnector
{
    /// <summary>
    /// FlatFileConnector showing implementation of SchemaOp, test, create, delete, update and search operations.
    /// </summary>
    [ConnectorClass("FlatFileConnector_
DisplayNameKey", typeof(FlatFileConfiguration))]
    {
        /// <summary>
        /// Flat file configuration instance. This instance has the target system information.
        /// </summary>
        private FlatFileConfiguration config;

        #region Init
        /// <summary>
        /// Create a connection to target and store it for later use. But here we just set attributes of target file
        /// name to Normal
        /// </summary>
        public void Init(Configuration config)
        {
            // does not exist');
             }
             if (this.Delimiter == null || this.Delimiter.Length == 0)
             {
                 throw new ConfigurationException("Configuration property Delimiter
cannot be null or empty");
             }
         }
    }
}
```
Developing a Flat File .NET Connector

```csharp
this.config = (FlatFileConfiguration)config;
File.SetAttributes(this.config.FileName, FileAttributes.Normal);
}

4. This connector supports only the CreateEqualsExpression operation. Implement
the CreateEqualsExpression. Example 11–3 illustrates the sample implementation

Example 11–3 Implementation of AbstractFilterTranslator<T>
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
namespace Org.IdentityConnector.FlatFileConnector
{
    /// <summary>
    /// FlatFileFilterTranslator. This translator converts the equalsFilter provided by the calling application to native query which can be used by the connector while searching.
    /// The implementation shown supports only equals filter. i.e it has provided implementation for only CreateEqualsExpression, this means that if any other filter is provided by the calling application, it would not be translated as a native query and search implementation gets all users and filtering will be done by ICF with all results.
    /// </summary>
    public class FlatFileFilterTranslator : AbstractFilterTranslator<String>
    {
        /// <summary>
        /// Creates a native query for equals filter and returns it only if equals filter is constructed for Name attribute and not for any other attributes.
        /// </summary>
        /// <param name="filter">Filter provided by calling application</param>
        /// <param name="not">not</param>
        /// <returns></returns>
        protected override string CreateEqualsExpression(EqualsFilter filter, bool not)
        {
            ConnectorAttribute attr = filter.GetAttribute();
            if (attr.Name.Equals(Name.NAME))
            {
                return 'Name:' + attr.Value.First().ToString();
            }
            return null;
        }
    }
}

5. Implement the different classes (as mentioned in steps 2, 3, and 4).
6. Make a note of AssemblyVersion present in the AssemblyInfo.cs of the project.

Sample AssemblyInfo.cs file:

using System.Reflection;
using System.Runtime.CompilerServices;
using System.Runtime.InteropServices;

// General Information about an assembly is controlled through the following set of attributes. Change these attribute values to modify the information associated with an assembly.
[assembly: AssemblyTitle("FlatFileConnector")]
[assembly: AssemblyDescription("")]
[assembly: AssemblyConfiguration("")]
[assembly: AssemblyCompany("Oracle Corporation")]
[assembly: AssemblyProduct("FlatFileConnector")]
[assembly: AssemblyCopyright("Copyright © Oracle Corporation 2012")]
[assembly: AssemblyTrademark("")]
[assembly: AssemblyCulture("")]

// Setting ComVisible to false makes the types in this assembly not visible to COM components. If you need to access a type in this assembly from
// COM, set the ComVisible attribute to true on that type.
[assembly: ComVisible(true)]

// The following GUID is for the ID of the typelib if this project is exposed to COM
[assembly: Guid("79eec317-62bd-49a5-9512-88d61135684c")]

// Version information for an assembly consists of the following four values:
//
// Major Version
// Minor Version
// Build Number
// Revision

// You can specify all the values or you can default the Build and Revision Numbers
// by using the '*' as shown below:
[assembly: AssemblyVersion("1.0.*")]
[assembly: AssemblyFileVersion("1.0.0.0")]

7. Build the project. The project must create the connector DLL.

11.2 Deploying the Identity Connector Bundle on .NET Connector Server

For all the connectors that are implemented in .NET, you need to have .NET Connector Server for the execution of the connector. The connector bundle cannot be deployed within Oracle Identity Manager. Therefore, you must perform the following procedures in order to integrate the ICF .NET Identity Connector with Oracle Identity Manager:

- Section 11.2.1, "Registering the Connector Bundle with .NET Connector Server"
- Section 11.2.2, "Creating Basic Identity Connector Metadata"
- Section 11.2.3, "Creating Provisioning Metadata"
- Section 11.2.4, "Creating Reconciliation Metadata"

11.2.1 Registering the Connector Bundle with .NET Connector Server

For registering or deploying the connector bundle on .NET Connector Server, perform the following steps:

1. Install the .NET Connector Server. See Section 9.6.2.1, "Installing the .NET Connector Server" for more information about installing the .NET Connector Server.
2. Stop the Connector Server. Make sure that Connector Server Service is not running.
3. Copy the connector DLL in the CONNECTOR_SERVER_HOME location. CONNECTOR_SERVER_HOME is the location where ConnectorServer.exe and other connector server related files are present after .NET Connector Server installation.
4. Start the .NET Connector Server.
11.2.2 Creating Basic Identity Connector Metadata

This metadata configuration is needed for both provisioning and reconciliation. Perform the following procedures by using the Oracle Identity Manager Design Console.

- **Section 11.2.2.1, "Creating the IT Resource Type Definition"**
- **Section 11.2.2.2, "Creating the Resource Object"**

11.2.2.1 Creating the IT Resource Type Definition

An IT resource type definition is the representation of a resource’s connection information. The configuration parameters in the IT resource type definition should be matched with the configuration parameters of the connector bundle. The values of the parameters in the IT resource will be set in the bundle configuration.

**Note:** You may include parameters the bundle configuration is not using. They produce no negative effects on the bundle operations.

1. Log in to the Oracle Identity Manager Design Console.
2. Click **IT Resource Type Definition** under Resource Management.
3. Create a new IT Resource Type Definition with the Server Type defined as Flat File.
4. Add the following parameters as illustrated in Figure 11–1.
   - Configuration Lookup is the marker of the main configuration lookup for the resource. The name of the parameter must be Configuration Lookup. It is a good practice to add a value to Default Field Value.
   - Delimiter maps to the Delimiter parameter in the bundle configuration. The value of this parameter will be passed.
   - FileName maps to the FileName parameter in the bundle configuration. The value of this parameter will be passed.
   - Connector Server Name, provide the connector server IT Resource name where .NET Connector Server is running.
11.2.2.2 Creating the Resource Object

The resource object is the Oracle Identity Manager representation of a resource. The connector bundle is tied to the resource object.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Resource Objects under Resource Management.
3. Create a new resource object with the name Flat File.

   As the resource object is a target resource, do not check the Trusted Source box as illustrated in Figure 11–2.

---

**Figure 11–1  IT Resource Type Definition in Design Console**

---

**Figure 11–2  Resource Objects in Design Console**
11.2.2.3 Creating Lookups

Separate lookups have to be defined for different objects supported by the connector bundle. This lookup can contain provisioning and reconciliation related information for those objects. The Main Configuration Lookup is the root for object specific lookups as it contains the pointers to those lookups. The following sections contain information on how to create lookups.

- Creating the Main Configuration Lookup
- Creating Object Type Configuration Lookup

11.2.2.3.1 Creating the Main Configuration Lookup The Configuration Lookup (as defined in Section 11.2.2.1, "Creating the IT Resource Type Definition") holds connector bundle configurations that are not counted as connection information. If a configuration parameter is not found in the IT Resource Type Definition, Oracle Identity Manager will look in the Configuration Lookup. The main Configuration Lookup contains bundle properties and bundle configurations. Bundle Property parameters are mandatory as they are needed for identifying the correct bundle. Bundle configurations that are not defined as part of the IT resource type definition (discussed in Section 11.2.2.1, "Creating the IT Resource Type Definition") can be declared here.

---

**Note:** The values for Code Key should match exactly as illustrated. The values for Decode are specific to the connector bundle.

---

1. Log in to the Oracle Identity Manager Design Console.
2. Click Lookup Definition under Administration.
4. Add the following Lookup Code Information as illustrated in Figure 11–3.
   - Add *AssemblyVersion* as the required Bundle Version.
   - Add *FlatFile.Connector* as the required Bundle Name. The bundle name can be identified from the connector dll name. Connector DLL is in BUNDLE_NAME.dll format.
   - Add *Org.IdentityConnector.FlatFileConnector.FlatFileConnector* as the required Connector Name.
   - OBJECT_TYPE_NAME Configuration Lookup is the configuration lookup for the particular object type. In this example, the object type is User as User Configuration Lookup is defined.
11.2.2.3.2 Creating Object Type Configuration Lookup  Object type configuration lookup contains the parameters specific to the particular object type. Object type is an entity over which an identity connector operates. It is mapped to ICF ObjectClass. In Section 11.2.2.3.1, "Creating the Main Configuration Lookup," User Configuration Lookup has been referenced so that User is the object type, in this case mapped to ObjectClass.ACCOUNT. (Roles and UserJobData are two other object types.) The object type name has to match with ObjectClass name supported by the identity connector bundle. The User object type is mapped to predefined ObjectClass.ACCOUNT, the Group object type is mapped to predefined ObjectClass.GROUP. If the identity connector supports multiple objects, then this step must be repeated for each.

Note: Because these use cases cover only the basic functionality, the configuration is kept to the mandatory attribute.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Lookup Definition under Administration.
3. Create a new Lookup and add Lookup.FlatFile.UM.Configuration as the Code.
4. Set the following attributes as illustrated in Figure 11–4.

Note: This tutorial focuses on the minimum configurations needed to run an identity connector.

- **Provisioning Attribute Map** takes a value of Lookup.FlatFile.UM.ProvAttrMap. This lookup contains the mapping between Oracle Identity Manager fields and identity connector attributes. The mapping is used during provisioning.

- **Reconciliation Attribute Map** takes a value of Lookup.FlatFile.UM.ReconAttributeMap. This lookup contains the mapping between Oracle Identity Manager reconciliation fields and identity connector attributes. The mapping is used during reconciliation.
11.2.3 Creating Provisioning Metadata

The following sections should be followed in order to configure Oracle Identity Manager for flat file provisioning.

- Section 11.2.3.1, "Creating a Process Form"
- Section 11.2.3.2, "Creating Adapters"
- Section 11.2.3.3, "Creating A Process Definition"
- Section 11.2.3.4, "Creating a Provisioning Attribute Mapping Lookup"

11.2.3.1 Creating a Process Form

A process form is used as the representation of object attributes on Oracle Identity Manager. This facilitates user input to set object attributes before passed to the connector bundle for an operation.

Attributes defined in the process form are not conventions. The form is a way to challenge the attributes that need to be passed to the identity connector. In general, define an attribute for each supported attribute in the identity connector.

*Note:* It is good practice to have a one to one mapping on the identity connector attributes.

There should be a field for querying the IT resource that should be associated with the respective IT Resource Type Definition. Variable type of each field should map to the type of the object attribute.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Form Designer under Development Tools.
3. Create a new form with the Table Name UD_FLATFILE as illustrated in Figure 11–5.
4. Add the attributes defined in the connector schema, as listed in Table 11–1.

Table 11–1 Form Designer Fields

<table>
<thead>
<tr>
<th>Name</th>
<th>Variant</th>
<th>Field Label</th>
<th>Field Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>UD_FLATFILE_NAME</td>
<td>String</td>
<td>Name</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLATFILE_AGE</td>
<td>String</td>
<td>Age</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLATFILE_QUALIFICATION</td>
<td>String</td>
<td>Qualification</td>
<td>TextField</td>
</tr>
<tr>
<td>UD_FLATFILE_GENDER</td>
<td>String</td>
<td>Gender</td>
<td>LookupField</td>
</tr>
<tr>
<td>UD_FLATFILE_RETURNIDQ</td>
<td>String</td>
<td>Return Id</td>
<td>DFOField</td>
</tr>
<tr>
<td>UD_FLATFILE_ITRESOURCE</td>
<td>Long</td>
<td>IT Resource</td>
<td>ITResourceLookupField</td>
</tr>
</tbody>
</table>

**Note:** The flat file column names are FirstName, ChangeNo, EmailID, Server, LastName, and AccountID.

5. Click the Properties tab.

6. Add the following properties to Server(ITResourceLookupField) as illustrated in Figure 11–6.
   - Required = true
   - Type = Flat File
7. Save the form.
8. Click Make Version Active.

11.2.3.2 Creating Adapters
An adapter has to be created for all operations supported by the connector bundle, including Create, Update, and Delete.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Adapter Factory under Development Tools.
3. Create a new adapter and add Flat File Create User as the Adapter Name.
4. Add Process Task as the Adapter Type.
5. Save the adapter.
6. Click the Variable List tab and add the following variables, as shown in Figure 11–7.
   - objectType with Type String and Mapped as Resolve at runtime.
   - processInstanceKey with Type long and Mapped as Resolve at runtime.
   - itResourceFieldName with Type String and Mapped as Resolve at runtime.
7. Add a Java functional task to the adapter by following this sub procedure, as shown in Figure 11–8.

a. Click the Adapter Tasks tab.

b. Select the adapter and click Add.

c. Select Java from the task options.

d. Select icf-oim-intg.jar from the API source.

e. Select oracle.iam.connetors.icfcommon.prov.ICProvisioninManager as the API Source.

f. Select createObject as the method for the task.

g. Save the configurations.

h. Map the variables (previously added to the Variables List) against the appropriate method inputs and outputs.

i. Map the configuration parameters against the appropriate method inputs and outputs.

Database Reference maps to Database Reference (Adapter References) and Return Variable maps to Return Variable (Adapter Variables).
8. Save and build the adapter.

### 11.2.3.3 Creating A Process Definition

Process Definition defines the behavior of the connector bundle for a particular operation. Every operation has a corresponding task associated with it. This procedure will configure the process definition and integration of the process task for the Create operation.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Process Definition under the Process Management tab.
3. Create a new process definition and name it Flat File as illustrated in Figure 11–9.

---

**Figure 11–8 Adapter Factory in Design Console**
4. Select Provisioning as the Type of process.

5. Provide the resource Object Name for the identity connector; in this example, Flat File.

6. Provide the process form Table Name; in this example, UD_FLATFILE.

7. Add a process task and name it Create User.

8. Double click Create User to edit as illustrated in Figure 11–10.
9. Click the Integration tab.

10. Click Add and select the adpFLATFILECREATEUSER from the list as illustrated in Figure 11–11.

The adapter will be available only after it is compiled.
11. Map the variables as follows to set the response code returned by the identity connector.

- Adapter Return Variable – Response Code
- Object Type – [Literal:String] User (Name of the object type)
- IT Resource Field Name – [Literal:String] UD_FLATFILE_ITRESOURCE (Form field name that contains the IT resource information)

12. Click the Responses tab and configure the responses as illustrated in Figure 11–12.

- UNKNOWN can be described as Unknown response received with a status of R (Rejected).
- SUCCESS can be described as Operation completed with a status of C (Completed).
- ERROR can be described as Error occurred with a status of R.
13. Click the Task to Object Status Mapping tab.

14. Update the Object Status to **Provisioned** for Status C, as shown in Figure 11–13:
15. Save the process task.

11.2.3.4 Creating a Provisioning Attribute Mapping Lookup

Provisioning Attribute Mapping Lookup contains mappings of Oracle Identity Manager fields to identity connector bundle attributes. In the Provisioning Attribute Mapping Lookup:

- Code keys are Field Labels of the process form.
- Decodes are identity connector bundle attributes.
- Child form attributes can be configured as embedded objects in inputs.
- The identity connector’s provisioning operation returns the UID in response. This can be set in a form field by coding it against the identity connector bundle attribute.

Following is the procedure to create a Provisioning Attribute Mapping Lookup.

1. Log in to the Oracle Identity Manager Design Console.
2. Click **Lookup Definition** under the Administration tab.
3. Create a new lookup and name it Lookup.FlatFile.UM.ProvAttrMap.

The name of this lookup is referred from the object type configuration lookup. See Section 11.2.2.3.2, “Creating Object Type Configuration Lookup.”
4. Add the form Field Labels as the code keys and identity connector bundle attributes as the decode as shown in Figure 11–14.

- Name: __NAME__
- Gender: Gender
- Return Id: __UID__
- Age: Age
- Qualification: Qualification

**Figure 11–14 Lookup Code Mapping**

11.2.3.4.1 Field Flags Used in the Provisioning Attributes Map

**Note:** These properties are advanced options and can be skipped for the current implementation of the connector.

For provisioning attributes mapping, the following field flags can be appended to the code key:

- **LOOKUP:** This must be specified for all fields whose values are obtained by running a lookup reconciliation job. The values obtained from lookup reconciliation job have IT Resource Name/Key appended to it. Specifying this flag helps ICF integration to remove the appended value just before passing them onto the bundle. For example, the code key for a field with label Database whose value is obtained by running a lookup reconciliation job looks similar to Database[LOOKUP].

**Note:** The LOOKUP flag can be specified for both Provisioning and Reconciliation Attribute Map. For provisioning, IT Resource Name/IT Resource Key prefix must be removed. For reconciliation, IT Resource Name/IT Resource Key prefix must be added.
■ **IGNORE:** This must be specified for all fields whose values are to be ignored and not sent to bundle. For example, the code key for a field with label Database whose value need not be sent to bundle looks similar to Database[IGNORE].

■ **WRITEBACK:** This must be specified for all fields whose values need to be written back into the process form right after the create or update operation. Adding this flag makes the ICF integration layer call ICF Get API to get values of attributes marked with the WRITEBACK flag. For example, the code key for a field with label Database whose value needs to be written back to the process form right after create/update looks similar to Database[WRITEBACK]. For this to work, the connector must implement the GetApiOp interface and provide an implementation for the ConnectorObject getObject(ObjectClass objClass,Uid uid,OperationOptions options) API. This API searches the target for the account whose Uid is equal to the passed in Uid, and builds a connector object containing all the attributes (and their values) that are to be written back to process form.

**Note:** If the connector does not implement the GetApiOp interface, then the WRITEBACK flag does not work and an error is generated.

■ **DATE:** This must be specified for fields whose type need to be considered as Date, without which the values are considered as normal strings. For example, the code key for a field with label Today whose value needs to be displayed in the date format looks similar to Today[DATE].

■ **PROVIDEONPSWDCHANGE:** This must be specified for all fields that need to be provided to the bundle(target) when a password update happens. Some targets expect additional attributes to be specified on every password change. Specifying the PROVIDEONPSWDCHANGE flag, tells ICF integration to send all the extra fields or attributes whenever a password change is requested. For example, the code key for a field with label Extra Attribute Needed for Password Change whose value needs to be provided to bundle(target) while password update looks similar to Extra Attribute Needed for Password Change[PROVIDEONPSWDCHANGE].

### 11.2.4 Creating Reconciliation Metadata

This section contains the procedures to configure the reconciliation of records from the flat file. We will use the target reconciliation as an example; trusted reconciliation can also be configured in a similar fashion. Do the procedures in the listed order.

■ Section 11.2.4.1, "Creating a Reconciliation Schedule Task"

■ Section 11.2.4.2, "Creating a Reconciliation Profile"

■ Section 11.2.4.3, "Setting a Reconciliation Action Rule"

■ Section 11.2.4.4, "Creating Reconciliation Mapping"

■ Section 11.2.4.5, "Defining a Reconciliation Matching Rule"

#### 11.2.4.1 Creating a Reconciliation Schedule Task

By default, reconciliation uses a Search operation on the connector bundle. This operation is invoked with a schedule task configured using Oracle Identity Manager. This procedure is comprised of the following sub procedures.

1. Section 11.2.4.1.1, "Defining the Schedule Task"
2. Section 11.2.4.1.2, "Creating a Scheduled Job"
11.2.4.1.1 Defining the Schedule Task  To define the scheduled task:

1. Create a Deployment Manager XML file containing the scheduled task details as shown in Example 11–4. Make sure to update database value to your database.

**Example 11–4  Deployment Manager XML with Scheduled Task Details**

```xml
<?xml version='1.0' encoding='UTF-8'?>
<xl-ddm-data version="2.0.1.0" user="XELSYSADM" 
database="jdbc:oracle:thin:@localhost:5524/estView.regress.dbms.dev.mycompany.com 
exported-date='1307546406635' description='FF'>
<scheduledTask repo-type="MDS" name="Flat File Connector User Reconciliation" 
mds-path="/db" mds-file="Flat File Connector User Reconciliation.xml"> 
<completeXml> 
  <scheduledTasks xmlns="http://xmlns.oracle.com/oim/scheduler"> 
    <task> 
      <name>Flat File Connector User Reconciliation</name>
      <class>oracle.iam.connectors.icfcommon.recon.SearchReconTask</class>
      <description>Flat File Connector User Reconciliation</description>
      <retry>0</retry>
      <parameters>
        <string-param required='false' encrypted='false' 
helpText="Filter">Filter</string-param>
        <string-param required='false' encrypted='false' 
helpText="Incremental Recon Date Attribute">Incremental Recon Date 
Attribute</string-param>
        <string-param required='false' encrypted='false' 
helpText="IT Resource Name">IT Resource Name</string-param>
        <string-param required='false' encrypted='false' 
helpText="Object Type">Object Type</string-param>
        <string-param required='false' encrypted='false' 
helpText="Latest Token">Latest Token</string-param>
        <string-param required='false' encrypted='false' 
helpText="Resource Object Name">Resource Object Name</string-param>
      </parameters>
    </task>
  </scheduledTasks>
</completeXml>
</scheduledTask>
</xl-ddm-data>
```

2. Save the file as Flat File Connector User Reconciliation.xml.

3. Login into the Identity System Administration. Under System Management, click Import.

4. Select the Flat File Connector User Reconciliation.xml file, and click Import.

5. Complete the steps in the wizard.

11.2.4.1.2 Creating a Scheduled Job  This procedure explains how to create a scheduled task.

1. Log in to the Oracle Identity Manager Advanced Administration.

2. Click Scheduler under the System Management tab.

3. Click New for creating a new scheduled job. After that provide the job name as Flat File and in the Task field, select the value as Flat File Connector User Reconciliation from the lookup. Once the job is created, provide the values in the job as shown in Figure 11–15.
4. Add a scheduled task and add Flat File Connector User Reconciliation as the type as illustrated in Figure 11–15.

Figure 11–15  Scheduled Task Screen in Advanced Console

5. Set the parameters as follows:
   - IT Resource Name takes a value of Flat File.
   - Resource Object Name takes a value of FLATFILE.
   - Object Type takes a value of User.

6. Click Apply.

11.2.4.2 Creating a Reconciliation Profile
A reconciliation profile defines the structure of the object attributes while reconciliation. The reconciliation profile should contain all the attributes that have reconciliation support.

1. Log in to the Oracle Identity Manager Design Console.
2. Click Resource Objects under Resource Management.
3. Open the Flat File resource object.
4. Click the Object Reconciliation tab as illustrated in Figure 11–16.
5. Add following reconciliation fields:
   - Return Id [String], Required
   - Name [String], Required
   - Gender [String]
   - Age [String]
   - Gender [String]
   - IT Resource Name [IT Resource], Required

6. Save the configuration.

11.2.4.3 Setting a Reconciliation Action Rule

A Reconciliation Action Rule defines the behavior of reconciliation. In this procedure, define the expected action when a match is found. This procedure assumes you are logged into the Oracle Identity Manager Design Console.

1. Open the Flat File resource object.

2. Click the Object Reconciliation tab.

3. Click the Reconciliation Action Rules tab in the right frame.
4. Add an action rule defined as One Process Match Found (Rule Condition) and Establish Link (Action).

5. Add an action rule defined as One Entity Match Found (Rule Condition) and Establish Link (Action).

6. Click **Create Reconciliation Profile**.

7. Click **Save**.

### 11.2.4.4 Creating Reconciliation Mapping

The reconciliation mapping has to be done in the process definition. This is to map the supported reconciliation fields (from resource object) to the process form fields. This mapping is needed only for configuring target reconciliation.

1. Log in to the Oracle Identity Manager Design Console.

2. Click **Process Definition** under Process Management.

3. Open the Flat File process definition.

4. Click the Reconciliation Field Mappings tab as illustrated in **Figure 11–18**.
5. Add mappings between the reconciliation profile fields and the process form fields.
   - ReturnId[String] = UD_FLATFILE_RETURNID
   - Name[String] = UD_FLATFILE_NAME, <KEY>
   - Age[String] = UD_FLATFILE_AGE
   - Gender[String] = UD_FLATFILE_GENDER
   - Qualification[String] = UD_FLATFILE_QUALIFICATION
   - IT Resource Name[IT Resource] = UD_FLATFILE_ITRESOURCE,<KEY>

6. Save the configuration.

11.2.4.4.1 Field Flags Used in the Reconciliation Attributes Map

**Note:** These properties are advanced options and can be skipped for the current implementation of the connector

For reconciliation attributes mapping, the following field flags can be appended to the code key:

- **TRUSTED:** This must be specified in the Recon Attribute Map for the field that represents the status of the account. This flag must be specified only for trusted reconciliation. If this is specified, then the status of the account is either Active or Disabled. Otherwise, the status is either Enabled or Disabled. For example, the code key for a field with label Status whose value needs to be either Active/Disabled must look similar to Status[TRUSTED].
DATE: In Recon Attribute Map, this must be specified for fields whose type need to be considered as Date. For example, the code key for a field with label Today whose value needs to be displayed in the date format must look similar to Today[DATE].

11.2.4.5 Defining a Reconciliation Matching Rule

A reconciliation matching rule defines the equation for calculating the user match.

1. Log in to the Oracle Identity Manager Design Console.
2. Open the Reconciliation Rules form under Development Tools.
3. Click Add Rule.

4. Select resource object Flat File.
5. Once the reconciliation rule element is added, make sure to check Active flag so that the reconciliation rule is made active.
6. Save and add the rule element.
   User Login from the user profile data equals the Name resource attribute.
7. Save the rule.

Note: You must recreate the reconciliation profile whenever you make any changes to the reconciliation rule.
11.3 Provisioning a Flat File Account

The flat file connector is ready to work so now the user needs to log in to Oracle Identity Manager and create an IT resource (target) using the following procedure.

- Create IT resource of type "Flat File".
- Provide the IT resource parameters as appropriate.
- Provide the configuration parameters in Lookup.FlatFile.Configuration as appropriate.
Oracle Identity Manager’s goal is to manage the business logic of Identity administration, and delegate the execution of provisioning and reconciliation operations to Identity Connector Framework (ICF). ICF with Oracle Identity Manager (OIM) unites all the scheduled tasks and the provisioning tasks for all ICF based connectors.

This chapter contains conceptual information about ICF-OIM integration in the sections:

- Section 12.1, "ICF Common"
- Section 12.2, "Integration Architecture"
- Section 12.3, "Global Oracle Identity Manager Lookups"
- Section 12.4, "IT Resource"
- Section 12.5, "Provisioning"
- Section 12.6, "Concepts of Reconciliation in ICF Common"
- Section 12.7, "Predefined Scheduled Tasks"
- Section 12.8, "ICF Filter Syntax"

12.1 ICF Common

OIM ICF Integration Layer is an implementation of ICF API on one side and invokes OIM APIs (icf-oim-intg.jar) on the other side. This reduces the complexity of the connector developer as it provides API abstraction. It also support provisioning and reconciliation operations. See Section 12.5, "Provisioning" and Section 12.6, "Concepts of Reconciliation in ICF Common" for more information about provisioning and reconciliation using ICF Common.

12.2 Integration Architecture

Figure 12–1 is the ICF-OIM integration architecture.
12.3 Global Oracle Identity Manager Lookups

Lookups is used to store OIM configuration metadata. IT Resource parameter Configuration Lookup points to main Configuration Lookup that encapsulates all the Oracle Identity Manager specific configuration information.

Based on the lookup configuration, you can classify your properties into the following three classes:

- **IT Resource**: connectivity properties: contains all properties that are used for making a connection to the target system.

- **Main Configuration Lookup Configuration Properties**: contains non-connectivity properties that alter the mode of reconciliation or provisioning, and are not required for connection. There is a thin line of difference between connectivity and configuration properties, therefore one property can be assigned to both of them.

- **Object Type**: specific lookups (for example, user management configuration), mapping lookups for specific object type (for example, User, Group, Organizational Unit).

**Note:** LOADFROMURL flag can be used in IT Resource or Main Configuration Lookup in the code (key) field, for example, sampleProperty[LOADFROMURL]. For properties marked as this, the value (decode value) is a URL. ICF integration will read the contents of the file stored in the given URL and use it as the value of given property at runtime. This is useful for large values that cannot fit directly into a lookup.
Figure 12–2 illustrates the global Oracle Identity Manager lookups from which most of the Connectors use the User Management Lookups.

![Oracle Identity Manager Connector Lookup Hierarchy](image)

This section discusses the following topics:

- **Section 12.3.1, "Main Lookup Configuration"**
- **Section 12.3.2, "User Management Configuration"**
- **Section 12.3.3, "Recon Transformation Lookup (Lookup.CONNECTOR_NAME.UM.ReconTransformation)"**
- **Section 12.3.4, "Recon Validation Lookup (Lookup.CONNECTOR_NAME.UM.ReconValidation)"**
- **Section 12.3.5, "Optional Defaults Lookup"**

### 12.3.1 Main Lookup Configuration

IT Resource parameter Configuration Lookup points to Main Configuration Lookup, which encapsulates all the OIM specific configuration information.

Configuration lookup, denoted as `Lookup.CONNECTOR_NAME.Configuration`, is the top level entry that refers to subordinate lookups for reconciliation and provisioning. The configuration lookup has the following structure:

<table>
<thead>
<tr>
<th>Configuration Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connector Name</td>
<td>org.identityconnectors.CO</td>
<td>Identity Connector Main Class. This is the class that implements SPI operations of ICF framework.</td>
</tr>
<tr>
<td>Name</td>
<td>NAME.Connector</td>
<td></td>
</tr>
</tbody>
</table>
These lookups control the mapping for provisioning and reconciliation. In addition, these lookups might also configure transformation and validation.

This lookup contains the following keys:

- **Before Create Action Language**: This key if present in the `Lookup.CONNECTOR_NAME.UM.Configuration` informs ICF that there is a script whose language is the value of this key. The value of this key (Groovy/cmd) informs the language of the script that needs to be executed by ICF before create operation.

- **Before Create Action File**: This key if present in the `Lookup.CONNECTOR_NAME.UM.Configuration` informs ICF that a script represented by the value of this key needs to be executed by ICF before create action. This script must be accessible to Oracle Identity Manager Server.

- **Before Create Action Target**: This key if present in the `Lookup.CONNECTOR_NAME.UM.Configuration` informs ICF that script as defined by previous two keys must be executed either on resource or on connector. Depending on this configuration the ICF API `runScriptOnConnector` or `runScriptOnResource` will be executed.

Table 12–1 describes the User Management lookup configuration.

### Table 12–1  (Cont.) **Lookup Configuration for Connector**

<table>
<thead>
<tr>
<th>Configuration Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bundle Name</td>
<td>org.identityconnectors.CONNECTOR_NAME</td>
<td>Identity Connector bundle name</td>
</tr>
<tr>
<td>Bundle Version</td>
<td>11.1.1.5.x</td>
<td>Identity Connector bundle version</td>
</tr>
<tr>
<td>User Configuration Lookup</td>
<td>Lookup.CONNECTOR_NAME.UM.Configuration</td>
<td>Link to User specific configuration lookup. <strong>Note</strong>: User should be the object type. If you need to support any other object type, you can use <code>OBJECT_TYPE Configuration Lookup</code> as the key.</td>
</tr>
</tbody>
</table>

12.3.2 **User Management Configuration**

These lookups control the mapping for provisioning and reconciliation. In addition, these lookups might also configure transformation and validation.

This lookup contains the following keys:

- **Before Create Action Language**: This key if present in the `Lookup.CONNECTOR_NAME.UM.Configuration`, which informs ICF that there is a script whose language is the value of this key. The value of this key (Groovy/cmd) informs the language of the script that needs to be executed by ICF before create operation.

- **Before Create Action File**: This key if present in the `Lookup.CONNECTOR_NAME.UM.Configuration`, informs ICF that a script represented by the value of this key needs to be executed by ICF before create action. This script must be accessible to Oracle Identity Manager Server.

- **Before Create Action Target**: This key if present in the `Lookup.CONNECTOR_NAME.UM.Configuration`, informs ICF that script as defined by previous two keys must be executed either on resource or on connector. Depending on this configuration the ICF API `runScriptOnConnector` or `runScriptOnResource` will be executed.

Table 12–1 describes the User Management lookup configuration.

### Table 12–2  **User Management Lookup Configuration for Connector**

<table>
<thead>
<tr>
<th>Configuration Key</th>
<th>Value</th>
<th>Mandatory Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provisioning Attribute Map</td>
<td>Lookup.CONNECTOR_NAME.UM.ProvAttr Map</td>
<td>Y</td>
<td>This lookup contains the mapping between Oracle Identity Manager fields and identity connector attributes. The mapping is used during provisioning.</td>
</tr>
<tr>
<td>Recon Attribute Map</td>
<td>Lookup.CONNECTOR_NAME.UM.ReconAttr Map</td>
<td>Y</td>
<td>This lookup contains the mapping between Oracle Identity Manager reconciliation fields and identity connector attributes. The mapping is used during reconciliation.</td>
</tr>
</tbody>
</table>
### Table 12–2 (Cont.) User Management Lookup Configuration for Connector

<table>
<thead>
<tr>
<th>Configuration Key</th>
<th>Value</th>
<th>Mandatory Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recon Attribute Defaults</td>
<td>Lookup.CONNECTOR _ NAME.UM.ReconDefaults</td>
<td>N</td>
<td>This mapping contains the default values for OIM attributes, that are substituted, if no value is provided by connector during reconciliation.</td>
</tr>
<tr>
<td>Recon Transformation Lookup</td>
<td>Lookup.CONNECTOR _ NAME.UM.ReconTransformation</td>
<td>N</td>
<td>Lookup for Transformation by doing Reconciliation Task. Transformation is used in all Reconciliation Tasks except LookupReconTask.</td>
</tr>
<tr>
<td>Recon Validation Lookup</td>
<td>Lookup.CONNECTOR _ NAME.UM.ReconValidation</td>
<td>N</td>
<td>Lookup used for Validation by running Reconciliation Task. Validation is used in all Reconciliation Tasks except LookupReconTask.</td>
</tr>
<tr>
<td>Recon Exclusion List</td>
<td>Lookup.CONNECTOR _ NAME.UM.ReconExclusionList</td>
<td>N</td>
<td>Exclusion list is a way to address un-managed accounts for the connector. While reconciliation/provisioning. Any match from the exclusion list will not be processed by OIM.</td>
</tr>
<tr>
<td>Provisioning Exclusion List</td>
<td>Lookup.CONNECTOR _ NAME.UM.ProvExclusionList</td>
<td>N</td>
<td>In provisioning, code key is the Form label name, and decode key is the excluded value/pattern.</td>
</tr>
</tbody>
</table>

There are two types of rules supported by the exclusion list:

- **Matching rules**
  - **Direct Matching Rule**
    - Code Key: Reconciliation field name
    - Decode Key: Excluded field value
  - **Pattern Matching Rule**
    - Suffix with [PATTERN] tag to enable pattern matching
    - Code Key: ReconFieldName[PATTERN]
    - Decode Key: Exclusion pattern
    - Exclusion patterns should follow the nomenclature defined in java.util.regex.Pattern
    - See the Recon Exclusion List key in this table.
ICF defines the concept of OperationOption, it is an extra parameter list, that can be sent to any operation. It is up to the connector implementation to define the use of these operation options.

For example, in Lookup.Domino.UM.OperationOptions the code key is CACertifier[UPDATE,DELETE] and the decode value is CACertifier, which means that this attribute will be sent to calls of Update and Delete operations as an extra operation option.

If you want to configure the action run, then you need to provide three parameters for scripting:

- Language
- File
- Target

You can configure Before/After actions for the following provisioning operations:

- Create
- Update
- Delete

### Table 12–2 (Cont.) User Management Lookup Configuration for Connector

<table>
<thead>
<tr>
<th>Configuration Key</th>
<th>Value</th>
<th>Mandatory Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provisioning Validation Lookup</td>
<td>Lookup.CONNECTOR R_ NAME.UM.ProvValidation</td>
<td>N</td>
<td>Lookup for Validation by Provisioning.</td>
</tr>
<tr>
<td>Operation Options Map</td>
<td>Lookup.CONNECTOR R_ NAME.UM.Operation Options</td>
<td>N</td>
<td>The code key is a constant Operation Options Map. The decode value name of lookup that will be used as a map of operation options. For example, in Lookup.Domino.UM.OperationOptions the code key is CACertifier[UPDATE,DELETE] and the decode value is CACertifier, which means that this attribute will be sent to calls of Update and Delete operations as an extra operation option.</td>
</tr>
<tr>
<td>Scripting Attributes</td>
<td></td>
<td></td>
<td>The triggering time of the script is controlled by these labels in your lookup key:</td>
</tr>
<tr>
<td>Before Create Action Language</td>
<td>SCRIPTING_ LANGUAGE_NAME</td>
<td>N</td>
<td>Language of the Action which will be executed, for example, Groovy/cmd. If you want to configure the action run, then you need to provide three options, Language/File/Target. You can configure Before/After actions for the following provisioning operations: Create/Update/Delete.</td>
</tr>
</tbody>
</table>
12.3.3 Recon Transformation Lookup (Lookup.CONNECTOR_NAME.UM.ReconTransformation)

Transformation code is in an external Oracle Identity Manager Java Task, used in all Reconciliation Tasks except LookupReconTask. It is a Java class uploaded (transforming data coming from Target System during reconciliation) to Oracle Identity Manager repository.

The Java class performing transformation needs to have a method with the signature public Object transform(HashMap arg0, HashMap arg1, String arg2) implemented. ICF would look for this method with the exact signature.

Transform java class template is as follows:

```java
public class MyTransformer implements oracle.iam.connectors.common.transform.Transformation {
    public Object transform(java.util.HashMap hmUserDetails, java.util.HashMap hmEntitlementDetails, String sField) {
        String sFirstName = (String)hmUserDetails.get("First Name");
        String sLastName = (String)hmUserDetails.get("Last Name");
        String sFullName = sFirstName + "." + sLastName;
        return sFullName;
    }
}
```

The name of lookup storing the Recon Transformation Lookup is defined in Main Configuration Lookup (Lookup.CONNECTOR_NAME.Configuration) as shown in Table 12–3.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Mandatory Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recon Field Name</td>
<td>&lt;transformationClassName&gt;com.validationexample.MyTransformer</td>
<td></td>
<td>Java class which performs transformation for this recon field.</td>
</tr>
</tbody>
</table>

12.3.4 Recon Validation Lookup (Lookup.CONNECTOR_NAME.UM.ReconValidation)

Validation code is in an external Oracle Identity Manager Java task, Used for validating data coming from Target System during Reconciliation. It is a Java class uploaded (transforming data coming from Target System during reconciliation) to Oracle Identity Manager repository.
The Java class performing validation needs to have a method with the signature public boolean validate(HashMap arg0, HashMap arg1, String arg2) implemented. ICF would look for this method with the exact signature.

The validation Java class template is as follows:

```java
public class MyValidator implements oracle.iam.connectors.common.validate.Validator {
    public boolean validate(java.util.HashMap hmUserDetails, java.util.HashMap hmEntitlementDetails, String sField) throws oracle.iam.connectors.common.ConnectorException {
        boolean isValid = false;
        // validation code goes HERE
        return isValid;
    }
}
```

The name of lookup storing the Recon Validation Lookup is defined in main configuration lookup (Lookup.CONNECTOR_NAME.Configuration) as shown in Table 12–4.

### Table 12–4 Reconciliation Validation Lookup

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recon Field Name</td>
<td>&lt;transformationClassName &gt;</td>
<td>Java class which performs validation for this recon field.</td>
</tr>
<tr>
<td></td>
<td>com.validationexample.MyValidator</td>
<td></td>
</tr>
</tbody>
</table>

#### 12.3.5 Optional Defaults Lookup

Missing values for reconciliation are substituted by default values defined in the following table. User Type is a required OIM attribute, that typically is not contained on the target resource. You can set the default value in here.

For example, trusted reconciliation requires a set of attributes from the connector to have a non-empty value. However, not all resources can supply all of these attribute types, so we need to provide some default values. Table 12–5 lists all required attributes for reconciliation, and possible default values for them.

If connector can supply all attributes needed in reconciliation, then this table becomes optional.

### Table 12–5 Lookup.CONNECTOR_NAME.UM.Recon.Defaults.Trusted Attributes

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last Name</td>
<td>CONNECTOR_DEPENDENT_VALUE</td>
</tr>
<tr>
<td>Organization</td>
<td>Xellerate users</td>
</tr>
<tr>
<td>User Type</td>
<td>End-User</td>
</tr>
<tr>
<td>Employee Type</td>
<td>Full-Time</td>
</tr>
<tr>
<td>First Name</td>
<td>CONNECTOR_DEPENDENT_VALUE</td>
</tr>
</tbody>
</table>

**Note:** These default values are supported only for single valued fields, which means the multivalued or child table attributes are not supported.
12.4 IT Resource

IT Resource contains connectivity parameters for Target System. These parameters are required for all the connectors using ICF integration.

Table 12–6 describes the common IT Resource parameters.

See Also: The documentation for the connector you are deploying for information about the IT Resource parameters of the target system and the Connector Server

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connector Server Name</td>
<td>IT Resource name of Connector Server. The IT Resource needs to be of type Connector Server. This field is a mandatory field, but the value is optional.</td>
</tr>
<tr>
<td>Configuration Lookup</td>
<td>Name of the main configuration lookup. This field is a mandatory field</td>
</tr>
</tbody>
</table>

12.5 Provisioning

The section contains the following topics:

- Section 12.5.1, "ICF Provisioning Manager"
- Section 12.5.2, "Provisioning Lookup"
- Section 12.5.3, "Non-User Object Types"
- Section 12.5.4, "Optional Lookups for Provisioning"
- Section 12.5.5, "Optional Flags in Lookups for Provisioning Attribute Map"
- Section 12.5.6, "Compound attributes in Provisioning Attribute Map"

12.5.1 ICF Provisioning Manager

ICF Provisioning Manager unites the access to provisioning methods of connectors into one Java Task that serves all connectors.

The public methods are divided into four groups:

- Section 12.5.1.1, "APIs for Provisioning"
- Section 12.5.1.2, "Account Related Operations"
- Section 12.5.1.3, "Multivalued Operations"
- Section 12.5.1.4, "Other operations"

12.5.1.1 APIs for Provisioning

The following are the single-valued CRUD object types.

createObject

Creates object of a specified type on the target resource, the values are taken from the current Form.

Signature: public String createObject(String objectType)
**deleteObject**  
Deletes object of a specified type on the target resource.  
Signature: public String deleteObject(String objectType)

**updateAttributeValue**  
Updates object on target resource, only the attribute with the provided label is updated.  
Signature: public String updateAttributeValue(String objectType, String attrFieldName)

**updatePassword**  
Use this method in Adapter ONLY if you need to provide old password value, currently there is no way to get the old value using the formAPI. If you don't need old password value to change the password, use #updateAttributeValue(String, String) method instead.  
Signature: public String updatePassword(String objectType, String pswdFieldLabel, String oldPassword)

### 12.5.1.2 Account Related Operations

The following are the account related provisioning operations.

**enableUser**  
Deprecated, use enableObject() instead.  
Signature: public String enableUser()

**disableUser**  
Deprecated, use disableObject() instead.  
Signature: public String disableUser()

**enableObject**  
Example usage for User: enableObject("User").  
Signature: public String enableObject(String objectType)

**disableObject**  
Signature: public String disableObject(String objectType)

### 12.5.1.3 Multivalued Operations

The following are the multivalued operations used in provisioning.

**updateAttributeValues**  
Use this method if there is a group update of fields. This will be useful when a set of attributes have to updated together.  
Signature: public String updateAttributeValues(String objectType, String[] labels)  
public String updateAttributeValues(String objectType, Map<String, String> fields)  
public String updateAttributeValues(String objectType, Map<String, String> fields, Map<String, String> oldFields)
**addChildTableValue**
Updates the target by adding the newly added row in child table.
Signature: public String addChildTableValue(String objectType, String childTableName, long childPrimaryKey)

**removeChildTableValue**
Updates the target by removing the row which was just deleted from child table.
Signature: public String removeChildTableValue(String objectType, String childTableName, Integer taskInstanceKey)

**updateChildTableValue**
Updates the target by removing the deleted row and adding the newly created row.
Signature: public String updateChildTableValue(String objectType, String childTableName, Integer taskInstanceKey, long childPrimaryKey)

**updateChildTableValue**
Updates values provided in child table on target resource.
Signature: public String updateChildTableValues(String objectType, String childTableName)

### 12.5.1.4 Other operations
The following is the other operation used in provisioning.

**setEffectiveITResourceName**
If the connector needs to use different IT Resource for provisioning operations, it can be set by this method.
Signature: public void setEffectiveITResourceName(String itResourceName)

### 12.5.2 Provisioning Lookup
Lookup.CONNECTOR_NAME.UM.ProvAttrMap contains basic attribute mapping for two classes of attributes:

- Single valued attributes: simple string key + value pairs.
- Multivalued attributes (Child tables in Oracle Identity Manager): These are further divided by the depth of hierarchy:
  - Simple multivalued attributes: represent records of data stored in child table, see second row in Table 12–7.
  - Complex multivalued attributes: multiple levels of embedded objects, see last row in Table 12–7.

#### Table 12–7 Provisioning Lookup Attributes

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Form Field Label</td>
<td>ConnectorAttributeName</td>
<td>This is a basic mapping type, simple Form Label Name to single value Connector Attribute Name</td>
</tr>
</tbody>
</table>
12.5.3 Non-User Object Types

There are number of other entities that can be provisioned for example LDAP Organizational Unit (also called OU), or LDAP Group or Group. In this case you need to fill in the OBJECT_TYPE in the following examples:

**Main Configuration Lookup Lookup.CONNECTOR_NAME.Configuration**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child Form Name&gt;~&lt;Child Form Field Label</td>
<td>ConnectorAttributeName</td>
<td>This maps child form field to multivalued ConnectorAttributeName</td>
</tr>
<tr>
<td>Child Form Name&gt;~&lt;Child Form Field Label</td>
<td>ConnectorAttributeName&gt;<del>&lt;EmbeddedObjectClass&gt;</del>&lt;EmbeddedAttributeName&gt;</td>
<td>This maps child form field to EmbeddedAttribute of the embedded object, which object class is EmbeddedObjectClass and it is included in ConnectorAttributeName</td>
</tr>
</tbody>
</table>

**Table 12–8 Configuration Lookup for Connector**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectType Configuration Lookup</td>
<td>Lookup.&lt;ConnectorName&gt;.&lt;objectType&gt;.ProvAttrMap</td>
<td>Example for LDAP Group</td>
</tr>
<tr>
<td>Group Configuration Lookup</td>
<td>Lookup.LDAP.Group.ProvAttrMap</td>
<td></td>
</tr>
</tbody>
</table>

**Provisioning Lookup Lookup.CONNECTOR_NAME.OBJECT_TYPE.ProvAttrMap**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORM_FIELD_LABEL_ON_THE_PROCESS_FORM</td>
<td>Target system attribute name</td>
<td>Attribute mapping between Oracle Identity Manager and the connector.</td>
</tr>
</tbody>
</table>

12.5.4 Optional Lookups for Provisioning

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORM_FIELD_NAME [Create, Update, Delete]</td>
<td>ConnectorOperation OptionName</td>
<td>This field is used for generic definition. For example, where the field is mapped to operation option for CreateOp that is sent to connector named as myOperationOption.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>myField[Create]</td>
<td>myOperationOption</td>
<td></td>
</tr>
</tbody>
</table>
12.5.4.1 Provisioning Validation Lookup

Validation code is in an external OIM Java Task, it is a Java class uploaded to OIM repository. Validation java class template:

```java
public class MyValidator implements oracle.iam.connectors.common.validate.Validator {
    public boolean validate(java.util.HashMap hmUserDetails, java.util.HashMap hmEntitlementDetails, String sField) throws oracle.iam.connectors.common.ConnectorException {
        boolean isValid = false;
        // validation code goes HERE
        return isValid;
    }
}
```

The name of lookup storing the Recon Validation Lookup is defined in Main Configuration Lookup (Lookup.CONNECTOR_NAME.Configuration).

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Form Field Label</td>
<td>validatorClassName</td>
<td>Java class which performs validation</td>
</tr>
<tr>
<td></td>
<td>com.validationexample.MyValidator</td>
<td>for this recon field.</td>
</tr>
</tbody>
</table>

12.5.5 Optional Flags in Lookups for Provisioning Attribute Map

ICF-OIM Integration offers some advanced flags that modify the way provisioning is done. The following is the example for formats of flags in look up key:

```xml
<key value>[<flag>]
<key value>[<flag1, flag2, flag3>]
```

Let us assume we have a Group OIM attribute that is mapped to UnixGroup Connector attribute. This OIM attribute is populated by a UI lookup. The correct row in Provisioning lookup will be:

```xml
nullLookup key: Group[LOOKUP]
Lookup value: UnixGroup }}
```

The following is the list of flags and their effects.

**Provisioning Lookup Flag: TRUSTED**

For some attributes (for example trusted reconciliation of __ENABLE__ attribute), you need to pass on different values for trusted and target mode of operation. For most of the connectors which support status Reconciliation use code key: Status[Trusted], and decode value: __ENABLE__.

**Provisioning Lookup Flag: IGNORE**

An attribute marked as IGNORE, will be ignored during provisioning.

**Provisioning Lookup Flag: WRITEBACK**

If a field has WRITEBACK property, then update of that form field is:

1. update the value on the target system
2. query the value back from the target system (in order to get a normalized value)
3. update this normalized value on the user form.
Provisioning Lookup Flag: DATE
Use this flag to mark date fields. Oracle Identity Manager will apply the localized date format to these fields.

Provisioning Lookup Flag: PROVIDEONPSWDCHANGE
Use this flag to mark additional attributes that are needed for password change operation. By default only __PASSWORD__ attribute is sent, if no flag is applied.

12.5.6 Compound attributes in Provisioning Attribute Map
ICF Common enables to use Groovy expressions on the right hand side, so that provisioned attribute can be computed based on multiple fields. For example, in Active Directory Connector, decode value for the name field is:

__NAME__=CN=${Common_Name},${Organization_Name}

12.6 Concepts of Reconciliation in ICF Common
ICF Common leverages the definition and types of reconciliation defined by Oracle Identity Manager server. IT Resource Name / Resource Object Name and Object Type are mandatory attributes reconciliation using ICF Common. Any target system attribute can be used as Latest Token Attribute.

This section contains the following topics:
- Section 12.6.1, "Types of Reconciliation"
- Section 12.6.2, "List of Reconciliation Artifacts in Oracle Identity Manager"

12.6.1 Types of Reconciliation
Reconciliation involves pulling identities from resource (also referred as target) to destination (Oracle Identity Manager). Reconciliation can be classified based on following criteria:
- Destination type: trusted, target recon.
- Scope: full, incremental recon.

Table 12–9 illustrates the common reconciliation parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Field Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter</td>
<td>Optional</td>
<td>Filter to limit the number of reconciled accounts, or to select specific set of users.</td>
</tr>
<tr>
<td>IT Resource Name</td>
<td>Mandatory</td>
<td>Name of IT Resource instance to reconciliation.</td>
</tr>
<tr>
<td>Object Type</td>
<td>Constant</td>
<td>User object class</td>
</tr>
<tr>
<td>Resource Object Name</td>
<td>Constant</td>
<td>Determines what OIM Resource Object to use for reconciliation.</td>
</tr>
</tbody>
</table>

12.6.1.1 Target and Trusted Reconciliation
Scheduled task name include keywords such as trusted, target, to determine the type of destination. By choosing the scheduled task, it is determined whether trusted or target reconciliation is launched.
12.6.1.2 Full, Incremental Reconciliation

Full reconciliation involves reconciling all existing user records from the target system into Oracle Identity Manager. During Full Reconciliation, scheduled task is launched for the first time, it is run in full reconciliation mode and from next runs happen in incremental mode. It is possible to switch manually between full/incremental reconciliation modes by emptying the Latest Token field on the scheduled task.

If no value is supplied in Incremental Recon Date Attribute and Incremental Recon Attribute, reconciliation is considered as Target Recon.

The following scheduled tasks offer optional incremental reconciliation:

- Connector Target User Reconciliation
- Connector Trusted User Reconciliation

12.6.1.3 Advanced Incremental Reconciliation

The format of Latest Token is altered by setting the Recon Date Format scheduled task parameter. The formatting string needs to follow standard pattern used in Java. For more information about formatting string used in Java, see Java Doc on Oracle Technology Network.

By default the Latest Token is long value that holds Unix/POSIX time.

12.6.1.4 Delete Reconciliation

Some connectors supports both trusted and target reconciliation of deleted accounts. Target reconciliation evaluate which OIM users have lost their account on the resource, and unassign this resource in Oracle Identity Manager. Trusted Delete Reconciliation goes further, and deletes the OIM User.

12.6.1.5 Group Lookup Reconciliation

Some connectors may support reconciliation of Groups, or other object classes to Lookups.

Before the first use of provisioning with the connector, it is advised to launch Lookup reconciliation. This reconciliation populate the Lookup.CONNECTOR_NAME.ObjectType table with groups available on an IT Resource that is being reconciled. The reconciliation is performed by the Connector Lookup Reconciliation scheduled task.

You need to set the IT resource parameter name, the rest of the parameters are constant as shown in Table 12–9.

Table 12–10 illustrates the common reconciliation parameters.

<table>
<thead>
<tr>
<th>Code Key</th>
<th>Decode Key</th>
<th>Object Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Form field name</td>
<td>Connector attribute</td>
<td>Group, or other</td>
</tr>
</tbody>
</table>

For example, the list of names returned by the connector is used to populate the lookup for provisioning. When a new user is provisioned, the group field can display the list of available groups.

12.6.2 List of Reconciliation Artifacts in Oracle Identity Manager

In Oracle Identity Manager, there are two methods of control over reconciliation:

- Lookups for Reconciliation: they define mapping, transformation of the attributes.
Scheduled tasks - they define the way reconciliation is executed on connector side, or determine account/lookup mode of reconciliation.

12.6.2.1 Lookups for Reconciliation
The following are the lookups for reconciliation:

Reconciliation Attribute Map Lookup
The reconciliation attribute map contains the following pairs:
- Code key: Resource Object reconciliation field name
- Decode: Target system attribute name

Table 12–11 illustrates this mapping (Lookup.CONNECTOR_NAME.UM.ReconAttrMap) used by Scheduled tasks that perform reconciliation.

---

**Note:** Resource Objects are different for Trusted and Target mode of reconciliation.

---

**Table 12–11 Attribute Mapping for Lookup.CONNECTOR_NAME.UM.ReconAttrMap**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recon Field Name</td>
<td>ConnectorAttributeName</td>
<td>This is a basic mapping type, single value</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Connector Attribute Name to simple Recon Field.</td>
</tr>
<tr>
<td>Recon Field Name~Child Recon Field Name</td>
<td>ConnectorAttributeName</td>
<td>This maps multivalued</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ConnectorAttributeName to child recon field.</td>
</tr>
<tr>
<td>Recon Field Name~Child Recon Field Name</td>
<td>ConnectorAttributeName<del>EmbeddedObjectClass</del>EmbeddedAttribute</td>
<td>This maps embedded attribute to child recon field.</td>
</tr>
</tbody>
</table>

---

Example showing Design Console updates to setup reconciliation with child table
The following is the example showing Design Console updates to setup reconciliation with child table:
- Child table name: UD_FF_CHILD
- Column name: UD_FF_CHILD_ROLE
- Field label: Role

To set up reconciliation with the above child table:
2. Create a new Reconciliation Data field under Object Reconciliation tab.

---

**Note:** While creating a new Reconciliation Data field, you must ensure that the field name be Roles and Field Type be Multi-Valued Attribute. This represents the child table as a whole UD_FF_CHILD.
3. Right click on the newly created Reconciliation Data Field and define a new property field as **Role**. This represents the actual column of the child table `UD_FF_CHILD_ROLE`.

4. Open **Reconciliation Field Mapping** under Process Definition.

5. Click on **Add Table Map**.

6. Select Field Name as **Roles**.

7. Select Table Name as `UD_FF_CHILD`.

8. Right click on the newly created field name Roles, click on **Define proper field name**.

9. Select **Role** for field name.

10. Select Process data field as `UD_FF_CHILD_ROLE`.

11. Update Lookup.CONNECTOR_NAME.UM.ReconAttrMap to include new lookup field with code key = Roles–Role and decode = Role (this should be connector side attribute name).

12. Go back to Resource Object and create reconciliation profile.

### 12.7 Predefined Scheduled Tasks

ICF-OIM integration provides the following list of predefined scheduled tasks that a connector supports:

- Section 12.7.1, “LookupReconTask”
- Section 12.7.2, “SearchReconTask”
- Section 12.7.3, “SearchReconDeleteTask”
- Section 12.7.4, “SyncReconTask”

#### 12.7.1 LookupReconTask

This scheduled task is based on ICF SearchOp based reconciliation. Oracle Identity Manager form field of type lookup stores a set of predefined values. These values originate from the connector’s search query. The Code Key Attribute is the form field’s name, and the Decode Attribute is the name of attribute on the target system (also called Connector).

Internally, this task invokes a search operation on the connector for the given Object Type that is translated to ICF Object Class eventually.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resource Name</td>
<td>Specifies the name of the IT resource for target system installation.</td>
</tr>
<tr>
<td>Object Type</td>
<td>User</td>
</tr>
<tr>
<td>Lookup Name</td>
<td>This attribute holds the name of the lookup definition that maps each lookup definition with the data source from which values must be fetched.</td>
</tr>
<tr>
<td>Decode Attribute</td>
<td>Specifies the Decode Key column of the lookup definition.</td>
</tr>
</tbody>
</table>
**12.7.2 SearchReconTask**

The following is the ICF SearchOp based reconciliation.

**Table 12–13 Identity Connector Target Search Reconciliation Attributes**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resource Name</td>
<td>Specifies the name of the IT resource for target system installation.</td>
</tr>
<tr>
<td>Resource Object Name</td>
<td>Specifies the name of the Resource Object used for reconciliation.</td>
</tr>
<tr>
<td>Object Type</td>
<td>User</td>
</tr>
<tr>
<td>Filter</td>
<td>Allows to create sophisticated filtration expressions in order to speed up/refine scheduled task execution.</td>
</tr>
<tr>
<td>Latest Token</td>
<td>Used in Filter as one of the criteria in incremental reconciliation. Any target system attribute can be used as Latest Token Attribute. This value is calculated as follows: If a reconciliation has fetched 100 records and Timestamp is chosen as a Incremental Recon Attribute, then Latest Token = Max Timestamp of all 100 records. It is not the Schedule task execution end timestamp.</td>
</tr>
<tr>
<td>Incremental Recon Date Attribute (optional, type Date)</td>
<td>Attribute used to update Latest Token. Note: If no value is supplied in Incremental Recon Date Attribute, then reconciliation is considered as Target Reconciliation.</td>
</tr>
<tr>
<td>Incremental Recon Attribute (optional, type long)</td>
<td>Attribute used to update Latest Token. Note: If no value is supplied in Incremental Recon Attribute, then reconciliation is considered as Target Reconciliation.</td>
</tr>
</tbody>
</table>

**12.7.3 SearchReconDeleteTask**

This scheduled task is used for ICF SearchOp based reconciliation.

**Table 12–14 Identity Connector Target Search Delete Reconciliation Attributes**

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resource Name</td>
<td>Specifies the name of the IT resource for target system installation.</td>
</tr>
<tr>
<td>Resource Object Name</td>
<td>Specifies the name of the Resource Object used for reconciliation.</td>
</tr>
<tr>
<td>Object Type</td>
<td>User</td>
</tr>
<tr>
<td>Filter</td>
<td>Allows to create sophisticated filtration expressions in order to speed up/refine scheduled task execution.</td>
</tr>
</tbody>
</table>

**12.7.4 SyncReconTask**

This scheduled task is used for ICF SyncOp based reconciliation. The Sync Token field persists the token of last synchronization.
12.8 ICF Filter Syntax

GroovyFilterBuilder allows to create sophisticated filtration expressions in order to speed up/refine scheduled task execution.

**WARNING:** The GroovyFilterBuilder uses the connector attribute name for filtration. See Connector documentation for the attribute name.

**Examples**
The following example could limit the number of reconciled accounts to only those, where account name starts with letter "a", this filter is denoted by the following expression:

$$\text{startsWith('__NAME__', 'a')}$$

Some more advanced search could require to filter only those account names, which end with "z" letter, therefore the filter is:

$$\text{startsWith('__NAME__', 'a')} \& \text{endsWith('__NAME__', 'z')}$$

**Figure 12–3** shows the graphical scheme of Filter Syntax.

### Table 12–15  Identity Connector Target Sync Reconciliation Attributes

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resource Name</td>
<td>Specifies the name of the IT resource for target system installation.</td>
</tr>
<tr>
<td>Resource Object Name</td>
<td>Specifies the name of the Resource Object used for reconciliation</td>
</tr>
<tr>
<td>Object Type</td>
<td>User</td>
</tr>
<tr>
<td>Filter</td>
<td>Allows to create sophisticated filtration expressions in order to speed up/refine scheduled task execution.</td>
</tr>
<tr>
<td>Sync Token</td>
<td>Token of last synchronization.</td>
</tr>
</tbody>
</table>
It is also possible to use a shortcut for and/or operators.
For example, `<filter1> & <filter2>` instead of `and (filter1, filter2)`, analogically replace or with |.

**Definition in EBNF format:**
The following is the Extended Backus–Naur Form (EBNF) description of the expression language used for Search Filters in reconciliation.

```plaintext
syntax = expression ( operator expression )*
operator = 'and' | 'or'
expression = ('not')? filter
filter = ('equalTo' | 'contains' | 'containsAllValues' | 'startsWith' | 'endsWith'
```
ICF Filter Syntax

```
| 'greaterThan' | 'greaterThanOrEqualTo' | 'lessThan' | 'lessThanOrEqualTo' |
attributeValue = singleValue | multipleValues
singleValue = 'value'
multipleValues = 'value_1' (',' 'value_n')* '
```

**Table 12–16** lists the filter syntax that you can use and the corresponding description and sample values.

**Note:** Filters with wildcard characters are not supported.

**Table 12–16  Keywords and Syntax for the Filter Attribute**

<table>
<thead>
<tr>
<th>Filter Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>String Filters</strong></td>
<td></td>
</tr>
</tbody>
</table>
| `startsWith('ATTRIBUTE_NAME', 'PREFIX')` | Records whose attribute value starts with the specified prefix are reconciled.  
**Example:** `startsWith('userPrincipalName', 'John')`  
In this example, all records whose userPrincipalName begins with 'John' are reconciled. |
| `endsWith('ATTRIBUTE_NAME', 'SUFFIX')` | Records whose attribute value ends with the specified suffix are reconciled.  
**Example:** `endsWith('sn', 'Doe')`  
In this example, all records whose last name ends with 'Doe' are reconciled. |
| `contains('ATTRIBUTE_NAME', 'STRING')` | Records where the specified string is contained in the attribute's value are reconciled.  
**Example:** `contains('displayName', 'Smith')`  
In this example, all records whose display name contains 'Smith' are reconciled. |
| `containsAllValues('ATTRIBUTE_NAME', ['STRING1', 'STRING2', ... , 'STRINGn'])` | Records that contain all the specified strings for a given attribute are reconciled.  
**Example:** `containsAllValues('objectClass', ['person', 'top'])`  
In this example, all records whose objectClass contains both 'top' and 'person' are reconciled. |
| **Equality and Inequality Filters** | |
| `equalTo('ATTRIBUTE_NAME', 'VALUE')` | Records whose attribute value is equal to the value specified in the syntax are reconciled.  
**Example:** `equalTo('sAMAccountName', 'Sales Organization')`  
In this example, all records whose sAMAccountName is Sales Organization are reconciled. |
### greaterThan('ATTRIBUTE_NAME', 'VALUE')
Records whose attribute value (string or numeric) is greater than (in lexicographical or numerical order) the value specified in the syntax are reconciled.

**Example 1:** `greaterThan('cn', 'bob')`
In this example, all records whose common name is present after the common name 'bob' in the lexicographical order (or alphabetical order) are reconciled.

**Example 2:** `greaterThan('employeeNumber', '1000')`
In this example, all records whose employee number is greater than 1000 are reconciled.

### greaterThanOrEqualTo('ATTRIBUTE_NAME', 'VALUE')
Records whose attribute value (string or number) is lexographically or numerically greater than or equal to the value specified in the syntax are reconciled.

**Example 1:** `greaterThanOrEqualTo('sAMAccountName', 'S')`
In this example, all records whose sAMAccountName is equal to 'S' or greater than 'S' in lexicographical order are reconciled.

**Example 2:** `greaterThanOrEqualTo('employeeNumber', '1000')`
In this example, all records whose employee number is greater than or equal to 1000 are reconciled.

### lessThan('ATTRIBUTE_NAME', 'VALUE')
Records whose attribute value (string or numeric) is less than (in lexicographical or numerical order) the value specified in the syntax are reconciled.

**Example 1:** `lessThan('sn', 'Smith')`
In this example, all records whose last name is present after the last name 'Smith' in the lexicographical order (or alphabetical order) are reconciled.

**Example 2:** `lessThan('employeeNumber', '1000')`
In this example, all records whose employee number is less than 1000 are reconciled.

### lessThanOrEqualTo('ATTRIBUTE_NAME', 'VALUE')
Records whose attribute value (string or numeric) is lexographically or numerically less than or equal to the value specified in the syntax are reconciled.

**Example 1:** `lessThanOrEqualTo('sAMAccountName', 'A')`
In this example, all records whose sAMAccountName is equal to 'A' or less than 'A' in lexicographical order are reconciled.

**Example 2:** `lessThanOrEqualTo('employeeNumber', '1000')`
In this example, all records whose employee number is less than or equal to 1000 are reconciled.

### Complex Filters
ICF Filter Syntax

Integrating ICF with Oracle Identity Manager

Records that satisfy conditions in both filter1 and filter2 are reconciled. In this syntax, the logical operator & (ampersand symbol) is used to combine both filters.

Example: `startsWith('cn', 'John') & endsWith('sn', 'Doe')`

In this example, all records whose common name starts with John and last name ends with Doe are reconciled.

Records that satisfy either the condition in filter1 or filter2 are reconciled. In this syntax, the logical operator | (vertical bar) is used to combine both filters.

Example: `contains('sAMAccountName', 'Andy') | contains('sn', 'Brown')`

In this example, all records that contain 'Andy' in the sAMAccountName attribute or records that contain 'Brown' in the last name are reconciled.

Records that do not satisfy the given filter condition are reconciled.

Example: `not(contains('cn', 'Mark'))`

In this example, all records that does not contain the common name 'Mark' are reconciled.

Table 12–16 (Cont.) Keywords and Syntax for the Filter Attribute

<table>
<thead>
<tr>
<th>Filter Syntax</th>
<th>Description</th>
</tr>
</thead>
</table>
| `<FILTER1> & <FILTER2>` | Records that satisfy conditions in both filter1 and filter2 are reconciled. In this syntax, the logical operator & (ampersand symbol) is used to combine both filters.  
Example: `startsWith('cn', 'John') & endsWith('sn', 'Doe')`  
In this example, all records whose common name starts with John and last name ends with Doe are reconciled. |
| `<FILTER1> | <FILTER2>` | Records that satisfy either the condition in filter1 or filter2 are reconciled. In this syntax, the logical operator | (vertical bar) is used to combine both filters.  
Example: `contains('sAMAccountName', 'Andy') | contains('sn', 'Brown')`  
In this example, all records that contain 'Andy' in the sAMAccountName attribute or records that contain 'Brown' in the last name are reconciled. |
| `not(<FILTER>)` | Records that do not satisfy the given filter condition are reconciled.  
Example: `not(contains('cn', 'Mark'))`  
In this example, all records that does not contain the common name 'Mark' are reconciled. |
To build a custom connector, you must first implement the Identity Connector (ICF-based connector) by implementing the ICF SPI. After this, you need to create OIM artifacts to integrate the Identity Connector to Oracle Identity Manager, which can reuse ICProvisioningManager (part of ICF integration) in their Adapter Tasks to invoke provisioning operations on Identity Connector, and also can reuse Reconciliation Tasks that are implemented in ICF integration. Therefore, by using ICF integration, you need not write any integration code in java, ICF integration uses ICF APIs to access the Identity Connectors.

For information about Java APIs related to ICF integration, see Oracle Fusion Middleware Java API Reference for Identity Connector Framework.

For information about Java APIs related to Oracle Identity Manager, see Oracle Fusion Middleware Java API Reference for Oracle Identity Manager.
This chapter provides the information about the common customization procedures that needs to be performed for all ICF connectors.

The following are the topics discussed under this chapter:

- Section 14.1, "Configuring Connector Load Balancer"
- Section 14.2, "Configuring Validation of Data During Reconciliation and Provisioning"
- Section 14.3, "Configuring Transformation of Data During User Reconciliation"
- Section 14.4, "Configuring Resource Exclusion Lists"
- Section 14.5, "Setting SSL for Connector Server and OIM"
- Section 14.6, "Adding Target System Attributes"

### 14.1 Configuring Connector Load Balancer

A connector server is an application that enables remote execution of an Identity Connector. If there are multiple connector servers, then you must ensure the high availability of the connector server for the remote execution of the Identity connector and failover management. Therefore, you must configure a load balancer for a connector server. Figure 14-1 depicts the typical configuration for a cluster of connector servers. The flow in the figure is based on the assumption that the required connector bundle is deployed across all the connector servers.
To configure the load balancer for a connector server:

1. Install connector server on nodes including the connector bundle. This involves copying and running the server binaries on all nodes.

2. Setup your load balancer so that every request on port 8759 (default for connector server, which is configurable) is being load balanced across the nodes created in Step 1.

3. Create a connector server IT resource, and point it to your host deployed with load balancer.

4. Configure your connector IT resource with the following details:
   - host: target address
   - connector server name: use the name created in Step 3.

Note: You must make sure to double-check that the incoming port of load balancer is same as the one given in connector server IT resource. In addition, you must check that the ports set up for cluster nodes match the one used for configuring your load balancer.
Configuring Validation of Data During Reconciliation and Provisioning

The Lookup.CONNECTOR_NAME.ProvValidations and Lookup.CONNECTOR_NAME.UM.ReconValidations lookup definitions hold single-valued data to be validated during provisioning and reconciliation operations, respectively.

For example, you can validate data fetched from the First Name attribute to ensure that it does not contain the number sign (#). In addition, you can validate data entered in the First Name field on the process form so that the number sign (#) is not sent to the target system during provisioning operations.

**Note:** The Lookup.CONNECTOR_NAME.UM.ProvValidations and Lookup.CONNECTOR_NAME.UM.ReconValidations lookup definitions are optional and do not exist by default.

You must add these lookups as decode values to the Lookup.CONNECTOR_NAME.UM.Configuration lookup definition to enable exclusions during provisioning and reconciliation operations. See the respective connector guide for more information about setting up the lookup definition for user operations.

To configure validation of data:

1. Write code that implements the required validation logic in a Java class with a fully qualified domain name (FQDN), such as org.identityconnectors.CONNECTOR_NAME.extension.CONNECTOR_NAMEValidator.

   This validation class must implement the validate method. The following sample validation class checks if the value in the First Name attribute contains the number sign (#):

   ```java
   package com.validationexample;

   import java.util.HashMap;

   public class MyValidator {
       public boolean validate(HashMap hmUserDetails, HashMap hmEntitlementDetails, String sField) throws ConnectorException {
           /* You must write code to validate attributes. Parent data values can be fetched by using hmUserDetails.get(field) * For child data values, loop through the ArrayList/Vector fetched by hmEntitlementDetails.get("Child Table") * Depending on the outcome of the validation operation, * the code must return true or false. */

           boolean valid = true;
           String sFirstName = (String) hmUserDetails.get(sField);
           for (int i = 0; i < sFirstName.length(); i++) {
               if (sFirstName.charAt(i) == '#') {
                   valid = false;
               }
           }
           return valid;
       }
   }
   ```

   **Note:** In this sample code, the value ‘false’ is returned if the field contains the number sign (#). Otherwise, the value ‘true’ is returned.
valid = false;
break;
}
return valid;
}

2. Log in to the Design Console.

3. Create one of the following new lookup definitions:
   - To configure validation of data for reconciliation:
     Lookup.CONNECTOR_NAME.UM.ReconValidations
   - To configure validation of data for provisioning:
     Lookup.CONNECTOR_NAME.UM.ProvValidations

4. In the Code Key column, enter the resource object field name that you want to validate. For example, Alias.

5. In the Decode column, enter the class name. For example, org.identityconnectors.CONNECTOR_NAME.extension.CONNECTOR_NAMEValidator.

6. Save the changes to the lookup definition.

7. Search for and open the Lookup.CONNECTOR_NAME.UM.Configuration lookup definition.

8. In the Code Key column, enter one of the following entries:
   - To configure validation of data for reconciliation:
     Recon Validation Lookup
   - To configure validation of data for provisioning:
     Provisioning Validation Lookup

9. In the Decode column, enter one of the following entries:
   - To configure validation of data for reconciliation:
     Lookup.CONNECTOR_NAME.UM.ReconValidations
   - To configure validation of data for provisioning:
     Lookup.CONNECTOR_NAME.UM.ProvValidations

10. Save the changes to the lookup definition.

11. Create a JAR with the class and upload it to the Oracle Identity Manager database as follows:

    Run the Oracle Identity Manager Upload JARs utility to post the JAR file created in Step 7 to the Oracle Identity Manager database. This utility is copied into the following location when you install Oracle Identity Manager:

    Note: Before you use this utility, verify that the WL_HOME environment variable is set to the directory in which Oracle WebLogic Server is installed.
Configuring Transformation of Data During User Reconciliation

For Microsoft Windows:

`OIM_HOME/server/bin/UploadJars.bat`

For UNIX:

`OIM_HOME/server/bin/UploadJars.sh`

When you run the utility, you are prompted to enter the login credentials of the Oracle Identity Manager administrator, URL of the Oracle Identity Manager host computer, context factory value, type of JAR file being uploaded, and the location from which the JAR file is to be uploaded. Select 1 as the value of the JAR type.

See Also: "Migrating JARs and Resource Bundle" on page 37-5 for detailed information about the Upload JARs utility

12. Run the PurgeCache utility to clear content related to request datasets from the server cache.

13. Perform reconciliation or provisioning to verify validation for the field, for example, Alias.

### 14.3 Configuring Transformation of Data During User Reconciliation

The Lookup.CONNECTOR_NAME.UM.ReconTransformations lookup definition holds single-valued user data to be transformed during reconciliation operations. For example, you can use First Name and Last Name values to create a value for the Full Name field in Oracle Identity Manager.

---

**Note:** The Lookup.CONNECTOR_NAME.UM.ReconTransformations lookup definition is optional and does not exist by default.

You must add this lookup as decode value to the Lookup.CONNECTOR_NAME.UM.Configuration lookup definition to enable exclusions during provisioning and reconciliation operations. See the respective connector guide for more information about setting up the lookup definition for user operations.

---

To configure transformation of single-valued user data fetched during reconciliation:

1. Write code that implements the required transformation logic in a Java class with a fully qualified domain name (FQDN), such as `org.identityconnectors.CONNECTOR_NAME.extension.CONNECTOR_NAMETransformation`.

This transformation class must implement the transform method. The following sample transformation class creates a value for the Full Name attribute by using values fetched from the First Name and Last Name attributes of the target system:

```java
package com.transformationexample;

import java.util.HashMap;

public class MyTransformer {
    public Object transform(HashMap hmUserDetails, HashMap hmEntitlementDetails, String sField) throws ConnectorException {
        // Your transformation logic here
    }
}
```

See Also: "Migrating JARs and Resource Bundle" on page 37-5 for detailed information about the Upload JARs utility.
* You must write code to transform the attributes.
* Parent data attribute values can be fetched by
  using `hmUserDetails.get("Field Name")`.
* To fetch child data values, loop through the
  `ArrayList/Vector` fetched by `hmEntitlementDetails.get("Child Table")`
  `Return the transformed attribute.`
*/

```java
String sFirstName = (String) hmUserDetails.get("First Name");
String sLastName = (String) hmUserDetails.get("Last Name");
return sFirstName + "." + sLastName;
```

2. Log in to the Design Console.

4. In the **Code Key** column, enter the resource object field name you want to transform. For example, `Alias`.

5. In the **Decode** column, enter the class name. For example, `org.identityconnectors.CONNECTOR_NAME.extension.CONNECTOR_NAMETransformation`.

6. Save the changes to the lookup definition.

7. Search for and open the `Lookup.CONNECTOR_NAME.UM.Configuration` lookup definition.

8. In the **Code Key** column, enter `Recon Transformation Lookup`.

9. In the **Decode** column, enter `Lookup.CONNECTOR_NAME.UM.ReconTransformations`.

10. Save the changes to the lookup definition.

11. Create a JAR with the class and upload it to the Oracle Identity Manager database as follows:

    Run the Oracle Identity Manager Upload JARs utility to post the JAR file created in Step 7 to the Oracle Identity Manager database. This utility is copied into the following location when you install Oracle Identity Manager:

    ```
    Note: Before you use this utility, verify that the `WL_HOME` environment variable is set to the directory in which Oracle WebLogic Server is installed.
    ```

    For Microsoft Windows:
    
    `OIM_HOME/server/bin/UploadJars.bat`

    For UNIX:
    
    `OIM_HOME/server/bin/UploadJars.sh`

    When you run the utility, you are prompted to enter the login credentials of the Oracle Identity Manager administrator, URL of the Oracle Identity Manager host computer, context factory value, type of JAR file being uploaded, and the location from which the JAR file is to be uploaded. Select 1 as the value of the JAR type.
12. Run the PurgeCache utility to clear content related to request datasets from the server cache.

13. Perform reconciliation to verify transformation of the field, for example, Alias.

### 14.4 Configuring Resource Exclusion Lists

The Lookup.CONNECTOR_NAME.UM.ProvExclusionList and Lookup.CONNECTOR_NAME.UM.ReconExclusionList lookup definitions hold user IDs of target system accounts for which you do not want to perform provisioning and reconciliation operations, respectively.

**Note:** The Lookup.CONNECTOR_NAME.UM.ProvExclusionList and Lookup.CONNECTOR_NAME.UM.ReconExclusionList lookup definitions are optional and do not exist by default.

You must add these lookups as decode values to the Lookup.CONNECTOR_NAME.UM.Configuration lookup definition to enable exclusions during provisioning and reconciliation operations. See the respective connector guide for more information about setting up the lookup definition for user operations.

The following is the format of the values stored in these lookups:

<table>
<thead>
<tr>
<th>Code Key</th>
<th>Decode</th>
<th>Sample Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Login Id resource object field name</td>
<td>User ID of a user</td>
<td>Code Key: User Login Id&lt;br&gt;Decode: User001</td>
</tr>
<tr>
<td>User Login Id resource object field name with the [PATTERN] suffix</td>
<td>A regular expression supported by the representation in the java.util.regex.Pattern class</td>
<td>Code Key: User Login Id[PATTERN]&lt;br&gt;To exclude users matching any of the user ID’s User001, User002, User088, then:&lt;br&gt;Decode: User001</td>
</tr>
</tbody>
</table>

To add entries in the lookup for exclusions during provisioning operations:

1. On the Design Console, expand Administration and then double-click Lookup Definition.

2. Create a new lookup definition, Lookup.CONNECTOR_NAME.UM.ProvExclusionList.
Configuring Resource Exclusion Lists

Note: To specify user IDs to be excluded during reconciliation operations, create a new lookup definition called
Lookup.CONNECTOR_NAME.UM.ReconExclusionList and add entries to that lookup.

3. Click Add.

4. In the Code Key and Decode columns, enter the first user ID to exclude.

Note: The Code Key represents the resource object field name on
which the exclusion list is applied during provisioning operations.

5. Repeat Steps 3 and 4 for the remaining user IDs to exclude.

For example, if you do not want to provision users with user IDs User001, User002, and User088 then you must populate the lookup definition with the following values:

<table>
<thead>
<tr>
<th>Code Key</th>
<th>Decode</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Login Id</td>
<td>User001</td>
</tr>
<tr>
<td>User Login Id</td>
<td>User002</td>
</tr>
<tr>
<td>User Login Id</td>
<td>User088</td>
</tr>
</tbody>
</table>

You can also perform pattern matching to exclude user accounts. You can specify regular expressions supported by the representation in the java.util.regex.Pattern class.

See Also: For information about the supported patterns, visit
http://download.oracle.com/javase/6/docs/api/java/util/regex
/Pattern.html

For example, if you do not want to provision users matching any of the user IDs User001, User002, and User088, then you must populate the lookup definition with the following values:

<table>
<thead>
<tr>
<th>Code Key</th>
<th>Decode</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Login Id[PATTERN]</td>
<td>User001</td>
</tr>
</tbody>
</table>

If you do not want to provision users whose user IDs start with 00012, then you must populate the lookup definition with the following values:

<table>
<thead>
<tr>
<th>Code Key</th>
<th>Decode</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Login Id[PATTERN]</td>
<td>00012*</td>
</tr>
</tbody>
</table>

6. Click Save.
14.5 Setting SSL for Connector Server and OIM

To set up the SSL communication between Connector Server and Oracle Identity Manager:

1. Generate a new SSL key (or you can reuse your existing key):
   
   ```
   keytool -genkey -alias keyconnserv -keyalg dsa -keystore <yourKeyStore.jks>  
   -storepass <yourPassword> -validity 360
   ```

2. Export the newly generated public key:
   
   ```
   keytool -export -keystore <yourKeyStore.jks> -storepass <yourPassword> -alias keyconnserv -file icfkey-public.cer
   ```

3. Configure your Connector Server for SSL, and start using the new keystore set in Step 1.

4. Import the public key generated in Step 2 (icfkey-public.cer) to OIM keystore.

5. Configure IT Resource such as host, port, and so on. These parameters will be passed on to Connector Server (an extra field of IT Resource).

6. Configure Connector Server, using SSL:
   
   a. Deploy an SSL certificate to the Connector Server’s system.
   b. Configure your Connector Server to provide SSL sockets.
   c. Configure your application to communicate with the Connector Server using SSL.

   Refer to the target system’s manual for specific notes on configuring connections to identity connector servers. You will indicate to your application that an SSL connection is required when establishing a connection for each SSL-enabled connector server. Additionally, if any of the SSL certificates used by your connector servers are issued by a non-standard certificate authority, your application must be configured to respect the additional authorities. Refer to your manual for notes regarding certificate authorities.

**Note:**

Java applications may solve the issue of non-standard certificate authorities by expecting the following Java system properties to be passed when launching the application:

- `javax.net.ssl.trustStorePassword`
  
  For example:
  
  `-Djavax.net.ssl.trustStorePassword=changeit`

- `javax.net.ssl.trustStore`
  
  For example:
  
  `-Djavax.net.ssl.trustStore=/usr/myApp_cacerts`

Alternately, the non-standard certificate authorities may be imported to the standard `${JAVA_HOME}/lib/security/cacerts` directory.

7. Import the public key generated in Step 2 to OIM keystore.

   If you follow to choose the default Weblogic keystore, perform the following:
Adding Target System Attributes

14.5.1 Troubleshooting SSL

The following is an example of exception in connector server logs:

java.net.SocketException: Default SSL context init failed: null

This means that the path to keystore is incorrect. To handle this exception, make sure you provide the following full/absolute path:

For UNIX

./connectorserver.sh /run "-J-Djavax.net.ssl.keyStore=/path/to/mykeystore.jks" 
"-J-Djavax.net.ssl.keyStorePassword=changeit"

For Windows

./connectorserver.sh /run "-J-Djavax.net.ssl.keyStore=C:\path\to\mykeystore.jks" 
"-J-Djavax.net.ssl.keyStorePassword=changeit"

You must also ensure the following check points:

- Check your configuration folder for the setting of connector server configuration to use SSL
- Restart your WLS after importing public keys from the connector server, if the public key present in OIM keystore

14.6 Adding Target System Attributes

Adding target system attributes includes the following subsections:

- Section 14.6.1, "Adding Target System Attributes for Provisioning"
- Section 14.6.2, "Adding Target System Attributes for Target Reconciliation"
- Section 14.6.3, "Adding Target System Attributes for Trusted Reconciliation"

**Note:** If you add an attribute with a Date type field, make sure that you add the [Date] suffix in the Lookup definition code key.

For example, if you add _LAST_PASSWORD_CHANGE_DATE_, when you make changes in the code key for Lookup.CONNECTOR_NAME.UM.ReconAttrMap or Lookup.CONNECTOR_NAME.UM.ProvAttrMap, specify the attribute as:

_LAST_PASSWORD_CHANGE_DATE_[Date]

14.6.1 Adding Target System Attributes for Provisioning

By default, the target system attributes are mapped for provisioning between Oracle Identity Manager and the target system. If required, you can map additional attributes for provisioning by performing these steps.
To add a target system attribute for provisioning, follow these steps:

1. Add a new form field. To add a new field to the Process form:
   a. Open the Form Designer form. This form is in the Development Tools folder of the Oracle Identity Manager Design Console.
   b. Query for the UD_CONNECTOR_NAMECON form.
   c. Click Create New Version. The Create a New Version dialog box is displayed.
   d. In the Label field, enter the name of the version.
   e. Click Save and close the dialog box.
   f. From the Current Version box, select the version name that you entered in the Label field in Step 4.
   g. On the Additional Columns tab, click Add.
   h. Specify the new field name and other values.
   i. Click Save.
   j. Click Make Version Active to make the new form field visible to the user.

Now, if you go to Oracle Identity Manager and try to provision a new user to Connector, you should see the new form field. Next, you must add the new form field to the Provisioning Mapping Lookup.

2. Add the new field to the Provisioning Mapping Lookup. After creating a new form field, you must add that field to the Provisioning Mapping Lookup, as follows:
   a. Expand Administration and then double-click Lookup Definition.
   b. In the Lookup Definition window, search for CONNECTOR_NAME.
      The Design Console returns Lookup.CONNECTOR_NAME.UM.ProvAttrMap.
   c. Select the Lookup Definition Table tab, and select Lookup.CONNECTOR_NAME.UM.ProvAttrMap.
      The Lookup Code Information tab maps the Oracle Identity Manager form field names and the CONNECTOR_NAME Identity Connector attributes. Where the Code Key column contains the Oracle Identity Manager field labels and the Decode column contains the attribute names supported by the CONNECTOR_NAME identity connector.
   d. Add a new record for the new form field. Type the new form field name into the Code Key column and type the CONNECTOR_NAME identity connector attribute name into the Decode column.
   e. Click Save.

Now, when you create a new CONNECTOR_NAME user, the connector will get the new attribute as part of the create operation.

At this point, the process task only handles creates. Next, you must change the process task to also handle updates. Instructions are described in the next steps.

Note: In this section, the term "attribute" refers to the identity data fields that store user data.
3. Change the process task to handle updates, as follows:
   a. In the Design Console, expand **Process Management** and then double-click **Process definition**.
   b. Search for and select process CONNECTOR_NAME User.
   c. In the Task column, look for an update task that is similar to the one you want to add and select that entry.
   d. Click **Add**.
   e. In the Creating New Task dialog, select the General tab and enter a Task Name and a Task Description.

   The Task Name is important because it will be the form name field. Be sure to include the event you want the task to handle. For example, if you add the Building field for provisioning, then add the Building Updated task. Now, this update event will be triggered when the Building field is updated.

   f. In the Task Properties section, set the following properties as noted:
      - Conditional: Enabled
      - Required for Completion: Disabled
      - Disable Manual Insert: Disabled
      - Allow Cancellation while Pending: Enabled
      - Allow Multiple Instances: Enabled

   You do not have to change any of the remaining properties.

   g. Save your changes.

   h. To add an Event Handler, select the Integration tab, and then click **Add**.

   i. When the Handler Select dialog box displays, select Adapter as the handler type and then perform the following steps:

      Select adapter **adpCONNECTOR_NAMECONNECTORUPDATEATTRIBUTEVALUE** and click **Save**.

      Map all of the variables that are configured for the event adapter.

      In the Adapter Variables section, double-click a variable name to open the Edit Data Mapping For Variable dialog box. Specify the following values for each variable in turn. Be sure to save your changes after each mapping.

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Map To</th>
<th>Qualifier</th>
<th>Literal Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>itResourceFieldName</td>
<td>Literal</td>
<td>String</td>
<td>UD_CONNECTOR_NAMECONNECTOR_SERVER</td>
</tr>
<tr>
<td>processInstanceKey</td>
<td>Process Data</td>
<td>Process Instance</td>
<td></td>
</tr>
<tr>
<td>Adapter return value</td>
<td>Response Code</td>
<td></td>
<td></td>
</tr>
<tr>
<td>objectType</td>
<td>Literal</td>
<td>String</td>
<td>User</td>
</tr>
<tr>
<td>attrName</td>
<td>Literal</td>
<td>String</td>
<td>Enter your new label</td>
</tr>
</tbody>
</table>

   j. Save and close the Creating New Task dialog.
k. Check the Task column on the Process Definition tab to verify that the new process task is listed. Also verify that the new form field is available and working in Oracle Identity Manager.

14.6.2 Adding Target System Attributes for Target Reconciliation

By default, the target system attributes are mapped for reconciliation between Oracle Identity Manager and the target system. If required, you can map additional attributes for target reconciliation as described in this section.

---

**Note:**

- Perform this procedure only if you want to add new target system attributes for reconciliation.
- In the following steps, a new attribute called BUILDING will be added, its connector attribute name is BUILDING, and the form field name is Building. Names are case-sensitive.

---

To add a new target system attribute for target reconciliation, follow these steps:

1. In the resource object definition, add a reconciliation field corresponding to the new attribute, as follows:
   a. Open the Resource Objects form. This form is in the Resource Management folder.
   b. Click **Query for Records**.
   c. On the Resource Objects Table tab, double-click the CONNECTOR_NAME User resource object to open it for editing.
   d. On the Object Reconciliation tab, click **Add Field** to open the Add Reconciliation Field dialog box.
   e. Specify a value for the field name that is the name of the new Attribute on your Form.
      For example: Building
   f. From the Field Type list, select a data type for the field.
      For example: String
   g. Save the values that you enter, and then close the dialog box.
   h. If required, repeat Steps d through g to map more fields.
   i. Click **Create Reconciliation Profile**. This copies changes made to the resource object into the MDS.

2. If a corresponding field does not exist in the process form, then add a new column in the process form, as follows:
   a. Open the Form Designer form. This form is in the Development tools folder.
   b. Query for the UDCONNECTOR_NAME CON form.
   c. Click **Create New Version**. The Create a New Version dialog box is displayed.
   d. In the Label field, enter the name of the version.
   e. Click **Save** and close the dialog box.
f. From the Current Version box, select the version name that you entered in the Label field in Step 3.

g. On the Additional Columns tab, click Add.

h. In the Name field, enter the name of the data field and then enter the other details of the field.

   Note: Repeat Steps g and h if you want to add more attributes.

i. Click Save and then click Make Version Active.

3. Modify the process definition to include the mapping between the newly added attribute and the corresponding reconciliation field:

   a. Open the Process Definition form. This form is in the Process Management folder of the Design Console.

   b. Click the Query for Records icon.

   c. On the Process Definition Table tab, double-click the CONNECTOR_NAME User process definition.

   d. On the Reconciliation Field Mappings tab, click Add Field Map to open the Add Reconciliation Field Mapping dialog box.

   e. From the Field Name list, select the name of the resource object that you added in Step 2e.

   f. Double-click Process Data Field and select the corresponding process form field from the Lookup dialog box. Then, click OK.

   g. Click Save and close the dialog box.

   h. If required, repeat Steps c through g to map more fields.

4. Go to the reconciliation lookup, Lookup.CONNECTOR_NAME.UM.ReconAttrMap, and add a new record for the new attribute using the following values:

   ■ Code Key - Name of the reconciliation field
   ■ Decode - Name of the CONNECTOR_NAME attribute

5. In the Design Console, regenerate the reconciliation profile for the Resource Object.

14.6.3 Adding Target System Attributes for Trusted Reconciliation

By default, the attributes for trusted source reconciliation are mapped between Oracle Identity Manager and the target system. If required, you can map additional attributes for trusted reconciliation as described in this section.

Note:

■ Perform this procedure only if you want to add new target system attributes for reconciliation.

■ In the following steps, a new attribute called BUILDING will be added, its connector attribute name is BUILDING, and the form field name is Building. Names are case-sensitive.

To add a new target system attribute for trusted reconciliation, follow these steps:
1. In the resource object definition, add a reconciliation field corresponding to the new attribute, as follows:
   a. Open the Resource Objects form. This form is in the Resource Management folder.
   b. Click **Query for Records**.
   c. On the Resource Objects Table tab, double-click the CONNECTOR_NAME Trusted User resource object to open it for editing.
   d. On the Object Reconciliation tab, click **Add Field** to open the Add Reconciliation Field dialog box.
   e. Specify a value for the field name that is the name of the new Attribute on your Form.
      For example: Building
   f. From the Field Type list, select a data type for the field.
      For example: String
   g. Save the values that you enter, and then close the dialog box.
   h. If required, repeat Steps d through g to map more fields.
   i. Click **Create Reconciliation Profile**. This copies changes made to the resource object into the MDS.

2. If a corresponding field does not exist in the process form, then add a new column in the process form, as follows:
   a. Open the Form Designer form. This form is in the Development tools folder.
   b. Query for the UD_CONNECTOR_NAMECON form.
   c. Click **Create New Version**. The Create a New Version dialog box is displayed.
   d. In the Label field, enter the name of the version.
   e. Click **Save** and close the dialog box.
   f. From the Current Version box, select the version name that you entered in the Label field in Step 3.
   g. On the Additional Columns tab, click **Add**.
   h. In the Name field, enter the name of the data field and then enter the other details of the field.
      *Note:* Repeat Steps g and h if you want to add more attributes.
   i. Click **Save** and then click **Make Version Active**.

3. Modify the process definition to include the mapping between the newly added attribute and the corresponding reconciliation field:
   a. Open the Process Definition form. This form is in the Process Management folder of the Design Console.
   b. Click the **Query for Records** icon.
   c. On the Process Definition Table tab, double-click the CONNECTOR_NAME Trusted User process definition.
   d. On the Reconciliation Field Mappings tab, click **Add Field Map** to open the Add Reconciliation Field Mapping dialog box.
e. From the Field Name list, select the name of the resource object that you added in Step 2e.

f. Double-click Process Data Field and select the corresponding process form field from the Lookup dialog box. Then, click **OK**.

g. Click **Save** and close the dialog box.

h. If required, repeat Steps c through g to map more fields.

4. Go to the reconciliation lookup, Lookup.CONNECTOR_NAME.UM.ReconAttrMap.Trusted, and add a new record for the new attribute using the following values:
   - Code Key - Name of the reconciliation field
   - Decode - Name of the CONNECTOR_NAME attribute
This chapter enlists the best practices and Frequently Asked Questions (FAQ) on ICF. The list is discussed in the following sections:

- Section 15.1, "Best Practices for ICF"
- Section 15.2, "FAQs on ICF"

15.1 Best Practices for ICF

The following are the best practices that you need to follow while using ICF:

- Use common Scheduled tasks, and ICProvisioningManager.
- Keep IT Resource parameters count to minimum, IT Resource should contain connectivity related parameters only, the rest needs to be in the Main Connector Configuration Lookup.
- Logging in ICF Connectors:
  ICF Integration for Oracle Identity Manager logs all the input/output parameters of all calls to ICF Connector interfaces. You must ensure that the following points are taken care while logging:
  - If required, you can enhance the logging with detailed logging messages.
  - You must not log messages that involves password information or sensitive data.
  - In case you encounter ConnectorException error, then you must wrap the target specific exception, and provide any additional details.
  - Turn on Logging for ICF Common by switching on logging for oracle.iam.connectors.icfcommon.
- Connector Load Balancer
  - In order to use SSL-encrypted communication between Oracle Identity Manager and connector servers, you need to copy the SSL keystore on all connector server nodes, and maintain its consistency if SSL key changes.
  - Connector server uses a proprietary (non-HTTP) protocol, and SSL encryption.
  - All connector server nodes under the load balancer should contain the same set of bundles.
15.2 FAQs on ICF

The following are the FAQs on ICF:

- Why lookup reconciliation data contains tilda (~)?
  Tilda (~) notation in lookup reconciliation is to separate Lookups for different IT Resources. In the following example, Key will be a programmatic key, whereas Value will be a user-friendly display name:
  Lookup Key: <IT Resource Key>--<Lookup key>
  Lookup Value: <IT Resource Name>--<Lookup value>

- What is bulk attribute update and how to set it up?
  Bulk attribute update in OIM means that all the changed attributes will be sent to the connector in one method call, instead of updating each attribute individually (default option).
  In order to enable your connector for bulk attribute update, make sure:
    - all your attributes have their respective process tasks for individual update, typically named as, ATTRIBUTE_NAME updated.
    - you have an extra process task named, UD_FORM_NAME updated. This task will be used for bulk update.

- Search-based versus sync-based reconciliation: when to use what?
  It is based on the capabilities of connector/target resource. Most connectors support search, some of them (LDAP) support sync operation too. Where available, sync-based reconciliation is preferred due to higher efficiency.
  Sync-based reconciliation is more efficient than search-based reconciliation because, it can process both additions/removals in one run. With search-based reconciliation, you need to run search reconciliation first and then run search delete reconciliation, which is double the effort.

- How to configure Connector Pooling?
  See Release 11.1.1.5.0 version of the Connector documentation for information about Connector Pooling and its configuration.

- How to use Groovy to extend connector functionality?
  In order to have an extendable connector, you need to implement ScriptOnConnector or ScriptOnResource ICF SPIs. Connectors might support various scripting languages, based on target resource capabilities. By default, ICF supports groovy scripts with ScriptOnConnector for all java based connectors. You must always refer the connector documentation to understand the scripting languages for a given connector. See Chapter 14, "Configuring ICF Connectors" for more information about how to customize the connector.

- What are the basic requirements (such as memory, disk space, CPU, and so on) for Connector Server?
  The connector server can run in any Java 6 environment and above. The requirements are same as of those of Java and Oracle Identity Manager.
  See Release 11.1.1.5.0 version of the Connector documentation for the supported versions of JDK and Oracle Identity Manager.

- Does one connector server version support all ICF Connector versions?
Connector Server version equals ICF version. ICF is backward compatible with previously released connector versions.

- **How to troubleshoot connector server related issues?**
  
  Set up log level to **FINEST** in logging configuration file of the Connector Server. If the default port 8759 is taken, than set a different port number in the Connector Server configuration.

- **When to deploy connector on Connector Server and when to deploy connector locally into Oracle Identity Manager?**
  
  Only .NET connectors require Connectors Server, others can be deployed directly into Oracle Identity Manager.
This chapter introduces generic technology connectors and the features that Oracle Identity Manager provides for working with generic technology connectors.

This chapter contains the following sections:

- Requirement for Generic Technology Connectors
- Functional Architecture of Generic Technology Connectors
- Features of Generic Technology Connectors
- Connector Objects Created by the Generic Technology Connector Framework
- Roadmap for Information on Generic Technology Connectors in This Guide

16.1 Requirement for Generic Technology Connectors

Predefined Oracle Identity Manager connectors are designed for commonly used target systems such as Microsoft Active Directory and PeopleSoft Enterprise Applications. A predefined connector is developed using the Adapter Factory approach, and its architecture is based on either the APIs that the target system supports or the data repository type and schema in which the target system stores user data.

Since they are developed using the Adapter Factory, predefined connectors offer extensive workflow and adapter customization capabilities. The use of a predefined connector is the recommended integration method when such a connector is available for the target system.

There may be scenarios in which you want to integrate Oracle Identity Manager with a target system that has no corresponding predefined connector. The following are examples of such scenarios:

Scenario 1: All employees of Acme Inc. are allotted disk space on a backup server. Employees send requests to the system administrator for managing their accounts on the backup server. The system administrator has developed a Web-based application to capture, review, and act on requests from employees. The front end of this application is a Web service that accepts and stores data in CSV format. Employee account data stored in the back end can be exported as XML files to a specified location.

Scenario 2: Ceeam Travels Inc. owns a custom Web-based application that its customers use to request airline fare quotes. Agents, who are also employees of Ceeam...
Travels, respond to these requests by using the same application. Customers register themselves to create accounts in this application. However, Ceeam Travels employees need to have accounts auto-provisioned based on their HR job title. Account management functions (such as create, update, and delete) of the application are available through Java APIs.

In both these scenarios, you need to create a custom connector to link the target system and Oracle Identity Manager. If you are looking for a simple way to create your custom connector and do not need the customization features of the Adapter Factory, you can create the connector by using the Generic Technology Connector feature of Oracle Identity Manager. As described in the Section 16.2, "Functional Architecture of Generic Technology Connectors", providers are the building blocks of generic technology connectors.

- In Scenario 1, you can use the predefined shared drive reconciliation transport provider and CSV reconciliation format provider to create a generic technology connector that reconciles data stored in a flat file into Oracle Identity Manager.
- In Scenario 2, there is no predefined provider available to integrate the custom application with Oracle Identity Manager. In this case, you can use the instructions provided in Chapter 18, "Creating Custom Providers for Generic Technology Connectors" to create the custom providers that call the Java APIs exposed by the target application.

16.2 Functional Architecture of Generic Technology Connectors

Like a predefined connector, a generic technology connector acts as the bridge for reconciliation and provisioning operations between Oracle Identity Manager and a target system. Functionally, a generic technology connector can be divided into a reconciliation module and provisioning module. When you create a generic technology connector, you can specify whether you want to include both modules, or include the reconciliation module only, or include the provisioning module only.

A predefined connector provides reconciliation and provisioning functionality in the context of the same target. In contrast, the reconciliation and provisioning modules of a generic technology connector are composed of reusable components that you choose. Each component performs a specific function during provisioning or reconciliation. For example, you can create a connector that performs trusted source reconciliation from flat files and provides target resource provisioning using the SPML protocol to an SPML-enabled target.

In this guide, the components that constitute a generic technology connector are called providers.

Each provider performs a transport, format change, validation, or transformation function on the data that it receives as input. In other words, data items processed by a provider are moved to a new location, validated against specified criteria, or undergo modification in structure or value. In this guide, the term data sets is used to describe data structures arranged in the form of layers, with data flowing from one layer to another during provisioning and reconciliation.

While creating a generic technology connector, you can specify the fields (user identity metadata) that must be included in each data set. You can also define mappings between fields of different data sets. A mapping serves one of the following purposes:

- Establishes a data flow path between fields of two data sets for use either in provisioning or reconciliation.
A mapping of this type forms the basis for validations or transformations to be performed on data that is fetched from the target system.

- Creates a basis for comparing (matching) field values of two data sets.

Figure 16–1 shows the functional architecture of a generic technology connector.

**Figure 16–1 Functional Architecture of a Generic Technology Connector**

The following sections describe the providers and data sets that constitute a generic technology connector:

- Providers and Data Sets of the Reconciliation Module
- Providers and Data Sets of the Provisioning Module
- Oracle Identity Manager Data Sets

### 16.2.1 Providers and Data Sets of the Reconciliation Module

The reconciliation module consists of the following providers and data sets:
- **Reconciliation Transport Provider**
  A reconciliation transport provider carries reconciliation data from the target system to Oracle Identity Manager. The manner in which this provider carries the reconciliation data depends on the implementation of the provider. For example, a reconciliation transport provider can read data from a file, or accept data from a Web service, or query a database.

- **Reconciliation Format Provider**
  A reconciliation format provider parses the reconciliation data fetched by the reconciliation transport provider and converts this data into data structures that can be stored in Oracle Identity Manager.

- **Source**
  A Source data set holds the data processed by the reconciliation format provider. This data set can have child data sets.

- **Validation Provider**
  A validation provider checks the data in the source data sets against criteria you specify before passing the data to the reconciliation engine of Oracle Identity Manager.

- **Transformation Provider**
  A transformation provider included in the reconciliation module modifies data received from the validation providers before passing on the data for the creation of reconciliation events in Oracle Identity Manager.

  The following is an example of a transformation provider function:

  Suppose the following are the values of two fields in the target system
  
  First Name: John
  Last Name: Doe

  A transformation provider can be used to create the following reconciliation field output:
  
  Login ID: John.Doe

- **Reconciliation Staging**
  A reconciliation staging data set holds user data that has been processed by the validation providers and transformation providers. This data set can have child data sets.

---

16.2.2 **Providers and Data Sets of the Provisioning Module**

The provisioning module consists of the following providers and data sets:

- **Transformation Provider**
  A transformation provider can be used to modify data items at the following stages:
features of generic technology connectors

understanding generic technology connectors

16.2.3 oracle identity manager data sets

the oracle identity manager data sets represent data that is stored in oracle identity manager. although these data sets are not part of the reconciliation or provisioning module, they are considered part of the generic technology connector because you can add fields to these data sets and create mappings between fields of these data sets and other data sets. the following are the oracle identity manager data sets:

- oim - user
  the oim - user data set holds the metadata (set of identity fields) that defines the oracle identity manager user. in trusted source reconciliation, this data set receives newly created or modified user account information from the reconciliation staging data set. in target resource reconciliation, the fields of the oim - user data set can be used to establish a match between target system user accounts and existing oracle identity manager users. this data set does not have child data sets.

- oim - account
  the oim - account data set holds the user account information that is stored in the process form fields of oracle identity manager. this user account information is received from the reconciliation staging data sets. the oim - account data set can have child data sets.

16.3 features of generic technology connectors

the following sections discuss the features of generic technology connectors:

- features specific to the reconciliation module
- other features

16.3.1 features specific to the reconciliation module

the following features are specific to the reconciliation module:
Features of Generic Technology Connectors

- Trusted Source Reconciliation
- Account Status Reconciliation
- Full and Incremental Reconciliation
- Batched Reconciliation
- Reconciliation of Multivalued Attribute Data (Child Data) Deletion
- Failure Threshold for Stopping Reconciliation

16.3.1.1 Trusted Source Reconciliation
A generic technology connector can be used for trusted source reconciliation. During reconciliation in trusted mode:

- If the reconciliation engine detects new target system accounts, it creates corresponding Oracle Identity Manager users.
- If the reconciliation engine detects changes to existing target system accounts, the same changes are made in the corresponding Oracle Identity Manager users.

Note: While creating a generic technology connector, if you do not select the Trusted Source reconciliation option, target resource reconciliation is enabled. In target resource reconciliation, only modifications to target system accounts are reconciled. New target system accounts detected during reconciliation are not created automatically in Oracle Identity Manager.

A generic technology connector that is used for trusted source reconciliation cannot be used for provisioning. This design feature was incorporated to ensure that you do not create or modify through Oracle Identity Manager user account information on a target system that is designated as a trusted source.

Connector objects, such as IT resources and resource objects, are created automatically at the end of the generic technology connector creation process. By default, the resource object of a generic technology connector is a trusted resource object. In other words, a generic technology connector is already compatible with the Multiple Trusted Source reconciliation feature. This feature is discussed in Chapter 5, "Developing Provisioning Processes".

Note: In trusted source reconciliation, the reconciliation of multivalued (child) data is not supported.

16.3.1.2 Account Status Reconciliation
User account status information is used to track whether or not the owner of a target system account is to be allowed to access and use the account. If the target system does not store account status information in the format in which it is stored in Oracle Identity Manager, you can use the predefined translation transformation provider to implement account status reconciliation.
16.3.1.3 Full and Incremental Reconciliation

While creating a generic technology connector, you can specify that you want to use the connector for full or incremental reconciliation.

You select incremental reconciliation if the target system supports a method for the reconciliation engine to identify records that have changed since the last reconciliation run. For example, if the target system time stamps the creation of or changes made to user records, the reconciliation engine can identify records that have been added or modified since the last reconciliation run. In incremental reconciliation, only target system records that have changed after the last reconciliation run are reconciled (stored) into Oracle Identity Manager.

You select full reconciliation if any one of the following conditions is true:

- The target system does not support any method for the reconciliation engine to identify records that have changed since the last reconciliation run.
- You want to perform first-time reconciliation of all user account records in the target system.

In full reconciliation, all the reconciliation records are extracted from the target system. However, the optimized reconciliation feature identifies and ignores records that have already been reconciled in Oracle Identity Manager. This helps reduce the space occupied by reconciliation data. If this feature were not present, the amount of data stored in the Oracle Identity Manager database would increase rapidly with each reconciliation run.

Note: The outcome of both full and incremental reconciliation is the same:

- All the target system records are reconciled during the first reconciliation run.
- From the second reconciliation run onward, target system records that are created or updated after the last reconciliation run are reconciled into Oracle Identity Manager.

16.3.1.4 Batched Reconciliation

You can specify a batch size for reconciliation. By doing this, you can break into batches the total number of records that the reconciliation engine fetches from the target system during each reconciliation run. This feature provides more control over the reconciliation process.

16.3.1.5 Reconciliation of Multivalued Attribute Data (Child Data) Deletion

You can specify whether or not you want to reconcile into Oracle Identity Manager the deletion of multivalued attribute data on the target system.
16.3.1.6 Failure Threshold for Stopping Reconciliation
During reconciliation, validation providers can be used to run checks on target system data before it is stored in Oracle Identity Manager. You can set a failure threshold to automatically stop a reconciliation run if the percentage of records that fail the validation checks to the total number of records processed exceeds the specified threshold percentage.

16.3.2 Other Features
The following features are not specific to the reconciliation or provisioning module:

- Custom Data Fields and Field Mappings
- Custom Providers
- Multilanguage Support
- Custom Date Formats
- Propagation of Changes in Oracle Identity Manager User Attributes to Target Systems

16.3.2.1 Custom Data Fields and Field Mappings
While creating a generic technology connector, you can specify the identity fields and field mappings (data flow paths) that must be used during reconciliation and provisioning.

16.3.2.2 Custom Providers
You can create custom providers if the predefined providers shipped with Oracle Identity Manager do not address the transport, format change, validation, or transformation requirements of your operating environment.

16.3.2.3 Multilanguage Support
Generic technology connectors can handle both ASCII and non-ASCII data (multibyte characters), which represent a user, an account, or some other type of provisioned resource object.

16.3.2.4 Custom Date Formats
While creating a generic technology connector, you can specify:

- The format of date values in target system records that are extracted during reconciliation
- The format in which date values must be sent to the target system during provisioning

---

**Note:** Generic technology connectors do not support the reconciliation of parent data deletion. For example, if the account of user John Doe is deleted from the target system, you cannot use a generic technology connector to reconcile this user account deletion into Oracle Identity Manager.
16.3.2.5 Propagation of Changes in Oracle Identity Manager User Attributes to Target Systems
While creating a generic technology connector, you can enable the automatic propagation of changes in Oracle Identity Manager User attributes to the target system.

16.4 Connector Objects Created by the Generic Technology Connector Framework
The list of connector objects created by the generic technology connector framework depends on the combination of the reconciliation and provisioning options that you select on the Step 1: Basic Information page:

- Both Reconciliation and Provisioning Are Selected
- Only Reconciliation Is Selected
- Only Provisioning Is Selected

Note: Except for the form names, the names of the generic technology connector objects are in the \text{GTC\_NAME\_GTC} format, where \text{GTC\_NAME} is the name that you assign to the connector.

For example, if you specify DBTables\_conn as the name of a generic technology connector that you create, all the connector objects (except the forms) are named DBTables\_conn\_GTC.

16.4.1 Both Reconciliation and Provisioning Are Selected
The following objects are created when you select both the provisioning and reconciliation options on the Step 1: Basic Information page:

- IT resource type
  The parameters of the IT resource type are the run-time parameters of the format and transport providers (for both reconciliation and provisioning) that you select on the first page.

- IT resource
  The IT resource is an instance of the IT resource type. It contains the run-time parameter values of the providers.

- Resource object
  The resource object holds the values of the fields that constitute the reconciliation staging parent data set. For each reconciliation staging child data set, multilevel reconciliation fields (with corresponding child fields as their attributes) are created automatically.

Note: When you select the trusted source reconciliation option, a trusted resource object is one of the objects created automatically at the end of the connector creation process.

- Application instance
The combination of IT resource (target connectivity and connector configuration) and resource object (provisioning mechanism). This is a provisionable entity.

- **Parent and child forms**
  Parent and child forms are based on the OIM - Account data set and its child data sets, respectively. By default, the names of the forms are the same as the names of their corresponding data sets. On the Step 3: Verify Form Names page, you can change the form names as required.

- **Process definition**
  The process definition contains the reconciliation field mappings and the system-defined and provisioning-specific process tasks. See Section 19.2.6, "Configuring Provisioning" for information about the process tasks that are included in the process definition.

- **Generic adapter**
  The generic adapter contains the code for all the provisioning functions that a generic technology connector performs.

- **Scheduled task**
  During a reconciliation run, the scheduled task triggers the reconciliation processes in the predefined sequence. Section 19.2.5, "Configuring Reconciliation" provides information about setting up the scheduled task.

- **Reconciliation rule**
  The reconciliation rule consists of rule elements. A single rule element represents a mapping created between a field of the reconciliation staging data set and a field of the OIM - User data set.

- **Action rules**
  Any one of the following default action rules are created for target resource reconciliation:

<table>
<thead>
<tr>
<th>Rule Condition</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>One Entity Match Found</td>
<td>Establish Link</td>
</tr>
<tr>
<td>One Process Match Found</td>
<td>Establish Link</td>
</tr>
</tbody>
</table>

Any one of the following default action rules are created for trusted source reconciliation:

<table>
<thead>
<tr>
<th>Rule Condition</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>No Matches Found</td>
<td>Create User</td>
</tr>
<tr>
<td>One Entity Match Found</td>
<td>Establish Link</td>
</tr>
<tr>
<td>One Process Match Found</td>
<td>Establish Link</td>
</tr>
</tbody>
</table>

The user group to which the creator of the generic technology connector belongs is made the administrator of the following connector objects that are created automatically during the generic technology connector creation process:

- **IT resource**
- **Resource object (Administrator and Object Authorizer)**
Roadmap for Information on Generic Technology Connectors in This Guide

- All forms
- Process definition
- Reconciliation fields
- Reconciliation field mappings

16.4.2 Only Reconciliation Is Selected

See "Both Reconciliation and Provisioning Are Selected" on page 16-9 for the list of objects that are created when you select both the Reconciliation and Provisioning options. From that list, the following objects are not created when you select only the Reconciliation option on the Step 1: Basic Information page:

- Generic adapter.
- Provisioning-specific process tasks.

However, the process definition itself and its constituent system-defined process tasks are created.

16.4.3 Only Provisioning Is Selected

See "Both Reconciliation and Provisioning Are Selected" on page 16-9 for the list of objects that are created when you select both the Reconciliation and Provisioning options. From that list, the following objects are not created when you select only the Provisioning option on the Step 1: Basic Information page:

- Scheduled task
- Reconciliation rule
- Reconciliation fields
- Reconciliation field mappings

16.5 Roadmap for Information on Generic Technology Connectors in This Guide

The following is an overview of the remaining chapters and appendixes on generic technology connectors:

- Chapter 17, "Predefined Providers for Generic Technology Connectors" provides a survey of available providers, which include the shared drive reconciliation transport provider, CSV reconciliation format provider, SPML provisioning format provider, Web Services provisioning transport provider, transformation provider, and validation provider.

- Chapter 18, "Creating Custom Providers for Generic Technology Connectors" explains the role of providers during provisioning and reconciliation, and describes how to create custom providers.

- Chapter 19, "Creating and Managing Generic Technology Connectors" describes how to create and maintain Generic Technology Connectors, and how to use the generic Connection Pool Framework in custom connectors.

- Chapter 20, "Troubleshooting Generic Technology Connectors" describes general and configuration issues related to Generic Technology Connectors and how to troubleshoot the issues.
The following predefined providers are shipped Oracle Identity Manager:

- Shared Drive Reconciliation Transport Provider
- CSV Reconciliation Format Provider
- SPML Provisioning Format Provider
- Web Services Provisioning Transport Provider
- Transformation Providers
- Validation Providers

### 17.1 Shared Drive Reconciliation Transport Provider

The shared drive reconciliation transport provider reads data from flat files stored in staging directories and moves the files to an archiving directory. The staging and archiving directories must be shared for access from the Oracle Identity Manager server.

The following are parameters of this provider:

- **Staging Directory (Parent identity data)**
  
  Use this parameter to specify the path of the directory in which files containing parent data are stored. It is mandatory to specify a value for this parameter. This is a run-time parameter.

  In this guide, *parent data* means the user account information that is stored in the target system.

  Sample value for this parameter:

  `T:/TargetSystemDirectory/ParentData`
Data stored in the parent data files must conform to the following conventions:

- **First line of the file**
  The first line of the parent data file must be the file header that describes the contents of the file.
  The file header can be preceded by any number of lines that begin with the hash-mark or pound-sign (#). These are ignored while the file is read. However, you must ensure that there are no spaces at the start of the header. If you are using a language other than English, you must not enter non-ASCII characters on this line.

- **Second line of the file**
  The second line of the parent data file must contain the field names (metadata) for the data in the file.
  If you are using a language other than English, you must not enter non-ASCII characters on this line. See the Note in the preceding point for more information about this limitation.

- **Third line of the file onward**
  From the third line onward, the parent data file can contain data in the language that you have selected for Oracle Identity Manager. This language can have an ASCII or non-ASCII character set. See "Multilanguage Support" on page 16-8 for more information about this limitation.
  Even if there is no data from the third line onward, reconciliation will take place and the files are archived.

The following are contents of a sample parent data file:

```plaintext
##Active Directory user
Name TD,Address TD,User ID TD
John Doe,Park Street,jodoe
Jane Doe,Mark Street,jadoe
```
See Also: "Permissions to Be Set on the Staging and Archiving Directories"

- **Staging Directory (Multivalued identity data)**

  Use this parameter to specify the path of the directory in which files containing multivalued (or child) account or identity data (for example, role membership data) are stored. It is *not* mandatory to specify a value for this parameter. This is a run-time parameter.

  **Note:** In this guide, the terms multivalued account or identity data and child data have been used interchangeably.

  Sample value for this parameter:

  T:/TargetSystemDirectory/ChildData

  **Note:**

  - The staging directory for parent data files cannot be the same as the staging directory for multivalued user data files. In addition, if the staging directory is not on the same server on which Oracle Identity Manager is installed, it must be shared and mapped as a network drive on the Oracle Identity Manager server.

  - If you select the Trusted Source Reconciliation option on the Step 1: Provide Basic Information page, you must not specify a value for the Staging Directory (Multivalued Identity Data) parameter. This is because the reconciliation of multivalued (child) data is not supported in trusted source reconciliation.

  For each type of multivalued account or identity data, there must be a different file in the shared directory. For example, if the multivalued user data for a particular target system is group membership data and role data, there must be one file for group membership data and a different file for role data.

  Data stored in the child data files must conform to the conventions (first line, second line, and remaining lines) that are specified for the parent data files.

  In addition, the same unique field must be present in the parent data file and each child data file. This field is used to uniquely link each record in the child data files with a single record in the parent data file. This structure is similar to the concept of integrity constraints (primary key-foreign key) in RDBMSs.

  **Note:** The unique field must be the first field in the child data files.

  The following are contents of a sample child data file holding role information that is linked to the sample parent data file listed earlier:

  ```
  ###Role
  User ID TD,Role Name TD,Role Type TD
  jodoe,admin1,admin
  jadoe,admin2,admin
  ```
The following are contents of a sample child data file holding group membership information that is linked to the sample parent data file listed earlier:

```text
### Group Membership
User ID TD, Group Name TD, Group Type TD
jodoe, OracleDev1, OracleDev
jodoe, OracleDev2, OracleDev
jodoe, OracleDev3, OracleDev
jodoe, OracleDev4, OracleDev
jodoe, OracleDev5, ConnectorDev
```

Note that the name of the unique field, `User ID TD`, is the same in the child data files and the parent data file.

On the Step 3: Modify Connector Configuration page as described in "Step 3: Modify Connector Configuration Page" on page 19-13, the name of a child data set is the same as the header that you provide in the child data file. For these sample child data files, the child data sets would be labeled `Role` and `Group Membership`. In addition, on the Step 4: Verify Connector Form Names page, the default names displayed for forms corresponding to the child data sets would be `Role` and `Group Membership`. As mentioned in "Step 4: Verify Connector Form Names Page" on page 19-28, you can either accept the default form names or change them.

**See Also:** "Permissions to Be Set on the Staging and Archiving Directories"

- **Archiving Directory**

  Use this parameter to specify the path of the directory in which parent and child data files that have already been reconciled are to be stored. This is a run-time parameter.

  It is mandatory to specify a value for this parameter.

  At the end of the reconciliation run, the data files are copied into the archiving directory and deleted from the staging directory.

  The files moved to the archiving directory are not time stamped or marked in any way. Therefore, while specifying the path of the archiving directory, bear in mind the following guidelines:

  - The archiving directory path that you specify must not be the same as the staging directory path. If you specify the same path, the existing files in the archiving directory are deleted at the end of the reconciliation run.

  - If data files with the same names as the files used in the last reconciliation run are placed in the staging directory, the existing files in the archiving directory are overwritten by the new files from the staging directory at the end of the current reconciliation run.

  These points are also mentioned in "Step 2: Specify Parameter Values Page" on page 19-6.

  **See Also:** "Permissions to Be Set on the Staging and Archiving Directories"

- **File Prefix**

  Use this parameter to specify the prefix used to filter the names of files in the staging directories for both parent and child data files. During reconciliation, all
files (in the staging directories) with names that start with the specified prefix are processed, regardless of the file extension. This is a run-time parameter.

For example:

If you specify `usrdata` as the value of the File Prefix parameter, data is parsed from the following files placed in the staging directory for multivalued (child) user data files:

```
usrdataRoleData.csv
usrdataGroupMembershipData.txt
```

Data is not extracted from the following files in the same directory, because the file names do not begin with `usrdata`:

```
RoleData.csv
GroupMembershipData.txt
```

- **Specified Delimiter**

  Use this parameter to specify the character that is used as the delimiter character in the parent and child data files. You can specify only a single character as the value of this parameter. This is a run-time parameter. This parameter overrides the Tab Delimiter parameter.

  **Note:** You cannot use the space character ( ) as a delimiter.

  In addition, you must ensure that the character you specify is used only as the delimiter in the data files. If this character is also used inside the data itself, the data row (or record) is not parsed correctly. For example, you must not use the comma (,) as the delimiter if any data value contains a comma.

- **Tab Delimiter**

  Use this parameter to specify whether or not the file is delimited by tabs. This is a run-time parameter. This parameter is ignored if you specify a value for the Specified Delimiter parameter.

- **Fixed Column Width**

  If the input file contains fixed-width data, use this parameter to specify the width in characters of the data columns. This is a run-time parameter.

  **Note:** In this context, the term "fixed-width" refers to the number of characters in the data field, not the byte length of the field. This means that, for example, four characters of single-byte data and four characters of multibyte data are the same in terms of width.

  This parameter is ignored if you specify a value for the Specified Delimiter or Tab Delimiter parameter.

- **Unique Attribute (Parent Data)**

  For multivalued user data, use this parameter to specify the field that is common to both the parent data and child data files. In the examples described earlier, the requirement for a unique attribute is fulfilled by the `User ID TD` field, which is present in both the parent and child data files. This is a run-time parameter.
File Encoding

Use this parameter to specify the character set encoding used in the parent and data files. This is a design parameter.

Specify Cp1251 for data files stored on a computer running an operating system with the English-language setting. This is the canonical name for the java.io API that is supported by the generic technology connector framework. For any other language that you select from the list given in the "Multilanguage Support" section, you must specify the canonical name for the corresponding java.io API.

Permissions to Be Set on the Staging and Archiving Directories

You must ensure that the required permissions are set on the staging and archiving directories. The following table describes the effect of the various permissions on the shared directories that are used to hold staging and archiving data files.

<table>
<thead>
<tr>
<th>Storage Entity</th>
<th>Access Permission</th>
<th>Reason for Access Permission Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Staging directory for parent data files</td>
<td>Read</td>
<td>This permission is required for reconciliation to take place. An error message is logged if this permission is not applied.</td>
</tr>
<tr>
<td>Staging directory for parent data files</td>
<td>Write</td>
<td>This permission is required for the deletion of data files from the parent staging directory at the end of the archive process.</td>
</tr>
<tr>
<td>Staging directory for parent data files</td>
<td>Execute</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Staging directory for child data files</td>
<td>Read</td>
<td>This permission is required for the reconciliation of child data. An error message is logged if this permission is not applied.</td>
</tr>
<tr>
<td>Staging directory for child data files</td>
<td>Write</td>
<td>This permission is required for the deletion of data files from the child staging directory at the end of the archive process.</td>
</tr>
<tr>
<td>Staging directory for child data files</td>
<td>Execute</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Archiving directory</td>
<td>Write</td>
<td>This permission is required for the copying of parent and child data files to the archiving directory during the archive process. Even if this permission is not applied:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>■ Parent and child data reconciliation takes place.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>■ Files are deleted from the parent and child staging directories if the required permissions have been set on those directories.</td>
</tr>
<tr>
<td>Archiving directory</td>
<td>Execute</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Parent or child data file in staging directory</td>
<td>Read</td>
<td>This permission is required for the reconciliation of the data in the file. An error message is logged if this permission is not applied.</td>
</tr>
<tr>
<td>Parent or child data file in staging directory</td>
<td>Write</td>
<td>This permission is required for the deletion of the data file at the end of the archive process. An error message is logged if this permission is not applied. However, data in this file is reconciled.</td>
</tr>
</tbody>
</table>
The CSV reconciliation format provider converts reconciliation data that is in character-delimited, tab-delimited, or fixed-length format into a format that is supported by Oracle Identity Manager. Although the CSV reconciliation format provider is packaged as a standalone provider, all of its parameters are bundled with the shared drive transport provider. If you select the shared drive transport provider on the Step 1: Provide Basic Information page, you must select the CSV format provider. When you select this provider, its parameters are displayed along with the shared drive transport provider parameters.

