Oracle® Enterprise Data Quality

Customer Data Services Pack Business Services Guide Release 11g R1 (11.1.1.7)

E40733-03

May 2014

1 Introduction

Oracle Enterprise Data Quality Customer Data Services Pack (EDQ-CDS) can be used as a standalone addition to EDQ, or it can be called by third-party applications.

The provided business services are ready for integration with Siebel Customer Relationship Management (CRM) or Universal Customer Master (UCM) but may also be called by other applications if they are configured to do so.

Ready-to-use, EDQ-CDS provides pre-configured data quality services which can be modified or enhanced by editing the underlying EDQ processes that implement their functionality. These three types of service can be used with Individual, Entity, and Address records:

- Cleaning
- Clustering (for use in Matching integrations)
- Matching

Note: It is possible to further extend the functionality of the EDQ-CDS pack by installing the Data Quality Health Check project, which allows users to perform batch data quality checking of customer data. For more information, see *Oracle Enterprise Data Quality Customer Data Services Pack Health Check Guide*.

2 Cleaning Services

There are three cleaning services provided in EDQ-CDS: Address Clean, Individual Clean and Entity Clean. The Individual and Entity Clean services are provided as placeholders, which are pre-integrated with Siebel, and easily integrated with other applications, but which need to be modified towards specific requirements.

2.1 Address Clean

The EDQ-CDS Address Clean web service provides the following functionality:

- Verification of an input address (returning a verification code and description)
- Geocoding of an address (returning latitude and longitude co-ordinates, with additional metadata)

 Correction, standardization and completion of input addresses (provided the address was verified to a sufficient, configurable, level)

The service is N:N; that is, single and multiple record input and output is possible, but only one record is returned for each record submitted. Each input address is verified and may be corrected, enhanced and geocoded, depending on the options that the job is run with, and the input parameters.

Siebel's Data Quality interface always calls the service with a single record per request, whether running in real-time or batch.

2.1.1 Use

The Address Clean web service is normally used for real-time verification and cleansing of addresses as they are entered and updated in an application, such as Siebel.

In the case of Siebel, the web service is also used in batch. When a batch address cleansing job is run, the web service will be used on all of the in-scope records in the batch job.

For other applications, it is recommended to add configuration to EDQ-CDS to map data from and to the Address Clean data interface in order to run the service in batch mode.

2.1.2 Interface

The following table provides a guide to the interface attributes of the Address Clean web service.

	Data		
Attribute Name	Data Type	Use	Notes
addressid	String	In/Out	Unique identifier for the address.
address1	String	In/Out	Address line 1
address2	String	In/Out	Address line 2
address3	String	In/Out	Address line 3
address4	String	In/Out	Address line 4
dependentlocality	String	In/Out	A smaller population center data element, dependent on the contents of the city field. For example, a Neighborhood in Turkey. For many countries, this attribute is not used.
doubledependentlocality	String	In/Out	The smallest population center data element, dependent on both the contents of the city and dependentlocality fields. For example, a village in the UK. For many countries, this attribute is not used.
city	String	In/Out	The locality, town or city of the address.
subadminarea	String	In/Out	The smallest geographic data element within a country. For example, a county in the USA.

Attribute Name	Data Type	Use	Notes
adminarea	String	In/Out	The most common geographic data element within a country. For example, a State in the USA or a Province in Canada.
postalcode	String	In/Out	Postal or zip code for the address, if relevant for the country.
country	String	In/Out	On input, an ISO two-character country code (preferred) or country name. On output, the full country name (even if the input is the country ISO code).
			Note: If the country field is blank, the service attempts to derive the country from the city attribute. When this is not present, the default specified in the Run Profile is used.
defaultcountrycode	String	Input only	Default ISO two-character country code to use if country not populated. This overrides the default value used when running the job.
case (parameter)	String	Input only	Transforms output according to the setting:
			U (Upper)- Transforms all text to Upper case.
			L (Lower)- Transforms all text to Lower case.
			M (Mixed) - Transform all text to Mixed case, except postalcode and adminarea. These field values are left as returned from the AV processor if the address was verified. If the address was not verified, the postalcode is left as entered, and the adminarea is converted to Mixed case.
			0 (Original) - Text is not transformed.
mode (parameter)	String	Input only	Mode in which the request is to be run.
			Currently, only \forall (Verify) is supported.
minimumverificationmatchscore (parameter)	Number	Input only	A numeric value between 0 and 100, representing the minimum score which a match must achieve to be used as a cleaned address. Input addresses will be left unchanged if the Match Score of the Address Verification processor for the address is lower than the input value.