**17.3 SPML Provisioning Format Provider**

The SPML provisioning format provider converts the provisioning data generated during a provisioning operation on Oracle Identity Manager into an SPML request that can be processed by an SPML-compatible target system.

---

**Note:** Each SPML request is sent in a SOAP message. The SOAP header carries authentication information for the request. The actual SPML request data is the SOAP message body.

See Chapter 32, "Using SPML Services" for information about the structure of the SPML-SOAP message.

You can access sample SOAP messages in the following directory:

```bash
OIM_HOME/GTC/Samples/spml
```

For information about the SPML specification, see the following Web page on the OASIS Web site at

http://www.oasis-open.org/specs/index.php#spmlv2.0

---

**Figure 17–1** shows the setup of the system in which the SPML provisioning format provider acts as the requesting authority (RA), and the target system provides the provisioning service provider (PSP) and the provisioning service target (PST).
During actual provisioning, a Velocity template engine is used to create the SOAP-SPML requests. For the following processes, the provider generates SOAP requests based on the SPML 2.0 DSML profile:

- Add request
- Modify request for the following Oracle Identity Manager process tasks:
  - Field updated
  - Add child data
  - Modify child data
  - Delete child data
- Suspend request (for Disable Oracle Identity Manager process tasks)
- Resume request (for Enable Oracle Identity Manager process tasks)
- Delete request

The Create Organization, Update Organization, and Delete Organization are not supported. This is because the resource object created for a generic technology connector does not support provisioning operations for organizations. The Create Group, Update Group, and Delete Group operations are not supported. This is because Oracle Identity Manager does not support operations to provision groups.

When you select this provider, the following identity fields are displayed by default on the Step 3: Modify Connector Configuration page as described in "Step 3: Modify Connector Configuration Page" on page 19-13, along with the ID field:

- objectClass
- containerID

For each provisioning task (for example, Create User and Modify User), the provider generates a request in a predefined format.

The following sections discuss the parameters of this provider:

- Run-Time Parameters
- Design Parameters

Depending on the application server that you use, some of the run-time and design parameters are mandatory and some have fixed values. The following sections discuss these parameters:

- Nonmandatory Parameters
- Parameters with Predetermined Values
17.3.1 Run-Time Parameters

The following are run-time parameters of the SPML provisioning format provider:

- **Target ID**
  
  This value uniquely identifies the target system for provisioning operations.

- **User Name (authentication)**
  
  This is the user name of the account required to connect to the target system (PST) through the Web service interface (PSP).

- **User Password (authentication)**
  
  This is the password of the user account required to connect to the target system (PST) through the Web service interface (PSP).

17.3.2 Design Parameters

The following are design parameters of the SPML provisioning format provider:

**See Also:** For more information about the SOAP elements and attributes mentioned in this section, visit the following Web site

http://www.w3.org/TR/wsd120/

- **Web Service SOAP Action**
  
  In the WSDL file, this is the value of the `soapAction` attribute of the `operation` element.

- **WSSE Configured for SPML Web Service?**
  
  Select this check box if the Web service is configured to authenticate incoming requests by using WS-Security credentials.

- **Custom Authentication Credentials Namespace**
  
  This is the name of the credentials namespace that you have defined for the Web service. In most cases, this namespace is the same as the target namespace.

  **Note:** You need not specify a value for this parameter if you select the SPML Web Service WSSE Configured? check box.

- **Custom Authentication Header Element**
  
  This is the name of the element that will contain the credentials of the user account used to connect to the target system. In other words, this is the parent element in the custom authentication section of the SOAP message header.

  **Note:** You need not specify a value for this parameter if you select the SPML Web Service WSSE Configured? check box.

- **Custom Element to Store User Name**
  
  **Note:** You need not specify a value for this parameter if you select the SPML Web Service WSSE Configured? check box.
This is the name of the element in the custom authentication section that will contain the user name you specify as the value of the User Name (authentication) parameter.

- **Custom Element to Store Password**

  - **Note:** You need not specify a value for this parameter if you select the SPML Web Service WSSE Configured? check box.

This is the name of the element in the custom authentication section that will contain the user name you specify as the value of the User Password (authentication) parameter.

- **SPML Web Service Binding Style (DOCUMENT or RPC)**

  In the WSDL file, this is the value of the `style` attribute of the `binding` element. You must enter either `DOCUMENT` or `RPC`.

  - **Note:** You must enter the value `DOCUMENT` or `RPC`. Do not use lowercase letters in the value that you specify.

- **SPML Web Service Complex Data Type**

  In the WSDL file, this is the value of the `name` attribute of the `complexType` element. This parameter is applicable only if the binding style is `DOCUMENT`. You must specify a value for this parameter if the target Web service is running on Oracle WebLogic Server.

- **SPML Web Service Operation Name**

  In the WSDL file, this is the value of the `name` attribute of the `operation` element. This parameter is applicable only if the binding style is `RPC`.

- **SPML Web Service Target Namespace**

  In the WSDL file, this is the value of the `targetNamespace` attribute of the `definition` element.

- **SPML Web Service Soap Message Body Prefix**

  This is the name of the custom prefix element that contains the SOAP message body. If the target Web service is running on Oracle WebLogic Server, IBM WebSphere Application Server, JBoss Application Server, or Oracle Application Server, then you need not specify a value for this parameter. However, if you are using a different application server, you must enter the name of the custom prefix element. The following is the prefix element if the Web service is running on Oracle WebLogic Server:

  ```xml
  <SPMLv2Document xmlns="http://xmlns.oracle.com/OIM/provisioning">
  </SPMLv2Document>
  ```

- **ID Attribute for Child Dataset Holding Group Membership Information**

  This is the name of the unique identifier field for a provisioning staging child data set that holds group membership information. For provisioning operations on the child data set that contains this field, the SOAP packet will contain SPML code for group operations. The following is an SPML code block for this type of group operation:

  ```xml
  <modification modificationMode="add">
    <capabilityData capabilityURI="urn:oasis:names:tc:SPML:2:0:reference"/>
  </modification>
  ```

  - **Note:** You need not specify a value for this parameter if you select the SPML Web Service WSSE Configured? check box.

  You must enter the value `DOCUMENT` or `RPC`. Do not use lowercase letters in the value that you specify.
For provisioning operations on the child data sets that do not contain this field, the SOAP packet will contain ordinary SPML code. The following is an SPML code block for this type of group operation:

```
<modification>
  <dsml:modification name='Group Membership' operation='add'>
    <dsml:value>AdminOra, System Admins, USA</dsml:value>
  </dsml:modification>
</modification>
```

### 17.3.3 Nonmandatory Parameters

For Oracle WebLogic Server, you need not specify values for the following parameters:

- SPML Web Service Complex Data Type
- SPML Web Service Soap Message Body Prefix
- ID Attribute for Child Dataset Holding Group Membership Information

### 17.3.4 Parameters with Predetermined Values

For Oracle WebLogic Server, you can specify predetermined values for the following parameters:

- **Web Service URL**: `http://IP_address:port_number/spmlws/OIMProvisioning`
- **SPML Web Service Binding style** (DOCUMENT or RPC): **RPC**
- **SPML Web Service Operation Name**: `processRequest`

### 17.4 Web Services Provisioning Transport Provider

The Web Services provisioning transport provider acts as a Web service client and carries provisioning request data from Oracle Identity Manager to the target system Web service.

The following types of target system Web services are supported:

- RPC-literal
- RPC-encoded
- DOCUMENT-literal

The following is the parameter of the Web Services provisioning transport provider:

**Web Service URL**

Use this parameter to specify the URL of the Web service that you want to use for sending a provisioning request to the target system. This is a run-time parameter. In the WSDL file, the Web service URL is the value of the `location` attribute of the `wsdlsoap:address` element.
If you include the Web Services provisioning transport provider in the generic technology connector that you create, you may want to configure Secure Sockets Layer (SSL) communication between the target system and Oracle Identity Manager. The following section provides information about this procedure.

17.4.1 Configuring SSL Communication Between Oracle Identity Manager and the Target System Web Service

This section describes the procedure to configure the application server on which Oracle Identity Manager is installed for SSL communication.

You can perform this procedure only if all the following conditions are true:

- You want to include the Web Services provisioning transport provider in the generic technology connector that you plan to create.
- The target Web service is running on an SSL-enabled application server.

To configure SSL communication between Oracle Identity Manager and the target system Web service:

---

**Note:** You can perform this procedure prior to creating the generic technology connector.

---

1. Export the target application server certificate as follows:

   - For a target system Web service deployed on JBoss Application Server, Oracle WebLogic Server, or Oracle WebLogic Server, run the following command:

     ```
     JAVA_HOME/jre/bin/keytool -export -alias default -file exported-certificate-file -keystore app-server-specific-keystore -storetype jks -storepass keystore-password -provider sun.security.provider.Sun
     ```

     In this command:

     * Replace `JAVA_HOME` with the full path to the SUN JDK directory.
     * Replace `exported-certificate-file` with the name of the file in which you want the exported certificate to be stored.
     * Replace `app-server-specific-keystore` with the path to the keystore on the application server.
     * Replace `keystore-password` with the password for the keystore.

   - For a target system Web service deployed on IBM WebSphere Application Server or Oracle WebLogic Server on AIX, run the following command:

     ```
     JAVA_HOME/jre/bin/keytool -export -alias default -file exported-certificate-file -keystore app-server-specific-keystore -storetype jks -storepass keystore-password -provider com.ibm.crypto.provider.IBMJCE
     ```

     In this command:

     * Replace `JAVA_HOME` with the full path to the IBM JDK directory.
     * Replace `exported-certificate-file` with the name of the file in which you want the exported certificate to be stored.
     * Replace `app-server-specific-keystore` with path to the keystore on the application server.
Replace `keystore-password` with the password for the keystore.

When the command is run, the exported certificate file is stored in the file that you specify as the value of `exported-certificate-file`.

2. Import the certificate file exported in the preceding step into the Oracle Identity Manager truststore as follows:
   a. Copy the certificate file exported in the preceding step into a temporary directory on the Oracle Identity Manager server.
   b. Run the following command:

```
JAVA_HOME/jre/bin/keytool -import -trustcacerts -alias servercert -noprompt
-keystore OIM_HOME/config/.xlkeystore -file certificate_file
```

   In this command:

   - Replace `JAVA_HOME` with full path to the JDK directory. For Oracle Identity Management Server deployed on IBM WebSphere Application Server, the path must be that of the IBM JDK directory. For Oracle Identity Manager deployed on JBoss Application Server, Oracle WebLogic Server, or Oracle WebLogic Server, the path must be that of the SUN JDK directory.
   - Replace `OIM_HOME` with the full path of the Oracle Identity Manager home directory
   - Replace `certificate_file` with the path of the temporary directory into which you copy the certificate file.

   **Note:** If the application server is enabled for one-way SSL communication, you need not perform the rest of this procedure.

3. Import the Oracle Identity Manager certificate into the target system application server truststore as follows:

   **Note:** Perform the following steps only if the application server is enabled for two-way SSL communication.

   a. Export the Oracle Identity Manager certificate file.

   For Oracle Identity Manager deployed on Oracle WebLogic Server, run the following command:

```
JAVA_HOME/jre/bin/keytool -export -alias xell -file OIM_HOME/config/xell.cert -keystore OIM_HOME/config/.xlkeystore -storetype jks -provider sun.security.provider.Sun
```

   In this command:

   - Replace `JAVA_HOME` with the full path to the SUN JDK directory.
   - Replace `OIM_HOME` with the full path of the Oracle Identity Manager home directory.

   b. Import the certificate file that you export in Step 3a into the truststore of the application server as follows:

   Copy the exported Oracle Identity Manager certificate file to a temporary directory on the target application server.
Next, run the following command on the target application server:

- If the target application server is JBoss Application Server, Oracle WebLogic Server, or Oracle WebLogic Server, run the following command:

```
```

In this command:
* Replace `JAVA_HOME` with the full path to the SUN JDK directory.
* Replace `alias` with an alias for the certificate in the truststore of the target application server.
* Replace `OIM-certificate-file` with the name of the exported Oracle Identity Manager certificate file.
* Replace `app-server-specific-truststore` with path to the truststore on the target application server.
* Replace `truststore-password` with the password for the truststore on the target application server.

- If the target application server is IBM WebSphere Application Server, run the following command:

```
```

In this command:
* Replace `JAVA_HOME` with the full path to the SUN JDK directory.
* Replace `alias` with an alias for the certificate in the target truststore.
* Replace `OIM-certificate-file` with the name of the exported Oracle Identity Manager certificate file.
* Replace `app-server-specific-truststore` with the path to the truststore on the target application server.
* Replace `truststore-password` with the password for the truststore on the target application server.

**See Also:** SSL configuration documentation for the target application server

### 17.5 Transformation Providers

**Note:** Use the information provided in this section while performing the instructions given in Section 19.2.4.3, "Step 3: Modify Connector Configuration Page".

A transformation provider is used to transform user data while it is in transit between the source and destination data sets listed in the following table.
The following predefined transformation providers are available in Oracle Identity Manager:

- Concatenation Transformation Provider
- Translation Transformation Provider

### 17.5.1 Concatenation Transformation Provider

You use the concatenation transformation provider to concatenate the values of two fields of data sets to create the input for a single field of another data set.

The following example explains the output format of this provider:

Suppose the input values are the following fields of the source data set:

- First Name: John
- Last Name: Doe

When the concatenation transformation provider is applied to these two fields, the output value is as follows:

John Doe

**Note:** As shown in the preceding example, the concatenation transformation provider adds a space between the values of the two input fields.

The following procedure describes how to add a concatenation transformation provider while creating a generic technology connector:

**Note:** This procedure explains in detail the instruction given in Step 5 of Section 19.2.4.3.1, "Adding or Editing Fields in Data Sets". It is assumed that you have already selected the Concatenation option from the Mapping Action list on the Step 1: Field Information page and that you have performed Steps 2 and 3 given in that section.

On the Step 2: Mapping page in the pop-up window, perform the following steps:

1. From the Dataset list in the Input 1 region, select the data set containing the first field that you want to concatenate. From the Field Name list, select the first field. Alternatively, you can use the Literal option to specify a literal (or fixed) value as the first concatenation input.

   For the example described earlier, from the Dataset list in the Input 1 region, select the data set containing the First Name field. Then, from the Field Name list, select First Name.
2. From the Dataset list in the Input 2 region, select the data set containing the second field that you want to concatenate. Then, from the Field Name list, select the second field. Alternatively, you can use the Literal option to specify a literal (or fixed) value as the second concatenation input.

For the example described earlier, from the Dataset list in the Input 2 region, select the data set containing the Last Name field. Then, from the Field Name list, select Last Name.

### 17.5.2 Translation Transformation Provider

A translation operation involves accepting a certain (literal) value as input and converting it into another value.

The following example illustrates a translation operation:

Suppose the Source data set contains the Country field and data values stored in this field can take one of the following values:

- Austria
- France
- Germany
- India
- Japan

When these values are propagated to the reconciliation staging data set, you want to convert these values to the following:

- AT
- FR
- DE
- IN
- JP

To automate this translation, you can use the translation transformation provider. To use the translation transformation provider:

1. Use the Design Console to create a lookup definition that stores the input and decoded values.

See Also: Section 7.2.1, "Creating a Lookup Definition"

**Note:** While creating a lookup definition in the Lookup Definition form, you must select the Lookup Type option, and not the Field Type option.

For the Country field example described earlier, the Code Key and Decode values are as shown in the following table.

<table>
<thead>
<tr>
<th>Code Key</th>
<th>Decode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Austria</td>
<td>AT</td>
</tr>
<tr>
<td>France</td>
<td>FR</td>
</tr>
</tbody>
</table>
2. Define a transformation (translation) mapping between the input field and output field for the translation. As mentioned earlier, a transformation can be set up between the following pairs of data sets:

- Source and Reconciliation Staging
- Oracle Identity Manager and Provisioning Staging

**Note:** This procedure explains in detail the instruction given in Step 5 of Section 19.2.4.3.1, "Adding or Editing Fields in Data Sets". It is assumed that you have already selected the **Concatenation** option from the **Mapping Action** list on the Step 1: Field Information page and that you have performed Steps 2 and 3 given in that section.

a. On the Step 3: Mapping page, from the **Dataset** list in the Input region, select the data set containing the field that will provide the input value for the translation operation. Then, from the **Field Name** list, select the field itself.

For the Country field example described earlier, select the data set containing the Country field and select the Country field.

b. In the Lookup Code Name region, select **Literal** and enter the name of the lookup definition that you create in the preceding step.

**Note:** You must not specify a data set name and field in the Lookup Code Name region. Although there is no validation to stop you from selecting a data set name and field, the translation operation would fail during actual reconciliation or provisioning operations. This point is also mentioned in the Mappings section.

For the Country field example described earlier, select **Literal** and select the lookup definition you create in Step 1.

### 17.5.2.1 Configuring Account Status Reconciliation

User account status information is used to track whether or not the owner of a target system account is to be allowed to access and use the account. If required, you can use the translation transformation provider to reconcile account status information.

**Note:** The Design Console offers an alternative method to configure account status reconciliation. This method does not involve the use of a generic technology connector. Section 5.3.2.2.1, "User Account Status Reconciliation" describes this method.
You need to use the translation transformation provider only if account status values used in the target system are not the same as the values used in Oracle Identity Manager. For a target resource, Oracle Identity Manager uses the following values:

- Enabled state: Enabled
- Disabled state: Disabled

For a trusted source, Oracle Identity Manager uses the following values:

- Enabled state: Active
- Disabled state: Disabled

The procedure to configure account status reconciliation can be summarized as follows:

---

**Note:** Detailed instructions to perform these steps are provided later in this section.

---

1. Create a lookup definition that maps the status values used in the target system with the values used in Oracle Identity Manager.

2. While creating the generic technology connector, use the translation transformation provider to create a transformation mapping between the fields that hold account status values in the Source data set and the reconciliation staging data set.

The following example describes the action that you must perform:

Suppose the following fields are used to hold account status values:

- The User Status field of the Source data set holds the values True (for a user in the Enabled state) and False (for a user in the Disabled state).
- The User Status field of the reconciliation staging data set must hold one of the following pairs of values:
  - For target resource reconciliation, the field must hold Enabled or Disabled.
  - For trusted source reconciliation, the field must hold Active or Disabled.

You must create a transformation mapping that converts the True/False values in the User Status field of the Source data set into corresponding Enabled/Disabled or Active/Disabled values. During reconciliation, these converted values are sent to the User Status field of the reconciliation staging data set.

3. Create a mapping between the field that holds account status values in the reconciliation staging data set and one of the following fields:

- The OIM Object Status field of the OIM – Account data set, for target resource reconciliation
- The Status field of the OIM – User data set, for trusted source reconciliation

During reconciliation, this mapping is used to propagate status values from the reconciliation staging data set to the OIM – Account or OIM – User data set.

Detailed steps to configure account status reconciliation are as follows:

1. Create a lookup definition that maps the status values used in the target system with the values used in Oracle Identity Manager.
The Code Key values in the lookup definition must be the same as the values used to represent the account status in the target system. The Code Key and Decode values for both trusted and target resource reconciliation are as shown in the following table:

<table>
<thead>
<tr>
<th>Code Key</th>
<th>Decode (for Trusted Source Reconciliation)</th>
<th>Decode (for Target Resource Reconciliation)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target system status value for a user account that is in the Enabled state</td>
<td>Active</td>
<td>Enabled</td>
</tr>
<tr>
<td>Target system status value for a user account that is in the Disabled state</td>
<td>Disabled</td>
<td>Disabled</td>
</tr>
</tbody>
</table>

Examples of Code Key values are True/False, Yes/No, and 1/0. The Decode values must be set to the exact value, including the case (uppercase and lowercase), shown in the table.

**Note:** While creating the lookup definition in the Lookup Definition form, you must select the Lookup Type option, and not the Field Type option.

**See Also:** Section 7.2, "Lookup Definition Form"

2. The procedure to create the generic technology connector is described in Chapter 19, "Creating and Managing Generic Technology Connectors". While creating the generic technology connector, perform the following steps on the Step 3: Modify Connector Configuration page:

**Note:** These steps are a condensed version of the procedure described in Section 19.2.4.3.1, "Adding or Editing Fields in Data Sets". Refer to that section for a description of the terms and GUI elements mentioned in the following steps.

**a.** If the target system status field is displayed on the Step 3: Modify Connector Configuration page, click the Edit icon for the field in the reconciliation staging data set. If the field is not displayed, click the Add icon of the reconciliation staging data set.

**b.** On the Step 1: Field Information page, specify values for the following GUI elements:

- **Field Name:** If you are adding the field, specify a name for it. The field name that you specify must contain only ASCII characters, because non-ASCII characters are not allowed.
- **Mapping Action:** Select Create Mapping With Translation from this list.
- **Matching Only:** Ensure that this check box is deselected.
- **Create End-to-End Mapping:** If you are adding the field, select this check box.
- **Multi-Valued Field**: Ensure that this check box is deselected.
- **Data Type**: Select the data type of the field.
- **Length**: Specify the character length of the field.
- **Required**: Select this check box if you want to ensure that the field always contains a value.
- **Encrypted**: Ensure that this check box is deselected.
- **Password Field**: Ensure that this check box is deselected.

c. Click **Continue**.

d. On the Step 3: Provide Mapping Information page, perform the following steps:

In the Input region:
- From the **Dataset** list, select **Source**.
- From the **Field Name** list, select the field that stores status values.

In the Lookup Code Name region, select **Literal** and enter the name of the lookup definition that you create in Step 1.

e. If required, select a validation check for the field and click **Add**. In other words, select the validation provider that you want to use.

f. Click **Continue**, and click **Close**.

3. Create a mapping between the status field of the reconciliation staging data set and either the OIM Object Status field of the OIM - Account data set or the Status field of the OIM - User data set as follows:

Note: These steps are a condensed version of the procedure described in Section 19.2.4.3.1, "Adding or Editing Fields in Data Sets".

a. For target resource reconciliation, click the edit icon for the OIM Object Status field of the OIM - Account data set.

For target resource reconciliation, click the edit icon for the Status field of the OIM - User data set.

Note: If a mapping already exists between the status field of the reconciliation staging data set and the OIM Object Status field or Status field, apply the instructions given in this step only where required.

b. On the Step 1: Field Information page, specify values for the following GUI elements:

- **Mapping Action**: Select **Create Mapping Without Transformation** from this list.
- **Matching Only**: Ensure that this check box is deselected.

c. Click **Continue**.

d. In the Input region on the Step 3: Mapping page, select the status field of the reconciliation staging data set.
e. Click Continue, Continue, and click Close.

f. To add or edit other fields displayed on the Step 3: Modify Connector Configuration page, continue with the procedure described in Section 19.2.4.3.1, "Adding or Editing Fields in Data Sets".

### 17.6 Validation Providers

Table 17–1 describes the validation providers that are shipped with Oracle Identity Manager.

**Note:** Except for the Validate Date Format provider, all the providers in this table are implementations of methods of the `GenericValidator` class in the Apache Jakarta Commons API.

<table>
<thead>
<tr>
<th>Validation Provider</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IsBlankOrNull</td>
<td>Returns true if the field value is null and is not blank</td>
</tr>
<tr>
<td>IsInRange</td>
<td>Returns true if the field value is within a range specified by a minimum and maximum value pair</td>
</tr>
<tr>
<td>IsByte</td>
<td>Checks if the field value can be converted to a byte primitive</td>
</tr>
<tr>
<td>IsDouble</td>
<td>Checks if the field value can be converted to a double primitive</td>
</tr>
<tr>
<td>IsFloat</td>
<td>Checks if the field value can be converted to a float primitive</td>
</tr>
<tr>
<td>IsInteger</td>
<td>Checks if the field value can be converted to an integer primitive</td>
</tr>
<tr>
<td>IsLong</td>
<td>Checks if the field value can be converted to a long primitive</td>
</tr>
<tr>
<td>IsShort</td>
<td>Checks if the field value can be converted to a short primitive</td>
</tr>
<tr>
<td>MatchRegexp</td>
<td>Checks if the field value matches the specified regular expression</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> A regular expression is a string that is used to describe or match a set of strings according to specific syntax rules.</td>
</tr>
<tr>
<td>MaxLength</td>
<td>Checks if the length of the field value is less than or equal to the specified value</td>
</tr>
<tr>
<td>MinLength</td>
<td>Checks if the length of the field value is greater than or equal to the specified value</td>
</tr>
<tr>
<td>Validate Date Format</td>
<td>Validates date values in target system records before these records are reconciled into Oracle Identity Manager</td>
</tr>
<tr>
<td></td>
<td>The value of the Source Date Format parameter is used as the basis for validation. This validation provider is applied if you specify a value for the Source Date Format parameter on the Step 2: Specify Parameter Values page, regardless of whether or not you select this provider on the Step 3: Modify Connector Configuration page.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Unlike the other providers in this table, the Validate Date Format is not an implementation of a method of the <code>GenericValidator</code> class in the Apache Jakarta Commons API.</td>
</tr>
</tbody>
</table>
Creating Custom Providers for Generic
Technology Connectors

You will need to create custom providers to address provider requirements that cannot be addressed by the predefined providers. This chapter discusses the steps to create custom providers.

Topics in this chapter include:
- Role of Providers
- Creating Custom Providers
- Reusing Providers
- Deploying the Custom Providers

18.1 Role of Providers

The following sections discuss the role of providers during generic technology connector creation and use:
- Role of Providers During Generic Technology Connector Creation
- Role of Providers During Reconciliation
- Role of Providers During Provisioning

18.1.1 Role of Providers During Generic Technology Connector Creation

You create a generic technology connector by using the Identity System Administration. Defining data sets and the flow of data between these data sets is one of the tasks of the connector creation procedure. The metadata detection process facilitates this task.

In the generic technology connector context, the term metadata refers to the set of identity fields that constitute the user account information. The term metadata detection refers to the reading and parsing of target system metadata by the providers.

The metadata detection feature is supported for all the provider types. In other words, when you create a custom provider, you can incorporate into the provider the capability to read metadata.

Note: The Javadocs use the term metadata definition instead of metadata detection.
Figure 18–1 shows the metadata detection process.

**Figure 18–1  Metadata Detection Process**

The following sequence of steps describe the process of metadata detection. This sequence of steps is based on the assumption that you select both the Reconciliation and Provisioning options while creating the generic technology connector. If you do not select either option, the corresponding steps are not performed.

**See Also:** Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for detailed information about the SPI methods and value objects mentioned in the following steps.

In the Javadocs, the terms metadata detection and metadata definition have been used interchangeably.

1. The initialize method of the reconciliation transport provider is called to create an instance of that provider.
2. The initialize method of the reconciliation format provider is called to create an instance of that provider.
3. The `getMetadata` method of the reconciliation transport provider is called to fetch metadata from the target system. The output of this method is the `TargetSchema` value object containing metadata fetched from the target system.

4. The `parseMetadata` method of the reconciliation format provider is called to parse metadata fetched from the target system. The output of this method is the `OIMSchema` value object containing metadata fetched from the target system.

---

**Note:** The `OIMSchema` value object corresponds to the Source data sets discussed in Section 16.2.1, “Providers and Data Sets of the Reconciliation Module”.

---

5. The `initialize` method of the provisioning transport provider is called to create an instance of that provider.

6. The `initialize` method of the provisioning format provider is called to create an instance of that provider.

7. If the reconciliation transport provider and reconciliation format provider are not able to detect metadata, Steps 1 through 4 are repeated for the provisioning transport provider and provisioning format provider.

---

**Note:** After a provider is initialized, it is stored in the Oracle Identity Manager cache until any one of the following events occurs:

- Cache is purged.
- Oracle Identity Manager is restarted.
- The generic technology connector is modified after it is created.

The validation providers and transformation providers are instantiated only when they are needed. They are not stored in cache.

---

The shared drive reconciliation transport provider and CSV reconciliation format provider can detect metadata from the target system. However, this function is not supported for the Web Services provisioning transport provider and SPML provisioning format provider.

### 18.1.2 Role of Providers During Reconciliation

Figure 18–2 shows the role of providers during reconciliation.
The following steps describe the role of providers during reconciliation:

1. If an instance of the reconciliation transport provider is not available in cache, the initialize method is called to create an instance of that provider.

2. If an instance of the reconciliation format provider is not available in cache, the initialize method is called to create an instance of that provider.

3. While using the Identity System Administration to create a generic technology connector, you can specify a batch size for the reconciliation run. By using this parameter, you break the total number of records that the reconciliation engine fetches from the target system, during each reconciliation run, into batches. The default value of this parameter is All.
If you do not specify a batch size, at this stage of reconciliation, the `getFirstPage` method of the reconciliation transport provider is called to fetch the entire set of target system records that are ready for reconciliation.

If you specify a batch size, the `getFirstPage` method of the reconciliation transport provider is called to fetch the first batch of target system records for reconciliation. The `getNextPage` method of the same provider is called (multiple times, if required) if there are more batches of target system records for reconciliation.

4. The `parseRecords` method of the reconciliation format provider is called to process each record of the `TargetRecord` value objects array. The output of this method is an array of `OIMRecord` value objects.

5. While creating the generic technology connector, if you select validation providers to validate data while it is in transit from the Source data sets to the reconciliation staging data sets:
   a. An instance of the validation provider is created.
   b. The `validate` method of each validation provider is run on the specified attribute of each record of the `OIMRecord` value objects array.

If you do not select validation providers while creating the generic technology connector, Step 5 is not performed and each element of the `OIMRecord` value objects array is passed on to Step 6.

6. While creating the generic technology connector, if you selected transformation providers to modify data that is in transit from the Source data sets to the reconciliation staging data sets:
   a. An instance of the transformation provider is created.
   b. The `transformData` method of the transformation providers processes the `OIMRecord` value objects array that was generated as the output of one of the following:
      - The `validate` method of each validation provider (if you selected validation providers)
      - The `parseRecords` method of the reconciliation format provider (if you did not select validation providers)

If you do not select transformation providers while creating the generic technology connector, Step 6 is not performed and each element of the `OIMRecord` value objects array from the previous step (Step 4 or 5) is passed on to Step 7.

7. At this stage, the `OIMRecord` value objects array corresponds to the reconciliation staging data sets discussed in Section 16.2.1, "Providers and Data Sets of the Reconciliation Module". Each element of the `OIMRecord` value objects array is passed on to the reconciliation engine.

8. At the end of the reconciliation procedure, the `end` method of the reconciliation transport provider is called. This method returns a string value, which the generic technology connector framework stores in the `Timestamp` parameter of the IT resource. The framework uses the `Timestamp` parameter to track the stage at which the reconciliation run was completed.

18.1.3 Role of Providers During Provisioning

Figure 18–3 shows the role of providers during provisioning.
The following steps describe the role of providers during provisioning:

1. If an instance of the provisioning transport provider is not available in cache, the `initialize` method is called to create an instance of that provider.

2. If an instance of the provisioning format provider is not available in cache, the `initialize` method is called to create an instance of that provider.

3. The generic technology connector adapter is one of the connector objects created when you create the generic technology connector. This adapter converts the provisioning data record into a hashmap of name-value pairs. This hashmap contains process instance data. Each hashmap is converted into an element of the `OIMRecord` value object. At this stage, the `OIMRecord` value object corresponds to the Oracle Identity Manager data sets discussed in Section 16.2.3, "Oracle Identity Manager Data Sets".
4. While creating the generic technology connector, if you select transformation providers to modify data that is in transit from the Oracle Identity Manager data sets to the provisioning staging data sets:
   a. An instance of the transformation provider is created.
   b. The `transformData` method of the transformation providers processes the specified attributes of the input `OIMRecord` value object and converts these records into an output `OIMRecord` value object. At this stage, the `OIMRecord` value object corresponds to the provisioning staging data sets discussed in Section 16.2.2, "Providers and Data Sets of the Provisioning Module".

5. The `formatData` method of the provisioning format provider is called to process the `OIMRecord` value object. The output of this process is the `TargetOperation` value object.

6. The `sendData` method of the provisioning transport provider is called to send the `TargetOperation` value object to the target system.

7. If the provisioning operation is a Create request, the outcome is one of the following events:
   - On successful completion of the Create operation on the target system, the ID field value assigned to the newly created user account is returned by the `sendData` method. This value is passed on to the generic technology connector framework, which posts this value to the database.
   - If the ID field value is not returned, it is assumed that the Create operation has failed. An error message is displayed on the Identity System Administration.
   - If the operation fails at any stage after the name-value pairs are created, an error message is displayed on the Identity System Administration.

If the provisioning operation is an Update or Delete request, the ID field is one of the name-value pairs. When this type of provisioning request is sent, the outcome is one of the following events:

- If the operation fails at any stage after the name-value pairs are created, an error message is displayed on the Identity System Administration.
- On successful completion of the Update or Delete operation, the ID field value may or may not be returned depending on the implementation of the provisioning transport provider.

In either case, the generic technology connector framework does not need the ID field value.

18.2 Creating Custom Providers

The procedure to create custom providers consists of the following steps:

1. Determining Provider Requirements
2. Identifying the Provider Parameters
3. Developing Java Code Implementations of the Value Objects
4. Developing Java Code Implementations of the Provider SPI Methods
5. Developing Java Code for Logging and Exception Handling
6. Creating the Provider XML File
7. Creating Resource Bundle Entries for the Provider
8. Deploying the Provider

18.2.1 Determining Provider Requirements

Guidelines for determining provider requirements are as follows:

- Determining the Reconciliation Provider Requirements
- Determining the Provisioning Provider Requirements

18.2.1.1 Determining the Reconciliation Provider Requirements

Apply the following guidelines to determine the reconciliation provider requirements:

- If you want to use the target system only as a source of user account information for Oracle Identity Manager, you need only the reconciliation transport provider and reconciliation format provider. You do not need the provisioning transport provider and provisioning format provider.

  If you are going to include the reconciliation module in the generic technology connector, you must include both the reconciliation transport provider and the reconciliation format provider, even if you do not need any one of these providers.

  The function of the reconciliation format provider is to convert target system data into a format that is supported by Oracle Identity Manager. Even if the target system generates data in a format supported by Oracle Identity Manager, you must include the reconciliation format provider when you create the generic technology connector.

- You must create custom providers only to address provider requirements that are not addressed by the predefined providers.

  The types of providers you must include in the generic technology connector depend on the data formats and data transport mechanisms that your target system supports. If any combination of the data formats and data transport mechanisms are compatible with any combination of the predefined providers, you need not create custom providers.

  For example, if your target system can generate reconciliation data files in comma-delimited format, you can use the shared drive reconciliation transport provider and CSV reconciliation format provider. You need not create custom reconciliation providers.

  See Also: Section 18.3, "Reusing Providers"

18.2.1.2 Determining the Provisioning Provider Requirements

Apply the following guidelines to determine the provisioning provider requirements for the provisioning module:

- If you want to use the target system only as a target for provisioning operations initiated on Oracle Identity Manager, you need only the provisioning transport provider and provisioning format provider. You do not need the reconciliation transport provider and reconciliation format provider.

  If you are going to include the provisioning module in the generic technology connector, you must include both the provisioning transport provider and the provisioning format provider, even if you do not need any one of these providers. This guideline is illustrated by the following example:

  The function of the provisioning format provider is to convert Oracle Identity Manager data into a format that is supported by the target system. Even if the
target system supports the output data format of Oracle Identity Manager, you must include the provisioning format provider when you create the generic technology connector.

- You must create custom providers only to address provider requirements that are not addressed by the predefined providers.

The types of providers you must include in the generic technology connector depend on the data formats and data transport mechanisms that your target system supports. If any combination of the data formats and data transport mechanisms are compatible with any combination of the predefined providers, you need not create custom providers.

For example, if your target system is a Web service that can accept and parse SPML-based provisioning requests packaged in SOAP messages, you can use the SPML provisioning format provider and Web Services provisioning transport provider. You need not create custom provisioning providers.

See Also: Reusing Providers on page 18-15

18.2.2 Identifying the Provider Parameters

Provider parameters are the values that a provider must have in order to perform its intended function. For example, a provisioning transport provider that copies provisioning request files to a target system server will need the connection parameters required to connect to the target system.

While creating a generic technology connector, you specify values for the parameters of the providers that you select for the generic technology connector.

For the custom provider that you are creating, you must identify all the parameters required for the provider to function. You must also categorize these parameters as run-time and design parameters.

A run-time parameter represents a value that is not constrained by the design of the provider. For example, the location of the directories containing data files that you want to reconcile is a run-time parameter. A design parameter represents a value or set of values that is defined as part of the provider design. For example, the character set encoding formats that can be parsed by a reconciliation format provider are a design parameter for that provider.

18.2.3 Developing Java Code Implementations of the Value Objects

Develop the Java code implementations of the value objects listed in Table 18–1. As described earlier, these value objects are used at various stages of provider operations.

Note: You need not develop Java code implementations of the value objects that you are not going to include in the generic technology connector.

<table>
<thead>
<tr>
<th>Area of Use</th>
<th>Value Object</th>
<th>Javadocs Package</th>
</tr>
</thead>
<tbody>
<tr>

<td>com.thortech.xl.gc.vo.designtime</td>
</tr>
<tr>
<td>Provisioning</td>
<td>TargetOperation</td>
<td>com.thortech.xl.gc.vo.runtime</td>
</tr>
</tbody>
</table>
18.2.4 Developing Java Code Implementations of the Provider SPI Methods

Develop the Java code implementations of the SPI methods that are used during provider operations. As described earlier, these SPI methods are called at various stages of provider operations. See the Package com.thortech.xl.gc.spi page of the Javadocs for links to information about the SPI methods of each provider.

**Note:** You need not develop Java code implementations of SPI methods for the providers that you are not going to include in the generic technology connector.

18.2.5 Developing Java Code for Logging and Exception Handling

Oracle recommends that you incorporate logging in the Java code implementations of the value objects and SPI methods. By doing this, you can simplify troubleshooting errors that may occur when you use the providers.

The logging modules for the generic technology connector framework are an extension of the logging functionality of Oracle Identity Manager. Table 18–2 lists the modules that are specific to the supported provider types.

<table>
<thead>
<tr>
<th>Logging Module</th>
<th>Functional Module of the Generic Technology Connector Framework</th>
</tr>
</thead>
<tbody>
<tr>
<td>XELLERATE.GC.PROVIDER.PROVISIONINGFORMAT</td>
<td>Provisioning format provider</td>
</tr>
<tr>
<td>XELLERATE.GC.PROVIDER.PROVISIONINGTRANSPORT</td>
<td>Provisioning transport provider</td>
</tr>
<tr>
<td>XELLERATE.GC.PROVIDER.RECONCILIATIONTRANSPORT</td>
<td>Reconciliation transport provider</td>
</tr>
<tr>
<td>XELLERATE.GC.PROVIDER.RECONCILIATIONFORMAT</td>
<td>Reconciliation format provider</td>

<tr>
<td>XELLERATE.GC.PROVIDER.TRANSFORMATION</td>
<td>Transformation Provider</td>
</tr>
<tr>
<td>XELLERATE.GC.PROVIDER.VALIDATION</td>
<td>Validation Provider</td>
</tr>
</tbody>
</table>

See Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for information about incorporating exception handling in the custom provider.

18.2.6 Creating the Provider XML File

The provider XML file contains the data required to register the provider with the generic technology connector framework. You must create the provider XML file. Table 18–3 describes the elements that you can include in the provider XML files for custom providers.

**Note:** You can use a single provider XML file to define any number of providers. Alternatively, you can create a provider XML file for each provider that you create.

---

**Table 18–1 (Cont.) Value Objects Used During Provider Operations**

<table>
<thead>
<tr>
<th>Area of Use</th>
<th>Value Object</th>
<th>Javadoc Package</th>

Table 18–3 (Cont.) Elements of the Provider XML File

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration</td>
<td>Parent element of the configuration elements of any type of provider</td>
</tr>
</tbody>
</table>
| Parameter     | Element that provides information about a parameter of a provider. The Parameter element has the following attributes:  
  ■ type: Type of parameter, either Runtime or DesignTime  
  ■ datatype: Data type of parameter, either String or Boolean. Any parameter whose data type is not Boolean must be represented as a string.  
  ■ required: Specifies whether or not the parameter is mandatory  
  ■ encrypted: Specifies whether or not the parameter display must be encrypted  
  ■ name: Name of the parameter  
  ■ datalength: Character length of the parameter value |
| DefaultAttribute | Child element of the Configuration element  
  This element must be included only in the ProvFormatProvider element. It has the following attributes:  
  ■ datatype: Data type of parameter, either String or Boolean. Any parameter whose data type is not Boolean must be represented as a string.  
  ■ name: Name of the parameter  
  ■ encrypted: Specifies whether or not the parameter display must be encrypted  
  ■ size: Size of the default attribute |
| Response      | Child element of the Configuration element  
  This element must be included only in the ProvFormatProvider, ProvTransportProvider, TransformationProvider, and ValidationProvider elements. It represents the response returned from the providers that are called by the provisioning engine. This response is displayed on the Identity System Administration. This element has the following attributes:  
  ■ code: Corresponds to the Oracle Identity Manager process task response code to be generated  
  ■ description: Corresponds to the description of the Oracle Identity Manager process task response code to be generated |

Note:  
For a provisioning format provider or provisioning transport provider, you must ensure that the sum of the number of characters of the name attribute of the ProvFormatProvider or ProvTransportProvider element and the number of characters of the Response element is less than or equal to 70. If the sum of the number of characters exceeds 70, the response code cannot be stored in the database and an error is thrown.

See Also:  
"Migrating User Modifiable Metadata Files" on page 37-1 for detailed information importing and exporting files and modifying Oracle Identity Manager metadata
18.2.7 Creating Resource Bundle Entries for the Provider

A resource bundle is a file containing locale-specific text strings. At run time, Oracle Identity Manager reads these text strings and displays them as GUI element labels and messages on the Identity System Administration. The file extension of a resource bundle is .properties.

During installation of Oracle Identity Manager, resource bundles for each of the supported languages are copied to the Oracle Identity Manager server. These include the resource bundles for the predefined providers.

For a custom provider, you must create resource bundle entries for each locale that you plan to use. The following is a summary of the steps involved in creating a resource bundle:

1. Open a new file in a text editor.
2. In this file, create entries for the following text strings:
   - **Provider names**
     The format for provider names is as follows:
     \[ gc.provider.Provider_Type.Provider_Name=Label_string_in_the_required_language \]
     The following is an English-language example of the provider name entry for a provisioning format provider:
     \[ gc.ProvFormatProvider.SPML=SPML \]
   - **Provider parameter labels and description**
     The format for provider parameter labels and parameter descriptions is as follows:
     \[ Provider_Type.Provider_Name.Parameter_Name.label=Parameter_label_in_the_required_language \]
     \[ gc.Provider_Type.ProvFormatProvider.SPML.targetID.label=Target ID \]
     \[ gc.ProvFormatProvider.SPML.targetID.description=Target ID of the provisioning target \]
   - **Response codes and descriptions**
     The format for response codes and descriptions is as follows:
     \[ GC.GCPROV.PROVIDER_TYPE.PROVIDER_NAME.RESPONSE_CODE=Response_code_in_the_required_language \]
GC.GCPROV.PROVIDER_TYPE.PROVIDER_NAME.RESPONSE_CODE.description=Description_in_the_required_language

The following is an English-language example of the response code and description entries for a provisioning format provider:
GC.GCPROV.ProvFormatProvider.SPML.SPML_VELOCITY_PROPERTIES_NOT_READ=SPML Velocity Properties Not Read
GC.GCPROV.ProvFormatProvider.SPML.SPML_VELOCITY_PROPERTIES_NOT_READ.description=Necessary SPML template properties could not be read.

- Metadata detection error messages

The format for metadata detection error messages is as follows:

gc.error.Provider_Type.Provider_Name.ERROR_CODE=Error_Description

Here, ERROR_CODE must be the same as the value of the errorCode string passed as an argument to the constructor of the exception class. For example, the following is one of the constructors of the ReconciliationTransportException class:

ReconciliationTransportException(java.lang.String errorCode, java.lang.String isMessage)

You must add lines in the resource bundle for all possible values of the errorCode string.

The following is an English-language example of the metadata detection error message for a reconciliation transport provider:

gc.error.ReconTransportProvider.SharedDrive.NO_READ_FILE=There are no readable files to detect metadata.

3. Save and close the resource bundle.

18.2.8 Deploying the Provider

To deploy the provider:

1. Deploy the JAR files as follows:
   a. Compile and package all the Java code files in a JAR file.
   b. Copy the JAR file into the following directory:
      
      OIM_HOME/JavaTasks

      In addition, upload the JAR files to Oracle Identity Manager database. See "Deploying the Custom Providers" on page 18-17 for details.

      Note: In a clustered environment, you must copy each file that you create to the corresponding directory on each node of the cluster.

2. Deploy the provider XML files as follows:
   a. Upload the provider XML file to MDS at the following location:
      
      PROVIDER_DEF_XML_LOCATION="/db/GTC/ProviderDefinitions"

   b. Restart Oracle Identity Manager.
Reusing Providers

Creating Custom Providers for Generic Technology Connectors

To check if the provider XML file has been correctly registered:

i. Log in to Oracle Identity System Administration.

ii. Under Configuration, click **Generic Connector**. Click **Create**. If there are any errors in the provider XML file, an error message is displayed.

If an error message is displayed, fix the problem in the XML file, restart Oracle Identity Manager, and repeat Steps i and ii.

Repeat this procedure until no error messages are displayed when you click Create.

3. Deploy the provider resource bundles as follows:

a. Upload the resource bundles to the MDS by using the **UploadResourceBundles.sh** utility present in the **OIM_HOME/bin/** directory. See "Migrating JARs and Resource Bundle" on page 37-5 for information about running the utility.

b. For the new resource bundle entries to take effect, either run the **PurgeCache** script or restart the application server.

18.3 Reusing Providers

Format providers and transport providers work in pairs. During reconciliation, the output of the reconciliation transport provider is passed on to the reconciliation format provider. During provisioning, the output of the provisioning format provider is passed on to the provisioning transport provider. This means that the implementation of the transport providers and format providers is linked through the implementation of the value objects that are passed between them. This dependency forms the basis of guidelines on reusing format providers and transport providers.

In contrast, a validation provider or transformation provider does not have any such dependency on other providers. Therefore, there are no guidelines on reusing validation Providers and transformation Providers. You can reuse both predefined and custom transformation and validation providers, because their action is not specific to the data format or data transport mechanism of the target system.

Guidelines on reusing format providers and transport providers are dividing into the following sections:

- Reusing Reconciliation Providers
- Reusing Provisioning Providers

18.3.1 Reusing Reconciliation Providers

As described in **Section 18.1.2, "Role of Providers During Reconciliation"**, the **TargetRecord** value object is used to exchange data between the reconciliation transport provider and the reconciliation format provider. The reconciliation transport provider creates an array of **TargetRecord** value objects for the target system records fetched during reconciliation. The reconciliation format provider processes the data in the value objects array and passes it on to the reconciliation engine.

Suppose the operating environment of your organization contains two target systems, **TS1** and **TS2**. **TS1** offers a Web-based interface for extracting data during reconciliation. **TS2** provides APIs for enabling other applications to read data from its identity store. Both target systems support the same data format. If you want to reconcile user data from both target systems, you must create one generic technology connector for each target system. For each generic technology connector, you must create a reconciliation
transport provider. However, instead of creating a reconciliation format provider for each generic technology connector, you can create and reuse a single reconciliation format provider. Similarly, if TS1 and TS2 supported the same data transport mechanism (even if they do not support the same data format), you can reuse the reconciliation transport provider and create different reconciliation format providers.

If you want to reuse a reconciliation transport provider, you must ensure that the implementation of the TargetRecord value object does not contain code that is specific to the function performed by the reconciliation format provider. If you want to reuse a reconciliation format provider, you must ensure that the implementation of the TargetRecord value object does not contain code that is specific to the function performed by the reconciliation transport provider.

Reusing the Predefined Reconciliation Providers

The implementation of the shared drive reconciliation transport provider and CSV reconciliation format provider is such that these predefined providers are built for a fixed combination of data formats and a single data transport mechanism. The shared drive reconciliation transport provider reads data from flat files and passes an array of TargetRecord value objects to the CSV reconciliation format provider.

Implementation of the shared drive reconciliation transport provider is based on two factors: paged reconciliation and multivalued (child) data reconciliation. These factors require the provider to be able to parse target system data before it can create an array of TargetRecord value objects. In other words, the ability of the shared drive reconciliation transport provider to parse certain types of target system data and the ability of the CSV reconciliation format provider to use only the output provided by the shared drive reconciliation transport provider makes them interdependent. Therefore, the parameters of the CSV reconciliation format provider are bundled along with those of the shared drive reconciliation transport provider.

For this reason, you cannot use the shared drive reconciliation transport provider with a custom reconciliation format provider and you cannot use the CSV format provider with a custom reconciliation transport provider.

18.3.2 Reusing Provisioning Providers

As described in Section 18.1.3, "Role of Providers During Provisioning", the TargetOperation value object is used to exchange data between the provisioning transport provider and the provisioning format provider. The provisioning format provider creates a TargetOperation value object out of the provisioning data to be sent to the target system. The provisioning transport provider passes this value object to the target system.

Suppose the operating environment of your organization contains two target systems, TS1 and TS2. TS1 offers a Web-based interface for accepting provisioning request data. TS2 provides APIs for enabling provisioning data to be written to the identity store. Both target systems support the same data format. If you want to perform provisioning operations on both target systems, you must create one generic technology connector for each target system. For each generic technology connector, you must create a provisioning transport provider. However, instead of creating a provisioning format provider for each generic technology connector, you can create and reuse a single provider.

If TS1 and TS2 supported the same data transport mechanism but different data formats, you can reuse the provisioning transport provider and create different provisioning format providers.
If you want to reuse the provisioning transport provider, you must ensure that the implementation of the `TargetOperation` value object does not contain code that is specific to the function performed by the provisioning format provider. If you want to reuse the provisioning format provider, you must ensure that the implementation of the `TargetOperation` value object does not contain code that is specific to the function performed by the provisioning transport provider.

### Reusing the Predefined Provisioning Providers

If the target system is a Web service, you can use the Web Services provisioning transport provider along with any custom provisioning format provider that you create. This is illustrated by the following example:

As mentioned earlier in this guide, the SPML provisioning format provider supports only a subset of the provisioning operations that are described in the SPML specification. You can develop a custom provisioning format provider that supports all the SPML provisioning operations. If the target system is a Web service, you can use the Web Services provisioning transport provider to carry SPML requests from your custom provisioning format provider to the target system.

Similarly, you can use the SPML provisioning format provider along with a custom provisioning transport provider to send SPML requests to an SPML-based target system.

The following is the implementation of the `TargetOperation` value object that is created by the SPML provisioning format provider and used as an input for the Web Services provisioning transport provider:

```java
com.thortech.xl.gc.impl.prov.WSTransportTargetOperation
```

See *Oracle Fusion Middleware Java API Reference for Oracle Identity Manager* for information about this class.

If you want to reuse the SPML provisioning format provider, you must create a custom transport provider that can accept an instance of this class as input and call the relevant `set` method. Similarly, if you want to reuse the Web Services provisioning transport provider, you must create a custom provisioning format provider that can create an instance of this class and call the relevant `get` method.

### 18.4 Deploying the Custom Providers

To deploy the custom providers:

1. Upload the Provider definition XML file to the MDS location `/db/GTC/ProviderDefinitions`. Oracle Identity Manager provides utilities to export/import data to and from MDS repository.

   See Chapter 36, "Understanding Customization Types" for information about the MDS utilities.

2. The provider resource bundles and JAR files need to be uploaded to Oracle Identity Manager database. Utilities are available in `OIM_HOME/bin/` directory for uploading resource bundles and JAR files to Oracle Identity Manager database.

   See Chapter 37, "Deploying and Undeploying Customizations" for information about the upload resource bundles and JAR utilities.
This chapter explains how to create and maintain Generic Technology Connectors. It contains these sections:

- Overview
- Creating Generic Technology Connectors
- Managing Generic Technology Connectors
- Using the Generic Connection Pool Framework in Custom Connectors
- Best Practices

19.1 Overview

Providers are the starting point for developing generic technology connectors. Oracle Identity Manager provides a standard set of providers that you can use as building blocks of your generic technology connectors. For details about these providers, see Chapter 17, "Predefined Providers for Generic Technology Connectors".

If no suitable provider is available, you can develop a provider to fit your requirements. For details, see Chapter 18, "Creating Custom Providers for Generic Technology Connectors".

Finally, if generic technology connectors do not meet your integration requirements, you can make use of the programmatic options available with adapters. For details, see Chapter 8, "Using the Adapter Factory".

19.2 Creating Generic Technology Connectors

This section explains how to create generic technology connectors.

The procedure to create a generic technology connector is composed of the following steps:

- Determining Provider Requirements
- Selecting the Providers to Include
- Addressing the Prerequisites
- Using Identity System Administration to Create the Connector
- Configuring Reconciliation
19.2.1 Determining Provider Requirements

As mentioned in Chapter 17, "Predefined Providers for Generic Technology Connectors", the following providers can be used as the building blocks of the generic technology connectors you create:

- Reconciliation Transport Provider
- Reconciliation Format Provider
- Provisioning Transport Provider
- Provisioning Format Provider
- Transformation Provider
- Validation Provider

See Section 16.2, "Functional Architecture of Generic Technology Connectors" for the definitions of these providers. Then, based on your knowledge of the data formats and data transport mechanisms supported by the target system, identify the providers that must be included in the generic technology connector that you create. If the target system supports multiple data formats and data transport mechanisms, you must select a single combination of the transport and format providers discussed in the first chapter. You cannot include, for example, multiple reconciliation format providers in a single generic technology connector.

See Also: Section 19.2.1, "Determining Provider Requirements"

19.2.2 Selecting the Providers to Include

Identify the predefined providers that can be used to meet your provider requirements. See Chapter 17, "Predefined Providers for Generic Technology Connectors" for information about the predefined providers.

If all your provider requirements are addressed by the predefined providers, you need not create custom providers. You must create custom providers to address only the requirements that are not addressed by the predefined providers. See Chapter 18, "Creating Custom Providers for Generic Technology Connectors" for information about creating custom providers.

19.2.3 Addressing the Prerequisites

You must address the following prerequisites:

- If you are creating the generic technology connector on a production server, enable the cache for the following cache categories:
  - GenericConnector
  - GenericConnectorProviders
- Testing connectivity between the target system server and the Oracle Identity Manager server

You must take steps to ensure that connectivity can be established between the target system server and the Oracle Identity Manager server. For example, in a
UNIX environment, you must enter the fully qualified host name of the Oracle Identity Manager server in the `/etc/hosts` file on the target system server.

- Creating the user account to be used for creating the generic technology connector

All users belonging to the `SYSTEM ADMINISTRATORS` group of Oracle Identity Manager can create generic technology connectors. Alternatively, members of a group to which you assign the required menu items and permissions can create generic technology connectors.

The required menu items are as follows:

- Create Generic Technology Connector menu item
- Manage Generic Technology Connector menu item

The required permissions are as follows:

- Form Designer (Allow Insert, Write Access, Delete Access)
- Structure Utility. Additional Column (Allow Insert, Write Access, Delete Access)
- Meta-Table Hierarchy (Allow Insert, Write Access, Delete Access)

If these permissions are not correctly assigned to the group, an error is thrown when the user clicks the Create button on the final Identity System Administration page for creating generic technology connectors.

---

**Note:** In an Oracle Identity Manager deployment that is integrated with Access Manager (OAM), the OIMSignatureAuthenticator authentication provider is not configured by default. If you use Oracle Identity Manager 9.x connectors, such as GTC, or if your custom code uses signature-based OIMClient login, then you must enable the OIMSignatureAuthenticator authentication provider.

For information about enabling OIMSignatureAuthenticator, see "OIMSignatureAuthenticator Not Configured for Oracle Identity Manager Domain Security Realm" in the *Oracle Fusion Middleware Release Notes*.

For authentication from custom code, see "Using OIMClient and tcUtilityFactory in Integrated Deployments" on page 31-2.

---

### 19.2.4 Using Identity System Administration to Create the Connector

To navigate to the first Identity System Administration page for creating a generic technology connector, login to Identity System Administration, and click **Generic Connector** under Configuration. In the Manage Connectors page, click **Create**.

From this point onward, page-wise instructions are provided in the following sections:

- **Step 1: Provide Basic Information Page**
- **Step 2: Specify Parameter Values Page**
- **Step 3: Modify Connector Configuration Page**
- **Step 4: Verify Connector Form Names Page**
- **Step 5: Verify Connector Information Page**
19.2.4.1 Step 1: Provide Basic Information Page

To provide basic information about the generic technology connector that you want to create, use this page as follows:

1. In the Name field, specify a name for the generic technology connector.

   The following are guidelines related to selecting a name for the generic technology connector:
   - The name must not be the same as that of any other connector (predefined connector or generic technology connector) on this Oracle Identity Manager installation.
   - The name must not be the same as that of any other connector object (such as resource objects, IT resources, and process forms) on this Oracle Identity Manager installation.

   **Note:** An error message is displayed if you specify a name that is the same as the name of an existing connector. However, an error message is not displayed if you specify a name that is the same as the name of an existing connector object. Therefore, you must ensure that the name you want to specify is not the same as the name of any existing connector object.

   See Section 16.4, "Connector Objects Created by the Generic Technology Connector Framework" for more information about connector objects that are automatically created as part of the generic technology connector creation process.

   - The name must not contain non-ASCII characters, because Oracle Identity Manager does not support non-ASCII characters in connector names. However, you can include the underscore character (_) in the name.

   **See Also:** Section 20.2.1, "Names of Generic Technology Connectors and Connector Objects" for information about limitations related to the names of generic technology connectors.

2. If you want to use the generic technology connector for reconciliation, select Reconciliation and perform the following steps:

   - From the Transport Provider list, select the reconciliation transport provider that you want to use for this connector. This list displays the predefined reconciliation transport providers and the reconciliation transport providers that you create.

   - From the Format Provider list, select the reconciliation format provider that you want to use for this connector. This list displays the predefined reconciliation format providers and the reconciliation format providers that you create.

   **Note:** If you select the shared drive reconciliation transport provider, you must also select the CSV reconciliation format provider because all the parameters of this provider are bundled with the parameters of the shared drive reconciliation transport provider.
If you want to use the connector to perform trusted source reconciliation with the target system, select **Trusted Source Reconciliation**.

---

**Note:** If you select the Trusted Source Reconciliation check box, the Provisioning region of the page is disabled. This is because you cannot provision to a target system that you designate as a trusted source. You can only reconcile data from a trusted source.

---

3. If you want to use the generic technology connector for provisioning, select **Provisioning** and perform the following steps:

---

**Note:** You can select only Reconciliation, only Provisioning, or both Reconciliation and Provisioning.

---

- From the **Transport Provider** list, select the provisioning transport provider that you want to use for this connector. This list displays the predefined provisioning transport providers and the provisioning transport providers that you create.

  If you select the Web Services provisioning transport provider and if Secure Sockets Layer (SSL) is enabled for the target Web service, you must perform the procedure described in Section 17.4.1, "Configuring SSL Communication Between Oracle Identity Manager and the Target System Web Service".

- From the **Format Provider** list, select the provisioning format provider that you want to use for this connector. This list displays the predefined provisioning format providers and the provisioning format providers that you create.

  If you select the SPML provisioning format provider, you must also select the Web Services provisioning transport provider because the parameters of this provider are related to the parameters of the Web Services provisioning transport provider.

4. Click **Continue**.

Table 19–1 lists sample entries for the GUI elements on the Step 1: Provide Basic Information page.

19.2.4.2 Step 2: Specify Parameter Values Page

Use this page to specify values for the parameters of the providers that you select on the Step 1: Provide Basic Information page.

On this page, the provider parameters are divided into two categories:

- Run-time parameters

  **See Also:** Chapter 17, "Predefined Providers for Generic Technology Connectors" for detailed information about the run-time parameters of predefined providers that you select on the Step 1: Provide Basic Information page

  Run-time parameters are input variables of the providers that you select on the previous page. A run-time parameter represents a value that is not constrained by the design of the provider. For example, the location of the directories containing the data files that you want to reconcile is a run-time parameter.

- Design parameters

  The parameters listed in this section are either design parameters of providers or reconciliation-specific parameters that are common to all generic technology connectors. A design parameter represents a value or set of values that is defined as part of the provider design.

  **See Also:** Chapter 17, "Predefined Providers for Generic Technology Connectors" for detailed information about the design parameters of predefined providers that you select on the Step 1: Provide Basic Information page

  For example:

  The format of data files that can be parsed by a format provider is a design parameter for that provider. While designing the provider, you define the set of formats the provider can parse. On the Step 2: Specify Parameter Values page, you specify the particular format (from the set of supported formats) that an instance of the format provider must parse.

  The following are reconciliation-specific design parameters:

  **Note:** If you do not select the Reconciliation option on the previous page, these reconciliation-specific design parameters are not displayed on this page.

  - **Batch Size**
    Use this parameter to specify a batch size for the reconciliation run. By using this parameter, you can break into batches the total number of records that the reconciliation engine fetches from the target system during each reconciliation run.

    The default value of this parameter is All.

  - **Stop Reconciliation Threshold**
    During reconciliation, data from the reconciliation format provider is accepted as input by the validation provider. Some of the reconciliation data records may not clear the validation checks. You can use the Stop Reconciliation Threshold parameter to automatically stop reconciliation if the percentage of
records that fail the validation checks to the total number of reconciliation records processed exceeds the specified value.

The following example illustrates how this parameter works:

Suppose you specify 20 as the value of the Stop Reconciliation Threshold parameter. This means that you want reconciliation to stop if the percentage of failed records to the total number of records processed becomes equal to or greater than 20. Suppose the second and eighth records fail the validation checks. At this stage, the number of failed records is 2 and the total number of records processed is 8. The percentage of failed records is 25, which is greater than the specified threshold of 20. Therefore, reconciliation is stopped after the eighth record is processed.

---

**Note:**

- The Stop Reconciliation Threshold parameter is used during reconciliation only if you select validation Providers on the Step 3: Modify Connector Configuration page.
- If reconciliation is stopped because the actual percentage of failed records exceeds the specified percentage, the records that have already been reconciled into Oracle Identity Manager are not removed.

The default value of this parameter is **None**. This default value specifies that during a reconciliation run, you want all the target system records to be processed, regardless of the number of records that fail the checks.

---

**Stop Threshold Minimum Records**

If you use the Stop Reconciliation Threshold parameter, there may be a problem if invalid records are encountered right at the beginning of the reconciliation run. For example, suppose you specify 40 as the value of the Stop Reconciliation Threshold parameter. When reconciliation starts, suppose the first record fails the validation checks. At this stage, the percentage of failed records to total records processed is 100. Therefore, reconciliation would stop immediately after the first record is processed.

To avoid such situations, you can use the Stop Threshold Minimum Records parameter in conjunction with the Stop Reconciliation Threshold parameter. The Stop Threshold Minimum Records parameter specifies the number of records that must be processed by the validation provider before the Stop Reconciliation Threshold validation is enabled.

The following example illustrates how this parameter works:

Suppose you specify the following values:

**Stop Reconciliation Threshold:** 20

**Stop Threshold Minimum Records:** 80

With these values, from the eighty-first record onward, the Stop Reconciliation Threshold validation is enabled. In other words, after the eightieth record is processed, if any record fails the validation check, the reconciliation engine calculates the percentage of failed records to total records processed.

The default value of this parameter is **None**.
Reconciliation Type

Use this parameter to specify whether you want the reconciliation engine to perform incremental or full reconciliation.

**Note:** The outcome of both full and incremental reconciliation is the same: target system records that are created or updated after the last reconciliation run are reconciled into Oracle Identity Manager.

In incremental reconciliation, only target system records that are newly added or modified after the last reconciliation run are brought to Oracle Identity Manager. Reconciliation events are created for each of these records.

In full reconciliation, all target system records are brought to Oracle Identity Manager. The optimized reconciliation feature identifies and ignores records that have already been reconciled. Reconciliation events are created for the remaining records.

You must select incremental reconciliation if either one of the following conditions is true:

* The target system time stamps or uniquely marks (in some way) files or individual data records that it generates, and the reconciliation transport provider can recognize records that have been time stamped or marked by the target system.

  For example:

  Suppose the target system can time stamp the creation of or modifications to user data records. If you can create a custom reconciliation transport provider that can read this time-stamp information, only new or modified data records will be transported to Oracle Identity Manager during reconciliation.

* The target system provides only data records that are newly added or modified after the last reconciliation run.

If neither of these conditions is true, you must select full reconciliation.

Reconcile Deletion of Multivalued Attribute Data

Use this parameter to specify whether or not you want to reconcile into Oracle Identity Manager the deletion of multivalued attribute data (child data) on the target system.

The following example explains how this design parameter works:

There is an account for user John Doe on the target system. This user is a member of two user groups, CREATE USERS and REVIEW PERMISSIONS, on the
target system. This user account (along with the group membership information) also exists on Oracle Identity Manager.

On the target system, suppose this user is removed from the REVIEW PERMISSIONS group. During the next reconciliation run, the action that will be taken in Oracle Identity Manager depends on whether or not you select the Reconcile Deletion of Multivalued Attribute Data check box:

* If you select the check box, information about this user being a member of the REVIEW PERMISSIONS group on the target system is removed from the Oracle Identity Manager database. All other changes made to this user account on the target system are also reconciled.

* If you do not select the check box, information about this user being a member of the REVIEW PERMISSIONS group on the target system is not removed from the Oracle Identity Manager database. However, all other changes made to this user account on the target system are reconciled.

**Source Date Format**

Use this parameter to specify the format in which date values are stored in the target system.

The format that you specify is used to validate date values fetched during reconciliation and to convert the date values to the format used internally by Oracle Identity Manager.

The Validate Date Format provider is one of the predefined validation providers. During a reconciliation run, the Validate Date Format provider uses the source date format to validate date values fetched from the target system. Only date values that match the source date format are converted to the date format used by Oracle Identity Manager and reconciled. This format validation and conversion applies to all date fields (for example, Date of Birth and Hire Date) of the target system.

**See Also:** "Validation Providers" on page 17-21 for more information about validation providers

For information about the date formats that you can specify, see the following page on the Sun Java Web site:

http://java.sun.com/docs/books/tutorial/i18n/format/simpleDateFormat.html

**Note:** If you want the source date format to be used in date validation, while performing the procedure described in Section 19.2.4.3.1, "Adding or Editing Fields in Data Sets", you must:

- Map date fields of the Source data sets to date fields of the reconciliation staging data sets.
- Edit each date field of the reconciliation staging data sets and set its data type to the Date data type.

The default value of the Source Date Format parameter is the date format specified as the value of the XL.DefaultDateFormat system property. If you do not specify a value for the Source Date Format parameter, the default date format is used for date validation during reconciliation.
Creating Generic Technology Connectors

The following example illustrates how the Source Date Format parameter is used:

Suppose the following are date values in the target system:

- **Date 1**: 05/04/2007 06:25:44 PM
- **Date 2**: 05/06/2007 07:31:44 PM
- **Date 3**: Thu, Apr 9, '98
- **Date 4**: 07/03/2008 02:15:55 PM

**Scenario 1:**

While creating the connector, you had entered the following as the value of the Source Date Format parameter:

```
MM/dd/yyyy hh:mm:ss a
```

During a reconciliation run, the record containing the Date 3 value is not reconciled because it does not conform to the specified source date format.

**Scenario 2:**

While creating the connector, you had not entered a value for the Source Date Format parameter. Therefore, during a reconciliation run, all four records are validated against the date format specified as the value of the `XL.DefaultDateFormat` system property.

The following is a provisioning-specific design parameter:

**Target Date Format**

Use this parameter to specify the format in which you want to send date values to the target system during provisioning operations.

During a provisioning operation, date values are converted to the format that you specify as the value of the Target Date Format parameter. This format conversion applies to all date fields (for example, Date of Birth and Hire Date) that are used in the provisioning operation.

For information about the date formats that you can specify, see the following page on the Sun Java Web site:

```
http://java.sun.com/docs/books/tutorial/i18n/format/simpleDateFormat.html
```

If you do not specify a date format, the following date format is used as the default value of this parameter:

```
yyyy/MM/dd hh:mm:ss z
```

The following example illustrates how the Target Date Format parameter is used:

See Also: "System Properties in Oracle Identity Manager" in the Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager for information about the system properties of Oracle Identity Manager.
During a provisioning operation, any date value that you enter will be in the 
\texttt{yyyy/MM/dd hh:mm:ss z} format.

**Scenario 1:**
While creating the connector, you had entered the following as the value of the 
Target Date Format parameter:
\texttt{yyyy.MM.dd G 'at' hh:mm:ss z}
During a provisioning operation, an Oracle Identity Manager date value (for 
example, 2007/05/04 06:25:44 IST) will be converted into the target date 
format (for example, 2007.05.04 AD at 06:25:44 IST) and sent to the target 
system.

**Scenario 2:**
While creating the connector, you had not entered a value for the Target Date 
Format parameter. During a provisioning operation, date values are sent to the 
target system in the (default) \texttt{yyyy/MM/dd hh:mm:ss z} format.

After you specify values for the run-time and design parameters, click \textbf{Continue}.

---

**Note:** If any value that you provide on this page is not correct, an 
error message is displayed at the top of the page after you click \textbf{Continue}. If this happens, fix the parameter value and click \textbf{Continue} again.

---

Table 19–2 lists sample entries for the Step 2: Specify Parameter Values page. The GUI 
elements displayed on this page are based on the entries made on the Step 1: Provide 
Basic Information page.

Creating Generic Technology Connectors

Creating and Managing Generic Technology Connectors

19.2.4.3 Step 3: Modify Connector Configuration Page

Use this page to define data sets and mappings between the fields of the data sets. In other words, you use this page to specify the user data fields that you want to:

- Propagate from the target system to Oracle Identity Manager during reconciliation
- Propagate from Oracle Identity Manager to the target system during provisioning

In the generic technology connector context, the term metadata refers to the set of identity fields that constitute the user account information on the target system.

First Name, Last Name, Hire Date, and Department ID are examples of user data fields that constitute metadata. The values assigned to these fields constitute the user data on the target system. For example, the identity information of user John Doe on the target system can be composed of the following fields:

- First Name: John
- Last Name: Doe
- Hire Date: 04-December-2007
- Department ID: Sales
- ...

After you click the **Continue** button on the Step 2: Specify Parameter Values page, the metadata displayed on the Step 3: Modify Connector Configuration page depends on the following factors:

- Input provided on the Step 1: Provide Basic Information and Step 2: Specify Parameter Values pages
- Availability of sample target system data

**Note:** In the generic technology connector context, the term metadata detection refers to the process in which sample user data is read from the target system and the corresponding metadata (identity field names) is displayed on the Step 3: Modify Connector Configuration page.

Table 19-2 (Cont.) Sample Entries for the Step 2: Specify Parameter Values Page

<td>Incremental</td>
<td>NA</td>
</tr>
</tbody>
</table>

Oracle Identity Manager performs the following steps while attempting to detect metadata:

1. The reconciliation transport provider and reconciliation format provider try to fetch and parse metadata from the target system.

   Together, the shared drive reconciliation transport provider and CSV reconciliation format provider can detect metadata from the target system. If you want custom providers to perform the same function, you must ensure that:
The Java code for the reconciliation transport provider contains an implementation of the `getMetadata()` method of the `ReconTransportProvider` interface.

The Java code for the reconciliation format provider contains an implementation of the `parseMetadata()` method of the `ReconFormatProvider` interface.

**See Also:** Chapter 18, "Creating Custom Providers for Generic Technology Connectors"

If these providers successfully fetch and parse metadata from the target system, Oracle Identity Manager uses information returned by them to display metadata and the following step is not performed.

2. If the reconciliation transport provider and reconciliation format provider cannot fetch and parse metadata from the target system, the provisioning transport provider and provisioning format provider try to perform this function.

The Web Services provisioning transport provider and SPML provisioning format provider cannot detect metadata from the target system. If you want custom providers to be able to detect metadata, you must ensure that:

- The Java code for the provisioning transport provider contains an implementation of the `defineMetadata()` method of the `ProvisioningTransportProvider` interface.

- The Java code for the provisioning format provider contains an implementation of the `parseMetadata()` method of the `ProvisioningFormatProvider` interface.

If the provisioning transport provider and provisioning format provider successfully fetch and parse metadata from the target system, Oracle Identity Manager uses information returned by these providers to display metadata. If these providers are not successful, only the default fields defined for any of the provisioning-specific providers that you select are displayed. For example, the ID field of the OIM - Account data set and the objectClass and containerID fields of the provisioning staging data set are displayed by default. These data sets and fields are discussed later in this guide.

Figure 19–1 shows the Step 3: Modify Connector Configuration page for the sample entries listed at the end of the “Step 1: Provide Basic Information Page” and “Step 2: Specify Parameter Values Page” sections.
Creating Generic Technology Connectors

Creating and Managing Generic Technology Connectors

19-15

Figure 19–1  Step 3: Modify Connector Configuration Page

Data Sets

- Source
  - The Source data sets are displayed only if you select the Reconciliation option on the first page, regardless of whether or not you select the Provisioning option.

- Reconciliation Staging
  - The reconciliation staging data sets are displayed only if you select the Reconciliation option on the Step 1: Provide Basic Information page, regardless of whether or not you select the Provisioning option.

- Oracle Identity Manager
  - The Oracle Identity Manager data sets are always displayed, regardless of the options you select on the Step 1: Provide Basic Information page. However, the OIM - Account data set and its child data sets are not displayed if you select the Trusted Source Reconciliation option on the Step 1: Provide Basic Information page. To overcome this issue, you must perform the following steps:
    1. Open the generic technology connector and navigate to Jgraph screen.
    2. In the Reconciliation Staging of the Jgraph screen, modify the field data type to **Date** for all the fields which holds date value.

Mappings

3. Save the connector.

The fields displayed in the OIM - User data set are predefined for the Oracle Identity Manager User. You can show or minimize the full list of OIM - User data set fields by clicking the arrow icon at the top of the data set. The following fields are displayed in the minimized state of the data set:

- User ID
- Email
- Password
- First Name
- Last Name

**Note:** If you select the Trusted Source Reconciliation option on the Step 1: Provide Basic Information page, all the fields of the OIM - User data set are displayed and you cannot use the arrow icon to minimize the display.

These fields constitute the minimum set of Oracle Identity Manager User fields for which values must be defined. You can designate some or all of the remaining OIM - User data set fields as mandatory Oracle Identity Manager User fields for your Oracle Identity Manager installation. You do this by ensuring that these fields always hold values when the Oracle Identity Manager User is created.

**Note:** Data set and field names that take up more than a certain amount of space are truncated and dots are displayed after the truncated part of the names. For example, the Deprovisioning Date field of the OIM - User data set is displayed as follows:

Deprovisioning Da..

To view the full name of a field, you can click the edit icon for that field or the field to which that field is mapped. In the pop-up window, the field name that you want to view is on either the first page or the second page, depending on the data set to which the field belongs.

You can add user-defined fields (UDFs) to the list of predefined Oracle Identity Manager User fields by using the Design Console. These UDFs are displayed in the OIM - User data set on the Step 3: Modify Connector Configuration page.

Depending on the options that you select on the Step 1: Provide Basic Information page, some fields are displayed by default on the Step 3: Modify Connector Configuration page:

- ID field

The ID field is displayed by default in the OIM - Account data set, regardless of whether or not you select the Reconciliation option or Provisioning option on the Step 1: Provide Basic Information page. When an account is created, this field is used to store the value that uniquely identifies the account in Oracle Identity Manager and in the target system. For a particular user, this unique field is used to direct other operations, such as modify, delete, enable, disable, and child data operations.
Every target system would have a unique field for tracking the creation of and updates made to a user account. While creating a custom provisioning transport provider, you must ensure that the provider retrieves this unique field value from the target system at the end of a Create User operation. This value must be used to populate the ID field of the OIM - Account data set.

During reconciliation, the value of the ID field must come from the corresponding unique field of the reconciliation staging data set. To set this up, you must create a mapping between the two fields. The procedure to create a mapping is discussed later in this section.

---

**Caution:** If you select both the Provisioning and Reconciliation options while creating a generic technology connector and if you do not create a mapping between the ID field and the unique field of the target system, records that are linked through reconciliation cannot be used for provisioning operations (such as modify, delete, enable, disable, and child data operations). This is because the ID field is not populated in the linked records.

- **objectClass field**
  The objectClass field is displayed by default in the OIM - Account data set and provisioning staging data set only if you select the SPML provisioning format provider on the Step 1: Provide Basic Information page.

- **containerID field**
  The containerID field is displayed by default in the OIM - Account data set and provisioning staging data set only if you select the SPML provisioning format provider on the Step 1: Provide Basic Information page.

**Provisioning Staging**

The provisioning staging data sets are displayed only if you select the Provisioning option on the first page, regardless of whether or not you select the Reconciliation option.

The display of data sets on the Step 3: Modify Connector Configuration page depends on the input that you provide on the Step 1: Provide Basic Information page and Step 2: Specify Parameter Values page. The display of fields within the data sets depends on whether or not metadata detection has taken place.

---

**Note:** Metadata detection does not take place if any of the following conditions are true:

- Sample target system data (including metadata) is not available.
- The Transport and format providers that you select are not capable of detecting metadata from sample target system data.

---

This is illustrated by the following example:

Suppose you select only the Reconciliation option on the Step 1: Provide Basic Information page. In addition, metadata detection has not taken place. Under these conditions, the display of data sets and fields on the Step 3: Modify Connector Configuration page can be summarized as follows:

The following data sets are displayed:
The fields that constitute the data sets are not displayed.

In addition, if you had selected the Trusted Source Reconciliation option on the Step 1: Provide Basic Information page, the OIM - Account data set and its child data sets are not displayed.

In Table 19–3, Scenario 1 shows the outcome of this set of input conditions. The rest of the scenarios in this table describe the display of data sets and fields under the combination of input conditions listed in the first row and first column of the table.

**See Also:** [Section 20.1.2, "Multi-language Support"] for information about limitations related to the display of non-ASCII characters on this page
Mappings
Each flow line displayed on the Step 3: Modify Connector Configuration page represents a mapping (link) between two fields of different data sets. A mapping serves one of the following purposes:

- Establishes a data flow path between fields of two data sets, for either provisioning or reconciliation
  A mapping of this type forms the basis for validations or transformations to be performed on data.
- Creates a basis for comparing (matching) field values of two data sets

The following are examples of matching-only mappings:

- Mappings created between fields of the reconciliation staging data set and the OIM - User data set form the basis of a reconciliation rule.
- A mapping between the unique field of the reconciliation staging data set and the ID field of the OIM - Account data set helps identify the key field for reconciliation matching. Along with the ID field, other fields of the OIM - Account data set can be (matching-only) mapped to corresponding fields of the reconciliation staging data set to create a composite key field for reconciliation matching.

You can perform the following actions on the Step 3: Modify Connector Configuration page:

- Adding or Editing Fields in Data Sets
- Removing Fields from Data Sets
- Removing Mappings Between Fields
- Removing Child Data Sets

19.2.4.3.1 Adding or Editing Fields in Data Sets
Identity fields detected through metadata detection are displayed on the Step 3: Modify Connector Configuration page. You can modify these fields and the mappings between them. If required, you can also add new fields on this page and create mappings between them.

The following is a summary of the actions that you can perform while adding or editing fields on the Step 3: Modify Connector Configuration page:

- Default attributes (such as the data type and length) are assigned to the fields displayed through metadata detection. You must edit these fields to set the required attributes for them.
You can create transformation mappings between fields by using a transformation provider. While performing this action, you can use the predefined concatenation transformation provider or translation transformation provider, or a custom transformation provider that you have created.

You can create matching-only mappings between fields of the reconciliation staging data set and Oracle Identity Manager data sets. Matching-only mappings that you create between the reconciliation staging data set and the OIM - User data set forms the reconciliation rule. Matching-only mappings that you create between the reconciliation staging data set and the OIM - Account data set identifies the key field for reconciliation matching.

You can add a child data set to an existing data set.

You can encrypt the value of a field, both in the process form and in the database.

You can designate a field as a lookup field and select an input source for the field. The input source can be a lookup definition or a combination of columns from Oracle Identity Manager database tables.

You can configure user account status reconciliation.

If you want to configure user account status reconciliation, refer to the "Configuring Account Status Reconciliation" section.

To add or edit a field in a data set:

Note: The display of the GUI elements and pages described in the following steps depends on the data set in which you are adding or editing a field. For example, the Required and Encrypted check boxes are not displayed if you are adding or editing a field in a Source data set.

1. Depending on whether you want to add or edit a field, click the Add icon for the data set or the edit icon for the field.

2. On the Step 1: Field Information page, specify values for the following GUI elements:

   See Also: Section 19.2.4.3, "Step 3: Modify Connector Configuration Page" for information about validations applied to the names of fields

   Field Name: If you are adding a field, specify a name for the field. The field name that you specify must contain only ASCII characters, because non-ASCII characters are not allowed.
■ **Mapping Action**: Select the type of mapping that you want to create with this field as the destination field of the mapping. You can select one of the following mapping actions:

- Select **Create Mapping Without Transformation** if you only want to create a one-to-one mapping between a source (input) field and the field that you are adding or editing, and you do not want to use a transformation provider.

- Select the **Remove Mapping** option if you are editing the field and you want to remove the mapping for which this field is the destination field. The procedure to remove a mapping is covered in detail in the Removing Mapping Between Fields section.

- The transformation mapping options displayed in the Mapping Action list are based on the predefined transformation providers and the custom transformation providers that you create. The following menu options correspond to the predefined transformation providers:
  * Create Mapping With Concatenation
  * Create Mapping With Translation

**See Also**: Section 17.5, “Transformation Providers” for information about these predefined transformation providers

Apply the following guidelines while selecting a transformation mapping:

* You can create transformation mappings only between fields of the following data sets:
  - Source and Reconciliation Staging
  - Oracle Identity Manager and Provisioning Staging

This means that, for example, you cannot create transformation mappings between a field in a reconciliation staging data set and a field in an Oracle Identity Manager data set.

You cannot create a 1-to-2 mapping with the following source and destination fields:

**Source field**: Unique field of the reconciliation staging data

**Destination fields**: User ID field of the OIM - User data set and ID field of the OIM - Account data set

This mapping is not supported. Instead, you must create a one-to-one mapping between the unique field of the reconciliation staging data and either the User ID field (of the OIM - User data set) or the ID field (of the OIM - Account data set).

* Ensure that all the fields of provisioning staging data sets are mapped to corresponding fields of OIM - User and OIM - Account data sets.

* When you create a mapping that has any field of the OIM - User data set as the source or destination field, the display of the OIM - User data set fields list is frozen in the position it was in (expanded or minimized) when the mapping was created. To unfreeze the display of the OIM - User data set so that you are able to use the arrow icon, you must remove all mappings that have any OIM - User data set field as the source or destination field.
A literal field can be used as one of the input fields of a transformation field. If you select the Literal option, you must enter a value in the field. You must not leave the field blank after selecting it.

See Section 19.2.4.3, “Step 3: Modify Connector Configuration Page” for information about limitations related to creating transformation mappings.

- **Matching Only**: Select this check box if the field is to be used as the destination field of a matching-only mapping. As mentioned earlier in this document, you can create the following types of matching-only mappings:

  - To create the reconciliation rule, you create matching-only mappings between fields of the reconciliation staging data set and the OIM - User data set. Each mapping represents a reconciliation rule element. If there are child data sets, you must ensure that the names of fields of the reconciliation staging data set that are input fields for the matching-only mappings are not used in any of the reconciliation staging child data sets.
  
  - To specify the key field for reconciliation matching, you create a matching-only mapping between the unique field of the reconciliation staging data set and the ID field of the OIM - Account data set. Along with the ID field, other fields of the OIM - Account data set can be (matching-only) mapped to corresponding fields of the reconciliation staging data set to create a composite key field for reconciliation matching.

**Caution:** If the name of a reconciliation staging field used in a matching-only mapping were to be reused as the name of a field in a reconciliation staging child data set, matching would not take place during a reconciliation run.

This known issue is explained in the Modify Connector Config Page section.

- **Create End-to-End Mapping**: If you are adding a field, select this check box if you want the same field to be added in all the data sets that are displayed to the right of the data set in which you are adding the field.

- **Multi-Valued Field**: Select this check box if you want to add a child data set. If you select this check box, the name that you specify in the Field Name field is used as the name of the child data set.

  **Note:** If you select the Trusted Source Reconciliation check box on the Step 1: Provide Basic Information page, this check box (in selected or deselected state) is ignored. This is because the reconciliation of multivalued (child) data is not supported in trusted source reconciliation.

- **Data Type**: Select the data type of the field.

  After metadata detection, the String data type is applied by default to all the fields of the reconciliation staging and OIM - Account data sets. Where
required, you must use the Data Type list to specify the actual data type of each field.

- **Length**: Specify the character length of the field.
- **Required**: Select this check box if you want to ensure that the field always contains a value.
- **Encrypted**: Select this check box if the value of the field must be stored in encrypted form in the Oracle Identity Manager database.
- **Password Field**: Select this check box if the value of the field must be encrypted on the process form. Values of fields for which this check box is selected are displayed as asterisks (*) on the process forms.

**Note**: If you select the Encrypted and Password Field check boxes, see Section 19.5.3.3, "Password-Like Fields" for information about guidelines that you must follow.

- **Lookup Field**: Select this check box if you want to make the field a lookup field.

3. Click Continue.

4. If you select the **Lookup Field** check box on the Step 1: Field Information page, the Step 2: Lookup Properties page is displayed. On this page, you can select and specify values for any combination of the lookup properties described in Table 19–4.

### Table 19–4  Lookup Properties

<table>
<thead>
<tr>
<th>Lookup Property</th>
<th>Value</th>
</tr>
</thead>
</table>
| Column Names          | In the **Property Value** field, enter the name of the database column containing the values that must be displayed in the lookup window. If required, you can enter multiple database column names separated by commas.  
**Note**: If you select the Lookup Column Name property, you must also select the Column Names property, which is described later in this table.  
After you enter a value in the **Property Value** field, click **Submit**.  
The following SQL query can be used to illustrate how the Column Names and Lookup Column Name properties are used:  
`SELECT USR_FIRST_NAME, USR_LOGIN, USR_LAST_NAME FROM USR`  
Suppose you set the following as the values of the two properties:  
- Column Names: USR_FIRST_NAME, USR_LAST_NAME  
- Lookup Column Name: USR_LOGIN  
When the user selects a particular USR_FIRST_NAME, USR_LAST_NAME combination from the lookup window, the corresponding USR_LOGIN value is stored in the database. |
| Column Captions       | In the **Property Value** field, enter the name of the column heading that must be displayed in the lookup window. If multiple columns are going to be displayed in the lookup window, enter multiple column captions separated by commas, for example, **Organization Name**, **Organization Status**.  
After you enter a value in the **Property Value** field, click **Submit**. |
### Table 19–4 (Cont.) Lookup Properties

<table>
<thead>
<tr>
<th>Lookup Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column Widths</td>
<td>In the <strong>Property Value</strong> field, enter the character width of the column that must be displayed in the lookup window. This must be the same as the maximum length of the underlying field or column from which data values are drawn to populate the lookup field. If the lookup window is going to display multiple columns, enter multiple column widths separated by commas. After you enter a value in the <strong>Property Value</strong> field, click <strong>Submit</strong>.</td>
</tr>
</tbody>
</table>

---
To specify a value for the **Lookup Query** property:

1. In the **Property Value** field, enter the SQL query (without the `WHERE` clause) that must be run when a user double-clicks the lookup field to populate the data columns displayed in the lookup window.
2. Click **Submit**.
3. On the Step 2: Add Validation page, select values from the following lists to create a `WHERE` clause for the `SELECT` statement that you specify in Step 1:
   - Filter Column
   - Source
   - Field Name

   From the values that you select, the `WHERE` clause is created as follows:

   ```
   WHERE Filter_Column=Source.Field_Name
   ```

4. Click **Save**.

   To correctly display the data returned from a query, you must add a `lookupfield.header` property to the `xlWebAdmin_locale.properties` file.

   For example, consider the following SQL query:

   ```
   SELECT usr_status FROM usr
   ```

   To view the data returned from the query, you must add the following entry to the `xlWebAdmin_locale.properties` files:

   ```
   lookupfield.header.users.status=User Status
   ```

   If the `xlWebAdmin_locale.properties` file does not contain a `lookupfield.header` property for your specified query, the Identity System Administration displays a lookup window after you click the corresponding lookup icon.

   The syntax for a `lookupfield.header` property is as follows:

   ```
   lookupfield.header.column_code=display value
   ```

   The `column_code` portion of the entry must be lowercase and any spaces must be replaced by underscore characters (_).

   By default, the following entries for lookup field column headers are already available in the `xlWebAdmin_locale.properties` file:

   ```
   lookupfield.header.lookup_definition.lookup_code_information .code_key=Value
   lookupfield.header.lookup_definition.lookup_code_information .decode=Description
   lookupfield.header.users.manager_login=User ID
   lookupfield.header.organizations.organization_name=Name
   lookupfield.header.it_resources.key=Key
   lookupfield.header.it_resources.name=Instance Name
   lookupfield.header.users.user_id=UserID
   lookupfield.header.users.first_name=First Name
   lookupfield.header.users.last_name=Last Name
   lookupfield.header.groups.group_name=Group Name
   lookupfield.header.objects.name=Resource Name
   lookupfield.header.access_policies.name=Access Policy Name
   ```

---

**Table 19-4 (Cont.) Lookup Properties**

<table>
<thead>
<tr>
<th>Lookup Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lookup Query</strong></td>
<td>To specify a value for the Lookup Query property:</td>
</tr>
</tbody>
</table>

1. In the **Property Value** field, enter the SQL query (without the `WHERE` clause) that must be run when a user double-clicks the lookup field to populate the data columns displayed in the lookup window.
2. Click **Submit**.
3. On the Step 2: Add Validation page, select values from the following lists to create a `WHERE` clause for the `SELECT` statement that you specify in Step 1:
   - Filter Column
   - Source
   - Field Name

   From the values that you select, the `WHERE` clause is created as follows:

   ```
   WHERE Filter_Column=Source.Field_Name
   ```

4. Click **Save**.

   To correctly display the data returned from a query, you must add a `lookupfield.header` property to the `xlWebAdmin_locale.properties` file.

   For example, consider the following SQL query:

   ```
   SELECT usr_status FROM usr
   ```

   To view the data returned from the query, you must add the following entry to the `xlWebAdmin_locale.properties` files:

   ```
   lookupfield.header.users.status=User Status
   ```

   If the `xlWebAdmin_locale.properties` file does not contain a `lookupfield.header` property for your specified query, the Identity System Administration displays a lookup window after you click the corresponding lookup icon.

   The syntax for a `lookupfield.header` property is as follows:

   ```
   lookupfield.header.column_code=display value
   ```

   The `column_code` portion of the entry must be lowercase and any spaces must be replaced by underscore characters (_).

   By default, the following entries for lookup field column headers are already available in the `xlWebAdmin_locale.properties` file:

   ```
   lookupfield.header.lookup_definition.lookup_code_information .code_key=Value
   lookupfield.header.lookup_definition.lookup_code_information .decode=Description
   lookupfield.header.users.manager_login=User ID
   lookupfield.header.organizations.organization_name=Name
   lookupfield.header.it_resources.key=Key
   lookupfield.header.it_resources.name=Instance Name
   lookupfield.header.users.user_id=UserID
   lookupfield.header.users.first_name=First Name
   lookupfield.header.users.last_name=Last Name
   lookupfield.header.groups.group_name=Group Name
   lookupfield.header.objects.name=Resource Name
   lookupfield.header.access_policies.name=Access Policy Name
   ```
If you want to edit the value of a property that is displayed in the table on the Step 2: Lookup Properties page, select the edit option for that property and click Edit. If you want to remove a property that is displayed in the table, select the delete option for that property and click Delete.

After you specify properties for the lookup field, click Continue.

5. If you select a transformation option from the Mapping Action list on the Step 1: Field Information page, the Step 3: Mapping page is displayed. Use this page to define the transformation function that you want to perform on the input data to the field that you are adding. The steps to be performed depend on the transformation provider option (concatenation, translation, or custom transformation provider) that you select on the previous page:

If you select a predefined transformation provider (transformation, concatenation or translation), see Transformation Providers for detailed information about the procedure to specify parameter values for the predefined transformation provider.

### Table 19–4 (Cont.) Lookup Properties

<table>
<thead>
<tr>
<th>Lookup Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lookup Code</td>
<td>In the Property Value field, enter the lookup definition code name. This code must generate all information pertaining to the lookup field, including lookup values and the text that is displayed with the lookup field when a lookup value is selected. The classification type of the lookup definition code must be of Lookup Type (that is, the Lookup Type option on the Lookup Definition form must be selected). To enter a lookup code, open the Lookup Definition form, query for the required code, and copy the code into the Property Value field. After you enter a value in the Property Value field, click Submit. Note: The Lookup Code property can be used to replace the combination of the Column Captions, Column Names, Column Widths, Lookup Column Name, and Lookup Query properties. In addition, the information contained in the Lookup Code property supersedes any values set in these five lookup properties. If you want to implement lookup fields reconciliation, create a scheduled task that populates the lookup code.</td>
</tr>
<tr>
<td>Lookup Column Name</td>
<td>In the Property Value field, enter the name of the database column containing the value that must be stored corresponding to the Column Names value selected by the user in the lookup window. If required, you can enter multiple database column names separated by commas. Note: If you select the Column Names property, you must also select the Lookup Column Name property. See the &quot;Lookup Column Name&quot; row in this table for more information about how these two properties are used. After you enter a value in the Property Value field, click Submit.</td>
</tr>
<tr>
<td>Auto Complete</td>
<td>If you enter True in the Property Value field, users can filter the values displayed in the lookup window by entering the first few characters of the value they want to select and double-clicking the lookup field. The outcome of this action is that only lookup values that begin with the characters entered by the users are displayed in the lookup window. For example, for the State lookup field, a user can enter New in the field. When the user double-clicks the State lookup field, only states that begin with New (for example, New Hampshire, New Jersey, New Mexico, and New York) are displayed in the lookup window. If you do not want to let users filter the display of values in the lookup field, enter False in the Property Value field. The default value of the Auto Complete property is False. After you enter a value in the Property Value field, click Submit.</td>
</tr>
</tbody>
</table>

If you want to implement lookup fields reconciliation, create a scheduled task that populates the lookup code.
That section also provides detailed information about configuring user account status reconciliation.

You must use the translation transformation provider if you want to configure the reconciliation of user account status information. This procedure is described in Section 17.5.2, "Translation Transformation Provider".

After you specify values for the transformation provider, click Continue.

6. If required, select a validation check for the field and click Add. In other words, select the validation provider that you want to use.

The validation options displayed in this list are based on the predefined validation Providers and any custom validation Providers that you create.

7. Click Continue, and click Close.

8. If you do not want to perform any other action on the Step 3: Modify Connector Configuration page, click the Close button that is displayed at the top of the page. You must perform the previous step before you click this Close button.

19.2.4.3.2 Removing Fields from Data Sets To remove a field from a data set:

1. Click the Delete icon for that field.

2. If you do not want to perform any other action on the Step 3: Modify Connector Configuration page, click the Close button that is displayed at the top of the page.

19.2.4.3.3 Removing Mappings Between Fields To remove a mapping:

1. Click the edit icon for the destination field of the mapping that you want to remove.

   Note: If the destination field itself is the source field for another mapping, that mapping is not removed.

2. On the Step 1: Field Information page, select Remove Mapping from the Transformation list.

3. Click Continue.

4. On the last page, click Close.

5. If you do not want to perform any other action on the Step 3: Modify Connector Configuration page, click the Close button that is displayed at the top of the page.

19.2.4.3.4 Removing Child Data Sets To remove a child data set:

1. Click the Delete icon for the data set.

2. If you do not want to perform any other action on the Step 3: Modify Connector Configuration page, click the Close button that is displayed at the top of the page.

Figure 19–2 shows the Step 3: Specify Connector Configuration page after the MyField field was added to the OIM - Account and provisioning staging data sets.
19.2.4.4 Step 4: Verify Connector Form Names Page

Use this page to specify form names for the process forms corresponding to the OIM - Account data set and its child data sets.

**Note:** If you select the Trusted Source Reconciliation option on the Step 1: Provide Basic Information page, the OIM - Account data set and its child data sets are not created. Therefore, this page is not displayed if you select the Trusted Source Reconciliation option.

The generic technology connector framework automatically creates certain objects after you submit all the information required to create a generic technology connector. Parent and child process forms corresponding to the OIM - Account data sets are examples of objects that are automatically created. Each process form on a particular Oracle Identity Manager installation must have a unique name.

**See Also:** Section 16.4, "Connector Objects Created by the Generic Technology Connector Framework"

On the Step 4: Verify Connector Form Names page, the generic technology connector framework displays default names for these process forms based on the names of the corresponding data sets. You must verify and, if required, change the names of these forms to ensure that they are unique for this installation of Oracle Identity Manager. While changing the name of a form, you must use only ASCII characters. An error message is displayed if you specify non-unique form names or if any name contains non-ASCII characters.
After you specify the form names, click **Continue**.

Instead of clicking Continue, you can click **Back** to return to the Step 2: Specify Parameter Values page. However, metadata detection does not take place if you make changes on this page and click the Continue button. This is to ensure that any customization in the data set structure and mappings made during the first pass through this page does not get overwritten. You can manually add or edit fields and mappings on the Step 3: Modify Connector Configuration page.

### 19.2.4.5 Step 5: Verify Connector Information Page

Use this page to review information that you have provided up to this point for creating generic technology connectors. The following is a page-wise explanation of the changes that are permitted on the earlier pages:

- **Step 1: Provide Basic Information page**

  You can use either the View link or Back button to reopen and view the information provided on the Step 1: Provide Basic Information page. You cannot change the information displayed on this page, because any change in this information would amount to creating a new generic technology connector.

- **Step 2: Specify Parameter Values page**

  You can use either the Change link or Back button to reopen this page. You can change parameter values on this page. However, metadata detection does not take place when you submit the changed values. This is to ensure that any customization in the data set structure and mappings made during the first pass through this page does not get overwritten. You can manually add or edit fields and mappings on the Step 3: Modify Connector Configuration page.

- **Step 3: Modify Connector Configuration page**

  You can use the Change link to reopen this page and add or edit fields and mappings.

- **Step 4: Verify Connector Form Names page**

  You cannot revisit this page.

After you verify all the information displayed on the Step 5: Verify Connector Information page, click **Create**.

At this stage, the generic technology connector framework creates all the standard connector objects on the basis of the information that you provide. The list of these objects includes the connector XML file, which is created and imported automatically into Oracle Identity Manager. Except for the form names, the names of the connector objects are in the `GTCname_GTC` format.

For example, if you specify `DB_conn` as the name of a generic technology connector that you create, all (except the forms) the connector objects are named `DB_CONN_GTC`.

**See Also:** Section 16.4, "Connector Objects Created by the Generic Technology Connector Framework"

At the end of the process, a message stating that the connector has been successfully created is displayed on the page.
Creating Generic Technology Connectors

19.2.5 Configuring Reconciliation

**Note:** If the creation process fails, objects that are created are not automatically deleted. This point is also mentioned in Section 20.1.1, "Creation Issues".

See Section 20.2.3, "Errors During Connector Creation" for a listing of error messages related to the creation process.

A reconciliation scheduled task is created automatically when you create the generic technology connector. To configure and run this scheduled task, follow the instructions in the "Creating and Managing Scheduled Tasks" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager*.

**Note:** The name of the scheduled task is in the following format:

\[GTC\textunderscore Name\_GTC\]

For example, if the name of the generic technology connector is `WebConn`, the name of the scheduled task is `WebConn_GTC`.

19.2.6 Configuring Provisioning

**Note:** If you select only the Reconciliation option on the Step 1: Provide Basic Information page, you can skip this section because you need not configure reconciliation.

A process definition is one of the objects that are automatically created when you create a generic technology connector. The name of the process definition is in the following format:

\[GTC\textunderscore name\_GTC\]

For example, if the name of the generic technology connector is `WebConn`, the name of the process definition is `WebConn_GTC`.

The process tasks that constitute this process definition can be divided into two types:

- System-defined process tasks
  
  System-defined process tasks are included by default in all newly created process definitions.

- Provisioning-specific process tasks
  
  Provisioning-specific process tasks are included in the process definition of a generic technology connector only if you select the Provisioning option on the Step 1: Provide Basic Information page, regardless of whether or not you select the Reconciliation option.

The following are provisioning-specific process tasks:
Creating Generic Technology Connectors

- Create User
- Delete User
- Enable User
- Disable User
- Updated *Field_Name* (this task is created for each field of the OIM - Account data set, except the ID field)

For mappings created between fields of the OIM - User data set and the provisioning staging data set, the following process tasks are created:

- Change *User_data_set_field_name*
- Edit *Provisioning_Staging_field_name*

For example, suppose you create a mapping between the Last Name field of the OIM - User data set and the LName field of the provisioning staging data set. The following process tasks are automatically created along with the rest of the provisioning-specific process tasks:

- Change Last Name
- Edit LName

In addition, the following provisioning-specific process tasks are created for each child data set of the OIM - Account data set:

- Child Table *Child_Form_Name* row Inserted
- Child Table *Child_Form_Name* row Updated
- Child Table *Child_Form_Name* row Deleted

All provisioning-specific process tasks have the following default assignments:

- **Target Type:** Group User With Highest Priority
- **Group:** SYSTEM ADMINISTRATORS
- **User:** XELSYSADM

If required, you can modify these default assignments by following the instructions given in "Modifying Process Tasks" on page 5-15.

19.2.7 Creating the Form and Publishing the Application Instance

To create the form and publish the application instance, which is created when you select both the provisioning and reconciliation options on the Step 1: Basic Information page, perform the following steps:

1. Create a form specific to the GTC resource object.
2. Attach the form to the GTC application instance.
3. Publish the GTC application instance to the required organizations.

**Note:** To view a provisioned account in the new UI, the process form should have a field for IT resource. The value for this IT resource field should be populated during a reconciliation run.
19.2.8 Enabling Logging

**Note:** This is an optional step. Perform the procedure discussed in this section only if you want to enable logging for the generic technology connector.

See "Enabling System Logging" in the Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager for information about enabling logging in Oracle Identity Manager.

19.3 Managing Generic Technology Connectors

The generic technology connector framework offers features that enable you to modify a generic technology connector. In addition, you can export or import a generic technology connector by using the Deployment Manager.

This section contains these topics:

- Modifying Generic Technology Connectors
- Exporting Generic Technology Connectors
- Importing Generic Technology Connectors

19.3.1 Modifying Generic Technology Connectors

**Caution:** The Design Console can be used to modify connector objects that are automatically created at the end of the generic technology connector creation process. If you use the Manage Generic Technology Connector feature to modify a generic technology connector whose connector objects have been customized by using the Design Console, all the customization work done using the Design Console would get overwritten. Therefore, Oracle recommends that you to follow one of the following guidelines:

- Do not use the Design Console to modify generic technology connector objects.
  The exception to this guideline is the IT resource. You can modify the parameters of the IT resource by using the Design Console. However, for the changes to take effect, you must purge the cache either before or after you modify IT resource parameters.

- If you use the Design Console to modify generic technology connector objects, do not use the Manage Generic Technology Connector feature to modify the generic technology connector.

See Section 16.4, "Connector Objects Created by the Generic Technology Connector Framework" for information about connector objects that are created automatically by the framework.

In addition, you can modify only one connector at a time. If you try to use the Modify pages for two different connectors at the same time on the same computer, the Modify features would not work correctly.

Appendix 20, "Troubleshooting Generic Technology Connectors" discusses both these points.
To modify a generic technology connector:

1. Login to the Identity System Administration.

2. Under Configuration, click **Generic Connector**.

3. Search for the connector that you want to modify. To simplify your search, you can use a combination of the search criteria provided on this page. Alternatively, to view all the generic technology connectors that have been created on this Oracle Identity Manager installation, click **Search connectors** without specifying any search criteria.

4. In the results that are displayed, click the generic technology connector that you want to modify.

5. Click **Edit Parameters**. The Step 2: Specify Parameter Values page of the connector creation process is displayed. From this point onward, follow the procedure described in the Step 2 section.

---

**Note:** The only difference between this procedure and the procedure that you follow to create the generic technology connector procedure is that automatic metadata detection does not take place when you modify an existing generic technology connector.

---

**Caution:** If you modify attributes of fields of the OIM - Account data set or its child data sets, corresponding changes are not made in the Oracle Identity Manager database entries for these data sets. At the same time, no error message is displayed.

Therefore, Oracle recommends that you do not modify the fields or child data sets of the OIM - Account data set.

This point has also been discussed in Section 20.2.2, "Step 3: Modify Connector Configuration Page".

---

### 19.3.2 Exporting Generic Technology Connectors

You can export the XML file of a generic technology connector. This XML file contains definitions for all the objects that are part of the connector. If you want to use the same generic technology connector on a new Oracle Identity Manager installation, you must first export the XML file and import it into the new Oracle Identity Manager installation.

To export the connector XML file:

1. In the Oracle Identity Manager Advanced Administration, under System Management, click **Export Deployment Manager File**.

2. On the first page of the Deployment Manager Wizard, select **Generic Connector** from the list and click **Search**.

3. In the search results, select the generic technology connector whose XML file you want to export.

4. Click **Select Children**.

5. For the selected generic technology connector, select the child entities that you want to export and click **Select Dependencies**.

6. Select the dependencies that you want to export, and click **Confirmation**.
7. After you verify that the elements displayed on the page cover your export requirements, click Add for Export.

8. Click Exit wizard and show full selection, and click OK.

19.3.3 Importing Generic Technology Connectors

To copy a generic technology connector to a different Oracle Identity Manager installation:

1. If the connector uses custom providers, you must copy the files created during provider creation to the appropriate directories on the destination Oracle Identity Manager installation.

See Also: "Chapter 18, "Creating Custom Providers for Generic Technology Connectors" for more information about these provider files and the directories into which you must copy them

2. Export the connector XML file on the source Oracle Identity Manager installation.

3. Import the connector XML file on the destination Oracle Identity Manager installation.

Caution: You must ensure that the names you select for a generic technology connector and its constituent objects on a staging server do not cause naming conflicts with existing connectors and objects on the production server.

The following scenario explains why you must follow this guideline:

Suppose you create a generic technology connector on a staging server, and want to import the connector to a production server. While creating the generic technology connector on the staging server, you would have ensured that the names of the generic technology connector and the connector objects are unique on that server. At the same time, you must also ensure that the names are not the same as the names of connectors and connector objects on the production server.

If any of the names happen to be the same, the old objects would be overwritten by the new objects when you import the connector XML file from the staging server to the production server. No message is displayed during the overwrite process, and the process would lead to eventual failure of the affected connectors.

This is also mentioned in Section 20.2.1, "Names of Generic Technology Connectors and Connector Objects"

To ensure that you are able to revert to a working state in the event that an object is overwritten, you must create a backup of the destination Oracle Identity Manager database before you import a connector XML file.

To import the connector XML file:

1. In the Oracle Identity Manager Advanced Administration, under System Management, click Import Deployment Management File. A dialog box for locating files is displayed.
2. Locate and open the connector XML file from the directory into which you copy it.

3. Click Add File.

4. Click Next, Next, and Skip.

5. Click View Selections.

The contents of the connector XML file are displayed on the Import page. You may see a cross-shaped icon along with some nodes. These nodes represent Oracle Identity Manager entities that are redundant. Before you import the connector XML file, you must remove these entities by right-clicking each node and selecting Remove.

6. Click Import. The connector file is imported into Oracle Identity Manager.

After you import the connector XML file, you must update the run-time parameters of the generic technology connector.

---

**Note:** These values are not copied in the connector XML file when you export it.

---

To update the values of the run-time parameters, follow the procedure described in Section 19.5.7, "Modifying Generic Technology Connectors".

### 19.4 Using the Generic Connection Pool Framework in Custom Connectors

Custom connectors can choose to use the Generic Connection Pool framework (sometimes referred to as the GCP) for any connection pooling needs.

Internally, the Generic Connection Pool framework uses Oracle Universal Connection Pool (UCP) as the default connection pooling mechanism.

Basic steps to use the Generic Connection Pool in a custom connector include:

1. Provide a concrete implementation for the `ResourceConnection` interface.
   
   The implementation should also have a default constructor with no parameters.

2. Define the additional fields in the `ITResource` definition.

3. Invoke the Generic Connection Pool to obtain and release connections from the pool.

Topics in this section include:

- Providing concrete implementation for `ResourceConnection` interface
- Defining Additional `ITResource` Parameters
- Getting and Releasing Connections from the Pool
- Using a Third-party Pool
- Example: Implementation of `ResourceConnection`

### 19.4.1 Providing concrete implementation for `ResourceConnection` interface

The connection pool makes use of the concrete implementation of `ResourceConnection` to create and close connections, and to validate connections to
the target. Thus, you should ensure that this concrete implementation class is available as a jar file under the JavaTasks folder.

Table 19–5 describes key methods of ResourceConnection:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Connection</td>
<td>This method is called while initializing the pool (to create initial number of connections) and for pool life-cycle events as needed. A hashmap named itResourceInfoMap is available as parameter with ITResource values to this method. The method returns the ResourceConnection which is the actual physical connection to the target.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>The pool invokes this method when it needs to close a connection in the course of pool life-cycle events.</td>
</tr>
<tr>
<td>Heartbeat</td>
<td>This method is used to maintain the TCP heartbeat (or TCP keepalive) of the connection to the target. The method keeps the TCP connection alive, so that the connection does not time out from the target side.</td>
</tr>
<tr>
<td>Validate</td>
<td>This method returns true or false to indicate whether the connection is still valid. The Generic Connection Pool invokes the method if &quot;validate connection on borrow&quot; is set to true. It is invoked for connections that have been in the pool for some time. If the method returns false, the pool will discard that connection, create a new connection, and return to the requester.</td>
</tr>
</tbody>
</table>

19.4.2 Defining Additional ITResource Parameters

Table 19–6 lists other ITResource parameters for which you should provide appropriate values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Sample Value and Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abandoned connection timeout</td>
<td>Connection timeout for abandoned connections in seconds. After the timeout elapses, the connection is reclaimed.</td>
<td>900</td>
</tr>
<tr>
<td>Connection wait timeout</td>
<td>Wait time in seconds for a connection to establish.</td>
<td>60</td>
</tr>
<tr>
<td>Inactive connection timeout</td>
<td>Connection timeout, in seconds, for inactive connections in the pool that are idle. Note: These are not borrowed connections.</td>
<td>300</td>
</tr>
<tr>
<td>Initial pool size</td>
<td>Initial number of connections in the pool.</td>
<td>3</td>
</tr>
<tr>
<td>Max pool size</td>
<td>Maximum number of connections that the pool can create.</td>
<td>30</td>
</tr>
<tr>
<td>Min pool size</td>
<td>Minimum number of connections that the pool must maintain.</td>
<td>2</td>
</tr>
<tr>
<td>Validate connection on borrow</td>
<td>Indicates if connections should be validated. See Table 19–5 for a detailed explanation.</td>
<td>true or false</td>
</tr>
<tr>
<td>Timeout check interval</td>
<td>Frequency, in seconds, at which to check timeout properties.</td>
<td>30</td>
</tr>
<tr>
<td>Pool preference</td>
<td>Denotes the preferred pooling mechanism. Default pool implementation is UCP.</td>
<td>&quot;Default&quot; (for UCP), &quot;Native&quot; (for Native implementation)</td>
</tr>
</tbody>
</table>
Note the following:

- Updating the ITResource parameters from the Design Console does not refresh the pool. Update values through the Identity System Administration or through the APIs.

- Avoid updating values when the pool is in use.

### 19.4.3 Getting and Releasing Connections from the Pool

Consumers of the Generic Connection Pool can invoke the ConnectionService to get pooled connections to the target, and also to return connections back to the pool.

This example code gets a connection from the pool and returns it based on ITResource Name:

```java
import com.oracle.oim.gcp.exceptions.ConnectionServiceException;
import com.oracle.oim.gcp.pool.ConnectionService;
import com.oracle.oim.gcp.resourceconnection.ResourceConnection;

public class ConnectionPoolClient {
    public void testConnection(String itResName) {
        try{
            //Request for connection from the connection pool
            ConnectionService service = new ConnectionService();
            ResourceConnection myConnection = service.getConnection(itResName);
        } catch (ConnectionServiceException e) {
            //Handle error
        }
    }
}
```

---

**Table 19–6 (Cont.) ITResource Parameters**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Sample Value and Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection pooling supported</td>
<td>Denotes whether pooling is supported. If pooling is not supported, returned connections will not be pooled connections. Recommended default is true.</td>
<td>true or false.</td>
</tr>
<tr>
<td>Target supports only one connection</td>
<td>Denotes whether the target system supports only one connection at a time. When set to true, irrespective of other properties, the following pool parameters are used:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- Min Pool Size = 0</td>
<td>true if target can handle only one connection, false otherwise.</td>
</tr>
<tr>
<td></td>
<td>- Initial Pool Size = 0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- Max Pool Size = 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Recommended default is false</td>
<td></td>
</tr>
<tr>
<td>ResourceConnection class definition</td>
<td>The concrete implementation of the ResourceConnection class</td>
<td>com.oracle.oim.ad.ADResourceConnectionImpl</td>
</tr>
<tr>
<td>Native connection pool class definition</td>
<td>The wrapper to the native pool mechanism that implements the GenericPool. Set a value only if the pool preference is set to Native.</td>
<td>com.oracle.oim.ad.ADNativePool</td>
</tr>
<tr>
<td>Pool excluded fields</td>
<td>Comma-separated list of fields not needed for creating a connection. When any of the specified fields are updated, the GCP pool is not refreshed. Note: Fields in this list are not available as part of the HashMap parameter to the createConnection method.</td>
<td>Recon TimeStamp,ADSync Enabled</td>
</tr>
</tbody>
</table>
/*myConnection* is the connection
//use the connection...

//Release connection back to the connection pool
//Connections should always be returned this way.

    service.releaseConnection(myConnection);
}
    
catch(ConnectionServiceException e)
    {
        //handle
    }

You can also request connections to the target using ITResource Key. Here is an example:

    ConnectionService service = new ConnectionService();
    ResourceConnection myConnection = service.getConnection(itResourceKey);

19.4.4 Using a Third-party Pool

As mentioned earlier in the section, you can use any third-party pool for your custom connector. However, in addition to the steps described earlier, you must provide a concrete implementation of the GenericPool interface as a wrapper to the third-party pool.

Note: If the custom connector does not wish to use the UCP pool, it can choose to use GCP with the Native option, though there are no significant advantages to this. With the Native pool preference, the responsibility of maintaining and implementing the pool rests with the custom connector.

Table 19–7 lists the methods invoked for the GenericPool interface:

<table>
<thead>
<tr>
<th>Method</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>initializePool(PoolConfiguration poolConfig)</td>
<td>To initialize the pool. The PoolConfiguration data object contains all pool-related parameters.</td>
</tr>
<tr>
<td>borrowConnectionFromPool()</td>
<td>To request a connection.</td>
</tr>
<tr>
<td>returnConnectionToPool(Resource Connection resConn)</td>
<td>To return a connection to the pool.</td>
</tr>
<tr>
<td>refreshPool(PoolConfiguration newPoolConfig)</td>
<td>To refresh the pool with updated values.</td>
</tr>
<tr>
<td>destroyPool()</td>
<td>To remove the pool (for example when ITResource is deleted).</td>
</tr>
</tbody>
</table>

19.4.5 Example: Implementation of ResourceConnection

This example demonstrates an implementation of the ResourceConnection interface. Key methods are highlighted.
Example 19–1 An Example of ResourceConnection Implementation

```java
/**
 * Sample implementation for Socket Connections:
 */
import java.io.IOException;
import java.net.InetSocketAddress;
import java.net.Socket;
import java.net.SocketException;
import java.net.UnknownHostException;
import com.oracle.oim.gcp.exceptions.ResourceConnectionCloseException;
import com.oracle.oim.gcp.exceptions.ResourceConnectionCreateException;
import com.oracle.oim.gcp.exceptions.ResourceConnectionValidationException;
import com.oracle.oim.gcp.resourceconnection.ResourceConnection;

public class SocketResourceConnectionImpl extends Socket implements ResourceConnection {
    public SocketResourceConnectionImpl() {
        super();
    }
    /**
     * Sample: Concrete implementation for closing a socket connection
     */
    public void closeConnection() throws ResourceConnectionCloseException{
        if(!this.isClosed()){
            try {
                this.close();
            } catch (IOException e) {
                throw new ResourceConnectionCloseException("[Client ResourceConnection implementation] Failed to close socket connection! ");
            }
        }
    }
    /**
     * Sample : Concrete implementation for creating a socket connection.
     * The return value is the actual physical socket connection
     */
    public ResourceConnection createConnection(HashMap itResInfoMap) throws ResourceConnectionCreateException {
        ResourceConnection r = null;
        SocketResourceConnectionImpl i = new SocketResourceConnectionImpl();
        try {
            //HashMap has all ITResource related information that is needed
            //for connecting to target.
            String serverAddress= ((String) itResInfoMap.get("Server Address")).trim();
            int port = getIntValue(((String)itResInfoMap.get("Port")).trim());
            //utility method getIntValue returns an int for a String
            int port =
getcIntValue(((String)itResInfoMap.get("Port")).trim());
            System.out.println("Connecting to Socket with IP Address "
                + serverAddress+" at port "+ port);
            InetSocketAddress inet = new
```
InetSocketAddress(serverAddress, port);
i.connect(inet);
if (!i.isConnected()){
    throw new ResourceConnectionCreateException
    (* Failed to create socket: connection failure*);
}
r = (ResourceConnection)i;
} catch (UnknownHostException e) {
    throw new
    ResourceConnectionCreateException("[Client ResourceConnection implementation]
    Failed to create socket connection!", e);
} catch (IOException e) {
    throw new
    ResourceConnectionCreateException("[Client ResourceConnection implementation]
    Failed to create socket connection! ", e);
}
return r;
}/**
 * Sample : Concrete implementation for heartbeat of a socket connection
 */
public void heartbeat() throws ResourceConnectionValidationxception {
    try {
        this.setKeepAlive(true);
    } catch (SocketException e) {
        throw new
        ResourceConnectionValidationxception
        ("[Client ResourceConnection implementation]
        Failed to set heartbeat ");
    }
}
}/**
 * Sample: Concrete implementation for validating connection
 */
public boolean isValid() {
    if (this.isBound()){
        return true;
    }else{
        return false;
    }
}
)

### 19.5 Best Practices

This section contains these topics:

- Working with the Provide Basic Information Page
- Working with the Specify Parameter Values Page
- Working with the Modify Connector Configuration Page
- Working with Shared Drive Reconciliation Transport Provider
19.5.1 Working with the Provide Basic Information Page

Apply the following guidelines while specifying a name for a generic technology connector:

- **Summary:**
  Ensure that the name contains only ASCII characters. You can include the underscore (_) character, but do not include any other non-ASCII character in the name.

- **Description:**
  For most of the connector objects that are automatically created at the end of the connector creation process, the name of the generic technology connector is part of the name of the object itself. For example, if the name of the generic technology connector is `WebConn`, the name of its scheduled task is `WebConn_GTC`.

  In the Oracle Identity Manager database, there is no provision for storing objects with names in non-ASCII characters. Therefore, an error message is displayed if you enter non-ASCII characters while specifying the name of a generic technology connector.

- Ensure that the name is not the same as the name of any connector or connector object on the Oracle Identity Manager installation.

- If you plan to create the generic technology connector on a staging server and move it to a production server, ensure that the name of the generic technology connector does not cause naming conflicts with existing connectors or connector objects on the production server.

- Before you import a generic technology connector created on a staging server to a production server, create a backup of the destination Oracle Identity Manager database to ensure that you are able to revert to a working state in the event that a connector object is overwritten.

- If you select the shared drive transport provider, you must select the CSV format provider.

- If you select the SPML provisioning format provider, you must select the Web Services provisioning transport provider.

- If you select the shared drive reconciliation transport provider, ensure that there is data in the prescribed format on at least the first two lines of the parent and child data files provided by the target system for reconciliation. The prescribed form of data is discussed in Section 17.1, "Shared Drive Reconciliation Transport Provider".

- If you select the shared drive reconciliation transport provider, ensure that the required permissions are set on the staging and archiving directories before reconciliation begins. The required permissions are discussed in the "Permissions to Be Set on the Staging and Archiving Directories" section.

- Do not try to create more than one generic technology connector at a time, even from different sessions of the Identity System Administration for the same Oracle Identity Manager installation.
19.5.2 Working with the Specify Parameter Values Page

This section describes the following known issues related to the input that you specify on the Step 2: Specify Parameter Values page:

- **Summary:**
  
  If you use the shared drive reconciliation transport provider, :

  - Do not specify the same path for the staging and archiving directories. Existing files in the archiving directory are deleted if you specify the same path for both directories.
  
  - Ensure that the names of files in the staging directory are different from the names of files in the archiving directory. If the file names happen to be the same, existing files in the archiving directory are overwritten at the end of a reconciliation run.

- **Description:**

  When you use the shared drive reconciliation transport provider, after each reconciliation run, data files are moved from the staging directory to the archiving directory. The files moved to the archiving directory are not time-stamped or marked in any way. Therefore, when you use the shared drive transport provider, bear in mind the following guidelines:

  - The archiving directory path and name that you specify must not be the same as the staging directory path and name. If you specify the same path and name, the existing files in the archiving directory are deleted at the end of the reconciliation run.

  - During the current reconciliation run, if data files with the same names as the files used in the last reconciliation run are placed in the staging directory, the existing files in the archiving directory are overwritten by the new files from the staging directory. This can be illustrated by the following example:

    Suppose that at the end of the last reconciliation run, the following files were moved automatically from the staging directory to the archiving directory:

    usrdDataParentData.csv
    usrdDataRoleData.csv
    usrdDataGroupMembershipData.txt

    For the current reconciliation run, you place the following files in the staging directory:

    usrdDataParentData.csv
    usrdDataRoleData_04Feb07.csv
    usrdDataGroupMembershipData_04Feb07.txt

    At the end of the current reconciliation run, these files are moved to the archiving directory. When this happens, the old usrdDataParentData.csv file is overwritten by the new one.

    Therefore, if you want to ensure that files in the archiving directory are not overwritten at the end of a reconciliation run, you must ensure that the names of files in the staging directory are not the same as the names of files in the archiving directory.

- **Summary:**

  Metadata detection does not take place a second time if you go back to the Step 2: Specify Parameter Values page. Therefore, if required, you must manually make
changes in the fields and field mappings displayed on the Step 3: Modify Connector Configuration page.

Description:

Suppose you want to change a value that you provide on the Step 2: Specify Parameter Values page. You can return to this page from the Step 4: Verify Connector Form Names or Step 5: Verify Connector Information page. However, metadata detection would not take place a second time when you click the Continue button after changing the provider parameter value. This functionality is aimed at preserving changes that you may have manually made on the Step 3: Modify Connector Configuration page.

As an extension of this functionality, metadata detection does not take place even when you modify an existing generic technology connector.

19.5.3 Working with the Modify Connector Configuration Page

This section discusses best practices related to the following areas:

- Names of Fields
- Password Fields
- Password-Like Fields
- Mappings
- Oracle Identity Manager Data Sets

19.5.3.1 Names of Fields

Note that the following validations are applied when you specify a field name while adding or editing fields:

- Two fields that belong to the same data set (parent or child) cannot have the same name.
- Two child data sets of the same parent data set cannot have the same name.
- The name of a field in a parent data set cannot be the same as the name of one of its child data sets.
- Two different child data sets can have fields that have the same name, regardless of whether or not the child data sets belong to the same parent data set. For example, the GroupMembership data set and Role data set can each have a field with the name UsrID.
- Two different parent data sets can have fields that have the same name. Similarly, these data sets can also have child data sets that have the same name.
- The name of a child data set can be the same as that of one of its fields.

19.5.3.2 Password Fields

To ensure the security of passwords, password information must not be reconciled through a generic technology connector. In other words, you must ensure that the Source and reconciliation staging data sets do not contain the Password field. In addition, you must not map any field of the reconciliation staging data sets to the Password field of the OIM - User data set.
19.5.3.3 Password-Like Fields
A password-like field is a field to which you set the Encrypted and Password Field attributes (by selecting the Encrypted and Password Field check boxes). You can create a password-like field by setting these two attributes to a field that you add to the OIM - Account data set.