Attribute Name	Data Type	Use	Notes
minimumverificationlevel (parameter)	Number	Input only	A numeric value between 1 and 5, representing the minimum verification level which a match must achieve to be used as a cleaned address.
			Input addresses will be left unchanged if the Verification Level of the Address Verification processor for the address is lower than the input value. For a description of what each level means, see Section, "Notes on Verification Levels".
allowedverificationresultcodes (parameter)	String	Input only	A list of any of the following single-letter result codes with no separator (for example, 'VPA'):
			∨ (Verified),
			P (Partially Verified)
			A (Ambiguous)
			R (Reverted)
			U (Unverified)
			Input addresses will be left unchanged if the Verification Result Code. For example, the first character of the verificationcode) for the address is not one of the listed input values.
fulladdress	String	Output only	Full verified address returned from address verification. The address lines are pipe-separated.
countrycode	String	Output only	ISO 2 char country code of verified address country.
verificationcode	String	Output only	Verification code for the address. See the online help for the EDQ Address Verification processor for more information on how to understand the returned code.
verified	String	Output only	Whether the result produced was verified to a sufficient level, according to the configuration of the process and the resultant verification code. This also indicates whether or not the input address was changed to the returned address from address verification. Possible returned values are Y (verified), N (not verified) or X (EDQ Address Verification is not installed).
verificationcodedescription	String	Output only	US English description of the verification code.
latitude	Number	Output only	WGS 84 latitude in decimal degrees format.

Attribute Name	Data Type	Use	Notes
longitude	Number	Output only	WGS 84 longitude in decimal degrees format.
geoaccuracycode	String	Output only	A code indicating the level of accuracy of the returned geocodes (latitude and longitude) co-ordinates. See the online help for the EDQ Address Verification processor for more information on how to understand the returned code.
geoaccuracycodedescription	String	Output only	US English description of the geoaccuracycode.
geodistance	Number	Output only	Radius of accuracy (in meters) for the returned geocodes. The higher the value, the less accurate the geocoding result.

2.1.3 Parameters

The Address Clean web service uses a number of input parameters to control its behavior when processing addresses, as listed and described in the table above.

The minimumverificationmatchscore, minimumverificationlevel and allowedverificationresultcodes parameters are all used as message-level thresholds to override whether or not to change (clean) an input address based on the confidence level that the EDQ Address Verification processor reaches when processing it. Normally, and when using the Address Clean service with Siebel, these parameters are not used, and the underlying settings in the Address Clean process are used to drive whether or not to change the address. In this process it is possible to set these same parameters on a per-country basis if required. Where country-specific thresholds are not provided, global default settings are applied, and these may be set using the EDQ-CDS Run Profile. The priority in which the thresholds are applied is therefore:

- 1. Per-message threshold settings using the parameter attributes as above
- 2. Per-country threshold values expressed in the Reference Data set Address Clean Country verification level and results
- **3.** The global default settings expressed in the process and overridden on a per-run basis by the use of a run profile.

An additional configuration option is available to control the number of address lines that are returned from the service. This is not exposed as a parameter on the interface, but can be set using the phase.*.process.Clean\ -\ Address.Number\ Of\ Address\ Lines Run Profile setting. The default number of lines to return is 4.

Notes on Verification Levels

The following verification levels are possible. The maximum verification level that it is possible to reach varies by country. For information on the maximum level in each country, see the Logate Oracle EDQ Portal website at

http://www.logate.com/oracle

The verification level is output as the second character of the Accuracy Code returned by the EDQ Address Verification processor. The 'post-processed' verification level is used (not the 'pre-processed' level); that is, the verification level achieved after EDQ Address Verification applies standardization and parsing to the input address.

Verification Level	Description
1	Verified to Administrative Area (State, Region or County) level
2	Verified to Locality (City or Town) level
3	Verified to Thoroughfare (Street) level
4	Verified to Premise (Building Number) level
5	Verified to Delivery Point (Sub-Building Number) level

Note: If EDQ Address Verification is not installed (or not installed correctly), the Address Clean service can still be installed, and the job that implements it can still be run. However, if a request is made to the service, all the output fields will be blank, except for the verified output field, which will have the value *X*, and the verificationcode output, which will have the value -1.0.

2.2 Individual Clean

The Individual Clean web service is designed to verify, correct, standardize or enhance records representing individuals, whether these be customers, prospective customers, contacts, or employees.

The **Clean - Individual** process that implements this service in EDQ-CDS is just a placeholder, and must be customized to requirements. A default process that converts the input name attributes to upper case is provided so that when connecting this service to Siebel or other applications, it is simple to test that the service is correctly connected.

The service is N:N; that is, single and multiple record input and output is possible, but only one record is returned for each record submitted.

The Siebel Data Quality interface always calls the service with a single record per request, whether running in real-time or batch.