To secure the contents of password-like fields, bear in mind the following guidelines while adding or editing these fields:

■ You can use the Password Field and Encrypted check boxes to secure the display and storage of password information in Oracle Identity Manager. However, when you map password-like fields to fields of the provisioning staging data set, you must take all necessary precautions to secure the data propagated in these fields. For example, you must ensure that this data is not stored in a plain-text file on the target system at the end of a provisioning operation.

Oracle recommends creating only one-to-one mappings between the password field of the OIM - Account data set and the provisioning staging data set. In other words, this password field must not be used as an input field for a transformation mapping with a provisioning staging field. The same precaution must be taken for the Password field of the OIM - User data set.

■ As mentioned earlier, the Password field is one of the predefined fields of the OIM - User data set. The Password Field and Encrypted attributes are set for this field. By using the Design Console, you can set the Password Field and Encrypted attributes for a UDF that you create. This would give the newly created UDF the same properties as the existing Password field. However, the generic technology connector framework treats this field the same as any other text field (with the String data type) and the contents are not encrypted in the Identity Self Service, Identity System Administration, or database.

See also Section 20.1, "General Issues for Generic Technology Connectors".

19.5.3.4 Mappings
Apply the following best practices while working with fields of the Oracle Identity Manager data sets:

■ Summary:
If you select the translation transformation provider to create a mapping, specify the name of a lookup definition in the Lookup Code Name region. If you specify a data set name and field in the Lookup Code Name region, translation would fail during actual reconciliation or provisioning operations.

■ Description:
If you select the translation transformation provider while creating a mapping, the Step 2: Mapping page displays options for selecting a field from a data set and specifying a literal. Because you are using the translation transformation provider, you must select the Literal option and enter the name of the lookup definition that contains the Code Key and Decode values for the translation. You must not select a data set name and field in the Lookup Code Name region. Although there is no validation to stop you from selecting a data set name and field, the translation operation would fail during actual reconciliation or provisioning operations.

Create a mapping between the ID field of the OIM - Account data set and the field that uniquely identifies records of the reconciliation staging data set.
Along with the ID field, other fields of the OIM - Account data set can be (matching-only) mapped to corresponding fields of the reconciliation staging data set to create a composite key field for reconciliation matching.

Create mappings between all fields in provisioning staging data sets and corresponding fields in Oracle Identity Manager data sets.

To create a reconciliation rule, you create matching-only mappings between fields of the reconciliation staging data set and the OIM - User data set. If there are child data sets, ensure that the names of fields of the reconciliation staging data set that are input fields for the matching-only mappings are not used in any of the reconciliation staging child data sets. If you do not follow this guideline, reconciliation would fail.

This has also been mentioned in the section "Step 3: Modify Connector Configuration Page".

A literal field can be used as one of the input fields of a transformation mapping. If you select the Literal option, you must enter a value in the field. You must not leave the field blank after selecting it.

19.5.3.5 Oracle Identity Manager Data Sets
Apply the following best practices while working with fields of the Oracle Identity Manager data sets:

- For trusted source reconciliation, the following fields of the OIM – User data set must always hold values:
  - User ID
  - First Name
  - Last Name
  - Organization Name
  - Xellerate Type
  - Role

In addition, you can select other OIM – User fields that must be populated when a user account is created through reconciliation. For each of these fields, you must create mappings with the corresponding fields of the reconciliation staging data sets. During a reconciliation run, you must ensure that the fields of the target system that serve as the source for these fields always hold values.

For provisioning, you can select fields of the OIM – User and OIM – Account data sets whose values must be propagated to the target system. After you identify these fields, create mappings between them and their corresponding fields in the provisioning staging data sets. During a provisioning operation, you must enter values for each of these fields.

- If required, add user-defined fields (UDFs) to the list of predefined OIM - User data set fields. See "Configuring User Attributes" in the Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager for details.

- Do not modify or delete attributes of OIM - Account data set fields in an existing generic technology connector.

19.5.4 Working with Shared Drive Reconciliation Transport Provider

Summary
If parent records and child data records are created and linked in both the target system and Oracle Identity Manager, you must ensure that the staging directory contains both parent data and child data files at the start of each reconciliation run.

**Description**

Suppose there are parent data records with associated child data records in the target system. To reconcile these records into Oracle Identity Manager, you place the parent and child data files containing these records in the staging directory. During the reconciliation run, the child data records are linked to their corresponding parent data records. Before the start of any subsequent reconciliation run, if you remove the child data files from the staging directory, reconciliation events are not created for this form of child data record deletion. If you want to remove child data records for specific parent data records, you must remove the child data records from the child data file. You must ensure that the child data file is placed in the staging directory for each reconciliation run, even if there are no child data records (from the third line onward) in the files.

### 19.5.5 Working with Custom Providers

Apply the following guideline while working with custom providers:

When you develop code for a custom provisioning transport provider, ensure that the provider returns the unique field value at the end of a Create User operation. This functionality is implemented by the `sendData` method of the provisioning transport provider. See "Role of Providers During Provisioning" for more information.

### 19.5.6 Working with Connector Objects

Apply the following guidelines while working with connector objects created automatically during generic technology connector creation:

- **Summary:**
  
  Do not attempt to use for provisioning the resource object created automatically for a reconciliation-only generic technology connector.

- **Description:**
  
  Suppose you select only the Reconciliation option while creating a generic technology connector. At the end of the creation process, a resource object is one of the objects created automatically for this generic technology connector. However, you cannot provision this resource object to any user because a generic adapter is not created for a reconciliation-only generic technology connector.

- **Summary:**
  
  Do not attempt to provision generic technology connector resource objects to organizations defined in Oracle Identity Manager.

- **Description:**
  
  A resource object is one of the connector objects that get created automatically during generic technology connector creation. This resource object can be provisioned only to Oracle Identity Manager Users. You must not attempt to provision it to organizations defined in Oracle Identity Manager.

  This has also been mentioned in the Connector Objects section.

- **You can use the Design Console to customize connector objects that are automatically created during generic technology connector creation. After you customize connector objects, if you perform a Manage Generic Technology**
Connector operation, all the customization done on the connector objects would be overwritten. Therefore, Oracle recommends that you apply one of the following guidelines:

- Do not use the Design Console to modify generic technology connector objects.

  The exception to this guideline is the IT resource. You can modify the parameters of the IT resource by using the Design Console. However, if you have enabled the cache for the GenericConnector and GenericConnectorProviders categories, you must purge the cache either before or after you modify IT resource parameters.

- If you use the Design Console to modify generic technology connector objects, do not use the Manage Generic Technology Connector feature to modify the generic technology connector.

  This has also been mentioned in Section 19.5.6, "Working with Connector Objects".

- Prepopulate adapters are not part of the set of connector objects that are created automatically when you create a generic technology connector. However, while creating a generic technology connector, you can map provisioning input to literals and user data fields. Although this feature cannot be used to prepopulate the User Defined Form, it can be used to prepopulate the provisioning data packet.

### 19.5.7 Modifying Generic Technology Connectors

Apply the following best practice while modifying generic technology connectors:

Do not try to modify more than one generic technology connector at a time, even from different sessions of the Identity System Administration for the same Oracle Identity Manager installation.
20 Troubleshooting Generic Technology Connectors

This chapter describes how to troubleshoot problems that you might encounter during development. It contains these sections:

- General Issues for Generic Technology Connectors
- Configuration Issues for Generic Technology Connectors

20.1 General Issues for Generic Technology Connectors

This section describes general issues for generic technology connectors. It contains these topics:

- Creation Issues
- Multi-language Support
- Other General Issues

20.1.1 Creation Issues

This section describes the following known issues related to the connector objects that are automatically created by the generic technology connector framework:

- Summary:
  - No warning is displayed if the name that you specify for a generic technology connector is the same as the name of an existing connector object.
  - No warning is displayed if an existing connector object is overwritten by a new connector object when you import a connector XML file.

- Description:
  
  This point has also been discussed in the "Names of Generic Technology Connectors and Connector Objects” section.

- Summary:
  
  After an error occurs during generic technology connector creation, form names are not displayed on the Step 4: Verify Connector Form Names page when you revisit that page by clicking Back on the Step 5: Verify Connector Information page.

  This is intentional and not the result of an issue or limitation of the software.
Description:
As mentioned earlier in this guide, some connector objects are automatically created even if the overall generic technology connector creation process fails. This set of connector objects includes process forms whose names you specify on the Step 4: Verify Connector Form Names page. In the event that the connector creation process fails, you are prompted to enter new form names through the display of blank fields on the Step 4: Verify Connector Form Names page. This is to ensure that the uniqueness checks on the process form names are reapplied when you submit the new form names.

As an alternative to revisiting the previous pages and providing input for creating the generic technology connector, you can start all over again from the Step 1: Provide Basic Information page and re-create the generic technology connector.

Summary:
You cannot provision generic technology connector resource objects to organizations defined in Oracle Identity Manager.

Description:
A resource object is one of the connector objects that get created automatically during generic technology connector creation. This resource object can be provisioned only to Oracle Identity Manager Users. You must not attempt to provision it to organizations defined in Oracle Identity Manager.

Summary:
Customization work done on objects of a generic technology connector would be overwritten if you perform a Manage Generic Technology Connector operation.

Description:
You can use the Design Console to customize connector objects that are automatically created during generic technology connector creation. However, after you customize connector objects, if you perform a Manage Generic Technology Connector operation, then all the customization done on the connector objects would be overwritten. Therefore, Oracle recommends that you to apply one of the following guidelines:

- Do not use the Design Console to modify generic technology connector objects.
  
  The exception to this guideline is the IT resource. You can modify the parameters of the IT resource by using the Design Console. However, if you have enabled the cache for the GenericConnector and GenericConnectorProviders categories, then you must purge the cache either before or after you modify IT resource parameters.

- If you use the Design Console to modify generic technology connector objects, then do not use the Manage Generic Technology Connector feature to modify the generic technology connector.

- Connector objects that are automatically created are not deleted even if the generic technology connector creation process fails.

Summary:
When you create a new GTC based on Database Application Table, configure connection parameters, and select the custom transformation provider in the reconciliation staging to apply a concatenation to the attribute, such as ID_EMPLEADO, the custom transformation provider is visible and you can select it,
but when you click Continue to provide mapping information, an error is logged, and you are not able to provide parameters to the Transformation. The error is similar to the following:

<Sep 29, 2011 6:31:32 PM CDT> <Error>
<org.apache.struts.tiles.taglib.InsertTag> <BEA-000000> <ServletException in '/gc/ModifyConnectorTransParamsTiles.jsp': null
javax.servlet.ServletException: java.lang.reflect.InvocationTargetException

Description:
The possible reason of this error is missing entries in the properties files. To resolve this issue, the resource bundles must be added in the following files:

- $MW_HOME/Oracle_IDM1/server/customResources/customResources_en.properties
- The corresponding translations for the other locales used

20.1.2 Multi-language Support
This section describes the following known issues related to the Multilanguage Support feature:

Summary:
No warning is displayed if there are non-ASCII characters in the first or second line of the data files in the staging directory.

Description:
There is no support for non-ASCII data in the metadata of target system user data. If you use the CSV Reconciliation format provider, then this limitation means that you cannot include non-ASCII characters in the metadata line (second line) of the parent and child data files that you store in the staging directory.

The reason for this limitation is as follows:
The generic technology connector framework creates User Defined process forms in Oracle Identity Manager and names the forms and their fields on the basis of the input metadata. In addition, database tables and columns are created for these forms and their fields, respectively. Because non-ASCII characters cannot be used in database object names, these characters are not supported in the target system metadata.

The generic technology connector framework may be able to parse and correctly display non-ASCII characters in the first and second lines of the data files. However, to ensure that the connector objects are created correctly, you must ensure that non-ASCII characters are not used in the first and second lines of the data files.

Note: From the third line onward in the data files, the field data values can contain non-ASCII characters. These data values are reconciled and stored in the Oracle Identity Manager database.

Summary:
For any language that Oracle Identity Manager supports, if the browser language setting does not match the operating system language setting of the Oracle
Identity Manager server, then data is not displayed correctly on the Step 3: Modify Connector Configuration page.

**Description:**

The Step 3: Modify Connector Configuration page displays an image that is dynamically created by the generic technology connector framework. The following are limitations related to the display of localized text items on this page:

The language in which you want field labels to be displayed must match the following language settings:

- Oracle Identity Manager language
- Operating system language
- Browser language

If the browser language setting is the same as the operating system language setting of the Oracle Identity Manager server, then all the text items (field names and GUI element labels) are displayed in the required language.

---

**Note:**

- Localized GUI element labels are displayed only if you create and use resource bundles that contain localized labels for these GUI elements.

- If you are using the Traditional Chinese or Simplified Chinese language, then the browser locale (language and country/region) must be the same as the operating system locale (language and country/region) for all the text items to be displayed in the required language.

---

If the browser language is not the same as the operating system language, then the following static labels would be displayed in English (regardless of the browser language):

- Labels of the OIM - User and OIM - Account data sets: "User" and "Account"
- Labels of the fields that constitute the OIM - User data set:
  - "User ID"
  - "Email"
  - "First Name"
  - "Last Name"

For non-ASCII languages, labels for the remaining items on the Step 3: Modify Connector Configuration page would not be displayed correctly.

---

**Summary:**

Certain text items displayed on the Step 3: Modify Connector Configuration page are always displayed in English.

**Description:**

Some of the static text displayed on the Step 3: Modify Connector Configuration page are not localized. For example, suppose you create a generic technology connector named **MyGTC**. When you provision the resource object of this connector to a user, the following text is displayed on the page:
Provisioning form for MyGTC

Child Form of MyGTC representing child-dataset: child_data_set_name

The static part of this text is always displayed in English.

If required, you can localize the static text as follows:

1. For the language to which you want to localize the text, open the corresponding customResources.properties file by importing it from MDS. The files for all the languages that Oracle Identity Manager supports are in MDS. To import the customResources.properties file from MDS, see "Migrating User Modifiable Metadata Files" on page 37-1.

The following example illustrates this step of the procedure.

Suppose you specify the following values while creating a generic technology connector:

- Connector Name: MyGTC
- Parent Form name: ADUser
- Child data set name: ADUserRole
- Child form name: ADURole1

If you want the static text to be displayed in the Spanish language, then open the customResources_es.properties file. This file is in MDS.

2. In the customResources.properties file for the required language, add the following lines:

   global.UD_PARENT_FORM_NAME.description=Localized_text_for_"Provisioning form for" GTC_name

   global.UD_CHILD_FORM_NAME.description=Localized_text_for_"Child Form of" GTC_name Localized_text_for_"representing the child data set": child_data_set_name

In these two lines, replace:

* PARENT_FORM_NAME with the name of the parent form

   The parent form name is always converted to uppercase letters in Oracle Identity Manager. Therefore, the name that you enter must be in uppercase letters.

* Localized_text_for_"Provisioning form for" with localized text for the words "Provisioning form for"

* GTC_name with the name of the generic technology connector

* CHILD_FORM_NAME with the name of the child form

   The child form name is always converted to uppercase letters in Oracle Identity Manager. Therefore, the name that you enter must be in uppercase letters.
* Localized_text_for_"Child Form of" with localized text for the words "Child form for"

* child_data_set_name with the name of the child data set

For example:

For the Spanish language, add the following lines in the customResources_en.properties file:

global.UD_ADUSER.description=Spanish_text_for_"Provisioning form for" MyGTC

global.UD_ADMINUSER.description=Spanish_text_for_"Child Form of" MyGTC

Spanish_text_for_"representing the child data set": ADUserRole

20.1.3 Other General Issues

This section describes the following known issues that do not fall under any of the preceding categories:

- **Summary:**
  
  Unsafe-Filename exceptions may be thrown during the generic technology connector creation process.

- **Description:**
  
  On Oracle WebLogic Server and Oracle Application Server, the Unsafe-Filename exception may be thrown during the generic technology connector creation process. This exception can be ignored. The generic technology connector creation process is not affected by the occurrence of these exceptions. This issue is not seen on IBM WebSphere Application Server and JBoss Application Server.

- Generic technology connectors do not support the reconciliation of parent data deletion.

  You cannot use a generic technology connector to reconcile the deletion of parent data. For example, if the account of user John Doe is deleted from the target system, then you cannot use a generic technology connector to reconcile this user deletion in Oracle Identity Manager.

- **Summary:**

  The contents of a UDF are not encrypted if the Password Field and Encrypted attributes have been set for the field by using the Design Console.

- **Description:**

  As mentioned earlier, the Password field is one of the predefined fields of the OIM - User data set. The Password Field and Encrypted attributes are set for this field. By using the Design Console, you can set the Password Field and Encrypted attributes for a UDF that you create. This would give the newly created UDF the same properties as the existing Password field. However, the generic technology connector framework treats this field the same as any other text field (with the String data type) and the contents are not encrypted in the Identity System Administration or database.

  The generic technology connector framework does not provide some of the functionality that the Design Console offers for creating reconciliation rules. Only reconciliation rules of the following pattern can be created:

  A equals B

  "and"
While creating a generic technology connector, you cannot specify that the target system requires a remote manager to communicate with the target system. Therefore, a generic technology connector cannot use a remote manager.

You use the Target Date Format parameter to specify the format in which date values must be sent to the target system during provisioning. Date validation for this parameter does not take place if you enter a date in numeric format. For information about the date formats that you can specify, see the following Web page:

http://java.sun.com/docs/books/tutorial/i18n/format/simpleDateFormat.html#datepattern

Scheduled tasks that are not currently running have the INACTIVE status. These tasks run at the next specified date and time. Under certain conditions, a scheduled task is automatically assigned the NONE status. However, this status change does not affect the functionality of the task, which continues to run at the specified date and time.

During a Manage Generic Technology Connector operation, if you change the data type of a field in the OIM - Account data set, then an error is thrown when you click Create on the Step 5: Verify Connector Information page.

20.2 Configuration Issues for Generic Technology Connectors

This section contains these topics:

- Names of Generic Technology Connectors and Connector Objects
- Step 3: Modify Connector Configuration Page
- Errors During Connector Creation
- Errors During Reconciliation
- Errors During Provisioning

20.2.1 Names of Generic Technology Connectors and Connector Objects

This section describes the following known issues related to the names that you specify for generic technology connectors and connector objects:

Summary:

- No warning is displayed if the name that you specify for a generic technology connector is the same as the name of an existing connector object.
- No warning is displayed if an existing connector object is overwritten by a new connector object when you import a connector XML file.

Description:

During the creation or modification of a generic technology connector, various objects are automatically created or modified by the generic technology connector framework. You are prompted to specify names for the generic technology connector and process forms. The framework automatically generates names for the remaining objects. These
autogenerated names are based on the name that you specify for the generic technology connector.

When you specify a name for the generic technology connector, you must ensure that the name is unique across all object categories (such as resource objects and IT resources) for that Oracle Identity Manager installation. Similarly, you must also ensure that the process form names are unique. This guideline must be followed even while importing a generic technology connector XML file to a different Oracle Identity Manager installation. You must ensure that the names of objects defined in the XML file are not the same as the names of objects belonging to the same category on the destination Oracle Identity Manager installation. For example, the name of the scheduled task defined in the XML file must not be the same as the name of any other scheduled task on the destination Oracle Identity Manager installation.

The scope of this guideline covers all connector objects, regardless of whether the object is used by a predefined connector or a generic technology connector on the destination Oracle Identity Manager installation.

If you do not follow this guideline, then existing objects that have the same name as imported objects are overwritten during the XML file import operation. No message is displayed during the overwrite process, and the process leads to eventual failure of the affected connectors.

This point has also been discussed in the "Connection Objects" section.

20.2.2 Step 3: Modify Connector Configuration Page

This section describes the following known issues related to the input that you specify on the Step 3: Modify Connector Configuration page:

- Summary:
  While modifying an existing generic technology connector, if you modify the fields or child data sets of the OIM - Account data set, then corresponding changes are not made in the Oracle Identity Manager database entries for the forms that are based on these data sets. At the same time, no error message is displayed.

  Description:
  The Step 3: Modify Connector Configuration page provides features to add, modify, and delete fields and field mappings. You can use these features to modify the length or data type of fields in the OIM - Account data set or its child data sets. However, this action would not translate into corresponding changes in the Oracle Identity Manager database entries for these data sets. At the same time, no error message is displayed.

  Therefore, you must not make changes in the fields or child data sets of the OIM - Account data set.

- Summary:
  Suppose you create a generic technology connector, use it for provisioning or reconciliation, and then delete fields or child data sets of the OIM - Account data set. An error occurs the next time you perform provisioning or reconciliation by using the same generic technology connector.

  Description:
  Suppose you create a generic technology connector and then use it for provisioning or reconciliation. You then delete some fields or child data sets of the
OIM - Account data set of this generic technology connector. The next time you perform provisioning or reconciliation by using the same generic technology connector, an exception is thrown.

After you use the generic technology connector for provisioning or reconciliation even once, deleting the fields or child data sets of the OIM - Account data set is an invalid operation. This is because data linked to the fields or child data sets that you delete has already been stored in the Oracle Identity Manager database.

Therefore, you must not delete fields or child data sets of the OIM - Account data set if the generic technology connector has already been used to perform provisioning or reconciliation.

- **Summary:**

If the name of a reconciliation staging field used in a matching-only mapping were to be reused as the name of a field in a reconciliation staging child data set, then reconciliation would fail.

**Description:**

You create a reconciliation rule by creating matching-only mappings between fields of the reconciliation staging data set and OIM - User data set. If there are child data sets, then you must ensure that the names of fields of the reconciliation staging data set that are input fields for the matching-only mappings are not used in any of the reconciliation staging child data sets. If the name of a reconciliation staging field used in a matching-only mapping were to be reused as the name of a field in a reconciliation staging child data set, then reconciliation would fail.

The following example illustrates this scenario:

The **AD_User** data set is the reconciliation staging parent data set. The following are the fields of this data set:

- User ID
- Name
- Designation
- Location

The **Admin_Groups** data set is a child data set of the **AD_User** data set. If you use the User ID field of the **AD_User** data set to create a matching-only mapping with the OIM - User data set, then you cannot have a field with the name User ID in the **Admin_Groups** data set. If this child data set were to contain a field with the name User ID, then reconciliation would fail.

- **Summary:**

The Password field is displayed in the OIM – User data set, even though this field is not reconciled by the reconciliation engine.

**Description:**

If you select the Trusted Source Reconciliation option on the Step 1: Provide Basic Information page, then the Password field is displayed in the OIM – User data set on the Step 3: Modify Connector Configuration page, even though this field is not reconciled by the reconciliation engine. If you create a mapping between this field and the corresponding target system field in the reconciliation staging data set, then the reconciliation field mapping that is automatically generated would try to map the field to the Password field. This, in turn, would cause the reconciliation event to fail.
There are limitations related to creating transformation mappings across the following data sets:

- Source and reconciliation staging
- Oracle Identity Manager and Provisioning Staging

These limitations are as follows:

- You cannot create a transformation mapping between a child data set of the Source or Oracle Identity Manager data set and a different (that is, not corresponding) child data set of the reconciliation staging or provisioning staging data sets. This also means that you cannot create a many-to-one mapping from multiple child data sets of one parent data set to a single child data set of another parent data set.

The following example illustrates this limitation:

Suppose the Source parent data set has the following child data sets:

**MyGTC:Group data set**
* Field 1: Group Name
* Field 2: Group Type

**MyGTC:Role data set**
* Field 1: Role Name
* Field 2: Role Type

Suppose the reconciliation staging parent data set has the following child data sets:

**MyGTC:Group data set**
* Field 1: Group Name
* Field 2: Group Type

**MyGTC:Role data set**
* Field 1: Role Definition

According to this limitation, you cannot create a transformation mapping between, for example, the Group Name field of the Source data set and the Role Definition field of the reconciliation staging data set.

However, you can create a many-to-one transformation mapping between, for example, the Role Name and Role Type fields of the Source data set and the Role Definition field of the reconciliation staging data set.

- You cannot create a transformation mapping between a Source or Oracle Identity Manager parent data set and a reconciliation staging or provisioning staging child data set.

The following example illustrates this limitation:

Suppose the following are Oracle Identity Manager data sets and their fields:

**OIM - Account data set**
* Field 1: Name
* Field 2: Address
* Field 3: User ID
Suppose the following are provisioning staging child data sets and their fields:

**Group data set**

* Field 1: Group Name
* Field 2: Group Type

According to this limitation, you cannot create a transformation mapping between, for example, the Name field of the OIM - Account data set and the Group Name field of the Group data set.

- To create a reconciliation rule, you create matching-only mappings between fields of the reconciliation staging data set and the OIM - User data set. If there are child data sets, then ensure that the names of fields of the reconciliation staging data set that are input fields for the matching-only mappings are not used in any of the reconciliation staging child data sets.

  If this guideline is not followed, then reconciliation would fail.

- Suppose you set the Date data type for a field on a child form. A Delete Child Record provisioning operation would fail if there is a date value in this field during the operation.

### 20.2.3 Errors During Connector Creation

The following are error messages that may be displayed at the end of the generic technology connector creation process. Each message explains the event that causes or during which the error message is displayed.

- An error was encountered while generating the import XML file for generic technology connector `connector_name`.
- An error was encountered while updating the IT resource parameters with the values provided for the run-time provider parameters of generic technology connector `connector_name`.
- An error was encountered while either generating the XML file for generic technology connector `connector_name` or saving it in the Oracle Identity Manager database.
- An error was encountered while importing the XML file for generic technology connector `connector_name`. The required lock on the import operation could not be acquired.
- An error was encountered while saving the information for generic technology connector `connector_name`. Check the application logs for more details.
- An error was encountered while creating a resource object for the generic technology connector `connector_name`. An existing resource object has the same name as the one being assigned to this resource object.

### 20.2.4 Errors During Reconciliation

Table 20–1 provides solutions to some commonly encountered problems associated with the reconciliation process.
Configuration Issues for Generic Technology Connectors

**Note:** These errors are logged only if you are using the shared drive reconciliation transport provider and the CSV Reconciliation format provider.

If any of these errors occurs, then the error message is written to the application server log file.

### Table 20–1: Common Errors Encountered During Reconciliation

<table>
<thead>
<tr>
<th>Problem Description (Error Message)</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>No run time provider parameters available</td>
<td>Use the Manage Generic Technology Connector feature to check the values specified for the run-time parameters. Then, retry reconciliation.</td>
</tr>
<tr>
<td>No design time provider parameters available</td>
<td>Use the Manage Generic Technology Connector feature to check the values specified for the design parameters. Then, retry reconciliation.</td>
</tr>
<tr>
<td>Staging directory location is not defined</td>
<td>Use the Manage Generic Technology Connector feature to check the value specified for the Staging Directory (Parent Identity Data) parameter. Then, retry reconciliation.</td>
</tr>
<tr>
<td>File encoding is not defined</td>
<td>Use the Manage Generic Technology Connector feature to check the value specified for the File Encoding (Parent Data) parameter. Then, retry reconciliation.</td>
</tr>
<tr>
<td>Archive directory location is not defined</td>
<td>Use the Manage Generic Technology Connector feature to check the value specified for the Archiving Directory parameter. Then, retry reconciliation.</td>
</tr>
</tbody>
</table>
| Cannot process files as not even fixed-width delimiter has been defined | Use the Manage Generic Technology Connector feature to check if a value has been specified for one of the following parameters:  
  - Specified Delimiter  
  - Tab Delimiter  
  - Fixed Column Width  
  Then, retry reconciliation. |
| No Parent files in staging directory                 | Ensure that data files are present in the directory specified as the value of the Staging Directory (Parent Identity Data) parameter. Then, retry reconciliation. |
| No files available for reading                       | Ensure that data files are present in the directory specified as the value of the Staging Directory (Multivalued Identity Data) parameter. Then, retry reconciliation. |
| No child data present in staging directory           | Ensure that directories specified as parameter values have the required permissions. See Section 17.1, “Shared Drive Reconciliation Transport Provider” for information about the required permissions. Then, retry reconciliation. |
| No files available for reading                       | Ensure that directories specified as parameter values have the required permissions. See Section 17.1, “Shared Drive Reconciliation Transport Provider” for information about the required permissions. Then, retry reconciliation. |
| The staging directory cannot be accessed. Either the directory path does not exist or necessary access permissions are missing | Ensure that directories specified as parameter values have the required permissions. See Section 17.1, “Shared Drive Reconciliation Transport Provider” for information about the required permissions. Then, retry reconciliation. |
| Data files could not be read as its File encoding is not supported. | Use the Manage Generic Technology Connector feature to check the value specified for the File Encoding parameter. Then, retry reconciliation. |
## 20.2.5 Errors During Provisioning

Table 20–2 provides solutions to some commonly encountered problems associated with the provisioning process.

<table>
<thead>
<tr>
<th>Problem Description (Error Message)</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not able to parse metadata</td>
<td>Check the metadata (contents of the second row) present in the parent and child data files. There may be a problem with the delimiter used in the files. Fix the problem, and then retry reconciliation.</td>
</tr>
<tr>
<td>Not able to parse header</td>
<td>Check the header (contents of the first row) of the data files. There may be a problem in the format of the header. See Section 17.1, &quot;Shared Drive Reconciliation Transport Provider&quot; for information about the header format. Fix the problem, and then retry reconciliation.</td>
</tr>
<tr>
<td>Current Record is erratic and cannot be parsed</td>
<td>Check the entry that is written to the application server log file. It may contain errors that cannot be parsed. Fix the problem, and then retry reconciliation.</td>
</tr>
</tbody>
</table>

**Note:** Most of these errors are logged only if you are using the Web Services provisioning transport provider and the SPML provisioning format provider.

If any of these errors occurs, then the error message is displayed on the UI and written to the application log file.

<table>
<thead>

This part contains chapters describing how to configure requests and SOA composites. It contains the following chapters:

- Chapter 21, "Developing Workflows for Approval and Manual Provisioning"
- Chapter 22, "Using Segregation of Duties (SoD)"

Part IV

Requests and Approval Processes
This chapter describes the concepts, features, and architecture of workflows in Oracle Identity Manager. It provides use cases for workflow, and instructions for designing, implementing, and deploying your first workflow. In addition, this chapter describes how to extend the request management operations by using plug-in points.

This chapter contains the following sections:

- Introducing Workflows
- Predefined SOA Composites
- Creating New SOA Composites
- Developing Workflows: Vision Request Tutorial
- Configuring Default Request-Level and Operation-Level Approval Composites
- Creating and Deploying Custom Task Details Taskflow
- Understanding Request Datasets
- Extending Request Management Operations
- Enabling Auto-Approval for Self Registration Requests

21.1 Introducing Workflows

This section describes the key workflow concepts in the following sections:

- Overview of Workflows
- Workflow Concepts
- Workflow Architecture

21.1.1 Overview of Workflows

Managing user access and orchestrating the business process so that users get the correct access is a key identity governance function. The process of changing users’ access can be initiated by the users through events in HR that trigger policies, or by administrators. Irrespective of how the change in access is initiated, organizations require the following:

- The business process that is initiated must be flexible, and must be able to meet changing business rules of the organization.
The business process must be able to decide between granting access immediately versus introducing manual intervention steps and seeking approval prior to granting access.

The business process must be able to perform validations, including Segregation of Duties (SoD) checks on what is being requested, by who, for whom, and in what context.

If manual intervention is required, then the business process must have the ability to assign to users or groups of users and escalate, reassign, or expire if no response is received in a timely manner.

For manual intervention, the business process must have the ability to gather information from the approvers, including comments and attachments.

The business process must be able to interact with external systems, such as ticketing systems, when automated access grants are not possible, or the organization's rules require that access is granted manually.

All decisions and actions must be audited and available in a reportable manner to allow the organization to measure performance of the process and also for auditors to fulfill compliance requirements.

Oracle Identity Manager provides flexible and powerful access request capabilities that allow organizations to meet these requirements.

21.1.2 Workflow Concepts

The key concept of workflows in Oracle Identity Manager involves the following terminologies:

- **Request**
  
  In Oracle Identity Manager, a request refers to the business process that is invoked when an operation on an identity or an account has to be performed. Examples of these operations include creating a user, provisioning an account, and granting a role to a user. A request can either be fulfilled immediately (also known as direct operation) or can require manual intervention in the form of approvals (also known as request-based operation). When a user tries to perform an operation, Oracle Identity Manager determines whether the operation would be direct or request-based on the authorization policies of the logged-in user.

- **Request-level approval**
  
  A request has to go through two independent approval processes before it can proceed for fulfillment. These are request-level approvals and operational-level approvals. Request-level approvals are invoked first and are followed by operational-level approvals. Request-level approvals are primarily used for bulk requests, which involve multiple target users or multiple requested entities or any combination of both.

  For bulk approvals, when the request-level approval has been received, the request engine splits the request into individual target user and requested operation or entity combination, and invokes the operational approval for each combination.

- **Operation-level approval**
  
  Operation-level approval is the second approval process that is invoked as part of approving a request. Operational approvals are always for a single target user and a single operation or requested entity.
- **Approval policy**
  
  An approval policy is a rule that allows the request engine to pick a SOA composite to invoke. Approval policies can be configured at request level or operation level. They can use all the data available at the request and operational levels to construct a rule. The rule helps the request engine determine if the request should be auto-approved or a SOA composite should be invoked.

- **SOA composite**
  
  A SOA composite is an assembly of services, service components, and references designed and deployed together in a single application. Wiring between the service, service component, and reference enables message communication. The composite processes the information described in the messages.

- **Partner Link**
  
  A partner link enables you to define the external services with which the BPEL process service component is to interact. You can define partner links as services or references (for example, through a JCA adapter) in the SOA Composite Editor or within a BPEL process service component in Oracle BPEL Designer.

- **BPEL process**
  
  BPEL processes provide process orchestration and storage of synchronous or asynchronous processes. You design a business process that integrates a series of business activities and services into an end-to-end process flow.

- **IT provisioner**
  
  The IT provisioner, also known as fulfillment user or Help Desk user, is the persona responsible for fulfilling manual provisioning requests.

- **Request web service**
  
  The request web service is a web service that is shipped with Oracle Identity Manager. It allows customers to expose request, user, role, organization, account, entitlement, application instance, and catalog information so that approval workflows can make data-driven routing decisions.

- **Request callback**
  
  The request callback is a web service that is invoked by the SOA composite when an approval outcome (approve/ reject) has been received. When the request engine invokes a SOA composite for the purpose of approval, it suspends the request until the composite invokes the request callback and provides an approve or reject decision. This decision allows the request engine to proceed with fulfilling the request (if approved) or rejecting the request (if rejected).

- **Provisioning callback**
  
  The provisioning callback is a web service that is invoked as part of disconnected provisioning. When the IT provisioner or fulfillment user fulfills a disconnected provisioning request and marks the task as completed, the SOA composite invokes the provisioning callback and sends the provisioning status allowing the provisioning workflow to complete.

- **Request payload**
  
  The request engine invokes the SOA composite and passes it some basic information about the request, requester, and target user. This information is called the request payload.

- **Human Task**
Human tasks provide workflow modeling that describes the tasks for users or groups to perform as part of an end-to-end business process flow.

### 21.1.3 Workflow Architecture

Workflows are used in Oracle Identity Manager to:

- Route requests to approvers for approval
- Route manual provisioning tasks to IT provisioners or Help Desk for fulfillment

Figure 21–1 provides an overview of workflows in Oracle Identity Manager:

**Figure 21–1  Workflow Architecture**

In Figure 21–1, the following actions occur:

1. User initiates an operation that results in a request. Examples of such operations include:
   - Self-registration
   - User profile modification, excluding lock, unlock, and password management operations
   - Role grant operations
   - Application instance operations, including disconnected provisioning
   - Entitlement operations
   - Bulk operations

2. A request is created. After appropriate validation, the request engine evaluates approval policies and selects a SOA composite to be invoked.

3. If approval policies are not configured, then the default request-level SOA composite is selected for request-level approval, and default operational-level SOA composite is selected for operational-level approval.

4. The SOA composite involves the Business Process Execution Language (BPEL) process.
5. The BPEL process invokes a web service to get additional details about the request including:

   - Item details from the catalog
   - Target user information
   - Requester information

6. The BPEL process invokes additional logic to calculate properties such as priority, approvers, and notification.

7. When manual intervention is required, such as during approval and manual fulfillment, the process invokes a Human Task.

   A Human Task contains the logic to assign, expire, or escalate the approval task to users or roles. The Human Task can assign the users and roles statically or dynamically. For static assignments, the approvers can be determined in the BPEL process and passed as parameters to the Human Task. For dynamic assignments, rules created using Oracle Business Rules (OBR) are used to dynamically determine the approvers.

   Typically, the BPEL process contains one Human Task. In some instances, the BPEL process might invoke a decision point to pick one of multiple Human Tasks.

8. When the human task completes, a response of approve or reject (for approval) or complete (for manual fulfillment), is returned via a callback service to Oracle Identity Manager, which resumes the operation.

21.2 Predefined SOA Composites

Table 21–1 lists the predefined SOA composites in Oracle Identity Manager that can be used as approval processes.

<table>
<thead>
<tr>
<th>Workflow Composite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultRequestApproval</td>
<td>This is the default request-level approval. By default, the request-level approval goes to the SYSTEM ADMINISTRATORS role, for request-level approval.</td>
</tr>
<tr>
<td></td>
<td>In addition, this composite is invoked by certification use cases.</td>
</tr>
<tr>
<td></td>
<td>The task will have one of the following states:</td>
</tr>
<tr>
<td></td>
<td>- Assigned to the beneficiary. Later, the task may be assigned to the beneficiary’s manager based on the decision of the beneficiary.</td>
</tr>
<tr>
<td></td>
<td>- Auto-approved if the certification requester is beneficiary’s manager.</td>
</tr>
</tbody>
</table>

**Note:** For information about the certification use cases, see "Managing Identity Certification" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.
Table 21–1  (Cont.) Predefined Workflow Composites

<table>
<thead>
<tr>
<th>Workflow Composite</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultOperationalApproval</td>
<td>This is the default operation-level approval. By default, the approval task is assigned to the SYSTEM ADMINISTRATORS role for operation-level approval. In addition, the composite is invoked by certification use cases, and the task will be auto-approved.</td>
</tr>
</tbody>
</table>
| BeneficiaryManagerApproval                | This requires approval from the beneficiary’s manager. This can be associated with the following:  
  ■ The request models that have a beneficiary. Examples of such request models are Provision Application Instance and Assign Roles.  
  ■ All user models except Create User and Self-Register User.  
This composite must be associated at the operational level of approval because a request can have multiple beneficiaries at the request level. |
| DefaultRoleApproval                       | This SOA composite creates a single approval task that is assigned to the SYSTEM ADMINISTRATORS role for approval.                               |
| RequesterManagerApproval                  | This SOA composite creates a single approval task that is assigned to the requester’s manager for approval.  
**Note:** This composite cannot be associated with unauthenticated request models, such as Self-Register User. |
| DefaultSODApproval                        | This SOA composite creates an approval task that is assigned to the System Administrator, starts SoD check, and after the SoD result is available, it creates another approval task assigned to the SOD Administrators role. This must be associated with request models to provision or modify resources at the operational level if SoD check is required. |
| DisconnectedProvisioning                  | This SOA composite assigns the task to the System Administrator to fulfil the disconnected provisioning.                                         |
| ProvideInformation                       | This SOA composite assigns the task to the requester seeking details of account/entitlement. For more information, see “Entitlement and Account Dependencies in Requests” in the *Oracle Fusion Middleware User’s Guide for Oracle Identity Manager*.  
CertificationProcess                      | This is the default Certification composite. This composite takes care of assigning the certification task to the certifier (user). This composite also manages the following certification task events:  
  ■ Expiry  
  ■ Proxy  
  ■ Escalation  
  ■ Re-assignment  
CertificationOverseerProcesses            | This composite assigns a certification task to the certifier (user). In addition, the composite also handles routing the task to the overseer after the certifier completes the task. Oracle SOA Business Rules are used to handle the task routing. This composite handles the following certification task events:  
  ■ Expiry  
  ■ Proxy  
  ■ Routing (Overseer)  
  ■ Escalation  
  ■ Re-assignment |
21.3 Creating New SOA Composites

To create a new SOA composite that can be used as an approval process, perform the following steps:

1. Creating a New SOA Composite
2. Deploying a SOA Composite in Oracle SOA Server
3. Prerequisites for Communication to Oracle Identity Manager Through SSL Mode

21.3.1 Creating a New SOA Composite

To use a SOA composite as an approval process, it must adhere to certain standards. These standards ensure that the request service is able to instantiate and manage such composites correctly. These standards are:

The following attributes are mandatory for BPEL process:

- RequestID of type String
- RequestModel of type String
- RequestTarget of type String
- URL of type String
- RequesterDetails of XML Element
- BeneficiaryDetails of XML Element
- ObjectDetails of XML Element
- OtherDetails of XML Element

The RequestID, RequestModel, RequestTarget, and URL attributes are always set with valid values for all types of requests.

RequesterDetails is an XML element. This element is filled up with valid values for all requests that requires authentication. Requester details is empty for the requests of type Self-Register User because the requester is anonymous user.

BeneficiaryDetails is an XML element. This element is filled up with valid values for all requests that have a beneficiary, for example, Provision Resource and Assign Roles. This is filled up only if the request is associated with single beneficiary. If the request is associated with multiple beneficiaries, then BeneficiaryDetails is empty. BeneficiaryDetails element always has valid value for simple requests and child requests that have a beneficiary. Therefore, it is recommended to use this XML element in SOA composites that are used as approval processes at the operational level of approval. This is because at the operational level of approval, the request is associated with only one beneficiary.

ObjectDetails is an XML element. This element is filled up with valid values for all requests that are associated with the Resource entity. This is filled up only if the request is associated with single resource. If the request is associated with multiple resources, then ObjectDetails is empty. The ObjectDetails element always has valid value for simple and child requests that are associated with resource. Therefore, it is recommended to use this XML element in SOA composites that are used as approval processes at the operational level of approval. This is because at the operational level of approval, the request is associated with only one resource.

All the attributes that are mandatory for the BPEL process are referred from RequestDetails.xsd and ApprovalProcess.xsd. These files are present in the template SOA composite, which must not be modified or deleted.
Oracle Identity Manager provides a helper utility for creating custom SOA composites. This utility creates a template SOA project that adheres to all the necessary standards. This utility is located in the `OIM_HOME/workflows/new-workflow` directory.

---

**Note:**
- JAVA_HOME environment variable must be set before running this utility.
- This utility requires Apache Ant version 1.7 or later.

---

To create a custom SOA composite by running the helper utility:

1. Run the following commands:
   ```
   cd OIM_HOME/workflows/new-workflow
   ant -f new_project.xml
   ```
2. Enter the JDeveloper application name when the following prompt is displayed:
   ```
   Please enter application name
   ```
3. Enter the JDeveloper project name when the following prompt is displayed:
   ```
   Please enter project name
   ```
4. Enter the name of the ADF binding service for the composite when the following prompt is displayed:
   ```
   Please enter the service name for the composite. This needs to be unique across applications
   ```

The new application is created in the `OIM_HOME/workflows/new-workflow/process-template/` directory. You can open the new application in JDeveloper for modification.

Human task in the template SOA composite is configured to send notifications to the assignee of the human task. In the custom composite that is created, the notification message can be modified based on the requirement. All the notifications to be sent to the approver must be configured in the SOA composite. For configuring Oracle SOA server to send notifications, refer to “Configuring Oracle User Messaging Service” in the *Oracle Fusion Middleware Administrator’s Guide for Oracle SOA Suite and Oracle Business Process Management Suite*.

Human task in the template SOA composite is configured to be assigned to the SYSTEM ADMINISTRATORS role.

### 21.3.2 Deploying a SOA Composite in Oracle SOA Server

For information about deploying the workflow composite in BPEL, see *Oracle Fusion Middleware Developer’s Guide for Oracle SOA Suite*.

---

**Note:** The composite should be redeployed with a new version. If a composite is redeployed with the same version in SOA, then all the pending approvals in Oracle Identity Manager initiated by the composite becomes stale and are removed from the user’s TaskList. See “Deploying an Existing SOA Archive in Oracle JDeveloper” in the *Oracle Fusion Middleware Developer’s Guide for Oracle SOA Suite* for information about deploying existing SOA composites.
21.3.3 Prerequisites for Communication to Oracle Identity Manager Through SSL Mode

If the communication to Oracle Identity Manager is through the SSL mode, then you must:

---

**Note:** For a non-SSL connection, skip this section.

---

- Set the `TRUSTSTORE_LOCATION` environment variable, where `TRUSTSTORE_LOCATION` is the trusted key store file location.
- Use `t3s` protocol instead of `t3`. For example, the URL for Oracle Identity Manager is:

  `t3s://HOST_NAME:PORT`

21.4 Developing Workflows: Vision Request Tutorial

This section describes how to design your first workflow in the following sections:

- Introducing the Tutorial
- Prerequisites
- Creating the Application Instance
- Configuring FinApp in the Catalog
- Creating and Configuring the SOA Composite for Approval

21.4.1 Introducing the Tutorial

This tutorial is based on the following use case:

- Vision Corp uses FinApp, a mainframe-based application. The application does not have APIs that can be remotely invoked. Therefore, accounts are managed manually by the Help Desk.
- Vision Corp employees use the Access Request Catalog to request accounts and entitlements in the application.
- Approvals are based on the risk level of the access being requested. If the risk level is Low Risk, approval is required only from the beneficiary's manager. If the risk level is Medium Risk, approval is required from either the beneficiary's manager or certifier. If the risk level is High Risk, approval is required from the beneficiary's manager and the Audit Review team.
- After approval, the request has to be fulfilled by members of the Asset Management team.

This tutorial describes how to create the application and the workflow, and how to configure the approval and fulfillment for the application.

The result of the tutorial is:

- An application instance
- A SOA composite for approval consisting of:
  - A BPEL process
  - Multiple Human Tasks
21.4.2 Prerequisites

The following assumptions are made for this tutorial:

- Oracle SOA Suite is installed on a host on which the SOA infrastructure is configured.
- JDeveloper 11.1.1.7 with SOA Design Time 11.1.1.7 is available.
- Mandatory patches, if any, for SOA Jdeveloper extension have been applied. For information about the mandatory patches, see “Mandatory Patches Required for Installing Oracle Identity Manager” in the Oracle Fusion Middleware Release Notes.
- You are familiar with basic BPEL constructs, including BPEL activities and partner links, and basic XPath functions.
- You are familiar with the SOA Composite Editor and Oracle BPEL Designer, the environment for designing and deploying BPEL processes. However, for detailed information about SOA composites, refer to Oracle Fusion Middleware Developer’s Guide for Oracle SOA Suite.
- Two roles, Audit Review Team and Asset Management Team, have been created and members have been assigned.
- An organization with name Vision is created.

21.4.3 Creating the Application Instance

This section contains the following topics:

- Creating the FinApp Application Instance
- Defining Application Instance Attributes and Creating a Form
- Publishing the Application Instance to One or More Organizations
- Linking Entitlements to the Application Instance
- Publishing the Application Instance With Entitlements to the Catalog

21.4.3.1 Creating the FinApp Application Instance

To create the FinApp application instance:

1. Login to Oracle Identity System Administration.
2. Click Sandboxes to access sandbox management, create a sandbox, and activate it. See “Managing Sandboxes” on page 30-4 for information about sandboxes and how to create, activate, and publish sandboxes.
3. Under Configuration, click Application Instances. Click Create on the toolbar to open the Create Application Instance page.
4. Enter Name and Display Name as FinApp.
5. Select the Disconnected option to specify a disconnected application instance.
6. Click Save, and then click OK to confirm creation of the FinApp application instance.

21.4.3.2 Defining Application Instance Attributes and Creating a Form

To define the attributes of the application instance and create a form:

1. Under Configuration, click Form Designer.
2. Search and select the FinApp form. This form is automatically created when the disconnected application instance is saved.

**Note:** You must be in an active sandbox to create and edit a form.

3. Click the **Fields** tab, and then click the Edit icon on the toolbar.

   By default, the following fields are created and are available for use:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resource</td>
<td>The IT resource instance where the account is being created</td>
</tr>
<tr>
<td>Account Login</td>
<td>The login for the application</td>
</tr>
<tr>
<td>Password</td>
<td>The password that is used while logging in to the application</td>
</tr>
<tr>
<td>Account ID</td>
<td>The unique identifier generated by the application when the account is created</td>
</tr>
<tr>
<td>Service Account</td>
<td>A flag that is used during access request only</td>
</tr>
</tbody>
</table>

**Note:** Attributes such as Account ID and IT Resource are typically not displayed in the access request user interface. Depending upon the use case, for example a mobile phone request, the attributes might not be relevant. To hide these attributes, you can customize the form. See "Configuring Custom Attributes" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for more information on how to customize the form.

4. Add additional attributes. In this example, add the following attribute:

   Account Description: Data type is Text.

   **Note:** See "Configuring Custom Attributes" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for more information on creating the custom attributes.

5. After adding the attributes, verify that the configuration in the Fields tab is similar to the following table:

<table>
<thead>
<tr>
<th>Display Label</th>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account Description</td>
<td>AccountDescription</td>
<td>Text</td>
</tr>
<tr>
<td>Account ID</td>
<td>UD_FINAPP_ACCOUNTID</td>
<td>Text</td>
</tr>
<tr>
<td>ITResource</td>
<td>UD_FINAPP_IT</td>
<td>Number</td>
</tr>
<tr>
<td>Account Login</td>
<td>UD_FINAPP_LOGIN</td>
<td>Text</td>
</tr>
<tr>
<td>Password</td>
<td>UD_FINAPP_PASSWORD</td>
<td>Text</td>
</tr>
<tr>
<td>Service Account</td>
<td>serviceaccount</td>
<td>Checkbox</td>
</tr>
</tbody>
</table>

6. To allow users to request entitlements, you must add a child object and add an attribute that is tagged as an Entitlement. To do so:
a. Click the Child Objects tab, and then click Add on the toolbar.

b. Enter the child object name, and click OK to create the child object.

c. Click the child object just created.

d. Select Action, Create to create a new attribute. From the popup window, select Lookup, and click OK. Enter values for the following fields:

Name: Profile Name
Display Name: Profile Name

e. Select Use in Bulk to allow requesters to specify a value when requesting access for multiple users.

f. Under Lookup Type, click Create a New Lookup Type.

g. Create the new Lookup and specify the values, as shown:

Code: Lookup.FinApp.Profile
Meaning: Lookup.FinApp.Profile
Description: Lookup.FinApp.Profile

h. Create three lookup codes by using the values given in the following table:

<table>
<thead>
<tr>
<th>Meaning</th>
<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>FinApp User</td>
<td>FinAppUser</td>
</tr>
<tr>
<td>FinApp Administrator</td>
<td>FinAppAdministrator</td>
</tr>
<tr>
<td>FinApp Operator</td>
<td>FinAppOperator</td>
</tr>
</tbody>
</table>

Note: You can also populate the lookup definition by using a scheduled task and the lookup APIs.

i. Select the Searchable, Entitlement, and Searchable Picklist options.

7. Click Save and Close.

8. Click Back to Parent Object.

9. Click Regenerate View to re-create the UI form with the new attributes.

10. Close all tabs.

11. Publish the sandbox.

21.4.3.3 Publishing the Application Instance to One or More Organizations

To publish the application instance to one or more organizations:

1. Open the FinApp application instance details page, and click the Organizations tab.

2. Click Assign. In the Select Organizations dialog box, select one or more organizations to publish the application instance to.

3. Select the Hierarchy option if you want the application instance to be published to the organization and its child organizations.

4. Click OK.
21.4.3.4 Linking Entitlements to the Application Instance

To link entitlements to the application instance:

1. Under System Management, click **Scheduler**.
2. Search for the Entitlement List scheduled job, and click **Run Now**.
3. Under Configuration, click **Application Instances**, and navigate to the FinApp application instance.
4. Click the **Entitlements** tab, and verify that the entitlements are displayed, as shown in **Figure 21–2**:

**Figure 21–2  Entitlements List**

5. Select an entitlement, and verify that it is published to the same organizations as the application instance, as shown in **Figure 21–3**:

**Figure 21–3  Entitlement Availability to Organizations**

6. Edit one or more entitlements, and enter a business friendly description. If required, modify the display name as well.
21.4.3.5 Publishing the Application Instance With Entitlements to the Catalog
To publish the application instance and its entitlements to the catalog:
1. Under System Management, click Scheduler.
2. Search for the Catalog Synchronization scheduled job, and click Run Now.

21.4.4 Configuring FinApp in the Catalog
To configure the application instance and its entitlements in the catalog:
1. Login to Oracle Identity Self Service as the Catalog Administrator.
2. Under Requests, click Catalog.
3. In the Catalog page, search for the application instance.
4. Select the application instance, and edit the catalog item details.
5. Provide values for the default attributes. Because this tutorial involves workflow routing based on risk level and manual fulfillment, you must provide a value for the Risk Level and Fulfillment Role attributes. However, it is recommended that you provide values for other attributes, especially User Defined Tags.

Figure 21–4 shows the attributes of the catalog item.

Figure 21–4  Catalog Item Attributes

21.4.5 Creating and Configuring the SOA Composite for Approval
This section contains the following topics:
- Creating the Approval Workflow
- Making Request and Catalog Data Available to the BPEL Process
- Configuring Workflow Selection
- Configuring Human Tasks
- Configuring the Human Task and BPEL Mappings
21.4.5.1 Creating the Approval Workflow

To create a new approval workflow:

1. Set the JAVA_HOME environment variable by running the setWLSEnv.sh script in the /server/bin/ subdirectory in the WebLogic Server installation directory.
2. Set the ANT_HOME environment variable to MIDDLEWARE_HOME/modules/org.apache.ant_1.7.1.
3. Set the PATH environment variable to $JAVA_HOME/bin:$ANT_HOME/bin:$PATH.
5. Run the following:
   ant-f new_project.xml
6. Provide the Application Name as AddAccessApprovalApplication.
7. Provide the Project Name as AddAccessApproval.
8. Provide the Service Name as AddAccess.
9. Wait for the utility to finish generating the new JDeveloper Workspace containing the Composite. The workspace is generated in /server/workflows/new-workflow/process-template.
10. Copy the directory to a location accessible to JDeveloper.

21.4.5.2 Making Request and Catalog Data Available to the BPEL Process

To make request and catalog data available to the BPEL process:

1. Switch to Design view of the BPEL process.
2. Drag the Invoke activity from the Component Palette and drop it below the AssignRequestWSURL activity. Rename it to InvokeRequestDetailsOperation.
3. Right-click InvokeRequestDetailsOperation, and select Edit.
4. Select partner link from the Partner Link Chooser as RequestWSPartnerLink, and operation as getRequestDetails, as shown in Figure 21–5.
5. Under the Variables section, click the plus (+) icon for the Input and Output fields to create the input and output variables. Name the input and output variables as requestDetails_InputVariable and requestDetails_OutputVariable respectively. Then click Apply and OK.

6. Drag and drop an assign activity, rename it to AssignRequestInput, and place it above the InvokeRequestDetailsOperation invoke activity, as shown in Figure 21–6.

7. Right-click AssignRequestInput, and select Edit to map the input of the InvokeRequestDetailsOperation, as shown in Figure 21–7.
8. Add an Invoke activity after the InvokeRequestDetailsOperation, as shown in Figure 21–8. Name the activity **InvokeCatalogOperation**.

*Figure 21–8 InvokeCatalogOperation*

9. Edit the InvokeCatalogOperation, and configure it as shown in Figure 21–9.
10. Add an Assign activity above InvokeCatalogOperation, as shown in Figure 21–10. Name the activity as AssignCatalogInput.
11. Right-click and edit the assign activity to map the input to the InvokeCatalogOperation, as shown in Figure 21–11.

**Figure 21–11 InvokeCatalogOperation Input Mapping**

---

**Note:** The following attributes will be returned as custom attributes through the catalog detail method of the request web service:

- APPROVER_USER_FIRSTNAME
- APPROVER_USER_LASTNAME
- APPROVER_USER_DISPLAYNAME
- APPROVER_USER_EMAIL
- CERTIFIER_USER_FIRSTNAME
- CERTIFIER_USER_LASTNAME
- CERTIFIER_USER_DISPLAYNAME
- CERTIFIER_USER_EMAIL
- FULFILLMENT_USER_FIRSTNAME
- FULFILLMENT_USER_LASTNAME
- FULFILLMENT_USER_DISPLAYNAME
- FULFILLMENT_USER_EMAIL

---

**21.4.5.3 Configuring Workflow Selection**

To define the workflow selection rules:

1. Define a variable called catalogData. To do so:
a. Click the **Variables** icon, and then click the **Create** icon on the Variable dialog box.

b. Choose **Type** as Element and click the **Search** icon next to the field.

c. In the dialog box, expand **Project Schema Files** and then **CatalogData.xsd** and select the CatalogData element. This variable will contain the catalog details returned as an output of the InvokeCatalogDetails step.

2. Define a variable called workflowtype. To do so:

   a. Select type as **Element** and click on **Search** icon next to the field.

   b. In the dialog box, expand **Project Schema Files** and then **BusinessRule.xsd** and select the StageOutput element. This variable will contain the type of workflow to be invoked.

3. Navigate to the SOA Composite view, and add a Business Rule component, as shown in Figure 21–12.

   **Figure 21–12  Adding Business Rule Component**

4. In the Create Business Rules dialog box, specify the name of the Rule Dictionary as WorkflowSelection.

5. Specify Input as CatalogData from CatalogData.xsd in Project Schema Files and Output as StageOutput from BusinessRule.xsd in Project Schema Files.

6. Switch to the BPEL process.

7. Expand SOA Components and add a Business Rule component between the InvokeCatalogOperation and ApprovalTask_1 components.

8. Edit the rule and rename it to WorkflowSelection.

9. In the Rule dialog box, click the Dictionary tab, and select the WorkflowSelection dictionary that you defined in step 4.

10. Select Assign Input Facts subtab in the Dictionary tab, and click the plus (+) icon.

11. Map the catalogData variable to the input to the Rule, as shown in Figure 21–13.

13. Map the workflowtype variable to the output to the Rule, as shown in Figure 21–14.

14. Add an Assign activity before the WorkflowSelection rule and rename it as AssignRuleInput, as shown in Figure 21–15.
15. Map the output of the InvokeCatalogOperation to the catalogData variable, as shown in Figure 21–16.

16. Switch to the SOA Composite view.
17. Right-click the Business Rule component, and select Edit.
18. Click Create Rule.
19. Rename the rule from Rule1 to Auto Approval.
20. Edit the rule, and specify the stageType property in the Properties dialog box, as shown in Figure 21–17.
To specify the stageType property:

a. Click the `<insert test>` action below **IF** (click it 3 times to add 3 conditions separated by Logical AND).

   Change conditions as:
   
   \[\text{CatalogDataType.itemRisk} \neq 3 \text{ and } \text{CatalogDataType.itemRisk} \neq 7 \text{ and } \text{CatalogDataType.itemRisk} \neq 5\]

b. Click the `<insert action>` below **THEN**.

c. Select assert new.

d. Click `<target>` that is added next to assert new, and select **Stage**.

e. Click `<edit properties>`. The Properties dialog box is displayed, as shown in Figure 21–17.

21. Similarly, create the Manager, Serial, and Parallel approval rules, as shown in Figure 21–18.
22. Switch to the BPEL process.

23. Add a switch activity after the WorkflowSelection rule, as shown in Figure 21–19.

24. Select the Switch activity and add two Switch Case steps, as shown in Figure 21–20.
25. Rename the conditions as Serial Approval, Parallel Approval, and Manager Approval, as shown in Figure 21–21.

26. Drag the default Human Task into the Manager Switch Case, as shown in Figure 21–22.
27. Switch to the SOA Composite view.

28. Add two Human Tasks, SerialApproval and ParallelApproval, as shown in Figure 21–23.

29. Switch to the BPEL Process.

30. Edit the Manager Approval Switch case, and add the following expression:

   `bpws:getVariableData('workflowtype','/ns18:StageOutput/ns18:stageType')='Manager'`
You must first configure the newly added Tasks and then wire them to the BPEL Process.

---

**Note:** Oracle recommends using expression builder to add the expression.

---

### 21.4.5.4 Configuring Human Tasks

Configuring the Human Task consists of the following:

- Configuring the Parallel Human Task
- Configuring the Serial Approval Task
- Configuring the Default Approval Task

#### 21.4.5.4.1 Configuring the Parallel Human Task

To configure the parallel Human Task:

1. Switch to the SOA Composite view.
2. Edit the Parallel Approval Task.
3. Click the Data tab, and add the attributes listed in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequestID</td>
<td>![<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>RequestModel</td>
<td>![<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>RequestTarget</td>
<td>![<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>RequesterDetails</td>
<td>![<a href="http://xmlns.oracle.com/request/RequestDetails%5DRequesterDetails">http://xmlns.oracle.com/request/RequestDetails]RequesterDetails</a></td>
</tr>
<tr>
<td>BeneficiaryDetails</td>
<td>![<a href="http://xmlns.oracle.com/request/RequestDetails%5DBeneficiaryDetails">http://xmlns.oracle.com/request/RequestDetails]BeneficiaryDetails</a></td>
</tr>
<tr>
<td>ObjectDetails</td>
<td>![<a href="http://xmlns.oracle.com/request/RequestDetails%5DObjectDetails">http://xmlns.oracle.com/request/RequestDetails]ObjectDetails</a></td>
</tr>
<tr>
<td>OtherDetails</td>
<td>![<a href="http://xmlns.oracle.com/request/RequestDetails%5DOtherDetails">http://xmlns.oracle.com/request/RequestDetails]OtherDetails</a></td>
</tr>
<tr>
<td>url</td>
<td>![<a href="http://xmlns.oracle.com/request/RequestDetails%5Durl">http://xmlns.oracle.com/request/RequestDetails]url</a></td>
</tr>
<tr>
<td>Catalogdata</td>
<td>![<a href="http://xmlns.oracle.com/RequestServiceApp/RequestDataService/CatalogData%5DCatalogData">http://xmlns.oracle.com/RequestServiceApp/RequestDataService/CatalogData]CatalogData</a></td>
</tr>
<tr>
<td>RequesterDisplayName</td>
<td>![<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>BeneficiaryDisplayName</td>
<td>![<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>Requester</td>
<td>![<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
</tbody>
</table>

4. Verify the task parameters in the Data tab.
5. Click the General tab.
6. Set the Task Title to `<%task:task:task:payload/ns2:BeneficiaryDetails/ns2:DisplayName%> has submitted a request for approval. To do so:
   a. Click Edit next to Task Title, and select task:payload, ns2:BeneficiaryDetails, ns2:DisplayName.
b. Click **Insert Into Expression**. Task Title is displayed as shown in **Figure 21–24**:

**Figure 21–24  The Task Title**

This can be edited to configure meaningful title, such as:

\[<\%/task:task/task:payload/ns2:BeneficiaryDetails/ns2:DisplayName%> has submitted a request for approval.\]

7. Set the Task Owner to Group and SYSTEM ADMINISTRATORS.

8. Click the **Notification** tab, and then click **Advanced**.

9. Select the **Make notification actionable** option.

10. Click the **Assignment** tab.

11. Add a Parallel stage. To do so, select Stage1 in the flow chart, and click the plus (+) icon, and select **Parallel stage**.

12. Select a stage and click **Edit**. Provide the name as **Manager**.

13. Select the other stage, and provide the name as **Certifier**, as shown in **Figure 21–25**.
14. Click the pencil icon after the two stages.

15. In the Vote Outcome dialog box, set the voted outcome to APPROVE. Set the default outcome to REJECT. This is because when both the approver reject the task, the request moves to completed state based on the default outcome.

16. Select the **Share attachments and comments** option.

17. In the Vote Outcome dialog box, click **OK**.

18. Ensure that the **Immediately trigger voted outcome when minimum percentage is met** option is selected.

19. Select `<edit participant>` in Manager Stage, and click **Edit**.

20. In the Add Participant Type dialog box, set the Participant type to Single. From the Build a list of participants using list, select **Rule-based** to build the participant list using Rules.

21. In List RuleSet field, enter Manager. Also, edit the label as Manager.

22. In the Add Participant dialog box, click **OK**. The ParallelApprovalRules.rules tab is displayed.

23. Create a rule, as shown in **Figure 21–26**.

**Figure 21–25  Manager and Certifier Stages**

**Note:** In the Create Rule page, the `<insert pattern>` in the IF clause is not displayed by default. To display `<insert pattern>`, expand Rule1 by clicking the two down arrows before Rule1 label, and select the Advanced Mode option as shown in **Figure 21–26**.
24. Similarly, configure the Certifier stage by specifying the following values in the Add Participant Type dialog box:
   - **Type:** Single
   - **Label:** Certifier
   - Build a list of participants using: **Rule-based**
   - **List Ruleset:** Certifier
   - Select **Let participants manually claim the task**

25. Create a participant rule, as shown in **Figure 21–27**.

**Figure 21–27  Certifier Rule**

![Certifier Rule Image]

21.4.5.4.2 Configuring the Serial Approval Task

To configure the serial approval task:

1. Switch to the SOA Composite view.
2. Edit the Serial Approval Task.
3. Click the **Data** tab.
4. Add the parameters listed in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequestID</td>
<td>[<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>RequestModel</td>
<td>[<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>RequestTarget</td>
<td>[<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>RequesterDetails</td>
<td>[<a href="http://xmlns.oracle.com/request/RequestDetails%5DRequesterDetails">http://xmlns.oracle.com/request/RequestDetails]RequesterDetails</a></td>

<td>[<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
</tbody>
</table>
5. Verify the task parameters in the Data tab.

6. Click the **General** tab.

7. Set the Task Title to

   `<%= task:task/task:payload/ns2:BeneficiaryDetails/ns2:DisplayName%> has submitted a request for approval.`

8. Set the Task Owner to Group and SYSTEM ADMINISTRATORS.

9. Click the **Notification** tab, and then click **Advanced**.

10. Select the **Make notification actionable** option.

11. Click the **Assignment** tab.

12. Add a Sequential stage and rename the stages as Manager and Review Team, as shown in **Figure 21–28**.

**Figure 21–28 Serial Stages**

13. Edit the Manager stage.

14. In the Add Participant Type dialog box, set the Participant type to Single and build the participant list using Rules.

15. Create the participant list rule as shown in **Figure 21–29**.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BeneficiaryDisplayName</td>
<td>[<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
<tr>
<td>Requester</td>
<td>[<a href="http://www.w3.org/2001/XMLSchema%5Dstring">http://www.w3.org/2001/XMLSchema]string</a></td>
</tr>
</tbody>
</table>
16. Similarly, configure the Review Team stage.

17. Create the participant list rule as shown in **Figure 21–30**.

### Figure 21–30  Rule for Review Team Stage

21.4.5.4.3 Configuring the Default Approval Task

To configure the default approval task:

1. Switch to SOA composite view.
2. Edit the Approval Task.
3. Click the **General** tab.
4. Set the task title, as shown in **Figure 21–31**.

### Figure 21–31  Default Approval Task

5. Click **Assignment**.
6. Select Stage1.Participant1, and click **Edit**.

7. In the Add Participant Type dialog box, set the Participant type to Single. From the Build a list of participants using list, select **Rule-based** to build the participant list using Rules.

8. Enter Manager in Label and RuleSet, and click **OK**, which opens the rules.

9. Create a Participant list rule, as shown in Figure 21–32.

**Figure 21–32  Participant List Rule**

![Participant List Rule Diagram](image)

21.4.5.5 Configuring the Human Task and BPEL Mappings

Configuring the Human Task and BPEL mappings involves:

- Configuring the Serial Approval Human Task
- Configuring the Parallel Human Task
- Configuring Auto Approval

21.4.5.5.1 Configuring the Serial Approval Human Task

To configure the serial approval Human Task:

1. Switch to BPEL process.

2. Add the following condition to the Serial Approval switch:

```java
bpws:getVariableData('workflowtype','/ns18:StageOutput/ns18:stageType') = 'Serial'
```

3. Drag and drop a Human Task activity from the SOA Components into the Serial Approval switch, as shown in Figure 21–33.
4. Edit the Human Task, and in the Human Task dialog box, select the Serial Approval Human Task definition.

5. Map Initiator to requester login, and map the task parameters to the BPEL variable as shown in Figure 21–34.

Figure 21–34 Task Parameters and BPEL Variable Mapping

6. Click the Advanced tab.

7. Map the Identification Key to the Request ID as shown in Figure 21–35.
8. Map Iniatator to requester login, and then click **Apply** and **OK**.

9. Select the Switch case for Task outcome is REJECT.

10. Replace the existing condition script with the following:

    ```
    bpws:getVariableData('SerialApproval1_globalVariable', 'payload', '/task:task/task:systemAttributes/task:outcome') = 'REJECT'
    ```

11. Select and edit the Assign activity under Task outcome is REJECT.

12. Delete all the copy rules except one. The copy rule that you retain can be any one so that you can replace it in the Source view.

13. Save and click the **Source** tab.

14. Select the copy activity.

15. Replace the activity with the following:

    ```xml
    <sequence>
      <assign>
        <copy>
          <from expression="string('rejected')"/>
          <to variable="outputVariable" part="payload"
              query="/ns3:processResponse/ns3:result"/>
        </copy>
        <copy>
          <from expression="ora:getConversationId()"/>
          <to variable="Invoke_1_callback_InputVariable_1" part="parameters"
              query="/ns1:callback/arg0"/>
        </copy>
      </assign>
    </sequence>
    ```
16. Repeat the steps for the Task outcome is APPROVE. Select the Switch Case and copy the following in the Condition field:

bpws:getVariableData('SerialApproval1_globalVariable','payload','/task:task/task:systemAttributes/task:outcome') = 'APPROVE'

17. Select the Assign activity under the Approve outcome, and replace the copy rules with the following:

18. Select the Assign activity under the Otherwise outcome, and replace the copy rules with the following:
21.4.5.5.2 Configuring the Parallel Human Task

To configure the parallel Human Task:

1. Add the following condition to the Parallel Approval switch activity:
   
   \[ \text{bpws:getVariableData('workflowtype', '/ns18:StageOutput/ns18:stageType') = 'Parallel'} \]

2. Drag and drop a Human Task activity from the SOA Components into the Parallel Approval switch.
3. Select the Parallel Approval Human Task.
4. Map the Human Task parameters in the same way as the Serial Human Task.
5. Map the Assign activity for the APPROVE outcome in the same way as the equivalent in the Serial Human Task.
6. Map the Assign activity for the REJECT outcome in the same way as the equivalent in the Serial Human Task.
7. Map the Assign activity for the Otherwise outcome in the same way as the equivalent in the Serial Human Task.

---

**Note:** You must specify appropriate global variable (ParallelApproval1_globalVariable) in the copy activity.

21.4.5.5.3 Configuring Auto Approval

To configure auto approval:

1. Drag and drop an Assign activity in the Otherwise switch case.
2. Select the Assign activity, and switch to Source view.
3. In the Assign activity, replace the following:

   \[ \text{<assign name="Assign1"/>} \]

   With:

   \[ \text{<sequence> \n   <assign> \n     <copy> \n       <from expression='string('approved')'/> \n       <to variable='outputVariable' \n          part='payload' \n          query='/ns3:processResponse/ns3:result'/> \n     </copy> \n   </assign> \n   </sequence>} \]

   \[ \text{<copy> \n     <from expression='ora:getConversationId()'/> \n     <to variable='Invoke_1_callback_InputVariable_1' \n          part='parameters' \n          query='/ns1:callback/arg1'/> \n   </copy>} \]
21.4.5.6 Deploying the SOA Composite

To deploy the SOA composite:

1. Select File, Save All to save your work.

2. Right-click the project, and select Deploy, COMPOSITE_NAME, Deploy to Application server. Alternatively, you can deploy to SAR (SOA Archive), and then deploy it by using Oracle Enterprise Manager.

---

**Note:**

- The default version is 1.0. You can also change the version, if you have existing composite instances running.
- If you are redeploying the composite and you have added or removed one or more human tasks, then it is recommended to deploy with a different version.

---

21.4.5.7 Creating the Approval Policies

The SOA composite that you have created can be used for all requests other than user operations, such as self-registration, create, modify, disable, enable, and delete. To ensure that all requests other than user operations invoke this composite, you must create an approval policy in Oracle Identity Manager. To create the approval policies in Oracle Identity Manager:

1. Login to Oracle Identity System Administration.

3. Create a request-level approval policy for Provision Application Instance, and set it to auto approve.

4. Create an operational-level approval policy for Provision Application Instance, and click Approval Process.

5. Select the SOA composite that you deployed.

6. Specify scope type to be All.

7. Create a default approval rule:

   Request.Request Type = Provision Application Instance

8. Save the approval policy.
21.5 Configuring Default Request-Level and Operation-Level Approval Composites

You can configure the default request-level and operation-level composites by setting the DefaultRequestLevelComposite and DefaultOperationLevelComposite properties in the oim-config.xml file. You can edit these properties by using System MBean Browser in Oracle Enterprise Manager. The default values for these properties are default/DefaultRequestApproval!3.0 and default/DefaultOperationApproval!3.0 respectively.

The values for these properties are in the following format:

NAMESPACE/COMPOSITE_NAME!VERSION

For example:

default/AddAccessApproval!2.0

If you change the default values of the DefaultRequestLevelComposite and DefaultOperationLevelComposite properties, then you must restart Oracle Identity Manager.

---

**Note**: The composites configured as default request-level and operation-level composites would be applicable for all request types. Therefore, these composites must be designed to work with all the request types.

21.6 Creating and Deploying Custom Task Details Taskflow

By default, all tasks are configured to use the default task details page in pending approvals. This taskflow is not customizable. However, you might want to customize the UI or show some other information in the task details page. This section describes how to build your own taskflow, and configure the human task in the DefaultRequestApproval composite to invoke your custom taskflow.

This section contains the following topics:
Creating and Deploying Custom Task Details Taskflow

- Prerequisites for Developing Custom Task Details Taskflow
- Developing Custom Task Details Taskflow
- Developing Custom Task Details for Email Notification (Optional)
- Deploying the Task Details Taskflow
- Configuring Human Task and Taskflow Permissions
- Testing the Custom Taskflow

21.6.1 Prerequisites for Developing Custom Task Details Taskflow

Before developing a custom task details taskflow, you must have the following software installed on your computer:

- Oracle Identity Manager 11g Release 2 (11.1.2.2.0)
- Oracle SOA 11g (11.1.1.7.0)
- JDeveloper 11g (11.1.1.7.0) with Oracle SOA Composite Editor extension

21.6.2 Developing Custom Task Details Taskflow

To build a custom taskflow for the human task in the DefaultRequestApproval composite:

1. Open Jdeveloper and create a new Generic Application. To do so:
   a. Enter Application Name as RequestApprovalTaskDetailsApp, and then click Next.
   b. Enter Project Name as RequestApprovalTaskDetails. Do not select any project technologies.
   c. Click Finish.
2. Add Oracle Identity Manager shared library. To do so:
   a. Right-click RequestApprovalTaskDetails project, and select Project Properties, Libraries and Classpath.
   b. Click Add Library.
   c. Click Load Dir.
   d. Navigate to the IAM_HOME/server/jdev.lib/ directory, and click Select.
   e. Select OIM View Shared library, OIM Model Shared library, and then click OK.
   f. Click OK.
3. Create task details taskflow. To do so:
   a. Navigate to the following directory in shiphome:
      
      IAM_HOME/server/workflows/composites/
b. Unzip the DefaultRequestApproval.zip file.

c. Go back to Jdeveloper, right-click **RequestApprovalTaskDetails**, and select **New**.

d. Select **Web Tier, JSF**, ADF task flow based on human task.

e. In the file browser, navigate to the directory in which you unzipped DefaultRequestApproval.zip. Select the DefaultRequestApproval/ApprovalTask.task file

f. In the Create Task flow dialog box, provide the following values:

   **File Name:** request-approval-details-tf.xml
   
   **Task Flow ID:** request-approval-details-tf

   g. Click **OK**.

4. Delete hwtaskflow.xml. To do so, go to Application Sources under RequestApprovalTaskDetails project, and then delete hwtaskflow.xml.

   For more information on workflow for multiple human tasks, see "How To Reuse the Task Flow Application with Multiple Human Tasks" in Oracle Fusion Middleware Developer’s Guide for Oracle SOA Suite Guide.

5. Create the task details page. To do so:

   a. Open request-approval-details-tf.xml. Switch to diagram mode.

   b. Rename **taskdetails1_jspx** view activity to **request-approval-details**.

   c. Right-click the **request-approval-details** view activity, and select **Create Page**. Provide the following values:

      **File name:** request-approval-details.jspx
      
      **Initial Page layout and content:** Blank Page

   d. Click **OK**.

6. Add managed bean for this page. To do so:

   a. Right-click the **RequestApprovalTaskDetails** project, and select **New, Java Class**. Provide the following values:

      **Name:** RequestApprovalDetailsStateBean
      
      **Package:** oracle.iam.ui.custom.view.backing

   b. Click **OK**.

   c. Add the following code to the managed bean:

   ```java
   package oracle.iam.ui.custom.view.backing;

   import javax.el.ELContext;
   import javax.el.ExpressionFactory;
   import javax.el.ValueExpression;
   import javax.faces.application.Application;
   import javax.faces.context.FacesContext;
   import oracle.iam.ui.platform.model.config.ConstantsDefinition;

   public class RequestApprovalDetailsStateBean implements java.io.Serializable{
   ```
Creating and Deploying Custom Task Details Taskflow

public RequestApprovalDetailsStateBean() {
super();
}
private String requestAction = ConstantsDefinition.REQUEST_ACTION_
APPROVAL_UPDATE;
private String requestType = ConstantsDefinition.REQUEST_TYPE_VIEW_
DETAIL;
public void setRequestAction(String requestAction) {
this.requestAction = requestAction;
}
public String getRequestAction() {
return requestAction;
}
public void setRequestType(String requestType) {
this.requestType = requestType;
}
public String getRequestType() {
return requestType;
}
public String getUserIds() {
Object benefDisplayName =
getValueFromELExpression("#{bindings.DisplayName.inputValue}");
//benefDisplayName would be "None" if beneficiary does not exist
if (benefDisplayName != null &&
!ConstantsDefinition.NONE_BENEF_DISPLAY_
NAME.equalsIgnoreCase(benefDisplayName.toString()))
return benefDisplayName.toString();
Object requestTarget =
getValueFromELExpression("#{bindings.RequestTarget.inputValue}");
if (requestTarget != null)
return requestTarget.toString();
return "";
}
private Object getValueFromELExpression(String expression) {
FacesContext facesContext = FacesContext.getCurrentInstance();
Application app = facesContext.getApplication();
ExpressionFactory elFactory = app.getExpressionFactory();
ELContext elContext = facesContext.getELContext();
ValueExpression valueExp =
elFactory.createValueExpression(elContext, expression,
Object.class);
return valueExp.getValue(elContext);
}

}
d.

Open request-approval-details-tf.xml in Overview mode. Select Managed
Beans sections and register the managed bean with the following details:
Name: requestApprovalDetailsStateBean

21-42 Oracle Fusion Middleware Developer's Guide for Oracle Identity Manager


Class: oracle.iam.ui.custom.view.backing.RequestApprovalDetailsStateBean
Scope: pageFlow

7. Create the details page structure. To do so:
   a. Open request-approval-details.jspx.
   b. From the Component Palette, add a `panelStretchLayout` to the page. In the Property Inspector, set `TopHeight=auto` for `panelStretchLayout`.
   c. Go to Data controls in Application Navigator. Expand `RequestApprovalTaskDetails_ApprovalTask`, `getTaskDetails`, `Return`. Drag and drop `Task` from Data Controls on to the Top Facet of `panelStretchLayout`, as shown in Figure 21–36. From the context menu, select **Human Task**, **Task Action**. The Human task actions are added to the Top Facet.

![Figure 21–36 Dragging Task to the Top Facet](image)

   d. From the Component Palette, add a `panelTabbed` layout to the Center Facet of `panelStretchLayout`.
   e. From the Component Palette, add two `showDetailItem` components to the `panelTabbed` layout. From property inspector, set the text name for these components as **Request Information** and **Task Information**.
   f. Click the **Request Information** tab. From the property inspector, set attribute `stretchChildren=first`.
   g. Add another `panelStretchLayout` in Request Information tab. Set attribute `topHeight=auto` for this `panelStretchLayout`. Figure 21–37 shows the Request Information and Task Information tabs.
8. Populate the **Request Information** tab. To do so:
   
   a. Go to Navigator Display Options, and select **Show Libraries**, shown in Figure 21–38. This will show **OIM View Shared Library** in the Application Navigator.
b. In the Application Navigator, expand **OIM View Shared Library**, **WEB-INF/oracle/iam/ui/catalog/tfs**. Drag and drop `request-summary-information-tf.xml` to the Top Facet of PanelStretchLayout added in step 7g. The Create context menu is displayed. Select **Region**. The Edit Task Flow Binding dialog box is displayed. You can provide parameters to the taskflow later. Therefore, click **OK**.

c. Similarly, drag and drop `catalog-tf.xml` to the Center Facet of PanelStretchLayout added in step 7g. The Create context menu is displayed. Select **Region**. The Edit Task Flow Binding dialog box is displayed. Click **OK**.

d. Click the **Bindings** tab at the bottom of the page to view the bindings. Click the plus (+) sign to add a binding in the following way:

i) Enter the following and click **OK**:

**Category:** Generic Bindings

**Item to be created:** attributeValues

ii) Click **Add Datasource**. Select `RequestApprovalTaskDetails_ApprovalTask`, `getTaskDetails`, `Return`, `Task`, `Payload`. Click **OK**.

iii) Specify Attribute as `RequestID`, and click **OK**.

e. Under executables, select `taskflow-requestsummaryinformation-tf1`. In the Property Inspector, add a taskflow parameter by clicking the plus (+) sign.
Edit the value field, and update it with \#[bindings.RequestID.inputValue], as shown:
ID=requestID, Value= \#[bindings.RequestID.inputValue]

f. Click the plus (+) sign to add another binding. This binding will be referenced in RequestApprovalDetailsStateBean.
   i) Enter the following and click OK:
   Category: Generic Bindings
   Item to be created: attributeValues
   ii) Click Add Datasource. Select RequestApprovalTaskDetails_ApprovalTask, getTaskDetails, Return, Task, Payload, BeneficiaryDetails. Click OK.
   iii) Specify Attribute as DisplayName, and click OK.

g. Click the plus (+) sign to add another binding. This binding will be referenced in RequestApprovalDetailsStateBean.
   i) Enter the following and click OK:
   Category: Generic Bindings
   Item to be created: attributeValues
   ii) From the list, select datasource RequestApprovalTaskDetails_ApprovalTask, getTaskDetails, Return, Task, Payload.
   iii) Specify Attribute as RequestTarget, and click OK.

h. Select taskflow-catalog.tf1 in Executables, click Edit on the top-right corner of Executables, and edit the values of the following in the Edit Task flow Binding dialog box:
   - Id=requestId, Value= \#[bindings.RequestID.inputValue]
   - Id=requestType,
     Value=\#[pageFlowScope.requestApprovalDetailsStateBean.requestType]
   - Id=requestAction,
     Value=\#[pageFlowScope.requestApprovalDetailsStateBean.requestAction]
   - Id=userIds,
     Value=\#[pageFlowScope.requestApprovalDetailsStateBean.userIds]

9. Populate the Task Information tab. To do so:
   a. Switch to Design mode. Click the Task Information tab.
   b. In the Application Navigator, go to Data Controls. Expand RequestApprovalTaskDetails_ApprovalTask, getTaskDetails, Return. Drag and drop Task in the Task Information tab. The Create context menu is displayed. Select Human Task, Complete Task without Payload, as shown in Figure 21–39.
c. A panelHeader wrapped inside panelGroupLayout is added to the Task Information tab. Navigate to the panelHeader and delete the Toolbar Facet of the panelHeader. The task actions have already been in step 7c). In addition, task details, task history, comments, and attachments are also added to the Task Information tab.

d. Save your work.

21.6.3 Developing Custom Task Details for Email Notification (Optional)

By default, for sending email notification, if there is no separate page for email, then the same task details page developed in "Developing Custom Task Details for Email Notification (Optional)" on page 21-47 is sent in email notification.

Sometimes, limited information needs to be sent in email notification. In such scenarios, separate page for email notification can be developed. The email page will also be part of the same task details taskflow.

For more information on building custom taskflow for email, refer to "Creating an Email Notification" in the Oracle Fusion Middleware Developer’s Guide for Oracle SOA Suite.

21.6.4 Deploying the Task Details Taskflow

To deploy the task details taskflow:

1. Deploy the Task Details as an ADF library jar. To do so:
   a. Right-click RequestApprovalTaskDetails, Project Properties, Deployment.
   b. Click New. The Create deployment profile dialog box is displayed.
   c. Provide following values, and click OK.

   Archive Type: ADF Library Jar File
   Name: adflibRequestApprovalTaskDetails
d. Right-click RequestApprovalTaskDetails, and select Deploy, adflibRequestApprovalTaskDetails.
e. In the deployment action popup, click Finish.

2. Package the adflibRequestApprovalTaskDetails.jar in custom shared library. To do so:
   a. Navigate to the IAM_HOME/server/apps/ directory.
   b. Create following directory structure:
       WEB-INF/lib/
   c. Copy adflibRequestApprovalTaskDetails.jar to the WEB-INF/lib/ directory.
   d. Update IAM_HOME/server/apps/oracle.iam.ui.custom-dev-starter-pack.war to add adflibRequestApprovalTaskDetails.jar. For example:

       jar uvf oracle.iam.ui.custom-dev-starter-pack.war WEB-INF/*

3. Restart Oracle Identity Manager managed server for the changes to custom shared library to take effect.

21.6.5 Configuring Human Task and Taskflow Permissions

To configure Human Task and taskflow permissions:

1. Add view permission for custom taskflow by using Authorization Policy Manager (APM). To do so:
   a. Login to APM application as WebLogic user.
   b. Navigate to Applications, OracleIdentityManager, Resource Types. Click Open.
   c. Click New to create a new resource type. Provide following details:
      – Display Name: ADF Taskflows
      – Name: ADFTaskFlows
      – Actions: personalize, customize, grant, view. Click New to add each action.
      – Supports Resource Hierarchy: No
      – Resource Delimiter: Slash(/)
      – Evaluation Logic: Permission Class
      – Permission Class: oracle.adf.controller.security.TaskFlowPermission
      – Action Name Delimiter: Comma(,)
   d. Click Save.
   e. Navigate to Applications, OracleIdentityManager, Default Policy Domain, Resource Catalog, Resources. Click Open.
   f. Click New to create a new resource. Provide the following values, and then click Save.
      – Resource Type: Select the resource type created in step 1(c).
      – Display Name: Provide a display name for your custom taskflow.
      – Name: Provide the name of the custom taskflow in the following format:
Creating and Deploying Custom Task Details Taskflow

**For example:**

/WEB-INF/request-approval-details-tf.xml#request-approval-details-tf

- **Description:** Provide a description for the custom taskflow.

**Note:** For each custom taskflow, you must create a resource as mentioned in step 1(f). You can use the same resource type that you created in step 1(c) for all your custom taskflows.

1. **g.** Navigate to Applications, OracleIdentityManager, Default Policy Domain, Authorization Policies. Click **Open**.
2. **h.** Select Find By Principal, and click **Search**. If you want to add to a displayed existing policy, then select it and click **Open**. Otherwise, click **New** to create a policy.
3. **i.** Add **name** and **principals** for the new policy.
4. **j.** Click **Add Targets** (+) sign. The Search Targets dialog box is displayed.
5. **k.** Click the **Resources** tab. Provide the resource type as defined in step 1(f), and then click **Search**.
6. **l.** Select the resource created in step 1(f). Click **Add Selected**.
7. **m.** Click **Add Targets**. The resource is added to the Targets table.
8. **n.** Expand the resource that you added to the table. Select the permissions you want to apply to the taskflow.
9. **o.** Click **Apply**.

2. Configure human task to use the custom taskflow. To do so:
   1. **a.** Login to Oracle Enterprise Manager as WebLogic user.
   2. **b.** Navigate to Farm_IAM_DOMAIN, SOA, soa_infra (SOA_SERVER), default, DefaultRequestApproval [4.0].
   3. **c.** Click **Component Metrics**, Approval Task.
   4. **d.** Click the **Administration** tab.
   5. **e.** Modify the URI in the existing entry to point to the custom taskflow, as shown:
      - **Application Name:** ANY_NAME
      - **Host Name:** OIM_SERVER_HOSTNAME
      - **HTTP Port:** OIM_HTTP_PORT
      - **HTTPS Port:** OIM_HTTPS_PORT (Optional)
      - **URI:** /identity/faces/adf.task-flow?_id=request-approval-details-tf&_document=WEB-INF/request-approval-details-tf.xml

**21.6.6 Testing the Custom Taskflow**

To test custom taskflow:

1. Login to Oracle Identity Self Service as an end user.
2. Go to My Information, and modify the value of the Telephone attribute. A request is created and the task is assigned to the System Administrator.

3. Login to Oracle Identity Self Service as System Administrator.

4. Go to Pending Approvals.

5. Click the Task Details link of the corresponding request. The custom task details page is displayed.

### 21.7 Understanding Request Datasets

Request datasets are XML files that store the data that can be associated with requests of given types.

---

**Note:** The information in this section is for reference. Oracle recommends that you do not modify, export, or import request datasets. To extend the user and application instance definition, use the Form Designer in Oracle Identity System Administration. See “Managing Forms” in *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for information about the Form Designer.

---

Table 21–2 lists the request types and the associated default request dataset file names that are shipped with Oracle Identity Manager.

**Table 21–2  Default Request Datasets Shipped with Oracle Identity Manager**

### 21.8 Extending Request Management Operations

You can customize certain aspects of request management operations to allow greater flexibility and implement customized logic for additional functionality. To achieve this, you can use request management plug-ins. There are plug-in points that you can use to implement customization.

This section discusses the plug-in points in the following topics:

- Running Custom Code Based on Request Status Change
- Validating Request Data
21.8.1 Running Custom Code Based on Request Status Change

In Oracle Identity Manager, a request undergoes change in status at each stage of its lifecycle. The request engine exposes a plug-in point that allows running of custom code during request status change. A plug-in with custom code that extends this plug-in point can be implemented and registered for running the code. The plug-in point is the `oracle.iam.request.plugins.StatusChangeEvent` interface with the `public void followUpActions(String reqId)` method. This method consists of the request id parameter, using which the request details can be obtained with the help of request management APIs.

See Also: Chapter 27, "Developing Plug-ins" for detailed information about plug-ins and plug-in points

Any code that is to be run during the status change must be implemented in the `followUpActions()` method in a plug-in class that implements the `oracle.iam.request.plugins.StatusChangeEvent` interface. You must specify at which request status change this plug-in is to be run in the plugin.xml file.

For example, when a request in Oracle Identity Manager moves to the Request Failed status, you want to run a custom code that sends a notification to an administrator. To do so:

1. Create a new plug-in class with name `RequestFailedChangeEvent` that implements the `oracle.iam.request.plugins.StatusChangeEvent` interface. This class must have the logic of sending a notification to the administrator in the `followUpActions(String reqId)` method.

2. Define plugin.xml in following standard format, as specified by the plug-in framework:

```xml
<oimplugins xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <plugins pluginpoint="oracle.iam.request.plugins.StatusChangeEvent">
    <plugin pluginclass="com.mycompany.RequestFailedChangeEvent" version="1.0" name="RequestFailedChangeEvent">
      <metadata name="status">
        <value>Request Failed</value>
      </metadata>
    </plugin>
  </plugins>
</oimplugins>
```

In this XML definition, the metadata part specifies at which stage the plug-in must be run. This is done by specifying the metadata value as `Request Failed`, which means that the `com.mycompany.RequestFailedChangeEvent` plug-in will run when a request moves to the Request Failed status.

3. Register the plug-in with Oracle Identity Manager. See "Registering Plug-ins" on page 27-7 for information about registering plug-ins in Oracle Identity Manager.

21.8.2 Validating Request Data

You can use the RequestDataValidator plug-in to add custom validation of request data after submission. The plug-in point for this is the `oracle.iam.request.plugins.RequestDataValidator` interface with public void `validate(RequestData requesterData)` method.
You can define the dataset validators and prepopulation adapters associated with the given plug-in. The request datasets associated with the plug-ins can be defined at the time of plug-in registration. The plugin.xml file is used to define the association between plug-ins and dataset validator or prepopulation adapters. The <metadata> node attached with the <plugins> element is used to define the association between data validators and prepopulation adapters.

**Note:** DatasetValidator plug-in specified for a dataset cannot be overridden by the plug-in enhancement of specifying the validators metadata in the plugin.xml itself. For instance, the predefined dataset 'ModifyUserDataset' shipped with default validator does not get overridden by the custom implementation class. Therefore, the validator in dataset will be given precedence, currently there is no option to override it.

Example 21–1 shows how the plug-ins can be associated with data validators and prepopulation adapters.

**Example 21–1  Associating plug-ins With Data Validators and Prepopulate Adapters**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oimplugins xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <plugins pluginpoint="oracle.iam.request.plugins.RequestDataValidator">
    <plugin pluginclass="oracle.iam.plugin.appinst.ApplicationInstanceDataValidator" version="1.0" name="AppInstDataValidator">
      <metadata name="DataValidator">
        <value>AppInstanceDataSet|ADAppDataSet|EBSDataSet</value>
      </metadata>
    </plugin>
  </plugins>
</oimplugins>
```

In this example, the following line of code indicates defining metadata xml element to indicate that the plug-in is associated with request data validator datasets:

```xml
<metadata name="DataValidator">
```

**Note:** Attribute name="DataValidator" in the metadata element indicates plug-in associated with request data validators. Defining the names of the datasets to be associated with the current plug-in is indicated by the following line:

```xml
<value>AppInstanceDataSet|ADAppDataSet|EBSDataSet</value>
```

**Note:** Request dataset names must be delimited by the single pipe character (|).

Consider the following scenarios:

- **Scenario I: Provisioning Users to a Target System**
- **Scenario II: Provisioning or Modifying Entitlement Request**
21.8.2.1 Scenario I: Provisioning Users to a Target System
Suppose Oracle Identity Manager is configured for provisioning users to the AD User APAC target. A RequestDataValidator specifies ADUserDataValidator is configured for the corresponding request dataset, as shown:

```xml
<plugin pluginclass="oracle.iam.plugin.appinst.ADUserDataValidator" version="1.0"
name="ADUserDataValidator">
<metadata name="DataValidator">
<value>ADUserAPACDataSet</value>
</metadata>
</plugin>
```

Later, if the System Configurator wants to configure Oracle Identity Manager for provisioning users to the AD User EMEA target, then the System Configurator would create a new application instance, and associate a UI form with it. Request dataset would be auto-generated in the process. If the data-validator is to be re-used for this request dataset, then perform the following:

1. Edit plugin.xml of the ADUserDataValidator.
2. In the `<metadata> <value>` subtag, add the name of the new request dataset separated by a delimiter. For example:

```xml
<value>ADUserAPACDataSet|ADUserEMEADataset</value>
```
3. Re-register the data-validator plug-in.

21.8.2.2 Scenario II: Provisioning or Modifying Entitlement Request
Entitlement data provided as part of Provision Entitlement and Modify Entitlement request can be validated by creating a dataset validator plug-in and specifying the following in the plug-in metadata (plugin.xml):

```xml
<metadata name="DataValidator">
  <value>EBSForm.UD_EBS_RESP</value>
</metadata>
```
Here, EBSForm is the name of the form associated with the application instance on which the account is provisioned, and UD_EBS_RESP is the name of the child form corresponding to the entitlement. UD_EBS_RESP identifies the entitlement type.

21.8.3 Prepopulation of an Attribute Value During Request Creation
Prepopulation plug-in is associated with an attribute reference or attribute in request dataset. This can be used to prepopulate an attribute value by running custom code during request creation. Requester can modify the value that is prepopulated if required.

The plug-in point for this is `oracle.iam.request.plugins.PrePopulationAdapter` with public `Serializable prepopulate(RequestData requestData)` method. Use this plug-in only for the following request types:

Defining metadata element to indicate that the plug-in is mapped to request data set attributes for filling up prepopulated data is indicated by the following line:

```xml
<metadata name="PrePopulationAdapter">
```

The association is defined by combining dataset name with attribute name in the following format:
Enabling Auto-Approval for Self Registration Requests

For example:

AppInstanceDataSet::First Name

Multiple attributes can be associated with the same prepopulation plug-in, where each association is separated by the single pipe character (|). For example:

<datasetname1>::<attribute1> | <datasetname2>::<attributename2> | <datasetname3>::<attribute3>

The following is an example of prepopulation plug-in:

<plugins pluginpoint="oracle.iam.request.plugins.PrePopulationAdapter">
  <plugin pluginclass="oracle.iam.plugin.appinst.ApplicationInstancePrePopulateAdapter" version="1.0" name="AppInstPrepopAdapter">
    <metadata name="PrePopulationAdapter">
      <value>
        AppInstanceDataSet::First Name|ADAppDataSet::Last Name
      </value>
    </metadata>
  </plugin>
</plugins>

**Note:** In addition to creating request datasets by using the catalog Form Designer, you can manually upload request datasets to MDS. You can also define DataSetValidator or PrepopulationAdapter elements within the request dataset. These dataset validators or prepoulation adapters configured in the dataset have the highest priority over other configuration.

For example, a plug-in EBSUserDataValidator is registered to associate it with a request dataset EBSUserDataSet, but the dataset has not been created or uploaded. Another plug-in ADUserDataValidator is registered but not associated with any request dataset. When you later create the request dataset EBSUserDataSet and use it for creating requests, the plug-in EBSUserDataValidator is called for validating the request data. Then, you add the DataSetValidator element to the request dataset EBSUserDataSet that you manually created, and specify another plug-in ADUserDataValidator. When you use EBSUserDataSet to create requests, the plug-in ADUserDataValidator is called. This is because ADUserDataValidator is configured as a part of the request dataset. If the DataSetValidator entry is removed from EBSUserDataSet, then the plug-in EBSUserDataValidator is invoked to validate the request data.

---

21.9 Enabling Auto-Approval for Self Registration Requests

Approval policies can be configured at request level or operation level. They can use all the data available at the request and operational levels to construct a rule. The rule helps determine whether the request should be auto-approved or a SOA composite should be invoked. For information about enabling auto-approval for request and operation levels, see “Creating Approval Policies” in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.*
After the approval policies are updated, perform the following steps to enable auto-approval for self registration requests:

1. To assign the organization automatically, add a pre-process handler that sets the organization value in the orchestration. The order should be set such that it is executed before the approval-related handlers. Set this to be executed soon after the CreateUserPreProcessHandler. See Chapter 28, "Developing Event Handlers" for information about orchestration and event handlers.

2. By default, the Role/User Type set for the self registration requests is Part-Time Employee. If you want to overwrite this value, then change the plug-in configured in the SelfCreateUserDataset.xml dataset.

3. You can create a new plug-in implementation for the value/logic required and change the plug-in configured in the dataset to bring the new one in affect. The new plug-in must implement oracle.iam.request.plugins.PrePopulationAdapter.

4. Register the plug-in that you created by using the Plugin Registration Utility. For details, see "Registering and Unregistering Plug-ins By Using the Plugin Registration Utility" on page 27-8.

5. To update the request dataset:
   a. Export the `/metadata/iam-features-requestactions/model-data/SelfCreateUserDataset.xml` request dataset from the MDS, as described in "Exporting Metadata Files to MDS" on page 37-1.

   b. Update the name of the plug-in configured for Role attribute, as shown:

   ```xml
   <AttributeReference name="Role" attr-ref="Role" available-in-bulk="false" type="String" length="255" widget="dropdown" lookup-code="Lookup.Users.Role" required="true">
     <PrePopulationAdapter classname="oracle.iam.selfservice.uself.uselfmgmt.plugins.RolePrepopulateAdapter" name="RolePrepopulateAdapter"/>
   </AttributeReference>
   
   c. Import the updated request dataset to MDS, as described in "Importing Metadata Files from MDS" on page 37-2.
Using Segregation of Duties (SoD)

The concept of Segregation of Duties (SoD) is aimed at applying checks and balances on business processes. Each stage of a business process may require the involvement of more than one individual. An organization can convert this possibility into a requirement for all IT-enabled business processes by implementing SoD as part of its user provisioning solution. The overall benefit of SoD is the mitigation of risk arising from intentional or accidental misuse of an organization’s resources.

This chapter describes SoD in the following sections:

- Understanding the SoD Validation Process
- Introducing the SoD Invocation Library
- Installing the SoD-enabled Connectors
- Deploying the SIL and SIL Providers
- Configuring the SoD Engine
- Enabling and Disabling SoD
- Enabling SSL Communication
- Configuring Workflows on Non SoD-enabled Connectors
- Marking Child Process Form Tables That Hold Entitlement Data
- Custom Combination of Target Systems and SoD Engines
- Performing Role SoD Check with Oracle Identity Analytics
- Using SoD in Provisioning Workflow
- Enabling Logging for SoD-Related Events
- Troubleshooting SoD Check

22.1 Understanding the SoD Validation Process

Oracle Identity Manager is a user provisioning solution with which entitlement requests can also be validated and managed. In the Oracle Identity Manager implementation of SoD, user requests for IT privileges (entitlements) are checked and approved by an SoD engine and other users. Multiple levels of system and human checks ensure that even changes to the original request are vetted before the request is cleared. This preventive approach helps identify and correct potentially conflicting entitlement assignments before the requested entitlements are assigned.
Introducing the SoD Invocation Library

The SoD validation process in Oracle Identity Manager occurs when a user creates a request for an entitlement on a particular target system. The request is funneled through a resource approval workflow and, if it passes that initial workflow, a resource provisioning workflow.

- The resource approval workflow is configured to validate requests in real time using an SoD engine. The SoD engine has predefined rules that are used to determine if the entitlement assignment would lead to SoD violations. The determination, once made, is returned to Oracle Identity Manager.

- The resource provisioning workflow provisions an entitlement request that has passed the resource approval workflow on the target system.

If the user’s request passes SoD validation (and an approver approves the request), the resource provisioning workflow is initiated. If the request fails SoD validation, the resource approval workflow can be configured to take remediation steps.

---

**Note:** The resource provisioning workflow can be configured to perform the SoD validation again - immediately before the entitlement assignment is provisioned to the target system - to ensure SoD compliance.

---

Oracle Identity Manager communicates with both the SoD engine and the target system. In addition, the target system and SoD engine communicate with each other to enable the synchronization of entitlement data. Figure 22–1 shows the flow of data during the SoD validation process.

*Figure 22–1  SoD Validation Process in Oracle Identity Manager*

---

### 22.2 Introducing the SoD Invocation Library

The SoD Invocation Library (SIL) forms the basis of the SoD implementation in Oracle Identity Manager. The SIL is a collection of Java-based adapters that enable integration with predefined Oracle Identity Manager connectors. The connectors, in turn, link Oracle Identity Manager with the target systems. The following Oracle Identity Manager connectors are preconfigured with adapters for SoD validation:
Introducing the SoD Invocation Library

Oracle e-Business User Management release 9.1.0 and later

SAP User Management release 9.1.2.5 and later

**Note:** With SAP UM 9.1.2.5, request entitlement does not work in Oracle Identity Manager 11g Release 2 (11.1.2.2.0).

The SIL also acts as the base for specialized adapters that integrate the SIL with SoD engines. These adapters are called SIL providers. A SIL provider acts as the interface between the SIL and a specific SoD engine. There are predefined SIL providers for the following SoD engines:

- **SAP Governance, Risk and Compliance Access Control (GRC AC)**
  
  If you want to configure and use the Access Risk Analysis or Access Request Management feature of this target system, then install one of the following:
  
  - SAP BusinessObjects Access Control 5.3 on SAP NetWeaver AS JAVA 7.00 Support Pack 14
    
    Install the VIRACLP 530_700_19, VIRAE 530_700_19, VIRCC 530_700_19, VIRRFF 530_700_19, and VIRRE 530_700_19 components.
    
    Use ECC 6.0 with RTA components VIRSAHR SP 10 and VIRSANH SP 10.

  **Note:** If you are using any other SAP application, then you must install the RTA component, which is compatible with that SAP application.

  - SAP BusinessObjects Access Control 10 on SAP NetWeaver AS ABAP 7.02 Support Pack 7
    
    Install the GRCFND_A SP 10 component.
    
    Use ECC 6.0 with RTA component GRCPIERP SP 9.

  **Note:** If you are using any other SAP application, then you must install the RTA component which is compatible with that SAP application.

- **SIL Provider for Oracle Application Access Controls Governor (OAACG) release 8.6.4**

  This provider is also known as the OAACG SIL Provider.

  **Note:** Install the latest patch set for OAACG before implementing and using SoD in Oracle Identity Manager. Contact Oracle Support for more information.

- **SIL Provider for Oracle Identity Analytics (OIA) 11g Release 1 Patch Set 1 Bundle Patch 2 (11.1.1.5.2)**

  This provider is also known as the OIA SIL Provider.
Installing the SoD-enabled Connectors

Figure 22–2 shows the architecture of SoD implementation in Oracle Identity Manager.

If required, you can configure any Oracle Identity Manager connector with either the SAP GRC SIL Provider, the OAACG SIL Provider or the OIA SIL Provider. For example, you can use the PeopleSoft User Management connector and the OAACG SIL Provider to automate SoD validation of requests for entitlements on PeopleSoft Enterprise Applications.

You can also create and use a SIL provider for a custom SoD engine, along with either one of the preconfigured Oracle Identity Manager connectors or an Oracle Identity Manager connector that you configure for SoD validation.

22.3 Installing the SoD-enabled Connectors

Instructions to install the SoD-enabled connectors listed below can be found in the specific connector documentation. The Oracle Identity Manager Connectors Documentation page is located at the following URL:

http://download.oracle.com/docs/cd/E11223_01/index.htm

- Oracle e-Business User Management release 9.1.0 and later
- SAP User Management release 9.1.2.5 and later

Note: You can download the current version of OIA from the My Oracle Support web site by navigating to the following URL and searching for Patch 13641335.

https://support.oracle.com
22.4 Deploying the SIL and SIL Providers

SIL registration is provided by default for the same target systems and SoD engines. No deployment steps are required for these default combinations of target systems and SoD engines. Target systems for which SIL registration is provided include:

- EBS and OAACG
- PSFT and OAACG
- SAP and SAP-GRC
- OIA

OIA SoD Engine synchronizes data with Oracle Identity Manager rather than any target system so the topology registered for OIA can be used with any connector configured with Oracle Identity Manager. OIA imports all data from Oracle Identity Manager. Therefore, from OIA perspective, Oracle Identity Manager is the target system.

You must perform the SIL registration process if you want to use any other combination of target systems or SoD engines. For more information, see Section 22.10, "Custom Combination of Target Systems and SoD Engines."

22.5 Configuring the SoD Engine

You must import entitlement data from the target system to the SoD engine. If required, you must also configure SoD validation rules on the SoD engine. The following sections provide these instructions for the preconfigured SoD engines.

- Configuring Oracle Application Access Controls Governor
- Configuring SAP GRC
- Configuring Oracle Identity Analytics

22.5.1 Configuring Oracle Application Access Controls Governor

Configuring Oracle Application Access Controls Governor (OAACG) involves the following procedures:

- Installing Oracle Application Access Controls Governor
- Creating an Oracle Application Access Controls Governor Account for SoD Operations
- Synchronizing Role and Responsibility Data from Oracle e-Business Suite to Oracle Application Access Controls Governor
- Defining Access Policies in Oracle Application Access Controls Governor

**Installing Oracle Application Access Controls Governor**

OAACG 8.6.4.5259 is supported with Oracle Identity Manager 11g Release 2 (11.1.2.2.0). OAACG 8.6.4.5259 can be directly installed. If you have existing OAACG 8.6.3 GA installation, then you can upgrade it to 8.6.4.5259.

To upgrade from 8.6.3 GA to 8.6.4.5259:

1. Logon to My Oracle Support.
2. Click the **Patches & Updates** tab.
3. Click **Advanced Search**.
4. Select Product Family as Oracle Application Access Controls Governor and release as AACG 8.6.4. Select the appropriate platform, and click Search. The following patches and other latest ones are displayed:
   - 14528065 - ORACLE APPLICATION ACCESS CONTROLS GOVERNOR 8.6.4.3347
   - 14786771 - ORACLE APPLICATION ACCESS CONTROLS GOVERNOR 8.6.4.4240
   - 16178807 - ORACLE APPLICATION ACCESS CONTROLS GOVERNOR 8.6.4.5259
5. Download the patches listed in step 4. Perform the upgrade in the following sequence:
   - 8.6.3 to 8.6.4.3347 to 8.6.4.4240 to 8.6.4.5259
   - Perform the OAACG upgrade or install by referring to the OAACG install guide.
6. For each deployment, re-run Access ETL against the active data sources.

Creating an Oracle Application Access Controls Governor Account for SoD Operations
Create an account of the Basic type for SoD validation operations. While performing the procedure described in "Creating an IT Resource to Hold Information about the SoD Engine" on page 22-37, provide the user name and password of this account.

See Oracle Application Access Controls Governor documentation for information about creating the account.

Synchronizing Role and Responsibility Data from Oracle e-Business Suite to Oracle Application Access Controls Governor
You must import (synchronize) role and responsibility data from Oracle e-Business Suite into Oracle Application Access Controls Governor. After first-time synchronization, you must schedule periodic synchronization of data.

See Oracle Application Access Controls Governor documentation for more information.

Defining Access Policies in Oracle Application Access Controls Governor
After you import role and responsibility data, set up access policies in Oracle Application Access Controls Governor. These access policies are based on various combinations of roles and responsibilities.

See Oracle Application Access Controls Governor documentation for more information.

22.5.2 Configuring SAP GRC
SAP GRC uses user, role, and profile data from SAP R/3 to validate requests for accounts, roles, and responsibilities. Configuring SAP GRC involves the following procedures:
   - Creating an SAP GRC Account for SoD Operations
   - Generating the Keystore
   - Configuring the Risk Terminator
   - Synchronizing User, Role, and Profile Data from SAP ERP to SAP GRC
Defining Risk Policies in SAP GRC

Creating an SAP GRC Account for SoD Operations
You must create an SAP GRC account for SoD operations. During SoD operations, this account is used to call the SAP GRC Web service.

When you create this user account, you must assign it to the following groups:

- Everyone
- Authenticated Users

You must not assign any roles to this account.

Generating the Keystore
To generate the keystore:

1. In a Web browser, open the Web Services Navigator page of SAP GRC Access Control. The URL is similar to the following:
   
   https://SAP_GRC_HOST:PORT_NUMBER/VirsaCCRiskAnalysisService/Config1?wsdl

2. Export the certificate.
3. Copy the certificate into the bin directory inside the JDK installation directory of SAP GRC.
4. Run the following command to create the keystore from the certificate file that you download:
   
   keytool -import -v -trustcacerts -alias sapgrc -file CERTIFICATE_FILENAME
   -keystore sgil.keystore -keypass changeit -storepass changeit

   **Note:** In this sample command, the keystore file name is sgil.keystore.

5. When prompted for the keystore password, specify changeit. This is the default keystore password.
6. When prompted to specify whether you want to trust the certificate, enter yes.
7. The sgil.keystore file is created in the bin directory. Copy the file to the OIM_HOME/config directory.

Configuring the Risk Terminator
The Risk Terminator is a feature of GRC Access Control. It is the main component of the SoD validation functionality of SAP GRC. Whenever a role is created in the profile generator or assigned to a user, the Risk Terminator verifies if this role creation or assignment would result in an SoD violation.

See the Risk Terminator Configuration document for detailed information.

Synchronizing User, Role, and Profile Data from SAP ERP to SAP GRC
User, role, and profile data must be imported (synchronized) from SAP ERP into SAP GRC. After first-time synchronization, you must schedule periodic synchronization of data.
Defining Risk Policies in SAP GRC
After you import role and responsibility data, use the Risk Analysis and Remediation feature of SAP GRC to define risk policies of type Segregation of Duty.
See SAP GRC documentation for more information.

22.5.3 Configuring Oracle Identity Analytics
Configuring Oracle Identity Analytics involves the following procedures:
- Creating an Oracle Identity Analytics Account for SoD Operations
- Synchronizing Oracle Identity Manager Metadata With Oracle Identity Analytics
- Defining Identity Audit Policies in Oracle Identity Analytics

Note: Oracle Identity Analytics 11.1.1.5.0 Patch Set 2 is certified for Oracle Identity Manager 11g Release 2 (11.1.2.0).

Creating an Oracle Identity Analytics Account for SoD Operations
Create an account on Oracle Identity Analytics and assign to it the SRM Admin role for SoD validation operations. When performing the procedure described in "Creating an IT Resource to Hold Information about the SoD Engine" on page 22-37, provide the user name and password of this account.
See the Oracle Identity Analytics documentation for information about creating the account.
Oracle Identity Analytics 11.1.1.5.2 provides information on the entitlements that caused a conflict. This information is visible under SoD Details. The entitlements under SoD Details will be displayed in an encoded form (for example, 4-695-24123) because this is how policies are created on OIA.

Note: The Oracle Identity Analytics Admin account with username rbacxadmin can also used.

Synchronizing Oracle Identity Manager Metadata With Oracle Identity Analytics
Import the resource metadata and resources from Oracle Identity Manage to Oracle Identity Analytics.
See the Oracle Identity Analytics documentation for more information.

Defining Identity Audit Policies in Oracle Identity Analytics
Set up identity audit rules and policies using Oracle Identity Analytics. Rules are created on the resource attributes. For entitlement SoD Check, give encoded values for roles and responsibilities as in Oracle Identity Manage.
See the Oracle Identity Analytics documentation for more information.

22.6 Enabling and Disabling SoD
The following sections contain information on enabling and disabling SoD.
- Enabling SoD
- Disabling SoD
22.6.1 Enabling SoD

To enable the SoD feature:

1. Set the 'Segregation of Duties (SOD) Check Required' system property to true. See "Managing System Properties" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about system properties.

2. Set the topologyName parameter in the Connector IT Resource instance to the value present in SILConfig.xml. If you are using default SIL registration, set the topologyName parameter in connector IT Resource to one of the following:
   - sodoaacg if you are using the EBS connector and OAACG as the SoD engine
   - oaacgpsft if you are using the PSFT connector and OAACG as the SoD engine
   - sodgrc if you are using GRC as the SoD engine
   - sodoia if you are using OIA as the SoD engine

   Note: Connector IT resource must have the ALL USERS role so that any user is able to access the IT Resource information. This is required for SOD requests raised by users.

3. Deploying SIL and SIL Providers

To deploy SIL and SIL providers for default combination of target systems and SoD engines:

   a. Create a new IT Resource for Sod Engine with the name (type) as follows:
      - For EBS-OAACG: OAACG-ITRes (eBusiness Suite OAACG)
      - For SAP-GRC: GRC-ITRes (SoD Provider)
      - For OIA: IT resource with name OIA-ITRes (OIA) is predefined.
      - For PSFT-OAACG: IT resource with name PSFT-OAACG-ITRes(OAACG) is predefined.

   b. Edit the created IT Resource as described in "Creating an IT Resource to Hold Information about the SoD Engine" on page 22-37.

   Note: To configure with OAACG 8.5 or higher, add a new field to this IT resource with name as sodServerURL and value http(s)://HOST_NAME:PORT/URI, where URL is grcc/services/GrccService. For OAACG8.2.1, the value of URL is ags/services/AGService.

4. Enabling SoD in Direct Provisioning and Access Policy Based Provisioning:

SoD is enabled only if Holder and SODChecker tasks are present in the provisioning workflow.

Enabling SoD in Request Provisioning:

Steps 1 and 2 enables default SoD check in approval. The default SoD check is performed before the request goes for approval. If the SoD check is required after one level of approval, then default SoD check approval workflow, which is DefaultSODApproval, must be attached by creating an approval policy. SoD check can also be performed in any approval workflow on demand. This can be done by
calling the SoD check Web service from BPEL. For more information, see "Modifying the Approval Workflow for SoD" on page 22-13.

---

**Note:** The DefaultSODApproval workflow consists of two approval tasks. When the workflow is triggered, an approval task is generated that is assigned to System Administrator, and SoD check is performed. Again an approval task is generated that is again assigned to System Administrators role. Any user who is a member of the System Administrators role can approve the second approval task after viewing the SoD Check results.

---

5. **Adding CSF Credentials for SoD Check:**
   a. Login to the Enterprise Manager, and on the left tab, expand Weblogic Domain.
   b. Open OIM_DOMAIN.
   c. On top of the right pane, from the WebLogic Domain list, select Security, and then open Credentials.
   d. Select the Create Key option, and then select Map 'oim'.
   e. Provide the key as sodcheck.credentials, and select Type as Password.
   f. Provide Username as oiminternal and password as **not used**. Click OK to save the key.

### 22.6.2 Disabling SoD

You can disable SoD by performing any one of the following:

- Set the 'Segregation of Duties (SOD) Check Required' system property to **false**.

- Set the value of the topologyName parameter for the connector IT Resource to **None** so that SoD check is not performed. Alternatively, you can remove this parameter to disable SoD check.

#### Disabling SoD in Direct Provisioning and Access Policy Based Provisioning

Disable the Holder and SODChecker process tasks.

**See Also:** The connector guide for detailed information about disabling these process tasks.

#### Disabling SoD in Request Provisioning

For disabling the default SoD check in approval, you can perform any one of the steps to disable SoD described in this section. If you want to perform the default SoD check in approval and only disable the SoD check in BPEL, then remove the approval policy for SoD, or remove the call to SoD Check web service from the approval workflow.

### 22.7 Enabling SSL Communication

The following sections contain information on enabling Secure Sockets Layer (SSL) communication for various SoD purposes.

- **Enabling SSL Between Oracle Application Access Controls Governor and Oracle Identity Manager**
22.7.1 Enabling SSL Between Oracle Application Access Controls Governor and Oracle Identity Manager

To enable SSL communication between Oracle Application Access Controls Governor and Oracle Identity Manager:

1. Export the certificate on the Oracle Application Access Controls Governor host computer as follows:

   a. Run the following commands from the JAVA_HOME/bin directory:
      
      ```
      keytool -genkey -alias tomcat -keyalg RSA -keystore JAVA_HOME/lib/security/.keystore
      keytool -export -alias tomcat -file JAVA_HOME/lib/security/server.cert -keystore JAVA_HOME/lib/security/.keystore
      ```
      
      After you run these commands, the server certificate (server.cert) is created in the JAVA_HOME/lib/security directory.

   b. In the TOMCAT_HOME/conf/server.xml file, enter the details of the keystore as attributes of the Connector element. See the following example:
      
      ```
      <Connector port="8443" maxHttpHeaderSize="8192" maxThreads="150" minSpareThreads="25" maxSpareThreads="75" enableLookups="false" disableUploadTimeout="true" acceptCount="100" scheme="https" secure="true" clientAuth="false" sslProtocol="TLS" keystoreFile="JAVA_HOME/lib/security/.keystore">
      ```
      
      2. Import the certificate on the Oracle Identity Manager host computer as follows:

      a. Copy the server certificate created on the Oracle Application Access Controls Governor host computer to the JAVA_HOME/lib/security directory of the Oracle Identity Manager host computer.

      b. Run the following command from the JAVA_HOME/bin directory:
      
      ```
      keytool -import -alias oaacg_trusted_cert -file JAVA_HOME/lib/security/server.cert -trustcacerts -keystore JAVA_HOME/lib/security/cacerts -storepass changeit
      ```

      Note: It is assumed that you have set sslEnable to true.
22.7.2 Enabling SSL Between SAP GRC and Oracle Identity Manager

To enable SSL communication between SAP GRC and Oracle Identity Manager export the certificate on the SAP GRC host computer as follows:

Note: In this section, JAVA_HOME refers to the directory on the Oracle Identity Manager host computer that is used to run the application server.

1. In a Web browser, open the Web Services Navigator page of SAP GRC Access Control. The URL is similar to the following:
   https://mysapserver01:50001/VirsaCCRiskAnalysisService/Config1?wsdl

2. The next step depends on the browser that you are using:
   - On Microsoft Internet Explorer: In the Security Alert dialog box, click View Certificate. On the Details tab of the dialog box, use the Copy to file button to export the certificate.
   - On Mozilla Firefox: Export the certificate as a .pem file. To be able to perform this step, you might need to download and install the Certificate Viewer enhancement from the Mozilla Web site.

3. Copy the certificate into the JAVA_HOME/lib/security directory used by the application server hosting Oracle Identity Manager.

4. In a terminal window, change to the JAVA_HOME/bin directory.

5. Run the following command to import the GRC certificate to cacerts:

   keytool -import -alias sapgrc_trusted_cert -file JAVA_HOME/lib/security/CERTIFICATE_FILENAME -trustcacerts -keystore JAVA_HOME/lib/security/cacerts -storepass changeit

   In this command:
   - CERTIFICATE_FILENAME is the name of certificate that has been exported from the SAP GRC host computer
   - The -storepass changeit clause specifies the password for the cacerts keystore.

6. When prompted to specify whether or not you want to trust the certificate, enter yes.

   The "Certificate was added to keystore" message is displayed.

22.7.3 Calling SoD Check Web Service Over SSL

SOA calls the Oracle Identity Manager Web service over the URL given as the oimFrontEndURL, which is the URL used to access the Oracle Identity Manager UI, in the oim-config.xml file. By default, this is a HTTP URL. You can change this to HTTPS so that communication takes place over SSL. The SSL port for Oracle Identity Manager can be viewed on the WebLogic Administrative Console.

To call SoD check Web service over SSL:

1. Locate the Oracle Identity Manager SSL port. To do so:
a. Login to the WebLogic Administrative Console.

b. Go to servers, OIM_SERVER. You can see that SSL Listen Port is enabled.

2. Change the oimFrontEndURL through the MBeans browser in Enterprise Manager. To do so:
   a. Login to Enterprise Manager.
   b. Go to OIM_SERVER.
   c. From the list on the top of the page, select System Mbeans Browser.
   d. Go to Application Defined Mbeans, oracle.iam, Server: oim_server1, Application: oim, XMLConfig, Config, XMLConfig.DiscoveryConfig, and Discovery. The attributes are displayed to the right.
   e. Click oimFrontEndURL, and change its value, as shown:

      https://HOST_NAME:SSL_PORT

    **Note:** The value of oimFrontEndURL can also be set at the time of installing Oracle Identity Manager.

3. Restart Oracle Identity Manager.

4. Create a request for SoD-enabled resource. You can view the new workflow instance in Enterprise Manager. The Web service will be called on SSL port.

    **Note:** It is assumed that Oracle Identity Manager and SOA are running on the same Java Runtime Environment (JRE). If SOA and Oracle Identity Manager are running on different JREs, then WebLogic certificate exchange is required for SSL communication. For details, see Oracle WebLogic Server 10g Release 3 (10.3) documentation in the Oracle Technology Network (OTN) Web site by using the following URL:

---

### 22.8 Configuring Workflows on Non SoD-enabled Connectors

Perform the procedures described in this section only if you are not using one of the preconfigured SoD-compatible connectors (Oracle e-Business User Management and SAP User Management). This section discusses the following procedures:

- **Modifying the Approval Workflow for SoD**
- **Modifying the Provisioning Workflow for SoD**

#### 22.8.1 Modifying the Approval Workflow for SoD

To modify the approval workflow for SoD validation:

    **Note:** Forms are created from the UI based on the connector process form. Request dataset is no longer required in Oracle Identity Manager.
1. In the IT resource of the connector, create the TopologyName parameter if it does not already exist. Figure 22–3 shows a sample IT resource in which this parameter has been added:

![Figure 22–3 The TopologyName Parameter](image)

If SoD Check property is set to true and topologyName parameter is set to the appropriate value in the connector IT Resource, then default SoD Check is performed in the preprocess stage of the approval workflow. After the request is created, the request status is changed to SoD check result pending for asynchronous SoD check and SoD check completed status for synchronous SoD check. For asynchronous SoD check, the Get SOD Check Results Approval scheduled job must be run to complete the SoD check.

**Note:** If there is an error while performing SoD check, then the SoD Check Status attribute in the request form is set to SoD check completed with error and the request moves for approval. Final decision is on the approver whether or not to approve the request although SoD check is not performed successfully.

2. In addition to the SoD check being triggered by default before any level of approval, it can be triggered by attaching the predefined DefaultSODApproval workflow. The workflow can be attached to the operational level of approval by creating an approval policy.

**Note:** In Oracle Identity Manager 11g, patches were required on SOA and WebLogic Server to allow the SoD workflow to work. Currently, no patch is required for Oracle Identity Manager.

For using the default workflow, see "Applying the Workflow By Using Approval Policy" on page 22-25. This workflow contains an approval task that is assigned to the system administrator. After this approval task, a call is made to the SoDCheck Web service to return the SoD check result. The workflow with SoDCheck Web service call is shown in Figure 22–4.
Note: There are two levels of approval for any request, request-level approval and operational-level approval. DefaultSODApproval workflow must only be attached at the operational level. For bulk requests, the request-level approval is common for all application instances and users. After this level of approval, separate requests are created for each combination of application instance and user. The workflow performs SoD check separately for each application instance and user at a time.

The workflow is useful when SoD Check is required after request-level approval. One such instance is when the connector IT resource information is entered by the approver.