2.2.1 Use

The Individual Clean web service may be extended for many purposes, including (but not limited to):

- Verification of input details related to individuals (for example, an email address)
- Standardization of input details related to individuals (for example, a job title)
- Enhancement of data related to individuals (for example, by matching reference data for individuals and returning additional attributes, such as social media handles)

Normally, the web service will be called in real-time, when individual records are added or updated in an application.

In the case of Siebel, the web service is also used in batch. When a batch contact cleansing job is run, the web service will be used on all of the in-scope records in the batch job.

For other applications, it is recommended to add configuration to EDQ-CDS to map data from and to the **Individual Clean** data interface in order to run the service in batch mode.

The interface used by the service is designed to map directly to the Contact business component in Siebel, but can be freely extended with new attributes on both input and output. Siebel's DQ vendor parameters may be extended to pass through different attributes to the service.

2.2.2 Interface

The following table provides a guide to the default Individual Clean web service interface. All attributes are both input and output by default. It is possible to input an empty value to the interface but to populate the attribute on output, so providing a data enhancement service.

Attribute Name	Data Type	Notes	
individualid	String	A unique identifier for the individual record.	
languages	String	3 character Siebel language code. This can be used to determine whether a name containing Kanji should be treated as Japanese or Chinese.	
nameid	String	Unique identifier for the name.	
title	String	Title	
firstname	String	First name	
middlename	String	Middle name	
lastname	String	Last Name	
gender	String	M or F	
dob	String	Date of Birth	
jobtitle	String	Job Title	
homephone	String	Home Phone Number	
workphone	String	Work Phone Number	
mobilephone	String	Mobile Phone Number	
faxphone	String	Fax Number	
alternatephone	String	Alternate Phone Number	
email	String	Email Address	
taxnumber	String	Tax Number	
nationalidnumber	String	Social Security Number (US) or equivalent.	

2.3 Entity Clean

The Entity Clean web service is designed to verify, correct, standardize or enhance records representing entities, whether these be company customers, prospective company customers, suppliers, or other organizations.

The **Clean - Entity** process that implements this service in EDQ-CDS is just a placeholder, and must be customized to requirements. A default process that converts the input name and subname attributes to upper case is provided so that when

connecting this service to Siebel or other applications, it is simple to test that the service is correctly connected.

The service is N:N; that is, single and multiple record input and output is possible, but only one record is returned for each record submitted.

The Siebel Data Quality interface always calls the service with a single record per request, whether running in real-time or batch.

2.3.1 Use

The Entity Clean web service may be extended for many purposes, including (but not limited to):

- Verification of input details related to entities (for example to check that a website is syntactically valid)
- Standardization of input details related to entities (for example company names and locations)
- Enhancement of data related to entities (for example by matching reference data for entities and returning additional attributes, such as DUNS numbers from Dun and Bradstreet)

Normally, the web service will be called in real-time, when entity records are added or updated in an application.

In the case of Siebel, the web service is also used in batch. When a batch account cleansing job is run, the web service will be used on all of the in-scope records in the batch job.

For other applications, it is recommended to add configuration to EDQ-CDS to map data from and to the **Entity Clean** data interface in order to run the service in batch mode.

The interface used by the service is designed to map directly to the Account business component in Siebel, but can be freely extended with new attributes on both input and output. Siebel's Data Quality vendor parameters may be extended to pass through different attributes to the service.

2.3.2 Interface

The following table provides a guide to the default Entity Clean web service interface. All attributes are both input and output by default. It is possible to input an empty value to the interface but to populate the attribute on output, so providing a data enhancement service.

Attribute Name	Data Type	Notes	
entityid	String	A unique identifier for the entity record.	
languages	String	3 character Siebel language code. This can be used to determine whether a name containing Kanji should be treated as Japanese or Chinese.	
nameid	String	Unique identifier for the name.	
name	String	Organization name for example, "Oracle Corporation UK".	
subname	String	Department or site for example, "Reading", "Accounts Payable", etc.	

Attribute Name	Data Type	Notes
phone	String	Phone Number
alternatephone	String	Alternate Phone Number
website	String	Website Address
taxnumber	String	Company Tax Number
vatnumber	String	Company VAT Number

3 Clustering Services

EDQ-CDS clustering services are designed to generate a number of key values for an individual, entity or address record. The returned key values for a record are then used by applications such as Siebel to select 'candidate' records for matching, where any existing record that shares any key value with the 'driving' record (the record submitted to the clustering service) should be considered a candidate. The driving and candidate records are then submitted in a single request to the relevant Matching service.

In addition to being called in real-time in order to prevent the insertion of duplicate records into an application, the clustering services are used in batch mode to populate the key values on all existing records in the application, so that real-time and incremental batch matching jobs, both of which use the key values for existing records for candidate selection, work correctly.

The clustering services are N:N; meaning that single and multiple record input and output is possible. In real-time, a single output record is returned containing an array of keys. In batch mode, each key is returned as a separate record in the staging table.

3.1 Use

The real-time clustering services are normally used as the first call to EDQ-CDS when a new or updated record needs to be checked for matches against records in an application. The returned key values are used to select candidate records to be submitted with the driving record to the matching service.

In order to ensure that keys are always up-to-date, the clustering services should be called whenever a record is updated. This includes the scenario when a master record in Siebel UCM, or other hub, is updated due to a confirmed match with an incoming driver record.

The clustering services are exposed using the following:

Web Services:

- IndividualCluster
- EntityCluster
- AddressCluster

Batch Jobs:

- Batch Individual Cluster
- Batch Entity Cluster
- Batch Address Cluster

3.2 Interface

The clustering web services present input interfaces with direct mappings to the shared 'Candidate' data interfaces as follows:

Web Service	Input Interface
IndividualCluster	See Section 5.1.1, "Individual Candidates."
EntityCluster	See Section 5.1.2, "Entity Candidates."
AddressCluster	See Section 5.1.3, "Address Candidates."

All the clustering web services return output attributes using the common Real-time Cluster Results Interface data interface, see Section 5.3, "Cluster Results Interfaces."

3.3 Parameters

The IndividualCluster, EntityCluster and AddressCluster web services all expose a clusterlevel parameter attribute, which is used to drive the sensitivity of the clustering service:

Parameter Attributes	Data Type	Accepted Values	Use
clusterlevel	String	A numeric value (1, 2 or 3)	1 = Limited, 2 = Typical, 3 = Exhaustive

The clusterlevel setting determines which methods of cluster key generation are used to generate keys for each driving record. If used, the per-message setting overrides the default setting in the process (that can be adjusted when running a job using the EDQ-CDS Run Profile).

The settings operate as follows:

1 (Limited)

Only cluster keys that do not normally return large numbers of candidate records are generated by the service. This is recommended if working with very large data sets with tight matching requirements.

2 (Typical)

Uses the default methods for generating cluster keys.

3 (Exhaustive)

Methods that may return a large number of candidate records are used to generate cluster keys. This includes methods that only use the name fields. This setting is recommended only when working with low volume data sets (for example, less than a million individuals, or less than 100,000 entities) with loose matching requirements.

4 Matching Services

The Matching services - sometimes referred to as the Match Scoring services in Siebel Universal Data Quality documentation - compare input (driver and candidate) records and produce a list of possible matches, with scores to indicate how good the matches are, and additional information about how the records matched.

In the matching services, the record for comparison is called a driver, and the records it is compared with are known as candidates. Driver records are also compared with each other, but candidate records are never compared with other candidates. Only the highest scoring match for any given record pair is returned.

Note that Siebel currently does not use the Address Matching service, in either batch or real-time, though this service may be integrated with other applications.

4.1 Use

There are three forms of Matching supported:

Real Time

A single driver record (possibly with multiple child entity records) is compared against many candidates.

Full Batch

All records are compared against one another (subject to clustering); for example, all are specified as drivers. This is an extensive operation that can take some time. It is normally used on a new installation, or perhaps as part of a regular maintenance operation.

Incremental Batch

A specific subset of record types are identified and specified as the driver records. Next, other records with matching cluster keys are identified, and specified as the candidates. The driver and candidate records are compared, and the driver records are compared with each other. An example of how this might be used is a regular check on all new records during a set time period, such as a week or month, against pre-existing records.

The real-time matching services are exposed via the following web services in EDQ-CDS:

- IndividualMatch
- EntityMatch
- AddressMatch

The batch and real-time processes that implement the matching services use the following Data Interfaces for input data (mapped to the above web services respectively for real-time matching):

- Individual Candidates
- Entity Candidates
- Address Candidates

The **Matches** data interface is used as a common output interface for all record types (Individual, Entity and Address), although the fields mapped for each record type vary.

4.2 Matching Using Multiple Identifier Values

Matching services within EDQ-CDS are designed to enable users to submit any number of alternative identifier values to use when matching a given individual or entity; for example, multiple email addresses, addresses or names.

EDQ-CDS can perform matching on multiple values of the following attributes if submitted as pipe-delimited lists:

- uid and eid attributes
- alternatephone
- email
- website
- taxnumber
- nationalidnumber
- vatnumber

However, in order for EDQ-CDS to match Individual or Entity records with multiple names or addresses, such records must first be split into multiple records. Each of these records must have the same <code>entityid</code> or <code>individualid</code>, but with different <code>nameid</code> and/or <code>addressid</code> attributes.