Approval-only field is not supported in Oracle Identity Manager 11g Release 2 (11.1.2.2.0).

Figure 22–4  Workflow with SoDCheck Web Service Call

After this, a switch case with approval tasks are assigned to the System Administrators role. Any user that has this role can claim the task and approve it. The switch is based on whether the SoD check result has passed or failed, as shown in Figure 22–5:
Figure 22–5  Switch Case With Approval Tasks

Figure 22–6 shows the assignment of the approval task.

Figure 22–6  Assignment of the Approval Task

Approval workflow has migrated to BPEL in Oracle Identity Manager 11g Release 2 (11.1.2.2.0), and therefore, you must use JDeveloper to view or modify the default workflows. The default SoD workflow is available in the OIM_HOME/workflows/composites/DefaultSODApproval.zip file. You can unzip this file and open the DefaultSODApproval.jpr in JDeveloper. In addition, you can
create a new workflow by modifying any of the default approval workflows to call the SoD Check Web service and start SoD check on demand. To do so:

**Creating and Deploying Workflows on SOA**

**a.** Create a new workflow project by running `OIM_HOME/workflows/new-workflow/new_project.xml`.

Here:

- `WEBLOGIC_HOME` is the directory on which Oracle WebLogic Server is installed.
- `NEW_PROJECT` is the name of the new project that you want to create.

To create the new workflow project, run the following command:

```
ant -f new_project.xml
```

This prompts for Project Name, Application Name, and Service Name for the new workflow name. Provide any name, such as SODWorkflow for all three. This creates a new project with the provided name in the `workflows/new-workflow/process-template/` directory.

**b.** Navigate to `process-template/APPLICATION_NAME/PROJECT_NAME/` and open `PROJECT_NAME.jpr` from JDevepoler, where `APPLICATION_NAME` and `PROJECT_NAME` are the names of the application and project respectively.

The `PROJECT_NAME.jpr` workflow is same as the DefaultRequestApproval workflow. You can modify this workflow to call the SoDCheck Web Service. **Figure 22-7** shows the default workflow modified to perform SoD Check after human approval:
Extract `OIM_HOME/workflows/composites/DefaultSODApproval.zip` and copy `SodCheckServicePortImplService.wsdl` from the extracted directory to `OIM_HOME/workflows/process-template/APPLICATION_NAME/PROJECT_NAME/`. Add a Web service, such as `SODCheckService1`, in the composite.xml and provide the `asyncsod.wsdl` as the WSDL file. The SoDCheck partner link is as shown in Figure 22–8:

**Note:** BPEL connects to all external entities through a partner link.
d. In the ApprovalProcess.bpel design, include the following BPEL activities:

- **ASSIGN:** An assign activity must be added before calling the SoD Check Web Service. This activity initializes the parameters required to call the Web Service. To create an assign activity:
  
  i) Drag and drop the activity in the BPEL process opened in JDeveloper.
  
  ii) After the activity is created, double-click the activity, and click the **Copy Rules** tab.
  
  iii) Click **Add**, and then select **Copy Operation**. Provide the values for the variables, as shown in Table 22–1:

**Table 22–1 Variables to Assign**

<table>
<thead>
<tr>
<th>Copy From</th>
<th>Copy To</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML Fragment</td>
<td>Variable</td>
</tr>
<tr>
<td>&lt;EndpointReference xmlns=&quot;http://www.w3.org/2005/08/addressing&quot;&gt;</td>
<td>partnerlink</td>
</tr>
<tr>
<td>&lt;Address/&gt;</td>
<td></td>
</tr>
<tr>
<td>&lt;/EndpointReference&gt;</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Expression</th>
<th>Partner Link, EndpointReference, Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>concat(substring-before(bpws:getVariableData('inputVariable', 'payload', '/client:process/ns1:url'), '/' + workflowservice/CallbackService'), '/sodcheck/SoDCheckInitiateService')</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Partner Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>partnerlink</td>
<td>SODCheckService1</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Payload, RequestId</th>
<th>Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>SODInvoke_initiate_InputVariable, where SODInvoke_initiate_InputVariable is the variable defined in Invoke BPEL Activity</td>
<td></td>
</tr>
</tbody>
</table>

The following figures show the values to be added:
Figure 22–9 shows the final assign activity:

**Figure 22–9 Final Assign Activity**

![Assign Activity Diagram]

- **INVOKE**: The details for this activity are:
  - **Interaction Type**: Partnerlink
  - **Partnerlink**: SODCheckService
  - **Operation**: Initiate
  - **Input Variable**: SODInvoke_initiate_InputVariable

Figure 22–10 shows the Invoke dialog box with sample values in the fields:

**Figure 22–10 The Invoke Dialog Box**

![Invoke Dialog Box Diagram]

- **RECEIVE**: The details for this activity are:
  - **Interaction Type**: Partnerlink
  - **Partnerlink**: SODCheckService1
**Operation:** Result

**Variable:** SODResultReceive_result_InputVariable

Figure 22–11 shows the Receive dialog box with sample values in the fields:

---

**Figure 22–11  The Receive Dialog Box**

---

- **SWITCH:** This activity is to switch between workflows based on SODCheck Result. The switch case is as shown in Figure 22–12:
Figure 22–12 Switch Case

- **New Human Tasks**: A new human task may be created and assigned to an approver other than the system administrator. The new approval task is same as the old one already present in the workflow, except that the approver is different. This human task is used in the switch case. For example, if the SoD check passes, then the approval task can be assigned to a role. If the SoD check fails, then the approval task can be assigned to the System Administrators role. DefaultSODApproval always assigns approval task to the System Administrators role.

**Note**: The SoDCheck Web service can be called multiple times.

e. **Applying SAML policy for request and callback for the AsyncSoD Web service**:

OWSM SAML token with Message Protection Policy, which is based on Security Assertion Markup Language (SAML), is used as security policy for message protection in asynchronous calls for SoD checks from the SOA composite to Oracle Identity Manager. In asynchronous SoD check Web service, it is mandatory to use SAML token with Message Protection Client Policy for Request and SAML token with Message Protection Service Policy for Callback, as described in this section.

To apply SAML token with Message Protection Client policy for request:

i) Right-click **AsyncSoD** Web service, and select Configure WS Policies, and then select For Request, as shown in Figure 22–13.
To configure Workflows on Non SoD-enabled Connectors using Segregation of Duties (SoD), follow these steps:

i) In the Configure SOA WS Policies dialog box, in the Security section, click the plus (+) icon to add a security policy.

ii) In the Select Client Security Policies dialog box, select `wss11_saml_token_with_message_protection_client_policy` as shown in Figure 22–14, and then click OK.

Figure 22–14  Select Client Security Policies

To apply SAML or Username token with Message Protection Service Policy for callback:

i) Right-click `AsynchSoD` Web service, and select `Configure WS Policies`, and then select `For Callback`.

Using Segregation of Duties (SoD)  22-23
ii) In the Configure SOA WS Policies dialog box, in the Security section, click the plus (+) icon to add a security policy.

iii) In the Select Server Security Policies dialog box, select `wss11_saml_or_username_token_with_message_protection_service_policy` as shown in Figure 22–15, and then click OK.

![Select Server Security Policies](image)

**Figure 22–15 Select Server Security Policies**

f. Compile the project to see if there are any errors. If there are no errors, then right-click the project, and select **Deploy**. In the dialog box that is displayed, select any one of the following options:

- **Deploy to Application Server**: Select this option and then select the appropriate server. The workflow is directly deployed to the application server.

- **Deploy to JAR**: A JAR file is created under the JDeveloper deploy directory with the name `sca_PROJECT_NAME_rev1.0.jar`, where `PROJECT_NAME` is the name of the project.

g. From the `SOA_HOME/bin/` directory, deploy the workflow on SOA server by running the following command:

```
ant -f ant-sca-deploy.xml -DserverURL=http://SOA_SERVER_HOSTNAME:SOA_PORT
-DsarLocation=JDeveloper/deploy/sca_PROJECT_NAME_rev1.0.jar -Duser=SOA_USER
-Dpassword=SOA_PASSWORD
```

**Note:**

- In this guide, `SOA_HOME` refers to the directory on which SOA server is installed.

- Before running this command, ensure that the SOA server is running.
Configuring Workflows on Non SoD-enabled Connectors

Note: You must replace the following with valid values:

- SOA_SERVER_HOSTNAME
- SOA_PORT
- PROJECT_NAME
- SOA_USER
- SOA_PASSWORD

This deploys a new composite on SOA server. You can check if the composite is deployed by navigating to the following URL:

http://SOA_SERVER_HOSTNAME:SOA_PORT/soa-infra

In the URL, replace SOA_SERVER_HOSTNAME with the host name of the SOA server, and SOA_PORT with the port on which the SOA server is installed.

h. Restart the SOA server.

See Also: "Developing Workflows for Approval and Manual Provisioning" on page 21-1 for general procedure for creating a new workflow

Applying the Workflow By Using Approval Policy

a. Create approval policy for the request model to which you want to apply the SoD workflow. For example, if you want to perform SoD check while provisioning an application instance, then create a policy for the Provision Application Instance request model. See "Creating Approval Policies" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about creating approval policies.

Note:

- Always attach SoD workflow at the operational level of approval because SoD is triggered separately for each resource.
- Whether SoD Engine is asynchronous or synchronous, the SoD Check Web Service is always asynchronous and workflow modification remains the same for both.

22.8.2 Modifying the Provisioning Workflow for SoD

Each process definition has a process task attached to provision entitlements to a user. The SoD validation process must be performed before triggering this task and immediately after inserting all data in the child table that holds entitlements on the target system. Therefore, you must hold this process task until the SoD validation process is completed after inserting the data in child tables. To achieve this, you create a Holder task that precedes the provisioning of an entitlement to a user.

The Holder task is added to prevent provisioning of a resource to a user before the SoD validation process is completed. User entitlements are provisioned only if this task is complete. The task is completed when the SoD engine validates that SoD policies or rules are not violated by the assignment of the entitlements.
If an SoD validation process has been performed in approval workflow, then the SoD validation process need not be performed again even if the SoD validation process is enabled at the provisioning level. Whether the SoD validation process needs to be performed or not can be assessed by checking the following before the SoD validation process at the provisioning level:

- Is the provisioning related to a request?
- If yes, is the SoDCheckStatus field set to SoDCheckCompleted?
- If yes, then do not perform the SoD validation process during entitlement provisioning.

**Note:** The SoD validation process will be performed again only when the process child form is edited to add, update, or remove entitlements.

To modify the provisioning workflow for SoD validation:

1. Add a Holder task to the provisioning workflow. This task must be made conditional and the Allow Multiple instances option must be selected.

   The following figure shows this Holder task:

   ![Editing Task: Holder](image)

2. Make the connector insert, update, and revoke entitlement tasks dependent on the Holder task.

   The following figure shows all entitlement tasks of the Oracle e-Business User Management connector dependent on the Holder task:
3. Add the SODChecker task (any task whose name starts with SODChecker). This task must be made conditional.

The following figure shows the SODChecker task:
4. Attach the InitiateSODCheck process task adapter to the SoDChecker task.

Attach the following response codes to the SODChecker task:

<table>
<thead>
<tr>
<th>Response Code</th>
<th>Task Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SODCheckResultPending</td>
<td>P</td>
<td>The SoD validation process is initiated and results are awaited.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> This response code is for an SoD engine that returns responses synchronously.</td>
</tr>
<tr>
<td>SODCheckCompleted</td>
<td>C</td>
<td>The SoD validation process results have been returned, and the response shows that there is no SoD violation.</td>
</tr>
<tr>
<td>SODCheckViolation</td>
<td>C</td>
<td>The SoD validation process results have been returned, and the response shows that there is an SoD violation.</td>
</tr>
</tbody>
</table>
|                              |             | **Note:** For request provisioning of the EBS 9.1.0.7.0 resource with conflicting entitlements, the SodCheckViolation field in the process form is not updated. The entitlement violation is mapped to the field with the SoDCheckEntitlementViolation label, while the EBS resource has the field with the SoDCheckViolation label. Therefore, the mapping does not occur. Direct provisioning and provisioning through access policy successfully takes place with the SoDCheckViolation field label. To workaround this issue for request provisioning, change the SodCheckViolation field label to SoDCheckEntitlementViolation in the EBS form by using the Design Console.
|                              |             | **Note:** If the value is SoDCheckEntitlementViolation, then all types of provisioning, such as request, direct, and access policy, works fine. Therefore, you can keep the value as SoDCheckEntitlementViolation instead of changing the values. |
| SODCheckNotInitiated         | C           | The SoD validation process has not been initiated because SoD has not been enabled in Oracle Identity Manager. |

The following figure shows these response codes:
22.9 Marking Child Process Form Tables That Hold Entitlement Data

Child process form tables can hold different types of multivalued data, for example, role data, profile data, and address information. You must mark the child process form tables holding entitlement data that you want to use for SoD operations. See “Marking Entitlement Attributes on Child Process Forms” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for more information.

22.10 Custom Combination of Target Systems and SoD Engines

This section contains the following topics:

- Using a Custom Target System
- Adding Custom SoD Engine

22.10.1 Using a Custom Target System

**Note:**

Perform the procedure described in this section only if you want to use a target system other than Oracle e-Business Suite and SAP R3. You must also perform the procedures given in "Adding Custom SoD Engine" on page 22-37 if you are using an SoD engine other than Oracle Application Access Controls Governor and SAP GRC.

You can perform this procedure either before or at any time after first-time implementation of SoD in Oracle Identity Manager.

The following is a summary of the procedure to configure the SIL for a new target system:

1. Follow instructions given in the section "Addressing Prerequisites" on page 22-37.
2. Create Java class implementations of the IdMvsSoDDataTransformationOper interface for the connector. See "Creating the Transformation Layer" on page 22-30 for instructions.

4. Add entries in the registration XML file for the new target system. See "Modifying the Registration XML File" on page 22-31 for instructions.

5. Perform the procedure described in "Configuring Workflows on Non SoD-enabled Connectors" on page 22-13.

7. Register the new target system. See "Registering the New Target System" on page 22-32 for instructions.

22.10.1.1 Addressing Prerequisites
Ensure that the following prerequisites are addressed:

1. Load entitlement data from the target system to the SoD engine. For details, see vendor documentation for the SoD engine.

2. Deploy the Oracle Identity Manager connector for the target system. See the connector documentation for more information.

22.10.1.2 Creating the Transformation Layer
The transformation layer is used to transform target system attribute values into values that can be used by the SoD engine. The transformation layer is required to be created for any new SoD engine or target system type.

You must create the transformation layer as an implementation of the IdMvsSoDDataTransformationOper interface. Create implementations of the transformInput and transformSoDAnalysisInput methods in the implementation class of the IdMvsSoDDataTransformationOper interface.

See Also: Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for information about the implementation methods

In earlier releases of Oracle Identity Manager, the approval workflow data is read from the object forms. In Oracle Identity Manager 11g Release 2 (11.1.2.2.0), object forms are replaced by request datasets in the approval processes. As a result, the transformation layer must be changed so that entitlement data is read from the request dataset instead of object forms.

Transformation layer must also check the request model. If the request model is Provision Resource, then data must be read only from the request dataset. But if the request model is Modify Provisioned Resource, then data must be read both from the request dataset and process form.

22.10.1.3 Deploying the Transformation Layer
Transformation Service component is deployed as follows:

1. Create a JAR file for the Java classes that you created for implementation of the IdMvsSoDDataTransformationOper service component type.

2. Use the UploadJar utility to upload the JAR file as ThirdParty.
22.10.1.4 Modifying the Registration XML File

Enter the details of the transformation layer in the registration.xml file as follows:

1. Import the Registration.xml file from the MDS. The Registration.xml file is present with namespace `metadata\iam-features-sil\db\Registration.xml` in MDS.
2. Open the Registration.xml file in a text editor.
3. Add the SystemType and ServiceComponent elements as shown in this block of XML lines:

   ```xml
   <SystemType name="SYSTEM_TYPE_NAME" type="Sod Source DataStore"></SystemType>

   <ServiceComponent type="IdMvsSODDataTransformationOper" name="NAME_FOR_IMPLEMENTATION"
   <Impl-Class>NAME_OF_IMPLEMENTATION_CLASS</Impl-Class>
   <IdMSystemType>OIM</IdMSystemType>
   <SoDEngineType>SoD_ENGINE</SoDEngineType>
   <srcSystemType>SYSTEM_TYPE_NAME</srcSystemType>

   <DataTransformation>
     <AttrSoD type="user" name="NAME_OF_ATTRIBUTE_ON_TARGET_SYSTEM" sourceIdMAttrName="NAME_OF_ATTRIBUTE_ON_SOD_ENGINE" isSourceKey="true"/>
     <AttrSoD type="user" name="firstname" sourceIdMAttrName="firstname" isSourceKey="false"/>
     <AttrSoD type="user" name="lastname" sourceIdMAttrName="lastname" isSourceKey="false"/>
     <AttrSoD type="duty" dutyType="ENTITLEMENT_TYPE" name="accessorigid" sourceIdMAttrName="ENTITLEMENT_NAME" isSourceKey="true"/>
   </DataTransformation>
   
   <DataTransformation>...
   </DataTransformation>
   
   <DataTransformation>...
   </DataTransformation>
   </ServiceComponent>

Apply the following guidelines while adding the SystemType and ServiceComponent elements in the registration.xml file:

- Replace the placeholders with the following values:
  - SYSTEM_TYPE_NAME: Specify a name for the system type.

---

**Note:** The UploadJar.sh or UploadJar.bat utility is in the `OIM_HOME/bin/` directory. Run the utility from this location to upload the created JAR file to MDS.

**Note:** Values that you must set are highlighted in bold. Guidelines and sample values are given after this block of XML.
In the <SystemType> tag, type can have the SoD Source DataStore value for a custom target system, or SoD Engine as value for a custom SoD engine.

NAME_FOR_IMPLEMENTATION: Specify a name for the service component. For example: DBToOAACG

NAME_OF_IMPLEMENTATION_CLASS: Specify the name that you have set for the class that you create by performing the procedure described in "Creating the Transformation Layer" on page 22-30. For example: oracle.iam.grc.sod.scomp.impl.oaacg.transformation.IdMvsSoDDataTransformationOperDBvsOAACG

SoD_ENGINE: Enter OAACG if you are using Oracle Application Access Controls Governor as the SoD engine. Enter GRC if you are using SAP GRC as the SoD engine. If you are using a custom SIL provider, then enter the name that you set for that SoD engine.

See Also: "Adding Custom SoD Engine" on page 22-37

SYSTEM_TYPE_NAME: Specify the system type name that you entered earlier.

NAME_OF_ATTRIBUTE_ON_TARGET_SYSTEM: Specify the name of the attribute on the target system.

NAME_OF_ATTRIBUTE_ON_SOD_ENGINE: Specify the name of the corresponding attribute on the SoD engine.

ENTITLEMENT_TYPE: Enter the type of entitlement. For example: ROLE

ENTITLEMENT_NAME: Enter the name of one instance of the entitlement. For example: Resource Manager

Add one DataTransformation element for each attribute mapping that you want to create.

4. Save and close the Registration.xml file.

5. Export the Registration.xml file back to MDS.

22.10.1.5 Registering the New Target System

To register the new target system, perform the procedure described in the following sections:

- Running the Registration Script and Providing Registration Information
- Recording the Names of the System Types

22.10.1.5.1 Running the Registration Script and Providing Registration Information

The registration script (registration.sh and registration.bat) drives the registration process. When you run this script, it prompts you for the required information. The initial set of prompts displayed by the script are read from the registration.xml file. The registration script is in the OIM_HOME/bin directory. The registration.xml file is in the MDS.
Note:

- Before running this utility, set `APP_SERVER, OIM_ORACLE_HOME, JAVA_HOME, MW_HOME, WL_HOME,` and `DOMAIN_HOME`.

- You can run the registration script multiple times, at any time during the lifecycle of the Oracle Identity Manager installation. For example, you might want to register a new SoD engine. When you run the script, use the prompts to guide you to the section (set of prompts) in which you want provide input. You can skip the remaining sections.

See Example 22–1 for a sample run of the registration script. In that example, it is assumed that an IT resource has been created to provide information about the SoD engine.

To run the script and provide registration information for the Oracle Identity Manager installation, SoD engine, and target system:

1. Export the `SILConfig.xml` file from MDS. The `SILConfig.xml` file is present in MDS with namespace `/metadata/iam-features-sil/db/SILConfig.xml`.

2. Open the `SILConfig.xml` file in a text editor and provide values for the `DOMBuilderFactoryImpl` element.

   The value of the `DOMBuilderFactoryImpl` element depends on the JRE that you are using:

   - If you are using the Sun JRE or Oracle JRockit JRE, then uncomment the `DOMBuilderFactoryImpl` element containing the following value:
     
     ```
     ```

   - If you are using the IBM JRE, then uncomment the `DOMBuilderFactoryImpl` element containing the following value:
     
     ```
     org.apache.xerces.jaxp.DocumentBuilderFactoryImpl
     ```

3. In a command window, switch to the `OIM_HOME/bin` directory and run the registration script.

   Enter login information for Oracle Identity Manager. You are prompted to provide the values for Username, Password, and URL. The sample run segment is given below:

   ```
   [Enter the admin username:] OIM_ADMINISTRATOR_LOGIN
   [Enter the admin password:] OIM_ADMINISTRATOR_PASSWORD
   [Enter the service url:] t3://OIM_HOST_NAME:OIM_PORT_NO
   [Enter the Context Factory:] CONTEXT_FACTORY
   ```

   Specify valid values for:

   - `OIM_ADMINISTRATOR_LOGIN`
   - `OIM_ADMINISTRATOR_PASSWORD`
   - `OIM_HOST_NAME`
   - `OIM_PORT_NO`

   An example of the T3 URL is:
You are prompted to specify whether or not you want to proceed with registration:

Do you want to proceed with registration? (y/n)

---

**Note:** From this point onward, an explanation of each prompt displayed by the script is followed by the actual message of the prompt. The actual message is shown in monospace font in this document.

4. Enter `y` to proceed with the registration. You are prompted to specify whether or not you want to register an Oracle Identity Manager installation:

Register System Instance for type OIM? (y/n)

5. Enter `n`.

---

**Note:** From this point onward, the flow is specific to the registration of an Oracle e-Business Suite and Oracle Application Access Controls Governor installation. The flow is almost the same for the SAP R/3 and SAP GRC installation.

6. You are prompted to specify whether or not you want to register an Oracle e-Business Suite installation:

Register System Instance for type EBS? (y/n)

7. Enter `n` if you want to use the existing Oracle e-Business Suite, which is registered by default. Enter `y` if you want to register a new EBS instance with another IT resource in Oracle Identity Manager.

8. If you enter `y`, then you are prompted to enter an instance name for the Oracle e-Business Suite installation:

Provide instance name

Enter a name for the Oracle e-Business Suite installation. For example:

ebs2

9. You are prompted to specify whether or not you want to register an Oracle Application Access Controls Governor installation:

Register System Instance for type OAACG? (y/n)

Enter `n` if you want to use the existing OAACG, which is registered by default. Enter `y` if you want to register a new OAACG instance with another IT resource in Oracle Identity Manager.

10. If you enter `y`, then you are prompted to enter an instance name for the Oracle Application Access Controls Governor installation:

Provide instance name

Enter a name for the Oracle Application Access Controls Governor installation. For example:
11. You are prompted to enter the name of the IT resource that you have created:

OIM ITResource Instance Name:

Enter the name of the IT resource that you created: OAACG ITR2

12. If there are no more SoD components (system instances) to register, then enter n in response to the remaining prompts. Otherwise, similar steps must be followed for SAP, GRC, OIM SDS, and OIA instances. After this, you are prompted for custom System Type that you added in Registration.xml, say NEW.

Register System Instance for type NEW? (y/n)

13. Enter y. You are prompted to enter an instance name for the custom type, as shown:

Provide instance name

14. Enter a name for the installation, for example, new1. If the added system type is SoD Engine, then you are prompted to enter the name of the IT resource that you have created:

OIM ITResource Instance Name:

15. Enter the name of the IT resource that you created: ITR_NEW.

16. Open the SILConfig.xml file in a text editor and provide values for the Topologies element. For information about topology values, refer to "Recording the Names of the System Types" on page 22-36.

The following block of XML shows the Topologies element and its child elements:

```
<Topologies>
  <Topology>
    <name>[@topologyName]</name>
    <IdmId>[@Idm RegistrationId]</IdmId>
    <SodId>[@Sod RegistrationId]</SodId>
    <SDSId>[@Sds RegistrationId]</SDSId>
  </Topology>
</Topologies>
```

Enter values for the following child elements of the Topologies element:

- @topologyName: Enter a name for the topology.

```
Note: If you have multiple target system and SoD engine combinations, then you can add multiple Topology elements inside the Topologies element.
```

- @Idm RegistrationId: Enter the registration ID of the Oracle Identity Manager installation.

```
Note: Set the same name for the Topology element as the value of the TopologyName IT resource parameter.
```

- @Sod RegistrationId: Enter the registration ID of the SoD engine.
Custom Combination of Target Systems and SoD Engines

- @Sds RegistrationId: Enter the registration ID of the target system.

See Also: Step 2 in "Recording the Names of the System Types" on page 22-36 for information about the child elements of the Topologies element.

17. Import SILConfig.xml back to MDS.

Example 22–1 shows the output of a sample run of the registration script. Here, it is assumed that an IT resource has been created to provide information about the SoD engine.

Example 22–1 Sample Run of the Registration Script

```sh
sh registration.sh
Enter data related to login to OIM Server
[Enter the admin username:] OIM_ADMINISTRATOR_LOGIN
[Enter the admin password:] OIM_ADMINISTRATOR_PASSWORD
[Enter the service url:] t3://localhost:14000
Do you want to proceed with registration? (y/n)
y
Register System Instance for type OIM ?(y/n)
n
Register System Instance for type EBS ?(y/n)
n
Register System Instance for type OAACG ?(y/n)
n
Register System Instance for type SAP ?(y/n)
n
Register System Instance for type GRC ?(y/n)
n
Register System Instance for type NEW ?(y/n)
y
Provide instance name
new1
OIM ITResource Instance Name:
ITR_NEW
```

22.10.1.5.2 Recording the Names of the System Types At the end of the registration process, the names of the system types are set in the Oracle Identity Manager database. You can retrieve these names from the database by using the registration script. After you retrieve these names, you must enter them in the SILConfig.xml file.

To retrieve and record the names of the service components:

1. In a command window, switch to the following directory:
   
   \OIM_HOME\bin/
   
   2. Run one the following commands:

   For Microsoft Windows:
   
   registration.bat printRegistrationIDs
   
   For UNIX:
   
   registration.sh printRegistrationIDs
   
   The following is sample output of this command:
   
   -----------------------------------------------
   System Type     Instance Name  Registration ID
   -----------------------------------------------
Custom Combination of Target Systems and SoD Engines

---

<table>
<thead>
<tr>
<th>OIM</th>
<th>oiminstance</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBS</td>
<td>ebsinstance</td>
<td>2</td>
</tr>
<tr>
<td>SAP</td>
<td>sapinstance</td>
<td>3</td>
</tr>
<tr>
<td>OAACG</td>
<td>oaacginstance</td>
<td>4</td>
</tr>
</tbody>
</table>

3. Copy these instance names for your reference.

### 22.10.2 Adding Custom SoD Engine

**Note:**

Perform the procedure described in this section only if you want to use an SoD engine other than Oracle Application Access Controls Governor and SAP GRC. You must also perform the procedures given in "Using a Custom Target System" on page 22-29 if you are using a target system other than Oracle e-Business Suite and SAP R3.

You must install the SoD engine before you begin creating the SIL provider.

You can perform this procedure either before or at any time after first-time implementation of SoD in Oracle Identity Manager.

The following is a summary of the procedure to create a SIL provider:

1. Follow instructions given in the section "Addressing Prerequisites" on page 22-37.
2. Create an IT resource to hold information about the SoD engine. See "Creating an IT Resource to Hold Information about the SoD Engine" on page 22-37.
3. Create Java class implementations of the interfaces for the SIL provider. See "Implementing the Service Components for the Provider" on page 22-38 for instructions.
6. Register the new SoD engine. See "Registering the New SIL Provider" on page 22-41 for instructions.

#### 22.10.2.1 Addressing Prerequisites

Ensure that the following prerequisites are addressed:

1. Load entitlement data from the target system to the SoD engine. You can use any ETL utility to perform this step. For details, see vendor documentation for the SoD engine.
2. On the SoD engine, create policy definitions or risk definitions by using the data loaded from the target system.
3. Deploy the Oracle Identity Manager connector for the target system. See the connector documentation for more information.

#### 22.10.2.2 Creating an IT Resource to Hold Information about the SoD Engine

You must create an IT resource to hold information about the SoD engine.
See Chapter 4, "Developing Application Instances" for detailed information about creating an IT resource type (if it does not already exist) and IT resource. You can specify any name for the IT resource type and IT resource. The following table specifies the names of the parameters that the IT resource must contain:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Datastore Name</td>
<td>Enter the name of the source data store (the target system) that you defined in the SoD engine. You specify a source data store name while performing the procedure described in the &quot;Configuring Oracle Application Access Controls Governor&quot; on page 22-5 section.</td>
<td>EBS STMD122</td>
</tr>
<tr>
<td>dbuser</td>
<td>Enter the user name of the schema owner on the database used by the SoD engine. This account is used to access the Application Access Controls Governor database during SoD operations. Note: This parameter is specific to Oracle Application Access Controls Governor.</td>
<td>databaseusr1</td>
</tr>
<tr>
<td>dbpassword</td>
<td>Enter the password of the schema owner on the database used by the SoD engine. Note: This parameter is specific to Oracle Application Access Controls Governor.</td>
<td>Cyp100ne</td>
</tr>
<tr>
<td>jdbcURL</td>
<td>Enter the JDBC URL for connecting to the database used by the SoD engine. Note: This parameter is specific to Oracle Application Access Controls Governor.</td>
<td>jdbc:oracle:thin:@10.123.123</td>
</tr>
<tr>
<td>password</td>
<td>Enter the password of the account created on the SoD engine for API calls.</td>
<td>K1rb1r0s</td>
</tr>
<tr>
<td>port</td>
<td>Enter the number of the port at which the SoD engine is listening.</td>
<td>8090</td>
</tr>
<tr>
<td>server</td>
<td>Enter the IP address of the host computer on which the SoD engine is running.</td>
<td>10.231.231.231</td>
</tr>
<tr>
<td>sslEnable</td>
<td>Enter true if the SoD engine accepts only HTTPS communication requests. Otherwise, enter false.</td>
<td>false</td>
</tr>
<tr>
<td>username</td>
<td>Enter the user name of an account created on the SoD engine. This account is used to call the SoD engine APIs that are used during SoD validation.</td>
<td>jdoe</td>
</tr>
<tr>
<td>sodServerURL</td>
<td>Enter the URL of the SoD server, in the following format: http(s)://HOST_NAME:PORT_NUMBER/URL</td>
<td><a href="http://10.231.231.231:8090/grcc/services/GrccService">http://10.231.231.231:8090/grcc/services/GrccService</a></td>
</tr>
</tbody>
</table>

**Note:** If you want to use multiple SoD engines, then create multiple IT resources with the same IT resource type.

### 22.10.2.3 Implementing the Service Components for the Provider

Create Java implementations of the following service components:

**See Also:** Oracle Fusion Middleware Java API Reference for Oracle Identity Manager
Custom Combination of Target Systems and SoD Engines

- **SoDAnalysisExecutionOper**: The SoD analysis layer must be implemented for any custom SoD engine, which is not provided by default.
- **IdMvsSoDDataTransformationOper**: Used to transform target system attribute values into values that can be used by the SoD engine. The transformation layer is required to be created for any new SoD engine or target system type.
- **CallBackIdMOper (optional)**: To be implemented if any callback is required from SoD Analysis Layer to access Oracle Identity Manager.
- **SoDDataValidationOper (optional)**: To be implemented to provide any validation on the attributes given in SoD Analysis layer.

22.10.2.4 Deploying the Service Components

Service components created in "Implementing the Service Components for the Provider" on page 22-38 are deployed as follows:

1. Create a JAR file for the Java classes that you created for Service Component implementation.
2. Use the UploadJar utility to upload the JAR file as ThirdParty.

---

**Note:** The UploadJar.sh or UploadJar.bat utility is in OIM_HOME/bin. Run the utility from this location to upload the created JAR file to MDS.

22.10.2.5 Modifying the Registration XML File for the New SoD Engine

Enter the details of the transformation layer in the Registration.xml file as follows:

1. Import the Registration.xml file from the MDS. The Registration.xml file is present with namespace \metadata\iam-features-sil\db\Registration.xml in MDS.
2. Open the Registration.xml file in a text editor.
3. Add the SystemType element for the SoD engine, as shown:

   ```xml
   <SystemType name="SYSTEM_TYPE_NAME" type="SYSTEM_TYPE" isSynch="IS_SYNCH">
     <!-- The Parameters which are required to connect the SoD Engine. -->
     <Parameter name="PARAM_NAME1" required='true' />
     <Parameter name="PARAM_NAME2" required='true' />
     ...
   </SystemType>
   ```

   Here, replace:
   - **SYSTEM_TYPE_NAME** with a name for the system type.
   - **SYSTEM_TYPE** with SoD Engine.
   - **IS_SYNCH** with true or false, depending on whether the SoD engine is synchronous or asynchronous.
   - **PARAM_NAME** with the name of the parameter used to connect the SoD engine. These parameter values must be provided while registering the SoD engine. These are read in service component implementation classes to connect to the SoD engine.
4. Add all implemented service components, as shown:

   ```xml
   <ServiceComponent type="SERVICECOMPONENT_TYPE" name="NAME_FOR_IMPLEMENTATION">
     <Impl-Class>NAME_OF_IMPLEMENTATION_CLASS</Impl-Class>
   </ServiceComponent>
   ```
Custom Combination of Target Systems and SoD Engines

Here, replace:

- **SERVICECOMPONENT_TYPE**: Can have values such as CallBackIdMOper,
  SoDAnalysisExecutionOper, SoDDataValidationOper, or
  IdMvsSoDDataTransformationOper depending upon the type of service
  component.

- **NAME_FOR_IMPLEMENTATION**: Specify a name for the service component,
  for example, DBToOAACG.

- **NAME_OF_IMPLEMENTATION_CLASS**: Specify the name that you have set
  for the class that you create by performing the procedure described in
  "Creating the Transformation Layer" on page 22-30. For example:
  oracle.iam.grc.sod.scomp.impl.oaacg.transformation.IdMvsSoDDataTran
  sformationOperDBvsOAACG.

- **SOD_ENGINE**: Enter OAACG if you are using Oracle Application Access
  Controls Governor as the SoD engine. Enter GRC if you are using SAP GRC as
  the SoD engine. If you are using a custom SIL provider, then enter the name
  that you set for that SoD engine.

  **See Also**:  "Adding Custom SoD Engine" on page 22-37

- **SYSTEM_TYPE_NAME**: Specify the system type name that you entered
  earlier.
- **NAME_OF_ATTRIBUTE_ON_TARGET_SYSTEM**: Specify the name of the attribute on the target system.
- **NAME_OF_ATTRIBUTE_ON_SOD_ENGINE**: Specify the name of the corresponding attribute on the SoD engine.
- **ENTITLEMENT_TYPE**: Enter the type of entitlement, for example, **ROLE**.
- **ENTITLEMENT_NAME**: Enter the name of one instance of the entitlement, for example, **Resource Manager**.

5. Save and close the Registration.xml file.
6. Export the Registration.xml file back to MDS.

### 22.10.2.6 Registering the New SIL Provider

To register the new SIL provider, perform the procedure described in the following sections:

1. See "Running the Registration Script and Providing Registration Information" on page 22-32 for information on rerunning the registration script. In this run of the script, do not enter values for service components that have already been registered.

2. See "Recording the Names of the System Types" on page 22-36 for information on entering data about the new target system in the SILConfig.xml file.

### 22.11 Performing Role SoD Check with Oracle Identity Analytics

Role SoD Check is performed when a request to assign roles to, or revoke roles from, a user is raised. Role SoD Check with Oracle Identity Analytics is performed only when the request is raised; when roles are directly assigned or revoked, an SoD Check is not performed.

- **Enabling Role SoD Check**
- **Using Role SoD Check**

---

**Note:** Integration between Oracle Identity Manager and Oracle Identity Analytics is a pre-requisite for performing an SoD Check with Oracle Identity Analytics.

---

### 22.11.1 Enabling Role SoD Check

To enable Role SoD Check with Oracle Identity Analytics, you need to do the following.

1. Set the value of the 'XL.SoDCheckSystemProperty' system property to TRUE. See "Managing System Properties" in the *Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager* for information about system properties.

2. Set the value of the 'RoleSoDCheckTopologyName' system property to **sodoia**. This topology is predefined and registered.

3. Set OIA Connection Details in the 'OIA-ITRes' IT resource, as shown in the following figure:
22.11.2 Using Role SoD Check

The following sections describe how to implement the Role SoD functionality:

- SoD Check When A User Requests a Role
- SoD Check When A User Revokes a Role
- SoD Check When an Administrator Requests To Assign Roles
- SoD Check When an Administrator Requests To Revoke Roles

22.11.2.1 SoD Check When A User Requests a Role

The following steps are performed when a user raises a request for roles. SoD Check will be done if it has been enabled. This example procedure assumes that the user has already been assigned the Audit Reviewer role.

Perform the following steps:

1. Login to Oracle Identity Self Service as the user.
2. Under My Profile, click My Access. Click the Roles tab, and then click Request Roles. The Catalog page is displayed where you can search for the role to be requested.
3. Search for the specific role you want to assign to the user, for example Asset Management Team.
4. Click Add to Cart. This shows one item in the cart. Then, click Checkout.
5. Click Submit to submit the request for the role. The request is created.
7. Search for the request that you created. Open the request to see the SoD Check results. The SoD Status column should display SoD check complete.
8. Click on the SoD Status to see the SoD Check result, as shown in the following figure:
Performing Role SoD Check with Oracle Identity Analytics

SoD Check result is Failed because the Asset Management Team role, for which request is raised, and Audit Reviewer role, which the user already had, are conflicting.

The SoD Check result is available before request-level approval. Here, SoD Check has failed, but the administrator can approve the request to assign the conflicting role to the user.

22.11.2.2 SoD Check When A User Revokes a Role

This procedure assumes that the user has already been assigned the role being revoked.

Perform the following steps:

1. Login to Oracle Identity Self Service as the user.
2. Navigate to My Profile, My Access, and then click the Roles tab. The roles assigned to the user are displayed.
3. Select the role to be removed, and then click Remove Roles. The Remove Roles page is displayed with the selected role as the cart item.
4. Click Submit. The request is created.

You can open the request details to see the SoD Check result, as shown in the following figure:
Performing Role SoD Check with Oracle Identity Analytics

The SoD Check result is now Passed because a conflicting role has been removed.

22.11.2.3 SoD Check When an Administrator Requests To Assign Roles

This procedure allows the system administrator to assign a role to the user.

1. Login to Oracle Identity Self Service as the System Administrator.

2. Navigate to Administration, Users, search for users, and then open the details of the selected user.

3. Click the Roles tab, and then click Request Roles. The Catalog page is displayed.

4. Search for the Asset Management Team and Audit Reviewer roles, and add them to the cart. Click Checkout. The cart details is displayed with the added roles.

5. Click Submit. A request is created. Because this is a bulk request, SoD Check is not initiated for it.

6. Login to Oracle Identity Self Service as the system administrator, and navigate to Inbox, Pending Approvals, and then approve the request. Two child requests are created and SoD Check is performed for each child request.

7. Navigate to Track Requests, and open each child request to see the SoD details. The following figure shows the SoD details for the request created for Audit Reviewer role:
The following figure shows the SoD details for the request created for the Asset Management Team role:

22.11.2.4 SoD Check When an Administrator Requests To Revoke Roles
This procedure allows the system administrator to revoke a role from the user:

1. Login to Oracle Identity Self Service as the system administrator.
2. Navigate to Administration, Users, search for users, and then open the details of the selected user.
3. Click the Roles tab, select the roles to be removed, and then click Remove Role.

**Note:** A request is created to remove more than one role. For a single role, no request is created, and therefore, no SoD Check is performed.

4. On the Remove Roles page, click Submit. A request is created.
5. Approve the request. Two requests are created and SoD Check is performed for each request. The following figure shows the SoD Check result for the request created for the Audit Reviewer role:
The following figure shows the SoD Check result for the request created for the Asset Management Team role:

Because the request is raised by the System Administrator and there is no SoD Conflict, both the child requests are approved by default.

**Note:** By default, operational-level approval is triggered for requests that are raised by the System Administrator only if the SoD Check result is Failed because a conflict is detected.

### 22.12 Using SoD in Provisioning Workflow

This section describes various use cases related to SoD:

**Note:** The procedures in this section are for Synchronous SoD Engine, for example OAACG, for which you do not need to run the scheduled job to complete the SoD check.

- Provisioning Application Instance With Child Data
- Modifying Application Instance to Add or Delete Child Data
- Provisioning Entitlements to a User
- Revoking Entitlements From a User
- Requesting for Roles and Entitlements
- Requesting for Roles and Application Instances With Child Data
- Request Provisioning With the DefaultSODApproval Workflow
- Requesting for Role With an Access Policy Attached
- Provisioning Based on Access Policies Without Approval
- Provisioning Based on Access Policies With Approval
- Requesting for Entitlements From Two Application Instances
22.12.1 Provisioning Application Instance With Child Data

To provision an application instance as the system administrator:

1. Create a user whose account is to be created on the target system.
2. On the User Details page, click the Accounts tab, and click Request Accounts. The Catalog page is displayed.
3. Search for the application instance, for example EBS.
4. Add the application instance to cart, and checkout.
   The form that is added to the application instance is displayed on the Cart Details page. This form contains the default SoD check fields, such as SoDCheckStatus, SoDCheckTrackingID, SoDCheckResult, SoDCheckTimestamp, and SoDCheckEntitlementViolation. These fields are populated with values for SoD check.
5. Provide the required details in the form. Make sure that you provide entitlement in the child forms. Otherwise, SoD check will not be performed because SoD is required only to check for conflicting entitlements.
6. Click Ready to Submit, and then submit the request. Because this a request for a single user for a single application instance, no request is created and the application instance is directly assigned to the user.

   Because synchronous SoD Check has happened, you can see the SoD Check result on the Account Details page. If you select conflicting entitlements, then the SoD Check will fail and the entitlements will not get provisioned on the target system. Figure 22–16 shows the SoD Check Result.

   **Figure 22–16  Conflicting Entitlements**

   ![Image of Conflicting Entitlements]

   If you open the resource history, the Holder task is displayed in Canceled state because SoD Check resulted in a conflict. In addition, the SoDChecker task is in Completed state indicating that SoD Check has completed. Figure 22–17 shows the resource provisioning details.

   **Figure 22–17  Resource Provisioning Details**

   ![Image of Resource Provisioning Details]
Using SoD in Provisioning Workflow

**Figure 22–17 Resource Provisioning Details**

![Resource Provisioning Details](image1.png)

If the steps to provision an application instance are performed by a user with viewer admin role, a request is created. SoD Check result is visible in this request. Approver has the authority to approve or reject the request after seeing the SoD Check result. Figure 22–18 shows the SoD Check result in request details:

**Figure 22–18 SoD Check Result in Request Details**

![SoD Check Result in Request Details](image2.png)

### 22.12.2 Modifying Application Instance to Add or Delete Child Data

Whenever you open the user details, select an already provisioned account, and try to modify it by adding, updating, or deleting an entitlement in the child form, SoD check is triggered. If this operation is performed by the system administrator, new Holder and SoDChecker tasks are generated. If the new entitlement conflicts with the old ones, then the new entitlement is not provisioned. Otherwise, the new entitlement is provisioned on the target system.

If the operation is performed by the user with view admin role, a new request for modifying application instance is created. SoD Check result can be seen in this request.
22.12.3 Provisioning Entitlements to a User

Entitlements are first level entities in Oracle Identity Manager. Therefore, entitlements can be directly requested, as follows:

- **System Administrator requests for a single entitlement for a user:** The SoD Check is done and entitlement is granted to the user if it does not conflict with any of the existing entitlements. SoD Check results can be seen in the Account Details page. The Holder and SoDChecker tasks are created for performing the SoD Check.

- **System Administrator requests for multiple entitlements:** For bulk operation, requests are created. Therefore, if the system administrator requests for two entitlements, then a request r1 is created. SoD Check is always done at the child request level, and therefore, no SoD Check is done for r1. After the request-level approval is obtained for r1, two child requests r2 and r3 are created. SoD Check is done for both the child requests. Result can be seen in the Request Details.

- **User requests for single entitlement:** This results in a request being created because the user cannot directly get the entitlement. An approver must approve it. SoD Check is done for the request. No Holder or SODChecker tasks are created.

22.12.4 Revoking Entitlements From a User

Revoke entitlement use cases are similar to provisioning entitlements, as described in "Provisioning Entitlements to a User" on page 22-49. When the last entitlement is revoked from the user, no SoD Check is done because the user does not have any entitlements.

22.12.5 Requesting for Roles and Entitlements

Oracle Identity Manager supports heterogeneous requests that allow you to request for roles along with entitlements. To do so, open the Catalog page, search for the required entities, select the entities, and submit. This result in the creation of a request. When this request is approved, child requests are created for the requested entities. SoD Check is done for each of these child requests. Roles and entitlements are sent for separate SoD Checks.

**Note:** SoD Check conflict is not detected between roles and target system entitlements. If request is raised for the two, they go through separate SoD Checks.

22.12.6 Requesting for Roles and Application Instances With Child Data

This is similar to requesting for roles and entitlements, as described in "Requesting for Roles and Entitlements" on page 22-49. Separate SoD Check is done for application instance and role.

22.12.7 Request Provisioning With the DefaultSODApproval Workflow

When the DefaultSODApproval workflow has been specified by using an approval policy, perform the following steps to request for provisioning:

1. Specify the DefaultSODApproval workflow at the operational level. Therefore, the steps before the operational level of approval remain the same.
2. When the request moves to operational level of approval, per the DefaultSODApproval workflow, the approval task is assigned to the System Administrators role. If the administrator approves this task, then the SoD check Web service is loaded, and SoD check is initiated.

This can be confirmed by checking the request status, which must be SoD check completed.

3. An approval task is generated that is again assigned to the System Administrator.

4. Before approving the task, verify the SoD check results in the request details. If the task is approved, then the account and/or entitlement provisioning continues.

In this use case, SoD check is performed two times. First is the default SoD check before any level of approval, and the second one is initiated by the DefaultSODApproval workflow.

22.12.8 Requesting for Role With an Access Policy Attached

If the role is requested by an end-user and the request is for multiple roles, then SoD Check is first be done for the roles. After the request is approved and the role is assigned to the user, run the Evaluate User Policies schedule job to evaluate the access policy. Then, account provisioning is triggered. This again results in SoD Check for the account being provisioned if child data is requested for. SoD Check result can be seen in the Account Details page. If account is provisioned without child data, then no SoD Check is done.

Note: See “Predefined Scheduled Tasks” in Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager the for information about the Evaluate User Policies schedule job.

22.12.9 Provisioning Based on Access Policies Without Approval

To perform provisioning based on access policies:

1. Create a new role.

2. Create an access policy (without approval) to provision SoD-enabled resource to the new role. Make sure that you provide entitlements in the child form.

3. Assign this role to a newly created user. Run the Evaluate User Policies scheduled job to trigger the access policy and provision the account on the target system. But entitlement provisioning will wait for SoD check.

4. Check the Account Details to verify the SoDCheckStatus field value. If the SoD check is successfully completed, then the value of the SoDCheckStatus field is SoD Check Completed, and the SoDChecker task will be in Completed state.

The Holder task status depends on the SoD Check result. If the SoD check passes, then the Holder task is completed and entitlements are provisioned. Otherwise, the Holder task is canceled and no entitlement provisioning takes place.

22.12.10 Provisioning Based on Access Policies With Approval

When an access policy is created with approval, request is created for account provisioning. After the role is assigned to the user and the Evaluate User Policies schedule job is run, a request is created to provision account to the user. SoD Check is done for this request.
22.12.11 Requesting for Entitlements From Two Application Instances

A request can be raised for two entitlements from different application instances, one for which SoD Check is enabled and other for which it is not enabled. Here, SoD Check is performed for the entitlement for which SoD Check is enabled.

Note: SoD Check is not supported between entitlements from different application instances. For example, SoD Check is not supported between an EBS and a PSFT entitlement.

22.13 Enabling Logging for SoD-Related Events

If you want to enable logging for all SoD-related events

1. In a text editor, open the $DOMAIN_HOME/config/fmwconfig/servers/OIM_SERVER/logging.xml file.
2. Search for the <loggers> element. The following is a sample <loggers> element:

   `<loggers>
     <logger name="" level="WARNING:1">
       <handler name="odl-handler"/>
       <handler name="wls-domain"/>
       <handler name="console-handler"/>
     </logger>
   </loggers>`

   You can change the logging level to INCIDENT_ERROR:1, ERROR:1, NOTIFICATION:1, NOTIFICATION:16, TRACE:1, TRACE:16, or TRACE:32. The default logging level prints the error and warning messages.

22.14 Troubleshooting SoD Check

Table 22–2 lists the troubleshooting steps that you can perform if you encounter errors while performing SoD check.
### Table 22–2  Troubleshooting SoD Check

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The SoDCheckStatus field in the process form displays no value or default value. For the field in EBS connector, SoD Check not initiated is the default value. Also, the SoDCheckResult field is not populated.</td>
<td>This means that SoD configuration is incorrect. Check if the Segregation of Duties (SOD) Check Required system property is set to <code>true</code>. If yes, then check the value of topologyName in connector IT resource field. If default registration is used, then the value of the topologyName parameter is <code>sodoaacg</code> for OAACG SoD engine and <code>sodgrc</code> for SAP GRC. If registration is done manually, then check if the corresponding topology is defined in the SILConfig.xml file and this file is seeded into MDS after the change.</td>
</tr>
</tbody>
</table>
| The SoDCheckStatus field in the Request form displays Sod check completed with error. | SoD configuration is correct but SoD engine connection information might be incorrect, or there is an error from the SoD engine. Errors from the SoD engine can occur because of the following reasons:  
  - SoD engine or its corresponding database is down.  
  - SoD engine is not completely synchronized with the target system.  
  Therefore, specific entitlements for which SoD check is initiated may not be present on the SoD engine.  
  Check the SoD engine log for further errors. If no tracking ID is returned by the SoD engine, then simulation is not started successfully. |
| The SoDCheckResult field displays Error from SoD Engine.                | Make sure that you run the Get SoD Check Results Provisioning scheduled job and not the scheduled job for approval. Make sure that the scheduled job is triggered. You may enable logging at DEBUG level to confirm this.  
  If the scheduled job is run and the SoD check is still not completing, then there must be an error from the SoD engine. Check the SoD engine log for details. |
| The SoDCheckStatus field in the process form is in the SoD Result Pending status, and does not move to the SoD Check Completed status even on running the scheduled job. | When requesting for SoD-enabled resource, no SoD fields are displayed in the Request form after creating the request, and the request directly moves to the request-level approval.  
  This error means that SoD configuration is incorrect. Check if the Segregation of Duties (SOD) Check Required system property is set to `true`. If yes, then check the value of topologyName in the connector IT resource field.  
  If default registration is used, then the value of the topologyName parameter must be `sodoaacg` for the OAACG SoD engine and `sodgrc` for SAP GRC.  
  If registration is performed manually, then check if the corresponding topology is defined in the SILConfig.xml file and this file is seeded into MDS after the change. |
| The SoDCheckStatus field in the Request form stays in the SoD Result Pending status and does not move to the SoD Check Completed status even on running the scheduled job. | Make sure that you run the Get SoD Check Results Approval scheduled job and not the scheduled job for approval. Make sure that the scheduled job is triggered. You may enable logging at DEBUG level to confirm this.  
  If the scheduled job is run and the SoD check is still not completing, then there must be an error from the SoD engine. Check the SoD engine log for details. |
| The SoD check is successfully performed during request provisioning, but the resource state in the user profile does not display as Provisioned. Therefore, the request is in the Operation Initiated status. | Make sure that you run the Get SoD Check Results Approval scheduled job and not the scheduled job for approval. Make sure that the scheduled job is triggered. You may enable logging at DEBUG level to confirm this.  
  If the scheduled job is run and the SoD check is still not completing, then there must be an error from the SoD engine. Check the SoD engine log for details. |

22-52  Oracle Fusion Middleware Developer’s Guide for Oracle Identity Manager
### Troubleshooting SoD Check

**Table 22–2 (Cont.) Troubleshooting SoD Check**

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The SoD check is successfully performed during direct provisioning, but the resource state in the user profile is not Provisioned.</td>
<td>Check the process tasks in the resource history. If only the System Validation task is displayed, then the required data might not have been saved in the form. This can happen if the Auto-Save option is on in the process definition, and therefore, the form is not displayed during direct provisioning. You can try saving the form manually by opening the form in edit mode and clicking Save. Disable the Auto-save option in the process definition for future requests. If other tasks, such as the task to create an account on the target system, are displayed in the resource history, then check the task details to verify if there is an error from the target system. For example, the account being created already exists on the target system.</td>
</tr>
<tr>
<td>Request provisioning has been successfully done and appropriate values are displayed in the Request form, but the SoD status and result are not reflected to the Account form.</td>
<td>Check the SoD field labels in the process form. They must be SoDCheckStatus, SoDCheckTrackingID, SoDCheckResult, SoDCheckTimestamp, and SoDCheckEntitlementViolation. If you change these field labels, then SoD field will not be mapped from the Request form to the Account form.</td>
</tr>
</tbody>
</table>
| A particular SoD request is being tried several times and generating error. | There may be a problem with the SoD configuration or error in data submitted in a particular request. If you see that the traces of error for a request though SoD configuration is correct and you want to ignore the particular request, then you can prevent the JMS message related to the request from being tried multiple times by changing the Redelivery Limit for the OIMSODQueue from the WebLogic Administrative Console. To do so:  

1. Login to the WebLogic Administrative Console.  
2. Go to Services, Messaging, JMS Modules, and OIMJMSModule. The list of all the queues are displayed.  
3. Click oimSODQueue, and then click Delivery Failure.  
4. Change the value of Redelivery Limit from -1 to a positive value. This determines how many times a SoD JMS message will be retried. |
| Error in task assignment rules evaluation. Error in task assignment rules evaluation for user null. The error is Error in getting owners for "[0]" in configuration "[1]". Error occurred in getting owners for "SYSTEM ADMINISTRATORS" in configuration "jazn.com". Ensure that the group name is valid and has associated owners. Contact Oracle Support if error is not fixable. Make sure that the rules specified for user null are valid. | Ignore this error. The reason for this error is that the OIMDBProvider does not support getting owners for a role. Therefore, SOA logs this error. |
### Table 22–2 (Cont.) Troubleshooting SoD Check

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>When trying to perform SoD check by using the DefaultSODApproval workflow, the following error message is displayed:</td>
<td>Add <code>sodcheck.credentials</code> as described in step 5 of &quot;Enabling SoD&quot; on page 22-9.</td>
</tr>
<tr>
<td>Unknown Credential type to find the password for the given map: oim key: sodcheck.credentials</td>
<td>The SoD Engine IT resource has not been created. Therefore, according to the SoD Engine that is to be used, the corresponding IT resource must be created. For example, for OAACG, create OAACG-ITRes.</td>
</tr>
<tr>
<td>The following error is displayed:</td>
<td></td>
</tr>
<tr>
<td>[exec] Caused By: Thor.API.Exceptions.tcITResourceNotFoundException</td>
<td></td>
</tr>
<tr>
<td>[exec] at com.thortech.xl.ejb.beansimpl.tcITResourceInstanceOperationsBean.getITResourceInstanceParametersData</td>
<td></td>
</tr>
</tbody>
</table>
| If SoD is enabled for more than one SoD Engine, for example OAACG and OIA, and you try to start SoD check with OIA, then errors might be logged from OAACG files. | This problem occurs if the topology entries in the SILConfig.xml file are incorrect. To see these entries, export the SILConfig.xml file from MDS. For default providers, the SILConfig.xml file has the SIL registration IDs corresponding to the topology names. The IDs in SILConfig.xml and the IDs that SIL registration script returns must be same. For example, the IDs for sodoia topology in SILConfig.xml are: |<IdmId>1</IdmId><SodId>7</SodId><SDSId>6</SDSId>

Then the IDs returned by the registration script are:
1 oimInstance
6 oimSDSInstance
7 oiaInstance

If these are different, then change the IDs in the SILConfig.xml file and reimport it by using the MDS utility. |
Part V
Data Synchronization

This part contains chapters that describe customizing reconciliation and developing LDAP containers and scheduled tasks.

It contains the following chapters:

- Chapter 23, "Customizing Reconciliation"
- Chapter 24, "Using the Bulk Load Utility"
- Chapter 25, "Configuring LDAP Container Rules"
- Chapter 26, "Developing Scheduled Tasks"
This chapter describes reconciliation features and architecture and the various aspects of customizing reconciliation operations in the following sections:

- Reconciliation Features
- Reconciliation Architecture
- Defining Reconciliation Rules
- Developing Reconciliation Scheduled Tasks
- Updating Reconciliation Profiles Manually
- Understanding Reconciliation APIs
- Postprocessing for Trusted Reconciliation
- Troubleshooting Reconciliation
- Populating Data in the RECON_EXCEPTIONS Table
- Reconciliation Best Practices
- Monitoring Reconciliation Performance Using DMS

23.1 Reconciliation Features

Reconciliation features can be divided into the following categories:

- Performance Enhancement Features
- Web-Based Event Management Interface
- Other Features

23.1.1 Performance Enhancement Features

The following features help increase performance during reconciliation:

- New Metadata Model - Profiles
- Parameters to Control Flow and Processing of Events
- Grouping of Events by Reconciliation Runs
- Grouping of Events by Batches
- Implementing Reconciliation Engine Logic in the Database
- Improved Java Engine
23.1.1.1 New Metadata Model - Profiles

If metadata is associated with a reconciliation target, then it limits the ability to run multiple jobs performing different types of reconciliation against the same target. Therefore, all configurations in various components of Oracle Identity Manager are stored centrally in an XML store called MDS.

For backward compatibility, current deployments continue managing their configurations through Oracle Identity Manager Design Console and the configuration continues to be stored in the Oracle Identity Manager database. The configuration APIs automatically read the configurations from the tables in Oracle Identity Manager and convert them into XML profiles, called default profiles, and associate those profiles with the existing reconciliation runs.

You manage all the metadata by using Oracle Identity Manager Design Console. Using Oracle Identity Manager Design Console, you can generate the default reconciliation profile. This can be used to regenerate the profile when reconciliation configurations are changed from Oracle Identity Manager Design Console. When configurations are imported from the Deployment Manager, the profile is generated by default.

All nondefault profiles can be completely managed by using any XML editor.

See Also: "Reconciliation Profile" on page 23-8 for information about reconciliation profiles

23.1.1.2 Parameters to Control Flow and Processing of Events

This section consists of the following topics:

- Parameters to Control Event Processing
- System Property to Control AutoRetry

Parameters to Control Event Processing

BatchSize is the parameter to control event processing. This dictates the size of the batch. A batch size of 1 is equivalent to processing of events one at a time. Batch size is available as a system property and can be managed from Oracle Identity Manager Design Console. The property name is OIM.ReconBatchSize. The default value of the system Batchsize parameter is 500. For information about system properties, see "Managing System Properties" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

System Property to Control AutoRetry

The Retry Count for recon event system property controls auto retry by indicating how many times an item needs to be retried before the reconciliation engine marks it as an error or sends it to manual queue. The value 0 for this property means that the auto retry option is not configured.

See Also: "Handling of Race Conditions" on page 23-5 for more information about auto retry

23.1.1.3 Grouping of Events by Reconciliation Runs

All the events created in the reconciliation database are grouped by reconciliation runs. All events in a reconciliation run are grouped with a common reconciliation run ID. Because each reconciliation run is associated with a profile, all events in a reconciliation run are processed by using the same profile. This helps in optimizing the
performance because the configurations have to be retrieved only once per reconciliation run.

Each profile can use a different batch size. This enhances system performance for each target reconciliation by tuning the appropriate batch for it.

### 23.1.1.4 Grouping of Events by Batches

Batches are introduced to increase system performance during reconciliation. A batch consists of a number of events. It is a unit of processing in the reconciliation engine. The size of the batch is configurable. Reconciliation runs are broken into fixed size batches. For example, if a reconciliation run consists of 9900 events and batch size is 1000, then that reconciliation run is divided into 10 batches each with size 1000, and last batch with size 900.

Processing a batch as a unit optimizes system performance by eliminating the overhead of processing one event at a time. This also allows performing bulk operations wherever possible. Batches can also run in parallel to balance the use of hardware resources.

### 23.1.1.5 Implementing Reconciliation Engine Logic in the Database

In earlier releases, all engine logic was implemented in Java and the processing happened one event at a time. In 11g Release 2 (11.1.2.2.0), most of the logic to process the events is implemented as stored procedures. A combination for processing at batch level and the logic being implemented in PLSQL makes it possible to perform bulk operations at the SQL layer. The following steps are performed in bulk (one batch at a time):

- Required data check
- Applying matching rules
- Applying action rules

### 23.1.1.6 Improved Java Engine

Processing that cannot be performed in stored procedures and must be performed in Java layer also provides better performance than earlier releases of the engine for the following reasons:

- Java engine performs bulk operations by default:
  - Submits events in batches to the database
  - Submits bulk postprocess orchestration depending on the action
- Performs bulk operations wherever possible.

### 23.1.1.7 Improved Database Schema

A notable performance enhancement from the new database schema in 11g Release 2 (11.1.2.2.0) is by using horizontal tables for storing event details for various targets instead of using a single vertical table for storing the event details from various targets. A horizontal table is used for each profile.

*See Also:* "Staging Tables" on page 23-4 for more information about horizontal tables
23.1.2 Web-Based Event Management Interface

Oracle Identity Manager provides a Web-based event management interface that allows you to manage the events from the Web. Authorized users are able to search for events, users, and handle exceptions by linking events with users and accounts. You can also close events, force failed events to be re-evaluated, and perform ad-hoc linking.

Ad-hoc linking refers to the ability provided to authorized users of the Event Management section to link an event to any user in Oracle Identity Manager. Although the reconciliation engine finds user matches for events, the user through this ad-hoc link feature can ignore those matches and select a different user. This allows you to handle exceptions resulting from error matches.

See Also: "Managing Reconciliation" in Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about the tasks performed to manage reconciliation events

23.1.3 Other Features

Other reconciliation features are described in the following sections:

- Staging Tables
- Handling of Race Conditions
- Ad Hoc Linking

23.1.3.1 Staging Tables

In earlier releases of Oracle Identity Manager, the reconciliation schema has one table to store all the event details from various targets. The list of attributes and their names and types that the various reconciliation events contain can vary from target to target. This means that events from one target can contain a different set of data compared to events from another target. The only way to store data from such events in a single table is by storing one attribute per row. Therefore, in earlier releases, each row in the event detail table represents a single attribute of reconciliation event data. For each attribute, it stores the event to which it belongs, the attribute name, type, and value. This is also referred to as vertical table in this document. Although vertical tables are beneficial from the point of view of flexibility and extensibility, it is not an efficient way to store event records from the performance prospective.

Storage in vertical tables is replaced by separate tables for each target, called horizontal tables or staging tables. They are called horizontal tables because instead of storing attributes of an event vertically in the table as rows (as many rows as there are number of attributes), the attributes of an event are stored as columns. This means that there are as many columns as there are number of attributes for a target. Each event is stored as a row. Because different targets can have different sets of attributes, each target has a separate table in the reconciliation schema to store event details. There can be multiple tables per target because of requirements to handle multi-valued attributes that are stored as rows in child tables.

Each row of the event detail table for a specific profile stores the list of reconciliation fields for a single event. For example, for trusted user reconciliation in which firstname, lastname, email attributes are being reconciled, there is the RA_XELLERATE_USER staging table with the following columns:

RE_KEY, RECON_FIRSTNAME, RECON_LASTNAME, RECON_EMAIL
Creating and Maintaining Staging Tables

Staging tables can be created only when a target is being deployed against Oracle Identity Manager. This is because, at the time of target deployment, the reconciliation system knows the list of attributes and their types for the target, which needs to be reconciled.

Staging tables are updated when configurations are imported from the Deployment Manager or changes are made by using Oracle Identity Manager Design Console. To generate a staging table from Oracle Identity Manager Design Console, in the Object Reconciliation form, click **Generate Reconciliation Profile**.

23.1.3.2 Handling of Race Conditions

In earlier releases of Oracle Identity Manager, when an event is being reconciled, the reconciliation engine may not be able to process it successfully because before this event can be reconciled, another event needs to be reconciled. For example, before the reconciliation engine can reconcile an event that is supposed to create an account, the engine needs to reconcile an event that is supposed to create a user. This is called a race condition.

In Oracle Identity Manager 11g Release 2 (11.1.2.2.0), the race conditions are handled by setting the value of the 'Retry Count for recon event' system property. To configure auto retry, specify a value greater than 0 for this property. If you do not want to configure auto retry, then specify 0 as the value of the Retry Count for recon event system property.

When auto retry is configured, the reconciliation engine checks for the race conditions. If a race condition is found, then the reconciliation engine puts the reconciliation event in a re-evaluate queue until the retry count is exhausted.

A Reconciliation Retry Scheduled Task periodically checks if there is any event waiting for retry and is ready to be re-evaluated and if yes, it queues them up for reconciliation engine processing. This scheduled task is configured by default.

---

**Note:** If the auto retry count is exhausted, the reconciliation engine does not further process the event and sets the status per the matching rules. However, you can manually retry by requesting for re-evaluate from Event Management. For information about re-evaluating events, see "Re-evaluating Events" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager*.

---

Auto retry can handle the following race conditions:

- An account event for creating an account in Oracle Identity Manager is processed before the user is created for this event because the event for creating user is not processed yet.

- A user event for creating a Xellerate user in Oracle Identity Manager is processed before the organization is created to which this user belongs.

All auto retry parameters are stored as part of the reconciliation profiles. This means that while the events belonging to one reconciliation run may have auto retry configured, the events belonging to another reconciliation run may not have auto retry configured.

In Oracle Identity Manager, there is no UI to manage these parameters within a profile and you must use an XML editor to manage them by directly editing the XML profile. For information about editing an XML profile, see "Creating and Updating
Reconciliation Profiles” on page 23-24.

23.1.3.3 Ad Hoc Linking

If the reconciliation engine is not able to determine the owner based on the matching rules, then you can manually link an account to a user by using Oracle Identity Manager Advanced Administration. Subsequent modifications to the account is automatically linked to that account.

Ad hoc linking is supported for user and account events. If the reconciliation engine is not able to determine the owner based on the matching rules, then you can manually link a user or account event to a user.

See Also: "Ad Hoc Linking” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about how to perform ad hoc linking

23.2 Reconciliation Architecture

Reconciliation is the process of pulling entity data from the target system into Oracle Identity Manager to keep the entity data in a consistent state between the two systems. The various components of Oracle Identity Manager involved in reconciliation and the interaction between these components are shown in the Figure 23–1:

Figure 23–1 Reconciliation Architecture

The reconciliation architecture is described in the following steps:

1. Each connector has scheduled tasks associated with it. The scheduler triggers the connector scheduled task, which invokes reconciliation APIs to generate events. The event can be of type Regular, Changelog, or Delete.

For more information about the scheduler, see "Managing the Scheduler” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager. For more information about scheduled tasks, see "Connector for Reconciliation” on
2. The reconciliation events are stored in the reconciliation event repository, which is Oracle Identity Manager database.

3. When batch size is met, an asynchronous message is submitted which processes the batch of events in bulk. At the end of the schedule task another asynchronous message is submitted for processing the events of the last batch.

---

**Note:**

- In Figure 23–1, the reconciliation engine encapsulates the Action JAVA Layer as well as parts of the Reconciliation Event Repository, and orchestrates all the arrows in that diagram.
- In this release, trusted source reconciliation is supported for users only. It is not supported for roles, role membership, and role hierarchy reconciliation.
- In this release, Oracle Identity Manager supports trusted source reconciliation and account reconciliation for organizations.

---

4. The processing involves data validation, matching of the entities and action (create, update, delete and so on). This is followed by post processing via kernel orchestrations. For information about the action module, see "Action Module" on page 23-15. For information about the reconciliation profile, see "New Metadata Model - Profiles" on page 23-2.

5. By default the reconciliation event processing happens in bulk, and therefore all the steps till post processing are performed by PL/SQL stored procedures. Event can be processed one at a time in the following scenarios (in this case all the steps till matching are done in PL/SQL and the action is performed in java layer):

   - When events are processed from the Event Management UI
   - When failed events are retried by the retry scheduled task that runs periodically

   For reconciliation single event processing, actions and post processing take place through the kernel.

6. Reconciliation events are made available to the Event Management UI by another API call in the reconciliation management service.

The functionality of various components of the reconciliation service are explained in the following sections:

- Reconciliation Profile
- Reconciliation Metadata
- Reconciliation Target
- Reconciliation Run
- Reconciliation APIs
- Reconciliation Schema
- Reconciliation Engine
- Connector for Reconciliation
- Archival
23.2.1 Reconciliation Profile

A reconciliation profile is the configuration defined to govern how reconciliation is run for a particular resource. A particular resource can have multiple reconciliation profiles, each of which defines matching rules, action rules, and field mappings, which can differ in each profile corresponding to the resource. For example, while one reconciliation run can perform reconciliation of new and modified accounts, another reconciliation run can reconcile deletion of accounts because you might want to run the deletions only once a day. In this example, you define two reconciliation runs and two profiles. Each profile is associated with respective reconciliation run and each profile having its own rules of reconciliation.

The profile is an XML-based configuration file stored in Oracle Identity Manager MetaData Store (MDS). Example 23–1 shows a sample reconciliation profile:

Example 23–1 Sample Reconciliation Profile

```xml
<?xml version='1.0' encoding='UTF-8'?>
<profile xmlns="http://www.oracle.com/oracle/iam/reconciliation/config" ownerType="User"
changeType="CHANGELOG" auditEnabled="true" batchSize="500" resourceType="Account" name="Modified AD User" config="true" active="true">
  <matchingRule>((UPPER(USR.usr_udf_obguid)=UPPER(RA_ADUSERE469E5C8.RA_OBJECTGUID)))</matchingRule>
  <form oimTableName="UD_ADUSER" stagingTableName="RA_ADUSERE469E5C8" name="Modified AD User"
mls0imTable="mls0IMTableIfAny" mlsStagingTable="mlsStagingTableIfmls0IMTable">
    <matchingRule>(UD_ADUSER.UD_ADUSER_OBJECTGUID=RA_ADUSERE469E5C8.RA_OBJECTGUID)</matchingRule>
    <targetAttributes>
      <targetAttribute type="String" name="Status">
        <stagingField type="String" length="256" name="RA_STATUS"/>
      </targetAttribute>
      <targetAttribute type="String" name="copyStatus" ref="Status" mls="true">
        <stagingField type="String" length="256" name="COPY_STATUS"/>
      </targetAttribute>
      <oimAttribute type="String" fieldName="OIM_OBJECT_STATUS" fieldType="String" name="OIM_OBJECT_STATUS"/>
    </targetAttributes>
    <targetAttribute type="String" name="password" encrypted="true" keyField="false" required="false">
      <stagingField type="String" length="256" name="PASSWORD"/>
      <oimAttribute type="String" fieldName="UD_ADUSER_PASSWORD" fieldType="String" name="AD Password"/>
    </targetAttribute>
    <targetAttribute type="Date" name="accountExpires">
      <stagingField type="Date" name="RA_ACCOUNTEXPIRES"/>
      <oimAttribute type="Date" fieldName="UD_ADUSER_DATE" fieldType="Date" name="Account Expiration Date"/>
    </targetAttribute>
    <targetAttribute type="ITResource" name="IT Resource" keyField="false">
      <stagingField type="ITResource" length="19" name="RA_ITRESOURCE15641F83"/>
      <oimAttribute type="Number" fieldName="UD_ADUSER_AD" fieldType="Number" name="AD Server"/>
    </targetAttribute>
  </form>
</profile>
```
Table 23–1 describes the elements and the structure of the reconciliation profile XML file.

</tr>
</tbody>
</table>
There is always a default profile associated with reconciliation configurations for any resource object. The default profile can be explicitly generated from Oracle Identity Manager Design Console in the developer’s environment or implicitly generated during import from the Deployment Manager. For details on how to create and update profiles, see "Updating Reconciliation Profiles Manually" on page 23-23.

### 23.2.2 Reconciliation Metadata

The reconciliation metadata consists of various configurations used in creating and processing the reconciliation events. The reconciliation metadata is stored in a logical container called a profile. For information about reconciliation profile, see "Reconciliation Profile" on page 23-8.

Examples of the reconciliation metadata are:

- **Mapping rules**: Used to map the data received from the target system to the data managed about that target system in Oracle Identity Manager.
■ **Matching rules:** Used during the processing of each reconciliation event to correlate the event data to a particular account, user, or role in Oracle Identity Manager.

■ **Action Rules:** Used to specify the actions taken by Oracle Identity Manager based on the result of the processing of a reconciliation event.

■ **List of target attributes:** Used to define the data attributes received from the target system via reconciliation. It is used in the mapping rules, and is configured by using Oracle Identity Manager Design Console.

The various configurations used in creating and processing the reconciliation events are managed by using Oracle Identity Manager Design Console, and for backward compatibility, is stored in the same Oracle Identity Manager tables as in Oracle Identity Manager release 9.1.0. In addition, the configurations are also stored in the reconciliation profile.

---

**Note:** For reconciliation in Oracle Identity Manager, a metadata model is being used. See "Managing Reconciliation Events" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager*.

---

### 23.2.3 Reconciliation Target

Reconciliation target refers to an instance of an application that acts as a source of changes for Oracle Identity Manager. An example of reconciliation target is an HR system, which acts as a source of identities for Oracle Identity Manager. A reconciliation target can be a source of users or accounts.

### 23.2.4 Reconciliation Run

Reconciliation run refers to the combination of a reconciliation connector and associated configurations which when run by the scheduled task, performs the reconciliation based on the rules defined in the associated configurations. The scheduler runs reconciliation periodically at fixed intervals. Reconciliation runs are scheduled within Oracle Identity Manager scheduler to run at a specified frequency. All events created during a reconciliation run are grouped together by a unique reconciliation run ID.

### 23.2.5 Reconciliation APIs

These are a set of published APIs to provide reconciliation data to Oracle Identity Manager in the form of reconciliation events. Connectors can use the APIs to push data to the reconciliation event repository. Scheduled tasks can be setup to run the APIs when reconciliation is to be run on a scheduled basis. The existing connectors do not need to be changed because the existing APIs are supported.

### 23.2.6 Reconciliation Schema

The data that comes from the target system for reconciliation is stored in the reconciliation schema. The data contains the changes to be reconciled with Oracle Identity Manager.

Reconciliation schema refers to the set of schema tables to store the reconciliation data. The reconciliation schema is redesigned for performance reasons and future extensibility. See "Improved Database Schema" on page 23-3 for more information about the reconciliation schema.
23.2.7 Reconciliation Engine

The reconciliation engine uses all configurable components and includes the data processor and rule evaluator that use these components to convert input data into a list of action items. It also includes the components that determine whether or not the actions can be automated based on the rule context. When an action is performed, either automatically or manually, the engine performs the appropriate updates and provisioning actions.

The main task of the reconciliation engine is to perform the comparison, determine the action to be taken, and apply the action in Oracle Identity Manager. It contains two modules, which are described in the following sections:

- Matching Module
- Action Module

23.2.7.1 Matching Module

The matching rule specified in the profile is used to identify whether the record being searched, exists in Oracle Identity Manager or not. Matching rules are rules to identify whether the data is for an identity that Oracle Identity Manager already has a record of, or to identify the owner of the account in Oracle Identity Manager.

For account entities, when no record is found, an owner match is then performed to identify the owner of the account.

For role hierarchy events, matching is performed to identify the parent and child role.

---

**Note:** While performing role hierarchy and role membership reconciliation, the matching criteria must contain both Namespace and Role Name in the matching criteria. The following is an example of a matching rule:

```
((UGP.ugp_rolename=x) and (UGP.ugp_namespace=y))
```

Here, x is the name of the staging table name column that is mapped to Role Name, and y is the name of the staging column that is mapped to Namespace.

---

At the end of the evaluation, the match table contains all the possible matches found within Oracle Identity Manager that meet the criteria for the event, and the state of the event is updated to one of the statuses listed in Table 23–2:

<table>
<thead>
<tr>
<th>Status Events</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Received</td>
<td>Event data has been created in the database and is ready for further processing.</td>
</tr>
<tr>
<td>Event Received</td>
<td>A reconciliation event has been created and is ready for further processing. The finishReconciliationEvent API has not yet been called.</td>
</tr>
<tr>
<td>Data Validation Failed</td>
<td>The reconciliation event record is invalid. For example, a role event with an invalid role category will fail to validate. This situation could indicate a race condition.</td>
</tr>
<tr>
<td>Data Validation Succeeded</td>
<td>The event data was successfully validated and the event can now safely be processed by the Engine.</td>
</tr>
</tbody>
</table>
### Table 23–2  (Cont.) Reconciliation Status Events

<table>
<thead>
<tr>
<th>Status Events</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiple Accounts Match Found</td>
<td>Given the current matching rules, multiple matching account records were found for the data.</td>
</tr>
<tr>
<td>No Account Match Found</td>
<td>Given the current matching rules, no matching account records were found for the data.</td>
</tr>
<tr>
<td>Single Account Match Found</td>
<td>Given the current matching rules, one matching account record was found for the data.</td>
</tr>
<tr>
<td>Multiple Org Matches Found</td>
<td>Given the current matching rules, multiple matching organization records were found for the data.</td>
</tr>
<tr>
<td>No Org Match Found</td>
<td>Given the current matching rules, no matching organization records were found for the data.</td>
</tr>
<tr>
<td>Single Org Match Found</td>

<td>No matching records for user membership within a role were found.</td>
</tr>
<tr>
<td>Single Role Grant Match Found</td>
<td>One matching record for user membership within a role was found.</td>
</tr>
<tr>
<td>Multiple Roles Match Found</td>
<td>Given the current matching rules, multiple matching role records were found for the data.</td>
</tr>
<tr>
<td>No Role Match Found</td>
<td>Given the current matching rules, no matching role records were found for the data.</td>
</tr>
<tr>
<td>Single Role Match Found</td>
<td>Given the current matching rules, one matching role record was found for the data.</td>
</tr>
<tr>
<td>No Role Members Found</td>
<td>The Reconciliation Engine did not find role members matching the data, given the current matching rules.</td>
</tr>
<tr>
<td>No Role Parent Found</td>
<td>The Reconciliation Engine did not find a role matching the data, given the current matching rules.</td>
</tr>
<tr>
<td>Multiple Role Relationships Match Found</td>
<td>Given the current matching rules, reconciliation has found multiple role-to-role relationships that match data in the event.</td>
</tr>
<tr>
<td>No Role Relationship Match Found</td>
<td>Given the current matching rules, reconciliation did not find any role-to-role relationships that match data in the event.</td>
</tr>
<tr>
<td>Single Role Relationship Match Found</td>
<td>Given the current matching rules, reconciliation has found one role-to-role relationship that matches data in the event.</td>
</tr>
<tr>
<td>Multiple Users Match Found</td>
<td>Given the current matching rules, multiple matching user records were found for the data.</td>
</tr>
<tr>
<td>No User Match Found</td>
<td>Given the current matching rules, no matching user records were found for the data.</td>
</tr>
<tr>
<td>Single User Match Found</td>
<td>Given the current matching rules, one matching user record was found for the data.</td>
</tr>
<tr>
<td>Invalid Event Data Passed</td>
<td>The event contains invalid data.</td>
</tr>
<tr>
<td>Being Re-evaluated</td>
<td>The reconciliation event is being re-evaluated from the reconciliation event management UI.</td>
</tr>
<tr>
<td>Being Re-tried</td>
<td>The reconciliation event is being retried automatically. This status event has been deprecated.</td>
</tr>
<tr>
<td>Creation Failed</td>
<td>The user/account/role entity was not created successfully.</td>
</tr>
</tbody>
</table>
23.2.7.2 Action Module

This module applies the action based on the event state, entity type, and the action rules, as listed in Table 23–3:

<table>
<thead>
<tr>
<th>Event State</th>
<th>Entity Type</th>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>Race condition</td>
<td>Does not perform an action. The event needs to be re-evaluated.</td>
</tr>
</tbody>
</table>

23.2.8 Connector for Reconciliation

The connector refers to the software that extracts the changes from the target system and creates events in the reconciliation schema by calling the reconciliation APIs. If the connector that you want to use is shipped with a predefined reconciliation module, then a scheduled task definition is available. You use this component to control the frequency at which the target system is polled for changes to track data and other connector-specific parameters.

The connector for reconciliation is deployed by using the Deployment Manager. When the connector is deployed, the corresponding reconciliation profile for that connector is created in the metadata store (MDS), and horizontal tables that store the event data are also created.
Reconciliation Architecture

23.9 Archival

The Reconciliation Archival utility allows you to move processed events from the active reconciliation tables to archive tables. The events to move can be selected based on a time range. Only linked and closed events, which means successfully processed or closed by an administrator, can be archived.

23.10 Backward Compatibility

You do not need to change the existing reconciliation configurations or scheduled tasks to leverage the new reconciliation service.

The existing configurations for reconciliation setup in earlier Oracle Identity Manager releases continues to function after upgrading to 11g Release 2 (11.1.2.2.0). As part of the upgrade, corresponding reconciliation event tables are created for each of the existing object types being reconciled.

23.11 Reconciliation Event Management

The reconciliation events are managed by using the Event Management section of Oracle Identity System Administration. The Event Management section lets you view and manage reconciliation events generated by Oracle Identity Manager reconciliation engine. These events are generated through scheduled reconciliation runs. The Event Management section provides search capabilities on reconciliation runs as well as events. Users can use the Event Management section to perform reconciliation manually on generated events.

See Also: "Managing Reconciliation Events" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for more information about the managing reconciliation events in the Oracle Identity System Administration

Figure 23–2 shows the various stages in the lifecycle of a reconciliation event.
### 23.3 Defining Reconciliation Rules

You can define reconciliation rules that are invoked at the following instances:

- When Oracle Identity Manager tries to determine which user or organization record is associated with a change on a trusted source. These rules are evaluated as soon as all required fields in the reconciliation event are processed on the Reconciliation Data tab of the Reconciliation Manager form.

- When Oracle Identity Manager attempts to determine which user or organization record is the owner of an account discovered on a target resource, for example, as a result of a change detected on that system. These rules are evaluated only when all required fields in the reconciliation event are processed on the Reconciliation Data tab of the Reconciliation Manager form, and no processes were matched to the event on the Processes Matched Tree tab of the same form.

The Reconciliation Rules form in the Design Console is used to create and manage reconciliation rules in Oracle Identity Manager. This form is located in the Development Tools folder. Figure 23–3 shows the Reconciliation Rules form.
As mentioned, rules defined by using this form are used to match either users or organizations associated with a change on a trusted source or target resource. Rules of these types are referred to as user-matching or organization-matching rules, respectively. These rules are similar to the ones you can define by using the Rule Designer form except that the rules created by using the Reconciliation Rules form are specific to the resource object (because they relate to a single target resource) and only affect reconciliation-related functions.

Topics in working with reconciliation rules include:

- Defining a Reconciliation Rule
- Adding a Rule Element
- Nesting a Rule Within a Rule
- Deleting a Rule Element or Rule

### 23.3.1 Defining a Reconciliation Rule

The following procedure describes how to define a reconciliation rule.

**Note:** In the following procedure, you must ensure that the Active check box is selected. If this check box is not selected, the rule will not be evaluated by Oracle Identity Manager’s reconciliation engine when processing reconciliation events related to the resource. However, you can only select this check box after Oracle Identity Manager has selected the Valid system check box. The Valid check box can only be selected after you have created at least one rule element, and Oracle Identity Manager has determined that the logic of this rule element is valid.

To define reconciliation rules for user or organization matching:

1. Go to the Reconciliation Rules form.
Defining Reconciliation Rules

2. Enter a name for the rule in the **Name** field.

3. Select the target resource with which this rule is to be associated in the **Object** field.

4. Enter a description for the rule in the **Description** field.

   Select the **And** or **Or** operator for the rule. If **And** is selected, all elements (and rules if they are nested) of the rule must be satisfied for the rule to be evaluated to true. If **Or** is selected, the rule will be evaluated to true if any element (or rule if one has been nested) of the rule is satisfied.

5. Click **Save**.

   The rule definition will be saved. Rule elements must now be created for the rule.

### 23.3.2 Adding a Rule Element

To define individual elements in a reconciliation rule:

1. Go to the Rule definition to which you want to add elements.

2. Click **Add Rule Element** on the **Rule Elements** tab.

   The Add Rule Element dialog box is displayed.

3. Click the **Rule Element** tab.

4. Select a user-related data item from the **User Data** menu.

   This will be the user data element that Oracle Identity Manager examines when evaluating the rule element. The menu will display all fields on the Oracle Users form (including any user-defined fields you have created).

   **Note:** If the rule being defined is for organization matching, both the data available and the name of the menus will be related to organizations, rather than users.

5. Select an operator from the **Operator** menu.

   This will be the criteria that Oracle Identity Manager applies to the attribute for data item you selected when evaluating the rule element. The following are valid operators:

   - **Equals:** If you select this option, the user or organization record’s data element must exactly match the attribute you select.

   **Note:**

   - If you configure trusted source reconciliation of users, you must ensure that the **User ID** field of the Oracle Identity Manager User account is used in the reconciliation matching rule.

   - If you configure trusted source reconciliation of organizations, you must ensure that the **Organization Name** field of the Oracle Identity Manager User account is used in the reconciliation matching rule.

   - **Contains:** If you select this option, the user or organization record’s data element must only contain (not be an exact match with) the attribute you select.
- **Start with:** If you select this option, the user or organization record’s data element must begin with the attribute you select.

- **End with:** If you select this option, the user or organization record’s data element must end with the attribute you select.

6. Select a value from the *Attribute* menu. The values in this menu are the fields that were defined on the Reconciliation Fields tab for the resource associated with the rule. If the reconciliation fields have not yet been designated for the resource, no values will be available.

   **Note:** When defining a rule element for a target resource (as opposed to a trusted source), only fields associated with parent tables of the resource’s custom process form are available for selection in the *Attribute* field.

7. If you want Oracle Identity Manager to perform a particular transformation on the data in the *Attribute* field (before applying the operator), select the desired transformation from the *Transform* menu.

   **Note:** If you select a value other than None from this menu, after you click *Save*, you must also select the tab and set the appropriate properties so that Oracle Identity Manager is able to perform the transformation correctly.

The possible transformations are described in Table 23–4.

<table>
<thead>
<tr>
<th>Transformation</th>
<th>Properties to Be Set on the Rule Element Properties tab</th>
</tr>
</thead>
<tbody>
<tr>
<td>Substring</td>
<td>Start Point, End Point</td>
</tr>
<tr>
<td>Endstring</td>
<td>Start Point</td>
</tr>
<tr>
<td>Tokenize</td>
<td>Delimiters, Token Number, Space Delimiter</td>
</tr>
</tbody>
</table>

8. Select the **Case-Sensitive** check box.

   For the rule element to be met, if this check box is selected, the value selected in the *Attribute* field must match the capitalization of the value being evaluated in the reconciliation event record. If this check box is deselected, the value selected in the *Attribute* field is not required to match the capitalization used in the value being evaluated in the reconciliation event record.

9. Click *Save*.

10. If you select a value (other than None) in the *Transform* menu and have not yet set the properties for the transformation, the Properties Set check box will not be selected.

    You must select the *Rule Element Properties* tab, set the appropriate properties, and click *Save* again.

    The rule element will be added to the rule.

11. Repeat this entire procedure for each rule element you wish to add to the rule.
23.3.3 Nesting a Rule Within a Rule

You can nest an existing rule within a rule. Oracle Identity Manager evaluates the criteria of the nested rule in the same way as any other element of the rule.

1. Go to the rule to which you want to add another rule.
2. Click Add Rule on the Rule Elements tab.
3. The Rule Choice lookup dialog box is displayed. Locate and select the desired rule.
4. Click OK.
   The selected reconciliation rule is added to the rule.
5. Repeat steps 2 through 4 for each rule you want to nest in the rule.

23.3.4 Deleting a Rule Element or Rule

To delete a rule element or a rule:

1. Go to the rule from which you want to delete an element.
2. Select the rule element or rule to be deleted on the Rule Elements tab.
3. Click Delete.

23.4 Developing Reconciliation Scheduled Tasks

Oracle Identity Manager provides connectors for reconciliation of users/accounts from various target systems, such as Microsoft Active Directory, Sun Java System Directory, Oracle Internet Directory, and Oracle E-Business Suite. For information about these connectors, see Oracle Identity Manager Connectors Documentation in the Oracle Technology Network (OTN) Web site at the following URL:

However, to create a custom connector, you must develop a new scheduled task that performs the following:

1. Retrieve user/account information from the target system.
2. Use reconciliation APIs to create reconciliation events to submit event data.
3. Create events for creating, modifying, or deleting an entity.

See Also: Chapter 26, "Developing Scheduled Tasks" for information about developing a scheduled task

To connect to a specific target system, you must:

- Create a new IT resource type
■ Define a new IT resource
■ Use the IT resource as an input parameter for the scheduled task

**See Also:** Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for information about the APIs to lookup IT resource definition

In Oracle Identity Manager, a provisioning process and a process instance is associated with activities related to users or accounts. This provides a hook or point to add customizations upon various actions.

Changes to the user state or the account state can occur via direct APIs or reconciliation. The changes can be of many types, such as:

**See Also:** "Understanding Reconciliation APIs" on page 23-25 for information about the reconciliation APIs

■ Data change in the user or account profile
■ Status change, such as enable or disable
■ Changes to user based on attestation processes
■ Organization change
■ Attribute propagation
■ Password propagation

For each of these changes, the process definition provides a facility to add hooks to be run upon any of these changes. For reconciliation, the process definition provides the hooks in the form of the following conditional tasks:

■ Reconciliation Insert Received: This conditional task is inserted when an account is created via reconciliation.
■ Reconciliation Update Received: This conditional task is inserted when an existing account linked to a user is updated via reconciliation. Data in the process form or status of the account are updated.
■ Reconciliation Delete Received: This conditional task is inserted when an existing account is revoked via reconciliation.

These tasks provide starting points for the workflows. You can create custom workflows in the provisioning process, and create a dependency between the reconciliation trigger tasks and the workflows. This causes the workflows to be run upon the respective triggers.

Every reconciliation event that is successfully linked to a user or an account inserts a single trigger from the conditional tasks. All the data in the user profile and the account profile is available as context-sensitive data for any adapter that is attached to one of these dependant tasks.

**See Also:** Part III, "Connectors" and Part IV, "Requests and Approval Processes" for details about creating conditional tasks, adapters, and dependencies

### 23.5 Updating Reconciliation Profiles Manually

This section describes updating reconciliation profiles manually in the following sections:
23.5.1 Creating and Updating Reconciliation Profiles

For reconciliation based on resource objects, the profile name is the same as that of the resource object. For example, if resource object name is testresource, then the default profile name is also testresource. The corresponding reconciliation staging table name is available in the profile. If the resource has Multi-Language Support (MLS) data, then the MLS staging and Oracle Identity Manager table names are also available in the profile. See Table 23–1, "Elements in the Reconciliation Profile XML" for information about the structure and the elements in the reconciliation profile.

If the resource object has child forms, then for each child form, the Oracle Identity Manager table name and staging table name are available in the profile. Each staging table has a corresponding entity definition XML file, the name is same as staging table name with dot xml extension (.xml), which is stored in the MDS.

To change anything in a reconciliation profile, for instance attribute batch size, either the profile can be updated manually or by using the Design Console. To update a reconciliation profile:

1. Export the /db/PROFILE_NAME profile document from MDS.
2. Make changes in the XML file, for example, change the batch size value.
3. Set the value of the configure attribute to true. For information about this attribute, Table 23–1, "Elements in the Reconciliation Profile XML".
4. Import the updated profile into MDS. See "Migrating User Modifiable Metadata Files" on page 37-1 for information about exporting and importing metadata to and from MDS.

This automatically updates the staging tables and the corresponding staging table entity definitions.

23.5.2 Changing the Profile Mode

You can use one of the following methods to change the profile mode property from CHANGELOG to REGULAR:

See Also: "Mode of Reconciliation" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about changelog and regular reconciliation modes.

- Change the value of the changeType attribute in the profile, for example:

```xml
<profile xmlns="http://www.oracle.com/oracle/iam/reconciliation/config"
    changeType="REGULAR" batchSize="500" resourceType='Organization'
    name='Xellerate Organization'>
```

- Change the attribute during event creation.
The event creation API, introduced in Oracle Identity Manager 11g Release 2 (11.1.2.2.0), contains three parameters. The first two parameters are same as those used in previous create event APIs. The third parameter can have attributes such as dateFormat, changeType, eventFinished, and actionDate. The following is the constructor for the third parameter:

```java
EventAttributes(boolean eventFinished, java.lang.String dateFormat, ChangeType changeType, java.util.Date actionDate)
```

See Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for more information about the third parameter.

You can use this API to set the changeType as follows:

```java
public long createReconciliationEvent(String objName, Map<String, Object> inputData, EventAttributes eventAttribs);
```

**Note:** Using the API to set the changeType attribute overrides the value of the changeType attribute set in the profile.

## 23.6 Understanding Reconciliation APIs

The reconciliation APIs are a set of published APIs that can be used to create reconciliation events with single-valued and multi-valued attribute data and other features.

Reconciliation connector developers must use these APIs to push data to the reconciliation event repository.

**See Also:** Chapter 31, "Using APIs" for more information about using APIs in Oracle Identity Manager

Most of these APIs existed in earlier versions of Oracle Identity Manager. However, in 11g Release 2 (11.1.2.2.0), the implementation has changed and is based on the new reconciliation architecture introduced in the release.

Existing standard connectors also use these APIs; since the earlier APIs continue to be supported, no changes are necessary to those connectors.

callingEndOfJobAPI is the only new reconciliation API in 11g Release 2 (11.1.2.2.0).

Each run of a connector is known as a job. In 11g Release 2 (11.1.2.2.0), reconciliation events are submitted to the reconciliation engine in batches. At the end of a job, the scheduler (which executes the connector scheduled task) executes a listener, which in turn invokes the callingEndOfJobAPI. This API submits any open batch for processing to the reconciliation engine.

The API calls are similar for Multilanguage Supported (MLS) and non-MLS data. The connector passes in data to be reconciled as a HashMap. The difference is that if an attribute is MLS-enabled, then the key is the attribute name, while the value is another HashMap of MLS data. The keys of this MLS-specific HashMap are language codes, and the values are the corresponding locale-specific data obtained from target system. If there is any MLS data that does not have a locale defined with it in the target system, that data is passed with key "base" in the MLS input data HashMap.
23.6.1 The ReconOperationsService API

The APIs in oracle.iam.reconciliation.api.ReconOperationsService are required for the following tasks:

- Ignore Event
- Create Event (single/bulk)
- Process Event
- Deletion Detection

See Also: Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for details about the APIs in oracle.iam.reconciliation.api.ReconOperationsService

The preferred API and the order of invocation of these APIs is as follows:

1. **Ignore Event:** This is a way to prevent event creation and processing of target system data that already exists in Oracle Identity Manager. The API invocation is as follows:

   ```java
   boolean ignoreEvent(String resourceObjectName, Map inputData, String dateFormat) throws tcObjectNotFoundException, tcAPIException
   ```

   This API is used to validate whether or not the reconciliation create event needs to be raised for the specified object. If this API returns true, then you can skip the event creation, which saves extra event creation in the database.

   Similar to the ignoreEvent API, the ignoreEventAttributeData method can be used to validate whether or not the reconciliation create event flow needs to be raised for single and multivalued data coming from the target system. In this release, only the account entity type has such data. The API is as shown:

   ```java
   boolean ignoreEventAttributeData(String resourceObjectName, Map inputData, String multiValueFieldName, Map[] childDataList, String dateFormat) throws tcAPIException, tcObjectNotFoundException
   ```

   **Note:** Either ignoreEvent or ignoreEventAttributeData must be invoked; both the APIs are not required to be invoked.

2. **Create Event:** This can happen via single event creation or bulk event creation APIs. This flow simply stores target system data in staging tables. The processing of this data asynchronously takes place later on.

   **Create Event (Single):** This consists of the following APIs:

   - Use the createReconciliationEvent method to provide the data for creating reconciliation events. If there is child or multivalued data, then set the value of the eventAttribs.eventFinished flag to false. Otherwise, set this value to true. It returns the eventId of the created Event.

     ```java
     long createReconciliationEvent(String resourceObjectName, Map<String, Object> inputData, EventAttributes eventAttribs)
     ```

   - The child data is provided using the addMultiAttributeData method. If there is no child data or the eventAttribs.eventFinished flag is set to true, then this API must not be invoked.
long addMultiAttributeData(long plReconciliationEventKey, java.lang.String psFieldName, java.util.Map poData) throws tcAPIException, tcEventNotFoundException, tcEventDataReceivedException, tcAttributeNotFoundException

The providingAllMultiAttributeData method specifies whether the multivalued data being provided is the entire list of data, or only changeset that has been added/updated. By default, the value of the pbFlag is false. If there is no child data or the eventAttribs.eventFinished flag is set to true, then this API must not be invoked.

public void providingAllMultiAttributeData(long plReconciliationEventKey, String psFieldName, boolean pbFlag) throws tcAPIException;

The finishReconciliationEvent method is used to mark the end of event creation flow. Particular event status is updated to Data Received, which means that all the data for the particular event, including the child data if any, has been provided. If the eventAttribs.eventFinished flag is set to true, then this API must not be invoked.

void finishReconciliationEvent(long eventId) throws tcAPIException, tcEventNotFoundException, tcEventDataReceivedException

The callingEndOfJobAPI method processes all the reconciliation batches in the job. For a scheduled job, this API is automatically called when the job ends. This API must be explicitly called for a nonscheduled job API invocation.

void callingEndOfJobAPI() throws tcAPIException

Create Event (Bulk): This consists of the following API:
ReconciliationResult createReconciliationEvents(BatchAttributes batchAttribs, InputData... input)

This is the bulk create API. It creates bulk reconciliation events for the data passed in input data. It accepts all the data including multivalued attributes, and submits it for processing as one batch if the size of data is less then or equals to the batch size. Otherwise, it submits the data in multiple batches. There is no need to call any other API after this.

3. Process Event: This is a way to force the backend processing of an already created event. The processReconciliationEvent(eventId) API is invoked after create event flow has finished and an already created event needs to be processed as well. This API processes only a particular event, it does not update the batch or job status. If batch status needs to be updated as well, then invoke the callingEndOfJobAPI API after this. Using this API is not recommended because it is synchronous and processes data one at a time, rather than in batch.

Note: For better performance with bulk multivalued attributes or the data for multiple child records instead of a single child record, use the following API:

void addDirectBulkMultiAttributeData(long reconciliationEventKey, long reconciliationAttributeKey, String tableFieldName, List dataList, String dateFormat) throws tcAPIException, tcEventNotFoundException, tcAttributeNotFoundException, tcEventDataReceivedException, tcInvalidAttributeException
4. **Deletion Detection:** This is a way to delete extra data in Oracle Identity Manager that does not exist in the target system. This consists of the following APIs:

- The `provideDeletionDetectionData` method takes the list of all the existing target system data for a resource object as input, and then returns a list of matching data found in Oracle Identity Manager.

  
  ```java
  Set provideDeletionDetectionData(String resourceObjectName, Map[] inputData) throws tcAPIException, tcIDNotFoundException, tcMultipleMatchesFoundException
  ```

- The `getMissingAccounts` method takes the list keys of already found data in Oracle Identity Manager, and returns a list of extra data that is in Oracle Identity Manager but not in the target system. It retrieves all keys from Oracle Identity Manager and compares them with the keys present in the set returned by the `provideDeletionDetectionData` method.

  ```java
  Thor.API.tcResultSet getMissingAccounts(String objectName, Set accountsFound) throws tcAPIException, tcIDNotFoundException, tcDataNotProvidedException
  ```

- The `deleteDetectedAccounts` method takes a list of data found only in Oracle Identity Manager as input, and invokes a delete type create reconciliation event API call, one at a time. The `tcResultSet` returned by the `getMissing Accounts` method is passed as parameter to this API.

  ```java
  long[] deleteDetectedAccounts(Thor.API.tcResultSet poDetectedAccounts) throws tcAPIException, tcAPIException
  ```

23.6.2 Invoking Non-scheduled Task-Based Reconciliation in a Multithreaded Environment

`Example 23–2` shows the sample code to invoke non-scheduled task-based reconciliation in a multithreaded environment:

```java
public class UserNonSTBasedRecon{

    private AtomicInteger threadCount = new AtomicInteger(0);

    public Long getRandomLong(int maxValue) {
        Random random = new Random();
        long token = random.nextInt(maxValue);
        return token;
    }

    @Test
    public void testCreateUsersUsingNonScheduleTaskConnectorWithThreads() throws Exception {
        Thread t = new CreateEvent();
    }
}
```
t.start();
Thread t2 = new CreateEvent();
t2.start();

while (true) {
    Thread.currentThread().sleep(5000);
    if (threadCount.get() == 2){
        OIMClient oimClient = null;
        ReconOperationsService reconServ =
oimClient.getService(ReconOperationsService.class);
        reconServ.callingEndOfJobAPI();
        break;
    }
}

public class CreateEvent extends Thread {

@Override
public void run() {

String ctxFactory = "weblogic.jndi.WLInitialContextFactory";
OIMProfileReader reader = new OIMProfileReader();
String appServerType = reader.getString("appserver.type");
String hostName = reader.getString("weblogic.host");
String port = reader.getString("weblogic.port");
String serverURL = "t3://" + hostName + ":" + port;
System.out.println("Server URL is : " + serverURL);
System.out.println("Context Factory is : " + ctxFactory);
Hashtable<String, String> env = new Hashtable<String, String>();
ev.put(OIMClient.JAVA_NAMING_PROVIDER_URL, serverURL);
ev.put(OIMClient.JAVA_NAMING_FACTORY_INITIAL, ctxFactory);

OIMClient client = new OIMClient(env);
String username = "xelsysadm";
String password = "Welcome1";
try {            
    client.login(username, password.toCharArray());
} catch (LoginException e1) {
    throw new SuperRuntimeException(e1.getMessage(), e1);
}

String uniq2 = getRandomLong(10000).toString();
long jobId = getRandomLong(10000);
ContextManager.setValue(Constants.JOB_HISTORY_ID, new
ContextAwareNumber(jobId));
ContextManager.setValue(Constants.JOB_NAME_CONTEXT, new
ContextAwareString(jobId +""));
ReconOperationsService recon;
try {            
    recon = client.getService(ReconOperationsService.class);
    int count = 50;
    HashMap<String, String> hm = new HashMap<String, String>();
    ArrayList<Long> eventKeys = new ArrayList<Long>();
    for (int i = 0; i < count; i++) {
        hm.put("UserLogin", uniq2 + "ThreadTest" + i);
        hm.put("FirstName", uniq2 + "Thread" + i);
        hm.put("lastname", "Test");
        hm.put("Type", "End-User");
        hm.put("OrganizationName", "Xellerate Users");
    }
    eventKeys.add(hm);    
    ReconServicesService recon =
    recon.callingEndOfJobAPI();
    break;
}
}
23.7 Postprocessing for Trusted Reconciliation

If the user login is not passed for trusted reconciliation, then the login handler generates the user login. The password is generated in postprocessing event handler. You can configure Oracle Identity Manager to send notification for the same.

Notification is sent only when the value of the Recon.SEND_NOTIFICATION system property is set to true. See "System Properties in Oracle Identity Manager" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about the Recon.SEND_NOTIFICATION system property.

In SSO disabled environment, for user creation via reconciliation, both the user login and password are generated in postprocess handlers and a single notification is sent for both user login and password.

In SSO enabled environment, because the password is not to be generated, if login is generated in postprocess handler, then notification is sent only for the user login.

23.8 Troubleshooting Reconciliation

Before troubleshooting issues related to reconciliation, change the reconciliation logging level to INFO. To do so, add the following logger by using Oracle Enterprise Manager:

- **Name**: oracle.iam.reconciliation
- **Oracle Diagnostic Logging Level (Java Level)**: NOTIFICATION:1(INFO)

For detailed steps of adding a logger, see "Configuring Logging" in Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.
Note: To change the logging level, you can also modify the `/domains/DOMAIN_NAME/config/fmwconfig/servers/OIM_SERVER/logging.xml` file. To do so:

1. In the logging.xml file, add a new logger, as shown:
   
   ```xml
   <LOGGER NAME="oracle.iam.reconciliation" LEVEL="INFO"/>
   ```

2. Change the logging level of the 'console-handler' log_handler to INFO.
3. Restart Oracle Identity Manager.

This section describes troubleshooting reconciliation issues in the following sections:

- Troubleshooting General Reconciliation Issues
- Troubleshooting Database-Related Reconciliation Issues
- Troubleshooting Reconciliation Profile Configuration Failures
- Troubleshooting LDAP Reconciliation Issues

### 23.8.1 Troubleshooting General Reconciliation Issues

Table 23–5 lists the troubleshooting steps that you can perform if you encounter reconciliation errors:

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failure in processing events</td>
<td>The error details can be obtained from the reconciliation tables, such as:</td>
</tr>
<tr>
<td></td>
<td>- For batch processing, the exception is stored in RECON_BATCHES.RB_NOTE column</td>
</tr>
<tr>
<td></td>
<td>- For single event processing, the exception is stored in RECON_EVENTS.RE_NOTE column</td>
</tr>
<tr>
<td>Various data corruption issues resulting due</td>
<td>Set the reconciliation batch size (batchSize parameter) to 0 in the reconciliation profile of</td>
</tr>
<tr>
<td>to duplicate processing (both single and</td>
<td>the affected resource object.</td>
</tr>
<tr>
<td>bulk processing) in case of push-based</td>
<td></td>
</tr>
<tr>
<td>connectors when they are processing</td>
<td></td>
</tr>
<tr>
<td>reconciliation using the processReconciliationEvent API</td>
<td></td>
</tr>
<tr>
<td>For example, duplicate account creation,</td>
<td></td>
</tr>
<tr>
<td>status unexpectedly getting changed, and so</td>
<td></td>
</tr>
<tr>
<td>on.</td>
<td></td>
</tr>
</tbody>
</table>
### Table 23–5  (Cont.) Troubleshooting Reconciliation

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failure occurring in kernel orchestration handler</td>
<td>The orchestration ID can be tracked from the reconciliation table, which can further be used to check the status of related handlers, such as:</td>
</tr>
<tr>
<td></td>
<td>■ For batch processing, the postprocess only orchestration ID can be read from the <code>RECON_BATCHES.RB_NOTE</code> column</td>
</tr>
<tr>
<td></td>
<td>■ For single event processing, end-to-end orchestration ID can be read from the <code>RECON_EVENTS.RE_NOTE</code> column</td>
</tr>
<tr>
<td></td>
<td>There is no UI that displays LDAP synchronization during reconciliation. Therefore, you can only track LDAP success or failure by checking the status of LDAP sync event handlers in orchestration based on the ID available in RB_NOTE/RE_NOTE columns.</td>
</tr>
<tr>
<td>After a job run, a lot of events are in the Data Received status.</td>
<td>Check if related batches are in Ready For Processing status by using the following statement:</td>
</tr>
</tbody>
</table>
|                                                                       | ```sql
select rb_batch_status, rb_note from recon_batches
where rb_batch_status = 'Ready For Processing' and rj_key = JOB_ID_ON_UI
```                                                                                                                                                          |
|                                                                       | In addition, in the `RECON_BATCHES.RB_NOTE`, there is some generic exception, such as Connection issue. Fix the issue, and then perform any one of the following:                                             |
|                                                                       | ■ If there is a lot of data, then rerun the reconciliation job.                                                                                                                                       |
|                                                                       | ■ There is a scheduled task provided for manual retry of such failed batches Retry Reconciliation Batch. This can be used for retrying specific batches only. Multiple comma-separated batches are supported.   |
|                                                                       | ■ There is no predefined job associated with this schedule task. A job can be created as required.                                                                                                    |
| Race Condition - Events are in failed status because some dependent attribute is still not reconciled, for example, user's manager/organization needs to be reconciled before user. | ■ If the size of the data is small, then retry reconciliation automatically handles the race condition, but it is slow.                                                                                   |
|                                                                       | ■ If the size of the data is large, then perform the reconciliation two times. Remove the mapping for the dependent field for the first full reconciliation, and then add the dependent field mapping and perform the full reconciliation second time. |
| The following error is generated when performing user update for trusted source reconciliation: | For of trusted source reconciliation, if the matching rule is based on `Usr_login`, then the matching rule must not be case-sensitive. Otherwise, updating users work as creating users, and the error might be generated. |

**ORA Error Code**

`=>ORA-00001: unique constraint (.) violated`
Troubleshooting Reconciliation

23.8.2 Troubleshooting Database-Related Reconciliation Issues

This section describes the following database-related issues for reconciliation:

Missing Critical Oracle Database 11g Release 1 Interim Patches
When the RDBMS interim patch# 7614692 is missing, the following error is logged:

ORA-02291: INTEGRITY CONSTRAINT (FK_RECON_EVENTS_USR) VIOLATED - PARENT KEY NOT FOUND
[EXEC] ORA-06512: AT "OIM_SP_RECONBLKUSERCRUD"
[EXEC] ORA-06512: AT "OIM_SP_RECONBLKUSRMLSWRAPPER"
[EXEC] ORA-06512:

To resolve this issue, the following patches must be installed on Oracle Database 11g Release 1 (11.1.0.7.0):

- p7614692_111070
- p7000281_111070
- p8327137_111070
- p8617824_111070

Note: You can download all interim patches from the following URL:

http://support.oracle.com

Missing Critical Oracle Database 11g Release 2 Interim Patches
Running some SQL scripts might generate incorrect or inconsistent results on Oracle Database 11g Release 2 (11.2.0.2.0), which do not cause problems in earlier release of Oracle Database.

To resolve this issue, patch# 10259620 for Oracle Database 11g Release 2 must be installed.
**Slow Reconciliation and Similar Traces in Error Log**

When the SQL scripts having matching rules involving large volume, the entity tables are slow probably because of FULL table scans or unoptimized SQL plans in the database.

Reconciliation can be slow when the matching rule columns are not properly indexed or schema statistics is outdated. The slowness results in error logs similar to the following:

```
oracle.iam.platform.utils.SuperRuntimeException: java.sql.SQLException:
ORA-01013: user requested cancel of current operation
ORA-06512: at "XL_SP_RECONBLKROLEMATCH"
ORA-06512: at "OIM_SP_RECONBLKROLEMLSWRAPPER"
ORA-06512:
```

To resolve this issue:

1. Verify that all the appropriate indexes are created over matching rule columns.
2. Verify that the database schema statistics are collected according to the guidelines.

**See Also:** "Reconciliation Best Practices" on page 23-37 for information about creating indexes for reconciliation and collecting database statistics

### 23.8.3 Troubleshooting Reconciliation Profile Configuration Failures

For any issues related to profile configuration failures, validate the profile by using the ProfileValidator Mbean available in Oracle Enterprise Manager. If the profile is invalid, then the profile is displayed along with the cause of the invalid profile.

Table 23–6 lists the troubleshooting steps that you can perform if you encounter reconciliation errors.
23.8.4 Troubleshooting LDAP Reconciliation Issues

This section describes the following issue related to LDAP reconciliation:

**LDAP User Create and Update Reconciliation Scheduled Job Fails With Error**

In an integrated environment of Oracle Identity Manager with Oracle Unified Directory (OUD) and libOVD, the LDAP User Create and Update Reconciliation scheduled job fails with the following error:

*Invalid syntax of the provided cookie*

This error occurs when a numeric change number value, for example 0, is being passed to libOVD when OUD is used as LDAP, and External Change Log (ECL) is enabled in the libOVD adapter. In the scheduled job page, the numeric value, for example 0, is set in the Last Change Number field. This attribute is used to specify the last changelog identifier processed by this scheduled job.

For OUD, when ECL mode is on, the value of the Last Change Number field must not be a numeric value but a string value, such as:

---

**Table 23–6  Troubleshooting Reconciliation Profile Configuration Failures**

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The profile is invalid, and it fails to load with the following exceptions:oracle.iam.reconciliation.exception.ConfigNotFoundException OR oracle.iam.reconciliation.exception.Config with internal exception org.xml.sax.SAXParseException</td>
<td>Perform any one of the following:</td>
</tr>
<tr>
<td></td>
<td>■ The exact problem can be diagnosed and fixed by checking the schema validation message.</td>
</tr>
<tr>
<td></td>
<td>■ Validate the reconciliation profile XML by using the MBean in Oracle Enterprise Manager or the Validate Recon Profile test in the Diagnostic Dashboard.</td>
</tr>
<tr>
<td></td>
<td>■ Validate the reconciliation profile by importing the profile and the XSD into an XML schema-aware editor and validate against that schema in that editor, which can point to the exact cause of the failure.</td>
</tr>
<tr>
<td>Importing a valid reconciliation profile XML into a system fails to create the necessary configurations.</td>
<td>Check the profile.configure attribute. The value of this attribute must be true.</td>
</tr>
<tr>
<td></td>
<td>Check the profile.active attribute. The value of this must be true. Or if the attribute is not present, then it means that profile.active is true.</td>
</tr>
<tr>
<td>The following error is generated:oracle.iam.reconciliation.exception .ReconciliationException: Exception occurred while inserting data into table STAGING_TABLE_NAME due to STAGING_TABLE_NAME</td>
<td>Check the profile.configure and profile.active attributes.</td>
</tr>
<tr>
<td>This means that a valid reconciliation profile is loaded, but it has not created any configuration in Oracle Identity Manager.</td>
<td><strong>Note:</strong> The ProfileValidator Mbean is available for validating the reconciliation profile. This MBean can be accessed by using Oracle Enterprise Manager.</td>
</tr>
</tbody>
</table>

---

Importing a valid reconciliation profile XML into a system fails to create the necessary configurations.

Check the profile.configure attribute. The value of this attribute must be true.

Check the profile.active attribute. The value of this must be true. Or if the attribute is not present, then it means that profile.active is true.

The following error is generated:

**oracle.iam.reconciliation.exception.ReconciliationException: Exception occurred while inserting data into table STAGING_TABLE_NAME due to STAGING_TABLE_NAME**

This means that a valid reconciliation profile is loaded, but it has not created any configuration in Oracle Identity Manager.

---

23.8.4 Troubleshooting LDAP Reconciliation Issues

This section describes the following issue related to LDAP reconciliation:

**LDAP User Create and Update Reconciliation Scheduled Job Fails With Error**

In an integrated environment of Oracle Identity Manager with Oracle Unified Directory (OUD) and libOVD, the LDAP User Create and Update Reconciliation scheduled job fails with the following error:

*Invalid syntax of the provided cookie*

This error occurs when a numeric change number value, for example 0, is being passed to libOVD when OUD is used as LDAP, and External Change Log (ECL) is enabled in the libOVD adapter. In the scheduled job page, the numeric value, for example 0, is set in the Last Change Number field. This attribute is used to specify the last changelog identifier processed by this scheduled job.

For OUD, when ECL mode is on, the value of the Last Change Number field must not be a numeric value but a string value, such as:
The following is an example command to get the expected value:

```
ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w welcome1 -b "" -s base 'objectclass=*' lastExternalChangelogCookie
```

### 23.9 Populating Data in the RECON_EXCEPTIONS Table

The RECON_EXCEPTIONS table in Oracle Identity Manager database is used to capture error messages generated during account reconciliation. This data is collected for the purpose of generating reports.

**See Also:** "Account Reconciliation" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for information about account reconciliation.

If a reconciliation match is found to a deleted user, then you must insert USER_DELETED in the REX_EXCEPTION column and the key of the deleted user in the USR_KEY column of the RECON_EXCEPTIONS table.

If no match is found, then insert USER_NOT_FOUND in the REX_EXCEPTION column.

If account match is found, then check if the account is already deprovisioned. Then insert into RECON_EXCEPTIONS table with the value RESOURCE_DEPROVISIONED in the REX_EXCEPTION column for the user who is to be provisioned.

To populate the RECON_EXCEPTIONS table with exception data:

1. Fetch all the events with the change type != ('Modify', 'Delete') and event status as ('Single User Match Found', 'Single Org Match Found').

2. Provision the resource object for the entities by performing the following:
   
   a. Collect the exception data from RECON_EXCEPTION DB table. To do so, perform any one of the following:
      
      - Check if the value of the XL.EnableExceptionReports property is TRUE. If it is set to TRUE, then continue to the next step. Otherwise, do not collect the exception data.
      
      - Select the obj_initial_recon_date in the obj table for the resource object being provisioned, and check if it is earlier than today's date. If an earlier date is displayed, then continue to the next step. Otherwise, do not collect the exception data.

   b. While provisioning the resource object to the user, check if the resource object has already been deprovisioned in Oracle Identity Manager:
      
      - If the resource object is already deprovisioned, then insert into RECON_EXCEPTIONS table the value RESOURCE_DEPROVISIONED in the REX_EXCEPTION column for the user who is to be provisioned.
      
      - If the resource object is not deprovisioned, then insert into RECON_EXCEPTIONS table the value RESOURCE_NEVER_PROVISIONED in the REX_EXCEPTION column for the user who is to be provisioned.
23.10 Reconciliation Best Practices

This section describes how to improve performance by identifying indexes that are required for connector tables and reconciliation tables. It contains the following topics:

- Additional Indexes Requirement for Matching Module
- Collecting Database Schema Statistics for Reconciliation Performance

---

**Note:** Oracle recommends configuring both the entitlement attribute and the key attribute for the child data in reconciliation field mappings to enable effective duplicate entitlement or child data validation. See "Duplicate Validation for Entitlement or Child Data" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about duplicate validation for entitlements or child data.

---

23.10.1 Additional Indexes Requirement for Matching Module

When Oracle Identity Manager is installed, the necessary indexes are created in the Oracle Identity Manager database schema. However, there can be additional indexes required because of dynamic nature of some of the features in Oracle Identity Manager. This is especially true for reconciliation.

Reconciliation uses matching algorithm to find if the user/account/role/organization for which the change is requested is already existing in Oracle Identity Manager or not. The matching algorithm compares the data in set of columns in Oracle Identity Manager with the data in target horizontal table columns. The columns that contain the matching rules are defined in the reconciliation profile. To improve the performance of the matching operation quickly, there must be correct indexes created on the matching rule columns.

To illustrate the recommended method of identifying the appropriate indexes, a sample Active Directory (ADUser) profile present in the Meta Data Store (MDS) repository is taken as an example.

**Selecting Indexes for Reconciliation**

To select indexes based on the matching rule criteria:

1. Open the AD profile file in a text editor.

**Note:** The AD user profile must be imported from the MDS by using the Oracle Enterprise Manager, as described in "Migrating User Modifiable Metadata Files" on page 37-1.

2. Search for all occurrences of `<matchingRule>` tag element in the AD profile, as shown in Figure 23–4:
3. After identifying the columns constituting each matching rule, create the indexes accordingly.

**Note:**

- If any key field is defined in Oracle Identity Manager as case-insensitive, then a function-based index on that key field must be created. For example, if the connector code internally performs a search for the first name, assuming that FIRST_NAME is a key, then appropriate indexing must be done.

- If multiple or composite keys are used for looking up a user, then choose between individual or composite indexes.

- Pointers for required indexes can also be taken by monitoring the real-time running of reconciliation process from the database side by using a performance-monitoring tool, such as Oracle Enterprise Manager, or through the Automatic Workload Repository (AWR) Reports available in Oracle Database 11g.

- To some extent, index creation is automated for profiles created or updated via the Design Console or Deployment Manager import. Validate the automatically created indexes per the rules defined in this section. You must rectify the indexes manually if there are any issues. For profiles created or updated manually, the indexes are not automated and must be created manually. In addition, there is no automation for dropping the indexes if the matching rule field has changed. Dropping indexes must be done manually.

- The list of existing indexes can be viewed on Oracle Enterprise Manager by using the ProfileValidator Mbean.
23.10.2 Collecting Database Schema Statistics for Reconciliation Performance

Database statistics is essential for the Oracle optimizer to select an optimal plan in running the SQL queries. Oracle recommends that the statistics are collected regularly for Oracle Identity Manager schema. Because Oracle Identity Manager 11g Release 2 (11.1.2.2.0) uses lot of database SQL features for reconciliation process, make sure that the schema statistics are updated before running the reconciliation.

Note:
- Other options with DBMS_STATS.GATHER_SCHEMA_STATS API can be used as required, such as DEGREE,ESTIMATE_PERCENT based on the environment, data profile, Oracle DB Edition and underlying hardware capabilities.
- See "Database Performance Monitoring" in the Oracle Fusion Middleware Performance and Tuning Guide for more information about collecting database schema statistics.

Because Oracle Identity Manager reconciliation process is a data-intensive process and quickly brings in large volume of data, database statistics must also be able to represent the underlying data correctly. To achieve this, refer to the following guidelines:

- Make sure that statistics is collected for reconciliation on a fresh setup or with a low volume with no or negligible existing data in the Oracle Identity Manager schema. Maximum row count in relevant Oracle Identity Manager tables must be between 100 and 1000 rows. Examples of tables are USR table for trusted source reconciliation and parent account (UD_*) tables for target resource reconciliation.

- For the statistics to be a proper representative of data distribution after reconciliation has started and is expected to bring in a large volume of data, such as more than 20000 users or accounts, collect Oracle Identity Manager schema statistics in the following manner:
  a. Plan to gather statistics after the initial collection only after reconciliation has started successfully and has been running for a while. To verify this, check the counts of a few key tables from the Oracle Identity Manager schema, such as USR table for trusted source reconciliation and parent account (UD_* ) tables for target resource reconciliation.
  b. After reconciliation has brought in almost 20000 to 25000 rows in the USR table or in the parent account tables, statistics can be collected.

Note:
- Statistics can be gathered concurrently with reconciliation running.
- The row counts specified in the guidelines are examples and you can determine any other row count for collecting statistics.

- After the statistics is collected, the performance might not improve immediately. However, as older SQL Plans are cleared from the shared pool of the Oracle Database, new and more efficient plans are created and performance improves.
23.11 Monitoring Reconciliation Performance Using DMS

Dynamic Monitoring Service (DMS) commands are used to view performance metrics and configure event tracing. The following DMS matrices are relevant for monitoring reconciliation performance:

- **OIM_ScheduledJob**: The time taken by a particular scheduled job run.
- **Reconciliation Service (ReconOperationsService Or tcReconciliationOpIntf)**: The time taken by each API on the reconciliation service for creating an event. Connector throughput can be calculated as ‘Total Scheduled Job time – Total time for creating the events’.
- **OIM_JMS**: ActionTask provides information about actual reconciliation processing (stored procedure) time. OrchestrationAsyncTask provides information about overall orchestration postprocessing. XLAuditMessage provides information about actual audit processing.
- **OIM_EventHandlers**: Time taken by each eventhandler within an orchestration.
- **DMS Dump**: If unable to resolve performance and functional issues, then DMS dumps should be provided for analysis. The command is:

```bash
${mwhome}/oracle_common/common/bin/wlst>>dms.log
Connect('adminusername','adminpassword');
dumpMetrics(format='xml');
Exit();
```

For detailed information about the command, see the "dumpMetrics" section in "DMS Custom WLST Commands" of the *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference*. 
Oracle Identity Manager may be one among many repositories of entity data in your organization. When you start using Oracle Identity Manager, you might want to load data from the other repositories into Oracle Identity Manager. The Bulk Load utility offers a solution to this requirement.

The Bulk Load utility is aimed at automating the process of loading a large amount of data into Oracle Identity Manager. It helps reduce the downtime involved in loading data. You can use this utility after you install Oracle Identity Manager or at any time during the production lifetime of Oracle Identity Manager. The Bulk Load utility can load users, accounts, roles, role hierarchy, role membership, and role category data.

This document is divided into the following sections:

- Features of the Bulk Load Utility
- Prerequisites for Running the Bulk Load Utility
- Running the Utility
- Performance Best Practices for Bulk Load
- Loading OIM User Data
- Loading Account Data
- Loading Role, Role Hierarchy, Role Membership, and Role Category Data
- Data Recorded During the Operation
- Gathering Diagnostic Data from the Bulk Load Operation
- Cleaning Up After a Bulk Load Operation
- Bulk Load High Volume Strategy and Case Studies

24.1 Features of the Bulk Load Utility

The following are features of the bulk load utility:

- The utility is compatible with Oracle Identity Manager release 9.1.0 and later.
- Data can be loaded into Oracle Identity Manager as OIM Users, accounts allocated (provisioned) to OIM Users, roles, role hierarchies, role memberships, or role categories.
- Data can be loaded from a single or multiple CSV files or a database table. Data imported into Oracle Identity Manager is automatically converted into OIM Users,
accounts provisioned to OIM Users, roles, role hierarchies, role memberships, or role categories.

- Data can be loaded from a single or multiple trusted sources.
- Data can be loaded into either an empty Oracle Identity Manager repository or an Oracle Identity Manager repository that already contains data about OIM Users and resources. In other words, user data can be loaded at any time, either immediately after Oracle Identity Manager installation or when the system is already in production.
- Exceptions generated during user data loading are handled, and records that fail the loading process can be retried.
- Audit snapshots can be generated after a bulk load operation for users.
- After bulk loading of OIM User data, password change at first login is enforced because a dummy password is used during the operation.

---

**Note**: You cannot use the utility to encrypt user attributes. In other words, if a user field in Oracle Identity Manager is encrypted, then the utility cannot be used to encrypt data that is loaded into that field.

---

### 24.2 Prerequisites for Running the Bulk Load Utility

Running the Bulk Load utility has the following prerequisites:

- **Installing the Bulk Load Utility**
- **Preparing Your Database for a Bulk Load Operation**

#### 24.2.1 Installing the Bulk Load Utility

To install the utility:

1. Zip and copy the following directory from the installation package into a directory on the Oracle Identity Manager database host computer:

   \texttt{MIDDLEWARE\_HOME/Oracle\_IDM1/server/db/oim/oracle/Utilities/oimbulkload}

   **Note**: You can run the utility from a remote host. It is not mandatory to run the utility from a directory in the Oracle Identity Manager database host.

   The utility can also be run directly from the \texttt{MIDDLEWARE\_HOME/Oracle\_IDM1/server/db/oim/oracle/Utilities/oimbulkload/} directory.

2. Extract the contents of the ZIP file.

   The \texttt{oimbulkload} directory is created when you extract the contents of the ZIP file. The following directories are created inside this directory:

   - **sqls**: This directory contains SQL scripts used during bulk load operations.
   - **scripts**: This directory contains the .sh and .bat scripts used during bulk load operations.
Prerequisites for Running the Bulk Load Utility

Using the Bulk Load Utility

24.2

■ csv_files: If you are going to use a single or multiple CSV files as the input source, then the CSV files must be stored in this directory.

■ lib: The directory contains the oimBulkLoad.jar file.

■ sample_data: This directory contains the following sample CSV files:
  – For OIM User load operations:
    master.txt
    OIDusers.csv
    HRusers.csv
  – For account load operations:
    parentAD.csv
    childAD.csv
  – For role-related load operations:
    Role.csv (Role load)
    Rolec.csv (Role category)
    Roleh.csv (Role hierarchy)
    Rolem.csv (Role membership)

■ Logs_{YYYYMMDD_hhmi}: The log directory contains the log files that store the summary of the bulk load operation. This directory is created at run time.

The following sections provide additional information about the utility and bulk load operations:

■ Scripts That Constitute the Utility

■ Temporary Tables Used During a Bulk Load Operation

■ Options Offered by the Utility

24.2.1.1 Scripts That Constitute the Utility

The following are the main scripts that constitute the utility:

■ oim_blkld.bat and oim_blkld.sh

  This script contains the code to perform bulk load operations. When it is run, this script calls other scripts and stored procedures.

■ oim_blkld_setup.sql

  This script is used to add a datafile in the Oracle Identity Manager tablespace and provide additional grants to the Oracle Identity Manager database user to perform required operations during Bulk Load. See "Creating a Datafile in the Oracle Identity Manager Tablespace" on page 24-5 for more information.

24.2.1.2 Temporary Tables Used During a Bulk Load Operation

The following temporary tables are used during a bulk load operation:

■ OIM_BLKLD_TMP_{SUFFIX}

  If you are using a CSV file as the input source, then the utility automatically creates the OIM_BLKLD_TMP_{SUFFIX} table and first loads data from the CSV file into this table. The suffix for the table name is determined as follows:
Prerequisites for Running the Bulk Load Utility

- The first 6 characters of the file name are taken into account.
- Special characters in the file name and the file extension (.csv) are ignored while determining the first 6 characters.
- A unique number is appended to the first 6 characters.
- For example, if the name of the file is acc_Data.csv, then the table that is created during the bulk load operation is named oim_blkld_tmp_accDat1.

If there are multiple CSV files, then one table is created for each file. Because the first six characters of each CSV file name are appended to the table name, you must ensure that the first six characters of each file's name are unique. This guideline is explained later in this document.

Note: if you are using a database table as the input source, then you can specify any name for the table. You provide the name of this table as one of the input parameters of the utility.

- OIM_BLKLD_EX_SUFFIX

The OIM_BLKLD_EX_SUFFIX table is used to hold data records that fail (are not loaded into Oracle Identity Manager) during a bulk load operation. One OIM_BLKLD_EX_SUFFIX table is created for each OIM_BLKLD_TMP_SUFFIX table. The EXCEPTION_MSG column of the table stores the reason for failure of each record in the table.

If you are using CSV files as the input source, then the first six characters of the CSV file name are added as a suffix to the table name. For example, if the name of the CSV file is usrdt120508.csv, then the name of the table is OIM_BLKLD_EX_usrdt1. If there are multiple CSV files, then one temporary table is created for each CSV file.

Note: If there are multiple CSV files, then you must ensure that the first six characters of each CSV file name are unique.

- OIM_BLKLD_LOG

During a bulk load operation, the utility inserts progress and error messages in the OIM_BLKLD_LOG table. You can query this table to monitor the progress of a bulk load operation. This procedure is described in detail later in this document.

24.2.1.3 Options Offered by the Utility

When you run the bulk load utility, it prompts you to select one of the following options:

Note: The utility prompts for more input depending on the option you select.

- Load User Data

You select this option if you want the utility to load OIM User data. In other words, data is imported into the USR table of Oracle Identity Manager. You can select the input source, CSV files or database tables, for the data that you want to load.
Prerequisites for Running the Bulk Load Utility

24.2.2 Preparing Your Database for a Bulk Load Operation

Preparing your database for a bulk load operation involves the following:

- Creating a Tablespace for Temporary Tables
- Creating a Datafile in the Oracle Identity Manager Tablespace

24.2.2.1 Creating a Tablespace for Temporary Tables

As mentioned in "Temporary Tables Used During a Bulk Load Operation", temporary database tables are used during the bulk load operation. It is recommended that you create a tablespace to accommodate these temporary tables instead of using the default tablespace of the Oracle Identity Manager database.

Follow the instructions in the database documentation to create a tablespace.

24.2.2.2 Creating a Datafile in the Oracle Identity Manager Tablespace

The default size of the datafile in the Oracle Identity Manager tablespace created during Oracle Identity Manager installation is 500 MB. You may need to add space to this datafile to accommodate the data that you are going to load. The alternative is to create a datafile.

To create a datafile in the Oracle Identity Manager tablespace:
1. Start a SQL*Plus session.
2. Connect to the Oracle Identity Manager database as SYSDBA.
3. Run the oim_blkld_setup.sql script. The script will prompt for the following:
   - Name of the Oracle Identity Manager tablespace
   - Full path and name for the datafile to be added in the Oracle Identity Manager tablespace
   - Oracle Identity Manager database user name

   After providing input to prompted Oracle Identity Manager database user name, appropriate grants to perform required operations during Bulk Load are provided to the database user.

### 24.3 Running the Utility

**Note:** If there are name conflicts with existing tables, then the utility overwrites existing temporary tables at the start of each run. If required, rename temporary database tables created during an earlier run of the utility.

To run the utility:

1. Stop Oracle Identity Manager.
2. Run one of the following scripts:

   **Note:** To load CSV file with non-ASCII data, before running the `oim_blkld.sh` or `oim_blkld.bat` script, set the NLS LANG environment parameter to the UTF8 characterset, in the following format:

   `NLS_LANG = LANGUAGE_TERRITORY.UTF8`

   For example:

   `NLS_LANG = American_America.UTF8`

   **Note:** OIMBulklload is the directory in which the scripts/sqls/csv_files/lib/sample_data directories are present.

3. From the main menu, select one of the options depending on the data you want to load, such as user, account, or role-related data, as described in "Options Offered by the Utility" on page 24-4.
4. From the second menu:
   - Select CSV File if you are using CSV files as the input source.
Select **DB Table** if you are using a database table as the input source.

5. When prompted, provide values for the input parameters described in "Determining Values for the Input Parameters of the Utility" on page 24-12.

---

**Note:** See "Determining Values for the Input Parameters of the Utility" on page 24-12 for information about the input parameters required for loading OIM User data. See corresponding sections for information about the input parameters required to load account, role, role hierarchy, role membership, and role category data.

---

6. Monitor the performance of the operation by following the steps given in "Monitoring the Progress of the Operation".

## 24.4 Performance Best Practices for Bulk Load

To enhance the performance of the Account Bulk Load operation:

1. Split the data load in phases for a high-volume entity data load for Users/Accounts/Role Membership, for example, when data load is greater than 1 million for Users and greater than 250 thousand for Accounts.

2. The phase-wise load can be in the initial size of 500 thousand, and thereafter, in the size of 2 to 3 million Entity data.

3. Perform Stats gathering operation essentially after the first and second batch of data load.

   For information about Stats gathering operation, see "Monitoring Oracle Identity Manager Performance" in the *Oracle Fusion Middleware Performance and Tuning Guide*.

4. For Account data load, when the source is a database table, then make sure that relevant indexes are present on the columns as per the reconciliation matching rules.

   For further details please refer to the documentation on "Additional Indexes Requirement for Matching Module" in the *Oracle Fusion Middleware Developer’s Guide for Oracle Identity Manager*.

## 24.5 Loading OIM User Data

The following is a summary of the steps involved in loading OIM User data:

1. Prepare your database for bulk load if not done already. See "Preparing Your Database for a Bulk Load Operation" on page 24-5 for details.

2. Create the OIM User whose password will be used as the default password for all OIM Users created during the bulk load operation.

3. Create the input source for the bulk load operation.

   If you want to use a database table as the input source, then create the table and copy user data into the table.

   If you want to use CSV files as the input source, then create the CSV files and copy user data into the files. In addition, create a master.txt file containing the names of the files in the sequence in which you want to load data from them.

4. Determine values for the input parameters of the utility.
5. Stop Oracle Identity Manager.
6. Run the oim_blkld.sh or oim_blkld.bat script. See "Running the Utility" on page 24-6 for information about running the oim_blkld.sh or oim_blkld.bat scripts.
7. Monitor the progress of the bulk load operation.
8. Determine the outcome of the bulk load operation.
9. If required, reload data that was not loaded during the first run.
10. Restart Oracle Identity Manager.
11. Verify the outcome of the bulk load operation.
12. Gather diagnostic data from the operation.
13. Remove temporary tables and files created during the operation.
14. Generate an audit snapshot.

The following sections provide detailed information about the steps involved in loading OIM User data:

- Setting a Default Password for OIM Users Added by the Utility
- Creating the Input Source for the Bulk Load Operation
- Determining Values for the Input Parameters of the Utility
- Monitoring the Progress of the Operation
- Handling Exceptions Recorded During the Operation
- Fixing Exceptions and Reloading Data Records
- Verifying the Outcome of the Bulk Load Operation
- Generating an Audit Snapshot

### 24.5.1 Setting a Default Password for OIM Users Added by the Utility

The utility does not encrypt passwords that it assigns to OIM Users created during the bulk load operation. Instead, it assigns the password of an existing OIM User to all OIM Users that are created during the operation.

---

**Note:** Each OIM User is required to change the password at first login.

---

When you run the utility, it prompts for the login name of the existing OIM User whose password you want to use as the default password for the new OIM Users. Before you run the utility, create this OIM User as follows:

---

**Note:** You can create a user in Oracle Identity Manager dedicated for the bulk load operation, and later delete the user if it not required any more. Otherwise, any existing OIM User can be used to perform bulk load operations.

---

1. Log in to the Oracle Identity Self Service as a user with Create User privileges.
2. On the left navigation pane, under Administration, click **Users**. The Search Users page is displayed.
3. From the Actions menu, select **Create**. The Create User page is displayed with input fields for user profile attributes.

4. Specify values for the following fields:
   - User Login
   - First Name (optional)
   - Last Name
   - Organization: Select Xellerate Users.
   - Password
   - Confirm Password

5. Click **Submit**.

### 24.5.2 Creating the Input Source for the Bulk Load Operation

Depending on the input source that you want to use, apply the guidelines given in one of the following sections:

- **Using CSV Files As the Input Source**
- **Creating Database Tables As the Input Source**

#### 24.5.2.1 Using CSV Files As the Input Source

If you want to use CSV files as the input source for the bulk load operation, then apply the following guidelines while creating the CSV files:

- The CSV files must be placed in the oimbulkload/csv_files directory.
- The first line in the CSV file is called the control line. This line must contain a comma-separated list of column names of the USR table in the Oracle Identity Manager database.

The following are sample contents of a CSV file:

```
USR_LOGIN,USR_FIRST_NAME,USR_LAST_NAME,UD_ADUSER_OBJECTGUID
john_doe, John, Doe, jdoe
jane_doe, Jane, Doe, janedoe
richard_roe, Richard, Roe, rroe
```

- If the value in any column contains a comma, then that value must be enclosed in double quotation marks (").
- The CSV file must contain values for all columns that are designated as mandatory in the USR table. The following table lists the mandatory columns required to load the USR table:

---

**Note:** Ensure that the Password column or any other encrypted column is not included in the list of columns. As mentioned earlier in this document, the utility assigns the password of an existing OIM User that you specify to all OIM Users that it loads into Oracle Identity Manager.
Each row in the CSV file must have a unique value for the USR_LOGIN column in the USR table. If there are multiple files, you must ensure that USR_LOGIN values are unique across the CSV files. This check for uniqueness of USR_LOGIN values must also cover existing OIM Users in Oracle Identity Manager.

Ensuring that USR_LOGIN values are unique can be a time-consuming exercise. As an alternative, you can first perform the bulk load operation, fix USR_LOGIN values that are not unique, and then retry the loading operation for the modified user records. This is possible because the utility checks for uniqueness of USR_LOGIN values at run time and copies records that fail this check into the OIM_BLKLD_EX table. Later in this document, there are instructions on retrying the bulk load operation for records that are not loaded during the first run.

If you want to include an organization name in each user record, then add ORG_NAME in the control line and enter the organization name for each user from the second line onward. If ORG_NAME is not included, then the users must be assigned to the Xellerate Users organization.

The utility looks up the USR_LOGIN values for managers after all user data, from all CSV files, is loaded into Oracle Identity Manager. If a USR_LOGIN value given in the MANAGER_NAME column does not exist in Oracle Identity Manager, then the lookup for that user record fails and the record is copied into the exception table, OIM_BLKLD_EX. At the end of the bulk load operation, you can perform the procedure described in "Fixing Exceptions and Reloading Data Records" to reload user records that fail the first run.

If you want to include a manager name in each user record, then add MANAGER_NAME in the control line and enter the USR_LOGIN value of the manager for each user from the second line onward.

Note that the following default values are inserted into Oracle Identity Manager if the CSV file does not contain values for these columns:

- ORG_NAME: Xellerate Users
- USR_TYPE: End-User
- USR_STATUS: Active

---

### Mandatory Column | Description

<table>
<thead>
<tr>
<th>USR_FIRST_NAME</th>
<th>The first name of the user</th>
</tr>
</thead>
<tbody>
<tr>
<td>USR_LAST_NAME</td>
<td>The last name of the user</td>
</tr>
</tbody>
</table>

**Note:**
- USR_LOGIN is not a mandatory column in Oracle Identity Manager 11g Release 2 (11.1.2.2.0).
- There are some key mandatory columns that you can ignore. For example, the ACT_KEY column in the USR table, which is populated by ORG_NAME.

---

All organization names listed under the ORG_NAME column in the CSV file must exist in Oracle Identity Manager.
Create a master TXT file containing the names of the CSV files containing user data to be loaded. You can specify any name for the file, for example, master.txt. Save the master file in the oimbulkload/csv_files directory.

If you want to load multiple CSV files, then enter the name of each data CSV file on a separate line in the master file. Order the list of CSV file names in the sequence in which you want the utility to load data from the files. For example, suppose you have created three data CSV files, London_Users.csv, NewYork_Users.csv, and Tokyo_Users.csv. In the master file, you enter the names of the data CSV files in the following order:

Tokyo_Users.csv
London_Users.csv
NewYork_Users.csv

When you run the utility, data is loaded in this order. This is because the user data in London and New York may have a dependency on the Tokyo users. This is to ensure the manager-user hierarchy.

If the CSV file is generated on Microsoft Windows and is to be loaded on Linux environment, then remove the special characters, such as `\n\r`, to avoid run-time errors.

24.5.2.2 Creating Database Tables As the Input Source

If you want to use a database table as the input source for loading OIM User data, then apply the following guidelines while creating the database table:

- Create the table in the Oracle Identity Manager database.
- The table must contain the following primary key column:
  
  | OIM_BLKLD_USRSEQ   | NUMBER(19) |
  |
  | The utility uses this column as the primary key. If required, you can use a database sequence to populate this column. |
- The rest of the columns must be the same as the ones in the USR table that you want to use. In other words, ignore optional USR_ columns that you do not want to include in the table that you create.
- Note that the following default values are inserted into Oracle Identity Manager if the table does not contain values for these columns:
  
  | ORG_NAME: Xellerate Users |
  | USR_TYPE: End-User |
  | USR_STATUS: Active |
  | USR_EMP_TYPE: Full-Time |
- If you want to include an organization name in each user record, then add ORG_NAME in the control line and enter the organization name for each user from the second line onward. If ORG_NAME is not included, then the users must be assigned to the Xellerate Users organization.
- If you want to include a manager name in each user record, then add MANAGER_NAME in the control line and enter the USR_LOGIN value of the manager for each user from the second line onward.

Table 24–1 shows the structure of a sample database table.
The following are input parameters of the utility:

- **Oracle Home**
  Value of the ORACLE_HOME environment variable on the host computer for the Oracle Identity Manager database.

- **Database Connection String**
  Connection string to connect to the database that must be entered in the following format:
  
  \[//HOST_IP_ADDRESS:PORT_NUMBER/SERVICE_NAME\]

- **OIM DB User**
  Database login ID of the Oracle Identity Manager database user.

- **OIM DB Pwd**
  Password of the Oracle Identity Manager database user.
  The database user password is to be entered twice when prompted.

- **Master file name**
  Name of the file containing names of the CSV data files to be loaded.
  This parameter is used only if the input source is a single or multiple CSV files.
  You place the master file and CSV data files in the oimbulkload/csv_files directory. See "Using CSV Files As the Input Source" for more information.

- **Tmp table name**
  Name of the temporary table to be used as the input source.
  This parameter is used only if the input source for the bulk load operation is a database table. See "Creating Database Tables As the Input Source" for more information.

- **Control Line**
  Comma-separated list of names of columns to be loaded from the database table into Oracle Identity Manager.
  This parameter is used only if the input source for the bulk load operation is a database table.

- **Tablespace Name**
  Name of the tablespace in which temporary tables are to be created during the bulk load operation. If the user does not provide the tablespace name, then it will pick the default tablespace.
See "Preparing Your Database for a Bulk Load Operation" on page 24-5 for more information.

- **Date format**
  Date format used by date columns in the CSV files
  This parameter is used only if the input source is a single or multiple CSV files.
  The date format must match the following:
  - Oracle supported date formats, such as dd-mm-yyyy or MM-DD-YYYY
  - The date format specified in the CSV file

- **Batch Size**
  Number of user records that must be processed by the utility as a single transaction
  The batch size can influence the performance of the bulk load operation. The default value of this parameter is 10000.

- **Debug Flag**
  You can specify Y or N as the value of this parameter. If this parameter is set to Y, then the utility records detailed information about events that occur during the bulk load operation. See "Data Recorded During the Operation" on page 24-32 for more information.

- **User ID for default password**
  Login name of the OIM User that you create by performing the procedure described in "Setting a Default Password for OIM Users Added by the Utility" on page 24-8.

### 24.5.4 Monitoring the Progress of the Operation

During the bulk load operation, you can query the OIM_BLKLD_LOG table for information about the progress of the operation. For example, you can run the following query to see progress messages generated during the bulk load operation to load OIM User data:

```sql
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'USER' AND LOG_LEVEL = 'PROGRESS_MSG'
ORDER BY MSG_SEQ_NO;
```

Errors encountered during the bulk load operation can be viewed by querying the OIM_BLKLD_LOG table. The following is an example of the query to retrieve error messages:

```sql
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'USER' AND LOG_LEVEL = 'ERROR'
ORDER BY MSG_SEQ_NO;
```

### 24.5.5 Handling Exceptions Recorded During the Operation

At the end of a bulk load operation, the utility records statistics related to the operation in the following file:

```
oimbulkload/logs_YYYYMMDD_hhmm/oim_blkld_user_load_summary.log
```

To determine if there were exceptions during the operation, open this log file and look for the number against the Number of Records Rejected label. If the number of rejected
records is greater than zero, then exceptions were thrown during the operation. User records that are rejected by the utility are recorded in the exception table (OIM_BLKLD_EX_SUFFIX). For each rejected record, the EXCEPTION_MSG column in the OIM_BLKLD_EX_SUFFIX table stores information about the reason the record could not be loaded.

Example 24–1 shows sample statistics recorded in the log file at the end of a bulk load operation to store OIM User data.

**Example 24–1  Sample Log File Generated After Loading OIM User Data**

****************************************************************
Processing File: u10.csv
USER LOAD STATISTICS FOR FILE : u10.csv
****************************************************************
Start Time:   08-AUG-08 11.44.12.228000 AM
End Time:     08-AUG-08 11.44.13.368000 AM
Number of Records Processed:  10
Number of Records Loaded:     8
Number of Records Rejected:  2
The name of the TMP table used during the load:
OIM_BLKLD_TMP_U101
The name of the Exception table used during the load:
OIM_BLKLD_EX_U101
****************************************************************
Processing File: u10b.csv
****************************************************************
USER LOAD STATISTICS FOR FILE : u10b.csv
****************************************************************
Start Time:   08-AUG-08 11.44.15.368000 AM
End Time:     08-AUG-08 11.44.15.540000 AM
Number of Records Processed:  16
Number of Records Loaded:     15
Number of Records Rejected:  1
The name of the TMP table used during the load:
OIM_BLKLD_TMP_U10B2
The name of the Exception table used during the load:
OIM_BLKLD_EX_U10B2
****************************************************************
Time taken in re-building indexes and enabling FK constraints
****************************************************************
Start time:      08-AUG-08 11.44.15.556000 AM
End Time:        08-AUG-08 11.46.50.586000 AM
****************************************************************
In this sample, the number of rejected records is 2. If the log file shows that any records were rejected by the utility, then see "Fixing Exceptions and Reloading Data Records" for information about retrying the load operation for these records.
24.5.6 Fixing Exceptions and Reloading Data Records

As mentioned earlier, errors encountered during the bulk load operation can be viewed by querying the OIM_BLKLD_LOG table. The following is an example of the query to retrieve error messages:

```
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'USER' AND LOG_LEVEL = 'ERROR'
ORDER BY MSG_SEQ_NO;
```

An exception table OIM_BLKLD_EX_SUFFIX is created for each data table used as the input source during the bulk load operation. Records that do not meet the criteria for the operation are copied into this exception table. The suffix appended to the name of each exception table is the same as suffix appended to the name of the corresponding data table.

To reload rejected records:

1. Create a backup of the exception table in which rejected records are stored.

```
Note: Although this is an optional step, it is recommended that you create a backup.
```

2. Review each record in the exception table, and fix errors in the data based on the message recorded in the EXCEPTION_MSG column.

3. After you fix errors in all the rejected records in an exception table, rename the table to OIM_BLKLD_TMP_SUFFIX and then use it as the input source.

4. Load records from the OIM_BLKLD_TMP_SUFFIX table by running the utility. See "Running the Utility" for more information.

5. Repeat Steps 1 through 4 until the Number of Records Rejected label in the oim_blkld_user_load_summary.log file shows the value 0.

6. Restart Oracle Identity Manager.

---

**Note:** At the end of each bulk load operation, it is recommended that you create a backup of the exception tables.
24.5.7 Verifying the Outcome of the Bulk Load Operation

To verify the outcome of the bulk load operation, check if you are able to perform the following steps for one of the OIM User added by the utility:

- Log in as the OIM User. The system should prompt you to change the password.
- Provision a resource for the OIM User.
- Add the OIM User to a role.
- Modify the account profile of the OIM User.
- Revoked the resource provisioned to the OIM User.
- Unassign the OIM User from the role to which the user was added earlier.
- Modify the account profile again to restore the profile to its original state.
- Check if the User Resource Access report (an operational report) and the User Resource Access History report can be generated for the user.

**Note:** Being a database-intensive operation by design, Bulk Load disables the constraints and indexes on the relevant Oracle Identity Manager entity tables during the start of the operation. Bulk Load operation failure towards the end of the load might at times render the indexes and constraints in disabled state. To identify and fix this issue, manually restore the indexes and constraints as follows:

1. Identify the unusable indexes and disabled constraints. To do so, the following SQL queries or similar mechanism can be used:

   ```sql
   SELECT TABLE_NAME, CONSTRAINT_NAME FROM user_constraints WHERE status = 'DISABLED';
   SELECT index_name FROM user_indexes WHERE status = 'UNUSABLE';
   ```

2. Enable the constraints and rebuild the indexes manually, as shown:

   ```sql
   ALTER TABLE TABLE_NAME ENABLE CONSTRAINT CONSTRAINT_NAME;
   ALTER INDEX INDEX_NAME REBUILD;
   ```

**Note:**

- These steps leave footprints in the system, and therefore, the bulk load verification must be performed by using a test user. If you do not want to leave the footprints in the system, then revert the changes. For example, if you have provisioned a resource to a OIM User, then deprovision the resource after testing the outcome of the bulk load operation.

- If Oracle Identity Manager is synchronized with LDAP, then after running the user data upload, run the Bulk Load Post Process scheduled job with the LdapSync option set to Yes. If you want to generate the random password and send an email to the user, then you must configure the email notification and set the Generate Password and Notification parameters to Yes in the Scheduler. See "Predefined Scheduled Tasks" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for information about the Bulk Load Post Process scheduled job.
Create an Attestation and check its status using the Diagnostic Dashboard.

24.5.8 Generating an Audit Snapshot

If required, you can generate an audit snapshot of Oracle Identity Manager data after a bulk load operation, or at any time during the bulk load operation. You can also generate audit snapshots by selecting option 7 in the Bulk Load utility. The utility uses the audit engine shipped with Oracle Identity Manager. Internally, the GenerateSnapshot script is called when you run the audit utility. Similarly, the GenerateSnapshot script is called when you select the option to generate an audit snapshot.

---
**Note:** Oracle Identity Manager must be up and running when you run the audit utility.

---

Before you generate an audit snapshot, for running the GenerateSnapshot script, you must set the following environment variables:

- **APP_SERVER**: weblogic
- **OIM_ORACLE_HOME**: c:\work1\Oracle_IDM1
- **JAVA_HOME**: C:\jdk160
- **MW_HOME**: c:\work1
- **WL_HOME**: c:\work1\wlserver_10.3
- **DOMAIN_HOME**: C:\work1\user_projects\domains\base_domain

---
**Note:** C:\work1\ is a sample directory path of MW_HOME.

---

See "Configuring Auditing" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about the procedure to generate audit snapshots.

### 24.6 Loading Account Data

The following is a summary of the steps involved in loading account data:

1. Prepare your database for a bulk load operation, if not already done. See "Preparing Your Database for a Bulk Load Operation" on page 24-5 for details.

2. Create the input source for the bulk load operation.
   
   If you want to use a database table as the input source, then create the table and copy account data into the table.
   
   If you want to use CSV files as the input source, then create the CSV files and copy account data into the files.

3. Determine values for the input parameters of the utility.

4. Stop Oracle Identity Manager.

5. Run the oim_blkld.sh or oim_blkld.bat script.

6. Monitor the progress of the bulk load operation.

7. Determine the outcome of the bulk load operation.
8. If required, reload data that was not loaded during the first run.

9. Restart Oracle Identity Manager.

10. Verify the outcome of the bulk load operation.

11. Gather diagnostic data from the operation.

12. Remove temporary tables and files created during the operation.

Requirements and Features of the Bulk Load Operation for Account Data

The following are requirements and features of the bulk load operation for account data:

- Reconciliation must be set up and you should be able to test reconciliation by importing a few accounts from the target system.

- Only accounts for which there are corresponding OIM Users can be loaded.

- A target system that requires multiple IT resources is not supported.

- Duplicate accounts cannot be detected during a bulk load operation. If there are multiple entries for the same account in the input source, then multiple accounts are created for the corresponding OIM User.

- For a particular target system, if there are multiple provisioning processes/process forms in Oracle Identity Manager, then the utility uses the default provisioning process for the resource object.

- Information about the stage up to which earlier bulk load operations progressed is not stored. In other words, the utility cannot resume a bulk load operation. You must backup the Oracle Identity Manager database before a bulk load operation. If you want to retry a bulk load operation, you must first restore the database and then rerun the procedure.

- Bulk Load utility takes the corresponding application instance name as input to load account data. If the application instance name is not known to the user, then Bulk Load utility prompts for the resource object name and IT resource name, based on which account data is loaded.

- Loading accounts where the target system is Active Directory, make sure that the input source (CSV file or database table) have the following attributes as mandatory in the attribute list along with its values:
  - UD_ADUSER_COMMONNAME
  - UD_ADUSER_USERPRINCIPALNAME

Failing to load values for these attributes at the time of Bulkload can result into failures in the provisioning-related operations at a later stage for this target.

The following sections provide detailed information about the steps involved in loading account data:

- Creating the Input Source for the Bulk Load Operation
- Determining Values for the Input Parameters of the Utility
- Monitoring the Progress of the Operation
- Handling Exceptions Recorded During the Operation
- Fixing Exceptions and Reloading Data Records
- Verifying the Outcome of the Bulk Load Operation
24.6.1 Creating the Input Source for the Bulk Load Operation

Depending on the input source that you want to use, apply the guidelines given in one of the following sections:

- Using CSV Files As the Input Source
- Creating Database Tables As the Input Source

24.6.1.1 Using CSV Files As the Input Source

If you want to use CSV files as the input source for the bulk load operation, then apply the following guidelines while creating the CSV files:

- The CSV files must be placed in the oimbulkload/csv_files directory.
- The first line in the CSV file is called the control line. This line must contain a comma-separated list of column names in the account (UD_*) table into which you want to load the account data. To find out the UD_table, go to the process form in the Design Console. See Chapter 5, "Developing Provisioning Processes" for information about process forms.

**Note:** Ensure that the Password column or any other encrypted column is not included in the list of columns.

- From the second line onward, the file must contain values for the columns in the control line. The order of columns in the first line and the values in the rest of the lines must be the same.
- If the value in any column contains a comma, then that value must be enclosed in double quotation marks (").
- The CSV file must contain values for all columns that are designated as mandatory in the account table. The key mandatory columns in the account table must be ignored.
- If you want to load account data into parent and child tables, then you must create one parent CSV file and one child CSV file for each child table. For example if you are loading data into one parent table and three child tables, then you must create one parent CSV file and three child CSV files.
- If you want to load account data into parent and child tables, then at least one column must be the same in both tables. This column corresponds to the link attribute between the parent and child CSV files. The following example illustrates this:

The following are sample contents of a parent CSV file:

```
UD_ADUSER_UID,,UD_ADUSER_FNAME,UD_ADUSER_LNAME,UD_ADUSER_MNAME,UD_ADUSER_FULLNAME,UD_ADUSER_OBJECTGUID
ADTEST1,"7-CN=ForeignSecurityPrincipals,DC=vivek01,DC=com",adtest1,adtest1,,adtest1,102
```

**Note:** The UD_ADUSER_OBJECTGUID column is mandatory in the parent CSV file for loading accounts by using the bulk load operation. This column must be added to the parent CSV file in spite of nullable column in the database.
The following are sample contents of a child CSV file:

```
UD_ADUSER_UID,UD_ADUSRC_GROUPNAME
ADTEST1,*7~CN=ForeignSecurityPrincipals,DC=vivek01,DC=com*,group2
```

The UD_ADUSER_UID column is common to both the parent file and the child file.
- If the CSV file is generated on Microsoft Windows and is to be loaded on Linux environment, then remove the special characters, such as '\n\r', to avoid run-time errors.

### 24.6.1.2 Creating Database Tables As the Input Source

If you want to use a database table as the input source for loading account data, then apply the following guidelines while creating the database table:

- Create the table in the Oracle Identity Manager database.
- The table must contain the following primary key column:
  ```
  OIM_BLKLD_USRSEQ   NUMBER(19)
  ```
  The utility uses this column as the primary key. If required, you can use a database sequence to populate this column.
- The rest of the columns must be the same as the ones in the account (UD_) table that you want to use. In other words, ignore optional UD_ columns that you do not want to include in the table that you create.

Table 24–2 shows the structure of a sample parent table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>UD_ADUSER_UID</td>
<td></td>
<td>VARCHAR2(20)</td>
</tr>
<tr>
<td>UD_ADUSER_ORGNAME</td>
<td></td>
<td>VARCHAR2(256)</td>
</tr>
<tr>
<td>UD_ADUSER_FNAME</td>
<td></td>
<td>VARCHAR2(80)</td>
</tr>
<tr>
<td>UD_ADUSER_LNAME</td>
<td></td>
<td>VARCHAR2(80)</td>
</tr>
<tr>
<td>UD_ADUSER_MNAME</td>
<td></td>
<td>VARCHAR2(80)</td>
</tr>
<tr>
<td>UD_ADUSER_FULLNAME</td>
<td></td>
<td>VARCHAR2(240)</td>
</tr>
<tr>
<td>OIM_BLKLD_SEQ</td>
<td>NOT NULL</td>
<td>NUMBER(19)</td>
</tr>
</tbody>
</table>

Table 24–3 shows the structure of a sample child table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>UD_ADUSER_UID</td>
<td></td>
<td>VARCHAR2(20)</td>
</tr>
<tr>
<td>UD_ADUSER_ORGNAME</td>
<td></td>
<td>VARCHAR2(256)</td>
</tr>
<tr>
<td>UD_ADUSRC_GROUPNAME</td>
<td></td>
<td>VARCHAR2(32)</td>
</tr>
<tr>
<td>OIM_BLKLD_SEQ</td>
<td>NOT NULL</td>
<td>NUMBER(19)</td>
</tr>
</tbody>
</table>

### 24.6.2 Determining Values for the Input Parameters of the Utility

The following are input parameters of the utility:
■ Oracle Home
Value of the ORACLE_HOME environment variable on the host computer for the Oracle Identity Manager database.

■ Database Connection String
Connection string to connect to the database that must be entered in the following format:

//HOST_IP_ADDRESS:PORT_NUMBER/SERVICE_NAME

■ OIM DB User
Database login ID of the Oracle Identity Manager database user.

■ OIM DB Pwd
Password of the Oracle Identity Manager database user. This must be entered twice when prompted.

■ Application instance name (APP_INSTANCE)
Name of the application instance corresponding to the account data to be loaded. If the user is not aware of the application instance name, then Account Bulkload utility prompts for the resource object name and IT resource name. The prompt is as shown:

Do you know the Application Instance name? (Y,y,N,n)

If you enter Y or y, then you are prompted for the application instance name. If you enter N or n, then you are prompted for the following:

– Resource Object Name (OBJ_NAME)
If the user is not aware of the application instance name, then Bulk Load utility prompts for the resource object name corresponding to the account data to be loaded.

– IT Resource Name
Name of the IT resource created for the target system. This is required only when the user is not aware of the application instance name. The account bulkload utility first prompts for resource object name, and then prompts for IT resource name.

■ CSV file names
Names of the CSV files to be used as the input source.

This parameter is used only if the input source is CSV files. See ”Using CSV Files As the Input Source” on page 24-19 for more information. If you are loading data from parent and child CSV file, then use a comma-delimited list to enter the names of the files. The name of the parent CSV file must be provided first, and it must be followed by the names of the child CSV files. In addition, enter the column that links the parent and child data.

■ Tmp table name
Name of the temporary table to be used as the input source.

This parameter is used only if the input source for the bulk load operation is a database table. See ”Creating Database Tables As the Input Source” on page 24-20 for more information.

■ Control Line
Comma-separated list of names of columns to be loaded from the database table into Oracle Identity Manager.

This parameter is used only if the input source for the bulk load operation is a database table.

- **Tablespace Name**
  Name of the tablespace in which temporary tables are to be created during the bulk load operation (if end user won't provide the tablespace name then it will pick the default tablespace).

  See "Preparing Your Database for a Bulk Load Operation" on page 24-5 for more information.

- **Date format**
  Date format used by date columns in the CSV files.

  This parameter is used only if the input source is a single or multiple CSV files.

  The date format must match the following:
  - Oracle supported date formats, such as dd-mm-yyyy or MM-DD-YYYY
  - The date format specified in the CSV file

- **Batch Size**
  Number of user records that must be processed by the utility as a single transaction.

  The batch size can influence the performance of the bulk load operation. The default value of this parameter is 10000.

- **Debug Flag**
  You can specify Y or N as the value of this parameter. If this parameter is set to Y, then the utility records detailed information about events that occur during the bulk load operation. See "Data Recorded During the Operation" on page 24-32 for more information.

- **Application Instance (APP_INSTANCE)**
  Name of the application instance corresponding to the account data to be loaded.

  If the user is not aware of the application instance name, then account bulkload utility prompts for the Object name (OBJ_NAME)

- **User ID (USR_LOGIN)**
  The user login ID that is used to determine the user that provisioned Accounts using Bulk Load utility.

### 24.6.3 Monitoring the Progress of the Operation

During the bulk load operation, you can query the OIM_BLKLD_LOG table for information about the progress of the operation. For example, you can run the following query to see progress messages generated during the bulk load operation to load account data:

```sql
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'ACCOUNT' AND LOG_LEVEL = 'PROGRESS_MSG'
ORDER BY MSG_SEQ_NO;
```
Errors encountered during the bulk load operation can be viewed by querying the OIM_BLKLD_LOG table. The following is an example of the query to retrieve error messages:

```sql
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'ACCOUNT' AND LOG_LEVEL = 'ERROR'
ORDER BY MSG_SEQ_NO;
```

### 24.6.4 Handling Exceptions Recorded During the Operation

At the end of a bulk load operation, the utility records statistics related to the operation in the following file:

`oimbulkload/logs/YYYYMMDD_hhmm/oim_blkld_account_load_summary.log`

To determine if there were exceptions during the operation, open this log file and look for the number against the Number of Records Rejected label. If the number of rejected records is greater than zero, then exceptions were thrown during the operation. User records that are rejected by the utility are recorded in the exception table (OIM_BLKLD_EX_SUFFIX). For each rejected record, the EXCEPTION_MSG column in the OIM_BLKLD_EX_SUFFIX table stores information about the reason the record could not be loaded.

**Example 24-2** shows sample statistics recorded in the log file at the end of a bulk load operation to store account data.

---

**Example 24–2**  Sample Log File Generated After Loading Account Data

```
ACCOUNT LOAD STATISTICS

Start Time:   22-JUL-08 03.59.30.206000 PM
End Time:     22-JUL-08 04.03.21.126000 PM
Number of Records Processed:  100026
Number of Records Loaded:     100000
Number of Records Rejected:   26

The names of the TMP tables used during the load:
OIM_BLKLD_TMP_P100001
OIM_BLKLD_TMP_C100002
The names of the Exception tables used during the load:
OIM_BLKLD_EX_P100001
OIM_BLKLD_EX_C100002

In this sample, the number of rejected records is 26. If the log file shows that any records were rejected by the utility, then see "Fixing Exceptions and Reloading Data Records" for information about retrying the load operation for these records.
```

---

**Note:** At the end of each bulk load operation, it is recommended that you create a backup of the exception tables.
24.6.5 Fixing Exceptions and Reloading Data Records

As mentioned earlier, errors encountered during the bulk load operation can be viewed by querying the OIM_BLKLD_LOG table. The following is an example of the query to retrieve error messages:

```
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'ACCOUNT' AND LOG_LEVEL = 'ERROR'
ORDER BY MSG_SEQ_NO;
```

An exception table OIM_BLKLD_EX_SUFFIX is created for each data table used as the input source during the bulk load operation. Records that do not meet the criteria for the operation are copied into this exception table. The suffix appended to the name of each exception table is the same as suffix appended to the name of the corresponding data table.

To reload rejected records:

1. Create a backup of the exception table in which rejected records are stored.

   **Note:** Although this is an optional step, it is recommended that you create a backup.

2. Review each record in the exception table, and fix errors in the data based on the message recorded in the EXCEPTION_MSG column.

3. After you fix errors in all the rejected records in an exception table, rename the table to OIM_BLKLD_TMP_SUFFIX and then use it as the input source.

4. Load records from the OIM_BLKLD_TMP_SUFFIX table by running the utility. See "Running the Utility" for more information.

5. Repeat Steps 1 through 4 until the Number of Records Rejected label in the oim_blkld_account_load_summary.log file shows the value 0.

6. Restart Oracle Identity Manager.

Note: If you want to load data from CSV files for multiple target systems, then you can apply one of the following approaches:

- **Approach 1:** Run the utility for all the sets of CSV files, and then perform the procedure described in this section.

- **Approach 2:** Run the utility for one set of CSV files, and perform the procedure described in this section. Then, repeat this procedure for the next set of CSV files.
Note: Being a database-intensive operation by design, Bulk Load disables the constraints and indexes on the relevant Oracle Identity Manager entity tables during the start of the operation. Bulk Load operation failure towards the end of the load might at times render the indexes and constraints in disabled state. To identify and fix this issue, manually restore the indexes and constraints as follows:

1. Identify the unusable indexes and disabled constraints. To do so, the following SQL queries or similar mechanism can be used:
   ```sql
   SELECT TABLE_NAME, CONSTRAINT_NAME FROM user_constraints WHERE status = 'DISABLED';
   SELECT index_name FROM user_indexes WHERE status = 'UNUSABLE';
   ```

2. Enable the constraints and rebuild the indexes manually, as shown:
   ```sql
   ALTER TABLE TABLE_NAME ENABLE CONSTRAINT CONSTRAINT_NAME;
   ALTER INDEX INDEX_NAME REBUILD;
   ```

24.6.6 Verifying the Outcome of the Bulk Load Operation

To verify the outcome of the bulk load operation, check if you are able to perform the following steps for one of the OIM Users for whom an account has been added by the utility:

- Log in as the OIM User, and check if the newly created account is displayed in the Accounts tab of the User details page or in My Accounts tab of My Access page for the user.
- Log in to the target system by using the credentials of the newly created account.

24.7 Loading Role, Role Hierarchy, Role Membership, and Role Category Data

The following is a summary of the steps involved in loading role-related data:

1. Prepare your database for a bulk load operation, if not already done. See "Preparing Your Database for a Bulk Load Operation" on page 24-5 for details.

2. Create the input source for the bulk load operation.
   - If you want to use a database table as the input source, then create the table and copy role-related data into the table.
   - If you want to use CSV files as the input source, then create the CSV files and copy role-related data into the files. In addition, create a master.txt file containing the names of the files in the sequence in which you want to load data from them.

3. Determine values for the input parameters of the utility.

4. Stop Oracle Identity Manager.

5. Run the oim_blkld.sh or oim_blkld.bat script.

6. Monitor the progress of the bulk load operation.

7. Determine the outcome of the bulk load operation.

8. If required, reload data that is not loaded during the first run.

9. Restart Oracle Identity Manager.
10. Verify the outcome of the bulk load operation.
11. Gather diagnostic data from the operation.
12. Remove temporary tables and files created during the operation.

The following sections provide detailed information about the steps involved in loading OIM User data:

- Creating the Input Source for the Bulk Load Operation
- Determining Values for the Input Parameters of the Utility
- Monitoring the Progress of the Operation
- Handling Exceptions Recorded During the Operation
- Fixing Exceptions and Reloading Data Records
- Verifying the Outcome of the Bulk Load Operation

24.7.1 Creating the Input Source for the Bulk Load Operation

Depending on the input source that you want to use, apply the guidelines given in one of the following sections:

- Using CSV Files As the Input Source
- Creating Database Tables As the Input Source
- Determining the UGP_NAME Generated After Role Load

24.7.1.1 Using CSV Files As the Input Source

If you want to use CSV files as the input source for the bulk load operation, then apply the following guidelines while creating the CSV files:

- The CSV files must be placed in the oimbulkload/csv_files directory.
- The first line in the CSV file is called the control line.
- This line must contain a comma-separated list of column names based on the selected role upload (role, role hierarchy, role membership, and role category) in the Oracle Identity Manager database.
- From the second line onward, the file must contain values for the columns in the control line. The order of columns in the first line and the values in the rest of the lines must be the same. The following is a sample content of a role (UGP) CSV file:

```
UGP_ROLENAME,UGP_NAMESPACE,USR_LOGIN,ORG_NAME,INCLUDE_HIERARCHY
"Finance Controllers",Default,XELSYSADM,Finance,YES
"Finance Controllers",Default,XELSYSADM,Requests,YES
```

- Role load is capable of publishing the roles to organizations to follow the security model in Oracle Identity Manager, with an option to include hierarchy.

As a value of the ORG_NAME parameter, specify the organization name, such as Finance or Requests, to which you want to publish the roles. Specify YES for INCLUDE_HIERARCHY if you want to publish the roles to the specified organization and its suborganizations. Specify NULL or NO for INCLUDE_HIERARCHY if you want to publish the roles only to the specified organization and not its suborganizations. If you do not specify values for the ORG_NAME and INCLUDE_HIERARCHY parameters, then by default, the roles are published to the Top organization with hierarchy.
If the value in any column contains a comma, then that value must be enclosed in double quotation marks (".").

The CSV file must contain values for all columns that are designated as mandatory in the respective role tables.

The CSV file must contain values for all columns that are designated as mandatory depending on the upload role data, role hierarchy data, role membership data, and role category data.

- Role (UGP): UGP_ROLENAME, UGP_NAMESPACE, USR_LOGIN, ORG_NAME, INCLUDE_HIERARCHY (UGP_NAMESPACE, ORG_NAME)
  INCLUDE_HIERARCHY can be left as null when not required.
- Role Hierarchy (GPG): UGP_NAME, GPG_UGP_NAME
- Role Membership (USG): UGP_NAME, USR_LOGIN
- Role Category (ROLE_CATEGORY): ROLE_CATEGORY_NAME

Each row in the CSV file must have a unique value for the combinationation of mandatory columns.

The following default values are inserted into Oracle Identity Manager if the CSV file does not contain values for these columns:

- For Role (UGP)
  ROLE_CATEGORY_NAME: Default
  UGP_DISPLAY_NAME: Defaults to UGP_NAME
  ORG_NAME: TOP
  INCLUDE_HIERARCHY: YES
- For Role Hierarchy (GPG)
  None
- For Role Membership (USG)
  RUL_KEY: RUL_KEY from RUL table with RUL_NAME as 'Default'
  USG_PRIORITY: group and rank based on UGP_KEY based on the rows given for upload.
- Role Category (ROLE CATEGORY)
  None

Create a master TXT file containing the names of the CSV files containing role data to be loaded. You can specify any name for the file, for example, master.txt. Save the master file in the oimbulkload/csv_files directory.

If you want to load multiple CSV files, then enter the name of each data CSV file on a separate line in the master file. Order the list of CSV file names in the sequence in which you want the utility to load data from the files. For example, suppose you have created three data CSV files, Role1.csv, Role2.csv, and Role3.csv. In the master file, enter the names of the data CSV files in the following order:

Role1.csv
Role2.csv
Role3.csv

When you run the utility, data is loaded in this order.
If the CSV file is generated on Microsoft Windows and is to be loaded on Linux environment, then remove the special characters, such as ‘\n\r’, to avoid run-time errors.

### 24.7.1.2 Creating Database Tables As the Input Source

If you want to use a database table as the input source for loading OIM User data, then apply the following guidelines while creating the database table:

- Create the table in the Oracle Identity Manager database.
- The table must contain the following primary key column:
  ```
  OIM_BLKLD_USRSEQ NUMBER(19)
  ```
  The utility uses this column as the primary key. If required, you can use a database sequence to populate this column.
- The rest of the columns must be the same as the ones in the respective role tables that you want to use.

Table 24–4 shows the structure of a sample database role table.

<table>
<thead>
<tr>
<th>Role</th>
<th>NULL</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>UGP_ROLENAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(2000)</td>
</tr>
<tr>
<td>UGP_NAMESPACE</td>
<td></td>
<td>VARCHAR2(512)</td>
</tr>
<tr>
<td>ORG_NAME</td>
<td>NOT NULL</td>
<td>VARCHAR2(256)</td>
</tr>
<tr>
<td>INCLUDE_HIERARCHY</td>
<td>NOT NULL</td>
<td>VARCHAR2(256)</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>OIM_BLKLD_USRSEQ</td>
<td>NOT NULL</td>
<td>NUMBER(19)</td>
</tr>
</tbody>
</table>

**Note:** ORG_NAME and INCLUDE_HIERARCHY are required for loading roles only, and not for role hierarchy, role membership, and role category.

### 24.7.1.3 Determining the UGP_NAME Generated After Role Load

Bulkload utility generates UGP_NAME during role load in the following format:

```
UGP_NAMESPACE.UGP_ROLENAME
```

By default, the value of UGP_NAMESPACE is Default, when you do not provide any specific value for UGP_NAMESPACE in the CSV file. To determine the generated UGP_NAME:

1. If UGP_NAMESPACE is null in the CSV file, then the namespace value is Default, and the generated UGP_NAME is equal to the value of UGP_ROLENAME.
2. If UGP_NAMESPACE is not null and has a defined value in the CSV file, then the generated UGP_NAME is equal to the value of UGP_NAMESPACE.UGP_ROLENAME.

On the basis of the UGP_NAME generation methodology, you can determine the UGP_NAME values for the next loading of role hierarchy, role membership, and role category, even if you do not have direct access to the database. Otherwise, you can check the generated value of UGP_NAME in the UGP table.
24.7.2 Determining Values for the Input Parameters of the Utility

The following are input parameters of the utility:

- **Oracle Home**
  Value of the ORACLE_HOME environment variable on the host computer for the Oracle Identity Manager database

- **Database Connection String**
  Connection string to connect to the database that must be entered in the following format:
  
  //HOST_IP_ADDRESS:PORT_NUMBER/SERVICE_NAME

- **OIM DB User**
  Database login ID of the Oracle Identity Manager database user

- **OIM DB Pwd**
  Password of the Oracle Identity Manager database user. Enter the password twice when prompted.

- **CSV file names**
  Names of the CSV files to be used as the input source
  This parameter is used only if the input source is CSV files. See "Using CSV Files As the Input Source" on page 24-26 for more information. If you are loading data from parent and child CSV file, then use a comma-delimited list to enter the names of the files. The name of the parent CSV file must be provided first, and it must be followed by the names of the child CSV files.

- **Tmp table name**
  Name of the temporary table to be used as the input source
  This parameter is used only if the input source for the bulk load operation is a database table. See "Creating Database Tables As the Input Source" on page 24-28 for more information.

- **Control Line**
  Comma-separated list of names of columns to be loaded from the database table into Oracle Identity Manager
  This parameter is used only if the input source for the bulk load operation is a database table. Note that the OIM_BLKLD_USRSEQ column created in the source table must not be listed as a control line column.

- **Tablespace Name**
  Name of the tablespace in which temporary tables are to be created during the bulk load operation (if end user won’t provide the tablespace name then it will pick the default tablespace)
  See "Preparing Your Database for a Bulk Load Operation" on page 24-5 for more information.

- **Date format**
  Date format used by date columns in the CSV files. This is prompted only for role load, and not for role hierarchy, role membership, and role category.
  This parameter is used only if the input source is a single or multiple CSV files.
The date format must match the following:
- Oracle supported date formats, such as dd-mm-yyyy or MM-DD-YYYY
- The date format specified in the CSV file

**Batch Size**
Number of user records that must be processed by the utility as a single transaction
The batch size can influence the performance of the bulk load operation. The default value of this parameter is 10000.

**Debug Flag**
You can specify Y or N as the value of this parameter. If this parameter is set to Y, then the utility records detailed information about events that occur during the bulk load operation. See "Data Recorded During the Operation" on page 24-32 for more information.

### 24.7.3 Monitoring the Progress of the Operation
During the bulk load operation, you can query the OIM_BLKLD_LOG table for information about the progress of the operation. For example, you can run the following query to see progress messages generated during the bulk load operation to load OIM Role data:

```sql
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'ROLE' AND LOG_LEVEL = 'PROGRESS_MSG'
ORDER BY MSG_SEQ_NO;
```

Errors encountered during the bulk load operation can be viewed by querying the OIM_BLKLD_LOG table. The following is an example of the query to retrieve error messages:

```sql
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'ROLE' AND LOG_LEVEL = 'ERROR'
ORDER BY MSG_SEQ_NO;
```

### 24.7.4 Handling Exceptions Recorded During the Operation
At the end of a bulk load operation, the utility records statistics related to the operation in the following file:

`oimbulkload/logs/YYYYMMDD_HHMM/oim_blkld_ENTITY_NAME_load_summary.log`

In the log file name, `ENTITY_NAME` stands for the entity being loaded. For example:

- For roles, the log file name is `oim_blkld_role_load_summary.log`.
- For role memberships, the log file name is `oim_blkld_rolemem_load_summary.log`.

To determine if there were exceptions during the operation, open this log file and look for the number against the Number of Records Rejected label. If the number of rejected records is greater than zero, then exceptions were thrown during the operation. User records that are rejected by the utility are recorded in the exception table (OIM_BLKLD_EX_SUFFIX). For each rejected record, the EXCEPTION_MSG column in the OIM_BLKLD_EX_SUFFIX table stores information about the reason the record could not be loaded.
Example 24–3 shows sample statistics recorded in the log file at the end of a bulk load operation to store OIM Role data.

**Example 24–3  Sample Log File Generated After Loading OIM Role Data**

```
**********************************************************************************
*****************
Processing File: Role.csv
==================================================================================
========
ROLE LOAD STATISTICS FOR FILE : Role.csv
==================================================================================
========
Start Time:   17-NOV-09 02.48.18.447767 AM
End Time:     17-NOV-09 02.48.19.228710 AM
Number of Records Processed:  2
Number of Records Loaded:     2
Number of Records Rejected:   0
==================================================================================
========
The name of the TMP table used during the load:
OIM_BLKLD_TMP_ROLE1

The name of the Exception table used during the load:
OIM_BLKLD_EX_ROLE1

Time taken in re-building indexes and enabling FK constraints

Start time:      17-NOV-09 02.48.19.243781 AM
```

In this sample, the number of rejected loaded is 2. If the log file shows that any records have been rejected by the utility, then see "Fixing Exceptions and Reloading Data Records" on page 24-31 for information about retrying the load operation for these records.

**Note:** You cannot use the utility to load data into a remote Oracle Identity Manager database.

**24.7.5 Fixing Exceptions and Reloading Data Records**

As mentioned earlier, errors encountered during the bulk load operation can be viewed by querying the OIM_BLKLD_LOG table. The following is an example of the query to retrieve error messages:

```
SELECT MSG FROM OIM_BLKLD_LOG
WHERE MODULE = 'ROLE' AND LOG_LEVEL = 'ERROR'
ORDER BY MSG_SEQ_NO;
```

An exception table OIM_BLKLD_EX_SUFFIX is created for each data table used as the input source during the bulk load operation. Records that do not meet the criteria for the operation are copied into this exception table. The suffix appended to the name of each exception table is the same as suffix appended to the name of the corresponding data table.

To reload rejected records:
1. Create a backup of the exception table in which rejected records are stored.

   **Note:** Although this is an optional step, it is recommended that you create a backup.

2. Review each record in the exception table, and fix errors in the data based on the message recorded in the EXCEPTION_MSG column.

3. After you fix errors in all the rejected records in an exception table, rename the table to OIM_BLKLD_TMP_SUFFIX and then use it as the input source.

4. Load records from the OIM_BLKLD_TMP_SUFFIX table by running the utility. See "Running the Utility" on page 24-6 for more information.

5. Repeat Steps 1 through 4 until the Number of Records Rejected label shows the value 0 in the oim_blkld_role_load_summary.log file or the corresponding log file for role membership, role hierarchy, and role category.

6. Restart Oracle Identity Manager.

   **Note:** Being a database-intensive operation by design, Bulk Load disables the constraints and indexes on the relevant Oracle Identity Manager entity tables during the start of the operation. Bulk Load operation failure towards the end of the load might at times render the indexes and constraints in disabled state. To identify and fix this issue, manually restore the indexes and constraints as follows:

   1. Identify the unusable indexes and disabled constraints. To do so, the following SQL queries or similar mechanism can be used:

```
SELECT TABLE_NAME, CONSTRAINT_NAME FROM user_constraints WHERE status = 'DISABLED';
SELECT index_name FROM user_indexes WHERE status = 'UNUSABLE';
```

   2. Enable the constraints and rebuild the indexes manually, as shown:

```
ALTER TABLE TABLE_NAME ENABLE CONSTRAINT CONSTRAINT_NAME;
ALTER INDEX INDEX_NAME REBUILD;
```

24.7.6 **Verifying the Outcome of the Bulk Load Operation**

To verify the outcome of the bulk load operation, check if you are able to perform the following steps for one of the OIM Role added by the utility:

1. Log in to Oracle Identity Self Service, and verify that the newly created role is displayed in the search result for roles.

2. For the newly created role hierarchy and role members, click the **Hierarchy** and **Members** tabs respectively on the role details page.

3. To verify the newly created role category, in the Welcome page of Oracle Identity Administration, click **Advanced Search - Role Categories**. Then, perform an advanced search to find the newly created role.

24.8 **Data Recorded During the Operation**

During the bulk load operation, the utility inserts progress and error messages in the OIM_BLKLD_LOG table. Data in this table is not deleted at the start of a new bulk
Data Recorded During the Operation

One of the columns in this table holds the time stamp at which messages are recorded in the table.

Table 24–5 describes the structure of the OIM_BLKLD_LOG table.

<table>
<thead>
<tr>
<th>Column</th>
<th>NULL</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG_SEQ_NO</td>
<td>NULL</td>
<td>NUMBER(19)</td>
<td>This column stores the number that denotes the order in which messages are inserted in this table. The column is populated by using the OIM_BLKLD_LOG_SEQ sequence. You can use this column to query for messages in the order in which they are recorded in the table.</td>
</tr>
<tr>
<td>MODULE</td>
<td>NOT NULL</td>
<td>VARCHAR2(20)</td>
<td>This column stores one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ROLE: This value indicates that the message has been recorded while loading OIM Role data.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ROLE HIERARCHY: This value indicates that the message has been recorded while loading role hierarchy data.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ROLE MEMBERSHIP: This value indicates that the message has been recorded while loading OIM role membership data.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ROLE CATEGORY: This value indicates that the message has been recorded while loading OIM role category data.</td>
</tr>
<tr>
<td>LOG_LEVEL</td>
<td>NOT NULL</td>
<td>VARCHAR2(20)</td>
<td>This column stores one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ERROR: Designates fine-grained informational events that are useful to debug.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DEBUG: Designates error events that might allow the application to continue running. Error is used to log all unhandled exceptions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>PROGRESS_MSG: Designates intermediate progress messages.</td>
</tr>
<tr>
<td>LOAD_SOURCE</td>
<td>NOT NULL</td>
<td>VARCHAR2(40)</td>
<td>This column indicates the source of data for the bulk load operation during which the row was inserted. The value can be one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>CSV File: FILE_NAME</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DB Table</td>
</tr>
</tbody>
</table>
24.9 Gathering Diagnostic Data from the Bulk Load Operation

As mentioned earlier in this document, the following log files are created during the bulk load operation:

- For OIM Users:
  oimbulkload/logs/YYYYMMDD_HHMM/oim_blkld_user_load_summary.log

- For accounts:
  oimbulkload/logs/YYYYMMDD_HHMM/oim_blkld_account_load_summary.log

- For roles, role hierarchies, memberships, and role categories:
  oimbulkload/logs/YYYYMMDD_HHMM/oim_blkld_ENTITY_NAME_load_summary.log

In the log file name, ENTITY_NAME stands for the entity being loaded. For example:
- For roles, the log file name is oimblkld_role_load_summary.log.
- For role memberships, the log file name is oimblkld_rolemem_load_summary.log.

Data recorded in this file can be used to collate performance-related information about the bulk load operation. The following information can be collected after the bulk load operation:

- Start time
- Input source
- Number of records in the system before the load
- Number of records successfully loaded
- Number of records rejected
- Total time taken

You can use this information during future runs of the utility.

See Also: Table 24–5, "Structure of the OIM_BLKLD_LOG Table" for information about the log levels that stores error events

<table>
<thead>
<tr>
<th>Column</th>
<th>NULL</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG</td>
<td>NOT NULL</td>
<td>VARCHAR2(4000)</td>
<td>This column stores a message corresponding to the value stored in the LOG_LEVEL column.</td>
</tr>
<tr>
<td>CREATE_DATE</td>
<td>DATE</td>
<td></td>
<td>This column holds the time stamp at which the record was created. The format for entries in this column is as follows: yyyy/mm/dd hh24:mi:ss For example: 2008/06/23 21:49:16.32</td>
</tr>
</tbody>
</table>

Table 24–5 (Cont.) Structure of the OIM_BLKLD_LOG Table
24.10 Cleaning Up After a Bulk Load Operation

If you do not want to save the results of a bulk load operation, then:

- Remove the OIM_BLKLD_TMP_SUFFIX, OIM_BLKLD_EX_SUFFIX, and OIM_BLKLD_LOG tables.
- Remove any files that you created or used during the operation.
- If you created a tablespace for the operation, then remove the tablespace.
- See "Gathering Diagnostic Data from the Bulk Load Operation" before you remove log files created in the logs_timestamp directory.

**Note:** At this point, you can restart Oracle Identity Manager if you have not already done so.

24.11 Bulk Load High Volume Strategy and Case Studies

For information about general best practices and few case studies about high-volume data load, see the Tech note titled *OIM 11G BulkLoad Utility Strategies & Case Studies* (Doc ID 1959363.1) in the My Oracle Support web site at:

https://support.oracle.com
Configuring LDAP Container Rules

In earlier releases of Oracle Identity Manager, role name (UGP:UGP_NAME in the database) is unique. This is a limitation because a lot of roles can exist in large enterprises, and as a result, it is possible that administrators need to create two or more roles in Oracle Identity Manager with the same name but for different purpose.

Oracle Identity Manager can be installed with LDAP synchronization enabled. When roles are coming from LDAP via reconciliation, it is possible that two or more roles have the same name. LDAP supports two roles with the same name if the roles are located under two different Organization Units (OUs).

In Oracle Identity Manager 11g Release 2 (11.1.2.2.0), namespace is introduced to handle two roles with the same name. Roles with the same name are supported if the roles are in different namespaces. However, two or more roles with the same name in the same namespace is not supported.

When LDAP is integrated with Oracle Identity Manager, the namespace maps to an OU. By the default configuration, there is only one default namespace called Default, and therefore, role names are unique. To configure multiple namespaces, you must create an XML file called LDAPContainerRules.xml and load it in the metadata store (MDS). The LDAPContainerRules.xml also specifies the namespace of a role based on the role attributes.

When LDAP synchronization is enabled, and a user is to be created, then a plug-in determines in which container the user is to be created. Similarly, if a role is to be created, then this plug-in determines the container in which the role is to be created. For this, Oracle Identity Manager calls a plug-in that implements the oracle.iam.ldapsync.LDAPContainerMapper interface. All the attributes of the user/role are passed to the plug-in, and it returns the Domain Name (DN) of the LDAP container. You can write your own plug-in, register the plug-in to Oracle Identity Manager, and then configure Oracle Identity Manager to use the plug-in by setting the LDAPContainerMapperPlugin system property. See “System Properties in Oracle Identity Manager” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about this system property.

Oracle Identity Manager provides a default plug-in for determining the LDAP container for user/role based on user or role attributes that are synchronized to LDAP. The default plug-in reads the rules from a XML file to determine the LDAP container. The XML file must deployed to MDS as /db/LDAPContainerRules.xml. When Oracle Identity Manager is installed with LDAP synchronization enabled, the installer asks for user and role container values. These values are stored in the /db/LDAPContainerRules.xml file at containers for which the expression is Default. The following is an example:
In the LDAPContainerRules.xml file, each rule contains the following sections:

- **Expression**: This specifies the actual rule that you use to find the namespace and the OU for LDAP.

  The `<expression>` tag must be defined based on user/role attributes. Only the equal to (=) operator is supported in the `<expression>` tag. The expression can be based on multiple attributes, as shown in the example, and the LDAP container is determined based on an AND operation of all the defined attributes. If none of the rules satisfy, then the users or roles are put in the container for which expression is Default.

- **Description**: This is the namespace that is used for the Role Namespace attribute.

  The description (namespace) associated to the default expression will always use Default. By default, roles do not have many attributes for creating meaningful expressions. Therefore, you need to add a new User Defined Field (UDF) attribute, for instance, the Role Location attribute. In this example, the Role Description attribute is used to define the rule.

- **Container**: This is the OU that is used to figure out where to create the user or role in LDAP.

  Suppose a user is to be created with the attributes Country=US and Locality Name=AMER. This user would be created in the container l=amer,dc=oracle,dc=com. If a user is to be created in Country=France and Locality Name=FR, then it would be created in the container l=apac,dc=oracle,dc=com.
l=users,dc=oracle,dc=com because no expression matches these two attributes, and therefore, the default container is selected.
Oracle Identity Manager contains a set of predefined tasks that can be scheduled as job runs. An example is a password warning task that sends email to users for password expiration.

Oracle Identity Manager also provides the capability of creating your own scheduled tasks. You can create scheduled tasks according to your requirements if none of the predefined scheduled tasks fit your needs.

For example, you can configure a reconciliation run using a scheduled task that checks for new information on target systems periodically and replicates the data in Oracle Identity Manager.

This chapter explains how to create and implement your custom scheduled tasks. It contains these topics:

- Overview of Task Creation
- Defining the Metadata for the Scheduled Task
- Configuring the Scheduled Task XML File
- Developing the Scheduled Task Class
- Configuring the Plug-in XML File
- Creating the Directory Structure for the Scheduled Task
- Scheduled Task Configuration File
- Best Practices for Creating Custom Scheduled Tasks
- Using the isStop() Method

### 26.1 Overview of Task Creation

This section outlines the essential steps in creating scheduled tasks, and presents an example to illustrate the process. Subsequent sections provide details on each step.

- Steps in Task Creation
- Example of Scheduled Task

### 26.1.1 Steps in Task Creation

The basic steps for configuring new scheduled tasks are as follows:
1. Review Oracle Identity Manager's predefined scheduled tasks to determine whether a custom task is necessary.

   For details about the predefined tasks, see "Managing Scheduled Tasks" in the Oracle Fusion Middleware System Administrator's Guide for Oracle Identity Manager.

2. Determine key features of the scheduled task, such as the task name and the parameters that control the actions performed by the task.

   For details, see Section 26.2, "Defining the Metadata for the Scheduled Task".

3. Add the task metadata to the scheduled task XML file.

   For details, see Section 26.3, "Configuring the Scheduled Task XML File".

4. Develop the scheduled task Java class.

   For details, see Section 26.4, "Developing the Scheduled Task Class".

5. Declare the new scheduled task as a plug-in.

   For details, see Section 26.5, "Configuring the Plug-in XML File".

6. Package the task files so that Oracle Identity Manager can locate the files and make the task available for jobs.

   For details, see Section 26.6, "Creating the Directory Structure for the Scheduled Task".

### 26.1.2 Example of Scheduled Task

To illustrate the steps in developing a scheduled task, we use an example scheduled task that retrieves employee records belonging to the given department from a given IT resource.

In addition, our scheduled task should allow the user to specify the number of records to be retrieved and whether to include disabled records in the retrieval.

### 26.2 Defining the Metadata for the Scheduled Task

Each scheduled task contains the following metadata information:

- Name of the scheduled task
- Name of the Java class that implements the scheduled task
- Description
- Retry Interval
- (Optional) Parameters that the scheduled task accepts. Each parameter contains the following additional information:
  - Parameter Name
  - Parameter Data Type
  - Required / Optional Parameter
  - Help Text
26.3 Configuring the Scheduled Task XML File

Configuring the scheduled task XML file involves updating the XML file that contains the definitions of custom scheduled tasks. This section describes how to update the task XML file with the details of the new custom scheduled task.

You can modify the task.xml file located in the /db namespace of Oracle Identity Manager MDS schema, or you can create a custom scheduled task file. If you create a custom file, then the file name must be the same as the scheduled task name, with the .xml extension. You must import the custom scheduled task file to the /db namespace of Oracle Identity Manager MDS schema.

**See Also:** Chapter 27, "Developing Plug-ins" for examples of plug-ins.

---

**Note:** The scheduled task XML file can be imported into MDS using the Oracle Enterprise Manager. In a clustered environment, having the file in MDS avoids the need to copy the file on each node of the cluster.

For details about importing files into MDS, see "Migrating User Modifiable Metadata Files" on page 37-1.

---

The elements in the XML file reflect the task parameters that you described in Section 26.2, "Defining the Metadata for the Scheduled Task".

**Example 26–1** shows a sample XML code for the scheduled task described in the preceding paragraph. Note that all the parameters are declared to be required parameters in this example.

### Example 26–1 Sample XML for a Scheduled Task

```xml
<scheduledTasks xmlns="http://xmlns.oracle.com/oim/scheduler">
  <task>
    <name>Test_scheduled_task</name>
    <class>oracle.iam.scheduler.TestScheduler</class>
    <description>Retrieve Employee Records For Given Department</description>
    <retry>5</retry>
    <parameters>
      <string-param required="true" encrypted="false" helpText="Name of the department">Department Name</string-param>
      <number-param required="true" helpText="Number of Records to Be Retrieved">Number of Records</number-param>
      <boolean-param required="false" helpText="Retrieve disabled employee records?">Get Disabled Employees</boolean-param>
    </parameters>
  </task>
</scheduledTasks>
```

**See Also:** "Scheduled Task Configuration File" on page 26-6 for details about the elements in the scheduled task configuration file.

This is basically exporting the task.xml from MDS and then adding the required tags to it and importing it back into MDS.
Developing the Scheduled Task Class

You must export the task.xml file from MDS, add the required tags to the file, and then import it back to MDS. See "Migrating User Modifiable Metadata Files" on page 37-1 for information about exporting and importing MDS files.

26.4 Developing the Scheduled Task Class

The next step is to create a Java class to execute the task whose metadata was defined in the XML file. The Java class that implements a scheduled task is known as a scheduled task class.

To develop a Java class for the scheduled task:

1. Create a Java class file that extends the oracle.iam.scheduler.vo.TaskSupport class and overrides the execute() method with processing logic based on your requirements. The Java class must also override the other abstract methods:

   public HashMap getAttributes();
   public void setAttributes();

2. Create a JAR file for the Java class that you created. Name the JAR such that you can readily associate this JAR with your custom scheduled task.

   The JAR file can contain the dependent classes of the Java class. You can also create a separate JAR file for the dependent classes and place it in the lib/directory.

3. Copy the JAR file into the lib/ directory.

4. Repeat Steps 1 through 3 for every Java class that you want to create.

26.5 Configuring the Plug-in XML File

You must configure the plugin.xml file in order to declare the scheduled task as a plug-in. See Chapter 27, "Developing Plug-ins" for more information about plug-ins.

Oracle recommends creating one plugin.xml file for one scheduled task. This is because when the plugin is unregistered, the corresponding package is deleted.

To configure the plugin.xml file:

1. Create the plugin.xml file by using any text editor.

   Create the plugin.xml file only if no such file exists. If there are existing plugins, then add a new plugin element for the new plugin.

2. Specify the plug-in point for the scheduled task by changing the value of the pluginpoint attribute of the plugins element to oracle.iam.scheduler.vo.TaskSupport.
The following XML code block from the plugin.xml file shows the value entered within the plugins element:

```xml
<plugins pluginpoint="oracle.iam.scheduled.vo.TaskSupport">

Note: For scheduled tasks, the <plugins> element remains the same for all scheduled tasks.

3. Add a <plugin> element for each scheduled task that you are adding.

To specify the class that implements the plug-in (in this case, the scheduled task), change the value of the pluginclass attribute of the plugin element to the name of the Java class that implements the scheduled task. The following XML code block from the plugin.xml file shows sample values entered within the plugin element:

```xml
<plugin pluginclass="oracle.iam.scheduled.TestScheduler" version="1.0.1" name="scheduler element"/>
```

After modification, the plugin.xml file looks similar to the following:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oimplugins xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<plugins pluginpoint="oracle.iam.scheduled.vo.TaskSupport">
<plugin pluginclass="oracle.iam.scheduled.TestScheduler" version="1.0.1" name="scheduler element"/>
</plugins>
</oimplugins>
```

4. Save and close the plugin.xml file.

### 26.6 Creating the Directory Structure for the Scheduled Task

The final step in configuring the scheduled task is to create a plugin.zip file with the directory structure specified in Example 26–2. In this example, a single plug-in is being added, but there can be multiple plugins in the plugin.zip file. Scheduler requires that files be zipped in a particular structure and named according to a particular naming convention. This ensures that Oracle Identity Manager identifies the custom scheduled tasks and makes it available in Oracle Identity System Administration while creating jobs.

**Example 26–2 Directory Structure for the Scheduled Task**

```
plugin/
  lib/
    PLUGIN.JAR
    plugin.xml
    META-INF (optional)
      METADATA.xml
```

Note that:

- The XML file for the plug-in must be named plugin.xml.
- The lib/ directory must contain only JAR files. The lib/ directory consists of JAR files that contains the classes implementing the plug-in logic and the dependent library JAR files. In most instances, this directory consists of a single JAR file with the implementation of all the plug-ins that are specified in plugin.xml. See
"Developing Plug-ins" on page 27-6 for information about the directory structure.

- The directory for the scheduled task must contain the following files:
  - XML for the plug-in
  - JAR files
- There is one plugin.zip file for all the plug-ins that you create.
- The META-INF folder is an optional folder, in which metadata (task definition) file can be stored. If this file is placed in the META-INF folder, then it is not required to be seeded in MDS.
- If META-INF folder does not exist or if the metadata file is not placed in the META-INF folder, then seed the file to MDS.

In the preceding example, CLASS_NAME.JAR is the JAR file that you create in Section 26.4, "Developing the Scheduled Task Class".

After you create the plugin.zip file, if deploying in a clustered environment, register the plug-in to the database by using appropriate APIs. See "Registering and Unregistering Plug-ins By Using APIs" on page 27-7 for details about registering plug-ins to Oracle Identity Manager by using APIs.

---

**Note:** The XML for the plug-in must be named plugin.xml. Ensure that the lib directory contains only JAR files.

### 26.7 Scheduled Task Configuration File

This appendix describes the structure and details of the XML file containing scheduler task definitions.

- Structure of the Scheduler XML File
- The scheduledTasks Element
- The task Element
- The name Element
- The class Element
- The description Element
- The retry Element
- The parameters Element
- The string-param Element
- The number-param Element
- The boolean-param Element

#### 26.7.1 Structure of the Scheduler XML File

The following is a list of elements in the configuration XML file:

```xml
<scheduledTasks xmlns="http://xmlns.oracle.com/oim/scheduler">
  <task>
    <name/>
    <class/>
    <description/>
    <retry/>
```

---

26-6 Oracle Fusion Middleware Developer's Guide for Oracle Identity Manager
The scheduledTasks Element

The scheduledTasks element is the root element in XML used to define scheduled tasks. Table 26–1 summarizes the properties of the scheduledTasks element.

Table 26–1 Properties of the scheduledTasks Element

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>NA</td>
</tr>
<tr>
<td>Attributes</td>
<td>The XML namespace is specified as an attribute of the scheduledTasks element as follows:</td>
</tr>
<tr>
<td></td>
<td>&lt;scheduledTasks xmlns=&quot;http://xmlns.oracle.com/oim/scheduler&quot;&gt;</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The xmlns parameter is mandatory.</td>
</tr>
<tr>
<td>Child Elements</td>
<td>task</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One for each scheduled task XML file to be created.</td>
</tr>
<tr>
<td>Element Value</td>
<td>NA</td>
</tr>
<tr>
<td>Mandatory or Optional?</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>

The task Element

The task element is the child element of the scheduledTasks element. You use the task element to define a scheduled task. The task element contains information about the scheduled task, for example, the name, class, description, and retry count of the scheduled task.

Table 26–2 summarizes the properties of the task element.

Table 26–2 Properties of the task Element

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>scheduledTasks</td>
</tr>
<tr>
<td>Attributes</td>
<td>None</td>
</tr>
<tr>
<td>Child Elements</td>
<td>name, class, description, retry, and parameters</td>
</tr>
</tbody>
</table>
### 26.7.4 The name Element

The name element is the child element of the task element. The name element is used to specify the name of the scheduled task being created. 

Table 26–3 summarizes the properties of the name element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>task</td>
</tr>
<tr>
<td>Attributes</td>
<td>None</td>
</tr>
<tr>
<td>Child Elements</td>
<td>None</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One</td>
</tr>
<tr>
<td>Element Value</td>
<td>Name of the scheduled task being created.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The name of the scheduled task must be unique.</td>
</tr>
<tr>
<td>Mandatory or Optional?</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>

### 26.7.5 The class Element

The class element is a mandatory element and is the child element of the task element. You use the class element to specify the name of the Java class that runs the scheduled task.

Table 26–4 summarizes the properties of the class element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>task</td>
</tr>
<tr>
<td>Attributes</td>
<td>None</td>
</tr>
<tr>
<td>Child Elements</td>
<td>None</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One</td>
</tr>
<tr>
<td>Element Value</td>
<td>Name of the Java class that runs the scheduled task. See &quot;Developing the Scheduled Task Class&quot; on page 26-4 for information on developing a class for the scheduled task.</td>
</tr>
<tr>
<td>Mandatory or Optional?</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>
26.7.6 The description Element

The description element is a mandatory element and is the child element of the task element. You can use the description element to provide a description of the task being created.

Table 26–5 summarizes the properties of the description element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>task</td>
</tr>
<tr>
<td>Attributes</td>
<td>None</td>
</tr>
<tr>
<td>Child Elements</td>
<td>None</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One</td>
</tr>
<tr>
<td>Element Value</td>
<td>Description of the task being created</td>
</tr>
<tr>
<td>Mandatory or Optional?</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>

26.7.7 The retry Element

Table 26–6 summarizes the properties of the retry element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>task</td>
</tr>
<tr>
<td>Attributes</td>
<td>None</td>
</tr>
<tr>
<td>Child Elements</td>
<td>None</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One</td>
</tr>
<tr>
<td>Element Value</td>
<td>Number of seconds the scheduler must wait before it tries to schedule the task again</td>
</tr>
<tr>
<td>Mandatory or Optional?</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>

26.7.8 The parameters Element

If you want to specify parameters at run time that the scheduled task requires for a successful job run, you must use the parameters element. For example, you might create a scheduled task that requires the user to specify the number of records to be retrieved at run time.

The parameters specified within this element are displayed under the Parameters section on the Create Job page.

Table 26–7 summarizes the properties of the parameters element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>task</td>
</tr>
<tr>
<td>Attributes</td>
<td>None</td>
</tr>
<tr>
<td>Child Elements</td>
<td>string-param, number-param, boolean-param</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One</td>
</tr>
</tbody>
</table>
26.7.9 The string-param Element

You can use the string-param element to specify the name of the field that can take a value of the string data type. In other words, the string-param element specifies a label for the field that can hold a value of the string data type.

Table 26–8 summarizes the properties of the string-param element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>parameters</td>
</tr>
<tr>
<td>Attributes</td>
<td>required, helpText, encrypted</td>
</tr>
<tr>
<td>Child Elements</td>
<td>None</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One for every parameter of the string data type</td>
</tr>
<tr>
<td>Element Value</td>
<td>Name of the string parameter</td>
</tr>
<tr>
<td>Mandatory or Optional?</td>
<td>Optional</td>
</tr>
</tbody>
</table>

As listed in Table 26–8, the string-param element contains the following attributes:

- **required**
  
  This is a mandatory attribute and it can take a value of either true or false.

  If the value of the required attribute is true, it is mandatory to enter a value for the parameter at run time.

  If the value of the required attribute is false, it is not mandatory to enter a value for the parameter at run time.

- **helpText**
  
  Use this attribute to specify the text that must appear at run time to help users know what to enter in the field. The text that is specified is usually the description of the field that is being created by the parameter.

- **encrypted**
  
  By default, it has a value of false and this can take a value of either true or false.

  If the value of the encrypted attribute is true, then the entered value for the parameter at run time is stored in encrypted form.

  If the value of the required attribute is false, then the entered value for the parameter at run time is stored in plain text.

26.7.10 The number-param Element

You can use the number-param element to specify the name of the field that can take a value of the long data type.

Table 26–9 summarizes the properties of the number-param element.
The behavior and description of the require and helpText attributes for the number-param and string-param elements is the same. See "The string-param Element" on page 26-10 for information about the require and helpText attributes.

26.7.11 The boolean-param Element

You can use the boolean-param element to specify the name of the field that can take a value of the boolean data type.

Table 26–10 summarizes the properties of the boolean-param element.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Element</td>
<td>parameters</td>
</tr>
<tr>
<td>Attributes</td>
<td>required, helpText</td>
</tr>
<tr>
<td>Child Elements</td>
<td>None</td>
</tr>
<tr>
<td>Number of Occurrences</td>
<td>One for every parameter of the boolean data type</td>
</tr>
<tr>
<td>Element Value</td>
<td>Name of field that can hold a boolean data type</td>
</tr>
<tr>
<td>Mandatory or Optional?</td>
<td>Optional</td>
</tr>
</tbody>
</table>

The behavior and description of the require and helpText attributes for the boolean-param element and the string-param element is the same. See "The string-param Element" on page 26-10 for information about the require and helpText attributes.

26.8 Best Practices for Creating Custom Scheduled Tasks

Table 26–11 provides the guidelines for using variables/constants for creating custom scheduled tasks:

<table>
<thead>
<tr>
<th>Type</th>
<th>Example</th>
<th>Stor/Retrieve Value From</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target system connection details</td>
<td>Hostname, port number, SSL</td>
<td>IT Resource/application instance</td>
</tr>
<tr>
<td>Target system configurations</td>
<td>Attribute mappings, Unique Attribute, User Object Class</td>
<td>Lookup</td>
</tr>
<tr>
<td>Scheduled job-specific variables/ constants</td>
<td>Application Instance Name, IT Resource Name, File Path, Search Filter, Batch Size, Retries</td>
<td>Scheduled job</td>
</tr>
</tbody>
</table>
When a job is stopped from the Scheduler section in Oracle Identity System Administration, the job does not stop and keeps running. To stop the scheduled task, you can perform the following:

If you have developed a custom scheduled task, then you can call the isStop() or isStopped() method at various stages inside the execute method. If this method returns true, then return from the execute method. If you have loops inside the execute method, then make sure that the isStop() or isStopped() method is called for each loop iteration.

In the execute method, add a check for getting the job status. This can be obtained by calling the isStopped() method of the com.thortech.xl.scheduler.tasks.SchedulerBaseTask class. If the isStopped() method returns TRUE, then return from the execute method without performing any execution for the scheduled task. The following is the code snippet for this:

```java
if(isStopped())
    return;
```

If you develop a custom scheduled task by extending the TaskSupport class in Oracle Identity Manager 11g Release 1 (11.1.1) or 11g Release 2 (11.1.2), then call the isStop() method in the execute method.

If the custom scheduled task code is extending legacy com.thortech.xl.scheduler.tasks.SchedulerBaseTask class of Oracle Identity Manager Release 9.x, then call the isStopped() method in the execute method.
Part VI
Custom Operations

This part contains chapters that describe how to develop customized operations in the Oracle Identity Manager.

It contains the following chapters:

- Chapter 27, "Developing Plug-ins"
- Chapter 28, "Developing Event Handlers"
- Chapter 29, "Understanding Context"
This chapter describes the concepts related to plug-in and how to develop and use a plug-in in the following sections:

- **Plug-ins and Plug-in Points**
- **Using Plug-ins in Deployments**
- **Plug-in Points**
- **Configuring Plug-ins**
- **Developing Custom Plug-ins**
- **Registering Plug-ins**
- **Migrating Plug-ins**

### 27.1 Plug-ins and Plug-in Points

A **plug-in** is a logical component that extends the functionality of features provided by Oracle Identity Manager. The plug-in framework enables you to define, register, and configure plug-ins, which extend the functionality provided by features. Plug-ins can be predefined or custom-developed, and they are utilized at plug-in points. A **plug-in point** is a specific point in the business logic where extensibility can be provided. An interface definition called the plug-in interface accompanies such a point. You can extend the plug-in interface based on the business requirements and register them as plug-ins. To do this, you develop a Plugin Java class and compile it before archiving in a JAR file, define plug-in metadata in an XML file, and ZIP these artifacts as a plug-in package that is ready to deploy.

For example, user creation is a business operation in Oracle Identity Manager. But this operation exposes a plug-in point for user name generation. If you want to model your custom logic of user name generation, then you must identify the plug-in point specifications and develop a plug-in accordingly.

The concepts related to plug-ins are described in the following sections:

- **Plug-ins and Event Handlers**
- **Plug-in Stores**

### 27.1.1 Plug-ins and Event Handlers

Most of the business operations in Oracle Identity Manager, such as user creation, role assignment to user, and user activation, are executed as orchestrations. Therefore, if
there is a requirement to induce any custom logic in these operations or orchestrations, then you can model that logic as event handlers at stages, such as validation, preprocess, and postprocess, in which customization is supported.

However, you can analyze if any such operation also exposes a plug-in point for inducing the custom logic. If a plug-in point is available, then you can utilize the plug-in point rather than operating the underlying orchestration. For example, you can implement username generation by using the exposed plug-in without writing that as an event handler in the create user orchestration.

Figure 27–1 shows a diagrammatic representation of plug-ins and event handlers.

**Figure 27–1 Plug-ins and Event Handlers**

![Diagram of plug-ins and event handlers]

### 27.1.2 Plug-in Stores

The plug-in framework can store plug-ins in two types of stores:

- File system
- The Oracle Identity Manage database

When looking for plug-ins, the framework first examines plug-ins registered in the database, and looks in the file system.

#### 27.1.2.1 File Store

The File Store consists of one or more directories on the Oracle Identity Manager host and is primarily used in development environments. This type of store is not appropriate for a production environment. File storage is convenient for the developer since there is no need to explicitly register the developed plug-ins with a file store.
Users can just drop in the plug-in zips or exploded plug-in directory to the designated location(s).

By default, Plug-in framework looks for the plug-ins under the `OIM_HOME/plugins` directory. Additional plug-in directories can also be specified.

If a monitoring thread is enabled, then the plug-in framework monitors all the additions, modification, and deletions of plug-in zip files under the registered plug-in directories in the file system, and automatically reloads the plug-ins. Plug-in metadata such as name, version, and ID is read from the plug-in zip and is maintained in memory. This metadata is updated based on any file changes. The latest plug-in zip file is considered to be the current version of the plug-in. For details about how to configure the file store, see "Configuring Plug-ins" on page 27-5.

---

**Note:** Oracle recommends not to use the file store in production. File store is more suitable during plug-in development because it is easy to change the plug-in, and you are required to change only the file in the file system. There is no need to register. However, in production, plug-ins are not changed often, and therefore, avoid using the file store because of certain disadvantages. It adds the overhead of file store monitoring. In addition, the plug-ins are required to be replicated in all nodes of a cluster for the clustered deployment of Oracle Identity Manager.

---

27.1.2.2 Database Store

Plug-ins can be stored in the Oracle Identity Manager database, so that they are accessible from any node in a cluster. The Plug-in Framework uses Operation DB as the database store. This type of store is appropriate for a production environment.

You must explicitly register any plug-ins that are stored in the database. You can use the Plugin Registration Utility, which is a command-line tool, to register and deregister plug-ins. You can also use the `registerPlugin` API for this purpose. See "Registering and Unregistering Plug-ins By Using APIs" on page 27-7 for more information about registering plug-ins.

---

**Note:** After registering a plug-in, the server must be restarted. However, restarting the server might also depend on the feature that defines the plug-in point.

---

27.2 Using Plug-ins in Deployments

As already mentioned in this document, plug-ins are used for customizing the default functionality in an Oracle Identity Manager deployment. The number of supported plug-in points is a defined and constrained set. Therefore, you can use the plug-in points to extend the functionality only for the list of supported plug-in points. See "Plug-in Points" on page 27-3 for a list of the supported plug-in points.

---

27.3 Plug-in Points

Table 27–1 lists the Java interfaces that act as plug-in points in Oracle Identity Manager:
<table>
<thead>
<tr>
<th>Plug-in Point</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.iam.ldapsync.LDAPContainerMapper</td>
<td>This is used by LDAP synchronization to determine which user/role container should be used to create the user/role in LDAP.</td>
</tr>
<tr>
<td>oracle.iam.platform.kernel.spi.EventHandler</td>
<td>This is the kernel event handler. See Chapter 28, &quot;Developing Event Handlers&quot; for information about kernel event handlers.</td>
</tr>
</tbody>
</table>
| oracle.iam.platform.auth.api.LoginMapper         | This is an implementation of a LoginMapper maps the JAAS user principal name to the corresponding Oracle Identity Manager username. This plug-in point is used to override the default mapping of JAAS user principal name to Oracle Identity Manager username for SSO scenarios. The default implementation returns the same value as the JAAS user principal name. This plug-in point is typically used in SSO scenarios where the JAAS user principal name and the Oracle Identity Manager username might be different. For example, the SSO system might set the email as the JAAS username but no user with that username exist in Oracle Identity Manager. For Oracle Identity Manager to recognize that user, the JAAS user principal name must be mapped to the Oracle Identity Manager username. This can be done by implementing a plug-in for LoginMapper, as shown:

```java
public class CustomLoginMapper implements LoginMapper{
    public String getOIMUserID(String jaasPrincipal) throws MappingException {
        return getUserName(jaasPrincipal);
    }

    private String getUserName(String emailID){
        String userName = null;
        //Use usermgmt APIs to get the username corresponding to this email id
        return userName;
    }
}
```

oracle.iam.identity.usermgmt.api.PasswordVerifier | This is used for verification of old password while changing the user's password. The class that is to be used for this validation is configured in the OIM.OldPasswordValidator system property. By default, use the container based authentication for verifying old password. |
| oracle.iam.request.plugins.StatusChangeEvent     | This allows running of custom code during request status change.                                                                                                                                           |
| oracle.iam.request.plugins.RequestDataValidator | This is used for custom validation of request data after submission.                                                                                                                                          |
| oracle.iam.request.plugins.PrePopulationAdapt er | This is used to prepopulate an attribute value by running custom code during request creation.                                                                                                          |
| oracle.iam.scheduler.vo.TaskSupport             | This is used to run the job in context. Execute method of the task is retrieved through the plug-in and is loaded.                                                                                          |
| oracle.iam.identity.usermgmt.api.UserNamePoli cy | This is an implementation of username policies that are used to generate/validate username.                                                                                                               |
| oracle.iam.identity.usermgmt.api.ReservationIn LDAP | This is an implementation for reservation of user attributes in LDAP.                                                                                                                                     |
27.4 Configuring Plug-ins

You use the oim-config.xml file in the MDS to configure the following:

- The directory or directories in which the files store will look for plug-ins.
- Whether to activate a thread that monitors the file store for any changes; the thread checks the zip files or exploded files in all the plug-in directories.
  The monitoring thread is typically activated in a dynamic development environment since plug-ins are being added or modified in such an environment; it can be inactive in a production system which contains a set of plug-ins. This is tracked by the reloadingEnabled attribute.
- The time interval at which the monitoring thread wakes up and looks for any changes.

The following is a code snippet from the oim-config.xml file:

```xml
<pluginConfig storeType="common">
  <storeConfig reloadingEnabled="true">
    reloadingInterval="20">
    <!--
    Plugins present in the OIM_HOME/plugins directory are added by default.
    For adding more plugins, specify the plugin directory as below:
    <registeredDirs>/scratch/oimplugins</registeredDirs>
    <registeredDirs>/scratch/custom</registeredDirs>
    -->
  </storeConfig>
</pluginConfig>
```

In this example:

- The **common** store designation tells the framework to monitor both database and file stores.

  **Note:** Do not modify the **Store** value; **common** is appropriate in all environments.

- One directory is configured; additional directories can be configured by simply adding more `<registeredDirs>` tags.
- The monitoring thread is active and looks for plug-in changes every 20 seconds by default.
Monitoring is typically active in development environments only. If you switch between active and inactive, you must restart the application server for the change to take effect.

---

**Note:** Restarting the application server is required for any changes made to plug-in data in the oim-config.xml file.

---

### 27.5 Developing Custom Plug-ins

This section describes how to develop custom plug-ins. It contains the following sections:

- Developing Plug-ins
- Declaring Plug-ins

#### 27.5.1 Developing Plug-ins

To develop a plug-in:

1. Identify the plug-in point to extend.
2. Identify the Java class that implements the plug-in point interface. Package the Java class and other dependent classes into a JAR file. Put the JAR file in the lib/ directory.
3. Create the plugin.xml file. See "Declaring Plug-ins" on page 27-7 for details.
4. Identify the resource files required by the plug-in, such as property files, resource bundles, and image files.
5. Zip the entire package.

An Oracle Identity Manager plug-in is distributed as a ZIP file with a specified directory structure. The directory structure is as follows:

- **The plugin.xml file:** The XML file contains the metadata associated with all the plug-ins such as the plug-in point it extends, the class implementing the plug-in, name, and the version number. All the fields in the XML are mandatory except the name. If the name is not given, then plugin class name is used as the name.

- **The lib/ directory:** The lib/ directory consists of JAR files that contains the classes implementing the plug-in logic and the dependent library JAR files. In most instances, this directory consists of a single JAR file with the implementation of all the plug-ins that are specified in plugin.xml.

- **The resources/ directory:** Contains resource files required by the plug-in, such as property files, resource bundles, and image files. These resources given in the resources directory of the plug-in zip can be accessed as follows:

  ```java
  this.getClass().getClassLoader().getResourceAsStream(<resource_name>);
  ```

- **The META-INF/ directory:** Contains XML files showing plug-in points for event handlers. Some services, such as the notification service, read the XML files from MDS or from the META-INF/ directory of the plug-in.

Multiple plug-ins implementing the same plug-in point can be part of the same ZIP file.
A plug-in has a Java class that implements the plug-in point interface. The plug-in library (JAR) can contain other dependent classes as well, but the class implementing the plug-in is the only one that is exposed to the feature. This class must be specified in plugin.xml.

6. Place the ZIP file in the file store (the OIM_HOME/plugins/ directory) or database store.

7. If the ZIP is placed in the database store, then register the plug-in by using the Plug-in Registration Utility, as described in "Registering Plug-ins" on page 27-7.

### 27.5.2 Declaring Plug-ins

To extend the functionality provided by Oracle Identity Manager, you can declare the plug-ins for the application.

A plug-in has a Java class that implements the plug-in point interface. Be sure to assign unique names to all the plug-ins associated with a specific plug-in point. If the plug-in names are non-unique, an exception will be thrown during plug-in registration.

Declare the plug-ins in the plugin.xml file. For example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oimplugins>
    ....
    <plugins pluginpoint="oracle.iam.sample.passwdmgmt.service.PasswordElement">
        <plugin pluginclass="oracle.iam.sample.passwdmgmt.custom.NumCustomPasswordElement" version="1.0.1" name="num pwd element"/>
        <plugin pluginclass="oracle.iam.sample.passwdmgmt.custom.DictionaryPasswordElement" version="1.0.1" name="Dictionary password element" />
    </plugins>
    ....
</oimplugins>
```

*Note:* You can have multiple versions of the plug-in stored and the feature can request a specific version of the plug-in from the plug-in framework. By default, all of the current plug-in points load the latest version of the plug-ins.

The XML shows two plug-in declarations. Both the plug-ins extend from the same plug-in point.

### 27.6 Registering Plug-ins

You can register the plug-ins by using APIs and Plugin Registration Utility.

- **Registering and Unregistering Plug-ins By Using APIs**
- **Registering and Unregistering Plug-ins By Using the Plugin Registration Utility**

#### 27.6.1 Registering and Unregistering Plug-ins By Using APIs

You can use the following APIs for registration-related tasks:

- PlatformService.registerPlugin
PlatformService.unregisterPlugin

Here is an example:

```java
System.out.println("Creating client....");
String ctxFactory = "weblogic.jndi.WLInitialContextFactory";
String serverURL = "t3://OIM_HOSTNAME:OIM_PORT";
System.setProperty("java.security.auth.login.config", "OIM_CLIENT_HOME/conf/authwl.conf");
String username = "USER_NAME";
char[] password = "PASSWORD".toCharArray();
Hashtable env = new Hashtable();
env.put(OIMClient.JAVA_NAMING_FACTORY_INITIAL,ctxFactory);
env.put(OIMClient.JAVA_NAMING_PROVIDER_URL, serverURL);

oimClient = new OIMClient(env);
System.out.println("Logging in");
oimClient.login(username, password);
PlatformService service = platform.getService(PlatformService.class);
File zipFile = new File(fileName);
FileInputStream fis = new FileInputStream(zipFile);
int size = (int) zipFile.length();
byte[] b = new byte[size];
int bytesRead = fis.read(b, 0, size);
while (bytesRead < size) {
    bytesRead += fis.read(b, bytesRead, size - bytesRead);
}
fis.close();
service.registerPlugin(b);
service.unregisterPlugin(pluginID, version);
```

**Note:** "Using OIMClient" on page 31-1 for information about using OIMClient for developing clients to integrate with Oracle Identity Manager.

### 27.6.2 Registering and Unregistering Plug-ins By Using the Plugin Registration Utility

You can use the Plugin Registration Utility for registering and unregistering plug-ins. The utility uses the following files:

- pluginregistration.xml
- ant.properties

These files are located in the OIM_HOME/plugin_utility/ directory.

**Note:** Plug-in registration utilities require Apache Ant version 1.7 or later.

Before using the utility, perform the following:

1. Set the values for wls.home and oim.home in ant.properties.

   For example:
   ```
   wls.home =.../middleware/wlserver_10.3
   oim.home =.../middleware/Oracle_IDM1/server
   ```
In addition, set the path for mw.home in the ant.properties file. Also, uncomment the following:

#login.config=${oim.home}/config/authwl.conf

2. Build the wlfullclient.jar in Oracle WebLogic server:
   a. Change directories to $WLS_HOME/server/lib.
   b. Run the following command:
      
      ```
      java -jar ../../../modules/com.bea.core.jarbuilder_1.3.0.0.jar
      ```

      **Note:** The exact JAR file version can be different based on the WLS. Use the corresponding file with the name as com.bea.core.jarbuilder at the $WLS_HOME/../.modules/ directory.

Registering a Plug-in

To register a plug-in:

1. Execute the ant target "register":

   ```
   ant -f pluginregistration.xml register
   ```

2. This will prompt for the Oracle Identity Manager username and password along with the server information and the location of the plugin zip file. Enter the complete path of the zip file location.

Unregister a Plug-in

To unregister a plug-in:

1. Execute the ant target "unregister":

   ```
   ant -f pluginregistration.xml unregister
   ```

2. This will prompt for the Oracle Identity Manager username and password along with the server information and the classname of the plug-in class. Enter the classname with the complete package.

27.7 Migrating Plug-ins

The Deployment Manager supports migrating plug-ins from one deployment of Oracle Identity Manager to another. For example, the event handlers can be implemented in a test environment, and then migrated to the production environment by using the Deployment Manager. Figure 27–2 shows exporting plug-ins via the Deployment Manager:
Figure 27–2  Exporting Plug-ins

See Also:  "Migrating Configurations and Customizations" on page 38-1 for information about the Deployment Manager
This chapter describes the concepts related to orchestration and how to write custom event handlers to extend the functionalities of Oracle Identity Manager. It contains the following topics:

- Orchestration Concepts
- Using Custom Event Handlers
- Developing Custom Event Handlers
- Sequencing the Execution of Event Handlers
- Writing Custom Validation Event Handlers
- Best Practices
- Migrating Event Handlers
- Troubleshooting Event Handlers

28.1 Orchestration Concepts

In an Identity Management system, any action performed by a user or system is called an operation. Examples of operations are creating users, modifying roles, and creating password policies. The process of any Oracle Identity Manager operation that goes through a predefined set of stages and executes some business logic in each stage is called an orchestration. The type of object that is changed by the orchestration is called an orchestration target. The data that is required to carry out the orchestration operation is called orchestration parameter.

A bulk orchestration is the process of orchestrating same operation on multiple entities. For example, if you want to update the organization of multiple users, then you can submit a bulk orchestration. As a result, the operation on all the entities are performed in a single call.

---

**Note:** If custom event handlers are required to be introduced for lock/unlock operations, then you must implement bulk orchestrations. From the UI, bulk orchestrations are triggered for a single user lock/unlock operation.

---

Orchestration is divided into predefined steps called stages. Every operation moves through these stages until it reaches finalization. Orchestration has the following stages:
Orchestration Concepts

- **Validation**: Stage to perform validation on the orchestration, such as validity of orchestration parameters. Orchestration parameter is the data that is required to carry out the orchestration operation.

- **Preprocess**: Stage to perform orchestration parameter manipulations or get approvals or perform Segregation of Duties (SoD) checks.

- **Action**: Stage in which the action takes place.

- **Audit**: Stage in which the auditing of operation is performed.

- **Postprocess**: Stage in which consequent operations related to the current operation takes place. Examples of consequent operations are auto role membership and policy evaluation on a user creation.

- **Finalization**: Last stage in the process to perform any clean up.

Each operation performed can have consequences for users or other entities. For example, creating a user might result in provisioning of resources to that user, and creating a new password policy can make certain user passwords invalid and require changes during next login. Each consequence is represented as an orchestration. A differed consequence is executed before the finalization of the current orchestration. An immediate consequence is executed immediately after the current event handler returns, before proceeding to the next event handler on the current orchestration. You can customize the consequences of some operations, such as create, modify, delete, enable, disable, lock, and unlock users, by writing event handlers, as described in subsequent sections.

There are orchestrations for which the starting point is the postprocess stage. If you are reconciling users from a trusted source or bulk loading users and want to add this data as is in Oracle Identity Manager. When the data is in Oracle Identity Manager, you can perform postprocess operations on the users to compute autogroup membership or evaluate policies. Therefore, reconciliation engine or bulk load utility submits postprocess-only orchestrations.

An **event handler** is a piece of code that is registered with an orchestration on various stages. These event handlers are invoked when the relevant orchestration stage is performed. Event handlers can either be asynchronous or synchronous. A synchronous event handler returns with a response right away, whereas an asynchronous event handler completes at a later stage. An event handler can be conditional, which means that the event handler is executed when certain conditions are satisfied.

What happens at each stage of orchestration is determined by branching and by the event handler, if any, that is deployed at that stage. If a stage has a branch, responses from the event handlers decide which branch to take. If a stage has no event handlers, or event handlers respond with no recommendation, then the operation follows the default path and moves to the next stage. However, a process can move to some out-of-the-band stages if the event handlers are invalid or canceled. These stages are:

- **Invalid**: Process is moved to this stage if orchestration validation fails.

- **Veto**: Process is moved to this stage if any of the preprocess event handlers are vetoed. For example, if approvals are rejected by the approver, then orchestration is vetoed.

- **Cancel**: Process is moved to this stage if the operation is stopped by calling the cancel method.

- **Compensation**: Process is moved to this stage if the operation is rolled back by calling the compensate method.
Using Custom Event Handlers

Oracle Identity Manager allows you to implement Service Provider Interfaces (SPIs) to customize the functionality of orchestration operations. Only customization of preprocess, postprocess, validation, and finalization stages of an operation in an entity orchestration is supported.

The following are examples of event handler implementation:

- When a user is created, the account status (enabled or disabled) is to be set based on some rules. A preprocess event handler can be implemented to achieve this.

- Users of type Contractors must have an email address at the time of creation. Other users can be created without email address. A validation event handler can be used to validate if the user is a Contractor, and then allow or disallow the user creation based on the validation result.

- Users of type Agents are to be notified in the user's alternate email address after the users are created. This can be achieved by implementing a postprocess event handler.

28.2 Using Custom Event Handlers

Figure 28–1 shows the various orchestration stages:

![Orchestration Stages Diagram](image)
Postprocess event handlers are most commonly implemented to meet business requirements. The following example describes how a postprocess event handler implementation can meet the given requirement:

**Requirement**
If the enterprise user is a Contractor, then after the user is created in Oracle Identity Manager, the user must be registered in the Contractor Registration System, which is an external application. This application is a database application. The database has a structure that stores the User ID, Contractor ID, First Name, and Last Name attributes of the users. After successful registration, the Contractor ID of the users must be retrieved and updated in the user's profile in Oracle Identity Manager.

**Solution**
This use case can be developed as a plug-in and deployed on Oracle Identity Manager. The plug-in can be used to retrieve the Contractor ID or any configured column name from specified database table and update the user profile in Oracle Identity Manager.

A postprocess event handler can be implemented and registered for the create operation of the user entity. It is a conditional event handler that executes for users only with type as Contractor. If the user type is Contractor, then the event handler connects to the external application to retrieve the Contractor ID based on the Oracle Identity Manager user ID, and update the user profile in Oracle Identity Manager with contractor ID.

The following is another common example of postprocess implementation of event handlers:

Custom attribute generation if the data that is reconciled into Oracle Identity Manager is not enough to implement all use cases and extra attributes need to be generated based on the reconciled data. This is a common use case, especially when the custom attributes are used in the role membership rules or access policies.

### 28.3 Developing Custom Event Handlers

An event handler consists of the following:

- **Java code**: Implementation of the operations
- **XML definition**: Association with the relevant orchestration at the right stage
- **Plug-in definition**: Registration of the event handlers and any extension code with Oracle Identity Manager plug-in framework

Developing a custom event handler comprises of implementing the operation through Java code, writing the XML definition, and creating and registering a plug-in. These are described in the following sections:

- Implementing the SPI and Creating a JAR
- Defining Custom Events Definition XML
- Creating and Registering a Plug-in ZIP

#### 28.3.1 Implementing the SPI and Creating a JAR

This section describes how to write the JAVA code by implementing the SPI, and thereafter, create a JAR file in the following sections:

- Development Considerations
Methods and Arguments

Code Samples

Creating a JAR File With Custom Event Handler Code

28.3.1.1 Development Considerations

The following points must be considered for writing custom event handlers:

- The supported orchestration stages in which a custom event handler can be registered are validation, preprocess, and postprocess.
- Validation, preprocess, and postprocess event handlers can be conditional. This means that the event handler will execute only if a particular condition is met. You can make the event handler conditional by implementing the oracle.iam.platform.kernel.spi.ConditionalEventHandler interface and its isApplicable method. Context data and orchestration parameters are available in this method. For conditional event handlers, the applicability of event handlers is computed when the operation is initiated. Therefore, if a context or orchestration parameters are modified during the orchestration flow, then it might lead to execution of event handlers that must not be executed.
- The event handlers can handle single as well as bulk entities.
- The event handlers can have associated failure handlers that callbacks certain operations on the parent handlers.
- Because retry of event handlers is supported, the event handlers can be re-entrant.
- When reconciliation submits postprocess orchestrations, it submits bulk orchestrations. The bulkExecute method on the event handlers is called for these orchestrations. Therefore, make sure to implement this method.
- If data is to be passed between custom event handlers, you can pass it by using inter event data. Calling the getInterEventData() method on orchestration returns a hashmap. In this map, you can put any object with key beginning with custom, and you can access this data in subsequent custom handlers. Do not modify or delete any predefined inter event data that is part of the same hashmap.
- To make API calls inside event handlers for write or delete operations, get the API services by using Platform.getServiceForEventHandlers method. API calls that are made using the services obtained through this method are performed synchronously including the postprocessing.
- Return type of event handlers, except validation handlers, are shown in the following table:

<table>
<thead>
<tr>
<th>Event Handler Type</th>
<th>On Success</th>
<th>On Failure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synchronous</td>
<td>new EventResult() in the execute method and new BulkEventResult() in bulk version of the execute method</td>
<td>EventFailedException</td>
</tr>
<tr>
<td>Asynchronous</td>
<td>Return null</td>
<td>EventFailedException</td>
</tr>
</tbody>
</table>

- You must not define object-level variables at the event handler.

28.3.1.2 Methods and Arguments

Table 28–1 lists the methods that you can implement in the various orchestration stages:
Developing Custom Event Handlers

28.3.1.3 Code Samples
This section provides code samples that illustrate how to write various kinds of event handlers.

Example 1: Custom Email Validation
Example 28–1 shows a sample custom validation handler code fragment that checks to ensure that the ampersand character (@) is used in the email id of the user.

Example 28–1 Custom Email Validation

```java
public void validate(long processId, long eventId, Orchestration orchestration) throws ValidationException, ValidationFailedException {
```

Table 28–1 Methods to Implement Event Handlers

<table>
<thead>
<tr>
<th>Method</th>
<th>Applicable Orchestration Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>initialize</td>
<td>preprocess, postprocess</td>
<td>This method is used to open connections and pool state or resources.</td>
</tr>
<tr>
<td>execute for single entity</td>
<td>preprocess, postprocess</td>
<td>This method is used to read the input attributes of the underlying operation and update to different values, if required.</td>
</tr>
<tr>
<td>execute for bulk orchestration</td>
<td>preprocess, postprocess</td>
<td>This method is used to read the input attributes of multiple underlying operations and update to different values, if required.</td>
</tr>
<tr>
<td>isApplicable</td>
<td>conditional</td>
<td>This method is used in conditional handlers to determine if the prerequisite condition for the event handler execution is met.</td>
</tr>
<tr>
<td>validate</td>
<td>validation</td>
<td>This method is used for validation handlers to validate input data.</td>
</tr>
<tr>
<td>cancel</td>
<td>preprocess, postprocess</td>
<td>This method is called when the orchestration operation is canceled.</td>
</tr>
<tr>
<td>compensate</td>
<td>preprocess, postprocess</td>
<td>This method is called when the orchestration operation is compensated.</td>
</tr>
</tbody>
</table>

For methods, such as execute, the following argument values are available:

- IDs that you can include in the code for troubleshooting purpose, which includes:
  - Process ID: The ID of the orchestration instance
  - Event ID: The ID of the event handler instance

- Orchestration object that consists of details of the underlying entity instance. This consists of:
  - Maps (key value pairs) containing ENTITY_ATTRIBUTE, VALUE from which the input attributes of the underlying entity is read.
  - Entity ID: To update back the values for the same or a different entity, use Entity Manager API and pass the Entity ID and data to it. For bulk orchestration, you get multiple Entity IDs and Maps.

**Note:** Use Platform.getServiceForEventHandlers to get the services for calling create, update, and delete operations in event handlers.

28-6 Oracle Fusion Middleware Developer's Guide for Oracle Identity Manager
HashMap<String, Serializable> parameters = orchestration.getParameters();
String email = (parameters.get("Email") instanceof ContextAware) ? (String) ((ContextAware) parameters .get("Email")).getObjectValue() : (String) parameters .get("Email");
if (!email.contains('@')) {
    throw new ValidationFailedException("Email doesn't contain @");
}

Example 2: Custom Preprocess Event Handler to Set Middle Name

Example 28–2 shows a sample custom preprocess event handler code fragment that sets the middle name to the first letter of the first name if the a value is not provided for middle name.

```java
// the middle initial when the user doesn't have a middle name
public EventResult execute(long processId, long eventId,
    Orchestration orchestration) {
    HashMap<String, Serializable> parameters = orchestration .getParameters();
    // If the middle name is empty set the first letter of the first name
    // as the middle initial
    String middleName = getParameterValue(parameters, "Middle Name");
    if ((middleName == null) || middleName.equals("")) {
        String firstName = getParameterValue(parameters, "First Name");
        middleName = firstName.substring(0, 1);
        orchestration.addParameter("Middle Name", middleName);
    }
    return new EventResult();
}

private String getParameterValue(HashMap<String, Serializable> parameters,
        String key) {
    if (parameters.containsKey(key)){
        String value = (parameters.get(key) instanceof ContextAware) ? (String) ((ContextAware) parameters .get(key)).getObjectValue() : (String) parameters.get(key);
        return value;
    } else{
        return null;
    }
}
```

Example 3: Custom Post-process Event Handler to Provision Resource Object

Example 28–3 shows a sample custom post process event handler code fragment that provisions a resource object OBJ005 to a user whose role is ROLE 005:

```java
// This custom post process event handler provisions resource object 'OBJ005'
// to a user who has role 'ROLE 005'
public EventResult execute(long processId, long eventId,
    Orchestration orchestration) {
    tcUserOperationsIntf userOperationsService =
        Platform.getService(tcUserOperationsIntf.class);
```
try {
    String userKey = getUserKey(processId, orchestration);
    if (hasRole(userKey, "ROLE 005")) {
        long objKey = findObject("OBJ001");
        userOperationsService.provisionResource(Long.getLong(userKey), objKey);
    }
} catch (Exception e) {
    throw new EventFailedException(null, "Error occurred", null, null, e);
}

return new EventResult();

// This method retrieves the key of the user entity on which an operation
// is performed
// This method shows how to retrieve the operation being performed, entity type
// and the associated value objects
private String getUserKey (long processID, Orchestration orchestration) {
    String userKey;
    String entityType = orchestration.getTarget().getType();
    EventResult result = new EventResult();
    if (!orchestration.getOperation().equals("CREATE")) {
        userKey = orchestration.getTarget().getEntityId();
    } else {
        OrchestrationEngine orchEngine = Platform.getService(OrchestrationEngine.class);
        userKey = (String) orchEngine.getActionResult(processID);
    }
    return userKey;
}

// This method checks if a given user has a given role.
// It demonstrates how to invoke a OIM 11g API from a custom event handler
private boolean hasRole(String userKey, String roleName)
    throws Exception {
    RoleManager roleManager = Platform.getService(RoleManager.class);
    List<Role> roles = roleManager.getUserMemberships(userKey, true);
    for (Iterator iterator = roles.iterator(); iterator.hasNext();) {
        Role role = (Role) iterator.next();
        if (roleName.equals((String)role.getAttribute("Role Name"))) {
            return true;
        }
    }
    return false;
}

// This method finds details about a resource object with the given name.
// It demonstrates how to invoke a 9.1.x API from a custom event handler
private long findObject(String objName) throws Exception {
    long objKey = 0;
    tcObjectOperationsIntf objectOperationsService =
        Platform.getService(tcObjectOperationsIntf.class);
    HashMap params = new HashMap();
    params.put("Objects.Name", objName);
    tcResultSet objects = objectOperationsService.findObjects(params);
    for (int i = 0; i < objects.getRowCount(); i++) {
        objects.goToRow(i);
        if (objects.getStringValue("Objects.Name").equals(objName)) {
            objKey = Long.parseLong(objects.getStringValue("Id"));
        }
    }
    return objKey;
}
Developing Custom Event Handlers

Example 4: Custom User Postprocess Event Handler With bulkExecute Method
Example 28–4 shows how to loop through users that are part of a bulk user create orchestration.

Example 28–4  Custom User Postprocess Event Handler With bulkExecute Method

public BulkEventResult execute(long processId, long eventId, BulkOrchestration orchestration){

    HashMap<String, Serializable>[] orchParamArray = orchestration.getBulkParameters();

    // Array of user keys
    String[] entityIds = orchestration.getTarget().getAllEntityId();
    for(int i=0; i<entityIds.length; i++){

    }

}

Example 5: Using Context in isApplicable method
Any operation in Oracle Identity Manager can take place in more than one context. For example, creating a user can happen in four different contexts, which are administrator creating a user as a direct operation, administrator creating a user by raising a request, creating a user through self registration, and user creation through trusted source reconciliation. In all these scenarios, Oracle Identity Manager submits the same user creation orchestrations having the same parameter names and values with same data types.

Example 28–5 shows how to find the context in which this operation is performed to figure out the applicability of the event handler.

Example 28–5  Using Context in the isApplicable Method

public boolean isApplicable(AbstractGenericOrchestration orchestration) {

    // Request Context
    if (ContextManager.getContextType() == ContextTypes.REQUEST) {
    
    // Recon context
    if (ContextManager.getContextType() == ContextTypes.RECON) {

    }

}

See Also: “Understanding Context” on page 29-1 for details about the information that can retrieved from context

28.3.1.4 Creating a JAR File With Custom Event Handler Code
To create a JAR with custom event handler code:

```java
objKey = objects.getLongValue("Objects.Key");
```

```java
return objKey;
```
1. Implement one of the SPIs mentioned in Table 28–2 to write a custom preprocess, postprocess, or validation handler.

<table>
<thead>
<tr>
<th>Stage</th>
<th>SPI to implement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preprocess</td>
<td>oracle.iam.platform.kernel.spi.PreProcessHandler</td>
</tr>
<tr>
<td>Postprocess</td>
<td>oracle.iam.platform.kernel.spi.PostProcessHandler</td>
</tr>
<tr>
<td>Validation</td>
<td>oracle.iam.platform.kernel.spi.ValidationHandler</td>
</tr>
<tr>
<td>Finalization</td>
<td>oracle.iam.platform.kernel.spi.FinalizationHandler</td>
</tr>
</tbody>
</table>

See Also: See Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for information about the SPIs listed in Table 28–2.

2. Include the following JAR files in the class path to compile a custom class:

From the OIM_ORACLE_HOME/server/platform/ directory:
- iam-platform-kernel.jar
- iam-platform-utils.jar
- iam-platform-context.jar
- iam-platform-authz-service.jar

From the OIM_ORACLE_HOME/designconsole/lib/ directory:
- oimclient.jar
- xlAPI.jar

If some other Oracle Identity Manager JAR files are required for compilation, then these can be found in the directories mentioned in this step.

3. Create a JAR file of the custom class.

28.3.1.5 Handling Exceptions

For event handler exception handling, you must use conventional JAVA exception handling methods. The following guidelines can be used for dealing with failures:

- In the event handler code, throw EventFailedException with the right arguments to indicate failure.

- Failures can be handled by registering failure handlers. As part of failure handler, you can implement necessary logic to remediate the failure. The failure handlers must return FailedEventResult with the following options as Response:
  - CANCEL: Indicates that operation must get canceled. The Cancel method on all event handlers that are executed and completed so far is called by Kernel in reverse order of execution.
  - COMPENSATE: Indicates that operation must get rolled back. The Compensate method on all event handlers that are executed and completed so far is called by Kernel in reverse order of execution.
  - MANUAL_COMPLETE: Indicates that the handler that failed is manually completed and will proceed with the rest of the event handlers.
  - RETRY: Indicates to kernel that the event handler that failed must be retried.
- **NULL**: Indicates that there is no response or recommendation by the failed handler.

### 28.3.1.6 Managing Transactions

In the event handler XML file, set the `tx` attribute to true. If any exception is thrown in the event handler, then the transaction will be rolled back or committed.

### 28.3.2 Defining Custom Events Definition XML

The custom events definition XML is described in the following sections:

- Elements in the Event Handler XML Files
- Sample Event Definitions

#### 28.3.2.1 Elements in the Event Handler XML Files

This section describes some of the elements and element attributes within Event Handlers XML files. It also describes a mandatory namespace for the event handler XML definitions.

**Elements**

The top-level (or parent) element in Event Handlers XML files is `eventhandlers`. Table 28–3 lists and describes sub-elements that are typically defined within the `eventhandlers` parent element.

**Table 28–3 Typical Sub-elements within the `eventhandlers` Element**

<table>
<thead>
<tr>
<th>Sub-element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>validation-handler</td>
<td>Identifies the validations that will be performed on the orchestration.</td>
</tr>
<tr>
<td>action-handler</td>
<td>Identifies the operations that will be performed at preprocess, postprocess, and action stages.</td>
</tr>
<tr>
<td>failed-handler</td>
<td>Identifies the event handlers that will be executed if an event handler in the default flow fails.</td>
</tr>
<tr>
<td>finalization-handler</td>
<td>Identifies the event handlers to execute at the end of the orchestration. Finalization is the last stage of any orchestration.</td>
</tr>
<tr>
<td>change-failed</td>
<td>Identifies event handlers to be executed in parent orchestration upon consequence orchestration failures.</td>
</tr>
<tr>
<td>out-of-band-handler</td>
<td>Defines the event handlers for out-of-band orchestration flows, such as veto and cancel.</td>
</tr>
<tr>
<td>compensate-handler</td>
<td>Identifies the event handlers that will be executed in the compensation flow of the orchestration.</td>
</tr>
</tbody>
</table>

**Element Attributes**

The elements within event handlers XML files contain attributes. Table 28–4 lists and describes attributes that are typically defined within elements.

**Table 28–4 Typical Attributes of Sub-elements within the `eventhandlers` Element**

<table>
<thead>
<tr>
<th>Element Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the event handler.</td>
</tr>
<tr>
<td>class</td>
<td>Full package name of the Java class that implements the event handler.</td>
</tr>
<tr>
<td>Element Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>entity-type</td>
<td>Identifies the type of entity the event handler is executed on. A value of ANY sets the event handler to execute on any entity. Most commonly defined entity types are user, role, rolerole (role hierarchy), and roleuser (user role membership).</td>
</tr>
<tr>
<td>operation</td>
<td>Identifies the type of operation the event handler is executed on. A value of ANY sets the event handler to execute on any operation. Typical operations are create, modify, and delete.</td>
</tr>
<tr>
<td>order</td>
<td>Identifies the order (or sequence) in which the event handler is executed. Order value is in the scope of entity, operation, and stage. Order value for each event handler in this scope must be unique. If there is a conflict, then the order in which these conflicted event handlers are executed is arbitrary. Supported values are FIRST (same as Integer.MIN_VALUE), LAST (same as Integer.MAX_VALUE), or a numeral.</td>
</tr>
</tbody>
</table>
| orch-target       | Identifies the type of orchestration, such as entity orchestration, Toplink orchestration, and so on. The following is a list of supported values:  
  - oracle.iam.platform.kernel.vo.EntityOrchestration  
  - oracle.iam.platform.kernel.vo.MDSOrchestration  
  - oracle.iam.platform.kernel.vo.RelationOrchestration  
  - oracle.iam.platform.kernel.vo.ToplinkOrchestration  
  The default value is oracle.iam.platform.kernel.vo.EntityOrchestration. This is the only supported type for writing custom event handlers. |
| sync              | This attribute is operational in only the action-handler and change-failed elements. The sync attribute indicates whether the event handler is synchronous or asynchronous. Supported values are TRUE or FALSE. If set to TRUE (synchronous), then the kernel expects the event handler to return an EventResult. If set to FALSE (asynchronous), then you must return null as the event result and notify the kernel about the event result later.  
  **Note:** The sync attribute must be set to TRUE for validation-handler elements. |
| stage             | This attribute is operational in only the out-of-band-handler, action-handler, and failed-handler elements. The stage attribute indicates the stage at which the event handler is executed. The following is a list of supported values:  
  - preprocess  
  - action  
  - audit  
  - postprocess  
  - veto  
  - canceled  
  |
| tx                | This attribute is operational in only the out-of-band-handler, action-handler, compensate-handler, and finalization-handler elements. The tx attribute indicates whether or not the event handler should run in its own transaction. Supported values are TRUE or FALSE. By default, the value is FALSE. |
Namespace Requirement in `<eventhandlers>` Element

All the event handler definitions must have the following mandatory namespace definition:

```
<eventhandlers xmlns="http://www.oracle.com/schema/oim/platform/kernel"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://www.oracle.com/schema/oim/platform/kernel
orchestration-handlers.xsd">
```

28.3.2.2 Sample Event Definitions

Create a metadata XML file containing definitions of all the custom events, as shown in Table 28–6:

Example 28–6 Sample Metadata XML File for Custom Event Definitions

```
<?xml version='1.0' encoding='utf-8'?>
<eventhandlers xmlns="http://www.oracle.com/schema/oim/platform/kernel"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://www.oracle.com/schema/oim/platform/kernel
orchestration-handlers.xsd">

<!-- Custom preprocess event handlers -->
<action-handler
  class='oracle.oim.extensions.preprocess.SamplePreprocessExtension'
  entity-type='User'
  operation='CREATE'
  name='SetUserMiddleName'
  stage='preprocess'
  order='1000'
  sync='TRUE'/>

<!-- Custom postprocess event handlers -->
<action-handler
  class='oracle.oim.extensions.postprocess.SamplePostprocessExtension'
  entity-type='User'
  operation='CREATE'
  name='SamplePostprocessExtension'
  stage='postprocess'
  order='1000'
  sync='TRUE'/>

<action-handler
  class='oracle.oim.extensions.postprocess.SamplePostprocessExtension'
  entity-type='User'
  operation='MODIFY'
  name='CustomResourceProv'
  stage='postprocess'
  order='1000'
  sync='TRUE'/>

<!-- Custom validation event handlers -->
<validation-handler
  class='oracle.oim.extensions.validation.SampleValidationExtension'
  entity-type='User'
  operation='CREATE'
  name='ValidateUserEmail'
  order='1000'/>

</eventhandlers>
```
28.3.3 Creating and Registering a Plug-in ZIP

To create plug-ins containing custom event handlers, you need to develop the appropriate event handler classes. See "Developing Plug-ins" on page 27-1 for detailed information about plug-ins and plug-in points.

To create a plug-in ZIP and register it:

1. Define the plug-in XML with the event handler plug-in point.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oimplugins>
  <plugins pluginpoint="oracle.iam.platform.kernel.spi.EventHandler">
    <plugin pluginclass="oracle.oim.extensions.preprocess.SamplePreprocessExtension"
      version="1.0"
      name="SamplePreprocessExtension"/>
    <plugin pluginclass="oracle.oim.extensions.postprocess.SamplePostprocessExtension"
      version="1.0"
      name="SamplePostprocessExtension"/>
    <plugin pluginclass="oracle.oim.extensions.validation.SampleValidationExtension"
      version="1.0"
      name="SampleValidationExtension"/>
  </plugins>
</oimplugins>
```

2. Package the plug-in XML and the JAR file that contains the custom class or classes into a plug-in ZIP file.

3. Package the event handler XML that is defined using the information described in "Defining Custom Events Definition XML" on page 28-11 into the same zip in a directory called META-INF.