So, an Individual record with three names must be split into three records, as follows:

individualid	nameid	firstname	lastname	enail	address1
A1	1	John	Smith	jsmith@jsmith.com	56 High Street
A1	2	Jon	Smith	jsmith@jsmith.com	56 High Street
A1	3	J	Smith	jsmith@jsmith.com	56 High Street

Similarly, an Entity record with two addresses must be split into two records:

entityid	nameid	name	subname	website	address1
B1	1	OracleLtd	Accounts Payable	www.oracle.com	Oracle Parkway
B1	2	Oracle Corporation UK	Accounts Payable	www.oracle.com	Oracle Parkway

And finally, an Entity record with two names and two addresses must be split into four records:

entityid	nameid	name	subname	website	addressid	address1
C1	1	OracleLtd	Accounts Payable	www.oracle.com	A	Oracle Parkway
C1	1	OracleLtd	Accounts Payable	www.oracle.com	В	Thames Valley Park
C1	2	Oracle Corporation UK	Accounts Payable	www.oracle.com	A	Oracle Parkway
C1	2	Oracle Corporation UK	Accounts Payable	www.oracle.com	В	Thames Valley Park

The EDQ Siebel Connector automatically prepares the data to use the matching service appropriately, where EDQ-CDS is integrated with Siebel. If the use of multiple child entities has been configured in Siebel, then the data is prepared in the structure required by the EDQ-CDS matching services. For example, concatenating multiple phone numbers into a pipe-delimited list, and splitting out multiple records if the use of multiple names or addresses is configured.

Note: For records with multiple child entities, only one match will ever be returned between a pair of records. This will always be the highest scoring match according to the match rules.

4.3 Interfaces

The matching web services present input interfaces with direct mappings to the shared 'Candidate' data interfaces as follows:

Web Service	Input Interface
IndividualMatch	See Section 5.1.1, "Individual Candidates."
EntityMatch	See Section 5.1.2, "Entity Candidates."
AddressMatch	See Section 5.1.3, "Address Candidates."

All the matching services return output attributes using the common **Matches Interface** data interface.

4.4 Parameters

The IndividualMatch, EntityMatch and AddressMatch web services all expose a matchthreshold attribute, which is used to suppress (not return) matches with a score below this threshold.

Parameter Attribute	Data Type	Accepted Values	Use
matchthreshold	Number	A numeric value between 0 and 100	Matches that are generated by the matching service with a score below the stated threshold will be suppressed (not returned in the web service response). If used, this overrides the default setting in the process, which can be adjusted when running a job using the EDQ-CDS Run Profile.
matchoptions	String	N/A	This parameter is not currently used. It is intended for use in future versions of EDQ-CDS.

5 Data Interfaces

This section describes the following EDQ-CDS data interfaces:

- Section 5.1, "Candidate Interfaces"
- Section 5.2, "Matches Interface"

Section 5.3, "Cluster Results Interfaces"

5.1 Candidate Interfaces

The Candidate interfaces are used for data input to individual/entity/address matching and clustering in both batch and real-time.

5.1.1 Individual Candidates

Attribute Name	Data Type	Supports Multiple Values? (Y/N)	Notes
candidate	String	N	0 = driving record, 1 = candidate. Used in matching only. All driving records are compared against each other and against each candidate, but candidates are not compared against each other. Note that in real-time matching, there must be one and only one logical driving record representing an Individual, Entity or Address. Multiple physical records for the same Individual or Entity are allowed if multiple child entities are in use. Multiple candidate records may always be presented.
individualid	String	N	Unique identifier of the individual (for example, customer, employee, or contact). Mandatory for batch jobs and real time requests containing multiple driver records.
languages	String	Y	3 character Siebel language code. Only used in name standardization to help determine whether a name containing Kanji is Japanese or Chinese.
uid1	String	Y	Unique ID 1 (single or pipe-delimited list of multiple values).
			Note: The Unique ID fields are used to match records based on custom unique identifiers, such as passport or tax numbers. For more information, see Oracle Enterprise Data Quality Customer Data Services Pack Business Services Guide.
uid2	String	Y	Unique ID 2 (single or pipe-delimited list of multiple values).
uid3	String	Y	Unique ID 3 (single or pipe-delimited list of multiple values).