4. Register the plug-in by using plug-in registration utilities. See "Registering Plug-ins" on page 27-7 for additional information.

28.4 Sequencing the Execution of Event Handlers

The list of custom event handlers that you deployed and registered can be viewed by using Oracle Enterprise Manager. The event handlers are displayed in the order of invocation. Using this list of event handlers, you can sequence the order of execution of the event handlers.

To specify the order for any custom event handler, you must know the list of existing event handlers and their order for a given operation. To do so, you must invoke a mbean from the Enterprise Manager by performing the following steps:
Writing Custom Validation Event Handlers

1. Login to the Enterprise Manager.
2. On the left navigation pane, expand Weblogic Domain, and select OIM DOMAIN.
3. Right-click the domain name, and select **System Mbean Browser**.
5. Navigate to **OIM_SERVER_NAME**, oim, IAMAppDesignMBean, ConfigQueryMBeanName.
6. Click the **Operations** tab.
7. Click the getEventHandlers method.
8. Provide entity name for the p1 parameter and operation name for the p2 parameter, and then click **Invoke**. The parameter values are not case-sensitive. The possible parameter values are:
   - entity name: Values can be User, Role, or RoleUser
   - operation: Values can be CREATE, MODIFY, or DELETE

28.5 Writing Custom Validation Event Handlers

An approver can update the attribute values before approving a request. To ensure sanitization of the data entered by the approver, Oracle Identity Manager invokes validation handlers again when approver updates the request. This means that validation handlers configured for a particular entity and operations are invoked multiple times in a single request flow, when the request is submitted and when the approver modifies the request during approval workflow.

For example, when a self-registration request is submitted, the set of validation handlers configured for USER CREATE is run. Next, when the approver modifies the request to populate Organization or other user attributes, these validation handlers are re-run.

Therefore, custom validation handlers must be developed in such a way that the validation logic is re-entrant because they are invoked multiple times in single request flow.

**Note:** You can add a custom password validation for cases that are not available through Oracle Identity Manager password policies. For example, you can add a password validation to ensure that the password is not a word in a dictionary.

To add a custom password validation, add a custom validation event handler and set the operation to CHANGECOUNTPASSWD for the event handler. Then, you can organize the order in which Oracle Identity Manager triggers the custom event handler.

Consider the following example use case:

There is a requirement of generating the HR Employee Number UDF by appending a random number to the value of the Department Number field. When the create user request or self-registration request is submitted, the HR Employee Number UDF will be auto-generated based on custom logic. If the approver edits the request during approval and modifies the Department Number value, then the HR Employee Number UDF should be re-calculated by using the new value provided for...
Department Number. But, if the approver does not change Department Number, then the previous values generated at the time of request submission should be used.

For this, a new validation handler must be developed for generating the HR Employee Number UDF by appending Department Number and a random number. This logic cannot be written in preprocess handler because preprocess handlers are invoked only once in the lifecycle of a request. The logic in this validation handler is as shown:

```java
package custom.handlers;

import java.io.Serializable;
import java.util.HashMap;
import java.util.Random;
import oracle.iam.identity.usermgmt.api.UserManagerConstants;
import oracle.iam.identity.utils.Utils;
import oracle.iam.platform.kernel.ValidationException;
import oracle.iam.platform.kernel.ValidationFailedException;
import oracle.iam.platform.kernel.spi.ValidationHandler;
import oracle.iam.platform.kernel.vo.BulkOrchestration;
import oracle.iam.platform.kernel.vo.Orchestration;

public class EmployeeNumberGenerationHandler implements ValidationHandler {

@Override
public void initialize(HashMap<String, String> parameters) {
}

@Override
public void validate(long processId, long eventId, Orchestration orchestration)
throws ValidationException, ValidationFailedException {

HashMap<String, Serializable> contextParams = orchestration.getParameters();
//1. Generate UDF Employee number during request submission as Department Number
//and a random number
//2. If request is in approval stage, then control has come here since approver
//has modified the request
//2a: Check if approver has modified Department Number. If yes, then re-generate
if( !Utils.isRequestInApprovalStage() ) //Utility method to find if request is in
approval stage or not? If it returns true, it means that approver is attempting to
update the request during approval
{

//Step 1:
String dept = contextParams.get(UserManagerConstants.AttributeName.DEPARTMENT_
NUMBER.getId()).toString();
String en = dept+'_random();
contextParams.put("SSN", en);
}
else
{
String dept = contextParams.get(UserManagerConstants.AttributeName.DEPARTMENT_
NUMBER.getId()).toString();
//compare with department number with which request was submitted, if modified by
approver; the regenerate SSN
if( !Utils.isAttributeModifiedByApprover(orchestration ,
UserManagerConstants.AttributeName.DEPARTMENT_NUMBER.getId()); )

// //Utility method to find if approver has edited the particular attribute or not
```
, during approval?
{
String en = dept+"_"+random();
contextParams.put('SSN', en);
}
}
}

private String random() {
Random random = new Random();
String randomStr = "" + random.nextLong();
randomStr = randomStr.replaceAll("-", "");
return randomStr;
}

@override
public void validate(long processId, long eventId,
BulkOrchestration orchestration) throws ValidationException,
ValidationFailedException {
}

28.6 Best Practices

As a best practice, analyze the operation before developing and implementing an
event handler. If plug-in is supported for the operation, then use the plug-in for
customization rather than developing an event handler. For example, username
generation must be implemented by using the available plug-in, and do not attempt
writing that as an event handler in the create user orchestration.

For information about points to consider for developing event handlers, see
"Development Considerations" on page 28-5.

28.7 Migrating Event Handlers

The Deployment Manager supports migrating plug-ins, and the registered event
handlers with the plug-ins, from one deployment of Oracle Identity Manager to
another. For example, the event handlers can be implemented in a test environment,
and then migrated to the production environment by using the Deployment Manager.
Figure 28–2 shows exporting plug-ins via the Deployment Manager:
28.8 Troubleshooting Event Handlers

Table 28–5 lists common problems and causes or solutions to help troubleshoot your event handler if it is not triggered when the operation is executed.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Cause/Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a user is created through reconciliation, the custom preprocess event handlers are not triggered.</td>
<td>Reconciliation submits postprocess only orchestration where starting stage is postprocess.</td>
</tr>
<tr>
<td>When a user is created through reconciliation, the custom postprocess event handler is triggered but the logic inside the execute method is not triggered.</td>
<td>Reconciliation submits bulk orchestrations. Therefore, make sure to implement the bulkExecute method.</td>
</tr>
</tbody>
</table>
| The orchestration operation taking too long to complete. | To determine the time spent on each event handler:  
   2. In the Metric Tables, click OIM_EventHandler. How long each event handler is taking is displayed in the processTime column. |

See Also: "Migrating Configurations and Customizations" on page 38-1 for information about the Deployment Manager.
Understanding Context

A context is the environment in which an Oracle Identity Manager operation is performed. For example, a user creation operation performed on the Oracle Identity Self Service is carried out in the Web context. The following information constitutes the context or environment in which this operation is performed:

- User performing the operation
- Date and time at which the request is submitted
- Proxy that is used to reach the application server

For example, if the user is created by running the bulk load utility, the context includes the user who started the bulk load utility, the computer from which the operation is being performed, and so on.

A context is maintained in main-memory. It consists of a set of context variables where each context variable has both a name and value. Each functional component involved in an operation, such as request management, reconciliation, or notification, can add values to the context. Context values can only be set, they cannot be modified. The context values act as a means of communication across components involved in an operation.

Context variable values are loaded into memory only when they are required. This enhances performance. A context also acts as a cache of the typical values required by event handlers. This helps reduce the need to fetch values from the repository each time the values are required.

- Child Context
- Context Types

29.1 Child Context

A child context is a subcontext that is initiated while an operation is in progress. For example, if user creation operation involves provisioning of resource through access policies, resource provisioning runs in the access policy context, which is the child context of the one in which user is being created. This means that contexts can be nested, and there can be a stack of contexts. New contexts can be created by functional components, and further processing starts using the newly created context.

29.2 Context Types

Context Manager supports the following context types:
- **SELF:** Operation is initiated through Oracle Identity Self Service.
- **ADMIN:** Operation is initiated through Oracle Identity System Administration. This is the default context.
- **RECON:** Operation is performed by reconciliation.
- **REQUEST:** Operation is performed by a request.
- **POLICY:** Operation is performed because of access policy.

Calling `ContextManager.getContextType()` should tell the type of context. Some of the information that you can retrieve under various contexts are:

- Scheduled tasks run in ADMIN context: Some of the information that can be retrieved are:
  - Job name: `ContextManager.getValue("JOBNAME")`
  - Task name: `ContextManager.getValue("TASKNAME")`

- Reconciliation context: The profile from which the reconciliation event has been created can be retrieved by `ContextManager.getValue("profileName")` method call.

- Request context: You can retrieve the request key by using the following code:
  ```java
  HashMap<String, ContextAware> requestContext = (HashMap<String, ContextAware>)
  ContextManager.getValue("requestData", true);
  requestContext.get("requestKey");
  ```

- Policy context: `ContextManager.getContextKey()` provides the policy that is evaluated. If multiple policies are applicable, then this returns the highest priority policy key.
This part describes how to customize the user interfaces available with Oracle Identity Manager.

It contains the following chapter:

- Chapter 30, "Customizing the Interface"
This chapter explains how to customize various aspects of the user interfaces available in Oracle Identity Manager.

**Note:** Oracle Identity Manager 11g Release 2 (11.1.2.2.0) includes a number of UI pages based on earlier UI technologies known as transitional UIs. Due to technical differences, the transitional UIs are displayed in popup windows and have a different look and feel. These UIs are discussed in the relevant sections in this chapter.

The Identity Self Service user interface (UI) in Oracle Identity Manager is based on Application Development Framework (ADF), which ensures consistent customization. ADF allows UI customization that is safe from patches and upgrades. This means that after you apply patches to Oracle Identity Manager or upgrade Oracle Identity Manager, the UI customizations are preserved.

This chapter describes customizing various aspects of the UI in the following sections:

- Customization Concepts
- Managing Sandboxes
- Skin Customization in Oracle Identity Manager
- Customizing Pages at Runtime
- Securing UI Components
- Customizing Oracle Identity Manager Help
- Customizing the Home Page
- Customizing Challenge Questions
- Customizing the Transitional UI
- Developing Managed Beans and Task Flows
- Customizing the UI for Providing Additional Request Information
- Migrating UI Customizations
- UI Customization Best Practices
- Rolling Back UI Customization
30.1 Customization Concepts

This section describes the concepts related to UI customization in the following sections:

- Deployment of UI Libraries and Applications
- Overview of MDS Customization
- Overview of the Web Composer

30.1.1 Deployment of UI Libraries and Applications

ADF supports inbuilt customization and MDS customization. The customization is achieved by developing new UI artifacts or skins, and packaging them in custom library WAR files. Skins and stylesheets are mechanisms to allow customization of the look and feel of the UI. The advantage of using stylesheet changes and custom skins is that they are centralized changes and easier to manage.

Figure 30–1 shows the various Oracle Identity Manager UI libraries and their dependency structure.

![Oracle Identity Manager UI Libraries](image)

The custom library is a placeholder library that you can use to add new taskflows built by using the default libraries. The Self Service EAR declares weblogic.xml dependency on the library-ref name oracle.iam.ui.custom. This library is provided by oracle.iam.ui.custom-dev-starter-pack.war. You can change the WAR file name for the custom library per naming conventions in your organization. However, the deployment name (library extension name in MANIFEST.MF) must be retained as oracle.iam.ui.custom. Otherwise, Self Service ear will not be deployed.
The Oracle Identity Analytics (OIA) deployment name is oracle.iam.ui.oia-view.

30.1.2 Overview of MDS Customization

Using the customization features provided by MDS, you can create applications that fall into the following customization patterns:

- Seeded customization: Seeded customization of an application is the process of taking a generalized application and making modifications to suit the requirements of a particular group, such as a specific industry or site. Seeded customizations exist as part of the deployed application, and endure for the life of a given deployment.

- User customization: User customization allows an end user to change the content of the application at runtime to suit individual preferences (for example, which columns are visible in a table), and have those changes retained the next time the user opens the application.

- Runtime customization: Using the features of Oracle WebCenter, you can create applications that are customizable at runtime. This allows business analysts or administrators to customize the application for their end users by using a Web browser interface.

For detailed information about customizing applications with MDS, see “Customizing Applications with MDS” in the Oracle Fusion Middleware Fusion Developer’s Guide for Oracle Application Development Framework.

30.1.3 Overview of the Web Composer

Oracle Web Composer is an innovative component that enables any application or portal to be customized or personalized after it has been deployed and is in use. Oracle Web Composer runs in all modern Web browsers and enables editing JSF applications and portal pages by selecting information and components from the Business Dictionary or Resource Catalog.

The customization capabilities of the Web Composer include inserting a logo or altering the colors to match those of your company, and complex customizations, adding items to a page, changing the layout of a page, altering a supplied process, and specifically tailoring the delivered application or portal to meet any business requirement. These customizations can be stored in the Oracle Identity Manager database by using Oracle Metadata Services (MDS). For example, to store customizations in the database, the Web Composer creates a copy or sandbox for the pages as they are being edited. The sandbox is a temporary storage area to save a group of runtime page customizations before they are either saved and pushed to other users, or discarded. In this way, customizations can be previewed by others and approved for use before they are visible to all users. See “Managing Sandboxes” on page 30-4 for more information about sandboxes.

Personalization changes your view of the interface or application page. Other users are not affected by the changes you make to a page. The pages can be personalized by individual users to add any combination of components to their page whenever they want them without affecting the view of the page for other users.

Oracle Web Composer is integrated with Oracle WebCenter Framework and WebCenter Services. You can add Oracle Web Composer components to your JSF application pages to enable users to edit those pages at runtime. You can add the components at any time during the development lifecycle, when the requirements of the application demand it. In addition, you can use the page service to enable users to create pages at runtime. Oracle Web Composer has been leveraged inside Oracle
WebCenter Spaces to allow users to customize and personalize personal and group spaces. The Oracle WebCenter Spaces application provides a working example of how users can take an active role in managing and altering their work environment to match their specific requirements. Figure 30–2 shows the Oracle Web Composer architecture.

![Oracle Web Composer Architecture](image)

**Figure 30–2  Oracle Web Composer Architecture**

### 30.2 Managing Sandboxes

All customizations and form management are performed in a sandbox. A sandbox allows you to isolate and experiment with customizations without affecting the environment of other users. Any user-interface changes made to a sandbox are visible only in the sandbox. You must create and activate a sandbox to begin using the customization and form management features. After customizations and extending forms are complete, you can publish the sandbox to make the customizations available to other users.

Some of the sandbox operations are:

- **Activate:** You must activate a sandbox to use it. After you activate the sandbox, any changes to UI metadata objects, for example pages and forms, are stored only in the sandbox. There can be only one active sandbox at a time. The information about the active sandbox is stored in the session. Therefore, a sandbox must be activated to continue with customization after every login to Oracle Identity Manager.

---

**Caution:** After creating a sandbox, you must activate it. If you do not activate a sandbox, then you will not be allowed to perform operations on the sandbox later, or might not get the desired result. For example, if you create a sandbox but do not activate it, create a disconnected application instance, run catalog synchronization scheduled job, login to Identity System Administration, and try to checkout the disconnected application instance on the Catalog page, an error will be generated. You can perform this operation without any error, if you activate the sandbox after creating it and after every login to Identity Self Service or Identity System Administration.
- **Deactivate**: Reverse operation to activating a sandbox. If no sandbox is active, then changes to metadata objects are not allowed, and therefore, no UI customization is allowed.

- **Publish**: You must publish a sandbox to merge the changes stored in the sandbox to the mainline and make it available to other users. After you publish the sandbox, the changes are merged to the mainline and cannot be reverted. The sandbox can no longer be activated, deactivated, exported, or deleted.

  **Note**: Before publishing a sandbox, close all tabs and pages of the Identity Self Service or Identity System Administration, and export the sandbox to a ZIP file to have a backup of UI customizations done.

  Oracle recommends creating a backup of the MDS before publishing any sandbox. MDS backup can be created by using tools, such as Oracle Enterprise Manager. See "Creating MDS Backup" on page 37-3 for information about creating a backup of the MDS by using Oracle Enterprise Manager.

- **Export**: You can export all changes stored in the sandbox including sandbox metadata to a ZIP file. Then, you can import these changes to the same or another environment.

- **Import**: You can import the sandbox archive (ZIP file) to an environment. Imported sandbox can be used normally as it would have been created in the environment. Beware when importing sandboxes that any available sandbox with the same name will be overwritten by the imported sandbox.

  **Caution**: Any available sandbox with the same name is overwritten by the imported sandbox.

Sandbox management and sandbox operations resemble operations with concurrent versioning system. You can think of a sandbox as a branch in the versioning system. Creating a sandbox is similar to creating a branch. Activating a sandbox is similar to performing changes on top of the branch, and publishing a sandbox is similar to merging the content of the branch to the main branch, sometimes referred to as trunk.

  **Note**: When you create a sandbox, a new branch is created. You can modify MDS content within that branch. Note that you will not be able to view the changes made in other sandboxes that are created later and published to the main branch. Similarly, when you try to merge this sandbox, a concurrent modification exception is generated. It is recommended that you edit the contents of the sandbox manually to remove the conflicting files. However, if manual editing is not possible, then create a new sandbox again and redo the change.

This section describes how to manage sandboxes in the following sections:

- Handling Concurrency Conflicts
- Creating a Sandbox
- Activating and Deactivating a Sandbox
- Viewing and Modifying Sandbox Details
30.2.1 Handling Concurrency Conflicts

Multiple users can customize an application by using sandboxes. While doing so, the following types of concurrency conflicts might take place:

- **Conflicts within a sandbox**: Users overwriting changes created by other users, either directly by changing the same artifact, or indirectly by affecting files that are shared between the artifacts.

  Conflicts within a sandbox can arise when multiple users are customizing an application by using the same sandboxes at the same time, because more than one user may be attempting to customize the same artifact, or performing a customization task that indirectly affects other shared files. An example of a direct conflict is when different users attempt to customize the same page, the same fragment, or the same metadata file in the same layer. An example of an indirect conflict is when two users, each creating their own object, cause a conflict in the metadata file that tracks which new objects have been created by both saving their changes around the same time. Conflicts may also arise when users are editing a shared artifact, such as when a user performs an operation that adds or edits a translatable string. For example, a user edits a field’s display label or help text, or a validation rule’s error message, while another user performs an operation around the same time that similarly affects translatable strings. Another example of a shared artifact conflict is when two or more users are working in navigator menus which are shared across applications.

- **Conflicts between sandboxes intended for publishing**: Multiple sandboxes with the same customized artifact publishing to the mainline.

  Conflicts between sandboxes can arise when there is more than one sandbox intended for publishing in use. If two sandboxes contain conflicting customization changes to the same artifact and both are being published, then the sandbox that is being published last will not be allowed to be published, and an error describing the conflict will be displayed. To avoid such conflicts, it is recommended to create and use only one sandbox at a time. These types of conflicts can also occur with shared metadata files such as resource bundles that store translatable strings.

When multiple users are working in a single sandbox, these guidelines must be followed:

- Multiple concurrent users in the same sandbox must operate only on different and unrelated objects. For example, if user1 updates object1, then user2 can update object2 but should not update object1. Be aware that if both modifications involve changes to translatable strings, then saving changes to separate objects around the same time may still cause a conflict in the resource bundle that stores the translatable strings.

- Users in the same sandbox can see the changes created by one another. The latest version of each object gets loaded on-demand the first time it is viewed. If there are ADF Business Components customizations, then users must log out and log in again to see those changes reflected in the UI.
Managing Sandboxes

When multiple users are working in multiple sandboxes, in addition to all guidelines applicable to multiple users working in a single sandbox, these guidelines must be followed:

- There can be any number of test-only sandboxes operating concurrently. Multiple users can use multiple sandboxes concurrently for testing even if these sandboxes are never published. Sandboxes that are used for testing only, and that are not published, cause no conflicts with each other, but all guidelines for multiple users working in a single sandbox must be followed. However, all modifications are lost when the sandboxes are deleted.

- For sandboxes that will be published, you can have multiple concurrent sandboxes only if they operate on mutually exclusive artifacts. For example, you can have one sandbox that contains a page that is being customized to add a task flow, and another sandbox that contains a different page from a different application.

- If an artifact is updated in both the mainline and in the sandbox (or two different sandboxes), when the sandbox is published, such conflicts are detected and an error is generated.

### 30.2.1.1 Troubleshooting Concurrency Issues

Table 30–1 lists the issues that you might encounter if there are concurrency conflicts in the sandbox usage and the possible solutions.

<table>
<thead>
<tr>
<th>Example Scenario</th>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Working on multiple sandboxes intended for publishing concurrently:</td>
<td>When you try to publish S1, an error is thrown.</td>
<td>Create a new sandbox and redo the changes.</td>
</tr>
<tr>
<td>Create sandbox S1, create sandbox S2, make changes to S2, publish S2,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>make changes to S1, and publish S1.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
30.2.2 Creating a Sandbox

To create a sandbox:

1. Log in to Oracle Identity Self Service or Oracle Identity System Administration.
2. On the upper navigation bar, click Sandboxes. The Manage Sandboxes page is displayed. This page has the following sections:
   - Available Sandboxes: Displays all the sandboxes that are available for testing the UI customizations, which are not yet published.
   - Published Sandboxes: Displays all the published sandboxes.
3. On the toolbar, click Create Sandbox. The Create Sandbox dialog box is displayed.
4. In the Sandbox Name field, enter a name for the sandbox. This is a mandatory field.

Table 30–1 (Cont.) Troubleshooting Concurrency Issues

</tbody>
</table>

30.2.2 Creating a Sandbox

To create a sandbox:

1. Log in to Oracle Identity Self Service or Oracle Identity System Administration.
2. On the upper navigation bar, click Sandboxes. The Manage Sandboxes page is displayed. This page has the following sections:
   - Available Sandboxes: Displays all the sandboxes that are available for testing the UI customizations, which are not yet published.
   - Published Sandboxes: Displays all the published sandboxes.
3. On the toolbar, click Create Sandbox. The Create Sandbox dialog box is displayed.
4. In the Sandbox Name field, enter a name for the sandbox. This is a mandatory field.
5. In the Sandbox Description field, enter a description of the sandbox. This is an optional field.

6. Click **Save and Close**. A message is displayed with the sandbox name and creation label.

   **Caution:** Selecting the Activate Sandbox option closes all the open tabs except the Manage Sandboxes tab and activates the created sandbox.

7. Click **OK**. The sandbox is displayed in the Available Sandboxes section of the Manage Sandboxes page.

### 30.2.3 Activating and Deactivating a Sandbox

To activate a sandbox:

   **Note:** You must close all tabs in the Self Service or System Administration interfaces before activating or deactivating a sandbox.

1. From the table showing the available sandboxes in the Manage Sandboxes page, select the sandbox that you want to activate.

2. On the toolbar, click **Activate Sandbox**. The table refreshes and a marker in the Active column is displayed. In addition, the Sandboxes link on the upper navigation bar also displays the active sandbox name in parentheses.

   **Caution:** If any other tabs are open except the Manage Sandboxes tab before activating the sandbox, then Oracle Identity Manager prompts that all the tabs will be closed before the sandbox can be activated.

To deactivate a sandbox:

1. From the table showing the available sandboxes in the Manage Sandboxes page, select the active sandbox that you want to deactivate.

2. On the toolbar, click **Deactivate Sandbox**. The page refreshes and the marker in the Active table disappears.

   **Caution:** If any other tabs are open except the Manage Sandboxes tab before deactivating the sandbox, then Oracle Identity Manager prompts that all the tabs will be closed before the sandbox can be deactivated.

### 30.2.4 Viewing and Modifying Sandbox Details

To view the details of a sandbox and modify the details:

1. In the table showing the available sandboxes in the Manage Sandboxes page, click the sandbox name link. A dialog box with the sandbox details is displayed.

2. Make the following changes:
In the Description field, you can enter a description for the sandbox.

View all the changes to the sandbox in the Change Details table.

Filter sandbox changes by using the Layer Names, Layer Values, and Change Types lists, and the Filter toolbar icon.

Delete any changes made in the sandbox by selecting the change in the table, and clicking **Delete Customization**.

Export the sandbox, if it contains any changes, by clicking **Export Sandbox**.

### 30.2.5 Exporting and Importing a Sandbox

To export a sandbox from an Oracle Identity Manager deployment to another:

1. From the table showing the available sandboxes in the Manage Sandboxes page, select the sandbox that you want to export.
2. On the toolbar, click **Export Sandbox**.

If the sandbox contains any changes, then the sandbox content ZIP file starts downloading. You can now take the ZIP file and import it to the same or another environment.

**Note:** The name of the sandbox ZIP file is not the sandbox name. The sandbox name usually starts with Idem and it is specified in the XML file located inside the ZIP in the `/mdssys/sandbox/` directory.

**Caution:** If the deployment on which the sandbox content ZIP file is being imported already contains a sandbox with the same name, then that sandbox will get overwritten.

To import a sandbox from an Oracle Identity Manager deployment to another:

1. On the toolbar, click **Import Sandbox**. The Import Sandbox dialog box is displayed.
2. In the Sandbox Archive field, enter a path to the sandbox archive that you exported.
3. Click **Import**.
4. Click Refresh. The sandbox, which is imported to the target deployment, is displayed in the Available Sandboxes tab.

### 30.2.6 Publishing a Sandbox

To publish a sandbox:

**Note:** Oracle recommends creating a backup of MDS before publishing the sandbox. A backup of MDS can be created by using Oracle Enterprise Manager. See "Creating MDS Backup" on page 37-3 for information about creating a backup of the MDS by using Oracle Enterprise Manager.

1. Before publishing the sandbox, close all the open tabs and pages.
2. From the table showing the available sandboxes in the Manage Sandboxes page, select the sandbox that you want to publish.

3. On the toolbar, click **Publish Sandbox**. A message is displayed asking for confirmation.

4. Click **Yes** to confirm. The sandbox is published and the customizations it contained are merged with the main line.

5. You can click the **Published Sandboxes** tab to view a list of the published sandboxes.

### 30.2.7 Checking Out an Item from Cart

To check out an item from cart:

1. Log in to Oracle Identity System Administration.
2. Create a sandbox. See "Creating a Sandbox" on page 30-8 for information about creating a sandbox.
3. Activate the Sandbox that you created. See "Activating and Deactivating a Sandbox" on page 30-9 for information about activating sandbox.

   **Caution:** If you do not activate the sandbox, you will not be allowed to save the disconnected application instance date.

4. Create a disconnected application instance "disc1". By default it will be published to top. See "Creating a Disconnected Application Instance" section in the *Oracle Fusion Middleware Developer’s Guide for Oracle Identity Manager* for information about creating a disconnected application instance.

5. Publish the Sandbox. See "Publishing a Sandbox" on page 30-10 for information about publishing a sandbox.

6. Run Catalog Synchronization Job.

7. Log in to Oracle Identity Self Service.

8. Click on **Catalog** and search for "disc1".

9. Click **Add** to add the item to the cart.

10. Click **Checkout from Cart**.

### 30.2.8 Deleting a Sandbox

To delete a sandbox:

1. From the table showing the available sandboxes in the Manage Sandboxes page, select the sandbox that you want to delete.

2. On the toolbar, click **Delete Sandbox**. A message is displayed asking for confirmation.

3. Click **Yes** to confirm. The sandbox is deleted and is no longer displayed in the Manage Sandboxes page.
### 30.2.9 Reverting Changes to Default Settings

You must perform all customizations within a sandbox. Until the sandbox is published, the changes are visible to you only and can be easily reverted by deactivating or deleting the sandbox. After the sandbox is published, the changes done cannot be reverted.

You can remove specific changes from the sandbox in any one of the following ways:

- Export the sandbox and modify it manually.
- Navigate to the Manage Sandboxes page, open the details of your sandbox, select a change, and delete it by clicking **Delete Customization**.

When an MDS sandbox is published, the documents are committed to the MAIN line. Your application starts using these documents immediately, and the application user views the effect of publishing the sandbox. Sometimes, you might inadvertently publish an incomplete or a wrong sandbox. In such instances, it is possible to recover your MAIN line to the state just before you created the wrong sandbox.

For example, if you create a sandbox called Show Admin Feature at time T1, and in that you customized a JSFF fragment published at time T2. You realize later that the sandbox you published is wrong, and you want to recover your state to time T1. To do so:

1. Login to Oracle Enterprise Manager.
2. On the left pane, expand **Application Deployments**, and open the `oracle.iam.ui.console.self-service` application.
3. On the top of the right pane, click **Application Deployment**, and select **MDS Configuration**.
4. At the lower part of the right pane, click the **Runtime MBean Browser** link. The screen refreshes.
5. Click the **Operations** tab.
6. Scroll down. Click and open the **list Metadata Labels** MBean operation, and then click **Invoke**. All the sandboxes recreation labels and post publish labels are displayed. Select the sandbox pre create to which you want to restore and copy it to clipboard.
7. Click **Return** to go back to the operations.
8. Select the promote Metadata Label MBean operation and invoke it by provisioning the value that you copied in step 6.

Your MDS main line is reverted to the state that was at the time of creation of the sandbox.

**Note:** You can also restore to the last successful sandbox that was published by restoring to the post label of that sandbox.
30.3 Skin Customization in Oracle Identity Manager

Oracle ADF uses skins along with styles to customize the appearance of an application. These concepts apply to all the Oracle Identity Manager interfaces, with the exception of the Transitional UI popups.

See Also: Before customizing style sheets, see Customizing the Appearance Using Styles and Skins in the Fusion Middleware Web User Interface Developer’s Guide in the following URL:

Following URL gives a list of all the CSS style selectors that can be used to customize the style sheets:

http://download.oracle.com/docs/cd/E15523_01/apirefs.1111/e15862/toc.htm

You configure new skins in trinidad-config.xml. The default skin for Oracle Identity Manager is "skyros":

```xml
<?xml version="1.0" encoding="windows-1252"?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">
  <skin-family>#{iamSkin.skinFamily}</skin-family>
  <skin-version>#{iamSkin.skinVersion}</skin-version>
  <accessibility-mode>#{accessibilityBean.accessibilityMode}</accessibility-mode>
  <accessibility-profile>#{accessibilityBean.accessibilityProfile}</accessibility-profile>
</trinidad-config>
```

There are two console-specific trinidad-config.xml files. The files are in the following directory paths:

- For Identity Self Service:
  /iam/iam-product/consoles/Identity/MainUI/publicum/WEB-INF/trinidad-config.xml

- For Identity System Administration:
  /iam/iam-product/consoles/Identity/AdvancedUI/public_html/WEB-INF/trinidad-config.xml

30.3.1 Configuring a New Skin

To create a new skin:

1. In each WEB-INF directory, create the trinidad-skins.xml file, as shown:

   ```xml
   <?xml version="1.0" encoding='utf-8'?>
   <skins xmlns="http://myfaces.apache.org/trinidad/skin">
     <skin>
       <id>myskin.desktop</id>
       <family>myskin</family>
       <extends>#{iamBean.skyros-v1.desktop}</extends>
       <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
       <style-sheet-name>skins/myskin/myskin.css</style-sheet-name>
     </skin>
   </skins>
   ```

2. Configure the following system properties:
Skin Family for OIM UI: The ADF skin family for Oracle Identity Manager UI that the application uses at runtime.

Skin Version for OIM UI: The skin version, if any, for the skin family being used for Oracle Identity Manager UI.

See Also: "System Properties in Oracle Identity Manager" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about the Skin Family for OIM UI and Skin Version for OIM UI system properties.

Change the values of these properties to your custom skin. Before setting the values of these properties, the custom ADF skin must be developed and then deployed into Oracle Identity manager.

Oracle ADF faces provide simplified default skins, such as skyros-v1.desktop, which are designed to be extended by custom skins. The ADF skin that you create must extend either one of the ADF skins that Oracle ADF provides or from an existing ADF skin that you created. Skins are reusable components and must be created in their own JDeveloper project or workspace. You can create an ADF skin file in the ADF Skin Editor that defines how ADF faces components render at runtime.

See Also:

- "Inheritance Relationship of the ADF Skins Provided by Oracle ADF" in the Oracle Fusion Middleware Skin Editor User’s Guide for Oracle Application Development Framework for information about the inheritance relationship between the ADF skins that Oracle ADF provides.

- "ADF Skins Provided by Oracle ADF" in the Oracle Fusion Middleware Skin Editor User’s Guide for Oracle Application Development Framework for information about the levels of customization in the ADF skins provided by Oracle ADF and for a recommendation about the ADF skin to extend.

3. If required, adjust the height of the top branding bar to fit the new logo image in the following:

```
oracle.iam.console.identity.self-service.ear/oracle.iam.console.identity.self-service.war/oracle/iam/ui/main
```

For the login page (signin.jspx):
```
<f:attribute name="globalBrandingSize" value="64"/>
```

For the page displaying challenge questions (firstlogin.jspx):
```
<f:attribute name="globalHeaderSize" value="64"/>
```

For the pages in Identity Self Service (identity.jspx):
```
<f:attribute name="globalHeaderSize" value="64"/>
```
4. In the oracle.iam.console.identity.self-service.ear/oracle.iam.console.identity.self-service.war/WEB-INF/web.xml file, include the following settings:

```xml
<context-param>
    <description>No obfuscation of CSS.</description>
    <param-name>org.apache.myfaces.trinidad.DISABLE_CONTENT_COMPRESSION</param-name>
    <param-value>true</param-value>
</context-param>
<context-param>
    <description>If this parameter is true, there will be an automatic check of the modification date of your JSPs, and saved state will be discarded when JSP's change. It will also automatically check if your skinning css files have changed without you having to restart the server. This makes development easier, but adds overhead. For this reason this parameter should be set to false when your application is deployed.</description>
    <param-name>org.apache.myfaces.trinidad.CHECK_FILE_MODIFICATION</param-name>
    <param-value>true</param-value>
</context-param>
```

**Note:** Oracle recommends not to customize the top section and the left navigation pane of the Identity Self Service. The customization in these sections might not work properly, and any existing customization might be lost.

### 30.3.2 Configuring Skin for Legacy Advanced Console

To keep the defaults coming from the 'skyros' skin and override certain style sheet elements:

1. Create the skin in the trinidad-skins.xml file. Declare the skin in a new file oim.ear/iam-consoles-faces.war/WEB-INF/trinidad-skins.xml, as shown:

```xml
<?xml version="1.0" encoding='utf-8'?>
<skins xmlns="http://myfaces.apache.org/trinidad/skin">
    <skin>
        <id>myskin.desktop</id>
        <family>myskin</family>
        <extends>skyros.desktop</extends>
        <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
        <style-sheet-name>skins/myskin/myskin.css</style-sheet-name>
        <bundle-name>oracle.iam.consoles.faces.resources.AdfComponentsMessageBundle</bundle-name>
    </skin>
</skins>
```

2. Register the new "myskin" in both the /WEB-INF/trinidad-config.xml file and the iam-consoles-faces.war/WEB-INF/trinidad-config.xml file, as shown:

```xml
<?xml version="1.0" encoding='utf-8'?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">
    <skin-family>myskin</skin-family>
</trinidad-config>
```
3. Create new skin CSS file
   oim.ear/iam-consoles-faces.war/skins/myskin/myskin.css.

4. In myskin.css, put stylesheet elements that are required to be overridden from the defaults. For example, to change the branding text color, add the following:
   
   `.AFBrandingBarTitle, .xdj
   {
     color:#800080;
   }

5. Redeploy (or update) the Oracle Identity Manager deployment through the Oracle WebLogic Server Administration Console.

   **Note:** To change the branding information as an alternative to the method in "Changing Branding and Logo" on page 30-16, create a custom skin and use the appropriate style classes given in the URL in this section.

### 30.3.3 Changing Branding and Logo

Customizing or changing UI artifacts, such as logo, buttons, and menu items, can be done at runtime by using Oracle WebCenter Composer.

   **Note:** The procedure documented in this section is for changing the branding and logo by customizing Oracle Identity Self Service. If you want to customize UI artifacts of the window that opens from the Oracle Identity System Administration, for example, the window that opens when you click System Configuration under System Management, then see "Branding Customization" at the following URL:
   
   http://docs.oracle.com/cd/E21764_01/doc.1111/e14309/uicust.htm#BABPCPID

To change the logo image:

1. Log in to Oracle Identity Self Service as the system administrator.
2. Create and activate a sandbox.

   **Note:** Creating and activating a sandbox is mandatory for customizing the UI by using the Web Composer. Without an active sandbox, Oracle Identity Manager does not allow to open any page in customization mode.

3. Click **Customize**. The Oracle WebCenter Composer opens. The top of the page shows 'Editing Page'.
4. From the View list, select **Source**. The object tree is displayed in the top pane. The object tree shows all the ADF components of the page.
5. Click the logo. The logo object is selected in the object tree, as shown in **Figure 30–3**.
Figure 30–3  The Object Library in WebCenter Composer

The ADF components displayed in the object tree is similar to the structure pane in JDeveloper, as shown in Figure 30–4:
6. Click Edit. The Component Properties dialog box is displayed.

7. Click the Style tab.

8. In the Background Image field, enter the path to the logo image that you want to set, for example, url(/identity/faces/images/mylogo.jpg).

**Tip:**

- Customizing the default EAR and WAR files, such as Self Service EAR, System Administration EAR, and xlWebApp.war, is not supported.
- The Oracle logo is 119x25 pixels. Therefore, you can use a custom logo of the same dimensions.

**Figure 30–5** shows the Style tab of the Component Properties dialog box:

---

**Note:** For a complete list of UI components, see *Oracle Fusion Middleware Web User Interface Developer’s Guide for Oracle Application Development Framework.*
Skin Customization in Oracle Identity Manager

Figure 30–5  The Component Properties Dialog Box

To change the Identity Self Service global banner, click the Identity Self Service text, and repeat steps 5 to 7.

Tip: To change the banner in the Oracle Identity Manager login page, you must open the login page in the customization mode. However, the Customize link is not available in the login page. Therefore, to open the login page in customization mode:

1. Login to Oracle Identity Self Service as an administrator with privileges to customize the UI.
2. In an active sandbox, click the Customize link. The Oracle Identity Self Service is in customization mode.
3. Perform the steps described in “Customizing the User Registration and Other Unauthenticated Pages” on page 30-30.

Tip: If you want to specify a font for any ADF component by using the Style tab of the Component Properties dialog box, then ensure that your target browsers and platforms support that specific font name. To look at the supported list for Mozilla Firefox, select Tools, Options, Content, Fonts and Colors. For Microsoft Internet Explorer, select Tools, Internet Options, General, Fonts.

9. Click Save to save the logo and global banner changes.

10. Click Close to close WebCenter Composer.

12. Publish the sandbox.
Customizing Pages at Runtime

**Note:** Runtime UI customization changes the banner text. However, it does not allow you change the browser title, for instance, the title that appears in the browser window, HTML>HEAD>TITLE text or the browser tab title if using tabs.

If you want to change the browser text title, then you have to manually edit the value in the resource bundle file OIMUIBundle_*.properties, and redeploy as follows:

```
oracle.iam.ui.view.war/WEB-INF/lib/adflibCommonUI.jar/oracle/iam/ui/OIMUIBundle_en.properties:
IDENTITY_SELF_SERVICE_TITLE=Identity Self Service
```

See "Internationalization for Resource Strings" on page 30-23 for information about creating and using the custom resource bundles.

### 30.4 Customizing Pages at Runtime

Customizing Oracle Identity Manager can be broadly categorized into customizing the UI and extending the object definitions of the user, role, catalog, and provisioning target resource entities.

Table 30–2 lists the artifacts that can be customized for each entity.

<table>
<thead>
<tr>
<th>Available Entity</th>
<th>Artifacts</th>
</tr>
</thead>
<tbody>
<tr>
<td>User</td>
<td>Create Page&lt;br&gt;Modify Page&lt;br&gt;User Attribute Details&lt;br&gt;Advanced Search Interface&lt;br&gt;My Information&lt;br&gt;Self Registration</td>
</tr>
<tr>
<td>Role</td>
<td>Create Page&lt;br&gt;Modify Page&lt;br&gt;Advanced Search Interface, which includes:&lt;br&gt;- Query Criteria&lt;br&gt;- Results Table columns</td>
</tr>
<tr>
<td>Catalog</td>
<td>Catalog Search Page that includes:&lt;br&gt;- Results Table columns&lt;br&gt;- Catalog Item Details</td>
</tr>
<tr>
<td>Provisioning target resource</td>
<td>Provisioning Target Resource Create Form&lt;br&gt;Provisioning Target Resource Modify Form&lt;br&gt;Provisioning Target Resource Bulk Form</td>
</tr>
</tbody>
</table>

**See Also:** "Managing Forms" and "Configuring Custom Attributes" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for information about creating and managing forms by using the Form Designer.
This section contains the following topics:

- Using Expression Language in UI Customization
- Showing or Hiding UI Components Conditionally
- Showing Request Profiles Conditionally
- Validating Input Data Using ADF Validators
- Marking Input Attribute as Required

The Web Composer enables you to customize the UI at runtime. This section describes the following UI customizations:

- Adding a Link or Button
- Hiding and Deleting an ADF Component
- Showing and Hiding Attributes
- Customizing the User Registration and Other Unauthenticated Pages
- Customizing Certification Pages

### 30.4.1 Using Expression Language in UI Customization

Expression Language (EL) allows you to access application data stored in JavaBeans components. For an introduction to EL and EL expression syntax, refer to the following URL:

#### 30.4.1.1 Available EL Expressions in the User Context

The OIMContext bean is defined as an ADF session scope bean in adfc-config.xml in your project. Table 30–3 lists the available EL expressions in the Oracle Identity Manager user context.

<table>
<thead>
<tr>
<th>EL</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#{oimcontext.currentUser['ATTRIBUTE_NAME']}</td>
<td>Access value of the ATTRIBUTE_NAME attribute of the logged-in user. For the list of default attributes defined for the user entity, see &quot;Attribute Definitions&quot; in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.</td>
</tr>
<tr>
<td>#{oimcontext.currentUser['UDF_NAME']}</td>
<td>Access value of the UDF_NAME attribute of the logged-in user. UDF attributes can be defined by using the Form Designer.</td>
</tr>
<tr>
<td>#{oimcontext.currentUser.roles}</td>
<td>Access the ROLE_NAME and RoleEntity mapping that contains the roles assigned to the logged-in user. RoleEntity is Java Bean having name, description, key, and displayName properties.</td>
</tr>
<tr>
<td>#{oimcontext.currentUser.roles['SYSTEM ADMINISTRATORS'] !== null}</td>
<td>Boolean EL that evaluates to true if the logged-in user has the System Administrator admin role. Similarly, you can modify the EL to check for any other role.</td>
</tr>
</tbody>
</table>
You can use EL expression to retrieve all available user attribute values from the oimcontext bean, as shown in the following examples:

- To get the user key of the currently logged-in user:
  
  `#{oimcontext.currentUser.usr_key}`

  OR:

  `#{oimcontext.currentUser['usr_key']}'`

- To get the list of role names of the currently logged-in user:

  `#{oimcontext.currentUser.roles}`

- To get the list of admin role names of the currently logged-in user:

  `#{oimcontext.currentUser.adminRoles}`

As an example, if you want to display a message with the user login name when a user logs in to Oracle Identity Self Service, then you can use EL expression to retrieve the login name of the currently logged-in user, and display it on the page. The expression to retrieve the user login name is the following:

`#{oimcontext.currentUser['User Login']}'`

### 30.4.1.2 Available EL Expressions in the RequestFormContext

RequestFormContext is a bean available in the pageFlowScope of entity form details task flow. The entity forms include user form, application instance form, role form, and entitlement form. RequestFormContext provides various context information. Using this context information, you can customize the forms based on specific business requirements.

Table 30–4 lists the EL expressions involving RequestFormContext.

<table>
<thead>
<tr>
<th>EL</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#{pageFlowScope.requestFormContext}</code></td>
<td>Access current instance of RequestFormContext.</td>
</tr>
<tr>
<td><code>#{pageFlowScope.requestFormContext.operation}</code></td>
<td>Access operation type that is being performed on the entity. The possible values are CREATE, MODIFY, ENABLE, DISABLE, and REMOVE.</td>
</tr>
<tr>
<td><code>#{pageFlowScope.requestFormContext.operation == 'MODIFY'}</code></td>
<td>Boolean EL that evaluates to true if current operation being performed on the entity is MODIFY.</td>
</tr>
<tr>
<td><code>#{pageFlowScope.requestFormContext.actionType}</code></td>
<td>Access action that is being performed by the user when the entity form is displayed. The possible values are APPROVAL, FULFILL, REQUEST, VIEW, and SUMMARY.</td>
</tr>
</tbody>
</table>
Customizing Pages at Runtime

30.4.1.3 Internationalization for Resource Strings

In Oracle Identity Manager, you can create custom resource bundles and reference them in the UI. If you want to modify some of the predefined UI elements such as labels, headers, and so on, or the values displayed on a certain page (for example, values displayed in the Status field of the Request Summary page), then perform the procedure described in this section.

**WARNING:** Any changes made to the default WAR or EAR files should be redone after any Bundle Patch (BP) is applied as the Bundle Patch will overwrite them.

To create custom resource bundles:

1. Open the custom project WAR file, which is oracle.iam.ui.custom-dev-starter-pack.war.
2. Create a new CustomResourceBundle.properties file.
3. In the new file, enter the key value pairs, for example:

    CUSTOMRB_BANNER_TEXT=My Identity and Access
4. Create all localized files, for example CustomResourceBundle_it.properties and CustomResourceBundle_es.properties, in the same directory.

5. Repackage the custom WAR, and update the custom WAR deployment in the server.

To use the resource bundles:

1. In Oracle Identity Self Service, create a sandbox, and click **Customize**.

2. On the Component Properties dialog box, open the Expression Editor for the specific property, and specify the expression, for example:

   `#{adfBundle['oracle.iam.ui.custom.CustomResourceBundle'].CUSTOMRB_BANNER_TEXT}`

3. Click **Test** to test the expression. Click **OK**, then click **Apply**.

4. Click **OK** to close the Component Properties dialog box.

5. Export the sandbox, and then publish the sandbox.

---

**Note:** Exporting the sandbox is optional, but it is a recommended step.

---

### 30.4.2 Showing or Hiding UI Components Conditionally

To conditionally show or hide UI components, use the rendered property of the component and assign EL expression to it that evaluates to Boolean. If the EL expression evaluates to true, then the component is shown. Consider the following examples:

---

**Note:** The rendered property of the component corresponds to the Show Component option in Oracle Web Composer.

---

- To show a UI component if the logged-in user has the System Administrators admin role:
  ```java
  #{oimcontext.currentUser.roles['SYSTEM ADMINISTRATORS'] != null}
  ```

  Similarly, the EL expression can be modified to check if the logged-in user has any other role.

- To show a UI component if signed-in user has the System Administrator admin role:
  ```java
  #{oimcontext.currentUser.adminRoles['OrclOIMSystemAdministrator'] != null}
  ```

  Similarly, the EL expression can be modified to check if the logged-in user has any other admin role.

- To show a UI component if the usr_key attribute of the logged-in user is 1:
  ```java
  #{oimcontext.currentUser['usr_key'] == 1}
  ```

- To show a UI component if the logged-in user's last name is Doe:
  ```java
  #{oimcontext.currentUser['Last Name'] == 'Doe'}
  ```

- To show a UI component if the logged-in user belongs to the Xellerate Users organization:
Customizing Pages at Runtime

To show a UI component if the user's UDF attribute called UDF_NAME equals to UDF_VALUE:

#{oimcontext.currentUser['UDF_NAME'] == 'UDF_VALUE'}

**Note:** “Showing Components Conditionally” on page 30-46 describes showing components based on certain conditions by implementing custom Managed Bean.

### 30.4.3 Showing Request Profiles Conditionally

To show a catalog request profile conditionally:

1. Login to Oracle Identity Self Service.
2. Activate a sandbox.
3. Navigate to the Catalog page.
4. Click Customize. From the View list, select Source.
5. Using the source tree, navigate to the iterator component within Request Profiles. The iterator component has panelGroupLayout subcomponent, which represents single request profile.
6. Select panelGroupLayout:horizontal, which is a subcomponent of panelGroupLayout:vertical inside the iterator component, and click Edit in the Web Composer.
7. Assign a Boolean EL expression to the rendered property. This is the Show Component in Web Composer.
   
   For example, if you want to display a resource profile called Profile to users of the Suppliers organization only, and display any other profile to other users, then use the following expression:

   #{(row.profileName == 'Profile' && oimcontext.currentUser['Organization Name'] == 'Suppliers') || row.profileName != 'Profile'}

   The EL expression is evaluated for every profile which is available. Similarly, you can modify/extend the EL expression to conditionally display any other profile.
8. Publish the sandbox to globalize the change.

### 30.4.4 Validating Input Data Using ADF Validators

To validate input component data using predefined ADF validators, you must modify the JSFF page fragment and include one of the ADF validators as a child element of input component. Table 30–5 lists the ADF validators:

<table>
<thead>
<tr>
<th>Validator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="">af:validateByteLength</a></td>
<td>Validates the byte length of strings when encoded</td>
</tr>
<tr>
<td><a href="">af:validateDateRestriction</a></td>
<td>Validates that the date entered is within a given restriction</td>
</tr>
<tr>
<td><a href="">af:validateDateTimeRange</a></td>
<td>Validates that the date entered is within a given range</td>
</tr>
</tbody>
</table>
For example, to validate that the only allowed characters for the User Login attribute are alphanumeric ASCII characters, you can include the following RegExp validator as a child element of the User Login input component:

```xml
<af:validateRegExp pattern="[a-zA-Z0-9]*"/>
```

ADF validators cannot be added directly by using the Web Composer. Instead, you can add another component as a child component of the User Login component, for example, another input text. After that you can export the sandbox containing this change. Finally, update the JSFF page fragment for the form in the exported sandbox, and then import the sandbox.

### 30.4.5 Marking Input Attribute as Required

To conditionally make an input field required, you can use the required property of the component, and assign it a Boolean EL expression. If the EL expression evaluates to true, then the component is marked as required, and the required validation is triggered.

For example EL expressions, see "Showing or Hiding UI Components Conditionally" on page 30-24.

For more information about making field conditionally mandatory based on the value of another field, see "Setting a Conditional Mandatory Field" on page 30-49.

### 30.4.6 Adding a Link or Button

To add a link to Oracle Identity Self Service:

1. From any page in Oracle Identity Self Service, open WebCenter Composer.
2. Select the top panel on which you want to include the link. The ADF component is selected in the object tree.

   Figure 30–6 shows the selected top panel and corresponding ADF component in the object tree.

### Table 30–5 (Cont.) ADF Validators

<table>
<thead>
<tr>
<th>Validator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="">af:validateDoubleRange</a></td>
<td>Validates that the date entered is within a given range</td>
</tr>
<tr>
<td><a href="">af:validateLength</a></td>
<td>Validates that the value entered is within a given length</td>
</tr>
<tr>
<td><a href="">af:validateLongRange</a></td>
<td>Validates that the value entered is within a given range</td>
</tr>
<tr>
<td><a href="">af:validateRegExp</a></td>
<td>Validates an expression by using Java regular expression syntax</td>
</tr>
</tbody>
</table>

For example, to validate that the only allowed characters for the User Login attribute are alphanumeric ASCII characters, you can include the following RegExp validator as a child element of the User Login input component:

```xml
<af:validateRegExp pattern="[a-zA-Z0-9]*"/>
```

ADF validators cannot be added directly by using the Web Composer. Instead, you can add another component as a child component of the User Login component, for example, another input text. After that you can export the sandbox containing this change. Finally, update the JSFF page fragment for the form in the exported sandbox, and then import the sandbox.

**Note:** "Implementing Custom Field Validation" on page 30-50 describes implementing the custom field validator by using custom Managed Bean.
3. Click **Add Content** and open Web Components. The Web Components component in the Add Content dialog box is shown in Figure 30–7:
4. Search for the link component that you want to add, and click **Add** in the same row. The link is added to the selected panel.

**Note:** For a complete list of UI components, see *Oracle Fusion Middleware Web User Interface Developer’s Guide for Oracle Application Development Framework*.

5. Click **Save** to save your changes, and close WebCenter Composer.

**Note:** For more details, see the following sections:

- "Launching Taskflows" on page 30-58
- "Creating an External Link" on page 30-60

Oracle Identity Manager allows you to add your own UI or taskflows, such as goLink, commandLink, commandButton, or launch a taskflow.

Perform the following steps to add your custom UI or taskflow:

1. Write a managed bean and register using adfc-config.xml in oracle.iam.ui.custom-dev-starter-pack.war.
2. Add a new commandLink or commandButton on the page where you want to display the link or button by using Web Composer.
3. Set the actionListener property of the link or button component that you added to point to the actionListener method.
4. Raise the contextual event using the managed bean, which will be handled by Oracle Identity Manager.

Shell launches the taskflow.

### 30.4.7 Hiding and Deleting an ADF Component

Hiding an ADF component results in the UI artifact being hidden from the user. To hide an ADF component:

1. In Oracle Identity Self Service, go to the page on which you want to hide a component.
2. Click **Customize** to open WebCenter Composer.
3. From the View menu, select **Source**. The object tree is displayed.
4. Click the component on the page that you want to hide. The corresponding ADF component in the object tree is selected.
5. Right-click the selected ADF component in the object tree, and select **Hide**.

To delete an ADF component:

1. From the Oracle Identity Self Service page on which you want to delete any UI component, open Web Composer.
2. From the View menu, select **Source**. The object tree is displayed.
3. Click the component on the page that you want to delete. The corresponding ADF component in the object tree is selected.
4. Right-click the selected ADF component in the object tree, and select **Delete**.
5. In the Delete Component Confirmation box, click **Delete**.

---

**Note:** Changing searchable property of default attributes is not supported.

### 30.4.8 Showing and Hiding Attributes

To show or hide attributes in a page:

1. Go to the page on which you want to show or hide the attribute. For example, navigate to the My Information page in the Oracle Identity Self Service if you want to show or hide the Telephone field.

2. Click **Customize** to open Web Composer.

3. From the View menu, select Source. The object tree is displayed.

4. Click the region or section that contains the attribute you want to hide, or you want the attribute to be shown.

   The Confirm Task Flow Edit message box is displayed.

5. Click **Edit**. The ADF component for the selected region is selected in the object tree.

6. On the toolbar, click **Edit**. The Component Properties dialog box is displayed.

7. Click the **Child Components** tab. All the UI components of the selected region are displayed. **Figure 30–8** shows a sample Child Components tab in the Component Properties dialog box.

**Figure 30–8 The Child Components Tab**

8. Select or deselect the checkbox corresponding to the attributes to show or hide the attributes respectively.
9. Click **Apply**. The selected attributes are hidden or shown based on your selection.

10. Click **OK**, and then click **Save** on the toolbar.

### 30.4.9 Customizing the User Registration and Other Unauthenticated Pages

To customize the User Registration and other unauthenticated pages of the Identity Self Service:

1. Login to Oracle Identity Self Service as the system administrator.
2. Create and activate a sandbox, and click **Customize**.
3. Select **View**, **Source**. Click the last visible link in the left navigation pane, for example, Open Tasks.

   **Note:** Do not open any tab. You need to customize the left navigation pane itself.

4. Confirm to edit task flow. Using the source tree pane, scroll down to find the grayed-out item 'Unauthenticated Pages'.

5. Right-click **Unauthenticated Pages**, and select **Show Component**. The links to go to unauthenticated pages are displayed on the left navigation pane, as shown in Figure 30–9.

**Figure 30–9 Unauthenticated Page Links**

![Unauthenticated Page Links](image)

6. Select **View**, **Design**. Click the **New User Registration** link in the left navigation pane. You are redirected to the User Registration screen.

---

**Note:** If you do not see an attribute listed here, then you must add the attribute into the form. See "Adding a Custom Attribute" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for details.
7. After filling required fields, select View, Source. Click Add Content and use the Data Component - User Registration, UserVO1 to add new fields.

8. Click Cancel to come back to the home page. After you are done, remember to hide the unauthenticated links in the left navigation pane, then right-click Unauthenticated Pages, and select Hide Component.

### 30.4.10 Customizing Certification Pages

The information from the row selected in the certification table can be used for customizing the detail pane found below the table. The procedure in this section can be used to customize the user certification detail pane. The same procedure can be followed for any certification type.

After you have entered the customization mode, perform the following steps:

1. Edit the panelFormLayout containing the User Detail Information.

2. Click Add Content.

3. Select Data Component - Certification.

5. Search for the attribute you want to add, for example Title, and click Add.

   The input component is added to the page, but a value for it is not displayed. A label is added that shows the name of the attribute.

7. Select the inputText component in the page source panel, and click Edit. The Component Properties dialog box is displayed.

8. Scroll down and find the Value attribute, and open the Expression Builder.

9. Edit the expression value and set it to the following:

   #{pageFlowScope.p1_row_idcTitle}

10. Save the changes and close Web Composer. Select a row in the table.

    When a row is selected from the table, the information is stored in the pageFlowScope. To display this information in the detail pane, steps 1 through 10 must be followed to extract the correct data. The format of the EL to follow is:

    #{pageFlowScope.p1_row_ATTRIBUTE_NAME}

    Page 1 table information can also be used in page 2 by using the same format. Because the data is stored in the pageFlowScope, the information remains in the scope making it available for display. Page 2 has a Page 1 Detail section at the top of the page showing a reference back to the item on page 1. You can add more page 1 details here using p1_row_ATTRIBUTE_NAME in the expression.

    The steps documented in this section apply to page1 or the summmary page, of the current certification. If you want to customize page 2 or the detail page, then use the following format:

    #{pageFlowScope.p2_row_ATTRIBUTE_NAME}

### 30.5 Securing UI Components

This section contains the following topics:
30.5.1 Securing a Custom Taskflow Using APM

You can add permissions to custom taskflows by using the Authorization Policy Manager (APM) UI to secure the taskflow. To do so:

1. Login to Authorization Policy Manager as WebLogic user by navigating to the following URL:

   http://ADMIN_HOST:ADMIN_PORT/apm

2. Navigate to Applications, OracleIdentityManager, Resource Types. Click Open.

3. Click New to create a new resource type. Provide following details, and then click Save.
   - **Display Name**: A display name for this resource, for example, ADF Taskflows
   - **Name**: A name for this resource, for example, ADFTaskflows
   - **Actions**: personalize, customize, grant, or view. Click New to add each action.
   - **Supports Resource Hierarchy**: No
   - **Resource Delimiter**: Slash(/)
   - **Evaluation Logic**: Permission Class
   - **Permission Class**: oracle.adf.controller.security.TaskFlowPermission
   - **Action Name Delimiter**: Comma(,)

4. Navigate to Applications, OracleIdentityManager, Default Policy Domain, Resource Catalog, Resources. Click Open.

5. Click New to create a new resource. Provide following values, and then click Save.
   - **Resource Type**: Select the resource type created in step 3.
   - **Display Name**: Provide a display name for your custom taskflow.
   - **Name**: Provide the name of the custom taskflow in the following format:
     TASKFLOW_DOCUMENT#TASKFLOW_ID
   - **Description**: Provide a description for the custom taskflow.

   **Note**: For each custom taskflow, you must create a resource as mentioned in step 5. You can use the same resource type that you created in step 3 for all your custom taskflows.

7. Select Find By Principal, and click Search. If you want to add to a displayed existing policy, then select it and click Open. Otherwise, click New to create a policy.

8. Add name and principals for the new policy.
9. Click **Add Targets**. The Search Targets dialog box is displayed.

10. Click the **Resources** tab. Provide the resource type as defined in step 3, and then click **Search**.

11. Select the resource created in step 5. Click **Add Selected**.

12. Click **Add Targets**. The resource is added to the Targets table.

13. Expand the resource that you added to the table. Select the permissions you want to apply to the taskflow.

14. Click **Apply**.

### 30.5.2 Securing a Task Flow Region Using EL Expressions

For each new task flow, there is an entry in the jazn-data.xml file, as shown in the following example:

```xml
<permission>
  <class>oracle.adf.controller.security.TaskFlowPermission</class>
  <name>/WEB-INF/oracle/iam/ui/catalog/tfs/request-summary-details-tf.xml#request-summary-details-tf</name>
  <actions>view</actions>
</permission>
```

This is the basic level of permission required for any task flow to be visible on the Identity Self Service UI. For advanced permissions dependent on admin roles, you can use EL expressions to enforce functional security.

For securing task flows, the task flow must be used as a region in the parent JSFF file. You can define EL expression for the region so that the task flow can be shown or hidden to the logged-in user based on the user's permissions.

For securing a region, consider the following example:

On the my-access-accounts.jsff page, the details-information-tf task flow is rendered selectively to the users by using the following EL expression:

```java
rendered="# {oimappinstanceAuth.view [bindings.appInstanceKey].allowed}"
```

Here:

- `oimappinstanceAuth` is the mapped name of the ApplicationInstanceAuthz.java authorization bean in the adfc-config.xml file.
- `view` is the name of the UIPermission that needs to be checked. The following permission is defined in ApplicationInstanceAuthz.java, which is the actual bean file for reference of `oimappinstanceAuth`:

```java
Private UIPermission view = new UIPermission
(PolicyConstants.Resources.APPLICATION_INSTANCE.getId(),
PolicyConstants.ApplicationInstanceActions.VIEW_SEARCH.getId());
```
- `appInstanceKey` is the ID of the application instance that the user is trying to view, which is passed as a parameter.

### 30.6 Customizing Oracle Identity Manager Help

Oracle Identity Manager lets you develop and use the following online Help systems in the Oracle Identity Self Service and Oracle Identity System Administration:

- **Adding Custom Help Topics**
30.6.1 Adding Custom Help Topics

In addition to the Oracle Identity Manager help topics, you can also create and use custom help topics.

To view the custom help topics:

1. Login to Oracle Identity Self Service.
2. On the navigation bar at the top, click Help. The Oracle Help for the Web window is displayed.
3. From the Book list, select Custom Help Topics for Oracle Identity Manager.
4. Expand the contents to view the help topics.

The custom help book is provided as a separate JAR file. This is the OIM_HOME/help/CUSTOMOHW.jar file. You can create your own help topics and custom help book JAR, and then replace the CUSTOMOHW.jar file to display your custom help topics in the UI.

You create the custom help topics by using Oracle Help for the Web (OHW). For detailed information about creating custom OHW help topics, see Oracle Fusion Middleware Developer’s Guide for Oracle Help.

After creating the new custom help books, modify the following configuration files in the OIM_HOME/help/ directory to reference the new help books:

- ohwconfig_identity.xml: Configuration file for custom help topics in Oracle Identity Self Service
- ohwconfig_sysadmin.xml: Configuration file for custom help topics in Oracle Identity System Administration

**Note:** The configuration files are overwritten when you upgrade Oracle Identity Manager, and you must modify the configuration files again to reference the custom help books.

After creating the custom help topics, create the custom help JAR file, and replace the CUSTOMOHW.jar file with the new JAR file. You can now add your custom help topics on the UI pages. The following procedure shows how to add a custom help topic to the Getting Started with Help container of the Home page in the Oracle Identity Self Service:

1. In Oracle Identity Self Service, activate a sandbox from the Manage Sandboxes page.
2. In the Home page, click Customize.
3. From the View menu, select Source. The object tree is displayed. Open Web Components from Top List.
4. Click the Getting Started Help Topics container. Click Edit in the Confirm Edit Task Flow popup.
5. Click Add Content. The Add Content dialog box is displayed.
6. Select Command Image Link, and then click Add in the same row. The selected component is added to the Getting Started Help Topics section.
7. Select the added component, and click **Edit**. The Component Properties dialog box is displayed.

8. Click the **Display Options** tab.

9. In the Text field, enter the text for the help topic that will be displayed in the page.

10. In the Image field, enter the path and file name for the help icon image.

11. In the Action Listener field, enter the URL with the HelpTopicID of the custom help topic.

12. Click **Apply**, and then click **OK**.

13. Save and close customization mode. The help topic is added to the Getting Started with Help container of the Home page. Clicking the help topic displays the help topic in the custom help book JAR file.

### 30.6.2 Adding Inline Help

Oracle Identity Manager does not provide inline help by default. However, you can add your inline help for the various UI components, such as add tooltip text for fields and buttons.

The content for the inline help is picked up from the files in the custom WAR library (oracle.iam.ui.custom-dev-starter-pack.war), such as the /oracle/iam/ui/custom/help/CustomHelpResourceBundle.properties file. If the CustomHelpResourceBundle.properties file is not available in the WAR library, then you can create it.

**Note:** You can change the custom WAR library name. If you do so, then specify the same library name in the entry for the WAR file in Manifest.MF.

You can specify the inline help content through the entries in the CustomHelpResourceBundle.properties file. The entries have a CUSTOMRB prefix, and have any one of the following suffixes:

- **_DEFINITION:** This specifies inline help for a field or UI component. For example:
  
  ```
  CUSTOMRB_EMAIL_DEFINITION=Enter your official e-mail ID if available.
  ```

  EMAIL is the field name, and the value of the entry is the inline help text displayed on placing your mouse pointer on the field.

- **_INSTRUCTIONS:** This specified inline help for a page layout. For example:

  ```
  CUSTOMRB_MY_INFO_INSTRUCTIONS=Profile update will get reflected post approvals.
  ```

  MY_INFO is the page, and the value of the entry is the inline help text displayed on the top of the page.

As an example, the following procedure shows how to add inline help to the Telephone field in the My Information page of Oracle Identity Self Service:

1. In the Oracle Identity Self Service, navigate to the My Information page, and expand the Basic User Information section.

2. Click **Customize**.

3. From the View menu, select **Source**. The object tree is displayed.
4. Click the Telephone field.

5. Click Edit. The Component Properties dialog box for the Telephone field is displayed.

6. In the Help Topic ID field, enter the help topic ID of the inline help that you want to associate with the Telephone field, such as CUSTOMRB_TELEPHONE. Note that specifying the _DEFINITION suffix is not required.

7. Click Apply, and then click OK.

8. Save and close customization mode. An information image with the interrogation sign (?) is displayed before the Telephone field. When you place the mouse pointer on the icon, the inline help text is displayed.

### 30.7 Customizing the Home Page

The Home page provides you a snapshot of the various functions in the Oracle Identity Self Service. You can personalize the Home page by adding and removing containers, and rearranging containers. See "Personalizing the Home Page" in the Oracle Fusion Middleware User’s Guide for Oracle Identity Manager for details.

When you add a container, you must add UI components to the container to use it. To add containers in the Home page and then add UI components:

---

**Note:** The personalization capabilities, such as adding and removing containers and changing layouts, are not governed by authorization policies. However, the contents available to each user for adding is governed by authorization policies.

---

1. Login to Oracle Identity Self Service, and navigate to the Home page.

2. Click Personalize. The Home is displayed in customization mode with toolbars that consist of icons.

3. Click the Add Box Above icon on the toolbar. Figure 30–10 shows the Add Box Above icon on the toolbar.
Figure 30–10  The Add Box Above Icon on the Toolbar

You can click the respective icons to add a box below, right, or left of the container in which you are clicking the icon.

After clicking the icon, a container is added to the Home page, as shown in Figure 30–11:

Figure 30–11  A New Container

4. Click **Add Content**. The Add Content dialog box is displayed with the list of homepage task flows that you can add to the container. Figure 30–12 shows the Add Content dialog box.
Customizing Challenge Questions

You can customize the number of challenge questions in multiple pages of the UI. To do so, change the value of the PCQ.NO_OF_QUES system property to specify the number of challenge questions that you want to display to the user. In addition, you customize the pages to show or hide the challenge questions that you add or remove respectively.

To set the number of challenge questions:

1. Login to Oracle Identity System Administration.
2. On the left pane, under System Management, click System Configuration. The System Configuration tab is displayed in a new window.
3. Search and open the 'Number of Questions' system property that has the PCQ.NO_OF_QUES keyword.
4. Change the value from 3 to 5, and click Save.
5. Close the new window.
6. In the Oracle Identity System Administration, under Configuration, click Lookups, and search for the Lookup.WebClient.Questions code, as shown in Figure 30–13.
7. Add additional questions by editing the lookup type.

Note: You can localize the questions for en_US bundle, as described in “Localizing Challenge Questions and Responses” in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

To set challenge questions for the user who is logging in to Oracle Identity Self Service or Oracle Identity System Administration:

1. Login to Oracle Identity Self Service as the System Administrator, and on home page click on Sandboxes.

2. On the Home page, click Sandboxes on the upper navigation bar. The Manage Sandboxes page is displayed.

3. On the toolbar, click Create Sandbox. In the Create Sandbox dialog box, enter a sandbox name, for example ChallengeQ, and click Save and Close. Leave the Activate Sandbox check box selected.

4. On the confirmation dialog box, click OK. The active sandbox is displayed in the table in the Manage Sandboxes page. Close the Manage Sandboxes page.

5. Open the My Information page. Collapse the Basic Information section, and expand the Challenge Questions section.

6. Click Customize. Then the toolbar, select View, Source.

7. Click the third question, and click OK to confirm editing the taskflow.

8. In the source tree, select the greyed-out panelGroupLayout just after the third question. This contains the fourth question. Right-click this panelGroupLayout, and then select Show Component.
9. Similarly, show the fifth question.

10. Click **Close** on the toolbar.

11. Repeat steps 4 through 9 for the other three pages on which challenge questions are displayed by pointing the browser to the following URLs:

   - The User Registration page: /identity/faces/register
   - The Forgot Password page: /identity/faces/forgotpassword
   - The Login page when the user logs in for the first time:
     /identity/faces/firstlogin?action=setchallenges

   Note that there is some variation by design, for example, the question on the Forgot Password page is rendered as `outputText` rather than a list, as shown in Figure 30–14:

![Figure 30–14 Challenge Question on the Forgot Password Page](image)

The number of questions displayed in the pages is relative. For example, JohnD is the user login provided at the first step of forgot password. If JohnD does not existent or JohnD has not set the challenge responses for self, then all the configured questions are displayed in the Forgot Password page. If JohnD has set some challenge questions for self, then only those questions are displayed.

12. Publish the sandbox and logout.
30.9 Customizing the Transitional UI

In the transitional UI pages of the Identity Self Service, when you click a menu item to perform tasks, such as managing access policies, a search page is displayed. For example, when you click the Manage link under the Access Policies menu item, the Manage Access Policies page is displayed with two drop-down menus for searching access policies. You can customize the number of drop-down menus, and what the items in the drop-down menus are.

When the search results display, you can determine the maximum number of rows in the results table displayed on each page. After a user selects an item from the results table, a detail page is displayed such as the Resource Detail page. The detail page contains an additional details menu. You can customize the items in these menus.

This section contains the following topics:

- Customizing Search Drop-Down Item
- Customizing Number of Search Drop-Down Items and Search Results

30.9.1 Customizing Search Drop-Down Item

Use the Design Console to change the lookup codes for search pages and additional details. To customize drop-downs:

1. Log in to the Design Console.
2. Open the Lookup Definition form by navigating to Administration, then to Lookup Definition.
3. Search to locate the desired lookup definition.
4. Make the desired changes to the lookup codes to set the options displayed in the drop-down menu for each search page.
   - The Code Key is the metadata for each column.
   - The Decode value is what is displayed in the Identity Self Service or Identity System Administration.
   - The order in which the items appear in the Code Key list are the order they appear in the drop-down list in the Identity Self Service. If you delete an entry and add it back, it is displayed last in the list.
5. Save your changes.

30.9.2 Customizing Number of Search Drop-Down Items and Search Results

To change the number of drop-down menus, and the maximum number of search results on each page, edit the xlDefaultAdmin.properties file.

To set the number of drop-down menus:

1. Open the xlDefaultAdmin.properties file.
2. Locate the property from Table 30-6, and edit it as required.
To change the maximum number of search results on each page, change the value of the property global.displayrecordNum.value to the desired value. The default value is 10.

4. Save the file.

5. Restart Oracle Identity Manager.

### 30.10 Developing Managed Beans and Task Flows

To implement advanced customization in Oracle Identity Manager, you can develop new task flows and managed beans by using JDeveloper IDE and then package them in the custom WAR file.

#### See Also: Figure 30–1, "Oracle Identity Manager UI Libraries" for information about the various Oracle Identity Manager UI libraries and their dependency structure

The beans are of the following types:

- **Request beans**: New instance of the bean is created for every request.jsff component bindings, and listeners are usually bound to request beans.
- **State beans**: Beans holding the state of the application, user session, or a particular flow. Values of components, such as af:inputText, can be bound to state beans. State beans must be serializable (implement java.io.Serializable) as ADF serializes/deserializes these beans between requests.

This section describes how to develop managed beans in the following topics:

- Setting Up the ViewController Project
- Setting Up a Model Project
- Adding Custom Managed Bean
- Deploying Custom Code to Oracle Identity Manager
- Using Managed Beans
- Using Managed Beans to Populate Request Attributes
- Using Public Taskflows

#### 30.10.1 Setting Up the ViewController Project

Managed beans are created in a ViewController project. All your custom taskflows, pages, and managed beans must be present in the ViewController project.

To setup the ViewController project:

1. Create a new JDeveloper application. To do so:
   - Start JDeveloper.
b. Select File, New.

c. Select Generic Application, and then click OK.

d. Provide the application name and directory, and then click Finish. The application is created using a sample project.

e. To delete the sample project, right-click the project, and select Delete.

2. Setup the ViewController project. To do so:

a. Select File, New.

b. Find and select ADF ViewController Project, and then click OK.

c. Provide the project name, for example CustomUI, and project directory, and then click Next.

d. Enter the default package name as oracle.iam.ui.custom, and then click Finish. The new project is created.

3. Add Oracle Identity Manager libraries to the project classpath. To do so:

a. Right-click the new project, and select Project Properties.

b. On the left navigation bar, select Libraries and Classpath.

c. Click Add Library. Add ADF Model Runtime.

d. Click Load Dir, provide the path as IDM_HOME/server/jdev.lib, and then click OK.

e. From the list of libraries, select the following:

   - OIM View Shared Library
   - OIM Model Shared Library
   - OIM Client Library

f. Click OK.

4. Define the deployment profile for the newly created ViewController project. To do so:

a. Right-click the project, and select Project Properties.

b. On the left navigation bar, select Deployment.

c. Delete any existing deployment profiles.

d. Click New, and select ADF Library JAR File as the archive type.

---

**Note:** The ADF Library JAR File and JAR File archive types are different. Make sure that you select the ADF Library JAR File archive type.

---

e. Provide and confirm the archive name, such as adflibCustomUI, and then click OK.

Your ViewController project setup is complete. You can now start adding custom taskflows, pages, and managed beans.
30.10.2 Setting Up a Model Project

All your custom EOs/VOs and classes interacting directly with Oracle Identity Manager APIs must be present in a model project. To setup the model project:

1. Click File, New.
2. Find and select ADF Model Project, and then click OK.
3. Provide the Project Name, for example CustomModel, and Project Directory, and then click Next.
4. Enter Default Package name as oracle.iam.ui.custom, and then click Finish. The new project is created.
5. Add Oracle Identity Manager libraries to the project classpath:
   a. Right-click the project, and select Project Properties.
   b. On the left navigation bar, select Libraries and Classpath.
   c. Click Add Library.
   d. Click Load Dir, provide the path as IDM_HOME/server/jdev.lib, and then click OK.
   e. From the list of libraries select the following:
      - OIM Model Shared Library
      - OIM Client Library
   f. Click OK.
6. Define the deployment profile for the newly created model project. To do so:
   a. Right-click the project, and select Project Properties.
   b. On the left navigation bar, select Deployment.
   c. Delete any existing deployment profiles.
   d. Click New, and select ADF Library JAR File as the archive type.

   Note: The ADF Library JAR File and JAR File archive types are different. Make sure that you select the ADF Library JAR File archive type.

   e. Provide and confirm the archive name, such as adflibCustomModel, and then click OK.

Your model project setup is complete. You can now start adding custom EOs, VOs, and classes for interacting with Oracle Identity Manager APIs.

Note: Some examples in the consecutive sections in this document use the FacesUtils class. For information about this class, see Appendix B, "The FacesUtils Class".
30.10.3 Adding Custom Managed Bean

To add your custom managed bean:

1. Right-click the ViewController project, and select **New**.
2. Select the Java Class category.
3. Provide the class name, for example CustomReqBean or CustomStateBean, and the package name.
4. After creating the class, to register it with a taskflow:
   a. If you are developing your own bounded task flow, then navigate to your task flow definition file, and open it. Otherwise, locate the adfc-config.xml file in your ViewController project, and open it.
   b. Click the **Overview** tab, and select **Managed Beans**.
   c. Add a new managed bean entry. To do so:
      i) Provide managed bean name, for example customReqBean or customStateBean. This is the name that you will later use to refer to an instance of your bean.
      ii) Provide the managed bean class name.
      iii) Provide the scope. For request beans use backingBean scope. For state beans, use pageFlow scope.

**Note:**

- The pageFlow scope beans are visible only in the taskflow for which they are defined.
- To refer to your managed bean from JSFF/taskflow definition or other places, you can use EL expression. For example, if you register your bean under the name customReqBean and put the bean to backingBean scope, then you can reference your bean by using the following EL expression:
  
  #{backingBeanScope.customReqBean}

If you put the bean to pageFlow scope, you can reference your bean by using the following EL expression:

#{pageFlowScope.customStateBean}

30.10.4 Deploying Custom Code to Oracle Identity Manager

To deploy an ADF library JAR file produced by your custom model or ViewController projects:

1. Locate the oracle.iam.ui.custom shared library, which is oracle.iam.ui.custom-dev-starter-pack.war. The shared library is in the IDM_HOME/server/apps/ directory.
2. Repackage the WAR and include your ADF libraries in WEB-INF/lib/.
3. Redeploy the shared library.
30.10.5 Using Managed Beans

This section provides the following use cases for developing managed beans to customize Oracle Identity Manager interface:

- Showing Components Conditionally
- Prepopulating Fields Conditionally
- Setting a Conditional Mandatory Field
- Implementing Custom Field Validation
- Implementing Custom Cascading LOVs
- Customizing Forms By Using RequestFormContext
- Overriding the Submit Button in Request Catalog
- Developing Home Page Portlets
- Launching Taskflows
- Creating an External Link

**Note:** The examples in this section use the FacesUtils class. For information about this class, see "The FacesUtils Class" on page B-1.

30.10.5.1 Showing Components Conditionally

You can show or hide certain fields conditionally based on the values of other fields. For example, to show the Contact Information panel on the Create User page only when the User Type is Full-Time Employee, perform the following steps:

1. In your custom request bean, define properties for component bindings of the User Type field and any parent component of the Contact Information panel, for example, the form root panel. To do so, use the following code:

   ```java
   private UIComponent rootPanelPGL;
   private UIComponent userTypeSOC;

   public void setRootPanelPGL(UIComponent rootPanelPGL) {
       this.rootPanelPGL = rootPanelPGL;
   }

   public UIComponent getRootPanelPGL() {
       return rootPanelPGL;
   }

   public void setUserTypeSOC(UIComponent userTypeSOC) {
       this.userTypeSOC = userTypeSOC;
   }

   public UIComponent getUserTypeSOC() {
       return userTypeSOC;
   }
   
   2. Create or extend existing valueChangeListener that will be invoked when user selects the new value in the User Type list. To do so, use the following code:

   ```java
   Note: The listener will refresh the form.
   ```
public void valueChangeListener(ValueChangeEvent valueChangeEvent) {
    if (valueChangeEvent.getSource().equals(userTypeSOC)) {
        // refresh form
        AdfFacesContext.getCurrentInstance().addPartialTarget(component);
    }
}

3. Create a method that returns boolean value. The method will determine if the Contact Information panel is to be displayed when the page is rendered. In this example, the Contact Information panel will be shown if the User Type is Full-Time Employee.

The method is as follows:

```java
private static final String USER_TYPE_ATTRIBUTE = "usr_emp_type__c";

public boolean isFullTimeEmployeeUserTypeSelected() {
    // return true if value of "usr_emp_type__c" binding attribute equals to "Full-Time"
    // "usr_emp_type__c" binding attribute is used to display value of User Type in the User Type drop-down
    return "Full-Time".equals(FacesUtils.getListBindingValue(USER_TYPE_ATTRIBUTE, String.class));
}
```

4. Package and deploy the managed bean, as described in "Developing Managed Beans and Task Flows".

5. To bind the code with JSFF:

a. Set component bindings for the User Type list and root panel components to point to the properties that you defined.

b. Define the valueChangeListener for the User Type list.

Note: Make sure that the autosubmit property is set to true for the User Type list.

c. Set EL expression for the rendered property, which is Show Component in Web Composer, on the Contact Information panel to point to the isFullTimeEmployeeUserTypeSelected() method defined in step 3.

Note: Ignore if the following error is displayed while setting EL expression for the rendered property:

javax.faces.validator.ValidatorException: java.lang.IllegalArgumentException: Control Binding 'usr_emp_type__c' not found"

30.10.5.2 Prepopulating Fields Conditionally

You prepopulate certain fields based on the values of other fields. For example, to prepopulate values in the User Login and E-mail fields on the Create User page based on the values of the First Name and Last Name fields, perform the following steps:

1. In your custom request bean, define properties for component bindings of First Name and Last Name fields and any parent component of the User Login and E-mail fields, for example, form root panel. To do so, use the following code:
Developing Managed Beans and Task Flows

private UIComponent firstNameIT;
private UIComponent lastNameIT;
private UIComponent rootPanelPGL;

public void setFirstNameIT(UIComponent firstNameIT) {
    this.firstNameIT = firstNameIT;
}

public UIComponent getFirstNameIT() {
    return firstNameIT;
}

public void setLastNameIT(UIComponent lastNameIT) {
    this.lastNameIT = lastNameIT;
}

public UIComponent getLastNameIT() {
    return lastNameIT;
}

public void setRootPanelPGL(UIComponent rootPanelPGL) {
    this.rootPanelPGL = rootPanelPGL;
}

public UIComponent getRootPanelPGL() {
    return rootPanelPGL;
}

2. Create or extend existing valueChangeListener that will be invoked when the user updates the First Name or Last Name fields. To do so, use the following code:

private static final String USER_LOGIN_ATTRIBUTE = "usr_login__c";
private static final String EMAIL_ATTRIBUTE = "usr_email__c";
private static final String LAST_NAME_ATTRIBUTE = "usr_last_name__c";
private static final String FIRST_NAME_ATTRIBUTE = "usr_first_name__c";

public void valueChangeListener(ValueChangeEvent valueChangeEvent) {
    if (valueChangeEvent.getSource().equals(firstNameIT)) {
        // get new value of first name from the event
        String firstName = (String)valueChangeEvent.getNewValue();
        // get existing value of last name through binding
        String lastName = FacesUtils.getAttributeBindingValue(LAST_NAME_ ATTRIBUTE, String.class);
        setUserLoginAndEmail(firstName, lastName);
    } else if (valueChangeEvent.getSource().equals(lastNameIT)) {
        // get new value of last name from the event
        String lastName = (String)valueChangeEvent.getNewValue();
        // get existing value of first name through binding
        String firstName = FacesUtils.getAttributeBindingValue(FIRST_NAME_ ATTRIBUTE, String.class);
        setUserLoginAndEmail(firstName, lastName);
    }
    // refresh form
    FacesUtils.partialRender(rootPanelPGL);
}

Note: The listener will update User Login and E-mail accordingly and refresh the form.
private void setUserLoginAndEmail(String firstName, String lastName) {
    StringBuilder sb = new StringBuilder();
    if (firstName != null) {
        sb.append(firstName);
    }
    if (firstName != null && !firstName.isEmpty() && lastName != null && !lastName.isEmpty()) {
        sb.append(".");
    }
    if (lastName != null) {
        sb.append(lastName);
    }
    String userLogin = sb.toString();
    // set new value for User Login and E-mail through binding
    FacesUtils.setAttributeBindingValue(USER_LOGIN_ATTRIBUTE, userLogin);
    FacesUtils.setAttributeBindingValue(EMAIL_ATTRIBUTE, userLogin + "@acme.com");
}

3. Package and deploy the managed bean, as described in "Developing Managed Beans and Task Flows".

4. Add the code to the JSFF. To do so:
   a. Set the component bindings for First Name, Last Name, and root panel to point to the properties that you defined.
   b. Define valueChangeListener for First Name and Last Name input texts, and make sure that the autosubmit property is set to true on both input texts.

30.10.5.3 Setting a Conditional Mandatory Field
You can make a field conditionally mandatory based on the value of another field. For example, to make the Manager field on the Create User page mandatory only if the User Type is Intern, perform the following steps:

---

**Note:** Enforcing field validation cannot be performed by setting the required property in Web Composer. You must develop a managed bean to perform field validation, as described in this section.

---

1. In your custom request bean, define properties for component bindings of the User Type field and any parent component of Manager field, for example, form root panel. To do so, use the following code:

```java
private UIComponent rootPanelPGL;
private UIComponent userTypeSOC;

public void setRootPanelPGL(UIComponent rootPanelPGL) {
    this.rootPanelPGL = rootPanelPGL;
}

public UIComponent getRootPanelPGL() {
    return rootPanelPGL;
}

public void setUserTypeSOC(UIComponent userTypeSOC) {
    this.userTypeSOC = userTypeSOC;
}
```
public UIComponent getUserTypeSOC() {
    return userTypeSOC;
}

2. Create or extend existing valueChangeListener that will be invoked when user selects new value in the User Type list. To do so, use the following code:

    Note: The listener will refresh the form.

    public void valueChangeListener(ValueChangeEvent valueChangeEvent) {
        if (valueChangeEvent.getSource().equals(userTypeSOC)) {
            // refresh form
            FacesUtils.partialRender(rootPanelPGL);
        }
    }

3. Create a method that returns boolean value. The method determines whether or not the field is mandatory. In this example, the Manager field will be marked as mandatory if User Type is Intern.

    The method is as follows:

    public boolean isInternUserTypeSelected() {
        // return true if value of "usr_emp_type__c" binding attribute equals to "Intern"
        // "usr_emp_type__c" binding attribute is used to display value of User Type in the User Type drop-down
        return "Intern".equals(FacesUtils.getValueFromELExpression("#{bindings.usr_emp_type__c.attributeValue}"), String.class);
    }

4. Package and deploy the managed bean, as described in "Developing Managed Beans and Task Flows".

5. Add the code to the JSFF. To do so:
   a. Set component bindings for the User Type list and root panel components to point to the properties you defined.
   b. Define valueChangeListener for the User Type list. Make sure that the autosubmit property is set to true for the User Type list.
   c. Set EL expression for the required property on the Manager field to point to the isInternUserTypeSelected() method defined is step 3.
   d. Set EL expression for the Show required property on the Manager field panelLabelAndMessage to point to the isInternUserTypeSelected() method defined is step 3.

30.10.5.4 Implementing Custom Field Validation
Managed beans can be used to introduce custom validations. For example, you can implement the following validations for the Start Date and End Date fields on the Account Effective Dates panel of the Create User page:

- Start Date cannot be after End Date.
- The interval between Start Date and End Date cannot exceed 180 days for Contractors.
To implement custom validation using Managed Beans:

1. In your custom request bean, define properties for component bindings of the Start Date and End Date fields, as shown:

   ```java
   private UIComponent startDateID;
   private UIComponent endDateID;

   public void setStartDateID(UIComponent startDateID) {
       this.startDateID = startDateID;
   }

   public UIComponent getStartDateID() {
       return startDateID;
   }

   public void setEndDateID(UIComponent endDateID) {
       this.endDateID = endDateID;
   }

   public UIComponent getEndDateID() {
       return endDateID;
   }
   ```

2. Add method for validation in your managed bean that will be invoked when the user selects new value for the Start Date or End Date field. The validator generates an error message when validation fails and attaches it to the field being updated. To do so, use the following code:

   ```java
   private static final String START_DATE_END_DATE_VALIDATION_MSG = "Start Date - End Date interval cannot exceed 180 days for Contractors.ou",
   private static final String START_DATE_AFTER_END_DATE_VALIDATION_MSG = "Start Date cannot be after End Date.",
   private static final String USER_TYPE_ATTRIBUTE = "usr_emp_type__c",
   private static final String START_DATE_ATTRIBUTE = "usr_start_date__c",
   private static final String END_DATE_ATTRIBUTE = "usr_end_date__c",

   public void validator(FacesContext facesContext, UIComponent uiComponent, Object object) {
       if (uiComponent.equals(startDateID)) {
           // get value of End Date through binding
           oracle.jbo.domain.Date jboEndDate = FacesUtils.getAttributeBindingValue(END_DATE_ATTRIBUTE, oracle.jbo.domain.Date.class);
           // only validate if both Start Date and End Date are set
           if (jboEndDate != null) {
               Date startDate = ((oracle.jbo.domain.Date)object).getValue();
               Date endDate = jboEndDate.getValue();
               validateStartDateEndDate(facesContext, uiComponent, startDate, endDate);
           } else if (uiComponent.equals(endDateID)) {
               // get value of Start Date through binding
               oracle.jbo.domain.Date jboStartDate = FacesUtils.getAttributeBindingValue(START_DATE_ATTRIBUTE, oracle.jbo.domain.Date.class);
               // only validate if both Start Date and End Date are set
               if (jboStartDate != null) {
                   Date startDate = jboStartDate.getValue();
               }
           }
       }
   }
   ```
// value of End Date is passed to validator
Date endDate = ((oracle.jbo.domain.Date)object).getValue();
validateStartDateEndDate(facesContext, uiComponent, startDate, 
endDate);
}
}
)

private void validateStartDateEndDate(FacesContext facesContext, 
UIComponent uiComponent, Date startDate, Date endDate) {
    Date startDatePlus180Days = new Date(startDate.getTime() + 180L * 24 * 
60 * 60 * 1000);
    if (startDate.after(endDate)) {
        // queue error message for the component which is being validated
        (either Start Date or End Date)
        facesContext.addMessage(uiComponent.getClientId(facesContext),
        new FacesMessage(FacesMessage.SEVERITY_ 
ERROR, START_DATE_AFTER_END_DATE_VALIDATION_MSG, null));
    } else if (isContractorUserTypeSelected() && 
startDatePlus180Days.before(endDate)) {
        // queue error message for the component which is being validated
        (either Start Date or End Date)
        facesContext.addMessage(uiComponent.getClientId(facesContext),
        new FacesMessage(FacesMessage.SEVERITY_ 
ERROR, START_DATE_END_DATE_VALIDATION_MSG, null));
    } else {
        // re-render -- in case there was an error message in queue for any
        of the two components it will be released
        FacesUtils.partialRender(startDateID);
        FacesUtils.partialRender(endDateID);
    }
}

public boolean isContractorUserTypeSelected() {
    // return true if value of "usr_emp_type__c" binding attribute equals
to "Contractor"
    // "usr_emp_type__c" binding attribute is used to display value of User
Type in the User Type drop-down
    return "Contractor".equals(FacesUtils.getListBindingValue(USER_TYPE_ 
ATTRIBUTE, String.class));
}

See Also: "The FacesUtils Class" on page B-1 for more information
about the FacesUtils class

3. Package and deploy the managed bean, as described in "Developing Managed
Beans and Task Flows".

4. Bind the code to the JSFF. To do so:
   a. Set component bindings for the Start Date and End Date fields to point to the
   properties that you defined.
   b. Define EL expression for validator property on Start Date and End Date fields
to point to the validator method that you defined in step 2. For example:
   <mds:attribute name="binding"
   value="#{backingBeanScope.validatorBean.startDateID}"/>
   <mds:attribute name="validator"
   value="#{backingBeanScope.validatorBean.validator}"/>
30.10.5.5 Implementing Custom Cascading LOVs

Cascading LOVs are LOV components for which the list of values in one component is dependent on the currently selected value in another component. For example, based on the selected value in the User Type list on the Create User page, you might want to display the Job Code list or another LOV component whose list of values is dependent on the currently selected value in the User Type list.

The following are the high-level guidelines to implement custom cascading LOVs:

1. Define component binding for the User Type field and any parent component of Job Code, for example, form root panel.

2. Implement the model for Job Code LOV component by ensuring the following:
   - The model must take into account the current value of the User Type field.
   - For af:selectOneChoice, you must implement a method that returns List<javax.faces.model.SelectItem>.
   - For af:inputListOfValues, you must implement a method that returns an instance of oracle.adf.view.rich.model.ListOfValuesMode.

   **See Also:** "Using List-of-Values Components" in the Oracle Fusion Middleware Web User Interface Developer’s Guide for Oracle Application Development Framework for information about using a LOV component to display a model-driven list of objects from which a user can select a value.

---

**Note:** The validator property cannot be added directly by using the Web Composer. This must be set manually in the MDS file for the JSFF. To do so:

1. Export the sandbox after setting component bindings for the Start Date and End Date fields by using the Web Composer.

2. Extract the contents of the ZIP file and locate the XML file for the form on which Start Date and End fields are modified. For example, the XML file for the Create User form is oracle/iam/ui/runtime/form/view/pages/mdssys/cust/site/site/user CreateForm.jsff.xml.

3. In a text editor, open the XML file and set validator for StartDate and EndDate fields. For Example:
   ```xml
   <mds:modify element="_xg_36">
     <mds:attribute name="binding" value="#{backingBeanScope.validatorBean.startDateID}"/>
     <mds:attribute name="validator" value="#{backingBeanScope.validatorBean.validator}"/>
   </mds:modify>
   <mds:modify element="_xg_13">
     <mds:attribute name="binding" value="#{backingBeanScope.validatorBean.endDateID}"/>
     <mds:attribute name="validator" value="#{backingBeanScope.validatorBean.validator}"/>
   </mds:modify>
   ```

4. Save the changes, repackage the ZIP file (the sandbox archive), and then import it back to your environment.
3. Implement valueChangeListener for the User Type field. Set the autosubmit property to true for the User Type field.

valueChangeListener must update model of Job Code LOV component with the current value of the User Type field. In addition, valueChangeListener must re-render the form so that Job Code LOV component is updated with the current list of values.

30.10.5.6 Customizing Forms By Using RequestFormContext

RequestFormContext is a bean available in the pageFlowScope of entity form details taskflow. The entity forms include user form, application instance form, role form, and entitlement form. The instance provides various context information. Using this context information, you can customize various forms based on specific business requirements.

You can get an instance of the class by using Java code, as shown:

RequestFormContext.getCurrentInstance();

You can also get an instance of the class by using EL, as shown:

#{pageFlowScope.requestFormContext}

RequestFormContext provides the following context information:

- **operation**: The operation that is being performed on the entity. The possible values are CREATE and MODIFY.
- **actionType**: The action that is being performed by the user when the entity form is displayed. The possible values are: APPROVAL, FULFILL, REQUEST, VIEW, SUMMARY.
- **bulk**: Whether or not it is a bulk operation.
- **beneficiaryIds**: The list of beneficiary or target user IDs. For example, if you are requesting an application instance for the user John Doe, then the list contains the user ID of John Doe.
- **cartItemIds**: The list of cart item IDs. For example, if you are requesting an application instance for a user, then the list contains the application instance ID that is being requested.
- **requestEntityType**: The entity type being requested, which is any one of ROLE, ENTITLEMENT, APP_INSTANCE, USER.
- **requestEntitySubType**: The subtype of entity being requested. For example, when requesting for an application instance, the requestEntitySubType is the application instance key.
- **instanceKey**: The key of the instance being modified.

The following is an example usage of the RequestFormContext:

You might want to add new Prepopulate button to the Create Application Instance form, and make the button visible only when there is only one target user. When the button is clicked, some of the application instance fields, such as User Login, First Name, and Last Name) will be prepopulated based on the current target user. To achieve this, perform the following steps:

1. In your custom request bean, define properties for component bindings of the Prepopulate button and the form root panel, as shown:

```java
private UIComponent rootPanel;
```
private UIComponent prepopulateButton;

public void setRootPanel(UIComponent rootPanel) {
    this.rootPanel = rootPanel;
}

public UIComponent getRootPanel() {
    return rootPanel;
}

public void setPrepopulateButton(UIComponent prepopulateButton) {
    this.prepopulateButton = prepopulateButton;
}

public UIComponent getPrepopulateButton() {
    return prepopulateButton;
}

2. Implement an actionListener that will be invoked when the Prepopulate button is clicked. The actionListener uses the target user ID and fetches user data, such as First Name and Last Name, by using Oracle Identity Manager API. Use the fetched data, and set certain application instance attributes through attribute binding, and finally refresh the form so that new values are displayed. The actionListener is as shown:

private static final String ACCOUNT_LOGIN_ATTRIBUTE = "UD_EBS2722_LOGIN__c";
private static final String ACCOUNT_ID_ATTRIBUTE = "UD_EBS2722_ACCOUNTID__c";
private static final String FIRST_NAME_ATTRIBUTE = "firstName__c";
private static final String LAST_NAME_ATTRIBUTE = "lastName__c";
public void actionListener(ActionEvent e) {
    if (e.getSource().equals(prepopulateButton)) {
        RequestFormContext requestFormContext = RequestFormContext.getCurrentInstance();
        List<String> beneficiaryIds = requestFormContext.getBeneficiaryIds();
        if (beneficiaryIds.size() == 1) {
            // prepopulate fields based on selected beneficiary
            User user = getUser(beneficiaryIds.get(0));
            FacesUtils.setAttributeBindingValue(ACCOUNT_LOGIN_ATTRIBUTE, user.getLogin());
            FacesUtils.setAttributeBindingValue(ACCOUNT_ID_ATTRIBUTE, user.getId());
            FacesUtils.setAttributeBindingValue(FIRST_NAME_ATTRIBUTE, user.getFirstName());
            FacesUtils.setAttributeBindingValue(LAST_NAME_ATTRIBUTE, user.getLastName());
        }
    }
    FacesUtils.partialRender(rootPanel);
}

private User getUser(String userId) {
    UserManager userManager = OIMClientFactory.getUserManager();
    try {
        return userManager.getDetails(userId, null, false);
    } catch (NoSuchUserException e) {
        throw new RuntimeException(e);
    } catch (UserLookupException e) {
throw new RuntimeException(e);
}
}

3. Create a method that returns Boolean value. The method determines if the Prepopulate button is to be displayed when the form is rendered. In this example, the Prepopulate button will be displayed when the number of target users is equal to 1. The method is as follows:

```java
public boolean isPrepopulateButtonRendered() {
    RequestFormContext requestFormContext = RequestFormContext.getCurrentInstance();
    return requestFormContext.getActionType() == RequestFormContext.ActionType.REQUEST &&
           requestFormContext.getBeneficiaryIds().size() == 1;
}
```

4. Bind the code with JSFF. To do so:
   a. Add a Prepopulate button to the Create Application Instance form.
   b. Set bindings for the Prepopulate button and the root panel.
   c. Set the Prepopulate button actionListener property to point to the actionListener method implemented in step 2.

---

**Note:** The actionListener property cannot be set by using the Web Composer. This must be set manually as follows:

1. Export the sandbox.
2. Edit the JSFF to set the actionListener attribute value. For example:
   ```xml
   <mds:attribute name="actionListener" value="#{backingBeanScope.accountFormReqBean.submitButtonActionListener}"/>
   ```
3. Import the updated sandbox.

This procedure is applicable to setting the actionListener property in all the examples in this document.

---

d. Set the rendered property to point to the isPrepopulateButtonRendered() method implemented in step 3.

### 30.10.5.7 Overriding the Submit Button in Request Catalog

Can override the Submit button in the request catalog and execute additional logic based on your requirements. For example, to add additional check for number of target users or beneficiaries when submitting a request, and allow submitting the request when the number of beneficiaries is not more than five, perform the following steps:

1. Implement actionListener that will override the original Submit button.

   The actionListener will be invoked when the user clicks the Submit button. The actionListener performs the extra check and either display error messages or executes the original actionListener bound to the Submit button. Original Submit button actionListener can be executed using the following EL expression:

   ```el
   #{backingBeanScope.cartReqBean.submitActionListener}
   ```

---

30-56 Oracle Fusion Middleware Developer's Guide for Oracle Identity Manager
The actionListener code is as shown:

```java
private static final String MORE_THAN_FIVE_TARGET_USERS_MSG = "Cannot submit request for more than five target users.");
public void submitButtonActionListener(ActionEvent e) {
    // only submit request if there is no more than 5 beneficiaries
    Boolean moreThanFiveTargetUsers =
        FacesUtils.getValueFromELExpression("#{backingBeanScope.cartReqBean.targetUserS
ize > 5}"), Boolean.class);
    if (moreThanFiveTargetUsers) {
        // display error message
        FacesMessage fm = new FacesMessage();
        fm.setSeverity(FacesMessage.SEVERITY_ERROR);
        fm.setSummary(MORE_THAN_FIVE_TARGET_USERS_MSG);
        FacesUtils.showFacesMessage(fm);
    } else {
        // execute original submit button action listener
        MethodExpression originalActionListener =
            FacesUtils.getMethodExpressionFromEL("#{backingBeanScope.cartReqBean.submitActi
onListener}", null, new Class[] { ActionEvent.class });
        originalActionListener.invoke(FacesUtils.getELContext(), new
        Object[] { e });
    }
}
```

2. Update the Submit button actionListener property to point to the new actionListener implementation.

### 30.10.5.8 Developing Home Page Portlets

Hompage portlet is a regular bounded taskflow that can be added to the user's Home page in Oracle Identity Self Service. Home page portlets must be created in ViewController projects. ViewController projects must have the deployment profile of type ADF Library JAR File. For information about setting up the ViewController project, see "Setting Up the ViewController Project" on page 30-42. For information about adding a custom managed bean, see "Adding Custom Managed Bean" on page 30-45.

**See Also:** Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework for information about developing ADF taskflows

After developing the bounded taskflow, you must deploy it. For information about deploying the bounded taskflow, see "Deploying Custom Code to Oracle Identity Manager" on page 30-45.

Every new taskflow must be granted a permission to make it visible in the Identity Self Service. See "Securing a Custom Taskflow Using APM" on page 30-32 for details.

The final step in developing Home page portlets is updating the resource catalog for the Home page. This allows the users to add the portlet to the homepage.

To update the Home page resource catalog:

1. Locate the oracle.iam.ui.custom shared library, which is oracle.iam.ui.custom-dev-starter-pack.war. This is available in the OIM_HOME/server/apps/ directory.

2. Unpack the WAR and locate the oracle/adf/rc/metadata/custom-catalog.xml file.
3. Update the file and include reference to your newly added bounded taskflow. The entry looks similar to the following:

```xml
<resource id="helloWorld" name="Hello World"
  description="Hello World Taskflow Reference"
  repository="application.classpath"
  path="afdflibHomepagePortletsUI.jar/ADF_TaskFlow/WEB-INF/oracle+iam+ui+sample+homepage+tfs+hello-world-tf.xml#hello-world-tf">
  <attributes>
    <attribute value="coreDefault" attributeId="attr.background" isKey="false"/>
  </attributes>
</resource>
```

**Note:** Make sure that the format of the path property is correct. The format must follow the same pattern as shown in step 3. In addition, ensure that the value of the repository property is application.classpath. For more information about the format of this file, see "resource" of the "Catalog Definition Attributes" section in the Oracle Fusion Middleware Developer’s Guide for Oracle WebCenter Portal.

4. Redeploy the shared library.

**Note:** Verify the following if you have performed the steps to update the Home page resource catalog, but the custom task flow is not displayed in the resource catalog after clicking the Add Content button:

- Ensure that the task flow permission is defined properly. See "Securing a Custom Taskflow Using APM" on page 30-32 for details.
- Ensure that the ADF library JAR file containing your task flow contains the META-INF/task-flow-registry.xml file and that the file contains a reference to your custom task flow. If the file is missing, then rebuild just the particular JDeveloper project containing your custom task flow, and check if it resolves the issue. To rebuild just the particular JDeveloper project, go to JDeveloper, right-click the ViewController project containing the custom task flow, select Deployment, and then select the deployment profile. The deployment profile must be of type ADF Library JAR File.

### 30.10.5.9 Launching Taskflows

You can launch a taskflow in the Self Service interface. For example, if you want to launch a tab with a bounded taskflow running in it, then perform the following steps:

1. Develop a custom managed bean with the following method:

   ```java
   public void launchMyTaskFlow(ActionEvent evt){
       User user =
       OIMClientFactory.getAuthenticatedSelfService().getProfileDetails(null);
       String taskFlowId = "/WEB-INF/oracle/iam/ui/taskflows/public/tfs/user-details-tf.xml#user-details-tf";
   }
   ```
Developing Managed Beans and Task Flows

Customizing the Interface

1. String id = "user-detail-tf";
   // This id uniquely identifies the taskflow after launch. Add a suffix, for example entityPrimaryKey, to make it unique.
   String name = user.getDisplayName() ;  // this is shown as the tab title
   String description = "" ;  // Add any suitable description
   String icon = "/images/user.png";
   String helpTopicId = ConstantsDefinition.DEFAULT_HELP_TOPIC_ID;  // Or your custom OHW integrated help topic id
   boolean inDialog = false;
   Map params = new HashMap();  // These are your taskflow’s input parameters being passed from this launcher method
   params.put("userLogin", user.getLogin());

   String jsonPayload = TaskFlowUtils.createContextualEventPayload(id, taskFlowId, name, icon, description, helpTopicId, inDialog, params);
   TaskFlowUtils.raiseContextualEvent(TaskFlowUtils.RAISE_TASK_FLOW_LAUNCH_EVENT, jsonPayload);

Note: The above code snippet uses the user details public taskflow to display the user details when the user login is provided. For a list of available public taskflows that you can use for customization of UI, see "Using Public Taskflows" on page 30-66.

Package and deploy the managed bean, as described in "Developing Managed Beans and Task Flows" on page 30-42.

2. Using sandbox and Web Composer customization, add an ADF CommandLink to the correct page (JSFF file), and then export the sandbox. Open the sandbox zip, and edit the jsff.xml to bind actionListener for that link to the managed bean method.

3. Ensure that the page definition of the jsff has the raiseTaskFlowLaunchEvent binding. To find the name of the page definition file, you first need to know the name of the jsff page on which you have the launch link.

   If the jsff page is the existing left navigation page, then the name is left-nav.jsff. The page definition file for this jsff page is left-nav_pageDef.xml. This page definition XML file already contains the eventBinding, and therefore, nothing is required to be changed.

   If your launch link is on a custom jsff page, for example, your page name is my-custom.jsff, then look for a file named my-custom_pageDef.xml within the same JDev project. JDev automatically creates this file for each jsff. You must add the following eventBinding into this pageDef xml file:

   <eventBinding id="raiseTaskFlowLaunchEvent">
      <events xmlns="http://xmlns.oracle.com/adfm/contextualEvent">
         <event name="oracle.idm.shell.event.TaskFlowLaunchEvent"/>
      </events>
   </eventBinding>

Note: Existing Oracle Identity Manager pages already contain the eventBinding. You must define the eventBinding for JSFF pages that you build.
30.10.5.10 Creating an External Link
To add a link or button that redirects the user to a certain URL:

1. In your custom request bean, create the following ActionListener that will be invoked when the user clicks a link or button:
   
   ```java
   public void actionListener(ActionEvent e) {
     FacesUtils.redirect("http://www.oracle.com");
   }
   ```

2. Add a new commandLink or commandButton to the page on which you want to display the link or button by using Web Composer. See "Adding a Link or Button" on page 30-26 for details.

3. Set the ActionListener property of the link or button component that you added to point to the ActionListener method.

30.10.6 Using Managed Beans to Populate Request Attributes
This section describes the following approaches for populating request attributes:

- Populating Request Attributes Using Managed Beans
- Populating Request Attributes by Using the Prepopulate Plug-in

30.10.6.1 Populating Request Attributes Using Managed Beans
This approach involves creating a managed bean that gets invoked when the user clicks a custom button. The managed bean must be deployed to the Oracle Identity Manager customization placeholder library, which is oracle.iam.ui.custom-dev-starter-pack.war. The button, referred to as the Prepopulate button, is part of the UI customization and must be manually added to the page by using Web Composer.

The managed bean code is responsible for fetching the information to be populated in the request form. It uses Oracle Identity Manager APIs to get the beneficiary information from the request and from the user management layer, and uses JSF/ADF APIs to update the request form UI components.

To populate request attributes by using managed beans and UI customization:

1. Create the JDev application workspace and project. See "Setting Up the ViewController Project" on page 30-42 for details.

2. Create a Java class. In this example, the complete class name is com.oracle.demo.iam.prepop.view.PrePopulateMBean. This class contains:
   - Two member variables that hold references to the UI components, the custom Prepopulate button and its parent container.
   - Accessor methods (get and set) for the variables member variables.
   - An action listener type method to be invoked when the user clicks the custom Prepopulate button.
   - A method that returns a boolean value determines when the custom Prepopulate button must be disabled

   The custom code for this example is:
   
   ```java
   public class PrePopulateMBean {
   
   private UIComponent rootPanel;
   private UIComponent prepopulateButton;
   ```
public PrePopulateMBean() {
    super();
}

public void setRootPanel(UIComponent rootPanel) {
    this.rootPanel = rootPanel;
}

public UIComponent getRootPanel() {
    return rootPanel;
}

public void setPrepopulateButton(UIComponent prepopulateButton) {
    this.prepopulateButton = prepopulateButton;
}

public UIComponent getPrepopulateButton() {
    return prepopulateButton;
}

public boolean isPrepopulateButtonRendered() {
    boolean ret = false;
    RequestFormContext requestFormContext = RequestFormContext.getCurrentInstance();
    if (requestFormContext != null) {
        boolean isActionRequest = (requestFormContext.getActionType() == RequestFormContext.ActionType.REQUEST);
        boolean singleUserRequest = false;
        if (requestFormContext.getBeneficiaryIds() != null) {
            singleUserRequest = (requestFormContext.getBeneficiaryIds().size() == 1);
        }
        ret = isActionRequest && singleUserRequest;
    }
    return (ret);
}

public void actionListener(ActionEvent e) {
    if (e.getSource().equals(prepopulateButton)) {
        RequestFormContext requestFormContext = RequestFormContext.getCurrentInstance();
        List<String> beneficiaryIds = requestFormContext.getBeneficiaryIds();
        if (beneficiaryIds.size() == 1) {
            try {
                User user = getUser(beneficiaryIds.get(0));
                FacesUtils.setAttributeBindingValue("UD_OID_USR_FNAME__c", user.getFirstName());
                FacesUtils.setAttributeBindingValue("UD_OID_USR_LNAME__c", user.getLastName());
            }
            catch (NoSuchUserException f) {
            }
        }
    }
}
private User getUser(String userKey) throws NoSuchUserException, UserLookupException {
    UserManager userMgr = OIMClientFactory.getUserManager();
    HashSet<String> searchAttrs = new java.util.HashSet<String>();
    searchAttrs.add(AttributeName.USER_LOGIN.getId());
    searchAttrs.add(AttributeName.LASTNAME.getId());
    searchAttrs.add(AttributeName.FIRSTNAME.getId());
    return userMgr.getDetails(userKey, searchAttrs, false);
}

In the code for the Java class:

- The `isPrepopulateButtonRendered` method returns true if a RequestContext is available, and if there is only one request beneficiary. The check on the RequestContext availability is required to avoid issues at the time of customization. This method is invoked when the custom Prepopulate button is loaded, or its container is refreshed.

- The `actionListener` method executes a user search in Oracle Identity Manager by invoking the `getUser` method, which uses the request beneficiary information. Then, it directly sets values on the UD_OID_USR_FNAME__c and UD_OID_USR_LNAME__c UI components with the information returned from the user search, and invokes a partial rendering on the rootPanel. This is the panel that holds the custom button and the request form. The partial rendering will display the values in the respective fields. It is important to mention here that this custom code contains a direct reference to the UI components, and that these direct references can be found by exporting the sandbox. This method is invoked when the custom Prepopulate button is loaded or its container refreshed.

- The FacesUtils class is responsible for rendering the UI changes. See Appendix B, "The FacesUtils Class" for the code for this class.

3. Declare the PrePopulateMBean class as a managed bean in the JDev project. This makes the MBean available in the UI so that it can be invoked by using EL expressions. To configure this, specify the following values in the Managed Beans section of the View Controller project:
   - **Name:** prepOpMBean
   - **Class:** com.oracle.demo.iam.prepop.view.PrePopulateMBean
   - **Scope:** backingBean

4. Deploy the View Controller project as an ADF library JAR file. This type of deployment can be created in JDeveloper through the deployment profiles option. The deployment generates a JAR file. Copy this file into oracle.iam.ui.custom-dev-starter-pack.war, which is Oracle Identity Manager.
placeholder library. This file is available along with the other Oracle Identity Manager application packages, such as EAR and WAR files, at the $OIM_ORACLE_HOME/server/apps/ directory. Create a backup of this file before modifying it.

5. To deploy the custom code:
   a. Copy the oracle.iam.ui.custom-dev-starter-pack.war to a temporary location.
   b. Open the oracle.iam.ui.custom-dev-starter-pack.war.
   c. Add the custom jar file to the WEB-INF/lib directory. If the lib directory does not exist, then create it.
   d. Save the oracle.iam.ui.custom-dev-starter-pack.war file.
   e. Copy the oracle.iam.ui.custom-dev-starter-pack.war file back to its original location in the $OIM_ORACLE_HOME/server/apps/ directory.
   f. Stop Oracle Identity Manager Managed Server.
   g. In WebLogic Administration Console, update the oracle.iam.ui.custom library deployment, and activate the changes.
   h. Start Oracle Identity Manager Managed Server.

6. Customize the UI. To do so:
   a. Create and activate a sandbox. In this example, the sandbox name is RequestPrePop.
   b. Login to Oracle Identity Self Service, and navigate to the Catalog page.
   c. Search for the specific application instance to be customized. In this example, the application instance is called Local OID. Add the application instance to the shopping cart, and Checkout.
   d. Click Customize.
   e. Select View, Source.
   f. In the Cart Items and Details sections of the page, click close to the Details label. Make sure that the showDetailHeader:Details component is selected.
   g. On the top-left, click Edit. In the dialog box that opens, edit the Binding property, and configure the following EL using the Expression Builder:

   ```el
   #{backingBeanScope.prepopMBean.rootPanel}
   ```

   This expression bind will make the UI invoke the setRootPanel method in the custom managed bean. Click OK.
   h. Make sure that the showDetailHeader:Details component selected. Click Add Content.
   i. Scroll down, and open the Web Components section.
   j. Click Add on the right of the Command Toolbar Button component. A button is added on the Details section.
   k. Click the button, and then click Edit.
   l. Edit the Text property, and set PrePopulate as the label.
   m. Edit the Binding property and configure the following EL using the Expression Builder:

   ```el
   #{backingBeanScope.prepopMBean.prepopulateButton}
   ```
This bind is for invoking the setPrepopulateButton method in the custom managed bean. Click OK.

**n.** Edit the Disabled property, and configure the following EL by using the Expression Builder:

```
#{!backingBeanScope.prepopMBean.prepopulateButtonRendered}
```

This is to invoke the isPrepopulateButtonRendered method in the managed bean. Click OK.

**o.** Click the **Style** tab. Set the Width property to 100, and the Margin - Left property to 100. Click **OK.** This configuration will properly place the PrePopulate button in the UI.

**p.** Exit the customization mode by clicking **Close.**

### 7. To manually configure the properties of the Prepopulate button:

**a.** Navigate to the Sandbox page. De-activate and export the sandbox.

**b.** Save the sandbox ZIP file in the local file system.

**c.** Extract the ZIP file. In a text editor, open the XML file corresponding to the customization. In this example, the file is `oracle/iam/ui/runtime/form/view/pages/mdssys/cust/site/site/OIDUserFormCreateForm.jsff.xml`.

**d.** Search for the section defining the custom Prepopulate button, which can be similar to the following:

```
  id="e8829502064"
  binding="#{backingBeanScope.prepopMBean.prepopulateButton}"
  text="PrePopulate"
```

**e.** Add the `actionListener` property to the custom Prepopulate button, as shown:

```
actionListener="#{backingBeanScope.prepopMBean.actionListener}"
```

**f.** Save the file and repackage the ZIP. Make sure that the path is preserved when repacking the content.

**g.** Import the sandbox, and import the ZIP file. Make sure that the sandbox is not active when importing it.

**h.** Activate the sandbox.

### 8. Test the customization. To do so:

**a.** Navigate to the Catalog, find the application instance and add it do the shopping cart.

**b.** In the cart summary page, the custom Prepopulate button is displayed. When clicking on it, the First Name and Last Name fields will be updated with the beneficiary's information.

**c.** Click the Prepopulate button. The First Name and Last Name fields are updated with the beneficiary's information.

### 9. Publish the sandbox.
30.10.6.2 Populating Request Attributes by Using the Prepopulate Plug-in

Prepopulate plug-ins can be used when the same logic is to be executed for both UI and API request creation, and can also be used when a UI interaction is not required. In this approach, a plug-in is present for each attribute that must be prepopulated in the request. The same plug-in can be used across different resources and different attributes.

The plug-in code implements the oracle.iam.request.plugins.PrePopulationAdapter interface. The following is an example code:

```java
package com.oracle.demo.iam.prepop.plugin;

import java.io.Serializable;
import java.util.HashSet;
import java.util.List;
import oracle.iam.identity.usermgmt.api.UserManager;
import oracle.iam.identity.usermgmt.api.UserManagerConstants.AttributeName;
import oracle.iam.identity.usermgmt.vo.User;
import oracle.iam.platform.Platform;
import oracle.iam.request.vo.Beneficiary;
import oracle.iam.request.vo.RequestData;

public class UserLoginPrePop implements oracle.iam.request.plugins.PrePopulationAdapter {

    public UserLoginPrePop() {
        super();
    }

    public Serializable prepopulate(RequestData requestData) {
        String prePopUserId = null;
        List<Beneficiary> benList = requestData.getBeneficiaries();
        if(benList.size()==1){
            UserManager usersvc = Platform.getService(UserManager.class);
            for(Beneficiary benf: benList){
                HashSet<String> searchAttrs = new java.util.HashSet<String>();
                searchAttrs.add(AttributeName.USER_LOGIN.getId());
                try {
                    User userBenef = usersvc.getDetails(benf.getBeneficiaryKey(), searchAttrs, false);
                    if (userBenef!= null) {
                        prePopUserId = userBenef.getLogin();
                    }
                } catch (Exception e) {
                    e.printStackTrace();
                }
            }
        }
        return prePopUserId;
    }
}
```
A prepopulate plugin is similar to any other plugin in Oracle Identity Manager. The plugin class is compiled and deployed to a JAR file. The JAR file must be added to a ZIP file in the lib directory. The ZIP file must contain in the root path a XML file declaring the plugin. The XML used in this example is as follows:

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<oimplugins xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <plugins pluginpoint="oracle.iam.request.plugins.PrePopulationAdapter">
    <plugin pluginclass="com.oracle.demo.iam.prepop.plugin.UserLoginPrePop" version="1.0" name="UserLoginPrePop">
      <metadata name="PrePopulationAdapater">
        <value>OracleDBUMForm::Username|OIDUserForm::User ID</value>
      </metadata>
    </plugin>
  </plugins>
</oimplugins>
```

In the XML code:

- The xmlns tag attribute must be present in the XML. Otherwise, the plugin is not invoked by Oracle Identity Manager.
- The value in the pluginpoint element must be oracle.iam.request.plugins.PrePopulationAdapter.
- The metadata tag contains a value child node. This value child node must contain the pairs of FormName::AttributeName. Each pair indicates a form attribute that will be populated by the prepopulate plugin. In this example, such attributes are Username in the OracleDBUMForm form and User ID in the OIDUserForm form. The form names are configured when the ApplicationInstances and their forms were created, and not the process form created when the connector is imported into Oracle Identity Manager.

The prepopulate plugin can be deployed to the $OIM_HOME/server/plugins/ directory, or it can be registered using the plugin registration script. In production environments, it is always recommended to deploy the plugin by using the command line so that the plugin Zip file is uploaded to the database.

### 30.10.7 Using Public Taskflows

Oracle Identity Manager provides default taskflows for using them in the customized pages of Oracle Identity Self Service and to invoke other taskflows. For example, you can customize the user details page so that the user details of the manager will be displayed if you click the manager login name in the user details page.

The default or predefined taskflows are called public taskflows. While launching the public taskflows, you must provide appropriate values for some parameters. For example, to launch the request details page for a particular request, you must provide the request ID for the request.

Table 30–7 lists the public taskflows provided by Oracle Identity Manager along with the input parameters that are required to invoke the taskflows.
### Table 30–7  Public Taskflows

<table>
<thead>
<tr>
<th>Taskflow Name</th>
<th>Taskflow path</th>
<th>Description</th>
<th>Parameter</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request Details</td>
<td>/WEB-INF/oracle/iam/ui/taskflows/public/tfs/request-details-tf.xml#request-details-tf</td>
<td>This is launched to view the details of a request that is submitted for approval.</td>
<td>requestID: The ID of the request whose details is to be displayed.</td>
<td>Yes</td>
</tr>
<tr>
<td>User Details</td>
<td>/WEB-INF/oracle/iam/ui/taskflows/public/tfs/user-details-tf.xml#user-details-tf</td>
<td>This is launched to view the details of a user.</td>
<td>userLogin: User Login attribute value of the user whose details is to be displayed.</td>
<td>Yes</td>
</tr>
<tr>

<td>/WEB-INF/oracle/iam/ui/taskflows/public/tfs/modify-user-tf.xml#modify-user-tf</td>
<td>This is launched to modify the user details.</td>
<td><strong>userLogins:</strong> User Login attribute values of the user(s) whose details are to be modified. If more than one userLogin attribute is provided as parameter, then bulk modify page is displayed. The values must be separated by commas.</td>
<td>Yes</td>
</tr>
<tr>
<td>Enable User</td>
<td>/WEB-INF/oracle/iam/ui/taskflows/public/tfs/enable-user-tf.xml#enable-user-tf</td>
<td>This is launched to enable the disabled user(s).</td>
<td><strong>userLogins:</strong> The User Login attribute values of the users that are to be enabled. The values must be separated by commas.</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Table 30–7 (Cont.) Public Taskflows

<table>
<thead>
<tr>
<th>Taskflow name</th>
<th>Taskflow path</th>
<th>Description</th>
<th>Parameter</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable User</td>
<td>/WEB-INF/oracle/iam/ui/taskflows/public/tfs/disable-user-tf.xml#disable-user-tf</td>
<td>This is launched to disable the enabled user(s).</td>
<td>userLogins: The User Login attribute values of the users that are to be disabled. The values must be separated by commas.</td>
<td>Yes</td>
</tr>
<tr>
<td>Delete User</td>
<td>/WEB-INF/oracle/iam/ui/taskflows/public/tfs/modify-user-tf.xml#modify-user-tf</td>
<td>This is launched to delete user(s).</td>
<td>userLogins: The User Login attribute values of the users that are to be deleted. The values must be separated by commas.</td>
<td>Yes</td>
</tr>
</tbody>
</table>
This is launched to specify the catalog search criteria and display the search results page or cart details page directly without using the catalog search page.

`searchCriteria`: Various string attributes in the following format:

```java
{criteriaName: "string",
allowSearch: "true/false",
profileName: "string",
directCheckout: "true/false",
showEntityTypeSelect or: "true/false",
hiddenTag: "string",
allowedEntityTypes: "string", tags: "string",
entityType: "string",
auditObjective: "string", riskLevel: "string",
ANY_
UDF: "string"}
```

Here:

- **criteriaName**: Optional string attribute that will be displayed in the catalog results page.
- **allowSearch**: Optional boolean attribute to control rendering of tag search field in results page.
- **profileName**: Optional string attribute to take user to cart page by simulating the saved profile click.
- **directCheckout**: Optional parameter to add search results to the cart and take user to checkout page (true/false).
- **showEntityTypeSelector**: Optional boolean attribute to show entityTypeSelector dropdown. This is displayed only if allowSearch is also set to true.

<td>Yes</td>
</tr>
</tbody>
</table>
Customizing the UI for Providing Additional Request Information

30.11 Customizing the UI for Providing Additional Request Information

Users can enter additional information for a request that can be useful for the request approvers. The following topics are discussed in this section:

- Additional Request Information Concepts
- AdditionalRequestInfo Interface
- Implementing Custom Taskflow for Additional Request Information
- Launching Custom Taskflow for Additional Request Information
- Customizing the UI at Cart (Request) Level
- Customizing the UI at Cart Item Level

30.11.1 Additional Request Information Concepts

You can customize the UI on Cart Details page to enable users to provide additional information when they are raising a request. You can add a link or a button at the cart or request level and at the cart item level, as shown in the following sample screenshot.