	Data	Supports Multiple Values?	
Attribute Name	Туре	(Y/N)	Notes
eid1	String	Y	Elimination ID 1 (single or pipe-delimited list of multiple values).
			Note : The Elimination ID fields are used to eliminate possible matches between records based on custom unique identifiers, such as passport or tax numbers. For more information, see <i>Oracle Enterprise Data Quality Customer Data Services Pack Business Services Guide</i> .
eid2	String	Y	Elimination ID 2 (single or pipe-delimited list of multiple values).
eid3	String	Y	Elimination ID 3 (single or pipe-delimited list of multiple values).
nameid	String	N	Unique identifier for the name, used to distinguish between different names for the same individual when multiple child entities are used. For more information, see Section 4, "Matching Services."
title	String	N	Title
firstname	String	N	First Name
middlename	String	N	Middle Name
lastname	String	N	Last Name
gender	String	N	Gender (M or F)
dob	String	N	Date of Birth, in any of the formats recognized by the *Date Formats reference data set in EDQ.
jobtitle	String	N	Job Title
homephone	String	N	Home Phone Number
workphone	String	N	Work Phone Number
mobilephone	String	N	Mobile Phone Number
faxphone	String	N	Fax Number
alternatephone	String	Y	Alternative Phone Number - either a single value, or a pipe-delimited list of multiple values.
email	String	Y	A single value or a pipe-delimited list of multiple email addresses.
taxnumber	String	Y	A single value or a pipe-delimited list of multiple tax numbers.
nationalidnumber	String	Y	Social Security Number (US) or equivalent, single value or pipe-limited list.
accountname	String	N	The name of the account (for example, entity) to which this individual belongs, if relevant.

	Data	Supports Multiple Values?	
Attribute Name	Туре	(Y/N)	Notes
addressid	String	N	Unique identifier for the address, used to distinguish between different addresses for the same individual when multiple child entities are used. For more information, see Section 4, "Matching Services."
address1	String	N	Address line 1
address2	String	N	Address line 2
address3	String	N	Address line 3
address4	String	N	Address line 4
dependentlocality	String	N	A smaller population center data element, dependent on the contents of the city field. For example, a Neighborhood in Turkey. For many countries, this attribute is not used.
doubledependentlocality	String	N	The smallest population center data element, dependent on both the contents of the city and dependentlocality fields. For example, a village in the UK. For many countries, this attribute is not used.
city	String	N	The locality, town or city of the address.
subadminarea	String	N	The smallest geographic data element within a country. For example, a county in the USA.
adminarea	String	N	The most common geographic data element within a country. For example, USA State or Canadian Province.
postalcode	String	N	Postal or zip code for the address, if relevant for the country.
			Note: With matching services, leading zeroes are stripped only on numeric postalcodes to avoid a numeric postalcode reinterpreted as a number by an external programs where leading zeroes are automatically stripped. For example, Excel may reformat numeric postalcodes as a number by removing the leading zeroes. This is enabled by default in the edq-cds-daas.properties Run Profile. If there are any alpha characters present, the leading zeroes are not stripped.
country	String	N	Country name or ISO 2 char code.
clusterlevel	String	N	1 = limited, 2 = typical, 3 = exhaustive. Used in clustering only. If a value is not supplied, the value defined by the override property is used if set; otherwise the default is 2.

Attribute Name	Data Type	Supports Multiple Values? (Y/N)	Notes
matchthreshold	Number	N	Minimum match rule score to return a result (0-100). Used in matching only. If a value is not supplied, the value defined by the override property in the Run Profile is used if set; otherwise the default is 70.
matchoptions	String	N	For future use.

5.1.2 Entity Candidates

Attribute Name	Data Type	Supports Multiple Values? (Y/N)	Notes
candidate	String	N	0 = driving record, 1 = candidate. Used in matching only. All driving records are compared against each other and against each candidate, but candidates are not compared against each other.
entityid	String	N	Unique record identifier. Mandatory for batch jobs and real time requests containing multiple driver records.
languages	String	Y	3 character Siebel language code. Only used in name standardization to help determine whether a name containing Kanji is Japanese or Chinese.
uid1	String	Y	Unique ID 1 (single or pipe-delimited list of multiple values).
			Note: The Unique ID fields are used to match records based on custom unique identifiers, such as passport or tax numbers. For more information, see Oracle Enterprise Data Quality Customer Data Services Pack Business Services Guide.
uid2	String	Y	Unique ID 2 (single or pipe-delimited list of multiple values).
uid3	String	Y	Unique ID 3 (single or pipe-delimited list of multiple values).
eid1	String	Y	Elimination ID 1 (single or pipe-delimited list of multiple values).
			Note : The Elimination ID fields are used to eliminate possible matches between records based on custom unique identifiers, such as passport or tax numbers. For more information, see <i>Oracle Enterprise Data Quality Customer Data Services Pack Business Services Guide</i> .
eid2	String	Y	Elimination ID 2 (single or pipe-delimited list of multiple values).