<table>
<thead>
<tr>
<th>Taskflow name</th>
<th>Taskflow path</th>
<th>Description</th>
<th>Parameter</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account Details</td>
<td>/WEB-INF/oracle/iam/ui/taskflows/public/tfs/account-details-tf.xml#account-details-tf</td>
<td>This is launched to display the details of a user’s account.</td>
<td>accountName: Name of the user’s account whose details is to be displayed.</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>userLogin: User Login attribute value of the user whose account password is to be changed.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Note:

- The parameters of all the public taskflows listed in Table 30–7 are of type java.lang.String.
- The public taskflows can be launched by using contextual event as described in "Launching Taskflows" on page 30-58. Otherwise, public taskflows can be embedded in an ADF faces page. To embed public taskflows in an ADF faces page, the following parameter (in addition to the parameters listed in Table 30–7) must be added to the taskflow definition in the page definition file of the ADF faces page:
  
  Parameter name: "uiShell"  
  value: "#{pageFlowScope.uiShell}"

<table>
<thead>
<tr>
<th>Table 30–7 (Cont.) Public Taskflows</th>
</tr>
</thead>
<tbody>
<tr>
<td>Taskflow name</td>
</tr>
<tr>
<td>---------------</td>
</tr>
<tr>
<td>Account Details</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Note:

- The parameters of all the public taskflows listed in Table 30–7 are of type java.lang.String.
- The public taskflows can be launched by using contextual event as described in "Launching Taskflows" on page 30-58. Otherwise, public taskflows can be embedded in an ADF faces page. To embed public taskflows in an ADF faces page, the following parameter (in addition to the parameters listed in Table 30–7) must be added to the taskflow definition in the page definition file of the ADF faces page:
  
  Parameter name: "uiShell"  
  value: "#{pageFlowScope.uiShell}"
When a user clicks a link, a popup window is displayed with custom fields. The user can enter appropriate information useful for the request approvers. The following sample screenshot shows Additional Request Information popup window for the cart/request:

The following sample screenshot shows Additional Request Information popup window for the individual cart item in the request:

The request approver can view and/or update additional request information provided at the cart (request) level and/or at the cart item level. The request approver can access the request from Identity Self Service on the Inbox page.
30.11.2 AdditionalRequestInfo Interface

AdditionalRequestInfo interface includes `setAttribute` and `getAttribute` methods. The `setAttribute` methods allow a custom taskflow to set additional request-only attributes that can be provided as part of the request. The `getAttribute` methods allow a custom taskflow to get the additional request attributes during tasks such as request approval, view, summary, and so on.

AdditionalRequestInfo interface supports setting and getting attributes at the cart/request level and at the cart item level. For cart item level attributes, the `cartItemId` parameter must be specified. You can use the `getUniqueCartItemId` EL expression in the RequestFormContext to access the selected cartItemId. For more information, see "Available EL Expressions in the RequestFormContext" on page 30-22.

AdditionalRequestInfo interface extends Serializable as shown in the following code. Therefore, an instance of AdditionalRequestInfo can be stored in pageFlowScope of the custom taskflow.

```java
public interface AdditionalRequestInfo extends Serializable {
    public void setAttribute(String name, Serializable value);
    public void setAttribute(String cartItemId, String name, Serializable value);
    public Serializable getAttribute(String name);
    public Serializable getAttribute(String cartItemId, String name);
}
```

30.11.3 Implementing Custom Taskflow for Additional Request Information

To implement a custom taskflow that can be used for providing and viewing additional request-only information:

1. Develop the custom taskflow as a bounded taskflow in ViewController projects. For information about setting up the ViewController project, see "Setting Up the ViewController Project" on page 30-42.

2. Define taskflow input parameters as required.

   The following table lists pre-defined input parameters that, if defined, pass appropriate values automatically when the taskflow is launched:
In addition to the pre-defined parameters, you can define other input parameters to be passed to the taskflow. These parameters are not known to Oracle Identity Manager. Therefore, the values to be passed to the taskflow are defined using clientAttribute of the link or the button that launches the custom taskflow.

Information about launching the taskflow and passing parameters to the taskflow is discussed in "Launching Custom Taskflow for Additional Request Information" on page 30-77.

3. Deploy the taskflow as part of the oracle.iam.ui.custom shared library. For information about deploying the bounded taskflow, see "Deploying Custom Code to Oracle Identity Manager" on page 30-45.

4. Add permissions to the custom taskflow by using the Authorization Policy Manager (APM) UI to secure the taskflow, as described in "Securing a Custom Taskflow Using APM" on page 30-32.

5. Grant permission to make it visible in the Identity Self Service. See "Securing a Task Flow Region Using EL Expressions" on page 30-33 for details.

### 30.11.4 Launching Custom Taskflow for Additional Request Information

You can enable users to provide additional information specific to a cart item, such as Application Instance, Role, or Entitlement. To do so, you can add a link or a button to Cart Items table using Oracle Web Composer. Cart Items table is displayed in the Cart Checkout, Request Summary, Request view, and Request Approval pages whenever the UI operation involves cart items.

A set of attributes defined as descendants of the component determine which custom taskflow to be launched and how the popup window is displayed. The following table summarizes the pre-defined attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>taskFlowId</td>
<td>java.lang.String</td>
<td>Yes</td>
<td>ID of the custom taskflow to be launched by the component.</td>
</tr>
</tbody>
</table>
Customizing the UI for Providing Additional Request Information

For example, the following code snippet creates the **Additional Cart Item Information** link:

```xml
<af:commandLink xmlns:af="http://xmlns.oracle.com/adf/faces/rich" id="e655321996"
    text="Additional Cart Item Information"
    actionListener="#{catalogRequestBean.launchAdditionalRequestInfoTaskFlow}"
    xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
    name="taskFlowId" value="/WEB-INF/oracle/iam/ui/sample/catalog/tfs/additional-cart-item-info-tf.xml#additional-cart-item-info-tf"/>
    name="dialogTitleIcon" value="/images/request_ena.png"/>
    name="headerText" value="Additional Cart Item Information"/>
</af:commandLink>
```

In this example code snippet:

- `/WEB-INF/oracle/iam/ui/sample/catalog/tfs/additional-cart-item-info-tf.xml#additional-cart-item-info-tf` is the taskflow launched in a popup window.
- `#{catalogRequestBean.launchAdditionalRequestInfoTaskFlow}` is the mandatory EL to be specified as a value of the component’s `actionListener` property.

The action listener launches the custom taskflow in a popup window.

- `/images/request_ena.png` is the path of the icon for the popup window.
- `headerText` is the taskflow input parameter.

---

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dialogTitle</td>
<td>java.lang.String</td>
<td>Optional</td>
<td>Title of the popup window in which the custom taskflow is launched. If no value is specified, then the title is blank.</td>
</tr>
<tr>
<td>dialogTitleIcon</td>
<td>java.lang.String</td>
<td>Optional</td>
<td>Path to the icon that is displayed in the popup window in which the custom taskflow is launched. If no value is specified, then the default icon is used.</td>
</tr>
</tbody>
</table>
Customizing the UI for Providing Additional Request Information

30.11.5 Customizing the UI at Cart (Request) Level

When you enable the users to provide additional request information, you can customize the UI at the cart (request) level in the following ways:

- Selectively display a link or a button at the cart level.
  
  For example, the custom UI component (link or button) can be displayed only when a user is creating or approving a request, but not when the user is tracking a request.

- Launch different taskflows based on the context.
  
  For example, different custom taskflows can be launched when a user is requesting and revoking access.

- Customize the popup window, such as icon and title for the window.

The following code snippet shows a sample customization using appropriate EL expressions:

```xml
    <af:clientAttribute xmlns:af="http://xmlns.oracle.com/adf/faces/rich" name="taskFlowId" value="#{backingBeanScope.additionalInfoHelperBean.additionalInfoTaskFlowIdForRequest}"/>
    <af:clientAttribute xmlns:af="http://xmlns.oracle.com/adf/faces/rich" name="dialogTitleIcon" value="/images/request_ena.png"/>
    <af:clientAttribute xmlns:af="http://xmlns.oracle.com/adf/faces/rich" name="dialogTitle" value="#{backingBeanScope.additionalInfoHelperBean.popupTitle}"/>
</af:commandLink>
```

In this sample code snippet, a custom Additional Cart Information link is added to cart details page. Here:

**Note:** When the Cart Item form contains mandatory fields, the Additional Request Information taskflows cannot be launched without entering values in the mandatory fields. In such a case, if you click on an Additional Request Information link or a button, an ADF error pops up as a result of the mandatory field validation.

To provide additional request information without entering values for the mandatory fields, the validation needs to be disabled. This can be achieved by UI customization, by setting `immediate` property of the `commandLink` or `commandButton` component to `true`.

Alternatively, you can edit the customized `cart-details.jsff.xml` file to set the value of immediate property to `true` within Additional Cart Information component, as follows:

```xml
```

In this sample code snippet, a custom Additional Cart Information link is added to cart details page. Here:
The custom link is selectively displayed for the rendered property using the EL expression,
#{backingBeanScope.additionalInfoHelperBean.renderAdditionalDetailsForRequest}.

To use this EL expression, develop a managed JAVA bean, say additionalRequestInfoHelperBean, with the isRenderAdditionalDetailsForRequest method. This method should return a boolean value (true or false) based on whether the link has to be displayed or not displayed. For more information about the managed bean, see "Developing Managed Beans and Task Flows" on page 30-42.

Launch different taskflows using the EL expression,
#{backingBeanScope.additionalInfoHelperBean.additionalInfoTaskFlowIdForRequest}, specified as the value of the taskFlowId attribute.

To use this EL expression, include the getAdditionalInfoTaskFlowIdForRequest method in the managed bean named additionalRequestInfoHelperBean. This method should return a String value representing the ID of the custom taskflow deployed as part of oracle.iam.ui.custom-dev-starter-pack.war. For example, /WEB-INF/oracle/iam/ui/sample/catalog/tfs/additional-cart-info-tf.xml#additional-cart-info-tf. For information about the taskFlowId attribute, see "Launching Custom Taskflow for Additional Request Information" on page 30-77.

Set different popup window titles using the EL expression,
#{backingBeanScope.additionalInfoHelperBean.popupTitle}, specified as the value of the dialogTitle attribute.

To use this EL expression, include the getPopupTitle method in managed bean named additionalRequestInfoHelperBean. This method should return the desired String value to be displayed as popup window title. For information about the dialogTitle attribute, see "Launching Custom Taskflow for Additional Request Information" on page 30-77.

You can use the following available data to achieve the required customization:

Data available in the pageFlowScope map by one of the following ways:

- By evaluating the EL expression, #{pageFlowScope}
- By invoking the AdfFacesContext.getCurrentInstance().getPageFlowScope() method

This method returns an instance of java.util.Map, which contains data as key-value pairs. A few useful values (Map Key values) stored in this map are:

- requestId: The value corresponding to this key would be a Request ID, which varies depending on the UI action performed by the user.

  For example, when the user is requesting for or modifying access, or performing any other operation supported by request, the value will be -1. For all other UI actions, such as tracking or approving request, the value will be a valid Request ID.

  You can use this value to distinguish request tracking or approval flows from request creation.

- requestAction: The value for this key (if not null) corresponds to the UI action performed by the user, such as APPROVAL_UPDATE, APPROVAL_VIEW, ACCOUNT_UPDATE, and ACCOUNT_VIEW.
You can use this value to distinguish request tracking flow from request approval flow. APPROVAL_VIEW corresponds to request tracking flow and APPROVAL_UPDATE corresponds to request approval flow.

- entityType: The value for this key (if not null) corresponds to the Oracle Identity Manager entity type involved in the operation, such as role and entitlement.

Data obtained from RequestFormContext, which holds information about the cart, by invoking the
oracle.iam.ui.platform.view.RequestFormContext.newInstance(null).getCurrentContext() method
This method returns an object of type
oracle.iam.ui.platform.view.RequestFormContext. For more information about RequestFormContext, see "Available EL Expressions in the RequestFormContext" on page 30-22.

### 30.11.6 Customizing the UI at Cart Item Level

When you enable the users to provide additional request information, you can customize the UI at the cart item level in the following ways:

- Selectively display a link or a button at the cart level.
  
  For example, when granting VPN Administrator and IT Administrator roles to a user, a delegated administrator may be able to provide additional information for VPN Administrator role, but not for the IT Administrator role.

- Launch different taskflows based on the context.
  
  For example, different custom taskflows or forms can be launched for widget supplier and IT Administrators roles.

- Customize the popup window, such as icon and title for the window.

The following code snippet shows a sample customization using appropriate EL expressions:

```af:commandLink xmlns:af="http://xmlns.oracle.com/adf/faces/rich" id="e3664710724" text="Additional Cart Item information" actionListener="#{catalogRequestBean.launchAdditionalRequestInfoTaskFlow}" rendered="#{backingBeanScope.additionalInfoHelperBean.renderAdditionalDetailsForCartItem}"
  <af:clientAttribute xmlns:af="http://xmlns.oracle.com/adf/faces/rich" name="taskFlowId" value="#{backingBeanScope.additionalInfoHelperBean.additionalInfoTaskFlowIdForCartItem}"/>
  <af:clientAttribute xmlns:af="http://xmlns.oracle.com/adf/faces/rich" name="dialogTitleIcon" value="/images/request_ena.png"/>
  <af:clientAttribute xmlns:af="http://xmlns.oracle.com/adf/faces/rich" name="dialogTitle" value="#{backingBeanScope.additionalInfoHelperBean.popupTitle}"/>
</af:commandLink>

In this sample code snippet, a custom Additional Cart Information link is added to cart details page. Here:

- The custom link for a cart item or row is selectively displayed for the rendered property using the EL expression,
Customizing the UI for Providing Additional Request Information

#{backingBeanScope.additionalInfoHelperBean.renderAdditionalDetailsForCartItem}.

To use this EL expression, develop a managed JAVA bean, say additionalRequestInfoHelperBean, with the isRenderAdditionalDetailsForCartItem method. This method should return a boolean value (true or false) based on whether the link has to be displayed or not displayed. For more information about the managed bean, see "Developing Managed Beans and Task Flows" on page 30-42.

- Launch different taskflows using the EL expression, #{backingBeanScope.additionalInfoHelperBean.additionalInfoTaskFlowIdForCartItem}, specified as the value of the taskFlowId attribute.

To use this EL expression, include the getAdditionalInfoTaskFlowIdForCartItem method in the managed bean named additionalRequestInfoHelperBean. This method should return a String value representing the ID of the custom taskflow deployed as part of oracle.iam.ui.custom-dev-starter-pack.war. For example, /WEB-INF/oracle/iam/ui/sample/catalog/tfs/additional-info-email-tf.xml#additional-info-email-tf. For information about the taskFlowId attribute, see "Launching Custom Taskflow for Additional Request Information" on page 30-77.

- Set different popup window titles using the EL expression, #{backingBeanScope.additionalInfoHelperBean.popupTitle}, specified as the value of the dialogTitle attribute.

To use this EL expression, include the getPopupTitle method in managed bean named additionalRequestInfoHelperBean. This method should return the desired String value to be displayed as popup window title. For information about the dialogTitle attribute, see "Launching Custom Taskflow for Additional Request Information" on page 30-77.

You can use the following available data to achieve the required customization:

- Data about the selected cart item or row by evaluating the #{row} EL expression

  This would return an object of type oracle.adfinternal.view.faces.model.binding.FacesCtrlHierNodeBinding. You can cast the result to FacesCtrlHierNodeBinding and use its API to get the cart item information.

  For example:

  ```java
  //Assume "row" is the result of evaluating EL expression "#{row}", and is NOT null.
  FacesCtrlHierNodeBinding rowData = (FacesCtrlHierNodeBinding)row;
  //This code populates cartItemDataMap with the data available in the row
  Map<String, Object> cartItemDataMap = new HashMap<String, Object>();
  for (String name : rowData.getAttributeNames()) {
    cartItemDataMap.put(name, rowData.getAttribute(name));
  }
  //Rest of the code can make use of the attrMap, which contains keys like entityType, entityName, entityDisplayName etc.
  //use the following cart item properties to achieve various customization usecases
  String entityType = (String)cartItemDataMap.get('entityType');
  ```
String entityName = (String)cartItemDataMap.get("entityName");
String entityDisplayName = (String)cartItemDataMap.get("entityDisplayName");

- Data available in the pageFlowScope map in one of the following ways:
  - By evaluating the EL expression, #{pageFlowScope}
  - By invoking the AdfFacesContext.getCurrentInstance().getPageFlowScope() method

  This method returns an instance of java.util.Map, which contains data as key-value pairs. A few useful values (Map Key values) stored in this map are:
  - requestId: The value corresponding to this key would be a Request ID, which varies depending on the UI action performed by the user.
    For example, when the user is requesting for or modifying access, or performing any other operation supported by request, the value will be -1. For all other UI actions, such as tracking or approving request, the value will be a valid Request ID.
    You can use this value to distinguish request tracking or approval flows from request creation.
  - requestAction: The value for this key (if not null) corresponds to the UI action performed by the user, such as APPROVAL_UPDATE, APPROVAL_VIEW, ACCOUNT_UPDATE, and ACCOUNT_VIEW.
    You can use this value to distinguish request tracking flow from request approval flow. APPROVAL_VIEW corresponds to request tracking flow and APPROVAL_UPDATE corresponds to request approval flow.
  - entityType: The value for this key (if not null) corresponds to the Oracle Identity Manager entity type involved in the operation, such as role and entitlement.

- Data obtained from RequestFormContext, which holds information about the cart, by invoking the oracle.iam.ui.platform.view.RequestFormContext.newInstance(null).getCurrentContext() method

  This method returns an object of type oracle.iam.ui.platform.view.RequestFormContext. For more information about RequestFormContext, see “Available EL Expressions in the RequestFormContext” on page 30-22.

30.11.7 Validating Additional Request Information

If the additional request information has any mandatory attribute values to be submitted, you can validate the submission using a RequestDataValidator plugin, which can validate RequestData.

See Also: Chapter 21, “Developing Workflows for Approval and Manual Provisioning” for more information about defining and configuring plugins for requests related to application instance.

The following is a sample configuration for Assign roles operation in the plugin.xml file while registering the validator plugin. This configuration ensures that mycompany.iam.plugin.validation.AssignRolesDataValidator is invoked for all Assign roles operations.

<plugins pluginpoint="oracle.iam.request.plugins.RequestDataValidator">
Migrating UI Customizations

Similarly, for Assign entitlements operation, plugin.xml can be configured as follows:

```xml
<plugins pluginpoint="oracle.iam.request.plugins.RequestDataValidator">
    <plugin pluginclass="mycompany.iam.plugin.validation.AssignEntitlementsDataValidator" version="1.0" name="AssignEntitlementsDataValidator">
        <metadata name="DataValidator">
            <value>EBSForm.UD_EBS_RESP</value>
        </metadata>
    </plugin>
</plugins>
```

30.12 Migrating UI Customizations

Migrating UI customizations from one Oracle Identity Manager environment to another environment or test to production (T2P) is described with the help of the following scenarios:

**Scenario I: Incremental T2P**
During the development cycle, you want to incrementally build configuration and keep moving the configuration from one Oracle Identity Manager setup to another. To do this, you use the Deployment Manager, as described in Chapter 38, "Migrating Configurations and Customizations". But exporting and importing data using the Deployment Manager does not include the UI customization, except migrating the resource bundles. For this reason, Oracle Identity Manager provides sandboxes, using which you can create customizations bound by sandboxes, test them, and eventually export/import them on an incremental basis.

However, incremental migration of customizations has a problem. You have to keep your sandboxes exported in advance, and then only publish the changes. You can test your changes only after publishing them. But if you have already published the changes, then you cannot export. This is a known issue.

**Scenario II: Fusion Middleware Framework-Based Full T2P**
After completion of the development and testing cycles, you want to setup the production environment on the first day of the real deployment. You want to move all configurations and customizations from the test to the production environment.

Full T2P of Oracle Identity Manager via Fusion Middleware framework-based utility also supports the movement of UI customizations. Fusion Middleware Framework-Based Full T2P is performed by using Fusion Middleware T2P utilities, such as copyBinary, pasteBinary, copyconfig, extractMoveplan, and pasteconfig, and does not use the Deployment Manager. See "Moving from a Test to a Production Environment" in the Oracle Fusion Middleware Administrator’s Guide for detailed information about Full T2P.

If in the T2P, the list of published sandboxes are not showing up, then it is not an issue because you are expected to track published/unpublished changes in your test environment (T2P source), not in the destination or production environment.
Any unpublished sandboxes in the source or test environment means:

- You want to move the unpublished sandboxes later as incremental work after increasing the scope of those sandboxes, but currently those have not been included in the production environment.
- The unpublished sandboxes have not been tested, and you do not want to include those in the production environment.

### 30.13 UI Customization Best Practices

This section describes the following UI customization best practices and guidelines:

**Create sandboxes with detailed description**

When creating a sandbox, create it with a detailed description and list all the entities for which you are creating the sandbox. For example, if you are creating an application instance, note that this sandbox is created for application instance creation. When the application instance is created, publish the sandbox, and then go to Identity Self Service to create another sandbox to perform the UI customization. This is to avoid issues when two or more users create different sandboxes to create the same entity (application instance in this example) and try to publish it at different times.

**Do not invoke Platform APIs from custom managed bean**

Invoking Platform APIs directly by using Oracle Identity Manager data source in custom managed bean is not supported. Only Public APIs that are exposed through OIMClient can be invoked.

### 30.14 Rolling Back UI Customization

If you are unable to login to Oracle Identity System Administration after customizing the interface and publishing the sandbox, then perform the following steps:

1. Login to Oracle Enterprise Manager.
2. In Application Deployments, select `oracle.iam.ui.console.self-service.ear`.
3. On the top-right of the page, select **Application Deployment**, and then select **MDS Configuration** from the list.
4. At the bottom of the screen, select **Runtime MBean Browser** under the Advanced Configuration section. The right side of the screen refreshes.
5. Click the **Operations** tab.
6. Scroll down and identify the listMetadataLabels MBean operation and invoke it. Select the MBean operation that does not take any parameters. Select the sandbox precreate that you want to restore, and copy it to the clipboard.
   For example, the value you copy can be similar to: `Creation_IdM_test_09:25:00`.
7. Click **Return** to go back to the Operation tab.
8. Find the promoteMetadataLabel MBean operation.
9. Invoke the promoteMetadataLabel MBean operation, and enter the value that you copied in step 6.
10. Restart Oracle Identity Manager.
11. Login to Oracle Identity System Administration.
This part describes the APIs and Web services that Oracle Identity Manager supports. It contains the following chapters:

- Chapter 31, "Using APIs"
- Chapter 32, "Using SPML Services"
- Chapter 33, "Using URLs"
Oracle provides a network-aware, Java-based application programming interface (API) that exposes Services, called Utility in earlier releases, available in Oracle Identity Manager. This API is based on Plain Old Java Objects (POJO) and takes care of all the plumbing required to interact with Oracle Identity Manager. This API can be used for building clients for Oracle Identity Manager and for integrating third-party products with the Oracle Identity Manager platform.

This chapter contains these sections:

- Accessing Oracle Identity Manager Services
- Oracle Identity Manager Services
- Commonly Used Services
- Developing Clients for Oracle Identity Manager
- Working With Legacy Oracle Identity Manager APIs
- Code Samples

31.1 Accessing Oracle Identity Manager Services

The entry point to Oracle Identity Manager Services is through oracle.iam.platform.OIMClient class. Thor.API.tcUtilityFactory used in earlier releases is also supported. Oracle recommends using the oracle.iam.platform.OIMClient for developing clients to integrate with Oracle Identity Manager.

This section describes the following topics:

- Using OIMClient
- Using the tcUtilityFactory
- Using OIMClient and tcUtilityFactory in Integrated Deployments

31.1.1 Using OIMClient

OIMClient is the entry point for accessing the services available in Oracle Identity Manager. You use the following sequence of steps when using OIMClient:

1. Create an instance of OIMClient with the environment information required to connect to Oracle Identity Manager application, as shown:

```java
Hashtable env = new Hashtable();
env.put("OIMClient.JAVA_NAMING_FACTORY_INITIAL", 
```
"weblogic.jndi.WLInitialContextFactory");
env.put(OIMClient.JAVA_NAMING_PROVIDER_URL, t3://OIM_HOSTNAME:OIM_PORT);
OIMClient oimClient = new OIMClient(env);

Here, replace OIM_HOSTNAME with the host name on which Oracle Identity Manager is deployed and OIM_PORT with the port number.

2. Login to the Oracle Identity Manager with the appropriate credentials, as shown:
   oimClient.login(OIM_USERNAME, OIM_PASSWORD);

3. Lookup a service, as shown:
   UserManager usermgr = oimClient.getService(UserManager.class);
   OR
tcLookupOperationsIntf lookupIntf =
oimClient.getService(tcLookupOperationsIntf.class);

4. Call method on a service, as shown:
   HashMap userAttributes = new HashMap();
   ............
   UserManagerResult result = userMgr.create(new User(null, userAttributes));

31.1.2 Using the tcUtilityFactory

Earlier releases of Oracle Identity Manager supports tcUtilityFactory for accessing Oracle Identity Manager Services (or Utilities, as they are called in legacy releases). tcUtilityFactory continues to be supported. However, as mentioned earlier, Oracle recommends using OIMClient for building all client applications for Oracle Identity Manager.

You use the following sequence of steps when using tcUtilityFactory:

1. Create an instance of tcUtilityFactory with the environment information, such as username and password, as shown:
   tcUtilityFactory ioUtilityFactory = new tcUtilityFactory(env, "OIM_USERNAME", "OIM_PASSWORD");

2. Look up utility or service by providing the fully qualified name of the utility, as shown:
   tcUserOperationsIntf moUserUtility =

3. Run operations on the utility, as shown:
   Hashtable mhSearchCriteria = new Hashtable();
   mhSearchCriteria.put("Users.First Name", psFirstName);
   tcResultSet moResultSet = moUserUtility.findUsers(mhSearchCriteria);

31.1.3 Using OIMClient and tcUtilityFactory in Integrated Deployments

In Oracle Identity Manager deployment that is integrated with Access Manager (OAM), OIMSSignatureAuthenticator is not configured in the Oracle Identity Manager domain’s security realm. Therefore, all the custom or partner applications that you want to integrate with Oracle Identity Manager must not use signature-based login to
Oracle Identity Manager. Instead, you must follow any one of the following approaches:

- **Oracle Platform Security Services (OPSS) Framework**: If the partner or client application is a J2EE application based on Fusion Middleware stack, then it can use the following from OPSS framework:

  **Note**: See "Introduction to Oracle Platform Security Services" in the Oracle Fusion Middleware Application Security Guide for information about OPSS and its main features

  - **OPSS credential store**: This allows credentials to be managed (store, retrieve, modify) in a secure manner. You can store the password in the OPSS credential store, and retrieve it while performing a Oracle Identity Manager client login by using user ID and password. See "Managing the Credential Store" in the Oracle Fusion Middleware Application Security Guide for more information about OPSS credential store.

  - **OPSS SubjectSecurity API**: If a partner application wants to invoke Oracle Identity Manager EJB/Service APIs with a higher privilege, such as system administrator user, then OPSS SubjectSecurity API can be used. The following sample partner application code tries to invoke Oracle Identity Manager API with higher privilege:

    ```java
    //Get ActionExecutor for OIM System administrator, xelsysadm
    ActionExecutor actionExecutor =
        SubjectSecurity.getInstance().getActionExecutor("xelsysadm");
    actionExecutor.execute(new PrivilegedAction<Object>() {
        public Object run() {
            //OIM EJB method invocation goes here...
            Hashtable env = new Hashtable();
            //serverURL - OIM server's RMI URL
            // ctxFactory - WLS/WAS context factory class
            env.put(OIMClient.JAVA_NAMING_PROVIDER_URL, serverURL);
            env.put(OIMClient.JAVA_NAMING_FACTORY_INITIAL,ctxFactory);
            OIMClient client = new OIMClient(env);
            //Invoking EJB service method as "xelsysadm"
            RequestService reqSrvc = client.getService(RequestService.class);
            reqSrvc.getBasicRequestData("1"); //1 is the request ID.
        }
    });
    ```

- If using the OPSS framework is not possible for some reason, then it is recommended to invoke the OIMClient API with user ID and password. However, it is up to the client or partner to store and manage the Oracle Identity Manager user's password in a secure manner.

### 31.2 Oracle Identity Manager Services

The Oracle Identity Manager API provides access to services available in Oracle Identity Manager. Because the APIs in Oracle Identity Manager 11g Release 1(11.1.1)
onwards and the legacy APIs use different conventions, this section discusses them separately in the following topics:

- Services in Oracle Identity Manager 11g
- Legacy Services or Utilities

### 31.2.1 Services in Oracle Identity Manager 11g

Services in Oracle Identity Manager 11g onwards are based on the following conventions:

- **Package Names:** Services are in packages whose names end with "api", for example:
  - `oracle.iam.request.api`
  - `oracle.iam.identity.usermgmt.api`

- **Service Interface Names:** Services introduced in 11g typically use the naming convention of "Service", for example:
  - `oracle.iam.request.api.RequestService`
  - `oracle.iam.selfservice.self.selfmgmt.api.AuthenticatedSelfService`

  Some Identity Administration APIs use the "Manager" naming convention for their APIs, for example:
  - `oracle.iam.identity.usermgmt.api.UserManager`

  Some new services introduced in Oracle Identity Manager 11g Release 2 (11.1.2.2.0) are:
  - `oracle.iam.api.OIMService`
  - `oracle.iam.platform.authopss.api.AuthorizationService`
  - `oracle.iam.provisioning.api.ProvisioningService`
  - `oracle.iam.provisioning.api.ApplicationInstanceService`

### 31.2.2 Legacy Services or Utilities

Legacy services, also called utilities, follow the following naming conventions

- **Package Names:** All legacy APIs are in Thor.API.Operations package.

- **Service Interface Names:** Service names are of the form "Intf", for example, `Thor.API.Operations.tcImportOperationsIntf`.

  **See Also:** Oracle Fusion Middleware Java API Reference for Oracle Identity Manager for a full list of services available in Oracle Identity Manager. You can use the naming conventions above to find the APIs.

### 31.3 Commonly Used Services

Table 31–1 lists some commonly used services in Oracle Identity Manager.

<table>
<thead>
<tr>
<th>Service Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserManager</td>
<td>Provides operations for user management, such as create, search, modify, and delete users</td>
</tr>
<tr>
<td>RequestService</td>
<td>Provides operations to submit, withdraw, close, and search requests.</td>
</tr>
</tbody>
</table>

Oracle Fusion Middleware Developer's Guide for Oracle Identity Manager
31.3.1 Mapping Between Legacy and New Services

In Oracle Identity Manager, some of the legacy APIs have been rewritten by using new architecture and the corresponding utility services or interface classes have been changed. Table 31–2 provides a high-level correspondence between the legacy and new interfaces.

<table>
<thead>
<tr>
<th>Legacy Service</th>
<th>New Service</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thor.API.Operations.tcUserOperationsIntf</td>
<td>oracle.iam.identity.usermgmt.api.UserManager</td>
</tr>
<tr>
<td>Thor.API.Operations.tcGroupOperationsIntf</td>
<td>oracle.iam.identity.rolemgmt.api.RoleManager</td>
</tr>
<tr>
<td>Note: The Group Manager APIs related all delegated admin APIs for adding and removing admins have been deprecated.</td>
<td></td>
</tr>
<tr>
<td>Thor.API.Operations.tcRequestOperationsIntf</td>
<td>oracle.iam.request.api.RequestService</td>
</tr>
<tr>
<td>Thor.API.Operations.tcSchedulerOperationsIntf</td>
<td>oracle.iam.scheduler.api.SchedulerService</td>
</tr>
<tr>
<td>Thor.API.Operations.tcEmailOperationsIntf</td>
<td>oracle.iam.notification.api.NotificationService</td>
</tr>
</tbody>
</table>

31.4 Developing Clients for Oracle Identity Manager

This section includes the following topics:

- Prerequisites for Developing Clients
- Setup and Configuration

31.4.1 Prerequisites for Developing Clients

The following prerequisites must be met for developing clients for Oracle Identity Manager:

- Java Development Kit (JDK) 1.6 installed and set in the path
- ANT 1.7 installed and set in the path
31.4.2 Setup and Configuration

Oracle Identity Manager package contains a ZIP file that contains the required libraries and configuration files for developing clients.

To run an application client for Oracle Identity Manager:

1. Copy `OIM_ORACLE_HOME/server/client/oimclient.zip` to the computer on which you want to develop the client, for example the oimclient/ directory. This directory is referred to as `OIM_CLIENT_HOME` in this document. Extract the ZIP file. Note that the oimclient.zip file consists of the conf, lib, and oimclient.jar.

2. Copy the following files manually after unzipping oimclient.zip in the remote machine:
   a. Copy `$OIM_HOME/server/client/oimWASClient.ear` to the same location of oimclient.jar.
   b. Copy `$OIM_HOME/server/client/config/xl.policy` to the conf directory.
   c. Copy `$OIM_HOME/server/client/config/authws.conf` to the conf directory.
   d. Copy `$MW_HOME/oracle_common/modules/oracle.jrf_11.1.1/jrf-api.jar` to the lib directory.

3. Copy the application server-specific client library to the `OIM_CLIENT_HOME/lib` directory. For Oracle WebLogic Server, wlfullclient.jar is the client library. It is created in `MIDDLEWARE_HOME/WL_HOME/server/lib/` directory, for example, `/scratch/beahome/wlserver_10.3/server/lib/`. Check if wlfullclient.jar is present. If not, then you must generate one by using the jarbuilder tool. See Oracle WebLogic Server documentation on how to generate wlfullclient.jar.

4. Pass the following system properties for running API clients:
   - `java.security.auth.login.config=OIM_CLIENT_HOME/conf/authwl.conf`
   - `APPSERVER_TYPE=wls`

5. Make sure following jars are in the class path:
   - commons-logging.jar
   - spring.jar
   - oimclient.jar
   - wlfullclient.jar
   - jrf-api.jar

31.5 Working With Legacy Oracle Identity Manager APIs

This section describes the following topics:

- Using a Result Set Object
- Handling Oracle Identity Manager Exceptions
- Cleaning Up

31.5.1 Using a Result Set Object

Legacy Oracle Identity Manager APIs extensively use the tcResultSet interface. The Thor.API.tcResultSet interface is a data structure that stores records retrieved from
the database. Methods in the Oracle Identity Manager API that must return a set of data use a result set. This is a two-dimensional data structure in which the columns correspond to the attributes and rows correspond to the entities. For example, a result set that is returned by the method that searches for users, each row would represent data pertaining to one user, and each column in the row would be an attribute for that user.

You can scroll through the result set and retrieve individual entries corresponding to particular attributes by using the various methods provided. To locate a particular row in the result set, use the `goToRow()` method with the row number as a parameter. To retrieve the values for the columns from a row, use appropriate accessor methods, such as `getStringValue()`. To obtain the value from a specific column, pass the column name as a parameter to the accessor method. The column name is the descriptive code defined in the Oracle Identity Manager Meta-Data system.

The following table shows some sample metadata values. This mapping is based on lookup codes and can be looked up in the Design Console by using the Lookup Definition Form.

<table>
<thead>
<tr>
<th>Column Code</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>IT Resources.Name</td>
<td>The name of an IT resource</td>
</tr>
<tr>
<td>Process Definition.Name</td>
<td>The name of a provisioning process</td>
</tr>
</tbody>
</table>

**Note:** Keep track of the result set objects that are retrieved, because they will be required when updating an existing record.

The following is an example of how to use a result set. This example obtains a result set by calling the `findAllUsers()` method. This method searches for all users matching certain criteria:

```java
tcResultSet moResultSet = moUserUtility.findAllUsers(mhAttribs);
```

To check if the `findAllUsers()` method returned any records, use the `isEmpty()` method, for example:

```java
boolean mbEmpty = moResultSet.isEmpty();
```

To retrieve the number of records found, use the `getRowCount()` method. If no records are found, then the method returns 0. The following is an example:

```java
int mnNumRec = moResultSet.getRowCount();
```

To select a particular record in the system, use the `goToRow()` method:

```java
moResultSet.goToRow(5);
```

To retrieve the values of attributes from the current row, use the appropriate accessor method, for example:

```java
String msUserLastName = moResultSet.getStringValue("Users.Last Name");
```

### 31.5.2 Handling Oracle Identity Manager Exceptions

The API methods throw Oracle-defined Java exceptions. Instead of using the `getMessage()` method on the exception object received, you can access the `isMessage` internal variable to retrieve the exception message.
31.5.3 Cleaning Up

The `tcUtilityFactory` class manages all resources used by a utility or factory instance and provides a means to release these resources after they are used.

If you instantiate and use `tcUtilityFactory` to obtain utility class instances, to release the resources that are associated with the utility class, call the `close(utility Object)` method on the factory class. If the session has ended, then call the `close()` method on the factory instance to release all the utility classes, the session objects, and the database objects.

If you obtain a utility class directly by using static calls, after the utility object is no longer needed, call the `close(object)` method on the utility object.

31.6 Code Samples

This section contains the following code samples:

- Retrieving Oracle Identity Manager Information
- Using Certification APIs
- Using OIMService API

31.6.1 Retrieving Oracle Identity Manager Information

Example 31-1 illustrates how to retrieve Oracle Identity Manager information. This example creates an instance of the factory class. The instance is then called several times to retrieve individual utility classes and use them to retrieve Oracle Identity Manager information.

Example 31–1 Retrieving Oracle Identity Manager Information

```java
/*
 * This class is intended to showcase some of OIM API's. These API's are specific to OIM 11g release. As an example, Legacy API's usage for Organization is also shown.
 */

package oracle.iam.samples;

// Role related API's
import oracle.iam.identity.rolemgmt.api.RoleManager;
import oracle.iam.identity.rolemgmt.vo.Role;
import oracle.iam.identity.exception.RoleSearchException;
import oracle.iam.identity.rolemgmt.api.RoleManagerConstants.RoleAttributeName;
import oracle.iam.identity.rolemgmt.api.RoleManagerConstants.RoleCategoryAttributeName;

// User related API's
import oracle.iam.identity.usermgmt.api.UserManager;
import oracle.iam.identity.usermgmt.vo.User;
import oracle.iam.identity.exception.UserSearchException;
import oracle.iam.identity.usermgmt.api.UserManagerConstants.AttributeName;

// Organization Legacy API's
import Thor.API.Operations.tcOrganizationOperationsIntf;
import Thor.API.tcResultSet;
import Thor.API.Exceptions.tcAPIException;
import Thor.API.Exceptions.tcColumnNotFoundException;
```
public class Sample {

    private static OIMClient oimClient;

    /*
     * Initialize the context and login with client supplied environment
     */
    public void init() throws LoginException {
        System.out.println("Creating client...");
        String ctxFactory = "weblogic.jndi.WLInitialContextFactory";
        String serverURL = "t3://OIM_HOSTNAME:OIM_PORT";
        String username = "xelsysadm";
        char[] password = "xelsysadm".toCharArray();
        Hashtable env = new Hashtable();
        env.put(OIMClient.JAVA_NAMING_FACTORY_INITIAL,ctxFactory);
        env.put(OIMClient.JAVA_NAMING_PROVIDER_URL, serverURL);
        env.put(OIMClient.JAVA_NAMING_FACTORY_INITIAL,ctxFactory);
        env.put(OIMClient.JAVA_NAMING_PROVIDER_URL, serverURL);

        oimClient = new OIMClient(env);
        System.out.println("Logging in");
        oimClient.login(username, password);
        System.out.println("Log in successful");
    }

    /**
     * Retrieves User login based on the first name using OIM 11g
     * UserManager service API.
     */
    public List getUserLogin(String psFirstName) {
        Vector mvUsers = new Vector();
        UserManager userService = oimClient.getService(UserManager.class);
        Set<String> retAttrs = new HashSet<String>();
        // Attributes that should be returned as part of the search.
        // Retrieve 'User Login' attribute of the User.
        // Note: Additional attributes can be specified in a
        // similar fashion.
        retAttrs.add(AttributeName.USER_LOGIN.getId());

        SearchCriteria criteria;
        try {
            criteria = new SearchCriteria(AttributeName.FIRSTNAME.getId(), psFirstName,
                                          SearchCriteria.Operator.EQUAL);
            List<User> users = userService.search(criteria, retAttrs, null);
        }
    }
}
for (int i = 0; i < users.size(); i++) {
    // Print User First Name and Login ID
    System.out.println("First Name : " + psFirstName + "  --  Login ID : " + users.get(i).getLogin());
    mvUsers.add(users.get(i).getLogin());
}

} catch (AccessDeniedException ade) {
    // handle exception
} catch (UserSearchException use) {
    // handle exception
}
return mvUsers;

/**
 * Retrieves the administrators of an Organization based on the Organization name. This is Legacy service API usage.
 */
public List getAdministratorsOfOrganization(String psOrganizationName) {
    Vector mvOrganizations = new Vector();
    tcOrganizationOperationsIntf moOrganizationUtility = oimClient.getService(tcOrganizationOperationsIntf.class);
    Hashtable mhSearchCriteria = new Hashtable();
    mhSearchCriteria.put("Organizations.Organization Name", psOrganizationName);
    try {
        tcResultSet moResultSet = moOrganizationUtility.findOrganizations(mhSearchCriteria);
        tcResultSet moAdmins;
        for (int i = 0; i < moResultSet.getRowCount(); i++) {
            moResultSet.goToRow(i);
            moAdmins = moOrganizationUtility.getAdministrators(moResultSet.getLongValue("Organizations.Key"));
            mvOrganizations.add(moAdmins.getStringValue("Groups.Group Name"));
            System.out.println("Organization Admin Name : " + moAdmins.getStringValue("Groups.Group Name"));
        }
    } catch (tcAPIException tce) {
        // handle exception
    } catch (tcColumnNotFoundException cnfe) {
        // handle exception
    } catch (tcOrganizationNotFoundException onfe) {
        // handle exception
    }
    return mvOrganizations;
}

/**
 * Retrieves Role Display Name based on Role name and Role Category using OIM 11g RoleManager service API. This example shows how to construct compound search criteria.
 */
public List getRoleDisplayName(String roleName, String roleCategory) {
    Vector mvRoles = new Vector();
    RoleManager roleService = oimClient.getService(RoleManager.class);
    Set<String> retAttrs = new HashSet<String>();
    // Attributes that should be returned as part of the search.
    // Retrieve the 'Role Display Name' attribute of a Role.
    // Note: Additional attributes can be specified in a similar fashion.
retAttrs.add(RoleAttributeName.DISPLAY_NAME.getId());

// Construct the first search criteria. This search criteria
// states 'Find Role(s) whose 'Name' equals 'roleName'".
SearchCriteria criteria1;
criteria1 = new SearchCriteria(RoleAttributeName.NAME.getId(), roleName,
SearchCriteria.Operator.EQUAL);

// Construct the second search criteria. This search criteria
// states 'Find Role(s) whose 'category' equals 'roleCategory'".
SearchCriteria criteria2;
criteria2 = new SearchCriteria(RoleCategoryAttributeName.NAME.getId(), roleCategory,
SearchCriteria.Operator.EQUAL);

// Construct the compound search criteria using 'criteria1' and
// 'criteria2' as arguments. This showcases how to construct
// compound search criterias.
SearchCriteria criteria = new SearchCriteria(criteria1, criteria2,
SearchCriteria.Operator.AND);

try {
// Use 'search' method of RoleManager API to retrieve
// records that match the search criteria. The return
// object is of type Role.
List<Role> roles = roleService.search(criteria, retAttrs, null);

for (int i = 0; i < roles.size(); i++) {
    //Print Role Display Name
    System.out.println("Role Display Name : " +
    roles.get(i).getDisplayName());
    mvRoles.add(roles.get(i).getDisplayName());
}
} catch (AccessDeniedException ade) {
    // handle exception
} catch (RoleSearchException use) {
    // handle exception
}
return mvRoles;
}

// Main method invocation
// Following assumptions are made
//1. A User 'Joe Doe' already exists in OIM
//2. An Organization "Example Organization" already exists in OIM
//3. A Role 'Foobar' already exists in OIM
public static void main(String args[]) {
    List moList = null;

    try {
        Sample oimSample = new Sample();

        // initialize resources
        oimSample.init();
        // retrieve User logins with first name 'Joe'
        moList=oimSample.getUserLogin("Joe");
        // retrieve User logins with first names starting with 'J'
        moList=oimSample.getUserLogin("J*");
        // retrieve the administrators of an Organization with name
        // 'Example Organization'
        moList=oimSample.getAdministratorsOfOrganization("Example Organization");
    } catch (AccessDeniedException ade) {
        // handle exception
    } catch (RoleSearchException use) {
        // handle exception
    }
}
// retrieve Role display name with role name 'FooBar'
// and role category as 'Default'
moList=oimSample.getRoleDisplayName('foobar', 'Default');

// release resources
oimClient.logout();
}
}
}

The following is the sample output:

[java] Creating client....
[java] Logging in
[java] Log in successful
[java] First Name : Joe -- Login ID : JDOE
[java] First Name : J* -- Login ID : JHOND
[java] First Name : J* -- Login ID : JDOE
[java] Organization Admin Name : SYSTEM ADMINISTRATORS
[java] Role Display Name : foobar

31.6.2 Using Certification APIs

This section provides code examples for using APIs related to certification, such as CertificationService.

Example 31–2 provides the code sample to get certifications belonging to a user.

Example 31–2 Retrieving Certifications Belonging to a User

public List<CertificationInstance> findCertifications(SearchCriteria searchCriteria, Set<String> retAttrs, Map<String, Object> configParams) throws CertificationServiceException;

Example of searchCriteria to use:

SearchCriteria searchCriteria1 = new SearchCriteria(CertificationConstants.CERTIFICATION_SEARCH_FIELDPRIMARY_REVIEWER_ID, userKey, SearchCriteria.Operator.EQUAL);
SearchCriteria searchCriteria2 = new SearchCriteria("certificationStatusForQuery", CertificationConstants.STATE_IN_PROGRESS.toString(), SearchCriteria.Operator.EQUAL);
SearchCriteria searchCriteria = new SearchCriteria(searchCriteria1, searchCriteria2, SearchCriteria.Operator.AND);

Example 31–3 provides the code sample to retrieve an application instance certification.

Example 31–3 Retrieving an Application Instance Certification

public List<IDCAccountAttributeAndRoleWrapper> loadBatchUserEntitlements(Long certificationId, String taskUid, Long userId, PaginationContext context, SearchCriteria searchCriteria) throws CertificationServiceException;

Example 31–4 provides the code sample to certify or deny entitlements.

Example 31–4 Certify or Deny Certifications

public void certifyUserEntitlements(Long certId, String taskUid, Long userEntityId, Set<Long> roleEntityIds, Set<Long> accountEntityIds, Set<Long>
accountAttributeEntityIds, Integer certified, Date statusEndDate, String comments) throws CertificationServiceException;

Example 31–5 provides the code sample to complete the certification.

Example 31–5  Complete the Certification

public CertificationInstance completeCertification(final Long certificationId, String taskUid, char[] cleartextPassword)

31.6.3 Using OIMService API

This section lists out sample usage for few operations by using the OIMService API. It contains the following topics:

- RequestData Object Construction
- Samples of OIMService API Usage

31.6.3.1 RequestData Object Construction

For invoking the operations supported through OIMService API, you must first construct the RequestData object.

For all the operations that involve target user and cart item, such as role, application instance, or entitlement, construct the RequestData object as follows:

1. Create an instance of the RequestData object.
2. Create List of Beneficiary object(s), set the fields, and associate the object with RequestData object by invoking:
   requestData.setBeneficiaries();
3. Create List of RequestBeneficiaryEntity object(s), and set the cart item data, such as entity type, entity key, and operation. Associate the object with Beneficiary object by invoking:
   beneficiary.setTargetEntities();

The entityKey, which is set by using the entity.setEntityKey() method for a given operation, must be based on Table 31–3.

<table>
<thead>
<tr>
<th>Operation</th>
<th>entityKey</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provision Application Instance</td>
<td>Application Instance Key</td>
</tr>
<tr>
<td>Modify Account</td>
<td>Account Key</td>
</tr>
<tr>
<td>Revoke Account</td>
<td>Account Key</td>
</tr>
<tr>
<td>Enable Account</td>
<td>Account Key</td>
</tr>
<tr>
<td>Disable Account</td>
<td>Account Key</td>
</tr>
<tr>
<td>Provision Entitlement</td>
<td>Entitlement Key</td>
</tr>
<tr>
<td>Modify Entitlement</td>
<td>Entitlement Instance Key</td>
</tr>
<tr>
<td>Revoke Entitlement</td>
<td>Entitlement Instance Key</td>
</tr>
</tbody>
</table>
4. Create List of RequestBeneficiaryEntityAttribute object(s), and set the attribute name and value in each object. Associate the object with the entity object by invoking `entity.setEntityData()`. This is required only if the cart item is associated with a form.

---

**Note:**
- `RequestData.setTargetEntities()` must not be used in this scenario.
- See ""[Samples of OIMService API Usage](#)" on page 31-14" for more details.

---

For all the operations that involve only the User entity, such as Create User, Modify User, Enable User, Disable User, and Delete User, the RequestData object must be populated as follows:

1. Create an instance of the RequestData object.
2. Create List of RequestEntity object(s) by setting entity type, entity key, and operation. Entity key must be set as user key for all the operations except Create User.
3. Create List of RequestEntityAttribute object(s), and set attribute name and value in each object. This is required only for Create User and Modify User operations.

### 31.6.3.2 Samples of OIMService API Usage

This section provides code samples of using the OIMService API.

**Example 31–6** provides the code sample for revoking an account.

**Example 31–6  Revoking an Account**

```java
RequestData requestData = new RequestData();
Beneficiary beneficiary = new Beneficiary();
beneficiary.setBeneficiaryKey("12"); //User with key 12
beneficiary.setBeneficiaryType(Beneficiary.USER_BENEFICIARY);

RequestBeneficiaryEntity entity = new RequestBeneficiaryEntity();
entity.setEntityType("ApplicationInstance");
entity.setEntityKey(String.valueOf(accountKey));
entity.setOperation("REVOKE");

List<RequestBeneficiaryEntity> entities = new ArrayList<RequestBeneficiaryEntity>();
etities.add(entity);
beneficiary.setTargetEntities(entities);

List<Beneficiary> beneficiaries = new ArrayList<Beneficiary>();
beneficiaries.add(beneficiary);
requestData.setBeneficiaries(beneficiaries);

OperationResult result = oimService.doOperation(requestData, OIMService.Intent.ANY);
if( result.getRequestID() != null ) {
    //Operation resulted in to request creation.
    System.out.println("Request submitted with ID: " + result.getRequestID());
} else {
    System.out.println("Account is revoked successfully");
}
```
**Example 31–7** provides the code sample for creating a user.

**Example 31–7  Creating a User**

```
RequestData requestData = new RequestData("Create User");
RequestEntity ent = new RequestEntity();
et.setRequestEntityType(OIMType.User);
et.setOperation("CREATE");
HashMap<String, String> userData = new HashMap<String, String>();
List<RequestEntityAttribute> attrs = new ArrayList<RequestEntityAttribute>();
RequestEntityAttribute attr = new RequestEntityAttribute("Last Name", "Doe",
RequestEntityAttribute.TYPE.String);
attrs.add(attr);
attr = new RequestEntityAttribute("First Name", "John",
RequestEntityAttribute.TYPE.String);
attrs.add(attr);
attr = new RequestEntityAttribute("User Login", "jdoe",
RequestEntityAttribute.TYPE.String);
attrs.add(attr);
Long organizationKey = new Long(1);
attr = new RequestEntityAttribute("Organization", organizationKey ,
RequestEntityAttribute.TYPE.Long);
attrs.add(attr);
attr = new RequestEntityAttribute("Role", "Full-Time",
RequestEntityAttribute.TYPE.String);
attrs.add(attr);
ent.setEntityData(attrs);
List<RequestEntity> entities = new ArrayList<RequestEntity>();
entities.add(ent);
requestData.setTargetEntities(entities);
OperationResult result = oimService.doOperation(requestData,
OIMService.Intent.ANY);
if( result.getRequestID() != null ) {
    //Operation resulted in to request creation.
    System.out.println("Request submitted with ID: " + result.getRequestID());
} else {
    System.out.println("User is created successfully");
}
```
Oracle Identity Manager provides client applications with the Identity Management service, which makes use of the Service Provisioning Markup Language (SPML).

This chapter describes the SPML XSD Web service interfaces supported by Oracle Identity Manager. It contains the following topics:

- Introduction
- General Considerations
- Create Identity (SPML Core Service: addRequest)
- Modify Users, Roles, Change Attributes and Role Memberships (SPML Core Service: modifyRequest)
- Delete an Identity or Role (SPML Core Service: deleteRequest)
- Check Request Status (SPML Core Service: statusRequest)
- List Available Targets (SPML Core Service: listTargets)
- Disable a User (SPML Suspend Service: suspendRequest)
- Enable a User (SPML Suspend Service: resumeRequest)
- Check if User is Active (SPML Suspend Service: activeRequest)
- Validate a Username (SPML Username Service: validateUsername)
- Obtain a Username (SPML Username: suggestUsername)
- Lookup an Identity or Role (SPML Core Service: lookupRequest)
- Reset Password (SPML Core Service: resetPasswordRequest)
- Lookup Username Policy (SPML Username Service: lookupUsernamePolicy)
- Cancel/Withdraw Request (SPML Async Service: cancelRequest)
- Batch Request (SPML Batch Request Service: batchRequest)
- Securing SPML Web Services

**Note:** Oracle Identity Manager does not support the SPML DSML service. However, you can manually deploy the spml-dsml.ear archive file for Microsoft Active Directory password synchronization usecase only.
32.1 Introduction

This section introduces the use of SPML services using XSD profile in Oracle Identity Manage.

32.1.1 About SPML Interactions

Oracle Identity Manager provides the identity management service to enable client applications to manage identities (users and roles). The service makes use of the Service Provisioning Markup Language (SPML), which is an XML framework based on specifications from the OASIS committee that provides for exchanging user, resource and service provisioning information.

This document lists and describes the SPML interactions that Oracle Identity Manager supports.

Profile Support
SPML has two profiles: the XSD profile and the DSML profile. This release of Oracle Identity Manage makes use of the XSD profile.

Types of Interactions
The SPML specification allows interactions to be synchronous or asynchronous.

Oracle Identity Manager supports only asynchronous interactions for add, modify, delete, lookup, suspend, and resume request. For username services, all services are synchronous. Lookup is supported for user and role, which happens in synchronous manner and it can be performed using entity key, unique user/role name, LDAP GUID, and LDAP DN. Out of these, LDAP GUID and LDAP DN are applicable when LDAP synchronization is enabled. Oracle Identity Manage responds immediately with a pending status, and it is up to the requestor to get the current state by issuing a statusRequest.

Search APIs
For search APIs in the Identity Management realm, refer to Oracle Identity Management APIs in the Oracle Fusion Middleware Java API Reference for Oracle Identity Manager.

32.1.2 Integration Interface

The integration interface is defined in terms of the Service Provisioning Markup Language (SPML). In Oracle Identity Manager, implementation of SPML supports managing identities and roles, and username reservation capabilities.

Both the asynchronous and synchronous execution modes are supported, although not all services support both modes. If an invalid mode is specified in a request, the service returns an unsupportedExecutionMode SPML error code.

To use the SPML services, the application must create a Web service client. The WSDL for this client is available at the following URL:

http://OIM_HOST:OIM_PORT/spml-xsd/SPMLService?WSDL
As an alternative, you can also navigate to the WSDL and XML schema definitions using a hosted SPML Web service end-point URL. The XSD (oracle_common_pso.xsd) is available at:

$OIM_HOME/features/spml-xsd.jar

### 32.2 General Considerations

Perform the following to ensure that SPML works with Oracle Identity Manager:

- Assigning SPML Admin Role to the User
- Creating Autoapproval Policies

#### 32.2.1 Assigning SPML Admin Role to the User

Oracle Identity Manager provides an admin role for SPML. The user with this admin role is able to perform SPML requests for all usecases. The name of the SPML admin role is SPML Admin.

The SPML Admin admin role has the following permissions:

- Create, modify, and delete users via request
- Search users on all the attributes
- Enable user status via request
- Disable user status via request
- Add role memberships via request
- Delete role memberships via request
- Search roles on all the attributes
- Create, modify, and delete roles via request

The SPML Admin admin role is a global admin role published to the TOP organization. Therefore, only System Administrator or Organization Administrator of the TOP organization can assign this admin role to any user, in scope of the TOP organization.

In a new deployment of Oracle Identity Manager, the SPML Admin admin role is not assigned to any users by default. As a result, System Administrator or Organization Administrator of the TOP organization must manually assign this role to relevant users. In addition, the SPML Admin admin role can be assigned in scope of the TOP organization with include hierarchy or include sub-orgs option enabled. As a result, all permissions of the SPML Admin admin role are assigned to the user for all organizations in Oracle Identity Manager.

Note: In an upgraded deployment of Oracle Identity Manager, the existing SPML users are upgraded to assign SPML Admin admin role so that they can continue to perform SPML requests.

To assign SPML Admin admin role to a user:

1. Login to Oracle Identity Self Service. If you want to assign the SPML Admin admin role to a new user, then create the user.
2. Open the TOP organization, and click the Admin Roles tab.
3. Select the SPML Admin admin role, and assign the user with this role.

4. Modify the newly added membership to select the \texttt{include-suborgs} option, and then click \texttt{Apply}.

### 32.2.2 Creating Autoapproval Policies

Autoapproval policy rules are required so that SPML requests are auto-approved. In Oracle Identity Manager 11g Release 2 (11.1.2.2.0), there are no request templates. Therefore, the autoapproval policy rules must be manually created by System Administrators for each SPML user.

The autoapproval policies created can be based on user login, and the approval process configuration for each policy must be selected as Auto Approval. You must create autoapproval policies for each SPML operation, such as create user, modify user, create role, and so on, so that all the SPML requests raised by SPML user for these operations are approved at both request level and operational level.

\textbf{Note:} Only request-level approval policies are required for role create, role modify, and role delete operations.

To create the autoapproval policy rules:

1. Create new auto approval policy rules for the following:
   - Create user request level
   - Create user operation level
   - Modify user request level
   - Modify user operation level
   - Delete user request level
   - Delete user operation level
   - Enable user request level
   - Enable user operation level
   - Disable user request level
   - Disable user operation level
   - Assign roles request level
   - Assign roles operation level
   - Remove roles request level
   - Remove roles operation level
   - Create role request level
   - Modify role request level
   - Delete role request level

2. Create rules in each policy based on the user login. Ensure that user login evaluation is case-sensitive. Figure 32–1 shows a sample rule.
32.3 Create Identity (SPML Core Service: addRequest)

To create an identity with user or role attributes, you implement the `addRequest` operation which supports asynchronous execution mode. Successful request submission returns a request submission tracking identifier and the request status is listed as pending.

When creating a user, you can also assign role memberships to that user by using the `addRequest` operation. To do this, you must use the SPML reference capability with `typeOfReference` set to `memberOf` and include the role GUID as PSO reference ID.

Note:
- If the username or password attributes are not provided, those attributes can be autogenerated in Oracle Identity Manage if the appropriate plug-ins are installed.
- For creating a user with a given password, provide the user password in Base64 encoded format within SPML create user payload. For example:

```xml
<pso:password>
  <pso:value>V2VsY29tZTc=</pso:value>
</pso:password>
```

You can use any standard Java library to obtain the Base64 encoded value for a string. An example of such a library is Apache commons library - `org.apache.commons.codec.binary.Base64.encodeBase64("PASSWORD").getBytes()`.
- Role created by user with SPML Admin role are autopublished to the TOP organization including its suborganizations.

Table 32–1 lists the features of identity creation with addRequest operation.
You implement the SPML `modifyRequest` service for these tasks:
- to assign or revoke role memberships from an existing user (identity)
- to modify an existing role
- to modify user attributes

Table 32–2 lists the features of role membership management with `modifyRequest` operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Asynchronous only</td>
</tr>
<tr>
<td>Input</td>
<td><code>modifyRequest</code> element as defined by [SPMLv2].</td>
</tr>
<tr>
<td></td>
<td>Use <code>modificationMode=&quot;delete&quot;</code> for deleting role membership and <code>modificationMode=&quot;add&quot;</code> for adding role membership.</td>
</tr>
<tr>
<td></td>
<td>Role memberships declared using Reference capability, with <code>typeOfReference=&quot;inheritsFrom&quot;</code> and Role GUID as PSO ID.</td>
</tr>
<tr>
<td>Output</td>
<td><code>modifyResponse</code> element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>The <code>modifyRequest</code> operation allows modifying an existing identity or existing role.</td>
</tr>
<tr>
<td></td>
<td>This operation checks for SPML execution mode for both identity and role. Invalid execution mode returns an <code>unsupportedExecutionMode</code> SPML error code.</td>
</tr>
<tr>
<td></td>
<td>If the modify request does not contain identity PSO object, or contains invalid GUIDs the operation returns <code>malformedRequest</code> or <code>invalidIdentifier</code> SPML malformed request error respectively.</td>
</tr>
<tr>
<td></td>
<td>Other runtime errors are reported using <code>customError</code> SPML custom error code.</td>
</tr>
</tbody>
</table>

32.4 Modify Users, Roles, Change Attributes and Role Memberships (SPML Core Service: `modifyRequest`)

You implement the SPML `modifyRequest` service for these tasks:
- to assign or revoke role memberships from an existing user (identity)
- to modify an existing role
- to modify user attributes

Table 32–2 lists the features of role membership management with `modifyRequest` operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Asynchronous only</td>
</tr>
<tr>
<td>Input</td>
<td><code>modifyRequest</code> element as defined by [SPMLv2].</td>
</tr>
<tr>
<td></td>
<td>Use <code>modificationMode=&quot;delete&quot;</code> for deleting role membership and <code>modificationMode=&quot;add&quot;</code> for adding role membership.</td>
</tr>
<tr>
<td></td>
<td>Role memberships declared using Reference capability, with <code>typeOfReference=&quot;inheritsFrom&quot;</code> and Role GUID as PSO ID.</td>
</tr>
<tr>
<td>Output</td>
<td><code>modifyResponse</code> element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>The <code>modifyRequest</code> operation allows modifying an existing identity or existing role.</td>
</tr>
<tr>
<td></td>
<td>This operation checks for SPML execution mode for both identity and role. Invalid execution mode returns an <code>unsupportedExecutionMode</code> SPML error code.</td>
</tr>
<tr>
<td></td>
<td>If the modify request does not contain identity PSO object, or contains invalid GUIDs the operation returns <code>malformedRequest</code> or <code>invalidIdentifier</code> SPML malformed request error respectively.</td>
</tr>
<tr>
<td></td>
<td>Other runtime errors are reported using <code>customError</code> SPML custom error code.</td>
</tr>
</tbody>
</table>
32.5 Delete an Identity or Role (SPML Core Service: deleteRequest)

You implement the SPML deleteRequest service to delete an existing role or user, as described in Table 32–3.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Asynchronous</td>
</tr>
<tr>
<td>Input</td>
<td>deleteRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>deleteResponse element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>The deleteRequest operation allows deletion of an existing identity or existing role. This operation checks for SPML execution mode for both identity and role. Invalid execution mode returns an unsupportedExecutionMode SPML error code. If the delete request does not contain identity PSO object, or contains invalid GUIDs the operation returns malformedRequest or invalidIdentifier SPML malformed request error respectively. Other runtime errors are reported using customError SPML custom error code.</td>
</tr>
</tbody>
</table>

Examples

See the example "SPML Example - Delete Role" on page 32-43.

32.6 Check Request Status (SPML Core Service: statusRequest)

The status operation enables a requestor to determine whether an asynchronous operation has:

- failed
- pending
- completed successfully

For any async operation, after the request is submitted, any errors after validation errors cannot be returned in the response. The errors, if any, are returned in the status response. If the statusRequest returns request status as failed, then the statusResponse might have some error message as well.

Table 32–4 lists the features of the statusRequest operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
</tbody>
</table>

Using SPML Services  32-7
List Available Targets (SPML Core Service: listTargets)

The SPML listTargets service enables a requestor to obtain the set of targets that a provider makes available for provisioning. The service also returns:

- the object types that each target supports
- the set of capabilities that the provider supports for each object in each target

The only target currently supported is Oracle Identity Manager; the object types that we support are all Oracle Identity Manager object types.

Table 32–5 lists the features of obtaining targets with listTargets.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>listTargetsRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>listTargetsResponse element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>Only the XML Schema profile is supported. Any another profile request results in a failure with the unsupportedProfile error code. A single, static provisioning target named Oracle Identity Manager is supported. The response is generated by inserting the PSO object schemas, the list of supported capabilities for each PSO, and the schema for the operation data capability into a listTargetsResponse element.</td>
</tr>
</tbody>
</table>

32.8 Disable a User (SPML Suspend Service: suspendRequest)

The suspend operation enables the requestor to suspend a user.

Table 32–6 lists the features of the suspendRequest operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Asynchronous</td>
</tr>
<tr>
<td>Input</td>
<td>suspendRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>suspendResponse element as defined by [SPMLv2].</td>
</tr>
</tbody>
</table>
Check if User is Active (SPML Suspend Service: activeRequest)

The activeRequest operation enables a requestor to determine whether a specified user is active or has been suspended.

Table 32–8 lists the features of the activeRequest operation.

### Table 32–8  Checking if User Has Been Suspended with activeRequest

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>activeRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>activeResponse element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>This operation requires a valid user PSO ID.</td>
</tr>
<tr>
<td></td>
<td>If the PSO identifier is invalid, the noSuchIdentifier error code is returned.</td>
</tr>
<tr>
<td></td>
<td>The activeRequest operation is applicable for users only. It returns unsupportedOperation error if the PSO object is not an identity.</td>
</tr>
</tbody>
</table>

32.9 Enable a User (SPML Suspend Service: resumeRequest)

The resumeRequest suspend service enables the requestor to resume/enable a suspended user.

Table 32–7 lists the features of the resumeRequest operation.

### Table 32–7  Re-enabling a User with resumeRequest

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Asynchronous</td>
</tr>
<tr>
<td>Input</td>
<td>resumeRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>resumeResponse element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>This operation requires a valid user PSO ID and optionally an effective resumption date.</td>
</tr>
<tr>
<td></td>
<td>If the PSO identifier is invalid, the noSuchIdentifier error code is returned.</td>
</tr>
<tr>
<td></td>
<td>The resume operation is applicable for users only. It returns unsupportedOperation error if the PSO object is not an identity.</td>
</tr>
<tr>
<td>Examples</td>
<td>See the example &quot;SPML Example - Resume User&quot; on page 32-33.</td>
</tr>
</tbody>
</table>

32.10 Check if User is Active (SPML Suspend Service: activeRequest)

The activeRequest operation enables a requestor to determine whether a specified user is active or has been suspended.

Table 32–8 lists the features of the activeRequest operation.
32.11 Validate a Username (SPML Username Service: validateUsername)

The validateUsername operation enables a requestor to determine whether a username already exists or it is reserved.

Table 32–9 lists the features of the resumeRequest operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>validateUsernameRequest element as defined by [SPMLv2]. userName is the only input parameter accepted.</td>
</tr>
<tr>
<td>Output</td>
<td>validateUsernameResponse element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>This operation takes a username and checks if the username exists.</td>
</tr>
<tr>
<td></td>
<td>Processing errors are reported with SPML customError code.</td>
</tr>
<tr>
<td>Examples</td>
<td>See the example “SPML Example - Validate User Name” on page 32-35.</td>
</tr>
</tbody>
</table>

32.12 Obtain a Username (SPML Username: suggestUsername)

The suggestUsername operation enables a requestor to obtain a valid username for a given policy.

Table 32–10 lists the features of the suggestUsername operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>suggestUsernameRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>suggestUsernameResponse element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Processing</td>
<td>This operation takes user information and uses it to construct a username based on the applicable username policy.</td>
</tr>
<tr>
<td></td>
<td>Processing errors are reported with SPML customError code.</td>
</tr>
<tr>
<td>Examples</td>
<td>See the example “SPML Example - Suggest User Name” on page 32-34.</td>
</tr>
</tbody>
</table>

32.13 Lookup an Identity or Role (SPML Core Service: lookupRequest)

The lookupRequest operation enables a requestor to lookup for a user or role in the system by using any one of entity key, user/role name, LDAP GUID, LDAP DN. Out of these, LDAP GUID and LDAP DN are applicable only in an environment for which LDAP synchronization is enabled. Lookup is supported only in synchronous mode.
Requestor can also choose to filter the response by using the returnData attribute, whose default value is everything. The returnData attribute can have the following values:

- **returnData='identifier'**: The provider returns only the identifier of a requested object.
- **returnData='data'**: The provider returns the identifier of a requested object and all the attributes associated with that object.
- **returnData='everything'**: The provider returns the identifier of a requested object, all the attributes associated with that object, and any capability data associated with the request object. For identity lookup, capability data contains the direct or indirect roles the user has. For role lookup, capability data contains the parent roles and the direct or indirect children roles.

Any user can perform the lookup by using the SPML interface. Based on authorization, the requestor can lookup user or role. If there is no appropriate authorization privilege, then error code is returned in the SPML response. Only authorized attributes on which requestor has permission to view is returned in the response.

Table 32–11 lists the features of the lookupRequest operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>lookupRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>lookupResponse element as defined by [SPMLv2].</td>
</tr>
</tbody>
</table>
The resetPasswordRequest operation enables a requestor to reset the password for a user.

Table 32–12 lists the features of the resetPasswordRequest operation.

### 32.14 Reset Password (SPML Core Service: resetPasswordRequest)

The resetPasswordRequest operation enables a requestor to reset the password for a user.

Table 32–12 lists the features of the resetPasswordRequest operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>resetPasswordRequest element as defined by [SPMLv2]. Optional notification data for controlling end user email notification.</td>
</tr>

<td>▪ “SPML Example - Reset Password” on page 32-49</td>
</tr>
<tr>
<td></td>
<td>▪ “SPML Example - Reset Password with Notification” on page 32-50</td>
</tr>
</tbody>
</table>

32.15 Lookup Username Policy (SPML Username Service: lookupUsernamePolicy)

The lookupUsernamePolicy operation enables a requestor to obtain details about the configured username policy in Oracle Identity Manager. You can also provide locale in the request to obtain details in the provided locale.

Table 32–13 lists the features of the lookupUsernamePolicy operation.

Table 32–13 Lookup Username policy details with lookupUsernamePolicy

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>lookupUsernamePolicyRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>

<tr>
<td>Processing</td>
<td>This operation returns the information about configured user name policy in Oracle Identity Manager.</td>
</tr>
<tr>
<td>Examples</td>
<td>See the example “SPML Example - Lookup User Name Policy” on page 32-51.</td>
</tr>
</tbody>
</table>

32.16 Cancel/Withdraw Request (SPML Async Service: cancelRequest)

The cancel request operation enables the requestor to withdraw the specified request ID. If the request is withdrawn successfully, then all the pending approvals are also withdrawn. Only the requester of the submitted request can withdraw it.

Table 32–14 lists the features of the cancelRequest operation.

Table 32–14 Cancel a Request with cancelRequest

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPML Execution Mode</td>
<td>Synchronous</td>
</tr>
<tr>
<td>Input</td>
<td>cancelRequest element as defined by [SPMLv2].</td>
</tr>
<tr>
<td>Output</td>
<td>cancelResponse element as defined by [SPMLv2].</td>
</tr>
</tbody>
</table>
32.17 Batch Request (SPML Batch Request Service: batchRequest)

The batch operation combines any number of individual requests into a single request as defined by SPML v2. Examples of individual requests that can be combined into a single request are creating a user Robert Klein, updating a user Terrence Hill, deleting a user John Doe, and reset password for a user Jane Doe in a single request.

Batch request does not support transactional semantics, which means that the failure of a nested request does not undo a nested request that has already been completed. Each individual response occupies the same position within the <batchResponse> that the corresponding individual request occupies within the <batchRequest>

This operation supports parallel processing only ("processing='parallel'") and runs the nested requests within the <batchRequest> in any order. When error condition occurs, it continues processing the subsequent subrequests, specified by "onError='resume'". If a request fails to be processed, then the next request is processed. If one or more of the nested requests in that batch fails, then operation returns a <batchResponse> with "status='failure'", even if some of the requests in that batch succeed.

Table 32–15 lists the features of the batchRequest operation.

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Processing</td>
<td>This operation cancels/withdraws the specified request. The runtime errors are reported by using the customError SPML custom error code.</td>
</tr>
<tr>
<td>Examples</td>
<td>See the example &quot;SPML Example - Cancel Request&quot; on page 32-51.</td>
</tr>
</tbody>
</table>

Table 32–15  Executing Batch Request with batchRequest

<table>
<thead>
<tr>
<th>Item/Feature</th>
<th>Description</th>

</table>

32.18 Securing SPML Web Services

This section explains how to secure SPML Web services. It contains these topics:

- About Web Services Security
- A Request Example
- Applying Policies

32.18.1 About Web Services Security

SPML XSD Web service uses Oracle Web Services Security Manager to provide security. SPML Web services is protected by using the following policies:
32.18.2 A Request Example

A sample Request looks like this:

```xml
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
  xmlns:ns1="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secxt-1.0.xsd" >
  <soap:Header>
    <ns1:Security>
      <ns1:UsernameToken>
        <ns1:Username>weblogic</ns1:Username>
        <ns1:Password>weblogic1</ns1:Password>
      </ns1:UsernameToken>
    </ns1:Security>
  </soap:Header>
  <soap:Body xmlns:ns1="urn:oasis:names:tc:SPML:2:0">
    <ns1:listTargetsRequest />
  </soap:Body>
</soap:Envelope>
```

32.18.3 Applying Policies

At deployment time, the administrator can use the Oracle Enterprise Manager Fusion Middleware Control Console to apply correct security policy to protect the service. Refer to the following documentation for details about using Fusion Middleware Control:

32.19 Operations Not Supported

Oracle Identity Manager 11g Release 2 (11.1.2.2.0) does not support the following SPML operations as part of the XSD profile:

- Search user
The SPML XSD Web Service uses Oracle Identity Manager as a back-end service to provide provisioning functionality to Fusion applications. A key building block of the SPML Web Service is the SPML Provisioning Service Object (PSO), which defines the object to be provisioned. Examples of PSO are identity and role.

This appendix shows the supported PSO attributes and their LDAP mappings, and explains the character restrictions on Oracle Identity Manager attributes. Finally, it describes additional operational data that the application can pass to the SPML Web Service. It contains the following sections:

- Identity PSO Attributes
- Role PSO Attributes
- Preference Attributes
- Special Character Restrictions in Oracle Identity Manage Attributes
- Operation Data

### 32.20.1 Identity PSO Attributes

Table 32–16 shows identity attributes supported by the SPML implementation in Oracle Identity Manager and how these attributes map to LDAP objects/attributes.

<table>
<thead>
<tr>
<th>SPML Attribute Name</th>
<th>Syntax</th>
<th>Description</th>
<th>LDAP Mapping (Oracle Internet Directory)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>String, Read-Only,</td>
<td>The identifier used to identify a user for modify request.</td>
<td>orclUserV2: orclguid</td>
</tr>
<tr>
<td></td>
<td>Required, Single</td>
<td></td>
<td></td>
</tr>
<tr>
<td>activeEndDate</td>
<td>Timestamp, Single</td>
<td>Termination time and date for the user</td>
<td>orclUserV2: orclActiveEndDate</td>
</tr>
<tr>
<td>activeStartDate</td>
<td>Timestamp, Single</td>
<td>Activation time and date for the user</td>
<td>orclUserV2: orclActiveStartDate</td>
</tr>
<tr>
<td>commonName</td>
<td>String, Required</td>
<td>The common names of the person, typically the person’s full name and any variations of the same.</td>
<td>person: cn</td>
</tr>
<tr>
<td>countryName</td>
<td>String, Single</td>
<td>The business country of the person, expressed as a two-letter [ISO3166] country code.</td>
<td>orclUserV2: c</td>
</tr>
<tr>
<td>departmentNumber</td>
<td>String, Single</td>
<td>Codes for the departments within an organization to which this person belongs. This can be strictly numeric or alphanumeric.</td>
<td>inetOrgPerson: departmentNumber</td>
</tr>
</tbody>
</table>

Note: The syntax column lists relevant attribute properties such as the type, required, and so on.
### SPML Attributes and LDAP Mappings, and Oracle Identity Manage Attributes

**Table 32–16  (Cont.)  Identity PSO Attributes**

<table>
<thead>
<tr>
<th>SPML Attribute Name</th>
<th>Syntax</th>
<th>Description</th>
<th>LDAP Mapping (Oracle Internet Directory)</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String, Single</td>
<td>Human-readable descriptive phrases about the person.</td>
<td>person: description</td>
</tr>
<tr>
<td>displayName</td>
<td>String, Single, MLS</td>
<td>The preferred name to use when displaying an entry for the person. Provides MultiLingual Support (MLS) and also accepts language values for locale, for example &quot;en&quot; and &quot;fr&quot;.</td>
<td>inetOrgPerson: displayName</td>
</tr>
<tr>
<td>employeeNumber</td>
<td>String, Single</td>
<td>Numeric or alphanumeric identifier assigned to a person, typically based on order of hire or association with an organization.</td>
<td>inetOrgPerson: employeeNumber</td>
</tr>
<tr>
<td>employeeType</td>
<td>String, Single</td>
<td>Identifies the type of employee. For the list of valid values see Table 32–17.</td>
<td>inetOrgPerson: employeeType</td>
</tr>
<tr>
<td>facsimileTelephoneNumber</td>
<td>String, Single</td>
<td>Telephone numbers for the person's business facsimile (FAX) terminals.</td>
<td>organizationalPerson: facsimileTelephoneNumber</td>
</tr>
<tr>
<td>generationQualifier</td>
<td>String, Single</td>
<td>Name strings that are typically the suffix part of the person's name (e.g. &quot;III&quot;, &quot;3rd&quot;, &quot;Jr.&quot;).</td>
<td>N/A</td>
</tr>
<tr>
<td>givenName</td>
<td>String, Single</td>
<td>Name strings that are part of a person's name that is not their surname (for example, first name).</td>
<td>inetOrgPerson: givenName</td>
</tr>
<tr>
<td>hireDate</td>
<td>Timestamp, Single</td>
<td>Date of hire.</td>
<td>orclUserV2: orclHireDate</td>
</tr>
<tr>
<td>homePhone</td>
<td>Single, String</td>
<td>Home telephone numbers associated with the person.</td>
<td>inetOrgPerson: homePhone</td>
</tr>
<tr>
<td>homePostalAddress</td>
<td>Single, String</td>
<td>The home postal addresses of the person.</td>
<td>inetOrgPerson: homePostalAddress</td>
</tr>
<tr>
<td>initials</td>
<td>String, Single</td>
<td>Some or all of an individual's names, except the surname(s)</td>
<td>inetOrgPerson: initials</td>
</tr>
<tr>
<td>localityName</td>
<td>Single, String</td>
<td>Names of a business locality or place, such as a city, county, or other geographic region.</td>
<td>N/A</td>
</tr>
<tr>
<td>mail</td>
<td>Single, String</td>
<td>Business Internet mail addresses of the person in Mailbox [RFC2821] form.</td>
<td>inetOrgPerson: mail</td>
</tr>
<tr>
<td>manager</td>
<td>Single, String</td>
<td>The manager of the person.</td>
<td>N/A</td>
</tr>
<tr>
<td>middleName</td>
<td>String, Single</td>
<td>The middle names of the person.</td>
<td>orclUserV2: middleName</td>
</tr>
<tr>
<td>mobile</td>
<td>Single, String</td>
<td>Mobile telephone numbers associated with the person.</td>
<td>inetOrgPerson: mobile</td>
</tr>
<tr>
<td>organization</td>
<td>String, Single</td>
<td>Name of an organization—for example, my_company.</td>
<td>organization</td>
</tr>
<tr>
<td>organizationUnit</td>
<td>String, Single</td>
<td>Name of a unit within an organization, for example, IT Support.</td>
<td>organizationalUnitName</td>
</tr>
<tr>
<td>pager</td>
<td>Single, String</td>
<td>The business pager telephone numbers of the person.</td>
<td>inetOrgPerson: pager</td>
</tr>
<tr>
<td>password</td>
<td>String, Single</td>
<td>Password of the user.</td>
<td>person: userPassword</td>
</tr>
</tbody>
</table>
Table 32–16 (Cont.) Identity PSO Attributes

<table>
<thead>
<tr>
<th>SPML Attribute Name</th>
<th>Syntax</th>
<th>Description</th>
<th>LDAP Mapping (Oracle Internet Directory)</th>
</tr>
</thead>
<tbody>
<tr>
<td>postalAddress</td>
<td>String, Single</td>
<td>Business addresses used by a Postal Service to perform services for the person.</td>
<td>organizationalPerson: postalAddress</td>
</tr>
<tr>
<td>postalCode</td>
<td>String, Single</td>
<td>Codes used by a Postal Service to identify postal service zones of the person’s business.</td>
<td>organizationalPerson: postalCode</td>
</tr>
<tr>
<td>postOfficeBox</td>
<td>String, Single</td>
<td>Postal box identifiers that a Postal Service uses when a customer arranges to receive mail at a box on the premises of the Postal Service.</td>
<td>organizationalPerson: postOfficeBox</td>
</tr>
<tr>
<td>preferredLanguage</td>
<td>String, Single</td>
<td>The preferred written or spoken language for the person. This is useful for international correspondence or human-computer interaction. Values for this attribute type MUST conform to the definition of the Accept-Language header field defined in [RFC2068] with one exception: the sequence “Accept-Language” ”:” should be omitted.</td>
<td>inetOrgPerson: preferredLanguage</td>
</tr>
<tr>
<td>state</td>
<td>String, Single</td>
<td>Full names of business states or provinces of the person.</td>
<td>organizationalPerson: st</td>
</tr>
<tr>
<td>street</td>
<td>String, Single</td>
<td>Site information from a business postal address (that is, the street name, place, avenue, and the house number) of the person.</td>
<td>organizationalPerson: street</td>
</tr>
<tr>
<td>surname</td>
<td>String, Single</td>
<td>Name strings for the family names (last name) of the person.</td>
<td>person: sn</td>
</tr>
<tr>
<td>telephoneNumber</td>
<td>String, Single</td>
<td>Business telephone number of the person.</td>
<td>organizationalPerson: telephoneNumber</td>
</tr>
<tr>
<td>title</td>
<td>String, Single</td>
<td>Title of the person in their organizational context.</td>
<td>organizationalPerson: title</td>
</tr>
<tr>
<td>username</td>
<td>String, Single</td>
<td>Computer system login names associated with the person.</td>
<td>uid</td>
</tr>
<tr>
<td>userType</td>
<td>String, Single</td>
<td>The type of user. This attribute is used to provide Design Console access to the end-users. The allowed values are true and false.</td>
<td></td>
</tr>
</tbody>
</table>

Table 32–17 shows the valid values for the `employeeType` attribute:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>

<td>Full-Time Employee</td>
</tr>
<tr>
<td>Part-Time</td>
<td>Part-Time Employee</td>
</tr>
<tr>
<td>Temp</td>
<td>Temp</td>
</tr>
<tr>
<td>Intern</td>
<td>Intern</td>
</tr>
<tr>
<td>Consultant</td>
<td>Consultant</td>
</tr>
</tbody>
</table>
Custom Identity Attributes

Custom attributes are provided to support Oracle Identity Manager functionality; these attributes are present in Oracle Identity Manager (such as when a user-defined field is added) but not in the PSO.

The custom attribute name must match the attribute name specified in the corresponding request dataset for the mapping to work end-to-end.

Here are some examples of custom attributes:

```xml
...<data>
  <pso:identity>
    <pso:attributes>
      <pso:attr name="Number Format">
        <pso:value>#,##0.##[,]</pso:value>
      </pso:attr>
      <pso:attr name="Currency">
        <pso:value>USD</pso:value>
      </pso:attr>
    </pso:attributes>
  </pso:identity>
...```

32.20.2 Role PSO Attributes

Table 32–18 lists the role attributes supported by the SPML implementation in Oracle Identity Manager and how these attributes map to LDAP objects/attributes.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>String, Read-Only, Required, Single</td>
<td>The PSO identifier that uniquely identifies a role. Usually directory GUID.</td>
</tr>
<tr>
<td>commonName</td>
<td>String, Required, MLS</td>
<td>The common name of the role.</td>
</tr>
<tr>
<td>description</td>
<td>Single</td>
<td>Human readable role description</td>
</tr>
<tr>
<td>displayName</td>
<td>String, Single, MLS</td>
<td>The preferred name to use when displaying an entry for the role.</td>
</tr>
</tbody>
</table>
32.20.2.1 Custom Role Attributes

Custom attributes are provided to support Oracle Identity Manager functionality; these attributes are present in Oracle Identity Manager but not in the PSO.

The custom attribute name must match the attribute name specified in the corresponding request dataset for the mapping to work end-to-end.

Here is an example of a custom role attribute:

```xml
<pso:attributes>
  <pso:attr name="Role Category Name">Cat1</pso:attr>
</pso:attributes>
```

Role Category Name is a special custom role attribute. It is the namespace for the roles. Each role belongs to a role category. This can be specified while creating a new role. If not specified, then the Default role category is selected. Each role category and role name uniquely identifies a role.

32.20.3 Preference Attributes

Table 32–19 lists the preference attributes supported by the SPML implementation in Oracle Identity Manager:
### Table 32-19  Preference Attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Syntax</th>
<th>Description</th>
<th>LDAP Mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number Format</td>
<td>String</td>
<td>The format to display numbers</td>
<td>orclNumberFormat</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Values are:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>#,##0.##[,.]</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>#,##0.##[\u00A0,]</td>

</table>
Special Character Restrictions in Oracle Identity Manage Attributes

This section lists character restrictions applicable to Oracle Identity Manager attributes. Failure to observe these restrictions will cause errors when performing operations with attributes.

- Characters Available in All Attributes
- Special Characters in the Password Field
- Usage of Single Quotation Mark
- Usage of Semicolon
- Unsupported Special Characters

### 32.20.4.1 Characters Available in All Attributes

Alphanumeric characters (a through z, A through Z, and 0 through 9) and the underscore character (_) can be used in all Oracle Identity Manager attributes.

### 32.20.4.2 Special Characters in the Password Field

There are no restrictions on the usage of special character in the password field. The only restriction on the special character in the password field is imposed by the applicable password policy of the user.

The user password must be provided in Base64 encoded format within SPML payload. For example:

```xml
<pso:password>
<pso:value>V2VsY29tZTc=</pso:value>
</pso:password>
```

### 32.20.4.3 Usage of Single Quotation Mark

The single quotation mark (‘) can be used only in the following attributes:

- Login
- Manager ID
- First Name
32.20.4.4 Usage of Semicolon
The semicolon (;) can be used only in access policy names.

32.20.4.5 Unsupported Special Characters
The following special characters are not supported in any Oracle Identity Manager attribute:

- Period (.)
- Number sign (#)
- Slash (/)
- Percent sign (%)
- Equal sign (=)
- Vertical bar (|)
- Plus sign (+)
- Comma (,)
- Backslash (\)
- Double quotation mark ("")
- Less than symbol (<)
- Greater than symbol (>)

32.20.5 Operation Data
Requesting application such as HCM Fusion Application will act as a SPML requestor. In addition to PSO data, the application can also pass some operational data to the SPML Web Service. This section describes how applications can pass the operation data.

- Passing Operation Data
- Passing Reference Data

32.20.5.1 Passing Operation Data
It is possible to pass a requestor ID for each operation. When the Fusion application supplies credentials in a request, that is an application ID. For auditing purposes, it is also possible to pass a requestor ID. Oracle Identity Manager audits this ID, instead of the application ID, as the actual requestor of the operation.

Along with the requestor ID, a justification for the request can also be specified.

The following is an example of the operation data:

```xml
&lt;/ps0:identity&gt;
```
32.20.5.2 Passing Reference Data
The application is also required to pass some reference data to SPML so that when a callback is received, it can be identified with the reference data for the callback in context. This is pass-through data, which is ignored by Oracle Identity Manager, but will be returned in the callback.

The following is an example that contains the <LdapRequestId>:

...  
...  
</ps:identity>  
</data>  
<capabilityData  
capabilityURI="http://xmlns.oracle.com/idm/identity/OperationData"  
mustUnderstand='true'>  
<operationData  
xmlns="http://xmlns.oracle.com/idm/identity/OperationData" requestorGUID="1" justification="i need this account">  
<LdapRequestId  
xmlns="http://xmlns.oracle.com/apps/hcm/users/ldapRequestService/">102329090340</LdapRequestId>  
</operationData>  
</capabilityData>  
</addRequest>

32.21 SPML Examples
This appendix provides the following SPML XSD examples:

- SPML Example - Add User
- SPML Example - Delete User
- SPML Example - Modify User
- SPML Example - Resume User
- SPML Example - Suggest User Name
- SPML Example - Suspend User
- SPML Example - Validate User Name
- SPML Example - Check If User is Active
- SPML Example - Lookup Username Policy
- SPML Example – Add User with Role Assignment
- SPML Example - Assign Role Membership
- SPML Example – Revoke Role Membership
SPML Examples

- SPML Example - Add Role
- SPML Example - Add Role with Parent
- SPML Example - Modify Role
- SPML Example - Add Parent to a Role
- SPML Example - Role Grant
- SPML Example - Delete Role
- SPML Example - Status Request
- SPML Example - Identity/Role Lookup
- SPML Example - Reset Password
- SPML Example - Reset Password with Notification
- SPML Example - Lookup User Name Policy
- SPML Example - Cancel Request
- SPML Example - Batch Request

32.21.1 SPML Example - Add User

The Request is as follows:

```xml
  <!--Zero or more repetitions:-->
  <data>
    <!--You have a CHOICE of the next 3 items at this level-->
    <pso:identity>
      <!--Optional:-->
      <pso:attributes>
        <!--Here, We are trying to set OIM Organization (act_key) -->
        <pso:attr name="oimOrganization">
          <pso:value>3</pso:value>
        </pso:attr>
        <!--Here, My Attribute is a UDF, with 'My Attribute' also added in CreateUserDataset.xml -->
        <pso:attr name="My Attribute">
          <pso:value>New Value</pso:value>
        </pso:attr>
        <!--Optional:-->
        <pso:activeEndDate>2009-06-12T00:00:00</pso:activeEndDate>
        <!--Optional:-->
        <pso:activeStartDate>2009-06-11T00:00:00</pso:activeStartDate>
        <pso:commonName>
          <pso:values>
            <pso:value>CommonName</pso:value>
          </pso:values>
        </pso:commonName>
        <pso:values>
          <pso:countryName>India</pso:countryName>
        </pso:values>
        <pso:values>
          <pso:departmentNumber>123456</pso:departmentNumber>
        </pso:values>
      </pso:attributes>
    </pso:identity>
</data>
</addRequest>
```
<!--Optional:-->
<ps:o:mail>
<ps:o:value>jdong12@mycompany.com</ps:o:value>
</ps:o:mail>
<!--Optional:-->
<ps:o:middleName>MiddleName</ps:o:middleName>

The Add User Response sample if multiple values are passed for attributes that accept only single value:

    <ns3:errorMessage>The attribute commonName is not multi-language enabled in OIM. Only the value John Smith will be saved.</ns3:errorMessage>
    <ns3:errorMessage>The attribute organization is not multi-language enabled in OIM. Only the value 1 will be saved.</ns3:errorMessage>
</ns3:addResponse>
32.21.2 SPML Example - Delete User

The Request is as follows:

```xml
<deleteRequest xmlns="urn:oasis:names:tc:SPML:2:0"
    xmlns:pso="http://xmlns.oracle.com/idm/identity/PSO" executionMode="asynchronous"
    locale="en" policyURI="http://www.sample.com/string/string"
    requestID="string" returnData="identifier" targetID="string">
    <psoID ID="identity:6C9B96E99FC8DC32E040E50A3D5252F5" />
</deleteRequest>
```

The Response is as follows:

```xml
<ns9:ResponseType xmlns="http://xmlns.oracle.com/idm/identity/PSO"
    xmlns:ns2="urn:oasis:names:tc:SPML:2:0"
    xmlns:ns3="urn:oasis:names:tc:SPML:2:0:reference"
    xmlns:ns4="urn:oasis:names:tc:SPML:2:0:password"
    xmlns:ns5="urn:oasis:names:tc:SPML:2:0:suspend"
    xmlns:ns6="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
    xmlns:ns9="oasis:names:tc:SPML:2:0" requestID="19" status="pending"/>
```

32.21.3 SPML Example - Modify User

The Request is as follows:

```xml
<modifyRequest xmlns="urn:oasis:names:tc:SPML:2:0"
    xmlns:pso="http://xmlns.oracle.com/idm/identity/PSO" executionMode="asynchronous"
    locale="string" policyURI="http://www.sample.com/string/string"
    requestID="string" returnData="identifier">
    <capabilityData capabilityURI="urn:oasis:names:tc:SPML:2:0:reference"
        mustUnderstand="true" />
    <psoID ID="identity:6C9B96E99FC8DC32E040E50A3D5252F5" />
    <modification modificationMode="add">
        <component path="/identity" namespaceURI="http://www.w3.org/TR/xpath20" />
        <data>
            <pso:identity>
                <!--1 or more repetitions:--><pso:initials>
                    <pso:value>J S</pso:value>
                </pso:initials>
            </pso:identity>
        </data>
    </modification>
    <modification modificationMode="replace">
        <component path="/identity" namespaceURI="http://www.w3.org/TR/xpath20" />
        <data>
        </data>
    </modification>
</modifyRequest>
```

Note:

- To find the status of the add user request, see "SPML Example - Status Request" on page 32-43.
- The displayName attribute has Multiple Language Support (MLS), and language values can be specified as "en", "fr", and so on.
<data>
  <pso:identity>

  xmlns:ns6="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
  xmlns:ns9="oasis:names:tc:SPML:2:0" requestID="15" status="pending"/>

32.21.4 SPML Example - Resume User

The Request is as follows:

<resumeRequest xmlns="urn:oasis:names:tc:SPML:2:0:suspend"
  requestID='120' />
<psoID ID='6C9B96E99FC8DC32E040E50A3D5252F5' />
</resumeRequest>

The Response is as follows:

<ns9:ResponseType xmlns="urn:oasis:names:tc:SPML:2:0"
  xmlns:ns2="http://xmlns.oracle.com/idm/identity/PSO"
  xmlns:ns3="urn:oasis:names:tc:SPML:2:0:password"
  xmlns:ns4="urn:oasis:names:tc:SPML:2:0:suspend"
  xmlns:ns5="urn:oasis:names:tc:SPML:2:0:reference"
  xmlns:ns6="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
32.21.5 SPML Example - Suggest User Name

The Request is as follows:

```xml
<ns4:suggestUsernameRequest
 xmlns:ns4="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
 xmlns="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
 xmlns:ns2="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
 xmlns:ns3="http://xmlns.oracle.com/idm/identity/PSO">
  <ns2:identity>
    <ns3:givenName>
      <ns3:value>testfn</ns3:value>
    </ns3:givenName>
    <ns3:surname>
      <ns3:values>
        <ns3:value>testln</ns3:value>
      </ns3:values>
    </ns3:surname>
  </ns2:identity>
</ns4:suggestUsernameRequest>
```

The Response is as follows:

```xml
<ns9:SuggestUsernameResponseType xmlns="urn:oasis:names:tc:SPML:2:0"
 xmlns:ns2="http://xmlns.oracle.com/idm/identity/PSO"
 xmlns:ns3="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
 xmlns:ns4="urn:oasis:names:tc:SPML:2:0:reference"
 xmlns:ns5="urn:oasis:names:tc:SPML:2:0:password"
 xmlns:ns8="urn:oasis:names:tc:SPML:2:0:reference"
 xmlns:ns9="oasis:names:tc:SPML:2:0" status="success">
  <ns3:username>testfn.testln@mycompany.com</ns3:username>
</ns9:SuggestUsernameResponseType>
```

32.21.6 SPML Example - Suspend User

The Request is as follows:

```xml
<suspendRequest xmlns="urn:oasis:names:tc:SPML:2:0:suspend"
 requestID="139">
  <psoID ID="6C9B96E99FC8DC32E040E50A3D5252F5"/>
</suspendRequest>
```

The Response is as follows:

```xml
<n9:ResponseType xmlns="urn:oasis:names:tc:SPML:2:0"
 xmlns:ns2="http://xmlns.oracle.com/idm/identity/PSO"
 xmlns:ns3="urn:oasis:names:tc:SPML:2:0:password"
 xmlns:ns4="urn:oasis:names:tc:SPML:2:0:suspend"
 xmlns:ns8="urn:oasis:names:tc:SPML:2:0:reference"
 xmlns:ns9="oasis:names:tc:SPML:2:0" requestID="28" status="pending"/>
```

32.21.7 SPML Example - Validate User Name

The Request is as follows:

```xml
<validateUsernameRequest
  xmlns="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username">
  <username>testfn.testln</username>
</validateUsernameRequest>
```

The Response is as follows:

```xml
<ns9:ValidateUsernameResponseType xmlns="urn:oasis:names:tc:SPML:2:0"
  xmlns:ns2="http://xmlns.oracle.com/idm/identity/PSO"
  xmlns:ns3="urn:oasis:names:tc:SPML:2:0:password"
  xmlns:ns4="urn:oasis:names:tc:SPML:2:0:reference"
  xmlns:ns5="urn:oasis:names:tc:SPML:2:0:async"
  xmlns:ns6="urn:oasis:names:tc:SPML:2:0:header"
  xmlns:ns7="urn:oasis:names:tc:SPML:2:0:suspend"
  xmlns:ns9="oasis:names:tc:SPML:2:0" valid="true" status="success"/>
```

32.21.8 SPML Example - Check If User is Active

The request is as follows:

```xml
<activeRequest xmlns="urn:oasis:names:tc:SPML:2:0:suspend" requestID="143">
  <psoID ID="5" targetID="string"/>
</activeRequest>
```

The Response is as follows:

```xml
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<ns4:ResponseType xmlns="urn:oasis:names:tc:SPML:2:0"
  xmlns:ns2="urn:oasis:names:tc:SPML:2:0:suspend"
  xmlns:ns3="http://xmlns.oracle.com/idm/identity/PSO"
  xmlns:ns4="oasis:names:tc:SPML:2:0"
  xsi:type="ns2:ActiveResponseType" active="true" requestID="143"
  status="success"/>
```

32.21.9 SPML Example - Lookup Username Policy

The Request is as follows:

```xml
<lookupUsernamePolicyRequest
```

The Response is as follows:
<ns9:LookupUsernamePolicyResponseType
xmlns="urn:oasis:names:tc:SPML:2:0"
xmlns:ns2="http://xmlns.oracle.com/idm/identity/PSO"
xmlns:ns3="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
xmlns:ns4="urn:oasis:names:tc:SPML:2:0:reference"
xmlns:ns5="urn:oasis:names:tc:SPML:2:0:async"
xmlns:ns6="urn:oasis:names:tc:SPML:2:0:password"
xmlns:ns7="urn:names:spml:ws:header"
xmlns:ns8="urn:oasis:names:tc:SPML:2:0:suspend"
xmlns:ns9="oasis:names:tc:SPML:2:0" status="success"
><ns3:description>Generates user name based on email id if it is available, else if first name is present then <first name>.<last name>@<domain>, else <last name>@<domain></ns3:description></ns9:LookupUsernamePolicyResponseType>

**Note:** To view policy description in a specific locale, you can set locale attribute in the payload. If this locale is not supported, then by is displayed in the server locale by default, as shown:

```xml
<lookupUsernamePolicyRequest locale="th"
```

### 32.21.10 SPML Example – Add User with Role Assignment

The Request to create user (identity) is as follows:

**Note:**

- There can only be one toPsoID element under a reference element. For multiple roles, individual reference element must be used.
- The GUID must be of 32 characters for all requests.

```xml
<addRequest
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns="urn:oasis:names:tc:SPML:2:0"
xmlns:spml="urn:oasis:names:tc:SPML:2:0"
executionMode="asynchronous"
policyURI="create_identity_policy_prc02.xml">
<spml:data xsi:type="spml:PSOType">
<identity
xmlns="http://xmlns.oracle.com/idm/identity/PSO"
xmlns:pso="http://xmlns.oracle.com/idm/identity/PSO">
<pso:commonName>
<pso:values>
<pso:value>John Doe</pso:value>
</pso:values>
</pso:commonName>
<pso:displayName>
<pso:values>
<pso:value>John Doe</pso:value>
</pso:values>
</pso:displayName>
<pso:givenName>
<pso:values>
<pso:value>John</pso:value>
</pso:values>
</pso:givenName>
```

    </reference>
</spml:capabilityData>
</addRequest>

The Response is as follows:
<spml:addResponse
    xmlns:spml="urn:oasis:names:tc:SPML:2:0"
    status="pending"
    requestID="10821"/>

The Add User with Role Assignment response sample containing partial invalid roles is as follows:
<env:Envelope xmlns:env="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:ns3="http://xmlns.oracle.com/idm/identity/PSO"
    xmlns:ns2="http://xmlns.oracle.com/idm/identity/PSO"
    xmlns:ns4="urn:oasis:names:tc:SPML:2:0:suspend"
    xmlns:ns5="http://xmlns.oracle.com/idm/identity/spmlv2custom/Username"
32.21.11 SPML Example - Assign Role Membership

The Request example is as follows:

```xml
<modifyRequest
xmlns="urn:oasis:names:tc:SPML:2:0"
xmlns:pso="http://xmlns.oracle.com/idm/identity/PSO"
executionMode="asynchronous"
locale="en"
policyURI="gant_role_01">
<psoID ID="identity:6C9B96E99FC8DC32E040E50A3D5252F5" />
<modification modificationMode="add">
<capabilityData
capabilityURI="urn:oasis:names:tc:SPML:2:0:reference"
mustUnderstand="true">
<reference
typeOfReference="memberOf">
<toPsoID ID="6C9B96E99FC8DC32E040E50A3D5252F5" />
</reference>
</reference>
</capabilityData>
</modification>
</modifyRequest>
```

The Response example is as follows:

```xml
<spml:modifyResponse
xmlns:spml="urn:oasis:names:tc:SPML:2:0"
status="pending"
requestID="10822"/>
```

32.21.12 SPML Example – Revoke Role Membership

The Request is as follows:

Note: only those roles can be granted to users via SPML Add Role Membership that are:

- Either published to the TOP organization with hierarchy, OR
- Published to at least one member organization of the user to whom the role is to be granted via SPML

All other role grant attempts via SPML will fail authorization checks. These roles must be explicitly published to relevant organizations by using the UI or APIs to let SPML Role grant work.
<modifyRequest xmlns="urn:oasis:names:tc:SPML:2:0" xmlns:pso="http://xmlns.oracle.com/idm/identity/PSO" executionMode="asynchronous" locale="en" policyURI="revoke_role_01">
  <psoID ID="identity:6C9B96E99FC8DC32E040E50A3D5252F5" />
  <modification modificationMode="delete">
    <capabilityData capabilityURI="urn:oasis:names:tc:SPML:2:0:reference" mustUnderstand="true">
      <reference xmlns="urn:oasis:names:tc:SPML:2:0:reference" typeOfReference="memberOf">
        <toPsoID ID="6C9B96E99FC8DC32E040E50A3D5252F5" />
      </reference>
    </capabilityData>
  </modification>
</modifyRequest>

The Response is as follows:

<spml:modifyResponse xmlns:spml="urn:oasis:names:tc:SPML:2:0" status="pending" requestID="10826"/>

32.21.13 SPML Example - Add Role

The Request is as follows:

<addRequest xmlns="urn:oasis:names:tc:SPML:2:0" xmlns:pso="http://xmlns.oracle.com/idm/identity/PSO" executionMode="asynchronous" locale="en_us" policyURI="Role Creation" requestID="string" returnData="identifier" targetID="string">
  <!--Zero or more repetitions:-->  
  <capabilityData capabilityURI="urn:oasis:names:tc:SPML:2:0:reference" mustUnderstand="true" />
  <data>
    <!--You have a CHOICE of the next 3 items at this level-->  
    <pso:role>
      <pso:attributes>
        <pso:attr name="Role Category Name">
          <!-- pso:value>OIM Roles</pso:value-->
          <pso:value>Default</pso:value>
        </pso:attr>
      </pso:attributes>
      <pso:commonName>
        <!--1 or more repetitions:-->  
        <pso:values>
          <!--1 or more repetitions:-->  
          <pso:value>TempAdmin</pso:value>
        </pso:values>
      </pso:commonName>
      <pso:description>
        <!--1 or more repetitions:-->  
        <pso:values>
          <!--1 or more repetitions:-->  
          <pso:value>Temporary Administrator</pso:value>
        </pso:values>
      </pso:description>
    </pso:role>
  </data>
</addRequest>
32.21.14 SPML Example - Add Role with Parent

The Request is as follows:

```xml
<addRequest xmlns="urn:oasis:names:tc:SPML:2:0"
xmlns:pso="http://xmlns.oracle.com/idm/identity/PSO" executionMode="asynchronous"
locale="en" policyURI="http://www.sample.com/string/string"
requestID="string" returnData="identifier" targetID="string">
  <data>
    <!--You have a CHOICE of the next 3 items at this level-->
    <pso:role>
      <!---1 or more repetitions:-->
      <pso:values>
        <!--1 or more repetitions:-->
        <pso:value>TempAdmin</pso:value>
      </pso:values>
    </pso:role>
    <!--1 or more repetitions:-->

```
32.21.18 SPML Example - Delete Role

The Request is as follows:

  <psoID ID="role:6C9B96E99FC8DC32E040E50A3D5252F5" />
</deleteRequest>

The Response is as follows:

32.21.19 SPML Example - Status Request

The Request is as follows:

<statusRequest xmlns="urn:oasis:names:tc:SPML:2:0:async" requestID="3456563" asyncRequestID="75779" />

The Response is as follows:

<statusResponse xmlns="urn:oasis:names:tc:SPML:2:0:async" requestID="3456563" status="success">
  <addResponse requestID="75779" status="pending" />
</statusResponse>

Another Request is as follows:

<statusRequest xmlns="urn:oasis:names:tc:SPML:2:0:async" requestID="12" asyncRequestID="1" returnResults="true" />
Here, returnResults=true. Therefore, the response will have all the attributes of the request.

The Response is as follows:

```xml

This part contains chapters that describe the notification service and callback service. It contains the following chapters:

- Chapter 34, "Developing Notification Events"
- Chapter 35, "Using the Callback Service"
This chapter describes how to develop notification events. It contains the following sections:

- Notification Concepts
- Developing Custom Notification

### 34.1 Notification Concepts

For developing custom notification for various operations in Oracle Identity Manager, the notification engine supports creation of notification events and notification templates.

An event is an operation that occurs in Oracle Identity Manager, such as user creation, request initiation, or any custom event created by the user. The events are generated as part of business operations or via generation of errors. Event definition is the metadata that describes the event. To define metadata for events, it is important to identify all event types supported by a functional component. For example, as a part of the scheduler component, metadata can be defined for scheduled job execution failed and shutting down of the scheduler. Every time a job fails or the scheduler is shut down, the events are raised and notifications associated with that event are sent.

Notification templates are associated to specific events. The templates are used for defining the format of the notification. Oracle Identity Manager provides predefined or default notification templates. In addition, you can create new notification templates.

For some events, Oracle Identity Manager sends notification by default. For example, when a user is created without username and password through UI or reconciliation, the login credentials are notified to the user and user’s manager.

You can define new notification events by using notification APIs and resolver class, as described in the subsequent sections. The following are examples of custom notification requirements:

- A user is assigned to a role. The user and role owner are to be notified.
- A user is assigned with a new application instance, which is financially significant, as part of reconciliation. The application instance owner and compliance officer is to be notified for prospective rogue attempts.
34.2 Developing Custom Notification

Developing custom notification is described in the following sections:

■ Building the Notification Logic
■ Creating Plug-in Pack Containing the Resolver Class
■ Building the Invocation Logic
■ Configuring the Notification Service

34.2.1 Building the Notification Logic

Building the notification login involves defining the event metadata XML and creating
the Resolver class, as described in the following sections:

■ Defining Event Metadata
■ Creating the Resolver Class
■ Creating the plugin.xml File

34.2.1.1 Defining Event Metadata

Corresponding to each event, you must create an XML file that has the specific schema
defined by the notification engine. Compliant to that schema (.xsd file), an XML file is
created that defines how an event looks like. When the event is defined, you can
configure a notification template for that event.

An event file must be compliant with the schema defined by the notification engine,
which is NotificationEvent.xsd. The event file contains basic information about the
event.

---

**Note:** The NotificationEvent.xsd file is in the
iam\iam-product\features\notification\metadata directory in the
MDS.

---

The following is a sample event XML file:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<Events xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation=" ../../../metadata/NotificationEvent.xsd">
  <EventType name="User Created">
    <StaticData>
      <Attribute DataType="X2-Entity" EntityName="User" Name="Granted User"/>
      <Attribute DataType="X2-Entity" EntityName="User" Name="Grantee User"/>
      <Attribute DataType="91-Entity" EntityName="User Group" Name="User Grp"/>
    </StaticData>
    <Resolver class="oracle.iam.notification.DemoResolver">
      <Param DataType="91-Entity" EntityName="Resource" Name="ResourceInfo"/>
    </Resolver>
  </EventType>
</Events>
```

The event XML file has the following elements:

■ **EventType name:** The name of the event that will be available while creating
  notification templates for the event.
- **StaticData:** The list of static parameters. This set of parameters specifically let the user add parameters that are not data dependent. In other words, this element defines the static data to be displayed when notification template is to be configured. For instance, the user entity is not data dependent, and when resolved, has the same set of attributes for all the event instances and notification templates.

- **Param DataType:** The list of dynamic parameters. This set of parameters specifically let the user add parameters that are data dependent. For instance, the Resource entity is data dependent. Corresponding to this field, a lookup is displayed on the UI. When the user selects the resource object, the call goes to the Resolver class provided to get the fields that are shown in the tree from which user can select the attribute to be used on the template.

---

**Note:** Available data is the list of attributes that can be embedded as a token in the template. These tokens are replaced by the value passed by the resolver class at run time. See step 7 of "Creating a Notification Template" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager for an example of a token.

Available data is displayed in a drop-down list while creating a notification template, as described in "Creating a Notification Template" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

Selected data is a single attribute that helps user to copy and paste the attribute name in a notification template. Selected data is the same attribute name as selected in the Available Data list.

---

The dynamic entities supported for lookup are user, resource, and organization. These entity names must be specified in the Param DataType element.

---

**Note:** The `<Param DataType>` element is not a mandatory element. However, when it is used, the entity names must be specified as User, Resource, or Organization.

---

- **Resolver class:** The Resolver class must be defined for each notification. It defines what parameters are available in the notification creation screen and how those parameters are replaced when the notification is to be sent. In other words, the resolver class resolves the data dynamically at run time and displays the attributes in the UI. See “Creating the Resolver Class” on page 34-4 for information about implementing the resolver class.

Notification service reads the custom event XML files from the META-INF directory of a plug-in.

The recommended way to use the event XML is by placing it in a plugin’s META-INF directory. The structure of the custom notification event plug-in is:

- The lib/ directory
  - Notification_Resolver.jar
- The META-INF directory
  - Notification_Event.xml
- plugin.xml
See "Developing Plug-ins" on page 27-1 for detailed information about creating the plug-in JAR and deploying it by using the Plugin Registration Utility.

34.2.1.2 Creating the Resolver Class
All classes have to implement the NotificationEventResolver interface. This interface provides the following methods:

The getAvailableData Method
public List<NotificationAttribute> getAvailableData(String eventType, Map<String, Object> params);

This API returns the list of available data variables. These variables are available on the UI while creating or modifying the templates and allows the user to select the variables so that they can be the part of the messages on the template.

The eventType parameter specifies the event name for which the template is to be read.

The params parameter is the map that has the entity name and the corresponding value for which available data is to be fetched. For instance:

map.put("Resource", "laptop");

This helps you fetch the fields associated with the laptop resource or other data according to the code that you have provided in the resolver class.

Sample code:

```java
/**
 * this is a dummy implementation and uses hardcoded values
 * Implementors need to iterate the XML as found through the event type
 * params : will have all the specific values that your resolver needs
 * for instance resource name = 'laptop' that you may want here to be resolved
 * through your custom implementation
 */

List<NotificationAttribute> list = new ArrayList<NotificationAttribute>();
NotificationAttribute subatr = new NotificationAttribute();
subatr.setName("Dynamic1"); subatr.setType("91-Entity");
subatr.setEntityName("Resource"); subatr.setRequired(false);
subatr.setSearchable(true); subatr.setSubtree(lookup91EntityMetaData("resource"),
params.get(0)); list.add(subatr);
```

The main tree contains the entity information and the subtree contains all the nodes that are available on the UI. The name field from each node in the subtree is available on the UI for selection.

The getReplacedData Method
HashMap<String, String> getReplacedData(String eventType, Map<String, Object> params);

This API returns the resolved value of the variables present on the template at run time when notification is being sent.

The eventType parameter specifies the event name for which the template is to be read.

The params parameter is the map that has the base values, such as usr_key and obj_key, required by the resolver implementation to resolve the rest of the variables in the template.
Sample code:

```java
HashMap<String, Object> resolvedData = new HashMap<String, Object>();
resolvedData.put("shortDate", new Date()); resolvedData.put("longDate", new Date());
String firstName = getUserFirstname(params.get("usr_key"));
resolvedData.put("fname", firstName); resolvedData.put("lname", "lastname");
resolvedData.put("count", "1 million");
return resolvedData;
```

**Example: Creating a Custom Resolver Class**

Consider the example of Oracle Identity Manager sending email notification to the user who has been added as a proxy. If the requirement is to change the date format in the notification email, then create a new resolver class file, such as AddProxyResolverModified, for notification while adding a proxy. The following is the code for the AddProxyResolverModified resolver class:

```java
package oracle.iam.selfservice.notification;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import java.util.Date;
import java.util.logging.Level;
import java.text.ParseException;
import java.text.SimpleDateFormat;
import static oracle.iam.identity.utils.Constants.PROXY_START_DATE;
import static oracle.iam.identity.utils.Constants.PROXY_END_DATE;
import static oracle.iam.identity.utils.Constants.PROXY_ORIGINAL_USR_NAME;
import static oracle.iam.identity.utils.Constants.PROXY_ORIG_USER_LOGIN;
import static oracle.iam.identity.utils.Constants.FIRSTNAME;
import static oracle.iam.identity.utils.Constants.LASTNAME;
import oracle.iam.notification.impl.NotificationEventResolver;
import oracle.iam.notification.vo.NotificationAttribute;
public class AddProxyResolverModified implements NotificationEventResolver {
  public List<NotificationAttribute> getAvailableData(String eventType, Map<String, Object> params) throws Exception {
    return null;
  }
  
  public HashMap<String, Object> getReplacedData(String eventType, Map<String, Object> params) throws Exception {
    SimpleDateFormat sdfSource = new SimpleDateFormat("MMMM DD,yyyy HH:mm:ss a z");
    SimpleDateFormat sdfDestination = new SimpleDateFormat("EEE, d MMM yyyy HH:mm:ss Z");
    Date sdate = null;
    Date edate = null;
    HashMap<String, Object> resolvedData = new HashMap<String, Object>();
    resolvedData.put("firstName",params.get(FIRSTNAME));
    resolvedData.put("lastName",params.get(LASTNAME));
    resolvedData.put("originalusername",params.get(PROXY_ORIG_USER_LOGIN));
    String proxy_startDate = (String )params.get(PROXY_START_DATE);
    System.out.println("proxy_startDate : "+proxy_startDate);
    return resolvedData;
  }
}
```
Developing Custom Notification

34.2.1.3 Creating the plugin.xml File

The plugin.xml file is a standard XML file used by the plug-in framework. If any feature uses plug-ins, then it exposes a plug-in point. This XML has the information of plug-in point.