	Data	Supports Multiple Values?	
Attribute Name	Type	(Y/N)	Notes
eid3	String	Y	Elimination ID 3 (single or pipe-delimited list of multiple values).
nameid	String	N	Unique identifier for the name, used to distinguish between different names for the same entity when multiple child entities are used. For more information, see Section 4, "Matching Services."
name	String	N	Organization name, for example, "Oracle Corporation UK".
subname	String	N	Department or site, for example, "Reading" or "Accounts Payable".
phone	String	N	
alternatephone	String	Y	A single or pipe-delimited list of multiple alternative phone number values.
website	String	Y	A single or pipe-delimited list of multiple alternative web site addresses.
taxnumber	String	Y	A single or pipe-delimited list of multiple tax numbers.
vatnumber	String	Y	A single or pipe-delimited list of multiple VAT numbers.
addressid	String	N	Unique identifier for the address, used to distinguish between different addresses for the same entity when multiple child entities are used. For more information, see Section 4, "Matching Services."
address1	String	N	Address line 1
address2	String	N	Address line 2
address3	String	N	Address line 3
address4	String	N	Address line 4
dependentlocality	String	N	A smaller population center data element, dependent on the contents of the city field. For example, Turkish Neighborhood
doubledependentlocality	String	N	The smallest population center data element, dependent on both the contents of the city and dependentlocality fields. For example, UK Village.
city	String	N	
subadminarea	String	N	The smallest geographic data element within a country. For example, USA County.
adminarea	String	N	The most common geographic data element within a country. For example, USA State or Canadian Province.

Attribute Name	Data Type	Supports Multiple Values? (Y/N)	Notes
postalcode	String	N	Postal or zip code for the address, if relevant for the country.
			Note: With matching services, leading zeroes are stripped only on numeric postalcodes to avoid a numeric postalcode reinterpreted as a number by an external programs where leading zeroes are automatically stripped. For example, Excel may reformat numeric postalcodes as a number by removing the leading zeroes. This is enabled by default in the edq-cds-daas.properties Run Profile. If there are any alpha characters present, the leading zeroes are not stripped.
country	String	N	Country name or ISO 2 char code.
clusterlevel	String	N	1 = limited, 2 = typical, 3 = exhaustive. Used in clustering only.
matchthreshold	Number	N	Minimum match rule score to return a result (0-100) . Used in matching only.
matchoptions	String	N	For Future Use.

5.1.3 Address Candidates

Attribute Name	Data Type	Supports Multiple Values? (Y/N)	Notes
candidate	String	N	0 = driving record, 1 = candidate. Used in matching only.
addressid	String	N	Unique identifier for the address.
address1	String	N	Address line 1
address2	String	N	Address line 2
address3	String	N	Address line 3
address4	String	N	Address line 4
dependentlocality	String	N	A smaller population center data element, dependent on the contents of the city field. For example, Turkish Neighborhood.
doubledependentlocality	String	N	The smallest population center data element, dependent on both the contents of the city and dependentlocality fields. For example, UK Village.
city	String	N	
subadminarea	String	N	The smallest geographic data element within a country. For example, USA County.

Attribute Name	Data Type	Supports Multiple Values? (Y/N)	Notes
adminarea	String	N	The most common geographic data element within a country. For example, USA State or Canadian Province.
postalcode	String	N	Postal or zip code for the address, if relevant for the country.
country	String	N	Country name or ISO 2 char code.
clusterlevel	String	N	1 = limited, 2 = typical, 3 = exhaustive. Used in clustering only.
matchthreshold	Number	N	Minimum match rule score to return a result (0-100). Used in matching only.
matchoptions	String	N	For future use.

5.2 Matches Interface

The Matches interface is used for the output of the matching services in batch and real-time. It is used for individuals, entities and addresses because it contains no attributes specific to any business object.

With Individual and Entity matching, if there are multiple matches between records with the same masterid and matchids (for example, due to multiple matches with different names and addresses), only the strongest match (by match score) is returned for the record pair.

Siebel does not currently use the returned masternameid, matchnameid, masteraddressid and matchaddressid attributes, though these may be used in other integrations to display the correct records in the application according to the best matches.

Attribute Name	Data Type	Notes
serverid	String	Server ID. Not applicable to Siebel.
jobid	String	Job ID. Not applicable to Siebel.
masterid	String	Driving record ID. Only used in Batch.
matchid	String	Matching record ID.
masternameid	String	Driving record name ID. Used to identify which driving record nameid matched, where multiple names were presented.
matchnameid	String	Matching record name ID. Used to identify which candidate record nameid matched, where multiple names were presented.
masteraddressid	String	Driving record address ID. Used to identify which driving record addressid matched, where multiple addresses were presented.
matchaddressid	String	Matching record address ID. Used to identify which candidate record addressid matched, where multiple addresses were presented.
matchscore	Number	Match score.

Attribute Name	Data Type	Notes
rulename	String	Match rule name.
reversedriverflag	String	A flag indicating that an additional, reversed match record has been generated where there is a match between driving records in Batch matching. Valid values are Y and N.

Note:

- In Siebel integrations, the driving record(s) are also returned in the output from real-time matching requests, with a blank match score and rule name. This behavior is controlled by the phase.*.process.*.Return\ Real-time\ Driving\ Record Run Profile property, and therefore could be configured for other types of integration if required.
- So that external applications, such as Siebel, can simply consume the output from batch matching to update both records in a match, CDS batch matching provides two records for each match between driving records. Therefore, if A matches B, a record is returned with masterid A and matchid B, and an additional record is generated and returned with masterid B and matchid A. This additionally generated record will have reversedriverflag set to Y in case the external application does not need the additionally generated record.
- The Match Rule Name cannot be displayed in Siebel due to the limitations of the Siebel Data Quality interface that only accepts a returned score related to each matched record.

5.3 Cluster Results Interfaces

Two data interfaces are used for the output of the results of clustering; one for batch and one for real-time. They are used for entities, individuals, and addresses as they contain no attributes specific to a particular business object. The batch and real-time interfaces contain similar information, with the main difference being the way in which the results are processed. The Batch and Real-Time Results Interfaces contain similar information, the main difference is the way in which the results are processed.

5.3.1 Real-Time Cluster Results Interface

The Real-time Cluster Results interface is used for the output of Clustering Services in real-time. The output values are returned in arrays in no specific order; the clustervalues and clusterlevels array element always correspond.

Attribute Name	Data Type	Notes
externalid	String	ID of the individual, entity or address of the clustered record.
clustervalues	StringArray	Cluster key value array.
clusterlevels	StringArray	Cluster key level array.

5.3.2 Batch Cluster Results Interface

The Batch Cluster Results interface is only used in the Batch Clustering service. It differs from the Real-time Cluster Results interface in that it returns one row per cluster value per record, rather than arrays of cluster values for a record.

Attribute Name	Data Type	Notes
serverid	String	Server ID. Not applicable to Siebel.
jobid	String	Job ID. Not applicable to Siebel.
externalid	String	ID of the individual, entity, or address of the clustered record.
clustervalue	String	Cluster key value.
clusterlevel	String	Cluster key level.

6 Real-Time Integration

The EDQ-CDS real-time matching services can be called by an external application without any changes to the default configuration. It is the responsibility of the calling application to manage the storage of record cluster keys and to perform the selection of match candidates to be passed to the matching service.

A typical interaction between the calling application (for example, a CRM or Master Data Management [MDM] application) and EDQ-CDS during real-time matching (for example, Contact duplicate prevention) is illustrated as follows:

4. Select Candidates
5. Construct Match Records
9. User reviews Duplicates
13. Store Keys

12. Return Keys

Data Tables

1. Send Driving Record

2. Generate Keys
7. Perform Matching
11. Generate Keys
12. Return Keys

Figure 1 Overview of Expected Integration Architecture with Matching Services

In detail the matching services operate as follows:

- **1. Send Driving Record** The application sends the new (driving) record and the configured cluster level to EDQ-CDS.
- **2. Generate Keys** EDQ-CDS generates the cluster key(s) for the driving record.
- **3. Return Keys** EDQ-CDS returns the driving record's cluster keys to the MDM application.
- **4. Select Candidates** The MDM application selects all (candidate) records that share any of the same cluster keys. If no candidates are identified then go to step 13.

- **5. Construct Match Data** The MDM application constructs the match data for the driving and candidate records
- **6. Send Match Records** The MDM application sends the data for the new (driving) record and candidates to EDQ-CDS.
- **7. Perform Matching** EDQ-CDS matches the driving record against the candidates to identify potential duplicates. Each match is assigned a score indicating the strength of match.
- **8. Return Duplicates with score** EDQ-CDS returns the IDs of the matched candidates (and scores) to the MDM application. The driving record is also returned, but with a blank score. If no duplicates were identified by EDQ-CDS then go to step 13.
- **9. User reviews Duplicates** As indicated.
- 10. Send Master Record If duplicates were identified by EDQ-CDS and selected by the user, then the driving record is merged with the existing duplicate record. If a merge operation occurred then the MDM application sends the new merged (master) record details back to EDQ-CDS.
- **11. Generate Keys** EDQ-CDS uses the details of the master record to generate cluster key values.
- **12. Return Keys** EDQ-CDS returns the master record's cluster keys to the MDM application.
- **13. Store Keys** The MDM application stores the cluster keys for new master record.