For notification event and resolver plug-in, the exposed plug-in point is:

oracle.iam.notification.impl.NotificationEventResolver

Sample plugin.xml for Notification event and resolver is:

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<oimplugins
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<plugins pluginpoint="oracle.iam.notification.impl.NotificationEventResolver">
<plugin pluginclass="gov.hhs.notification.resolver.SendChallengeQuestionsResolver" version="1.0" name="Challenge Question Resolver" />
</plugins>
</oimplugins>
```

34.2.2 Creating Plug-in Pack Containing the Resolver Class

After creating the Resolver class, you must package it into a plug-in JAR file, and deploy the JAR file by using the Plug-in Registration Utility. See “Developing Plug-ins” on page 27-1 for detailed information about creating the plug-in JAR and deploying it by using the Plugin Registration Utility.

34.2.3 Building the Invocation Logic

After building the notification logic by defining event metadata XML and creating the Resolver class, you can call the notification logic at a specific operation in Oracle Identity Manager. This is achieved by using event handlers.

The invocation logic for the notification is built as a custom event handler. The custom event handler is then configured at the right stage in the relevant operation. The custom event handler is then deployed by using the Plugin Registration Utility. See "Developing Event Handlers" on page 28-1 for details about developing event handlers.
34.2.4 Configuring the Notification Service

You have the following options for creating the infrastructure-level configuration for notification:

- **Notification Configuration in Oracle Identity Manager**: In Oracle Identity Manager, notification configurations are handled via notification providers. UMS is the default notification provider. For information about notification providers, see "Managing Notification Providers" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager*.

- **Notification Configuration in BPEL workflow**: SOA exposes notification service, which can be called in BPEL workflow for notification. For information about SOA email notification, see "Configuring SOA Email Notification" in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager*.

---

**Note:** You can configure e-mail definitions for using in provisioning processes by using the Email Definition Form in the Design Console. See "Email Definition Form" on page 5-1 for details.
Using the Callback Service

The callback service invokes deployment-specific logic at predetermined points during Oracle Identity Manager event processing. Callback service is described in the following sections:

- Introducing the Callback Service
- Mapping Oracle Identity Manager Attributes
- Sending Event Callbacks
- Configuring the Callback Service
- Troubleshooting the Callback Service

35.1 Introducing the Callback Service

The callback service triggers notifications and callbacks that allow external applications to perform some action as a part of Oracle Identity Manager event processing. For example, if a user is created by using Oracle Identity Manager, an external application that is registered to be apprised of that type of provisioning event will be notified, and therefore, the application can add the same user information to their own local data store. This is a notification. Notifications allow applications to sync changes and data.

Note: A Web service endpoint for the external application must be registered in the Callback Service configuration. See “Configuring the Callback Service” on page 35-8 for more information.

When an external application initiates the user provisioning event with Oracle Identity Manager, other external applications that are registered to be apprised of that type of provisioning event are contacted by Oracle Identity Manager. If Oracle Identity Manager itself is invoked by the external application as part of the provisioning process, then the notification is referred to as a callback. Therefore, a callback is simply notification of an external application followed by a callback to Oracle Identity Manager. Callbacks sync up information about an event between all registered parties and Oracle Identity Manager. A callback can also indicate success or failure status for the event.

Note: The callback service infrastructure handles both callbacks and notifications. In this document, callbacks is used to refer to both.
There are a number of callback types handled by the callback service. They include:

- **Post-processing callbacks** that are returned to external applications. For example, a request to provision a user profile in the configured Oracle Identity Manager data store is sent from an external application to Oracle Identity Manager as a Web service call. The profile is created and a post-processing callback is returned to the application to confirm the profile creation. These callbacks can be synchronous or asynchronous depending on the Oracle Identity Manager configuration.

- **Status change callbacks** are sent to interested parties when there is any change in the request status. For example, if the status of a user provisioning request is changed to completed or failed, or a request status change is recognized because of a Segregation of Duties (SoD) check, then a status change callback is sent.

---

**Note:** This functionality was previously referred to as a completion callback.

---

- **Callback responses** are generated by third parties and communicate to Oracle Identity Manager that a response to a post-processing callback will be returned. This Callback Response Service is manually configured as documented in “Configuring the Callback Service” on page 35-8.

The callback service is built to invoke callbacks for events from any source including a user interface, Oracle Identity Manager request API or Service Provisioning Markup Language (SPML) client. It is a listener service that receives responses to asynchronous client callbacks. When a client Web service is invoked, Oracle Identity Manager generates a unique identifier and sends it along with the call. When the client responds back, it must use this identifier to correlate the response with the original Web service request. The callback service takes appropriate action based on the client response. The following sections contain additional information regarding the components of the Callback Service:

- **Using Callbacks**
- **Understanding Event Processing**
- **Retrying Callbacks**

### 35.1.1 Using Callbacks

This section describes a use case for Oracle Identity Manager callbacks. This use case is specific to Segregation of Duties (SoD) status change notifications. The use case concerns James North, an existing user and member of the POApprover role. James is requesting two additional roles: the POCreator and Buyer. The request goes through the following process:

1. Oracle Identity Manager receives the request and creates an Assign Roles request with an ID of 21.
   
   A *Request ID* is a unique identifier generated by Oracle Identity Manager and used to correlate the request with future responses and communications.

2. Oracle Identity Manager initiates an SoD validation with Oracle Applications Access Control Governor (OAACG).

3. The Oracle Identity Manager request status changes and a callback is returned to the callbacks-registered Web services indicating SoD Check in Progress. The callback contains the request ID, the requested operation (MODIFY), the target type (IDENTITY), the targetGUID (JNORTH) and the locale (en_US).
4. OAACG returns an Approved with Conditions response indicating the Buyer role is acceptable but the POCreater role is in violation due to James’ existing POApprover role.

5. The Oracle Identity Manager request status changes and a second callback is sent to the callbacks-registered Web services indicating an SoD Remediation In Progress. It contains the same identification information as the previous callback.

6. A TAG named CFOOVERRIDE is placed in the rejection notes, indicating the Chief Financial Office (CFO) can approve this violation in selective cases.

You must configure OBR rules to invoke an exception approval if any tag is placed with the rejection notes that uses ‘OVERRIDE’ at the end.

7. AMX Rules decipher the tag and determine that CFO approval is required so that the task is assigned to the person with title ‘CFO’.

8. The CFO either approves the request, or rejects it.
   a. If the request is rejected, then the Oracle Identity Manager request status changes and a third callback is returned as SoD Remediation Rejected. The Oracle Identity Manager request is then closed with the SoD Remediation Rejected status.

   **Note:** If one portion of the request is rejected, then the entire request is rejected. Therefore, in this example, although the Buyer role does not have an SoD violation, it is not provisioned to the user.

   b. If the request is approved, then the Oracle Identity Manager request status changes and a third callback is returned as SOD Remediation Approved. The Oracle Identity Manager request is updated with the SOD Remediation Approved status. OAACG and requesting application is notified of the approval, and the roles are provisioned.

9. When the Oracle Identity Manager request status changes to Request Completed, then a final callback is sent to all the callbacks-registered Web services indicating that the request is completed with the Request Completed status.

### 35.1.2 Understanding Event Processing

Figure 35–1 illustrates how an event is processed. Oracle Identity Manager uses asynchronous invocation, giving the calling applications flexibility to process the event as needed, such as starting a human approval workflow.
For this release, the callback service supports a handler and a plugin event. They are:

- **Post-processing Handler**: Invoked after the provisioning event is processed but before the request is marked as complete. The default post-processing handler will invoke multiple callbacks based on the callback service configuration.

- **Status Change Plugin**: Invoked when there is any change in the request status; for example, if the status of a user provisioning request is changed to completed or failed, or a request status change is recognized due to a Segregation of Duties (SoD) check, then a status change callback will be sent. The default Status Change Plugin may invoke multiple callbacks based on the callback service configuration.

### 35.1.3 Retrying Callbacks

The callback service retries callbacks if there are network errors when invoking a service. Oracle Identity Manager retries the callback a fixed three times after a fixed five second interval. These values are not configurable.

### 35.2 Mapping Oracle Identity Manager Attributes

The names of attributes used by Oracle Identity Manager are proprietary. For example, a third-party application may refer to a user's last name as *surname* while Oracle Identity Manager uses *Last Name*. Because of this, attribute mapping is essential.

**Note:** The callback service uses the same attributes defined by the Service Provisioning Markup Language (SPML) layer of Oracle Identity Manager. These are referred to (singularly) as a SPML Provisioning Service Object (PSO). See "SPML Attributes and LDAP Mappings, and Oracle Identity Manage Attributes" on page 32-16 for details.

Mapped attribute names are used in messages sent as well as in callback configuration (particularly, in the ConstraintAttribute parameter). Table 35–1 defines how Oracle Identity Manager user type attributes are represented in callbacks using SPML PSOs.

Table 35-2 defines how Oracle Identity Manager role type attributes are represented in callbacks using SPML PSOs.
If the attribute name is not in either of these tables, it is referenced by its Oracle Identity Manager attribute.

### 35.3 Sending Event Callbacks

By default, callbacks are enabled (sent) for all Oracle Identity Manager events listed in EventHandlers.xml, the handler invoked by the Orchestration Engine during the post-processing stage of the provisioning process. Each event specifies the applicable entity type and operation. Specific callbacks may be disabled by changing the configuration. Table 35–3 summarize the user and role events for which Oracle Identity Manager makes callbacks and the information returned with the callback.

#### Table 35–2  **Oracle Identity Manager / Callback Service Role Attribute Mapping**

35.4 Configuring the Callback Service

Configuration of the callback service specifies how and when one or more callbacks are invoked. The following sections contain information on the configuration file and the procedure to import this file to the Metadata Services repository.

- Understanding CallbackConfiguration.xml
- Importing CallbackConfiguration.xml
- Adding the OIM.DefaultTenantGUID System Property

35.4.1 Understanding CallbackConfiguration.xml

The configuration is stored in a single file called CallbackConfiguration.xml. This configuration file is located in the Oracle Identity Manager meta directory repository. It is used by the default event handlers and validation plug-in. The following parameters are configurable:

- **Policy name**: Defines the name of the callback policy. The value comes from the provisioning request. This is unique to Oracle Identity Manager and takes a string value.
- **Entity type**: Refers to the entity type for which the callback policy is applicable. It is a required, single value. Possible values are User, Role, and RoleUser.
- **Operation**: Refers to the database operations for which the callback policy is applicable. The required value may be either Create or Delete.
- **Description**: Takes a localized string that is a description of the policy.
- **ConstraintAttribute** and **ConstraintAttributeValue**: Fields specify a simple constraint that allows handlers and plug-in code to decide whether to invoke the particular callback for the given object. The attribute will be searched for in the entity data available to the handler, either in the form of orchestration data or RequestData. If the data does not exist, the constraint will not apply.
  - **ConstraintAttribute**: Takes as a value the name of an attribute on which the constraint is specified. The name must be the attribute name as defined on the application side as opposed to the name defined on the Oracle Identity Manager side. See "Mapping Oracle Identity Manager Attributes" on page 35-4 for more information.
  - **ConstraintAttributeValue**: Takes a value equal to the value the ConstraintAttribute must have. The value here must be the same as the value of the ConstraintAttribute present in the orchestration or request data. If the data has multiple values, at least one must match. This parameter is relevant only when ConstraintAttribute itself has a value.

### Table 35–3 (Cont.) Callback Initiated Events

<table>
<thead>
<tr>
<th>Entity / Operation</th>
<th>Event Initiator</th>
<th>Returned in Post-Processing Handler</th>
<th>Returned in Status Change Plugin Callback</th>
</tr>
</thead>
</table>
| Role Delete        | All sources: third party requests, the console and through a reconciliation event. | ■ Target Type  
■ Target GUID  
■ Operation  
■ Request ID | ■ OIM Request Status  
■ Target Type  
■ Target GUID  
■ Operation  
■ Request ID |

- Role Delete: All sources: third party requests, the console and through a reconciliation event.
Configuring the Callback Service

Note: ConstraintAttribute and ConstraintAttributeValue are not multi-valued attributes in the callback policies. Therefore, you can provide only one constraintAttribute and constraintAttributeValue attribute for each callback policy. If you specify multiple constraintAttribute and constraintAttributeValue in a single callback policy, then the callback will be triggered even if all the constraints do not match.

- **Tenant GUID:** Indicates the tenant GUID to which a callback policy is applicable in the multi-tenant (MT) mode of Oracle Identity Manager. The callback URLs for different policies in the MT mode are different, and therefore, the tenant GUID must be specified to uniquely identify the tenant to which the callback is to be sent. An example of the usage of this tag is `<tenantGUID>202</tenantGUID>`. This tag is not used in the non-MT mode.

- **Provisioning Steps:** Specifies the orchestration step for which this callback policy should be used. Possible values are:
  - validation
  - preProcessing
  - approval
  - postProcessing
  - completion

- **stepName:** Refers to a Web service endpoint for the external application.

- **description:** Takes a localized string that is a description of the Web service endpoint.

- **InvokeOnChange:** Takes as a value one or more attribute names and is applicable only to modify operations. The callback will be invoked only when one of the attributes listed as a value of this parameter has changed. The value must be the attribute name as defined on the application side as opposed to the name defined on the Oracle Identity Manager side. See “Mapping Oracle Identity Manager Attributes” on page 35-4 for more information.

- **CallbackOnly:** Specifies whether Oracle Identity Manager should wait for a response from the external application. Possible values are true or false. If true, then Oracle Identity Manager will wait for a response from the application and, until a response is received, the orchestration process will be waiting. If false, then Oracle Identity Manager will not wait for a callback response and the orchestration process will continue.

- **targetIDAttribute:** Takes as a value an attribute that should be used as the target GUID in the message. The value must be the attribute name as defined on the application side as opposed to the name defined on the Oracle Identity Manager side. See “Mapping Oracle Identity Manager Attributes” on page 35-4 for more information. The default value is LDAP GUID.

- **roleIDAttribute:** Takes as a value the role attribute that should be used as role GUID in the message. The value must be the attribute name as defined on the application side as opposed to the name defined on the Oracle Identity Manager side. See “Mapping Oracle Identity Manager Attributes” on page 35-4 for more information. The default value is LDAP GUID.

Example 35–1 is a sample configuration file.

</policy>
35.4.2 Importing CallbackConfiguration.xml

Following is the procedure to configure the callback service. It entails importing the CallbackConfiguration.xml file. This file contains list of callback policies for a given entity type or operation.

1. Create a credential entry in the Credential Store Framework (CSF) with the map name oim and key appid.keycredentials.

This entry stores the user name and password that Oracle Identity Manager will use to identify itself for callbacks. The CSF is available as part of domain creation when Oracle Identity Manager is installed.

   See Also: Oracle Fusion Middleware Security Guide for information about the Credential Store Framework

2. Import CallbackConfiguration.xml to the Metadata Services (MDS) repository using the Oracle Enterprise Manager.

   It should be loaded under the /metadata/iam-features-callbacks/sample_data/namespace.
The following should be considered when importing CallbackConfiguration.xml:

- Ensure that the CallbackConfiguration.xml file is imported to the MDS repository under the exact metadata namespace: /metadata/iam-features-callbacks/sample_data/
- Remove old CallbackConfiguration.xml files in other metadata namespaces. For example, /metadata/iam-features-callbacks/old_config/CallbackConfiguration_st3b16.xml and /metadata/iam-features-callbacks/old_config/CallbackConfiguration.xml are not valid. Remove any invalid entries found in the MDS repository using weblogicDeleteMetadata.sh.
- If modifications are made to CallbackConfiguration.xml after it has been imported, then reimport the modified file as documented and purge the Oracle Identity Manager cache by using the PurgeCache.sh utility located in the OIM_HOME/server/bin/ directory.

### 35.4.3 Adding the OIM.DefaultTenantGUID System Property

In non-MT mode of Oracle Identity Manager, the OIM.DefaultTenantGUID system property must be set with a value that works as a tenant GUID for applications that expect a value for the tenant GUID. A sample value for this is 201. Oracle Identity Manager will not send any callback if this property is not set. If the application receiving the callbacks does not expect any specific tenant GUID, then provide any random value.

See Table 5-2: Nondefault System Properties in the *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager* for information about this system property.

### 35.5 Troubleshooting the Callback Service

Table 35–4 lists the troubleshooting steps that you can perform if you encounter callback service errors:
### Table 35–4  Troubleshooting Callback Service

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
</table>
| Not able to submit SPML request (Failed Authentication). | Make sure that the SPML request is submitted with a valid SPML user (member of SPML_App_Role group) with its correct credentials. If the request is submitted from client APIs, then note that compatible client policy must be applied. The following is the sample error response displayed when a SPML request is submitted with incorrect credentials:  

```xml
<env:Envelope>
```
Troubleshooting the Callback Service

### Table 35–4 (Cont.) Troubleshooting Callback Service

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>For a given request type, for example Assign Role, Oracle Identity Manager is making callbacks to more than one callback Web service although the policyName matches with one callback service.</td>
<td>This is because when callbackOnly is set to false for all the eligible entity type and operation, for example Assign Role request types, the callbacks are triggered for all matching entity types and operations. PolicyName matching is ignored when callbackOnly attribute is set to false. If callbackOnly Attribute is set to true, then it checks for the policy name. All the callback Web service URLs present in that policy are triggered when the entity type and operation condition is also met. All the callback Web service URLs present in that policy are triggered when the entity type and operation condition is also met.</td>
</tr>
<tr>
<td>The policy reference URI 'oracle/wss_saml_or_username_token_service_policy' is not valid.</td>
<td>Make sure that WSM Policy Manager is deployed and targeted to the interacting servers such as Oracle Identity Manager and SPML request starting server. In addition, make sure that WSM Policy Manager is in active mode and is ready for serving the requests.</td>
</tr>
<tr>
<td>Not sure what is SPML APPID and Oracle Identity Manager APPID, and where these APPIDs are to be created.</td>
<td>SPML APPID is used for submitting SPML requests to Oracle Identity Manager. Any client that seeks user provisioning service with Oracle Identity Manager must contain SPML APPID in their repository. For example, when Fusion Applications is the client to Oracle Identity Manager, Fusion Applications typically use LDAP directory as their repository. Oracle Identity Manager APPID is used for sending callbacks to all the Web services registered in the CallbackConfiguration.xml file for a given SPML request type. Oracle Identity Manager repository or database contains only SPML APPID. Oracle Identity Manager APPID is not present in Oracle Identity Manager repository but is present in the Credentials Store Framework (CSF) under map name oim and with key appid.credentials. SPML repository or LDAP contains both SPML APPID and Oracle Identity Manager APPID. When Fusion Applications sends a SPML request to Oracle Identity Manager, it uses SPML APPID to communicate to Oracle Identity Manager. This SPML APPID is present in the SPML repository or LDAP. This user is authenticated at Oracle Identity Manager side against the database. Therefore, Oracle Identity Manager database contains SPML APPID in it. When Oracle Identity Manager communicates with Fusion Applications, it uses Oracle Identity Manager APPID to communicate to Fusion Applications. This Oracle Identity Manager APPID is present in the CSF. This user is authenticated at Fusion Applications side again LDAP by checking the Oracle Identity Manager APPID in LDAP repository. Therefore, LDAP contains Oracle Identity Manager APPID in it.</td>
</tr>
</tbody>
</table>
This part describes how to use the customization utilities provided by Oracle Identity Manager and migrate the customization from one deployment to another.

It contains the following chapters:

- Chapter 36, "Understanding Customization Types"
- Chapter 37, "Deploying and Undeploying Customizations"
- Chapter 38, "Migrating Configurations and Customizations"
Understanding Customization Types

All customizations in Oracle Identity Manager are managed by using the following types of utilities:

- **Deployment and undeployment utilities**: The following types of utilities can be used for deployment and undeployment purposes:
  - **Database-specific utilities**: These are utilities in Oracle Identity Manager that have the capability to take the input customization and insert it in the relevant database table. For example, the Plug-in Registration Utility takes the plugin pack and inserts it into the Plugin table in Oracle Identity Manager database. See "Developing Plug-ins" on page 27-1 for information about the Plug-in Registration Utility.
  - **SOA ANT-based utilities**: There are some ANT-based utilities from SOA suite for deploying or undeploying a SOA composite or approval workflow. Refer to SOA documentation for information about SOA ANT-based utilities.
  - **OPSS policy migration tool**: This tool is used for migrating Oracle Identity Manager authorization OES policies that you have changed based on some advanced authorization customizations.
  - **Oracle Enterprise manager**: The Enterprise Manager (EM) is the Fusion Middleware diagnostic and monitoring application. Using EM, you can deploy or undeploy customizations in Meta Data Store (MDS) and SOA composites or approval workflows.
    
    You can use EM to insert data in to the MDS. For example, you can use the EM to insert the LDAP synchronization user attribute mapping XML into MDS. See "Deploying and Undeploying Customizations" on page 37-1 for information about exporting and importing metadata files to and from MDS.
  - **IDE**: Integrated Development Environment (IDE), such as Jdeveloper, provides ways to deploy SOA composites or approval workflows.

- **Test to Production utilities**: This refer to the utilities used to migrate the customizations from an Oracle Identity Manager deployment to another. For example, you can customize Oracle Identity Manager in a test environment, and then migrate the customizations to the production environment. This is done by using the Deployment Manager utility, as described in "Migrating Configurations and Customizations" on page 38-1.

Another example of Test to Production utility is the Sandbox, which is used to migrate UI customizations from one deployment to another. See "ManagingSandboxes" on page 30-4 for information about the Sandbox.
Table 36–1 lists the Oracle Identity Manager artifacts that can be migrated via the deployment/undeployment and Test to Production utilities:

Table 36–1 (Cont.) Oracle Identity Manager Artifacts and Type of Utilities
This chapter contains the following topics:

- Migrating User Modifiable Metadata Files
- Migrating JARs and Resource Bundle

37.1 Migrating User Modifiable Metadata Files

The user modifiable metadata XML files can be exported to MDS, imported from MDS, and deleted from MDS by using Oracle Enterprise Manager.

This section contains the following topics:

- Exporting Metadata Files to MDS
- Importing Metadata Files from MDS
- Deleting Metadata Files from MDS
- User Modifiable Metadata Files
- Creating MDS Backup
- Exporting All MDS Data for Oracle Identity Manager

37.1.1 Exporting Metadata Files to MDS

To export metadata XML files to MDS:

1. Login to Oracle Enterprise Manager as the administrator user by navigating to the URL in the following format:
   http://ADMINISTRATION_SERVER/em
   Make sure that the Administrative Server and at least one Oracle Identity Manager Managed Server are running.

4. Export metadata by using the operations. To do so:
   a. Select and open the first exportMetadata operation in the list.
b. For toLocation, provide the path to a temporary directory, in which this file is to be exported. This file will be exported to the computer on which Oracle Identity Manager is running. Therefore, make sure that the directory path you specify exist on that computer.

c. For docs, click the pencil icon, click Add, and in the Element box, provide the full path of the file to be exported. By clicking Add, you can provide the path to multiple docs. Click OK at the bottom after adding the metadata docs to be exported.

d. Invoke the operation.

### 37.1.2 Importing Metadata Files from MDS

To import metadata XML files from MDS:

1. Login to Oracle Enterprise Manager as the admin user. Make sure that the Administrative Server and at least one Oracle Identity Manager Managed Server are running.

2. Navigate to Identity and Access, oim, oim(VERSI0N). Right-click and navigate to System MBean Browser.

4. Import metadata by using the operations. To do so:
   a. In the Operations tab, select the first importMetadata operation in the list.
   b. For fromLocation, provide the directory path of the Oracle Identity Manager host from where documents are to be imported.
   c. For docs, click the pencil icon, click Add, and in the Element box, provide the full path of the file to be imported. By clicking Add, you can provide the path to multiple docs. If no value is provided, then it imports everything under the fromLocation directory recursively.
   d. Invoke the operation.

### 37.1.3 Deleting Metadata Files from MDS

To delete metadata XML files from MDS.

1. Navigate to MDS runtime mbeans, as described in step 1 of "Exporting Metadata Files to MDS" on page 37-1.

2. Delete metadata by using the operations. To do so:
   a. In the Operations tab, select the first deleteMetadata operation in the list.
   b. For docs, click the pencil icon, click Add, and in the Element box, provide the full path of the file to be deleted. By clicking Add, you can provide the path to multiple docs to be deleted.
   c. Invoke the operation.

### 37.1.4 User Modifiable Metadata Files

The following metadata is used for configuring LDAP Container Rules to determine in which container user and roles should be created in LDAP.
The following metadata contains the predefined event handler definitions for Oracle
Identity Manager operations:

Note: These are read only documents. Contact Oracle support if there is a need to modify and delete any of the event handlers that are defined in these metadata file.

37.1.5 Creating MDS Backup

You might need to create a backup of the MDS before performing customizations. To create a backup of the MDS by using Oracle Enterprise Manager:

1. Login to Oracle Enterprise Manager as the administrator.
2. On the landing page, click oracle.iam.console.identity.self-service.ear(V2.0).
3. From the Application Deployment menu at the top, select MDS configuration.
4. Under Export, select the Export metadata documents to an archive on the machine where this web browser is running option, and then click Export.

All the metadata is exported in a ZIP file.
37.1.6 Exporting All MDS Data for Oracle Identity Manager

Some configurations for Oracle Identity Manager are stored in an MDS repository rather than on a file system on the Oracle Identity Manager Server. Troubleshooting configuration issues can sometimes require exporting all MDS data in order to examine it and make corrections if required.

To export all of the Oracle Identity Manager metadata contained in the MDS repository:

1. Setup the environment as a prerequisite:
   a. To perform MDS operations, log in to the Oracle Identity Manager server host with the account used to install and run WebLogic Application Server.
   b. Set your environment variables for the Oracle Identity Manager domain by running the appropriate `setDomainEnv` script found in the `MIDDLEWAR_HOME/user_projects/domains/DOMAIN_NAME/bin/` directory. The command is as shown:
      
      ```
      $ cd MIDDLEWAR_HOME/user_projects/domains/OIMDomain/bin
      $ .setDomainEnv.sh
      ```
   c. Create a temporary directory, such as `/tmp/OIM/MDSData/`, which will be used to store the resulting XML files from the database.
   d. Verify that the application server is up and running.
   e. Ensure that you know the WebLogic administrator username and the URL to the Admin Server.

2. Perform the export, as follows:
   a. In the command shell or console window, go to the `OIM_ORACLE_HOME/common/bin/` directory.
   b. Run the `wlst.sh` command, and then run the `connect()` command, as shown:
      
      ```
      $ ./wlst.sh
      CLASSPATH=/opt/oracle/Middleware/wlserver_10.3/server/ext/jdbc/oracle/11g/ojdbc6dms.jar:
      ...
      Your environment has been set.
      ...
      Initializing WebLogic Scripting Tool (WLST) ...
      Welcome to WebLogic Server Administration Scripting Shell
      Type help() for help on available commands
      wls:/offline> connect()
      Please enter your username [weblogic] :
      Please enter your password [welcome1] :
      Please enter your server URL [t3://localhost:port] :
      Connecting to t3://localhost:port with userid weblogic ...
      Successfully connected to Admin Server 'AdminServer' that belongs to domain 'OIMDomain'.
      
      Warning: An insecure protocol was used to connect to the server. To ensure on-the-wire security, the SSL port or Admin port should be used instead.
      ```
   c. Provide the WebLogic administrator username and password and the URL to the Admin Server.
d. Run the `exportMetadata` command providing at least the `application`, `server`, and `toLocation` arguments, as shown:

```
Note: Be sure to pass the argument data in single quotes, such as:
server='oim_server1'
```

```
wls:/OIMDomain/serverConfig> exportMetadata(application='OIMMetadata',
server='oim_server1', toLocation='/tmp/OIM/MDSData')
```

e. A list of the files exported is displayed. At this point, you can run the `disconnect()` command followed by the `exit()` command, as shown:

```
wls:/OIMDomain/serverConfig> disconnect()
Disconnected from weblogic server: AdminServer
wls:/offline> exit()
```

Exiting WebLogic Scripting Tool.

$f$

f. Go to the `/tmp/OIM/MDSData/` directory, and view the `db/oim-config.xml` file, or the `db/form-metadata/FormMetaData.xml` file, or any other exported MDS file.

The following is an example WLST script for exporting all MDS files:

```
connect('WEBLOGIC_USERNAME', 'PASSWORD', 't3://localhost:PORT')
exportMetadata(application='OIMMetadata', server='oim_server1',
toLocation='/tmp/OIM/MDSData')
disconnect()
ext()
```

You can save this script in a `.py` file, for example `/tmp/exportOIMMDS.py`, which you can run to automatically produce the same results. The following is a sample `.py` file:

```
cd MIDDLEWARE_HOME/user_projects/domains/OIMDomain/bin
.setDomainEnv.sh
mkdir -p /tmp/OIM/MDSData
 cd $OIM_ORACLE_HOME/common/bin
./wlst.sh /tmp/exportOIMMDS.py
```

### 37.2 Migrating JARs and Resource Bundle

When migrating from test to production environment, all the connector artifacts must be migrated to the respective database tables, which can be done by using the following utilities to migrate JAR files and resource bundle:

- Upload JAR Utility
- Download JAR Utility
- Delete JAR Utility
- Upload Resource Bundle Utility
- Download Resource Bundle Utility
Delete Resource Bundle Utility

**Note:**

- All the Upload JAR and Resource Bundle utilities must be run from the OIM_HOME/bin/ directory.
- Make sure that wlfullclient.jar is generated before running these utilities.
- Set APP_SERVER, OIM_ORACLE_HOME, JAVA_HOME, MW_HOME, WL_HOME, and DOMAIN_HOME before running the scripts.
- All the scripts for the JAR files and resource bundles support both interactive mode and command-line mode usage. But it is recommended to use interactive mode because this is secure and the passwords are not echoed on the console.
- For running the scripts in command-line mode, run it with the -help argument. For example:
  
  sh UploadJars.sh -help

To upload a JAR file in the silent mode:

```
UploadJars.sh [-username USERNAME] [-password PASSWORD]
[-serverURL <t3://OIM_HOSTNAME:OIM_PORT>] [-ctxFactory
<weblogic.jndi.WLInitialContextFactory>] [-JavaTasks LOCATION_OF_JAVA_TASK_JAR]
```

For information about configuring the utilities to upload/download JAR files and resource bundle over SSL, see "Configuring SSL for Oracle Identity Manager Utilities" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

To upload multiple JAR files in the silent mode:

```
UploadJars.sh [-username USERNAME] [-password PASSWORD]
[-serverURL <t3://OIM_HOSTNAME:OIM_PORT>] [-ctxFactory
```

In this document, interactive mode usage of the JAR and Resource Bundle utilities are explained because it is a secure way of running the utilities and is recommended.

To run the JAR or Resource Bundle utilities in interactive mode, run the scripts without specifying any arguments. For example:

```
sh UploadJars.sh
```

After running the UploadResourceBundles.sh script, you must purge Oracle Identity Manager cache or restart Oracle Identity Manager to load the new objects from MDS into Oracle Identity Manager cache. If Oracle Identity Manager cache is not refreshed, then Oracle Identity Manager reads the contents from the local resource bundle files.
37.2.1 Upload JAR Utility

The UploadJars.sh and UploadJars.bat scripts are available in the OIM_HOME/bin/ directory. Running these scripts upload the JAR files in to the database.

A sample invocation of this utility is as shown:

[Enter Xellerate admin username :] ADMINISTRATOR_LOGIN
[Enter the admin password :] ADMINISTRATOR_PASSWORD
[[Enter serverURL (Ex. t3://oimhostname:oimportno for weblogic or corbaloc:iiop:localhost:2801 for websphere)]:] t3://xyz.com:14000
[[Enter context (Ex. weblogic.jndi.WLInitialContextFactory for weblogic or com.ibm.websphere.naming.WsnInitialContextFactory for websphere)]:] weblogic.jndi.WLInitialContextFactory
Enter the jar type
1. JavaTasks
2. ScheduleTask
3. ThirdParty
4. ICFBundle
1
Enter the path/location of jar file:
/tmp/example.jar
Do u want to load more jars [y/n] : n

Note: 14000 is Oracle Identity Manager port.

37.2.2 Download JAR Utility

The DownloadJars.sh and DownloadJars.bat scripts are available in the OIM_HOME/bin/ directory. Running these scripts download the JAR files from the database.

A sample invocation of this utility is as shown:

[Enter Xellerate admin username :] ADMINISTRATOR_LOGIN
[Enter the admin password :] ADMINISTRATOR_PASSWORD
[[Enter serverURL (Ex. t3://oimhostname:oimport for weblogic or corbaloc:iiop:localhost:2801 for websphere)]:] t3://localhost:14000
[[Enter context (i.e.: weblogic.jndi.WLInitialContextFactory for weblogic or com.ibm.websphere.naming.WsnInitialContextFactory for websphere)]:] weblogic.jndi.WLInitialContextFactory
Enter the jar type
1. JavaTasks
2. ScheduleTask
3. ThirdParty
4. ICFBundle
1
Enter the full path of the download directory:
/home/joe/tmp
Enter the name of jar file to be downloaded from DB:
example.jar
Do u want to download more jars [y/n] : n

Note: 14000 is Oracle Identity Manager port.
Migrating JARs and Resource Bundle

37.2.3 Delete JAR Utility

The DeleteJars.sh and DeleteJars.bat scripts are available at the OIM_HOME/bin/ directory. Running these scripts delete the JAR files from the database.

A sample invocation of this utility is as shown:

```
[Enter Xellerate admin username :] ADMINISTRATOR_LOGIN
[Enter the admin password :] ADMINISTRATOR_PASSWORD
[Enter serverURL (Ex. t3://oimhostname:9080 for weblogic or corbaloc:iiop:localhost:2801 for websphere)]: t3://localhost:14000
[Enter context (i.e.: weblogic.jndi.WLInitialContextFactory for weblogic or com.ibm.websphere.naming.WsnInitialContextFactory for websphere)]: weblogic.jndi.WLInitialContextFactory
Enter the jar type
1. JavaTasks
2. ScheduleTask
3. ThirdParty
4. ICFBundle
1
Enter the name of jar to be deleted from DB :
example.jar
Do u want to delete more jars [y/n] : n
```

37.2.4 Upload Resource Bundle Utility

The UploadResourceBundles.sh and UploadResourceBundles.bat scripts are available in the OIM_HOME/server/bin/ directory. Running these scripts upload the connector or custom resources to the database.

A sample invocation of this utility is as shown:

```
Enter Xellerate admin username :] ADMINISTRATOR_LOGIN
[Enter the admin password :] ADMINISTRATOR_PASSWORD
[Enter serverURL (Ex. t3://oimhostname:9080 for weblogic or corbaloc:iiop:localhost:2801 for websphere)]: t3://localhost:14000
[Enter context (i.e.: weblogic.jndi.WLInitialContextFactory for weblogic or com.ibm.websphere.naming.WsnInitialContextFactory for websphere)]: weblogic.jndi.WLInitialContextFactory
Enter the resource bundle type
1. Custom Resource
2. Connector Resource
2
Enter the path/location of resource bundle file : /tmp/example.properties
Do u want to load more resource bundles [y/n] : n
```

37.2.5 Download Resource Bundle Utility

The DownloadResourceBundles.sh and DownloadResourceBundles.bat scripts are available in the OIM_HOME/bin/ directory. Running these scripts download the resource bundles from the database.

A sample invocation of this utility is as shown:

```
Enter Xellerate admin username :] ADMINISTRATOR_LOGIN
[Enter the admin password :] ADMINISTRATOR_PASSWORD
[Enter serverURL (Ex. t3://oimhostname:9080 for weblogic or corbaloc:iiop:localhost:2801 for websphere)]: t3://localhost:14000
[Enter context (i.e.: weblogic.jndi.WLInitialContextFactory for weblogic or com.ibm.websphere.naming.WsnInitialContextFactory for websphere)]: weblogic.jndi.WLInitialContextFactory
```

37-8 Oracle Fusion Middleware Developer's Guide for Oracle Identity Manager
Migrating JARs and Resource Bundle

Deploying and Undeploying Customizations

```
websphere])]}weblogic.jndi.WLInitialContextFactory
Enter the resource bundle type
1. Custom Resource
2. Connector Resource
2
Enter the full path of the download directory:
/home/joe/tmp
Enter the name of resource bundle file:
example.properties
Do u want to download more resource bundles [y/n] : n
```

37.2.6 Delete Resource Bundle Utility

The DeleteResourceBundles.sh and DeleteResourceBundles.bat are available in the OIM_HOME/bin/ directory. Running these utilities delete the resource bundles from the database.

A sample invocation of this utility is as shown:

```
[Enter Xellerate admin username : ] ADMINISTRATOR_LOGIN
[Enter the admin password : ] ADMINISTRATOR_PASSWORD
[[Enter serverURL (Ex. t3://oimhostname:9080 for weblogic or corbaloc:iiop:localhost:2801 for websphere)]: ] t3://localhost:14000
[[Enter context (i.e.: weblogic.jndi.WLInitialContextFactory for weblogic or com.ibm.websphere.naming.WsnInitialContextFactory for websphere)]: ] weblogic.jndi.WLInitialContextFactory
Enter the resource bundle type
1. Custom Resource
2. Connector Resource
2
Enter the name of resource bundle file to be deleted from DB:
example.properties
Do u want to delete more resource bundles [y/n] : n
```
Configurations and customizations in Oracle Identity Manager can be migrated from one deployment to another deployment. For example, you might want to migrate the configurations and customizations from a test environment to a production environment. This is referred to as Test to Production (T2P).

T2P can be performed in the following ways:

- **Incremental T2P:** In this type of T2P, you use the Deployment Manager tool for exporting and importing Oracle Identity Manager configurations and customizations. The Deployment Manager lets you export the objects that constitute the Oracle Identity Manager configuration. See "Using the Deployment Manager" on page 38-1 for more information.

- **Full T2P:** Fusion Middleware Framework-based movement scripts are used for this type of T2P. These scripts are used to move all the properties of an environment to another environment without the environment-specific attributes, which can be reconfigured. See "Moving from a Test to a New Production Environment Using Movement Scripts" on page 38-16 for more information.

- **Policy migration:** You can migrate the policies from one Oracle Identity Manager deployment to another, for example, from a test environment to production environment, by using a command-line utility provided by Oracle Platform Security. See "Migrating the Policies" on page 38-22 for more information.

This chapter contains the following topics:

- Using the Deployment Manager
- Moving from a Test to a New Production Environment Using Movement Scripts
- Migrating the Policies

### 38.1 Using the Deployment Manager

The Deployment Manager is a tool for exporting and importing Oracle Identity Manager configurations and customizations. The Deployment Manager lets you export the objects that constitute the Oracle Identity Manager configuration. Usually, you use the Deployment Manager to migrate a configuration from one deployment to
another, for example, from a test to a production deployment, or to create a backup of your system.

---

**Important:**

- To use Deployment Manager, JRE 1.4.2 or a higher version must be installed on any computer that is running the Oracle Identity System Administration.
- To use the Deployment Manager with the latest Java 7 update 51, update the security information in the Java Console. To do so, open the Java Console, click the **Security** tab, and add the site name. The site name is in the following format:
  
  `http://HOST:PORT/xlWebApp/DeploymentManager/loadDU.d o`

---

You can save some or all of the objects in your configuration. This lets you develop and test your configurations in a test environment, and then import the tested objects into your production environment. You can export and import an object and all of its dependent and related objects at the same time. Alternatively, you can export and import each object individually.

The Deployment Manager allows you to retrieve configuration information and binary data from the source system, store the information in an XML file, and then import the information from the XML file to the target system. The binary data includes plug-ins, JARs, and custom resource bundles. The Deployment Manager allows you to import data from the Oracle Identity Manager database, Meta Data Store (MDS) repository, or API repository. As a result, you can import all types of objects from these repositories, such as system properties, jobs, and scheduled tasks, which are not in the same repository. For example, you can import the scheduled tasks that are in the MDS repository instead of the database.

An object exported from one type of repository is imported to the same type of repository. For example, if a scheduled task is exported from the MDS repository, then the scheduled task is imported to the same repository, which is MDS, in the target system.

---

**Note:** In addition to the Deployment Manager, you can use the sandbox feature to migrate configurations and customizations from one deployment to another. See “Managing Sandboxes” on page 30-4 for information about working with sandbox.

---

This section includes the following topics:

- **Features of the Deployment Manager**
- **Exporting Deployments**
- **Importing Deployments**
- **Best Practices Related to Using the Deployment Manager**
- **Troubleshooting the Deployment Manager**
- **Monitoring Deployment Manager Performance Using DMS**
38.1.1 Features of the Deployment Manager

The Deployment Manager helps you to migrate Oracle Identity Manager deployments from one server environment to another, such as from a testing environment to a staging environment, or from a staging environment to a production environment.

The Deployment Manager enables you to:

- Update individual components of a deployment in different test environments
- Identify objects associated with components to be exported, so that those resources can be included
- Provide information about exported files
- Add comments

The Deployment Manager handles the following types of information:

- Application instances
- Catalog definitions
- Plug-ins
- JAR files
- Custom resource bundles
- Roles
- Organizations
- Access policies
- Attestation processes
- User metadata
- Role metadata
- Organization metadata
- Scheduled tasks
- Scheduled jobs
- IT resources
- Resource objects
- Lookup definitions
- Process forms
- Provisioning workflows and process task adapters
- Data object definitions
- Rules
- Notification templates
- Generic Technology Connectors (GTC)
- GTC providers
- Error codes
- System properties
- E-mail definitions
Using the Deployment Manager

- Password policies
- IT resource definition
- Request datasets
- Approval policies
- Event handlers
- Prepopulation adapters
- Process definitions
- Risk configuration
- Certification definition

**Note:** On the source, certification definition that is being exported might contain references to specific users, roles, application instances, entitlements, or organizations. These specific references are scrubbed while exporting the certification definition and then importing it on the target setup. On the target, the definition must be opened from the certification definition management UI and updated for selection of these entities on the target. The definitions cannot be used unless they are updated and will result in errors if used as is. Any definition that is generic and do not contain specific references can be used as it is after importing.

- Certification configuration

The following are limitations of the Deployment Manager:

- **Merge Utility:** The Deployment Manager is not a merge utility.
  It cannot handle modifications done in both production and test environments. It replaces the object in the target system with that in the XML file.

- **Version Control Utility:** The Deployment Manager does not track versions of imported files, and does not provide rollback functionality.
  You can only use it as a means to move data between environments.

### 38.1.2 Exporting Deployments

You can export objects from your Oracle Identity Manager system and save them in an XML file. The Deployment Manager has an Export Wizard that lets you create your export file. Add objects by type, one type at a time, for example, roles, then forms, then processes, and so on.

**Note:** Application instances are exported and imported without the datasets. Datasets are migrated as a part of UI customization.

If you select an object that has child objects or dependencies, you have the option to add them or not. After adding objects of one type, you can go back and add other objects to your XML files. When you have all the objects you want, the Deployment Manager saves them all at once in a single XML file.
To export a deployment:

1. Login to Oracle Identity System Administration.

2. In the left pane, under System Management, click **Export**. The Deployment Manager opens and the Search Objects page of the Export Wizard is displayed.

3. On the Search Objects page, select an object type from the menu, and enter search criteria. If you leave the criteria field blank, an asterisk (*) is displayed automatically to find all the objects of the selected type.

   All the objects supported by Deployment Manager for migration are available for exporting. See "Features of the Deployment Manager" on page 38-3 for the list of objects supported by Deployment Manager for migration.

4. Click **Search** to find objects of the selected type.

   To select an object, select the option of the object.

5. Click **Select Children**.

   The Select Children page is displayed with the selected objects and all of their child objects.

6. Select the child objects that you want to export.

   To select or remove an item, select the appropriate option.

   Click **Back** to go to the Search Objects page.

7. Click **Select Dependencies**.
The Select Dependencies page is displayed with any objects required by the selected objects.

8. Select the dependent objects that you want to export.
   To select or remove an item, select the option of the item.
   Click Back to go to the Select Children page.

9. Click Confirmation.
   The Confirmation page is displayed.

10. Ensure that all the required items are selected, then click Add for Export.
    After you click Add for Export, you can still add more items to this export file.
    Select Add More and click OK to go to Search Objects Page to add more objects for export.

11. Use the wizard to add more items, or finish and exit the wizard. Select the appropriate option and click OK.
    If you select Add more, repeat Steps 3 through 10. Otherwise, the Export page is displayed.
    The Export page displays your current selections for export. Your selections have icons next to them that indicate what types of objects are selected. The Summary information pane shows the objects you are exporting. The Unselected Dependencies pane displays the list of dependent or child objects that you did not select for export.

12. Make any adjustments to your export file as follows:
    - Click Reset to clear the form.
    - Click Legend to see icon definitions.
    - Click Add Objects to restart the wizard and add more items to your export file.
    To remove an object from the Current Selections list:
    - Right-click the object to remove and select Remove from the shortcut menu. If the object has child objects, then select Remove including children from the shortcut menu to remove the child objects all at the same time.
    - Click Remove to confirm. If the object is a child or dependency of a selected item, then it is added to the Unselected Children or Unselected Dependencies list.
    To add an object back to the Current Selections list from the Unselected Children or Unselected Dependencies list,
    a. Right-click the object, and select Add.
    b. Click Confirmation.
       The Confirmation page is displayed.
    c. Click Add for Export.

13. Click Export.
    The Add Description dialog box is displayed.

14. Enter a description for the file.
    This description is displayed when the file is imported.
15. Click Export.
   The Save As dialog box is displayed.

16. Enter a file name.
   You can browse to find a location.

17. Click Save.
   The Export Success dialog box is displayed.

18. Click Close.

38.1.3 Importing Deployments

Objects that were exported into an XML file by using the Deployment Manager can be imported into Oracle Identity Manager by using the Deployment Manager. You can import all or part of the XML file, and you can import multiple XML files at once. The Deployment Manager ensures that the dependencies for any objects you are importing are available, either in the import or in your system. During an import, you can substitute an object you are importing for one in your system. For example, you can substitute a group specified in the XML file for a group in your system.

To import an XML file:

Note: Before importing data that contains references to menu items, you must first create the menu items in the target system.
Note: To open the Deployment Manager by using Mozilla Firefox Web browser, an additional authentication dialog box might be displayed. Providing authentication in this dialog box allows access to the Deployment Manager. To avoid this additional authentication:

1. In Mozilla Firefox, from the Tools menu, select Options. The Options dialog box is displayed.
2. Click Privacy.
3. Select the Accept third-party cookies option.
4. Click OK.

The additional authentication is not required when the Deployment Manager is opened by using Microsoft Internet Explorer, Google Chrome, and Apple Safari Web browsers.

   The Import dialog box is displayed.

4. Click Open.
   The File Preview page is displayed.

5. Click Add File.
   The Substitutions page is displayed.

6. To substitute a name, click the New Name field adjacent to the item you want to replace, and enter the name.
   You can substitute only items that exist in the target system.

7. Click Next. If you are exporting an IT resource instance, then the Provide IT Resource Instance Data page is displayed. Otherwise, you are redirected to the Confirmation page.

8. Modify the values in the current resource instance and click Next, or click Skip to skip the current resource instance, or click New Instance to create a new resource instance.
   The Confirmation page is displayed.

9. Confirm that the information displayed on the Confirmation page is correct.
   To go back and make changes, click Back, or click View Selections.

   The Deployment Manager Import page displays your current selections.

   The Import page also displays icons next to your current selections. The icons indicate what types of objects are selected. The icons on the right indicate the status of your selections. The file names of any selected files, summary information about the objects you are importing, and substitution information are displayed on the left side of the page. On the right, the Objects Removed from Import list displays any objects in the XML file that will not be imported.

10. Make any of the following adjustments:
    - Click Reset to clear the form.
    - Click Legend to see icon definitions.
■ To remove an object from the Current Selections list, right-click the object, select **Remove** from the shortcut menu, and then click **Remove** to confirm that you want to remove the object.

If the object has child objects, then select **Remove including children** from the shortcut menu to remove all the child objects at the same time. The item is added to the Objects Removed From Import list.

■ To add an item back to the Current Selections list, right-click the list, and click **Add**.

If the object has child objects, then select **Add including children** from the shortcut menu to add all the child objects at the same time.

■ To make substitutions, click **Add Substitutions**.

■ To add objects from another XML file, click **Add File** and repeat Steps 3 through 9.

■ Click **Show Information** to see information about your imported information.

The Information page is displayed.

To see more information, select the **Show Info Level Messages** option, and then click **Show Messages**. Click **Close** to close the Information page.

11. To import the current selections, click **Import**.

A confirmation dialog box is displayed.

12. Click **Import**.

The Import Success dialog box is displayed.

13. Click **OK**.

The objects are imported into Oracle Identity Manager.

### 38.1.4 Best Practices Related to Using the Deployment Manager

The following are some of the suggested practices and pitfalls to avoid while using Deployment Manager:

■ **Export System Objects Only When Necessary**
■ **Export Related Groups of Objects**
■ **Group Definition Data and Operational Data Separately**
■ **Use Logical Naming Conventions for Versions of a Form**
■ **Export Root to Preserve a Complete Organizational Hierarchy**
■ **Provide Clear Export Descriptions**
■ **Check All Warnings Before Importing**
■ **Check Dependencies Before Exporting Data**
■ **Match Scheduled Task Parameters**
■ **Deployment Manager Actions on Reimported Scheduled Tasks**
■ **Compile Adapters and Enable Scheduled Tasks**
■ **Export Entity Adapters Separately**
■ **Check Permissions for Roles**
38.1.4.1 Export System Objects Only When Necessary
You should export or import system objects, for example, Request, Xellerate User, and System Administrator, only when it is absolutely necessary. Exporting system objects from the testing and staging environments into production can cause problems. If possible, exclude system objects when exporting or importing data.

You may want to export or import system objects when, for example, you define trusted source reconciliation on Xellerate User resource objects.

Caution: The Deployment Manager keeps track of imported components and structures, but not of completed imports. After an import is completed, you cannot roll it back to a previous version. A new import is required.

38.1.4.2 Export Related Groups of Objects
Oracle recommends that you use the Deployment Manager to export sets of related objects. A unit of export should be a collection of logical items that you want to group together.

Avoid exporting everything in the database in one operation, or exporting items one at a time. For example, suppose that you manage an integration between Oracle Identity Manager and a target system that includes processes, resource objects, adapters, IT resource type definitions, IT resource definitions, scheduled tasks, and so on. For this environment, you should create groups of related objects before exporting.

For example, if you use the same e-mail definitions in multiple integrations, you should export the e-mail definitions as one unit, and the integrations as a different unit. This enables you to import changes to e-mail definitions independently of target system integration changes. Or, if multiple resources use the same IT resource type definition, you can export and import the type definition separately from other data.

You can import one or more sets of exported data at a time. For example, you can import a resource object definition, an e-mail definition, and an IT resource type definition in a single operation.

38.1.4.3 Group Definition Data and Operational Data Separately
You must group and export definition data and operational data separately.

You configure definition data in the testing and staging environment. Definition data includes resource objects, processes, and rules.

You typically configure operational data in the production environment. Operational data includes groups and group permissions. The testing and staging servers usually do not include this data.

By grouping data according to where it is changed, you know what data goes to testing and staging, and what goes to production. For example, if approval processes are changed in production, you should group approval processes and export them with other operational data.
38.1.4.4 Use Logical Naming Conventions for Versions of a Form
You often revise forms multiple times before exporting them. Avoid generic names, for example, "v23," to differentiate among versions of a form. Create meaningful names, for example, "Before Production" or "After Production Verification." Do not use special characters, including double quotation marks, in version names.

38.1.4.5 Export Root to Preserve a Complete Organizational Hierarchy
When you export a leaf or an organization in an organizational hierarchy, only one dependency level is exported. To export a complete organizational hierarchy, you must export the root of the hierarchy.

38.1.4.6 Provide Clear Export Descriptions
The Deployment Manager records some information automatically, for example, the date of the export, who performed the export, and the source database. You must also provide a meaningful description of the content of the export, for example, "resource definition after xxx attributes added in reconciliation." This informs the importer of the file of the contents of the data being imported.

38.1.4.7 Check All Warnings Before Importing
When importing information to the production environment, check all the warnings before completing the import operation. Treat each warning seriously.

38.1.4.8 Check Dependencies Before Exporting Data
The wizard in the top right pane shows resources that must be available in the target system.

Consider the following types of dependencies:

- If the resources are already available in the target system, they do not need to be exported.
- If the resources are new (not in the target system), they must be exported.
- If the target system does not include the resources, such as lookups, IT resource definitions, or others that are reused, then record the data and export it in a separate file so it can be imported if necessary.

Note: When you export a resource, groups with Data Object permissions on that form are not exported with the resource.

38.1.4.9 Match Scheduled Task Parameters
Scheduled tasks depend on certain parameters to run properly. You can import scheduled task parameters to the production server. Table 38–1 shows the rules for determining how to import scheduled tasks. Note that parameters may be available for tasks that no longer reside on the target system.

<table>
<thead>
<tr>
<th>Parameter Exists in Target System</th>
<th>Parameter Exists in the XML File</th>
<th>Action Taken</th>
</tr>
</thead>
</table>
| Yes                               | No                               | Remove the parameter from the target system.

Table 38–1 Parameter Import Rules
38.1.4.10 Deployment Manager Actions on Reimported Scheduled Tasks
A scheduled task is one of the objects that you can import by using the Deployment Manager. Typically, you import a scheduled task into your Oracle Identity Manager environment and later change the values of the scheduled attributes to meet your production requirements. However, if you import the same scheduled task a second time into the same Oracle Identity Manager server, the Deployment Manager does not overwrite the attribute values in the database. Instead, the Deployment Manager compares the attribute value of the reimported XML file to any corresponding attribute values in the database.

The following table summarizes the actions performed by the Deployment Manager during a scheduled task reimport:

<table>
<thead>
<tr>
<th>Does the Scheduled Task have attribute values in the XML file being imported?</th>
<th>Are there any corresponding attribute values in the database?</th>
<th>Deployment Manager Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>No</td>
<td>Store attribute values in the database</td>
</tr>
<tr>
<td>No</td>
<td>Yes</td>
<td>Delete existing attribute values in the database</td>
</tr>
<tr>
<td>Yes</td>
<td>Yes (Newer attribute values indicated by time stamp)</td>
<td>No change in the database</td>
</tr>
<tr>
<td>Yes (New attribute values indicated by time stamp)</td>
<td>Yes</td>
<td>Update the database with the new attribute values</td>
</tr>
</tbody>
</table>

38.1.4.11 Compile Adapters and Enable Scheduled Tasks
After an import operation, the adapters are set to recompile and the scheduled tasks are disabled. After importing the classes and adjusting the task attributes, manually recompile the adapters and enable the scheduled tasks.

38.1.4.12 Export Entity Adapters Separately
Entity adapters are modified to bring just the entity adapter, not its usage. If you want to export the usage of an entity adapter, you must separately export each use with a data object by exporting the data object. If you export a data object, all the adapters and event handlers attached to the object along with the permissions on the object are exported. You must pay special attention when exporting data objects. For example, to export a form, you should also add the data object corresponding to the form. This ensures that the associated entity adapters can use the form.

38.1.4.13 Check Permissions for Roles
When you export roles, the role permissions on different data objects are also exported. However, when you import data, any permissions for missing data objects are ignored. If the role is exported as a way of exporting role permission setup, then
check the warnings carefully to ensure that permission requirements are met. For example, if a role has permissions for objects A, B, and C, but the target system only has objects A and B, the permissions for object C are ignored. If object C is added later, the role permissions for C must be added manually, or the role must be imported again.

When you export role that have permissions for viewing certain reports, ensure that the reports exist in the target environment. If the reports are missing, then consider removing the permissions before exporting the role.

### 38.1.4.14 Back Up the Database

Before you import data into a production environment, back up the database. This enables you to restore the data if anything goes wrong with the import. Backing up the database is always a good precaution before making significant changes.

---

**Note:** When you import forms and user-defined fields, you add entries to the database. These database entries cannot be rolled back or deleted. Before each import operation, ensure that the correct form version is active.

---

### 38.1.4.15 Import Data When the System Is Quiet

You cannot complete an import operation in a single transaction because it includes schema changes. These changes affect currently running transactions on the system. To limit the effect of an import operation, temporarily disable the Web application for general use and perform the operation when the system has the least activity, for example, overnight.

### 38.1.4.16 Migrating Custom Data Objects

The SDK table contains metadata definitions for user-defined data objects. When you import data from an XML file into the SDK table, the values in the SDK_SCHEMA column might be modified with the schema name of the source system where the XML file was created. For this reason, after you import data from an XML file into the SDK table, you must check the schema name in the SDK_SCHEMA column, and if necessary, manually change it to the schema name on the target system where the Oracle Identity Manager database is running. To update the schema name in the SDK_SCHEMA column, run a SQL query similar to the following with SQL*Plus on Oracle Database installations or with SQL Query Analyzer on Microsoft SQL Server installations:

```sql
UPDATE SDK SET SDK_SCHEMA='target system schema name'
```

If you do not update the schema name in the SDK_SCHEMA column, an error similar to the following might be generated when you import other XML files that modify user-defined field (UDF) definitions:

```
CREATE SEQUENCE UGP_SEQ
java.sql.SQLException: ORA-00955: name is already used by an existing object
```

### 38.1.4.17 Remove Data Object Fields Before Importing Event Handlers as Dependencies

The Deployment Manager does not import event handlers that include data object fields if the event handlers are imported as dependencies. For this reason, you must remove the data object fields from any event handlers that you want to import as dependencies with the Deployment Manager.
38.1.5 Troubleshooting the Deployment Manager

This section contains the following topics:

- Troubleshooting Deployment Manager Issues
- Enabling Logging for the Deployment Manager

38.1.5.1 Troubleshooting Deployment Manager Issues

While importing data by using the Deployment Manager, the following information is displayed on the UI for an import failure:

- The entity for which the import failed
- The type of the entity for which the import failed
- The specific error message from the exception object

This information is also printed in logs along with the exception trace.

Figure 38–1 shows a sample error message that is displayed when Deployment Manager import fails.

![Deployment Manager Import Failure](image)

This helps the user in identifying which entity is causing the failure and why, and the user can try removing that particular entity and importing again if it is not necessary to be imported on the target system. This also helps the support team and developers in identifying the issue if it happens.

Table 38–2 lists the troubleshooting steps that you can perform if you encounter a failure:
38.1.5.2 Enabling Logging for the Deployment Manager

To enable logging for the Deployment Manager:

1. Add a new logger for the Deployment Manager by editing the logging.xml file, which is located in the following directory path:

   \( \text{DOMAIN\_NAME}/\text{config/fmwconfig/servers/\text{SERVER\_NAME}/} \)
For instance, to enable Notification-level logging for Deployment Manager, add
the following logger inside the <loggers> section:

```xml
<logger name='XELLERATE.DDM' level='NOTIFICATION:1' /></logger>
```

2. Change the log level defined in the relevant <log_handler>.

See Also: "Configuring Logging" in the Oracle Fusion Middleware
Administrator’s Guide for Oracle Identity Manager for information about
logging level and log handlers in Oracle Identity Manager

### 38.1.6 Monitoring Deployment Manager Performance Using DMS

Oracle Dynamic Monitoring Service (DMS) can be used to view performance metrics.
The following DMS metrics are relevant for monitoring Deployment Manager performance:

- **DeploymentManager**: Metrics that show the time taken by different method calls
  in Import/Export Operation Beans.
- **DeploymentManager_APIManager**: Metrics that show the time taken by different
  method calls for APIHandler in Import/Export.

For more information about DMS, see "Understanding the Oracle Dynamic
Monitoring Service" in the Oracle Fusion Middleware Performance and Tuning Guide.

### 38.2 Moving from a Test to a New Production Environment Using Movement Scripts

Oracle Identity Manager is a part of the Fusion Middleware environment. To move
Oracle Identity Manager from test to production, you use the movement scripts. These
scripts copy the Oracle Identity Manager binaries, artifacts, and configurations, and
configures production Oracle Identity Manager with new end-points. The movement
scripts interact with Oracle Identity Manager artifacts at the test and production
environments and updates the production environment to make Oracle Identity
Manager functional on the production environment. For detailed information about
using the movement scripts, see "Moving from a Test to a Production Environment” in
the Oracle Fusion Middleware Administrator’s Guide. For the complete procedure for
moving Oracle Identity Manager components, see "Moving Identity Management
Components to a New Target Environment” in the Oracle Fusion Middleware
Administrator’s Guide.

**Note:** Before proceeding with migrating a source Oracle Identity
Manager setup to a target setup, you can refer to "Limitations in
Moving from Test to Production” in the Oracle Fusion Middleware
Release Notes for information about the limitations and known issues
related to moving from test to production. In addition, see
"Troubleshooting Movement From Test to Production Environment
Using Movement Scripts” on page 38-19 for information about the
issues that you might encounter while migrating a source Oracle
Identity Manager setup and the possible solutions.

To migrate a source Oracle Identity Manager setup to a target setup:

1. Migrate Oracle Identity Manager database schema data from source to target DB
   host by using the expdp/impdp (Data Pump Utility), as described in "Task 4
Perform Prerequisite Task for Oracle Identity Manager” under section "Moving Identity Management to a New Target Environment” in the Oracle Fusion Middleware Administrator’s Guide.

2. Create the target setup by using the FMW T2P utilities. To do so:
   a. Run the following commands from the ORACLE_COMMON_HOME/bin/directory.

   **Note:**
   - On Microsoft Windows, run the commands with .cmd extension, such as copyBinary.cmd and pasteBinary.cmd. For example, the copyBinary script is ORACLE_COMMON_HOME/bin/copyBinary.sh for UNIX and ORACLE_COMMON_HOME/bin/copyBinary.cmd for Microsoft Windows.
   - Some arguments might be invalid for Windows operating system. For example, the -ipl PATH_TO_ORACLE_INVENTORY_POINTER argument does not work in Windows.
   - This document provides the syntax for running the copyBinary, copyConfig, extractMovePlan, and pasteBinary scripts. For detailed information about these scripts, parameters, and example usages, see "Using the Movement Scripts” in the Oracle Fusion Middleware Administrator’s Guide.

   ```bash
   ./copyBinary.sh -javaHome PATH_TO_JDK -al ARCHIVE_LOCATION -smw SOURCE_MW_HOME -silent false -idw true -ipl PATH_TO_ORACLE_INVENTORY_POINTER -silent true -ldl PATH_TO_LOG_DIRECTORY
   ```

   ```bash
   ./copyConfig.sh -javaHome PATH_TO_JDK -archiveLoc ARCHIVE_LOCATION -sourceDomainLoc SOURCE_DOMAIN_LOCATION -sourceMwHomeLoc MIDDLEWARE_HOME_LOCATION -domainHostName DOMAIN_HOST_NAME -domainPortNum DOMAIN_PORT_NUMBER -domainAdminUserName DOMAIN_ADMIN_USERNAME -domainAdminPasswordFile DOMAIN_ADMIN_PASSWORD_FILE -silent true -ldl PATH_TO_LOG_DIRECTORY
   ```

   ```bash
   ./extractMovePlan.sh -javaHome PATH_TO_JDK -archiveLoc ARCHIVE_LOCATION -planDirLoc MOVE_PLAN_DIRECTORY
   ```

   In between running the extractMovePlan and pasteConfig scripts, update the moveplan with the new values for configuring the target. See "Modifying Move Plans" in the Oracle Fusion Middleware Administrator’s Guide for information about common moveplan modifications. See the moveplan property descriptions in “Table 20-22 Move Plan Properties for Oracle Identity Manager” in the Oracle Fusion Middleware Administrator’s Guide.
Moving from a Test to a New Production Environment Using Movement Scripts

b. On the target host, create a new directory and copy pasteBinary.sh from the SOURCE_MACHINE/Middleware/oracle_common/bin/ directory. In addition, copy the cloningclient.jar file from the SOURCE_MACHINE/Middleware/oracle_common/jlib/ directory to the target host. Make sure that these two files are in the same location, for example /scratch/aime1/scripts. Then, run the following command:

```
./pasteBinary.sh -javaHome PATH_TO_JDK -al ARCHIVE_LOCATION -tmw TARGET_MW_HOME -silent false -idw true -esp true -ipl PATH_TO_ORACLE_INVENTORY_POINTER -ldl PATH_TO_LOG_DIRECTORY -silent true
```

c. Go to the TARGET_MIDDLEWARE_HOME/bin/ directory, and run the following command:

```
./pasteConfig.sh -javaHome PATH_TO_JDK -archiveLoc ARCHIVE_LOCATION -targetDomainLoc TARGET_DOMAIN_PATH -targetMWHomeLoc TARGET_MIDDLEWARE_HOME_PATH -movePlanLoc MOVE_PLAN_PATH -domainAdminPasswordFile DOMAIN_ADMIN_PASSWORD_FILE -silent true -ldl PATH_TO_LOG_DIRECTORY
```

3. Verify or modify the following configurations after full T2P migration:

- In the xlclient.cmd file, update the JDK path if the JDK library that was configured with the Design Console on the source is no longer accessible on the target.

- The IT Resource configurations are not part of the moveplan in the T2P procedure. After completing the T2P steps and starting the servers on the target setup, you can configure the IT Resource parameters as per the production setup. In Oracle Identity System Administration, under Configuration, click IT Resource. On the Manage IT Resource page, click the edit icon for the IT resource that you want to modify.

**Note:**

- While editing the moveplan, provide the listen address of the target in the Oracle Identity Manager Managed Server details.
- The datasource JDBC URL coming from source to the moveplan can either be in SID format, which is "jdbc:oracle:thin:@HOST:PORT:SID", or in service name format, which is "jdbc:oracle:thin:HOST:PORT/SERVICE_NAME". But you must always provide the JDBC URL in the datasources details in the service name format.

- You might need to change the permissions on the TARGET_MIDDLEWARE_HOME and the target directory on which the JAR has been placed.
- Provide consistent directory paths for each of the parameters. For example, if you are using absolute path for MIDDLEWARE_HOME, then specify this path in the same way at all places.
- Some entities, such as users and provisioned accounts, are not migrated from source to target during the T2P procedure, as they are considered transactional data. Therefore, user personalization settings such as sort order, saved searches, and layout changes will not be found on the target setup.

- Some users, such as role owners, are referenced in many places in Oracle Identity Manager. After full T2P migration, references to such users are replaced with reference to `SYSTEM_ADMINISTRATOR_USERNAME`, the Oracle Identity Manager system administrator.

- Customization done on the LDAP Sync configuration, such as Role Category Container Rules has to be configured on the T2P environment post migration.

### 38.2.1 Troubleshooting Movement From Test to Production Environment Using Movement Scripts

Table 38–3 lists the troubleshooting step that you can perform if you encounter issues related to movement from a test to a new production environment by using movement scripts.
<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>After migrating from an Oracle Identity Manager clustered deployment to another, SOA Server is running but you are not able to access soa-infra. This is because the coherence settings are pointing to source.</td>
<td>Change the coherence settings accordingly by referring to “Specifying the Host Name Used by Oracle Coherence” in the Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Identity Management, and then restart the SOA Server.</td>
</tr>
</tbody>
</table>

The following section is logged in the cloning error logs:

- **NOTIFICATION**: PManager instance is created without multitenancy support as JVM flag "oracle.multitenant.enabled" is not set to enable multitenancy support.
- **SEVERE**: java.io.FileNotFoundException: ./config/jps-config.xml (No such file or directory)
- **NOTIFICATION**: Auditing is disabled for component MDS.
- **NOTIFICATION**: PManager instance is created without multitenancy support as JVM flag "oracle.multitenant.enabled" is not set to enable multitenancy support.

This section of the cloning error logs is benign and can be safely ignored.
38.3 Migrating the Policies

You can migrate the policies from one Oracle Identity Manager deployment to another, for example, from a test environment to production environment, using the migrateSecurityStore WLST command utility provided by Oracle Platform Security. For example, to migrate all Oracle Identity Manager approval policies from the source to target, run the following migration command in overwrite mode from the WLST prompt:

```wlst
migrateSecurityStore(type="appPolicies", configFile="<configuration file path>", src="DBsourceContext", dst="DBdestinationContext", srcApp="OIM", dstApp="OIM", overWrite="true")
```

For information about the various parameters used with the migrateSecurityStore command and the usage options for the utility, see the 'migrateSecurityStore' section in "Infrastructure Security Custom WLST Commands" in the Oracle Fusion Middleware WebLogic Scripting Tool Command Reference for 11g Release 2 (11.1.2).

For information about constructing the configuration file, see "Migrating Policies Manually" in the Oracle Fusion Middleware Application Security Guide for 11g Release 1 (11.1.1).
38.3.1 Troubleshooting Migration of Policies

Table 38–4 lists the troubleshooting step that you can perform if you encounter issues related to migration of policies.

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>The following error is displayed:</td>
<td>Not being able to connect or find the policy store can be the possible causes of this error message. To troubleshoot the problem, check the configuration file for the database connectivity details, root name, and farm name for both source and target.</td>
</tr>
<tr>
<td>oracle.security.jps.service.policystore.PolicyStoreIncompatibleVersionException:</td>
<td></td>
</tr>
<tr>
<td>JPS-06100: Policy Store version 11.0 and Oracle Platform Security Services Version 11.1.1.6.0 are not compatible</td>
<td></td>
</tr>
</tbody>
</table>
Part XI
Reports and Audit

This part describes about audit engine and how to configure reports in Oracle Identity Manager.

It contains the following chapters:

- Chapter 39, "Configuring Reports"
- Chapter 40, "Understanding Auditing"
This chapter describes Oracle Identity Manager Reports and contains the following topics:

- What is Oracle Identity Manager Reports?
- What is Oracle BI Publisher?
- Licensing
- Deploying Oracle Identity Manager Reports
- Configuring Oracle Identity Manager Reports
- Generating Oracle Identity Manager Reports

### 39.1 What is Oracle Identity Manager Reports?

Oracle Identity Manager Reports enables you to use Oracle BI Publisher as the reporting solution for Oracle Identity Management products.

Note: Oracle Identity Manager Reports are classified based on the functional areas. For instance, Access Policy Reports, Attestation, Request and Approval Reports, Password Policy Reports and so on. It is no longer named Operational and Historical.

Oracle Identity Manager Reports provides a restricted-use license for Oracle BI Publisher and easy-to-use reporting packages for multiple Oracle Identity Management products.

As shown in Figure 39–1, Oracle Identity Manager Reports uses Oracle BI Publisher to query and report on information in Oracle Identity Management product databases. With minimal setup, Oracle Identity Manager Reports provides a common method to create, manage, and deliver Oracle Identity Manager Reports.
What is Oracle BI Publisher?

Oracle BI Publisher is an Oracle's enterprise reporting solution and provides a single reporting environment to author, manage, and deliver all of your reports and business documents. Utilizing a set of familiar desktop tools, such as Microsoft Word, Microsoft Excel, or Adobe Acrobat, you can create and maintain report layouts based on data from diverse sources, including Oracle Identity Management products.

39.3 Licensing

Oracle Identity Manager can be separately licensed, independent of any Oracle Application Server or WebLogic edition. BI Publisher is included when you separately license Oracle Identity Manager:

- Shipped BI Publisher reports. Layout changes are allowed, AND
- Shipped or newly created BI Publisher reports that are modified to access data from the existing Identity Management schema that has not been customized.

39.4 Deploying Oracle Identity Manager Reports

This section explains how to deploy Oracle Identity Manager Reports 11g Release 2 (11.1.2.2.0) and contains the following topics:

- Creating the Metadata Repository
- Installing BI Publisher 11g (11.1.1.7.1)
### 39.4.1 Creating the Metadata Repository

Each Oracle Business Intelligence system (BI domain) requires its own set of database schemas. Two or more systems cannot share the same set of schemas or repositories.

You must create a repository in your database by using the Repository Configuration Utility (RCU) before installing BI Publisher 11g (11.1.1.7.1). For this, you need the RCU utility, which you can download from the Oracle Web site by using the following URL:

For installing BI Publisher 11g (11.1.1.7.1), the following metadata repositories are required:

- Metadata Store (MDS)
- Business Intelligence Platform (BI Platform)

To create the repository in your database by using the RCU utility:

1. Log in to the database as SYSDBA.
   
   To run RCU, you must have the DBA privilege. Therefore, you must log in as SYSDBA, for example, as user SYS.

2. Navigate to the RCU_HOME/bin/ directory.

3. To start RCU:
   
   - For UNIX, run:
     
     ./rcu
   
   - For Microsoft Windows, run:
     
     rcu.bat

4. In the Welcome screen that is displayed, click Next. The Repository Creation Utility wizard is displayed.

5. In step 1 of the wizard, select Create, and then click Next. Step 2 of 7: Database Connection Details page is displayed.

6. Specify the connection details, as listed in the following table:
Deploying Oracle Identity Manager Reports

7. Click Next. Step 3 of 7: Component Detail page is displayed.
8. Select the Oracle Business Intelligence component. This action automatically selects the MDS schema under the AS Common Schemas group, which is also required by Oracle Business Intelligence.
9. Click Next. Step 4 of 7: Schema Passwords page is displayed.
10. Specify the same password for schemas.
11. Click Next. Step 5 of 7: Map TableSpaces page is displayed.
12. Click Next. A message is displayed after the validation is complete.
13. Click OK. Step 6 of 7: Summary page is displayed with the details about the component, schema owner, tablespace type, and tablespace name.
14. Click Next. Step 7 of 7: Completion Summary page is displayed.
15. Click Close. The metadata repository is created in your database.

7. Click Next. Step 3 of 7: Component Detail page is displayed.
8. Select the Oracle Business Intelligence component. This action automatically selects the MDS schema under the AS Common Schemas group, which is also required by Oracle Business Intelligence.
9. Click Next. Step 4 of 7: Schema Passwords page is displayed.
10. Specify the same password for schemas.
11. Click Next. Step 5 of 7: Map TableSpaces page is displayed.
12. Click Next. A message is displayed after the validation is complete.
13. Click OK. Step 6 of 7: Summary page is displayed with the details about the component, schema owner, tablespace type, and tablespace name.
14. Click Next. Step 7 of 7: Completion Summary page is displayed.
15. Click Close. The metadata repository is created in your database.

39.4.2 Installing BI Publisher 11g (11.1.1.7.1)

All Oracle Business Intelligence products run on Oracle WebLogic Server domains. Therefore, Oracle WebLogic Server must be installed and configured before you install BI Publisher 11g (11.1.1.7.1).

If you do not have Oracle WebLogic Server installed, then OBIEE 11g installs the WebLogic Server by default, and creates the bi domain named bifoundation_domain under the user_projects/domains directory. See "Deploying Oracle Identity Manager Reports on OBIEE Environment" on page 39-7 for information about deploying Oracle Identity Manager reports on OBIEE environment.

Installing BI Publisher 11g (11.1.1.7.1) is described in the following sections:

- Starting the Oracle Business Intelligence Wizard
- Installing BI Publisher 11g (11.1.1.7.1) When Oracle WebLogic Server is Not Installed
- Installing BI Publisher 11g (11.1.1.7.1) When Oracle WebLogic Server is Installed
Deploying Oracle Identity Manager Reports on OBIEE Environment

Starting the Oracle Business Intelligence Wizard
To start the Oracle Business Intelligence wizard, go to thebishiphome/Disk1/directory, and run the following:

For UNIX:
./runInstaller

For Microsoft Windows:
setup.exe

Installing BI Publisher 11g (11.1.1.7.1) When Oracle WebLogic Server is Not Installed
After starting the Oracle Business Intelligence wizard, perform the following steps:

1. In Step 1 of 15: Welcome page of the wizard that is displayed, click Next. Step 2 of 15: Type Install page is displayed.
2. Select the Install Software Updates option, and click Next. Step 3 of 15: Select Installations Type page is displayed.
3. Select the Enterprise Install option, and click Next. Step 4 of 15: Pre-requisite Check page is displayed.
4. Click Next. Step 5 of 15: Create or Scale BI System page is displayed.
5. Select the Create New BI System option. Then, enter values in the following fields:
   - User Name: Enter the WebLogic user name.
   - Password: Enter a password for the WebLogic user.
   - Confirm Password: Re-enter the password for the WebLogic user.
   - Domain Name: Name of the WebLogic domain, which is bifoundation_domain by default.
6. Click Next. Step 6 of 15: Specify Install Location page is displayed.
7. Enter the directory paths for the installation, and click Next.
8. Click Next. Step 7 of 12: Configure Components page is displayed.

---

**Note:** When you are installing BI Publisher 11g (11.1.1.7.1), the wizard in Configure Components page displays the following options:

- Business Intelligence Enterprise Edition
- Business Intelligence Publisher
- Real Time Decisions
- Essbase Suite

If you are using the report function for Oracle Identity Manager 11g, then ensure that you select the **Business Intelligence Publisher** option only, and not any other option.

9. Click Next. Step 8 of 12: Database Details page is displayed.
10. Enter the details of your database with the credentials that you have specified in the Step 5 of "Creating the Metadata Repository" on page 39-3.

11. Complete the remaining steps of the wizard by clicking Next.

Installing BI Publisher 11g (11.1.1.7.1) When Oracle WebLogic Server is Installed

When BI Publisher 11g (11.1.1.7.1) is already installed, perform the following steps in the Oracle Business Intelligence wizard:

1. In Step 2 of 15: Type Install page, select the Simple Install option, and click Next. Step 3 of 15: Prerequisite Check page is displayed.

2. Click Next. Step 4 of 12: Middleware Home page is displayed.

3. Enter the Middleware home directory path without trailing space, for example, /u01/app/Oracle_IDM1/Middleware/.

4. Click Next. Step 5 of 12: Administrator Details page is displayed.

5. Enter the administrator user name and password. This account is used for the administration of the WebLogic Server and Enterprise Manager.

6. Click Next. Step 6 of 12: Configure Components page is displayed.

---

Note: When you are installing BI Publisher 11g (11.1.1.7.1), the wizard in Configure Components page displays the following options:

- Business Intelligence Enterprise Edition
- Business Intelligence Publisher
- Real Time Decisions
- Essbase Suite

If you are using the report function for Oracle Identity Manager 11g, then ensure that you select the Business Intelligence Publisher option only, and not any other option.

---

7. Click Next. Step 7 of 12: Database Details page is displayed.

8. Enter the details of your database with the credentials that you have specified in the Step 5 of "Creating the Metadata Repository" on page 39-3.

9. Complete the remaining steps of the wizard by clicking Next.

---

Note: If you intend to use the Software Only Install type as part of your strategy to later extend an existing Oracle WebLogic Server domain, then ensure the following:

- The domain is empty, that is, no other software products exist in the domain.
- The domain physically exists on the same computer where you plan to install and configure Oracle Business Intelligence. Extending domains remotely is not supported.

For more information, see "Installing Oracle Business Intelligence" at the following URL:

http://docs.oracle.com/cd/E23943_01/bi.1111/e10539/c4_installing.htm#BIEIG366
Deploying Oracle Identity Manager Reports on OBIEE Environment

To deploy Oracle Identity Manager reports on OBIEE environment:

1. Copy the oim_product_BIP11gReports_11_1_2_2_0.zip file to the BI Publisher directory.

2. Extract the zip file and check for the Oracle Identity Manager and Translations directories created.

3. To sync the catalog with /analytics:
   a. Login to BI Publisher, so that Oracle Identity Manager reports are displayed in the catalog folder on BIP.
   b. Click Administration.
   c. In System Maintenance, click Server Configuration.
   d. In Catalog, select the Oracle BIEE Catalog catalog type, and click Apply.
   e. Restart the BI Server.

39.5 Configuring Oracle Identity Manager Reports

This section describes configuring BI Publisher 11g (11.1.1.7.1) in the following topics:

- Configuring Security on BI Publisher 11g (11.1.1.7.1)
- Configuring Data Sources for Running Oracle Identity Manager Reports

39.5.1 Configuring Security on BI Publisher 11g (11.1.1.7.1)

To configure security in BI Publisher 11g (11.1.1.7.1):

1. Login to BI Publisher. To do so:
   a. In a Web browser, enter the URL in the following format:
      http://HOST_NAME:PORT_NUMBER/xmlpserver/
      For example, http://localhost:7001/xmlpserver/
   b. In the Oracle BI Publisher login page, enter the username and password with WebLogic privileges.

3. Enable Local Superuser and register an authorized superuser. For example, xelsysadm.

4. Restart the BI Publisher Server (bi_server1).

5. Ensure that you are able to log in to the BI Publisher as a registered superuser. For example, xelsysadm.

6. Copy the oim_product_BIP11gReports_11_1_2_2_0.zip file to the BI Publisher directory.

7. Extract the zip file and check for the Oracle Identity Manager and Translations directories created.

8. Navigate to Home and Catalog Folders in the BI Publisher. You can see the Oracle Identity Manager folder under the Shared Folders option.

9. Select Administration, Data Sources, and JDBC Configuration.
10. In the JDBC Configuration location, create two data sources for OIM 11g using the following details:

- **Data Source Name:** OIM JDBC
  - **Driver Type:** Oracle 11g
  - **Database Driver Class:** oracle.jdbc.OracleDriver
  - **Connection String:** jdbc:oracle:thin:@oimhost:1521:orcl
  - **Username:** DEV_OIM
  - **Password:** <PASSWORD>

- **Data Source Name:** BPEL JDBC
  - **Driver Type:** Oracle 11g
  - **Database Driver Class:** oracle.jdbc.OracleDriver
  - **Connection String:** jdbc:oracle:thin:@oimhost:1521:orcl
  - **Username:** DEV_SOAINFRA
  - **Password:** <PASSWORD>

### 39.5.2 Configuring Data Sources for Running Oracle Identity Manager Reports

For Oracle Identity Manager reports, JDBC connections described in the following sections are required:

- Configuring Oracle Identity Manager JDBC Connection
- Configuring BPEL-Based JDBC Connection

#### 39.5.2.1 Configuring Oracle Identity Manager JDBC Connection

To configure Oracle Identity Manager JDBC connection:

1. Click the **Administration** link on the top of the Home page. The BI Publisher Administration page is displayed.
2. Under Data Sources, click the **JDBC Connection** link. The Data Sources page is displayed.
3. In the JDBC tab, click **Add Data Source** to create a JDBC connection to your database. The Add Data Source page is displayed.
4. Enter values in the following fields:
   - **Data Source Name:** Specify the Oracle Identity Manager JDBC connection name, for example, OIM JDBC.
   - **Driver Type:** Select a driver type to suit your database. For example, you can select Oracle 10g or Oracle 11g to suit your database.
   - **Database Driver Class:** Specify a driver class to suit your database, such as oracle.jdbc.driver.OracleDriver.
   - **Connection String:** Specify the database connection details in the format jdbc:oracle:thin:@HOST_NAME:PORT_NUMBER:SID. For example, jdbc:oracle:thin:@localhost:7003:orcl.
   - **Username:** Specify the Oracle Identity Manager database user name.
   - **Password:** Specify the Oracle Identity Manager database user password.
5. Click Test to verify the connection, and then click Apply to establish the connection.

6. If the connection to the database is established, a confirmation message is displayed indicating the success. Click Apply.

In the JDBC page, you can see the newly defined Oracle Identity Manager JDBC connection in the list of JDBC data sources.

39.5.2.2 Configuring BPEL-Based JDBC Connection

In BI Publisher, only one data source can be assigned to a report. The first data source is the Oracle Identity Manager data source. The following reports have a secondary data source, which connects to the BPEL database to retrieve BPEL data:

- Task Assignment History
- Request Details
- Request Summary
- Approval Activity

To configure a secondary data source for BPEL-based reports:

1. In the BI Publisher Home page, click Administration. The BI Publisher Administration page is displayed.

2. Under Data Sources, click the JDBC Connection link. The Data Sources page is displayed.

3. In the JDBC tab, click Add Data Source to create a JDBC connection to your database. The Add Data Source page is displayed.

4. Enter values in the following fields:
   - **Data Source Name**: Specify the BPEL JDBC connection name, for example, BPEL JDBC.
   - **Driver Type**: Select a driver type to suit your database. For example, you can select Oracle 10g or Oracle 11g to suit your database.
   - **Database Driver Class**: Specify a driver class to suit your database, such as oracle.jdbc.driver.OracleDriver.
   - **Connection String**: Specify the database connection details in the format jdbc:oracle:thin:@HOST_NAME:PORT_NUMBER:SID. For example, jdbc:oracle:thin:@localhost:7003:orcl.
   - **User name**: Specify the SOA database user name.
   - **Password**: Specify the SOA database user password.

5. Click Test to verify the connection, and then click Apply to establish the connection.

6. If the connection to the database is established, a confirmation message is displayed indicating the success. Click Apply.

In the JDBC page, you can see the newly defined BPEL JDBC connection in the list of JDBC data sources.
39.6 Generating Oracle Identity Manager Reports

This section explains how to generate Oracle Identity Manager Reports and contains the following topics:

- Generating Sample Reports Against the Sample Data Source
- Generating Reports Against the Oracle Identity Manager JDBC Data Source
- Generating Reports Against the BPEL-Based JDBC Data Source

---

39.6.1 Generating Sample Reports Against the Sample Data Source

If you want to see an example of what report data will look like without running a report against the production JDBC Data Source, you can generate a sample report against the Sample Data Source. You must create the Sample Data Source before you can generate sample reports. Refer to appropriate section for your Oracle Identity Management product in “Configuring Oracle Identity Manager Reports” on page 39-7 for information on creating the Sample Data Source.

After you create the Sample Data Source you can generate sample reports against it by performing the following steps:

1. Login to Oracle BI Publisher. See step 3 in Configuring Security on BI Publisher 11g (11.1.1.7.1) for more information about logging in to Oracle BI Publisher.

2. Click Shared Folders, Oracle Identity Manager Reports, and then select Sample Reports.

3. Click View for the sample report you want to generate.

4. Select an output format for the sample report and click View.

   The sample report is generated.

---

39.6.2 Generating Reports Against the Oracle Identity Manager JDBC Data Source

To generate reports against the Oracle Identity Manager JDBC data source:

1. Log in to Oracle BI Publisher. See step 3 in Configuring Security on BI Publisher 11g (11.1.1.7.1) for more information about logging in to Oracle BI Publisher.

2. Navigate to Oracle Identity Manager reports. To do so:
   a. In the BI Publisher Home page, under Browse/Manage, click Catalog Folders. Alternatively, you can click Catalog at the top of the page.

      The Catalog page is displayed with a tree structure on the left side of the page and the details on the right.

   b. On the left pane, expand Shared Folders, and navigate to Oracle Identity Manager. All the objects in the Oracle Identity Manager folder are displayed.

      You are ready to navigate to BI Publisher 11g and use the Oracle Identity Manager BI Publisher reports.

3. Click View for the report you want to generate.

---

Note: BI Publisher cannot be accessed through the Oracle Identity Self Service or Oracle Identity System Administration. You must open BI publisher explicitly to access the Oracle Identity Manager 11g reports.
4. Select an output format for the report and click View.

The report is generated.

---

**See Also:** Oracle Business Intelligence Publisher Documentation to learn more about Oracle BI Publisher.

### 39.6.3 Generating Reports Against the BPEL-Based JDBC Data Source

The following four reports have a secondary data source, which connects to the BPEL database to retrieve BPEL data:

- Task Assignment History
- Request Details
- Request Summary
- Approval Activity

These reports have a secondary data source, which is the BPEL-based JDBC Data Source, and is called BPEL JDBC.

To generate reports against the BPEL-based JDBC data source:

1. Ensure that a BPEL data source exists in BI Publisher. This BPEL Data Source must point to the BPEL database. See "Configuring BPEL-Based JDBC Connection" on page 39-9 for more information about creating a BPEL data source.

2. Log in to Oracle BI Publisher. See step 3 in Configuring Security on BI Publisher 11g (11.1.1.7.1) for more information about logging in to Oracle BI Publisher.

3. Navigate to Oracle Identity Manager reports. To do so:
   a. In the BI Publisher Home page, under Browse/Manage, click Catalog Folders. Alternatively, you can click Catalog at the top of the page.
      
      The Catalog page is displayed with a tree structure on the left side of the page and the details on the right.
   b. On the left pane, expand Shared Folders, and navigate to Oracle Identity Manager. All the objects in the Oracle Identity Manager folder are displayed.
      
      You are ready to navigate to BI Publisher 11g and use the Oracle Identity Manager BI Publisher reports.

4. Click Open for the report you want to generate.

5. Select an output format for the report, and click Apply.

The report is generated based on the BPEL-based JDBC data source.
User profile audits cover changes to user profile attributes, user membership, resource provisioning, access policies, and resource forms.

The audit engine collects auditing information in Oracle Identity Manager. Whenever a profile is modified, the audit engine captures the changes (the delta) and updates (or generates, if missing) the snapshots of the user and role profiles and stores these snapshots and deltas in XML format. The audit engine also contains post-processors, which, based on the generated XML, populate the reporting tables with relevant data. To maintain high performance, by default the audit engine performs these tasks in an asynchronous and offline manner by using the underlying Java Messaging Service (JMS) provided by the application server.

This chapter discusses the following topics:

- **Audit Levels**
- **Tables Used for Storing Information About Auditors**
- **Issuing Audit Messages**

### 40.1 Audit Levels

As mentioned earlier in this chapter, when you install Oracle Identity Manager user profile auditing is enabled by default and the auditing level is set to Resource Form. If you change the auditing level, then you must run the GenerateSnapshot.sh script (on UNIX) or the GenerateSnapshot.bat script (on Microsoft Windows). This script is in the `IDM_HOME/server/bin` directory. The script examines all users in Oracle Identity Manager database and generates new snapshots based on the new auditing level.
When you run the GenerateSnapshot script, you are prompted to enter the following:

[Enter Xellerate admin username :] SYSTEM_ADMINISTRATOR_USERNAME
[Enter password for xelsysadm :] SYSTEM_ADMINISTRATOR_PASSWORD
[Threads to use [ 8 ]]
[Enter serverURL : [t3://OIM_HOST:OIM_PORT]
[Enter context Factory : { weblogic.jndi.WLInitialContextFactory}

**Note:** Before running the GenerateSnapshot script, you must set the following environment variables:

- **APP_SERVER:** Set the value to weblogic.
- **OIM_ORACLE_HOME:** Set it to the directory on which Oracle Identity Manager is installed.
- **JAVA_HOME:** Set it to the directory path of the Java Runtime directory for the Oracle Identity Manager server.
- **WL_HOME:** Set it to the directory on which Oracle WebLogic Server is installed.
- **MW_HOME:** Set it to the directory on which Oracle Fusion Middleware is installed.
- **DOMAIN_HOME:** Set it to the Oracle Identity Manager domain.

When you run the GenerateSnapshot script, you are prompted to enter the following:

You can configure the "level of detail for auditing" aspect of the auditing engine and specify the audit level as the value of the XL.UserProfileAuditDataCollection system property in the Advanced Administration.

**See Also:** "System Properties in Oracle Identity Manager" in the Oracle Fusion Middleware Administrator's Guide for Oracle Identity Manager for information about this system property

The supported audit levels are:

- **Process Task:** Audits the entire user profile snapshot together with the resource lifecycle process.
- **Resource Form:** Audits user record, role membership, resource provisioned, and any form data associated to the resource.
- **Resource:** Audits the user record, role membership, and resource provisioning.
- **Membership:** Only audits the user record and role membership.
- **Core:** Only audits the user record.
- **None:** No audit is stored.
### 40.2 Tables Used for Storing Information About Auditors

Information about auditors is stored in the following tables of the database:

- **AUD**: This table stores metadata about all the auditors defined in Oracle Identity Manager.

- **aud_jms**: This table stores data to be consumed by the audit engine and eventually by the auditors. It is an operational and intermediate staging table.

  The key in this table is sent to the JMS. Oracle Identity Manager uses this table to control the order of the changes when multiple changes are made to the same user. You can use the Issue Audit Messages Task scheduled task to automate the reissue of messages that are not processed. For more information about this scheduled task, see "Managing the Scheduler" in *Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager*.

### 40.3 Issuing Audit Messages

Oracle Identity Manager provides a scheduled task named Issue Audit Messages Task. This scheduled task retrieves audit message details from the aud_jms table and sends a single JMS message for a particular identifier and auditor entry in the aud_jms table. An MDB processes the corresponding audit message.

The following is the attribute of this task:

**Max Records**

Use the Max Records attribute to specify the maximum number of audit messages to be processed for a specified scheduled task run. The default value of this attribute is 400.

If there is a backlog of audit messages in the aud_jms table, then you can increase the value of the Max Records attribute. The value that you set depends on how many messages the JMS engine can process during the default scheduled task execution interval. This, in turn, depends on the performance of the application server and database. Before increasing the Max Records value, you must determine how much time is taken to process the number of audit messages in the JMS destination (oimAuditQueue) by, for example, using the administrative console of the application server. If the time taken is less than the scheduled task interval, then you can make a corresponding increase in the value of the Max Records attribute.
This part contains the following appendixes:

- Appendix A, "General Customization Concepts"
- Appendix B, "The FacesUtils Class"
- Appendix C, "Username Reservation and Common Name Generation"
Oracle Identity Manager customization is enabled by the Design Console that lets you deal with configuration and design functions, such as designing forms and workflows and creating and managing adapters. Using the Design Console, you can grant user privileges to work on particular areas of the application configuration.

This appendix describes the following topics:

■ Rule Elements, Variables, Data Types, and System Properties
■ Service Accounts
■ Design Console Actions

A.1 Rule Elements, Variables, Data Types, and System Properties

The Design Console lets you perform Oracle Identity Manager customization tasks such as adding and modifying rule elements for a rule, creating or editing e-mail definitions, and creating forms. For these customization tasks, you must set parameters, variables, and data types. This section describes these parameters, variables, and data types.

In the Rule Elements tab of the Rule Designer form, you can create and manage elements and nested rules for a rule. Table A–1 lists the rule elements that can be used to create Oracle Identity Manager rules, by using the Rule Designer form.

Table A–3 describes the properties that can be associated with different data types used to create Oracle Identity Manager forms, by using the Form Designer form.

Table A–3  Properties Associated with Data Types for Creating Oracle Identity Manager Forms

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Data Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text Field</td>
<td>Required</td>
<td>If this text field must be populated for the form to be saved, then enter &quot;true&quot; into the corresponding Property Value field. Otherwise, type &quot;false&quot; into this field. Note: The default value for this data property is false.</td>
</tr>
<tr>
<td>Visible Field</td>
<td></td>
<td>If you want this text field to be displayed when Oracle Identity Manager generates the form, then enter “true” into the corresponding Property Value field. Otherwise, type “false” into this field. Note: The default value for this data property is true.</td>
</tr>
<tr>
<td>Lookup Field</td>
<td>Auto Complete</td>
<td>By entering “true” in the corresponding Property Value field, Oracle Identity Manager filters the lookup field. A user can then add characters to the lookup field before double-clicking it. By doing so, only those Lookup values which match these characters are displayed in the Lookup window. As an example, for a State lookup field, a user can enter “new” into the field. Then, once the user double-clicks the lookup field, only those states that begin with the letters “new” (for example, New Hampshire, New Jersey, New Mexico, and New York) are displayed in the Lookup window. If you do not want Oracle Identity Manager to filter the lookup field, then enter “false” into the associated Property Value field. The default property value for the Auto Complete property is false.</td>
</tr>
<tr>
<td></td>
<td>Column Captions</td>
<td>In the corresponding Property Value field, enter the name of the column heading that is displayed in the Lookup window when a user double-clicks the lookup field. If the Lookup window has multiple columns, then enter each column heading into the Property Value field, separating them with commas. For example, Organization Name, Organization Status.</td>
</tr>
<tr>
<td>Lookup Field</td>
<td>Column Names</td>
<td>In the corresponding Property Value field, enter the name of the database column that represents the column caption that you want to be displayed in the Lookup window. If the Lookup window has multiple columns, then enter each database column into the Property Value field, separating them with commas.</td>
</tr>
</tbody>
</table>
### Table A–3 (Cont.) Properties Associated with Data Types for Creating Oracle Identity Manager Forms

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Data Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column Widths</td>
<td>In the corresponding <strong>Property Value</strong> field, enter the width of the column that is displayed in the Lookup window. If the Lookup window has multiple columns, then enter each column width into the <strong>Property Value</strong> field, separating them with commas, for example, 20,20.</td>
<td></td>
</tr>
<tr>
<td>Lookup Column Name</td>
<td>In the corresponding <strong>Property Value</strong> field, enter the name of the Lookup column as it is displayed in the database, which must be saved to the database.</td>
<td></td>
</tr>
<tr>
<td>Lookup Query</td>
<td>In the corresponding <strong>Property Value</strong> field, enter the name of the SQL query that runs when a user double-clicks the lookup field. As a result, the appropriate Lookup columns are displayed in the Lookup window. To correctly display the data returned from a query, you must add a <code>lookupfield.header</code> property to the <code>xlWebAdmin_locale.properties</code> file. For example, consider the following SQL query: <code>select usr_status from usr</code>. To view the data returned from the query, you must add the following entry to the <code>xlWebAdmin_locale.properties</code> file: <code>lookupfield.header.users.status=User Status</code>. If the <code>xlWebAdmin_locale.properties</code> file does not contain a <code>lookupfield.header</code> property for your specified query, then the Identity System Administration displays a lookup window after you click the corresponding lookup icon. The syntax for a <code>lookupfield.header</code> property is as follows: <code>lookupfield.header.column_code=display value</code>. The <code>column_code</code> portion of the entry must be lowercase and any space must be replaced by the underscore character (_). By default, the following entries for lookup field column headers are already available in the system resource bundle: <code>lookupfield.header.lookup_definition.lookup_code_information.code_key=Value</code>, <code>lookupfield.header.lookup_definition.lookup_code_information.decode=Description</code>, <code>lookupfield.header.users.manager_login=User ID</code>, <code>lookupfield.header.organizations.organization_name=Name</code>, <code>lookupfield.header.it_resources.key=Key</code>, <code>lookupfield.header.it_resources.name=Instance Name</code>, <code>lookupfield.header.users.user_id=User ID</code>, <code>lookupfield.header.users.last_name=Last Name</code>, <code>lookupfield.header.users.first_name=First Name</code>, <code>lookupfield.header.groups.group_name=Group Name</code>, <code>lookupfield.header.objects.name=Resource Name</code>, <code>lookupfield.header.access_policies.name=Access Policy Name</code></td>
<td></td>
</tr>
</tbody>
</table>
Lookup Field

**Lookup Code**

In the corresponding **Property Value** field, enter the lookup definition code. This code contains all information pertaining to the lookup field, including lookup values and the text that are displayed with the lookup field once a lookup value is selected.

**Important**: The Lookup Code data property can be used in lieu of the Column Captions, Column Names, Column Widths, Lookup Column Name, and Lookup Query properties. In addition, the information contained in the Lookup Code property supersedes any values set in these five data properties.

**Tip**: An easy way to enter a lookup code is by starting the Lookup Definition form, querying for the desired code, copying this code to the Clipboard, and pasting it into the Lookup Code field.

**Note**: The classification type of the lookup definition code must be of Lookup Type (the Lookup Type radio button on the Lookup Definition form must be selected).

**Required**

If this **Lookup** field must be populated for the form to be saved, then enter "true" into the corresponding **Property Value** field. Otherwise, type "false" into this field.

**Note**: The default value for this data property is false.

**Visible Field**

If you want this lookup field to be displayed when Oracle Identity Manager generates the form, then enter "true" into the corresponding Property Value field. Otherwise, type "false" into this field.

**Note**: The default value for this data property is true.

**Text Area**

Number of Rows

In the corresponding **Property Value** field, enter the row length of the text area. So, if you want the text area to be five rows in length, then type "5" into the **Property Value** field.

**Required**

If this text area must be populated for the form to be saved, then enter "true" into the corresponding **Property Value** field. Otherwise, type "false" into this field.

**Note**: The default value for this data property is false.

**Visible Field**

If you want this text area to be displayed when Oracle Identity Manager generates the form, then enter "true" into the corresponding Property Value field. Otherwise, type "false" into this field.

**Note**: The default value for this data property is true.

**IT Resource Lookup Field**

Type

If you select this data property, then a box is displayed in the **Property Value** field. From this box, select the type of Server for the IT Resource.

**Important**: This property is required.

**Required**

If this lookup field must be populated for the form to be saved, then enter "true" into the corresponding **Property Value** field. Otherwise, type "false" into this field.

**Note**: The default value for this data property is false.

**Visible Field**

If you want this lookup field to be displayed when Oracle Identity Manager generates the form, then enter "true" into the corresponding **Property Value** field. Otherwise, type "false" into this field.

**Note**: The default value for this data property is true.

**Date and Time Window**

Required

If this text field must be populated for the form to be saved, enter "true" into the corresponding **Property Value** field. Otherwise, type "false" into this field.

**Note**: To populate this text field, double-click it, and select a date and time from the Date & Time window that is displayed.

**Note**: The default value for this data property is false.

---

</tr>
</tbody>
</table>
### Visible Field
If you want this text field to be displayed when Oracle Identity Manager generates the form, then enter "true" into the corresponding **Property Value** field. Otherwise, type "false" in this field.

**Note:** The default value for this data property is true.

### Password Field
**Required**
If this text field must be populated for the form to be saved, enter "true" into the corresponding **Property Value** field. Otherwise, type "false" in this field.

**Note:** The default value for this data property is false.

### Lookup Field
**Lookup Code**
In the corresponding **Property Value** field, enter the lookup definition code. This code contains all information pertaining to the lookup field, including lookup values and the text that are displayed with the lookup field once a lookup value is selected.

**Lookup Query**
In the corresponding **Property Value** field, enter the name of the SQL query that runs when a user double-clicks the lookup field. As a result, the appropriate Lookup columns are displayed in the Lookup window.

To correctly display the data returned from a query, you must add a `lookupfield.header` property to the `xlWebAdmin_locale.properties` file. For example, consider the following SQL query: `select usr_status from usr`. To view the data returned from the query, you must add the following entry to the `xlWebAdmin_locale.properties` files:

```
lookupfield.header.users.status=User Status
```

If the `xlWebAdmin_locale.properties` file does not contain a `lookupfield.header` property for your specified query, then the Identity System Administration displays a lookup window after you click the corresponding lookup icon.

The syntax for a `lookupfield.header` property is as follows:

```
lookupfield.header.column_code=display value
```

The `column_code` portion of the entry must be lowercase and any space must be replaced by the underscore character (_).

By default, the following entries for lookup field column headers are already available in the system resource bundle:

```
lookupfield.header.lookup_definition.lookup_code_information .code_key=Value
lookupfield.header.lookup_definition.lookup_code_information .decode=Description
lookupfield.header.users.manager_login=User ID
lookupfield.header.organizations.organization_name=Name
lookupfield.header.it_resources.key=Key
lookupfield.header.it_resources.name=Instance Name
lookupfield.header.users.user_id=UserID
lookupfield.header.users.last_name=Last Name
lookupfield.header.users.first_name=First Name
lookupfield.header.groups.group_name=Group Name
lookupfield.header.objects.name=Resource Name
lookupfield.header.access_policies.name=Access Policy Name
```
### Properties Associated with Data Types for Creating Oracle Identity Manager Forms

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Data Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Column Names</td>
<td>In the corresponding <strong>Property Value</strong> field, enter the name of the database column that represents the column caption that you want to be displayed in the Lookup window. If the Lookup window has multiple columns, then enter each database column into the <strong>Property Value</strong> field, separating them with commas.</td>
</tr>
<tr>
<td><strong>Radio Button</strong></td>
<td>Required</td>
<td>If a radio button must be selected for the form to be saved, then enter “true” into the corresponding <strong>Property Value</strong> field. Otherwise, type “false” in this field. <strong>Note:</strong> The default value for this data property is false.</td>
</tr>
<tr>
<td></td>
<td>Visible Field</td>
<td>If you want this radio button (or group of radio buttons) to be displayed when Oracle Identity Manager generates the form, then enter “true” into the corresponding <strong>Property Value</strong> field. Otherwise, type “false” in this field. <strong>Note:</strong> The default value for this data property is true.</td>
</tr>

</table>
A.2 Service Accounts

Service accounts are general administrator accounts that are used for maintenance purpose. They are typically shared by a set of users. Service accounts are requested, provisioned, and managed in the same manner as regular accounts. A service account is distinguished from a regular account by an internal flag.

When a user is provisioned with a service account, Oracle Identity Manager manages a mapping from the user’s identity to the service account. This user is considered the owner of the Service Account. When the user is deleted or the resource is revoked, the provisioning process for the service account does not get canceled, which would cause the undo tasks to fire. Instead, a task is inserted into the provisioning process in the same way Oracle Identity Manager handles Disable and Enable actions. This task removes the mapping from the user to the service account, and returns the service account to the pool of available accounts. This management capability is exposed through APIs.

Table A–4 describes the service account management tasks and their corresponding APIs.

### Table A–4 Service Account Management Tasks and Corresponding APIs

<table>
<thead>
<tr>
<th>Tasks</th>
<th>Description</th>
<th>API Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Account</td>
<td>You can change an existing regular account to be a service account or change an existing service account to be a regular account. Either way, the Service Account Change task is inserted into the provisioning process, becoming active in the Tasks tab of the Process Definition. Any adapter that is associated with this provisioning process runs. If there is no adapter, then a predefined response code is attached.</td>
<td>tcUserOperationsIntf.changeFromServiceAccount tcUserOperationsIntf.changeToServiceAccount</td>
</tr>
<tr>
<td>Service Account</td>
<td>When a user with a linked service account is deleted or disabled, the Service Account Alert task is inserted into the provisioning process of the service account instance. You can use this task to start the appropriate actions in response to the event that occurred for the user.</td>
<td>NA</td>
</tr>
<tr>
<td>Service Account</td>
<td>You can transfer ownership of a service account from one user to another. This translates into the provisioning instance showing up in the resource profile of the new owner, and no longer in the resource profile of the old user. The Service Account Moved task is inserted into the provisioning process of the resource instance after the account is moved. Any adapter associated with this provisioning process runs. If there is no adapter, then a predefined response code is attached.</td>
<td>tcUserOperationsIntf.moveServiceAccount</td>
</tr>
</tbody>
</table>
A.2.1 Service Account Customization: Scenario One

The following scenario describes how to allow a user to request a service account on Active Directory. To create a service account, you first create a regular account, and then use the changeToServiceAccount API to change the regular account to a service account. The following is the process to achieve this:

1. The user logs in and requests a service account.
2. The system prompts the Active Directory supervisor for approval.
3. The Active Directory supervisor approves the request.
4. The service account is created.
5. Notification is sent to the employee that the request has been approved.
6. Later, when the service account owner is off-boarded, the owner's supervisor should be assigned as the new owner of the service account and a notification is sent to the owner.

To implement this scenario, perform the following steps:

1. On the Active Directory object form, add a check box field so that the user can select whether the requested account is a service account or a regular account.
2. Modify the Active Directory process form to incorporate the check box field and establish data-flow.
3. Grant the user permissions to update the object form.
4. Add a conditional task to the provisioning process that will get inserted after the creation of the account and that will check the "is service account" flag on the process form and invoke the changeToServiceAccount() API by using the current account's oui_key .

When provisioning starts, the provisioning process checks the flag and loads the changeToServiceAccount() API.

Note that tasks can send out e-mail notifications when the tasks are completed.
5. When the user is off-boarded, attach an adapter to the "Service Account Alert" task so that the system can identify the current user, look up that user's manager or supervisor, and load the tcUserOperationsIntf.moveServiceAccount() API to reassign ownership of the service account appropriately.

A.2.2 Service Account Customization: Scenario Two

This section describes at a high level how to allow a user to request that service account ownership be transferred away from another user and to the requesting user. The following is the process to achieve this:

1. The user logs in to Oracle Identity Manager and requests a transfer of ownership for a particular Active Directory service account away from the current user and to the requesting user.
2. The request is forwarded to the current service account owner for approval.
3. The service account is transferred to the requesting user upon approval of the current owner.

To implement this scenario, perform the following steps:
Because the Oracle Identity Manager user interface does not support account ownership transfer requests, create a dummy resource with custom logic that will query the service accounts present in the system for particular resource objects.

The approver in this scenario is the service account owner. Therefore, use a task assignment adapter to first retrieve the service account owner, and then assign the task to that owner.

As noted in the previous scenario, tasks can send out e-mail notifications when tasks are completed.

After the approval goes through, load the moveServiceAccount() API to transfer ownership of the service account to the requester.

### A.3 Design Console Actions

Table A–5 lists the Oracle Identity Manager actions, and the conditions and results of these actions.

<table>
<thead>
<tr>
<th>Action</th>
<th>Condition</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>A user is deleted.</td>
<td>Oracle Identity Manager cancels all the existing tasks in process instance and inserts undo tasks for these tasks, if they are defined.</td>
<td>If so, then the condition for this task has been met (the user has been revoked), and Oracle Identity Manager inserts the task into the existing process. If the task has an adapter attached to it, then it will run.</td>
</tr>
<tr>
<td>A user is disabled.</td>
<td>Oracle Identity Manager checks each process for any tasks that display the Disable selection in the Task Effect combo box.</td>
<td>If so, then the condition for this task has been met (the user has been disabled), and Oracle Identity Manager inserts the task into the existing process. If the task has an adapter attached to it, then it will run.</td>
</tr>
<tr>
<td>A user is enabled.</td>
<td>Oracle Identity Manager checks each process for any tasks that display the Enable selection in the Task Effect combo box.</td>
<td>If so, then the condition for this task has been met (the user has been enabled), and Oracle Identity Manager inserts the task into the existing process. If the task has an adapter attached to it, then it will run.</td>
</tr>
<tr>
<td>A user's password has been modified on the Users form</td>
<td>Oracle Identity Manager checks each process to see if it has a Change User Password task.</td>
<td>If so, then the condition for this task has been met (the user's password has been modified), and Oracle Identity Manager inserts the task into all existing processes, which have that task defined. If the task has an adapter attached to it, then it will run.</td>
</tr>
<tr>
<td>The data fields of an application process form have been modified.</td>
<td>Oracle Identity Manager checks each process to see if it has a task that starts with the field label Updated naming convention (for example, HomeDirectory Updated).</td>
<td>The condition for this task is met (the process task begins with the field label Updated naming convention). Oracle Identity Manager inserts the task into all existing processes, which have that task defined. If the task has an adapter attached to it, then it will run.</td>
</tr>
</tbody>
</table>

Note: This use case requires heavy customization.
A user’s profile information has been moved to a different organization. Oracle Identity Manager checks each process to see if it has a task that begins with the words Move User. The condition for this task is met (the user’s profile information has been moved to a different organization). Oracle Identity Manager inserts the task into the existing process. If the task has an adapter attached to it, then it will run.
The FacesUtils Class

The FacesUtils class is used in the customization use cases shown in "Using Managed Beans" on page 30-46. This class contains various helper methods for re-rendering components, evaluating EL expressions, and accessing attributes through binding.

Example B–1 provides the code snippet of the FacesUtils class with implementation of some of the methods:

```java
package oracle.iam.ui.sample.common.view.utils;

import java.io.IOException;
import java.util.Map;
import java.util.ResourceBundle;
import javax.el.ELContext;
import javax.el.ExpressionFactory;
import javax.el.MethodExpression;
import javax.el.ValueExpression;
```

**Note:** If you add the code from Example B–1 in any ViewControllerProject source code, then some packages, such as the following, might not be found:

```java
import oracle.adf.model.BindingContext;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.adf.model.binding.DCControlBinding;
import oracle.binding.AttributeBinding;
import oracle.binding.ControlBinding;
```

You must add ADF Model Runtime to the class path to resolve the errors related to importing these packages. To add ADF Model Runtime to project class path:

1. Right-click the project, and select Project Properties.
2. On the left navigation bar, select Libraries and Classpath.
3. Click Add Library.
5. Click OK.
6. Click OK.

---

**Example B–1 Sample FacesUtils Class**

```java
package oracle.iam.ui.sample.common.view.utils;

import java.io.IOException;
import java.util.Map;
import java.util.ResourceBundle;
import javax.el.ELContext;
import javax.el.ExpressionFactory;
import javax.el.MethodExpression;
import javax.el.ValueExpression;
```
import javax.faces.application.Application;
import javax.faces.application.FacesMessage;
import javax.faces.component.UIComponent;
import javax.faces.context.FacesContext;
import oracle.adf.model.BindingContext;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.adf.model.binding.DCControlBinding;
import oracle.adf.view.rich.context.AdfFacesContext;
import oracle.binding.AttributeBinding;
import oracle.binding.ControlBinding;
import oracle.iam.ui.platform.utils.TaskFlowUtils;
import oracle.jbo.uicli.binding.JUCtrlActionBinding;
import oracle.jbo.uicli.binding.JUCtrlListBinding;
import oracle.jbo.uicli.binding.JUEventBinding;

    throw new RuntimeException(ex);
}
}
This appendix contains the following topics:

- Username Reservation
- Common Name Generation

C.1 Username Reservation

When the request for user creation is submitted, the following scenarios are possible:

- While the request is pending, another create user request is submitted with the same username. If the second request is approved and the user is created, then the first request, when approved, fails because the username already exists in Oracle Identity Manager.

- While the request is pending, another user with the same username is directly created in the LDAP identity store. When the create user request is approved, it fails while provisioning the user entity to LDAP because an entry already exists in LDAP with the same username.

To avoid these problems, you can reserve the username in both Oracle Identity Manager and LDAP while the create user request is pending for approval. If a request is created to create a user with the same username, then an error message is displayed and the create user request is not created.

For reserving the username:

- The USER ATTRIBUTE RESERVATION ENABLED system property must be set to TRUE for the functionality to be enabled. For information about searching and modifying system properties, see "Managing System Properties" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

- Reservation in LDAP is done only if reservation functionality is enabled, and LDAP is in sync with Oracle Identity Manager database. For information about synchronization between Oracle identity Manager and LDAP identity store, see "Integration Between LDAP Identity Store and Oracle Identity Manager" in Oracle Fusion Middleware Developer’s Guide for Oracle Identity Manager.
If user attribute reservation is enabled, the reservation happens in two phases:

In the first phase, an entry is created in Oracle Identity Manager database and a user is created in reservation container. This entry in Oracle Identity Manager database is removed after successful creation of user, rejection by approver, or request failure.

In the second phase, in LDAP, on successful creation, the user is moved to the reservation container. In other cases such as rejection by approver or request failure, the user is removed from the reservation container.

After the request-level and operation-level approvals are obtained for the create user request, the username is no longer reserved in the username container in LDAP. The username is moved to the container in which the existing users are stored. The user is also created in Oracle Identity Manager.

This section consists of the following topics:

- Enabling and Disabling Username Reservation
- Configuring the Username Policy
- Writing Custom User Name Policy
- Releasing the Username
- Configuring Username Generation to Support Microsoft Active Directory

### C.1.1 Enabling and Disabling Username Reservation

The username reservation functionality is enabled by default in Oracle Identity Manager. This is done by keeping the value of the USER ATTRIBUTE RESERVATION ENABLED system property to TRUE. You can verify the value of this system property in the System Configuration section of the Oracle Identity Manager System Administration Console.

To disable username reservation:

1. Log in to Oracle Identity System Administration.
2. In the left pane, under System Management, click System Configuration. The Advanced Administration opens in a new window.
3. In the left pane, click the search icon to search for all existing system properties. A list of system properties are displayed in the search results table.
4. Click User Attribute Reservation Enabled. The System Property Detail page for the selected system property is displayed, as shown in Figure C–1:
5. In the Value field, enter **False**.

6. Click **Save**. The username reservation functionality is disabled.

### C.1.2 Configuring the Username Policy

Username Policy is a plugin implementation for username operations such as username generation and username validation. You can change the default policies from the System Configuration section in Oracle Identity System Administration.

In case of a Create User usecase, the plugins are invoked only if the user login is not provided. In such a case, the plugin to be invoked is picked up from the system property, "Default policy for username generation". The custom user name policy is honored in all the following use cases:

- Create Admin User
- Create User Request
- Reconciliation
- Bulk Load

**Table C–1** lists the predefined username policies provided by Oracle Identity Manager. In this table, the dollar ($) sign in the username generation indicates random alphabet:

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Expected Information</th>
<th>Username Generated</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.EmailIdPolicy</td>
<td>E-mail</td>
<td>E-mail value is used as the auto-generated user name</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.LastNameFirstInitialLocalePolicy</td>
<td>First name, last name, and locale</td>
<td>last name + first initial.locale, last name + middle initial + first initial.locale, last name + $ + first initial.locale (all possibilities of single random alphabets), last name + $$ + first initial.locale</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.FirstInitialLastNameLocalePolicy</td>
<td>Firstname, Lastname, Locale</td>
<td>first initial + lastname.locale, first initial + middle initial + first name.locale, first initial + $ + lastname.locale, first initial + $$ + lastname.locale</td>
</tr>
</tbody>
</table>
The policy implementations generate the username, check for its availability, and if the username is not available, then generate other username based on the policy in the order mentioned in Table C–1, and repeat the procedure. The dollar ($) sign in the username generation indicates random alphabet. If any of the expected information is missing, then the policies generate errors.

Values must be provided for all the parameters of the username generation format. If any of the parameters are not provided, then Oracle Identity Manager generates an error. For example, If the firstname.lastname policy is configured and the firstname is

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Expected Information</th>
<th>Username Generated</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.LastNameFirstInitialPolicy</td>
<td>Firstname, Lastname</td>
<td>lastname+firstInitial, lastname+middleinitial+firstInitial, lastname+$+firstInitial (all possibilities of single random alphabets) , lastname+$$+firstInitial</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.FirstInitialLastNamePolicy</td>
<td>Firstname, Lastname</td>
<td>firstInitial+lastname, firstInitial+middleInitial+firstname, firstInitial+$+lastname, firstInitial+$$+lastname</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.LastNameFirstNamePolicy</td>
<td>Firstname, Lastname</td>
<td>lastname.firstname, lastname.middleinitial.firstname, lastname.$firstname (all possibilities of single random alphabets) , lastname.$$.firstname</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.FirstNameLastNamePolicy</td>
<td>Firstname, Lastname</td>
<td>firstname.lastname, firstname.middleinitial.lastname, firstname.$lastname (all possibilities of single random alphabets) , firstname.$$.lastname</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.DefaultComboPolicy</td>
<td>Any one of the following: - Email - Firstname, Last Name - Last name.</td>
<td>If e-mail is provided, then username is generated based on the e-mail. If e-mail is not available, then it generates username based on firstname and lastname by appending a user domain to it. If first name is not available, then it generates the username based of the last name only by appending a user domain to it. The user domain is configured as the Default user name domain system property, and the default value is @oracle.com</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.LastNamePolicy,</td>
<td>Lastname</td>
<td>lastname, middle initial + lastname , $ + lastname, $$ + lastname</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.LastNameLocalePolicy</td>
<td>Lastname, Locale</td>
<td>lastname.locale, middle initial + lastname.locale , $ + lastname.locale, $$ + lastname.locale</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.FirstNameLastNamePolicyForAD</td>
<td>Firstname, Lastname</td>
<td>firstname+lastname, substring of firstname+lastname+$, substring of firstname+ substring of lastname+$$</td>
</tr>
<tr>
<td>oracle.iam.identity.usermgmt.impl.plugins.LastNameFirstNamePolicyForAD</td>
<td>Lastname, Firstname</td>
<td>lastname+firstname, lastname+substring of firstname+$, substring of lastname+ substring of firstname+$$</td>
</tr>
</tbody>
</table>
not provided, then the error would be “An error occurred while generating the Username. Please provide firstname as expected by the firstname.lastname policy”.

The username generation is exposed as public APIs in User Manager. Oracle Identity Manager provides an utility class for accessing the functionality of generating user names. The class that contains utility methods is as shown:

oracle.iam.identity.usermgmt.api.UserManager

The UserManager class exposes the following public API for username generation and validation:

```java
//Method that will generate username based on default policy
public String generateUserNameFromDefaultPolicy(Map<String, Object> attrMap)
    throws UserNameGenerationException, UserManagerException;

//Method that will generate username based on policy
public String generateUserNameFromPolicy(String policyId, Map<String, Object> attrMap)
    throws UserNameGenerationException, UserManagerException;

//Method that will check whether username is valid against default policy
public boolean isUserNameValidForDefaultPolicy(String userName, Map<String, Object> attrMap)
    throws UserManagerException;

//Method that will check whether username is valid against given policy
public boolean isUserNameValidForPolicy(String userName, String policyId, Map<String, Object> attrMap)
    throws UserManagerException;

//Method to return all policies (including customer written)
public List<Map<String, String>> getAllUserNamePolicies(Locale locale);

//Method that will return policy description in given locale
public String getPolicyDescription(String policyID, Locale locale);
```

Table C–2 lists the constants defined in oracle.iam.identity.usermgmt.utils.UserNameGenerationUtil to represent the policy ID of the default username policies:

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>EmailIDPolicy</td>
<td>EMAIL_ID_POLICY</td>
</tr>
<tr>
<td>LastNameFirstInitialLocalePolicy</td>
<td>FIRSTNAME_LASTNAME_POLICY</td>
</tr>
<tr>
<td>FirstInitialLastNameLocalePolicy</td>
<td>LASTNAME_FIRSTNAME_POLICY</td>
</tr>
<tr>
<td>LastNameFirstInitialPolicy</td>
<td>FIRSTINITIAL_LASTNAME_POLICY</td>
</tr>
<tr>
<td>FirstInitialLastNamePolicy</td>
<td>LASTNAME_FIRSTINITIAL_POLICY</td>
</tr>
<tr>
<td>LastNameFirstNamePolicy</td>
<td>FIRSTINITIAL_LASTNAME_LOCALE_POLICY</td>
</tr>
<tr>
<td>FirstNameLastNamePolicy</td>
<td>LASTNAME_FIRSTINITIAL_LOCALE_POLICY</td>
</tr>
<tr>
<td>DefaultComboPolicy</td>
<td>DEFAULT_COMBO_POLICY</td>
</tr>
</tbody>
</table>
When called to generate username, the policy classes expect the attribute values to be set in a map by using the key constants defined in the oracle.iam.identity.utils class.Constants. This means that a proper parameter value must be passed to call the method by using the appropriate constant defined for it, for example, the FirstName parameter has a constant defined for it.

The default username policy can be configured by using the Oracle Identity System Administration. To do so:

1. Navigate to the System Configuration section.
2. Search for all the system properties.
3. Click **Default policy for username generation**. The System Property Detail page for the selected property is displayed, as shown in Figure C–2:

![Figure C–2 The Default Username Policy Configuration](image)

The XL.DefaultUserNameImpl system property is provided for picking up the default policy implementation. By default, it points to the default username policy, which is oracle.iam.identity.usermgmt.impl.plugins.DefaultComboPolicy displayed in the Value field.

4. In the Value field, enter `oracle.iam.identity.usermgmt.impl.plugins.POLICY`. Here, `POLICY` is one of the policy implementations.

### Table C–2 (Cont.) Constants Representing Policy IDs

<table>
<thead>
<tr>
<th>Policy Name</th>
<th>Constant</th>
</tr>

5. Click Save.

C.1.3 Writing Custom User Name Policy

You can write your own policies by adding new plug-ins and changing the default policies from the System Configuration section in Oracle Identity System Administration.

See Also: "Developing Plug-ins" on page 27-1 for information about the plug-in framework

The UserManager exposes APIs for username operations. The APIs take the user data as input and return a generated username. The APIs make a call to plug-ins that return the username. This allows you to replace the default policies with custom plug-ins with your implementation for username operations.

Note:

- For user name generation and validation, public APIs are exposed in UserManager.
- While creating the policy, ensure that the attributes used in generating the username are defined in the request data set.

You can write your own username policies by implementing the plug-in interface, as shown:

```java
package oracle.iam.identity.usermgmt.api;

public interface UserNameGenerationPolicy extends oracle.iam.identity.usermgmt.api.UserNamePolicy {
    public String getUserName(Map<String, Object> reqData) throws UserNameGenerationException;
    public boolean isGivenUserNameValid(String userName, Map<String, Object> reqData);
    //methods inherited from old user name policy interface
    //oracle.iam.identity.usermgmt.api.UserNamePolicy
    public String getUserNameFromPolicy(HashMap<String, String> reqData) throws UserNameGenerationException;
    public boolean isUserNameValid(String userName, HashMap<String, String> reqData);
    public String getDescription(Locale locale);
}
```

Note: All the plug-ins must be registered with Oracle Identity Manager by using the /identity/metadata/plugin.xml file. A sample plugin.xml file is as shown:

```xml
<plugins
    pluginpoint="oracle.iam.identity.usermgmt.api.UserNamePolicy">
    <plugin
        pluginclass="oracle.iam.identity.usermgmt.impl.plugins.LastNameFirstNamePolicy"
        version="1.0" name="LastNameFirstNamePolicy"/>
</plugins>
```
This plug-in point is exposed as a kernel plug-in that takes request data as input and returns the username. Each plug-in expects some information and generates username based on that information provided.

**Note:** Oracle Identity Manager provides an abstract implementation of the `oracle.iam.identity.usermgmt.api.UserNameGenerationPolicy` interface as the `oracle.iam.identity.usermgmt.api.AbstractUserNameGenerationPolicy` class name. Therefore, you need not implement the following two methods:

```java
public String getUserNameFromPolicy(HashMap<String, String> reqData) throws UserNameGenerationException;

public boolean isUserNameValid(String userName, HashMap<String, String> reqData);
```

Create the plug-in ZIP with lib (containing the JAR) and plugin.xml, and then register it by performing the procedure in section "Registering and Unregistering Plug-ins By Using the Plugin Registration Utility" on page 27-8. The following is a sample plugin.xml file:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oimplugins>
<plugins pluginpoint="oracle.iam.identity.usermgmt.api.UserNamePolicy">
  <plugin pluginclass="oracle.iam.identity.usermgmt.impl.plugins.CustomDepartmentNumberEmployeeNumberPolicy" version="1.0" name="CustomDepartmentNumberEmployeeNumberPolicy"/>
</plugins>
</oimplugins>
```

The following are the guidelines on while writing custom user name policies:

- Policies should implement the new interface `oracle.iam.identity.usermgmt.api.UserNameGenerationPolicy`.
- Custom user name policies must be re-entrant. This means that the custom code in the policy should return the same user login if approver has updated an attribute that does not contribute in generating the user login.

For sample implementation please refer below:

```java
package oracle.iam.identity.usermgmt.impl.plugins;

import java.util.Locale;
import java.util.Map;
import oracle.iam.identity.exception.UserNameGenerationException;
import oracle.iam.identity.usermgmt.api.AbstractUserNameGenerationPolicy;
import oracle.iam.identity.usermgmt.api.UserNameGenerationPolicy;

public class CustomDepartmentNumberEmployeeNumberPolicy extends AbstractUserNameGenerationPolicy implements UserNameGenerationPolicy {

    private String departmentNumberKey =
        UserManagerConstants.AttributeName.DEPARTMENT_NUMBER.getId();

    private String employeeNumberKey =
```
@Override
public String getUserName(Map<String, Object> reqData)
throws UserNameGenerationException {

String departmentNumber = reqData.get(departmentNumberKey) == null ? null : reqData.get(departmentNumberKey).toString();

String employeeNumber = reqData.get(employeeNumberKey) == null ? null : reqData.get(employeeNumberKey).toString();

// Required in case of approver edit. If approver has not modified any attribute which contributes in user name generation, then return same old user login

// Check if user data is not changed using checkForSameUserLogin method present in AbstractUserNameGenerationPolicy, then return same user login

// OR use Map<String, Object> existingData = (Map<String, Object>) reqData.get(oracle.iam.identity.usermgmt.api.UserManagerConstants.EXISTING_DATA) to implement your own comparison logic

// If existingData is NULL, it means generate a new user login. If it is not NULL, then it means policy is invoked during approver edit.

// If it is NOT NULL, Compare value of participating attributes from existingData and reqData. If same, return same user login as present in existingData; otherwise generate a new user login.

String oldUserLogin = checkForSameUserLogin(reqData, new String[]{departmentNumberKey, employeeNumberKey});
if(oldUserLogin!=null)
return oldUserLogin;

// TODO: DO basic validations. Also, Ensure newly generated user name is unique and not reserved. You may use utility methods in oracle.iam.identity.usermgmt.utils.UserNamePolicyUtil for preforming validations.

return departmentNumber + "-" + employeeNumber;
}

@override
public boolean isGivenUserNameValid(String userName, Map<String, Object> reqData) {
// TODO : custom implementation
return true;
}

@override
public String getDescription(Locale locale) {
    return "User Name Generation Policy using department number and employee number";
}

C.1.4 Releasing the Username
The username is released in the following scenarios:
When the request is approved, and the user is successfully created in Oracle Identity Manager and provisioned to LDAP, and the username from the reserved table is removed. The reserved username is removed after successful user creation after the approvals. The reserved entry in LDAP is removed and the actual user is created.

- If the request is rejected, then the reserved entry of username in LDAP and Oracle Identity Manager is removed.
- If the request fails while or before creating a user in Oracle Identity Manager or LDAP, then the reserved username is deleted.

**C.1.5 Configuring Username Generation to Support Microsoft Active Directory**

In Oracle Identity Manager deployment with LDAP synchronization is enabled, where Microsoft Active Directory (AD) is the data store, the User Login attribute in Oracle Identity Manager is mapped to the uid attribute in LDAP, which in turn is mapped to the sAMAccountName attribute. The sAMAccountName attribute is used as login for all AD-based applications. There is a limitation on the maximum length supported for value contained in the sAMAccountName attribute in AD. It cannot exceed 20 characters.

Oracle Identity Manager accepts user name as an input at the time of user creation and it can be more than 20 characters. Because AD does not support user name of more than 20 characters, Oracle Identity Manager can be configured to generate the user name, which consists of less than 20 characters.

When AD is used as data store, you can configure the autogeneration of user name by setting the value of the XL.DefaultUserNamePolicyImpl system property to any one of the following:

- **FirstNameLastNamePolicyForAD**: Generates the user login by prefixing a substring from the first name to that of the last name
- **LastNameFirstNamePolicyForAD**: Generates the user login by prefixing a substring from last name to that of the first name

See "Administering System Properties" for information about the XL.DefaultUserNamePolicyImpl system property and setting values of system properties.

---

**Note**: If AD is the data store, then any one of the FirstNameLastNamePolicyForAD or LastNameFirstNamePolicyForAD policies must be used. Any other user name generation policy will fail to generate the user name.

---

**C.2 Common Name Generation**

The generation of the Common Name user attribute value in Oracle Identity Manager is described in the following sections:

- **Common Name Generation for Create User Operation**
- **Common Name Generation for Modify User Operation**

**C.2.1 Common Name Generation for Create User Operation**

In an LDAP-enabled deployment of Oracle Identity Manager, Fusion applications such as Human Capability Management (HCM) does not pass the common name via SPML
request. Given that the common name is a mandatory attribute in LDAP and Oracle Identity Manager is setup to use it as the RDN, Oracle Identity Manager must generate a unique common name.

Based on the description on Common Name, it is the user’s display name consisting of first name and last name. Therefore, Oracle Identity Manager generates the Common Name with the help of a common name generation policy that specifies the Common Name in the "firstname lastname" format.

To configure common name generation in Oracle Identity Manager, set the value of the XL.DefaultCommonNamePolicyImpl system property to oracle.iam.identity.usermgmt.impl.plugins.FirstNameLastNamePolicy. For information about the XL.DefaultCommonNamePolicyImpl system property and setting the value of a system property, see "Managing System Properties" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

The following are the details of the FirstNameLastNamePolicy:

- Expected information: Firstname, Lastname
- Common Name generated: firstname.lastname, firstname.$$.lastname (all possibilities of single random alphabets), firstname.$$$.lastname and so on until a unique common name is generated

---

**Note:** The common name must be reserved until the user is created by the request so that multiple requests generated simultaneously having same first and last names do not generate the same common name.

---

### C.2.2 Common Name Generation for Modify User Operation

When the user profile is modified, one or more attributes can change. HCM cannot filter out and send only the modified data to Oracle Identity Manager because it does not have the old user attributes and cannot determine which ones are modified. Therefore, all attributes including the common name (CN) are passed to Oracle Identity Manager by the SPML request. Because the CN changed, Oracle Identity Manager attempts a modify operation (modrdn) in the directory resulting in DN change. Because of this unintended DN change, the group membership DN becomes stale resulting in the user loosing membership in that group. This subsequently results in authorization failure. This happens when referential integrity is turned off in the LDAP server, and therefore, the referenced groups are not updated when the RDN of the user changes. Therefore, referential integrity must be turned on in the target LDAP server. Otherwise, the group memberships become stale. The referential integrity issue is also applicable to roles. Groups are also members of other groups and any RDN changes must be reflected as well.

You can turn on the referential integrity by setting the value of the XL.IsReferentialIntegrityEnabled system property to TRUE. For information about this system property, see "Managing System Properties" in the Oracle Fusion Middleware Administrator’s Guide for Oracle Identity Manager.

Table C–3 lists the possible scenarios when RDN is modified:
<table>
<thead>
<tr>
<th>Referential Integrity in LDAP</th>
<th>XL.IsReferentialIntegrity Enabled</th>
<th>Result of Modify Operation (modrdn)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>FALSE</td>
<td>Oracle Identity Manager generates an error and operation fails.</td>
</tr>
<tr>
<td>Disabled</td>
<td>TRUE</td>
<td>Modify operation passes from Oracle Identity Manager and RDN is changed in LDAP. However, the group references are not updated and are stale. This configuration is not recommended.</td>
</tr>
<tr>
<td>Enabled</td>
<td>FALSE</td>
<td>Oracle Identity Manager generates an error and modify operation fails. This property must be set to TRUE in Oracle Identity Manager because referential integrity is enabled in LDAP.</td>
</tr>
<tr>
<td>Enabled</td>
<td>TRUE</td>
<td>Modify operation passes and RDN is updated. In addition, the references for the DN are updated in LDAP.</td>
</tr>
<tr>
<td>Multiple directories with roles and users stored in separate directories. Referential integrity property is not relevant here.</td>
<td>FALSE</td>
<td>Modify operation fails from Oracle Identity Manager. This is not supported by LDAP. Therefore, FALSE is the recommended value in Oracle Identity Manager for the property.</td>
</tr>
<tr>
<td>Multiple directories with roles and users stored in separate directories. Referential integrity property is not relevant here.</td>
<td>TRUE</td>
<td>Modify operation passes and RDN is modified. However, because LDAP does not support referential integrity in multiple directories, the group references are stale and must be manually updated.</td>
</tr>
</tbody>
